If theſe ſonnets could be ſuppoſed to be genuine, this paſſage would overthrow at once all the letters and both the contracts which were produced; and would prove, with the force of demonſtration, that the ſeizure of Mary by Bothwell was *not* with her own conſent; that he actually committed a *rape* upon her; that ſhe had for him *no love*; and that ſhe married him merely as a *refuge to her injured honour*. The ſonnets, however, are undoubtedly ſpurious; but, conſidered in this light, the verſes before us prove with equal force the full conviction in the minds of the rebels of what in an unguarded moment they actually confeſſed to Throgmorton, and was manifeſt to all the world: viz. that "the queen their ſovereign was *led captive*, and by FEAR, FORCE, and (as by many conjectures may be well ſuſpected) other EXTRAORDINARY and more UNLAWFUL means COMPELLED to become bedfellow to another wife's huſband." They prove likewiſe, that after the rape, finding Mary highly indignant at the brutality done her, Bothwell actually ſtabbed himſelf; not, we may believe, with any intention to take away his own life, but merely that by ſhedding many a "drachm" of blood he might mollify the heart of the queen.

But we mean not to purſue the hiſtory of the ſonnets any farther. Though they were undoubtedly invented in aid of the letters, to prove that fundamental principle of the conſpirators,—that the love of Mary to Bothwell was inordinate; yet they are ſo incompatible with hiſtory, and with one another, that they demonſtrate the ſpuriouſneſs of themſelves, and of the evidence which they were intended to corroborate. By thus endeavouring to give an air of nature and probability to their monſtrous fictions, the rebels at once betrayed the fabrication of the whole. They have themſelves ſupplied us with a long and particular journal, to ſhow the true dates of facts; and by that journal have their letters and their ſonnets been demonſtrated to be ſpurious. "The *makers* of theſe papers (ſays Mr Whitaker) have broken through all the barriers of their *own hiſtory*. They have ſtarted aſide from the *orbit* of *their own* chronology. They have taken a flight beyond the bounds of *their own* creation, and have there placed themſelves conſpicuous in THE PARADISE OF FOOLS."

This maſs of forgery was clandeſtinely ſhown to Eliſabeth's commiſſioners during the conferences at York: (See SCOTLAND.) It was ſhown again to the ſame commiſſioners and others during the conferences at Weſtminſter. But neither Mary nor her commiſſioners could ever procure a ſight of a ſingle letter or a ſingle ſonnet. By the biſhop of Roſs and the Lord

Herries ſhe repeatedly demanded to ſee the papers ſaid to be written by her; but that requeſt, in itſelf ſo reaſonable, Elizabeth, with an audacity of injuſtice of which the hiſtory of mankind can hardly furniſh a parallel, thought fit to refuſe. Mary then inſtructed her commiſſioners to demand *copies* of the letters and ſonnets; and offered even from theſe to demonſtrate in the preſence of the Engliſh queen and parliament, and the ambaſſadors of foreign princes, that the pretended originals were palpable forgeries. Even this demand was denied her; and there is undoubted evidence ſtill exiſting, that neither ſhe nor her commiſſioners had ſo much as a *copy* of theſe criminal papers till after thoſe important conferences had for ſome time been at an end. This laſt demand perplexed Elizabeth; the conferences were ſuddenly broken up; Murray was diſmiſſed with his box to Scotland; and the letters were ſeen no more!

But the letters, we are told, were at Weſtminſter compared with letters of the queen's, and found to be in the ſame Roman hand. They were indeed compared with other writings; but with what writings? This queſtion let Elizabeth's commiſſioners themſelves anſwer. They collated them, they ſay "with others her letters, which were ſhewed yeſternight, and avowed by THEM (the rebel commiſſioners) to be written by the ſaid queen." This was ſuch a collation as muſt have pronounced them to be idiots §, if we had not known them to be otherwiſe; and ſuch as muſt pronounce them to be *knaves*, as we know them to have been men of ſenſe. Like perſons totally incompetent to the management of buſineſs, but in truth acting miniſterially in the work of profligacy, they compared the letters produced, NOT with letters furniſhed by Mary's commiſſioners, NOT with letters furniſhed even by indifferent perſons, BUT with letters *preſented by the producers themſelves*.—"This (ſays Mr Whitaker) is ſuch an inſtance of impoſition upon Mary and the world, as can ſcarcely be paralleled in the annals of knavery. Many inſtances of impoſition, indeed, occur in the wretched hiſtory of our race; but we can hardly find one, in which the impoſition was ſo groſs, ſo formal, ſo important, and ſo clear. It was very groſs, becauſe it has not a ſhred of artifice to cover its ugly nakedneſs. It was very formal, becauſe it was done by men ſome of whom were of the firſt character in their country; and all were bound by honour, and tied down by oaths, to act uprightly in the buſineſs. It was very important, becauſe no leſs than the reputation of a queen, and the continuance of an uſurpation, depended upon it. And it is very clear, becauſe we have the fact related to us by the commiſſioners themſelves, recorded to their ſhame in their own journal, and tranſmitted by their own hands to poſterity with everlaſting infamy on their heads."

§ Whitaker

When Tytler's *Inquiry into the Evidence produced by the Earls of Murray and Morton againſt Mary Queen of Scots* was firſt publiſhed, it was reviewed in the Gentleman's Magazine by the late Dr Johnſon. The review, which conſiſts of a brief analyſis of the work, with reflections interſperſed on the force of the evidence, concludes thus:—"That the letters were forged is now made ſo probable, that perhaps they will never more be cited as teſtimonies." Subſequent experience has ſhown, that the great critic's knowledge of human nature had not deſerted him when he guarded his prediction with the word *perhaps*. Few authors poſſeſs the magnanimity of Fenelon; and it is not to be expected that he who has once maintained the letters to be genuine, ſhould by reaſoning or criticiſm be compelled to relinquiſh them: but we are perſuaded, that, after the preſent generation of writers ſhall be extinct, theſe letters and ſonnets will never be cited as evidence, except of the profligacy of thoſe by whom they were fabricated. Having ſaid this, we leave the general character of Mary to the reflection of the reader (A).

She wrote, 1. Poems on various occaſions, in the Latin, French, and Scotch languages. One of her poems is printed among thoſe of A. Blackwood; another in Brantome's *Dames illuſtres*, written on the death of her firſt huſband Francis. 2. Conſolation of her long impriſonment, and royal advice to her ſon. 3. A copy of verſes, in French, ſent with a diamond-ring to queen Elizabeth. There is a tranſlation of theſe verſes among the Latin poems of Sir Thomas Chaloner. 4. Genuine Letters of Mary queen of Scots, to James earl of Bothwell; tranſlated from the French, by E. Simmonds, 1726. There are, beſides, many other of her epiſtles to queen Elizabeth, ſecretary Cecil, Mildmaye, &c. which are preſerved in the Cottonian, Aſhmolean, and other libraries.

MARY II. queen of England, eldeſt daughter of James II. by his firſt wife, was born at St James's in 1662. She was bred up a Proteſtant, and married to William Henry of Naſſau, then prince of Orange, afterward king of England, in the 16th year of her age. She ſtaid in Holland with her huſband till February 12. 1689, when ſhe came over, and was ſolemnly proclaimed queen of England, &c. She was an equal ſharer with her huſband in all the rights belonging to the crown; but the adminiſtration and execution thereof was lodged ſolely in the king. She was a princeſs endowed with the higheſt

---

(A) This article ſtands in need of an apology; but whether for its length or its ſhortneſs, our readers may perhaps differ in opinion. If it be conſidered as a piece of common biography, and compared with the limits which we have preſcribed to our other articles of the ſame kind, it has ſwelled to an extent beyond all proportion. But as a piece of common biography it ought not to be conſidered: it is intimately connected with the hiſtory of Scotland at a very intereſting period; and it has been juſtly obſerved, by one of the ableſt writers of the age, that "the fact under diſpute in the life of Mary, is a fundamental and eſſential one; and that, according to the opinion which the hiſtorian adopts with regard to it, he muſt vary and diſpoſe the whole of his ſubſequent narration." Viewed in this light, our abſtract of the evidence which has been urged on both ſides of this controverſy will by many be deemed too ſhort. To ſuch as wiſh for complete ſatisfaction, we can only recommend the unbiaſſed ſtudy of the writings of *Buchanan*, *Leſlie* biſhop of Roſs, *Goodal*, *Robertſon*, *Hume*, *Tytler*, *Sir David Dalrymple*, *Stuart*, and *Whitaker*.

eſt perfections both of body and mind: ſhe loved hiſtory, as being proper to give her uſeful inſtructions; and was alſo a good judge as well as a lover of poetry. She ſtudied more than could be imagined, and would have read more than ſhe did if the frequent returns of ill-humours in her eyes had not forced her to ſpare them. She gave her minutes of leiſure to architecture and gardening; and ſince it employed many hands, ſhe ſaid ſhe hoped it would be forgiven her. She was the moſt gracious of ſovereigns to her ſubjects, and the moſt obliging of wives to her huſband, as well as the moſt excellent of miſtreſſes to her ſervants: ſhe ordered good books to be laid in the places of attendance, that perſons might not be idle while they were in their turns of ſervice. She was exceeding zealous for a reformation of manners; charitable in the higheſt degree, without the leaſt oſtentation. This excellent queen died on the 28th of December 1695, at Kenſington, of the ſmall-pox, in the 33d year of her age. In her the arts loſt a protectreſs, the unfortunate a mother, and the world a pattern of every virtue. As to her perſon, ſhe was tall, of a majeſtic graceful mien, her countenance ſerene, her complexion ruddy, and her features beautiful.

Mary Magdalen's Day, a feſtival of the Romiſh church, obſerved on the 22d of July.

Mary-Gerane's-Houſe, a name given to Dunmore-head, in the pariſh of Dunqueen, county of Kerry, and province of Munſter, in Ireland. It is the moſt weſtern point of all Europe, and called by the Iriſh *Ty Vorney Geerone*. It is a point as much celebrated by them as John-of-Groat's-houſe by the Scots, which is the utmoſt extremity of North Britain.

MARYBOROUGH, a borough, market, and poſt town, and the aſſizes town to the Queen's county, in the province of Leinſter, in Ireland, ſo called in honour of Mary queen of England, who reduced this part of the country to ſhire-ground by act of parliament 6th and 7th Philip and Mary. It is governed by a burgo-maſter and bailiffs, and has a barrack for a troop of horſe. It returns two members to parliament, and has five fairs. It is diſtant from Dublin 40 miles. N. Lat. 53. 0. W. Long. 7. 20.

MARYBURGH. See *Fort-William*.

MARYGOLD. See CALTHA.

Corn Marygold. See CHRYSANTHEMUM.

French Marygold. See TAYGETES.

MARYLAND, one of the Thirteen United States of America. It received that name in honour of Henrietta Maria, the conſort of king Charles I. who made a grant of this country, with very extraordinary powers, to Lord Baltimore. It lies between 38 and 40 degrees north latitude, and in longitude from 74 to 78 degrees weſt from London. It is bounded on the north by Pennſylvania; on the eaſt by the Delaware ſtate; on the ſouth-eaſt and ſouth by the Atlantic Ocean, and a line drawn from the ocean over the peninſula (dividing it from Accomack county in Virginia) to the mouth of Patomack river, thence up the Patomack to its firſt fountain, thence by a due north line till it interſects the ſouthern boundary of Pennſylvania, in lat. 39° 43′ 18″; ſo that it has Virginia on the ſouth, ſouth-weſt, and weſt. It contains about 14,000 ſquare miles, of which about one-ſixth is water. It is divided into 18 counties, 10 of which are on the weſtern and 8 on the eaſtern ſhore of Cheſapeak bay, St Mary's, Somerſet, Calvert, Montgomery, Waſhington, Queen Ann's, Caroline, Kent, Charles, Talbot, Dorcheſter, Baltimore, Ann Arundel, Worceſter, Hatford, Cœcil, Frederick, and Prince George's. Each of the counties ſends four repreſentatives to the houſe of delegates; beſides which the city of Annapolis and town of Baltimore ſend each two, making in the whole 76 members. The climate is generally mild and agreeable, ſuited to agricultural productions and a great variety of fruit-trees. In the interior hilly country the inhabitants are healthy; but in the flat country, in the neighbourhood of the marſhes and ſtagnant waters, they are, as in the other ſouthern ſtates, ſubject to intermittents. Cheſapeak bay divides this ſtate into the eaſtern and weſtern diviſions. It affords ſeveral good fiſheries; and, in a commercial view, is of immenſe advantage to the ſtate. It receives a number of the largeſt rivers in the United States. From the eaſtern ſhore in Maryland, among other ſmaller ones, it receives Pokomoke, Choptank, Cheſter, and Elk rivers; from the north the rapid Suſquehannah; and from the weſt Patapſco, Severn, Patuxent, and Patomack, half of which is in Maryland and half in Virginia. Except the Suſquehannah and Patomak, theſe are ſmall rivers. Eaſt of the blue ridge of mountains, which ſtretches acroſs the weſtern part of this ſtate, the land, like that in all the ſouthern ſtates, is generally level and free of ſtones. Wheat and tobacco are the ſtaple commodities of Maryland. In the interior country, on the uplands, conſiderable quantities of hemp and flax are raiſed.

The number of inhabitants in this ſtate, including the negroes, is 254,050; which is 18 for every ſquare mile. The inhabitants, except in the populous towns, live on their plantations, often ſeveral miles diſtant from each other. To an inhabitant of the middle, and eſpecially of the eaſtern ſtates, which are thickly populated, they appear to live very retired and unſocial lives. The effects of this comparative ſolitude are viſible in the countenances as well as in the manners and dreſs of the country people; there being among them very little of that cheerful ſprightlineſs of look and action which is the invariable and genuine offſpring of ſocial intercourſe; nor do they pay that attention to dreſs which is common, and which decency and propriety have rendered neceſſary, among people who are liable to receive company almoſt every day. As the negroes perform all the manual labour, their maſters are left to ſaunter away life in ſloth, and too often in ignorance. Theſe obſervations, however, muſt in juſtice be limited to the people in the country, and to thoſe particularly whoſe poverty or parſimony prevents their ſpending a part of their time in populous towns, or otherwiſe mingling with the world.

The chief towns in this ſtate are Anapolis and Baltimore.—*Anapolis*, the capital, and the wealthieſt town of its ſize in America, is ſituated juſt at the mouth of Severn river, 30 miles ſouth of Baltimore. The houſes are generally large and elegant; and the ſtadt-houſe is the nobleſt building of the kind in America.—*Baltimore* has had the moſt rapid growth of any town on the continent, and is the fourth in ſize and the fifth in trade in the United States. It lies in lat. 39. 21. on the north ſide of Patapſco river, around what is called the Baſon. The ſituation of the town is low. The houſes were numbered in 1787, and found to be 1955; about 1200 of which were in the town and the reſt at Fell's point. The number of ſtores was 152; and of churches 9, which belong to German Calviniſts and Lutherans, Epiſcopalians, Preſbyterians, Roman Catholics, Baptiſts, Methodiſts, Quakers, Nicolites, or New Quakers. The number of inhabitants is between 10,000 and 11,000. There are many very reſpectable families in Baltimore, who live genteelly, are hoſpitable to ſtrangers, and maintain a friendly and improving intercourſe with each other; but the bulk of the inhabitants, recently collected from almoſt all quarters of the world, bent on the purſuit of wealth, varying in their habits, their manners, and their religions, if they have any, are unſocial, unimproved, and inhoſpitable. The trade of Maryland is principally carried on from Baltimore, with the other ſtates, with the Weſt Indies, and with ſome parts of Europe. To theſe places they ſend annually about 30,000 hogſheads of tobacco, beſides large quantities of wheat, flour, pig iron, lumber, and corn—beans, pork, and flax-ſeed, in ſmaller quantities; and receive in return, clothing for themſelves and negroes, and other dry goods, wines, ſpirits, ſugars, and other Weſt India commodities. The balance is generally in their favour.

The Roman Catholics, who were the firſt ſettlers in Maryland, are the moſt numerous religious ſect. Beſides theſe, there are Proteſtant Epiſcopalians, Engliſh, Scots, and Iriſh Preſbyterians, German Calviniſts, German Lutherans, Friends, Baptiſts, Methodiſts, and Nicolites, or New Quakers. The colleges in this ſtate have all been founded ſince the year 1782, and are yet in their infancy. The names of the ſeveral ſeminaries are, Waſhington College at Cheſtertown, inſtituted in 1782; St John's College at Anapolis, founded in 1784; Cakeſbury College at Abingdon, inſtituted by the Methodiſts in 1785; and a college founded by the Roman Catholics at Georgetown. There are a few other literary inſtitutions, of inferior note, in different parts of the ſtate, and proviſion is made for free ſchools in moſt of the counties: though ſome are entirely neglected, and very few carried on with any ſucceſs; ſo that a great proportion of the lower claſs of people are ignorant, and there are not a few who cannot write their names. But the revolution, among other happy effects, has rouzed the ſpirit of education, which is faſt ſpreading its ſalutary influences over this and the other ſouthern ſtates.

The legiſlature of this ſtate is compoſed of two diſtinct branches, a ſenate and houſe of delegates; and ſtyled *The General Aſſembly of Maryland*. The ſenate conſiſts of 15 members, choſen every five years. Nine of theſe muſt be reſidents on the weſtern ſhore and ſix on the eaſtern; they muſt be more than 25 years of age, muſt have reſided in the ſtate more than three years next preceding the election, and have real and perſonal property above the value of L. 1000. The houſe of delegates is compoſed of four members for each county, choſen annually on the firſt Monday in October. The city of Anapolis and town of Baltimore ſend each two delegates. The qualifications of a delegate are, full age, one year's reſidence in the county where he is choſen, and real or perſonal property above the value of L. 500. The qualifications of a freeman are, full age, a freehold eſtate of 50 acres of land, and actual reſidence in the county where he offers to vote; property to the value of L. 30 in any part of the ſtate, and a year's reſidence in the county where he offers to vote.

On the ſecond Monday in November annually a governor is appointed by the joint ballot of both houſes. The governor cannot continue in office longer than three years ſucceſſively, nor be elected until the expiration of four years after he has been out of office. The qualifications for the chief magiſtracy are, 25 years of age, five years reſidence in the ſtate next preceding the election, and real and perſonal eſtate above the value of L. 5000, L. 1000 of which muſt be freehold eſtate. This conſtitution was eſtabliſhed by a convention of delegates at Anapolis, Auguſt 14. 1776.

Maryland was granted, as has been already noticed, by King Charles I. to Cecilius Calvert, baron of Baltimore in Ireland, June 20. 1632. The government of the province was by charter veſted in the proprietary; but it appears that he either never exerciſed theſe powers alone, or but for a ſhort time. The honourable Leonard Calvert, Eſq; Lord Baltimore's brother, was the firſt governor or lieutenant-general. In 1638, a law was paſſed, conſtituting the firſt regular houſe of aſſembly, which was to conſiſt of ſuch repreſentatives, called *burgeſſes*, as ſhould be elected purſuant to writs iſſued by the governor. Theſe burgeſſes poſſeſſed all the powers of the perſons electing them; but by any other freemen, who did not aſſent to the election, might take their ſeats in perſon. Twelve burgeſſes or freemen, with the lieutenant-general and ſecretary, conſtituted the aſſembly or legiſlature. This aſſembly ſat at St Mary's, one of the ſouthern counties, which was the firſt ſettled part of Maryland. In 1689, the government was taken out of the hands of Lord Baltimore by the grand convention of England. Mr Copley was appointed governor by commiſſion from William and Mary in 1692, when the Proteſtant religion was eſtabliſhed by law. In 1716, the government of this province was reſtored to the proprietary, and continued in his hands till the late revolution; when, being an abſentee, his property in the lands was confiſcated, and the government aſſumed by the freemen of the province, who formed the conſtitution now exiſting. At the cloſe of the war, Henry Hatford, Eſq; the natural ſon and heir of Lord Baltimore, petitioned the legiſlature of Maryland for his eſtate; but his petition was not granted. Mr Harford eſtimated his loſs of quit-rents, valued at 20 years purchaſe, and including arrears, at L. 259,488, 5 s.—dollars at 7s. 6d. and the value of his manors and reſerved lands at L. 327,441 of the ſame money.

MARYPORT, a ſea-port town of Cumberland, ſituated at the mouth of the Elne. It has a good harbour; and has 70 or 80 ſail of ſhipping from 30 to 250 tons burden, principally employed in the coal-trade; ſome of them ſail up the Baltic for timber, flax, iron, &c. They have a furnace for caſt-iron and a glaſs-houſe. A chapel was erected here in 1760.

MAS (Lewis du), natural ſon to Jean Louis de

Montcalm Seigneur de Candiac, and a widow of rank of Rouergue, was born at Nimes in 1676. His firſt attention was beſtowed on juriſprudence; but afterwards he was altogether occupied with mathematics, philoſophy, and the ſtudy of the languages. Father Mallebranche cultivated his acquaintance and eſteemed his virtues. His firſt appearance was ſevere, his general temper tranquil; yet he had a lively and fertile imagination. His mind was active, full of reſources, and methodical. We are indebted to his induſtry for the Typographical Bureau. This invention is the more ingenious, as it preſents the tedious parts of education, namely, reading, writing, and the elements of languages, to the youthful mind as a delightful entertainment, and many people in France both in the capital and in the provinces have adopted it with ſucceſs. After he had conceived the idea of this invention, he made the firſt trial of it on the young Candiac, who was remarkable for his underſtanding in his earlieſt years. Du Mas conducted his pupil to Paris and the principal cities in France, where he was univerſally admired. This prodigy was carried off in the year 1726 before he was ſeven years of age, and his loſs had nearly deprived Du Mas of his reaſon. A dangerous illneſs was the conſequence of his vexation; and he would have died of want, if a gentleman had not taken him from his garret and entertained him in his own houſe. Du Mas afterwards retired with Madame de Vaujour within two leagues of Paris, and died in the year 1774, aged 68. He was a philoſopher both in genius and character. His works are, 1. *L'Art de tranſpoſer toutes ſortes de Muſiques ſans etre obligé de connoitre, ni le temps, ni le mode*, publiſhed at Paris in 4to, 1711. This work is extremely curious, but of no advantage to the ſtudy of muſic. 2. A volume in quarto, printed at Paris 1733, in four parts, intitled, *Bibliotheque des enfans*. In this treatiſe he has placed, in a clear point of view, the ſyſtem and economy of his Typographical Bureau. This invention, like every thing new, was cenſured by ſome and admired by others. The author himſelf defended it with much ſucceſs in the journals and in ſeveral occaſional pamphlets. This collection, however, is become exceedingly ſcarce. The Typographical Bureau was brought to perfection by M. Reybert a citizen of Avignon, who enriched it with many articles containing uſeful and agreeable information in geography, hiſtory, fable, &c. &c. 3. *Memoires de l'Ecoſſe ſous le regne de Marie Stuart*, by Crawford, and tranſlated from the Engliſh. This tranſlation was found in manuſcript in the library of the late marquis d'Aubais, with whom du Mas had lived in the moſt intimate habits of friendſhip.

Mas Planta, a plant which upon the ſame root produces male flowers only. See *Masculus Flos*.

MASAFUERO, an iſland of the South-Sea, lying in S. Lat. 33. 45. W. Long. 80. 46. It is very high and mountainous, and at a diſtance ſeems to conſiſt of one hill or rock. It is of a triangular form, and ſeven or eight leagues in circumference. There is ſuch plenty of fiſh, that a boat with a few hooks and lines may very ſoon catch as many as will ſerve 100 people. Here are coal-fiſh, cavilliers, cod, hallibut, and cray-fiſh. Captain Carteret's crew caught a kingfiſher that weighed 87 pounds, and was five feet and an half long. The ſharks were here ſo ravenous, that, in taking ſoundings, one of them ſwallowed the lead, by which they hauled him above water; but he regained his liberty by diſgorging his prey. Seals are ſo numerous here, that Captain Carteret ſays, if many thouſands were killed in a night, they would not be miſſed next morning. Theſe animals yield excellent train-oil; and their hearts and plucks are very good food, having a taſte ſomething like thoſe of a hog; their ſkins are covered with a very fine fur. There are many birds here, and ſome very large hawks. Of the pintado bird one ſhip caught 700 in one night. Commodore Byron landed here with difficulty in 1765, in order to take in wood and water, of both which he found plenty. He found alſo great numbers of goats, whoſe fleſh taſted as well as veniſon in England.

MASBOTHÆI, or Mesbothæi, the name of a ſect, or rather of two ſects; for Euſebius, or rather Hegeſippus whom he cites, makes mention of two different ſects of Maſbothæans. The firſt was one of the ſeven ſects that aroſe out of Judaiſm, and proved very troubleſome to the church; the other was one of the ſeven Jewiſh ſects before the coming of Jeſus Chriſt.

The word is derived from the Hebrew שבת, *ſchabat*, "to reſt or repoſe," and ſignifies *idle eaſy indolent people*. Euſebius ſpeaks of them as if they had been ſo called from one Maſbotheus their chief: but it is much more probable that their name is Hebrew, or at leaſt Chaldaic, ſignifying the ſame thing with a Sabbatarian in our language; that is, one who makes profeſſion of keeping Sabbath.

Valeſius will not allow the two ſects to be confounded together: the laſt being a ſect of Jews before, or at leaſt contemporary with Chriſt; and the former a ſect of heretics deſcended from them. Rufinus diſtinguiſhes them in their names: the Jewiſh ſect he calls Maſbuthæi; and the heretics Maſbuthæani. The Maſbuthæans were a branch of the Simonians.

MASCARDI (Auguſtin), a diſtinguiſhed perſon in the republic of letters, was born at Sarzane, a city of the ſtate of Genoa, in 1591. He ſpent the early part of his life among the Jeſuits, and afterwards became chamberlain to Pope Urban VIII. He was naturally ſo eloquent, that this ſame pope, merely to exerciſe his talent, founded a profeſſorſhip of rhetoric for him in the college de la Sapienza 1628, and ſettled upon him for life a penſion of 500 crowns. Maſcardi filled the chair with great reputation; but his love of letters made him neglect what is of more conſequence than even letters, the management of his affairs: for he was always poor, and always in debt. He wrote a great many things in verſe and proſe; and among the reſt, a treatiſe intitled *Dell' arte hiſtorica*. In his "Hiſtory of the Conſpiracy of the Comtede Fieſque," he has very frequently attacked the religion of Hubert Folietta; and in his other books he uſed ſome writers in the ſame way, which occaſioned him to be attacked in his turn. The objections which were made to him, together with his anſwers, were added to the ſecond edition of the hiſtory juſt mentioned. He died at Sarzane, 1640, in his 49th year.

MASCARON (Julius), biſhop of Agen, and a moſt eminent French preacher, was born at Marſeilles in 1634. He inherited of his father, who was the moſt celebrated advocate of the parliament of Aix, that uncommon talent of eloquence which diſtinguiſhed him. He was admitted a member of the congregation of the oratory very young; and from his 22d year taught rhetoric at Mans. Soon after this he commenced preacher, and preached with great ſucceſs in St Peter's church at Saumur. The biſhop of Mans, willing to engage ſo able a preacher in his church, made him prebendary of it. He was much admired at Paris, when he preached the advent at the oratory. He preached after this five or ſix years at court, and was promoted to the biſhopric of Tulle in 1671. He was afterwards tranſlated to the biſhopric of Agen. He was called in 1694 to preach the Lent ſermon at court. The year following, he opened the aſſembly of the clergy, and returned to his dioceſe; where he died of a dropſy in his cheſt, Dec. 16. 1703. There is nothing printed of this great man excepting A Collection of Funeral Orations made upon the queen-mother, the dauphineſs, the duke of Beaufort, the chancellor Seguier, mareſchal Turenne; and at the head of this collection there is a ſhort life of him.

MASCLEF (Francis), was at firſt a curate in the dioceſe of Amiens, the place of his birth, and afterwards theologian and confidant to the virtuous De Brou biſhop of that dioceſe. He was appointed to the charge of a ſeminary of learning under that prelate. He deſerved this employment both from his piety and profound learning. The oriental languages were as familiar to him as his native tongue. He purſued his reſearches into the idioms of the eaſt with the ſpirit and the ingenuity of a philoſopher. He was made canon of Amiens a little before the death of De Brou, which happened in 1706. His opinions on the Janſeniſt controverſy were ſo offenſive to Sabbatier, the ſucceſſor of that worthy prelate, that he was removed from the care of the ſeminary and from almoſt every other public office which he held. The regard of the dead comforted Maſclef under the oppreſſion of the living. He devoted himſelf to ſtudy with ſo much ardour, that he contracted a diſeaſe of which he died the 14th Nov. 1728, aged 66 years. His principal works are, 1. A Hebrew Grammar in Latin, after his new method, printed at Paris 1716, in 12mo. This grammar was again printed in two volumes in 12mo in the year 1730, under the direction of M. de la Bletterie at that time prieſt of the oratory and the friend of Maſclef. All the objections which Father Guarin made in his Hebrew grammar to Maſclef's method of reading Hebrew without the uſe of points are attended to in this edition. There is nothing more neceſſary, according to this plan, than to take the vowel which is next the conſonant in the order of the alphabet. This method was approved of by ſome learned men, but rejected by a great many more. 2. *Les Conferences Eccleſiaſtiques du dioceſe d'Amiens*, in 12mo. 3. *Le Catechiſme d'Amiens*, in 4to. 4. *Une Philoſophie et une Theologie*, in MS. Theſe would have been publiſhed had they not diſcovered a partiality to the principles of Janſeniſm. The author was an auſtere man, equally reſpectable for his manners and his knowledge.

MASCULINE, ſomething belonging to the male, or the ſtronger of the two ſexes. See Male.

Masculine, is more ordinarily uſed in grammar to ſignify the firſt and worthieſt of the genders of nouns. See Gender.

The maſculine gender is that which belongs to the male kind, or ſomething analogous to it.

Moſt ſubſtances are ranged under the heads of maſculine or feminine.—This, in ſome caſes, is done with a ſhow of reaſon; but in others is merely arbitrary, and for that reaſon is found to vary according to the languages and even according to the words introduced from one language into another.—Thus the names of trees are generally feminine in Latin and maſculine in the French.

Farther, the genders of the ſame word are ſometimes varied in the ſame language. Thus *alvus*, according to Priſcian, was anciently maſculine, but is now become feminine. And *navire*, "a ſhip," in French, was anciently feminine, but is now maſculine.

Masculine Rhyme, in the French poetry, is that made with a word which has a ſtrong, open, and accented pronunciation; as all words have, excepting thoſe which have an *e* feminine in their laſt ſyllable. For inſtance, *amour* and *jour*, *mort* and *ſort*, are maſculine rhymes; and *pere* and *mere*, *gloire* and *memoire*, are feminine. Hence alſo verſes ending with a maſculine rhyme, are called *maſculine verſes*, and thoſe ending with a feminine rhyme, *feminine verſes*. It is now a rule eſtabliſhed among the French poets never to uſe the above two maſculine or two feminine verſes ſucceſſively, except in the looſer kind of poetry. Marot was the firſt who introduced this mixture of maſculine and feminine verſes, and Ronſard was the firſt who practiſed it with ſucceſs. The maſculine verſes ſhould always have a ſyllable leſs than the feminine ones.

Masculine Signs. Aſtrologers divide the ſigns into maſculine and feminine; by reaſon of their qualities, which are either active, and hot or cold, accounted maſculine; or paſſive, dry and moiſt, which are feminine.—On this principle they call the Sun, Jupiter, Saturn, and Mars, *maſculine;* and the Moon and Venus *feminine.* Mercury, they ſuppoſe, partakes of the two. Among the ſigns, Aries, Libra, Gemini, Leo, Sagittarius, Aquarius, are maſculine: Cancer, Capricornus, Taurus, Virgo, Scorpio, and Piſces, are feminine.

MASCULUS flos, in botany. See Flos.

MASH, a drink given to a horſe, made of half a peck of ground malt put into a pail, into which as much ſcalding hot water is poured as will wet it very well: when that is done, ſtir it about, till, by taſting, you find it as ſweet as honey; and when it has ſtood till it is lukewarm, it is to be given to the horſe. This liquor is only uſed after a purge, to make it work the better; or after hard labour, or inſtead of drink in the time of any great ſickneſs.

MASK. See Masque.

MASINISSA, a king of a ſmall part of Africa, who at firſt aſſiſted the Carthaginians in their wars againſt Rome; but afterwards joined the Romans, and became the firmeſt ally they ever had. See Numidia.

MASON, a perſon employed under the direction of an architect, in the raiſing of a ſtone-building.

The chief buſineſs of a maſon is to make the mortar; raiſe the walls from the foundation to the top, with the neceſſary retreats and perpendiculars; to form the vaults, and employ the ſtones as delivered to him. When the ſtones are large, the buſineſs of hewing or cutting them belongs to the ſtone-cutters, though theſe are frequently confounded with maſons: the ornaments of ſculpture are performed by carvers in ſtones or ſculptors. The tools or implements principally uſed by them are the ſquare, level, plumb-line, bevel, compaſs, hammer, chiſſel, mallet, ſaw, trowel, &c. See SQUARE, &c.

Beſides the common inſtruments uſed in the hand, they have likewiſe machines for raiſing of great burdens, and the conducting of large ſtones; the principal of which are the lever, pulley, wheel, crane, &c. See LEVER, &c.

Free and Accepted MASONS, a very ancient ſociety or body of men: ſo called, either from ſome extraordinary knowledge of maſonry or building, which they are ſuppoſed to be maſters of, or becauſe the firſt founders of the ſociety were perſons of that profeſſion. Theſe are now very conſiderable, both for number and character, being found in every country in Europe, and conſiſting principally of perſons of merit and conſideration. As to antiquity, they lay claim to a ſtanding of ſome thouſand years. What the end of their inſtitution is, ſeems ſtill in ſome meaſure a ſecret; and they are ſaid to be admitted into the fraternity by being put in poſſeſſion of a great number of ſecrets, called the *maſon's word*, which have been religiouſly kept from age to age, being never divulged. See *Free-MASONRY*.

MASONRY, in general, a branch of architecture, conſiſting in the art of hewing or ſquaring ſtones, and cutting them level or perpendicular, for the uſes of building: but, in a more limited ſenſe, maſonry is the art of aſſembling and joining ſtones together with mortar.

Hence ariſe as many different kinds of maſonry as there are different forms and manners for laying or joining ſtones. Vitruvius mentions ſeveral kinds of maſonry uſed among the ancients: three of hewed ſtone, *viz.* that in form of a net, that in binding, and that called the *Greek maſonry*; and three of unhewed ſtones, *viz.* that of an equal courſe, that of an unequal courſe, and that filled up in the middle; and the ſeventh was a compoſition of all the reſt.

Plate CCLXXX

Net-maſonry, called by Vitruvius *reticulatum*, from its reſemblance to the meſhes of a net, conſiſts of ſtones ſquared in their courſes, and ſo diſpoſed as that their joints go obliquely; and their diagonals are the one perpendicular and the other level. This is the moſt agreeable maſonry to the eye, but it is very apt to crack. See n° 1.

Bound-maſonry, that in which the ſtones were placed one over another, like tiles; the joints of their beds being level, and the mounters perpendiculars, ſo that the joint that mounts and ſeparates two ſtones always falls directly over the middle of the ſtone below. This is leſs beautiful than the net-work; but it is more ſolid and durable. See n° 2.

Greek maſonry, according to Vitruvius, is that where after we have laid two ſtones, each of which makes a courſe, another is laid at the end, which makes two courſes, and the ſame order is obſerved throughout the building; this may be called *double-binding*, in regard the binding is not only of ſtones of the ſame courſe with one another, but likewiſe of one courſe with another courſe. See n° 3.

Maſonry by equal courſes, called by the ancients *iſodomum*, differs in nothing from the bound maſonry, but only in this, that its ſtones are not hewn. See n° 4.

Maſonry by unequal courſes, called *pſeudiſodomum*, is alſo made of unhewed ſtones, and laid in bound work; but then they are not of the ſame thickneſs, nor is there any equality obſerved excepting in the ſeveral courſes, the courſes themſelves being unequal to each other. See n° 5.

Maſonry filled up in the middle, is likewiſe made of unhewed ſtones, and by courſes; but the ſtones are only ſet in order as to the courſes: (ſee n° 9). A, the courſes; B, the parts filled up; C, a coat of plaſter.

Compound maſonry is of Vitruvius's propoſing, ſo called as being formed of all the reſt. In this the courſes are of hewed ſtone; and the middle being left void, is filled up with mortar and pebbles thrown in together: after this the ſtones of one courſe are bound to thoſe of another courſe with iron-cramps faſtened with melted lead: (See n° 7). E, the ſtones cramped; F, the cramps; G, the middle part filled up.—N° 8. repreſents another ſort of compound maſonry, the middle of which is ſtone, and the edges boards.

All the kinds of maſonry now in uſe may be reduced to theſe five, *viz.* bound maſonry; that of brick-work, where the bodies and projectures of the ſtones incloſe ſquare ſpaces or pannels, &c. ſet with bricks; that de moilon, or ſmall work, where the courſes are equal, well ſquared, and their edges or beds ruſticated; that where the courſes are unequal; and that filled up in the middle with little ſtones and mortar.

Free-MASONRY, denotes the ſyſtem of myſteries and ſecrets peculiar to the ſociety of free and accepted maſons.

The origin of this ſociety is very ancient; but we have no authentic account of the time when it was firſt inſtituted, or even what was the reaſon of ſuch an aſſociation of people under the title of *Maſons*, more than of any other mechanical profeſſion.—In Dr Henry's hiſtory we find the origin of the Free Maſon Society in Britain attributed to the difficulty found in former times, of procuring a ſufficient number of workmen to build the multitude of churches, monaſteries, and other religious edifices which the ſuperſtition of thoſe ages prompted the people to raiſe. Hence the maſons were greatly favoured by the popes, and many indulgences were granted in order to augment their numbers. In times like thoſe we ſpeak of, it may well be ſuppoſed that ſuch encouragement from the ſupreme paſtors of the church muſt have been productive of the moſt beneficial effects to the fraternity; and hence the increaſe of the ſociety may naturally be deduced. The Doctor quotes, in confirmation of this, the words of an author who was well acquainted with their hiſtory and conſtitution. "The Italians (ſays he), with ſome Greek refugees, and with them French, Germans, and Flemings, joined ed into a fraternity of architects, procuring papal bulls for their encouragement and their particular privileges; they ſtyled themſelves *Free-maſons*, and ranged from one nation to another, as they found churches to be built: their government was regular; and where they fixed near the building in hand, they made a camp of huts. A ſurveyor governed in chief; every tenth man was called a *warden*, and overlooked each nine. The gentlemen in the neighbourhood, either out of charity or commutation of penance, gave the materials and carriages. Thoſe who have ſeen the accounts in records of the charge of the fabrics of ſome of our cathedrals near 400 years old, cannot but have a great eſteem for their economy, and admire how ſoon they erected ſuch lofty ſtructures."

By other accounts, however, the antiquity of maſonry is carried up much higher, even as early as the building of Solomon's temple. In Britain the introduction of maſonry has been fixed at the year 674, when glaſs-making was firſt introduced; and it appears indeed, that from this time many buildings in the Gothic ſtyle were erected by men in companies, who are ſaid to have called themſelves *free*, becauſe they were at liberty to work in any part of the kingdom. Others have derived the inſtitution of free maſons from a combination among the people of that profeſſion not to work without an advance of wages, when they were ſummoned from ſeveral counties, by writs of Edward III. directed to the ſheriffs, to aſſiſt in rebuilding and enlarging the caſtle, together with the church and chapel of St George at Windſor. At this time, it is ſaid, the maſons agreed on certain tokens by which they might know and aſſiſt each other againſt being impreſſed, and not to work unleſs free and on their own terms.

In a treatiſe on Maſonry publiſhed in 1792 by William Preſton, maſter of the Lodge of Antiquity, the origin of maſonry is traced from the creation. "Ever ſince ſymmetry began, and harmony diſplayed her charms (ſays he), our order has had a being." Its introduction into England he likewiſe ſuppoſes to have been prior to the Roman invaſion. There are, according to him, the remains yet exiſting, of ſome ſtupendous works executed by the Britons much earlier than the time of the Romans; and even theſe diſplay no ſmall ſhare of ingenuity of invention: ſo that we can have no doubt of the exiſtence of maſonry in Britain even during theſe early periods. The Druids are likewiſe ſaid to have had among them many cuſtoms ſimilar to thoſe of the maſons, and to have derived their government from Pythagoras; but the reſemblance betwixt their uſages and thoſe of the free-maſon ſocieties now exiſting cannot be accurately traced even by the maſons themſelves.

Maſonry is ſaid to have been encouraged by Cæſar, and many of the Roman generals who were appointed governors of Britain: but though we know, that at this period the fraternity were employed in erecting many magnificent fabrics, nothing is recorded concerning their lodges and conventions; and we have but a very imperfect account of the cuſtoms which prevailed in their aſſemblies.

For a long time the progreſs of maſonry in Britain was obſtructed by the frequent wars which took place; and it did not revive till the time of Carauſius, by whom it was patroniſed. This general, who hoped to be the founder of a Britiſh empire, encouraged learning and learned men; collecting alſo the beſt artificers from many different countries, particularly maſons, whom he held in great veneration, and appointing Albanus his ſteward the principal ſuperintendant of their aſſemblies. Lodges, or conventions of the fraternity, began now to be introduced, and the buſineſs of maſonry to be regularly carried on. The maſons, through the influence of Albanus, obtained a charter from Carauſius to hold a general council, at which Albanus himſelf ſat preſident, and aſſiſted at the reception of many new members. This Albanus was the celebrated St Alban, the firſt who ſuffered martyrdom in Britain for the Chriſtian faith. Mr Preſton quotes an old MS. deſtroyed with many others, ſaid to have been in the poſſeſſion of Nicholas Stone, a curious ſculptor under Inigo Jones; from which we learn that St Alban was a great friend to maſons, and gave them two ſhillings per week beſides threepence for their chear; while, before that time, they had no more than one penny per day and their meat. He likewiſe obtained "a charter from the king and his council for them to hold a general council, which was named an *aſſembly*." The ſame circumſtances are mentioned in a MS. written in the time of James II. only this increaſes the weekly ſalary of the maſons to 3s. 6d. and 3d. per day for the bearers of burthens.

The progreſs of maſonry was greatly obſtructed by the departure of the Romans from Britain; and in a ſhort time fell into abſolute neglect. This was occaſioned firſt by the furious irruptions of the Scots and Picts, which left no time for the cultivation of the arts; and afterwards by the ignorance of the Saxons, whom the ill-adviſed Britons called in as allies, but who ſoon became their maſters. After the introduction of Chriſtianity, however, the barbarity of theſe conquerors began to wear off, the arts received ſome encouragement, and maſonry particularly began to flouriſh. Lodges were now formed; but theſe being under the direction of foreigners, were ſeldom convened, and never attained to any degree of conſideration or importance. In this ſituation it continued till the year 557, when St Auſtin, with 40 more monks, among whom the ſciences had been preſerved, came into England. By theſe the principles of Chriſtianity were propagated with ſuch zeal, that all the kings of the heptarchy were converted; after which maſonry was taken under the patronage of St Auſtin, and the Gothic ſtyle of building was introduced into England by the numerous foreigners who reſorted at this time to the kingdom. Auſtin himſelf appeared at the head of the fraternity in founding the old cathedral of Canterbury in 600; that of Rocheſter in 602; St Paul's in London in 604; St Peter's in Weſtminſter in 605, as well as many others. The number of maſons in England was thus greatly increaſed, as well as by his other buildings of caſtles, &c. throughout the kingdom.

In 640 a few expert brethren arrived from France, and formed themſelves into a lodge under the direction of Bennet abbot of Wirral; whom Kenred king of Mercia ſoon after appointed inſpector of the lodges, and general ſuperintendant of the maſons. During the whole time of the heptarchy, however, maſonry was in a low ſtate, but began to revive in 856 under the patronage of St Swithin, whom Ethelwolf employed to repair ſome religious houſes; and from that time the art gradually improved till the year 872, when it found a zealous protector in Alfred the Great. This prince was a moſt eminent patron of all kinds of arts and manufactures; and, with regard to maſonry in particular, he appropriated a ſeventh part of his revenue for maintaining a number of workmen, whom he conſtantly employed in rebuilding the cities, caſtles, &c. ruined by the Danes. During the reign of his ſucceſſor Edward, the maſons continued to hold their lodges under the ſanction of Ethred, huſband to the king's ſiſter, and Ethelward his brother, to whom the care of the fraternity was intruſted. The latter was a great architect, and founded the univerſity of Cambridge.

The true re-eſtabliſhment of maſonry in England, however, is dated from the reign of King Athelſtane; and there is ſtill extant a grand lodge of maſons at York, who trace their exiſtence from this period. This lodge, the moſt ancient in England, was founded in 926, under the patronage of Edwin the king's brother, who obtained for them a charter from Athelſtane, and became grand maſter himſelf. By virtue of this charter it is ſaid, that all the maſons in the kingdom were convened at a general aſſembly in that city, where they eſtabliſhed a general or grand lodge for their future government. Under the patronage and juriſdiction of this lodge it is alſo alleged that the fraternity increaſed very conſiderably, and that kings, princes, and other eminent perſons who had been initiated into the myſteries, paid due allegiance to the aſſembly. But as the times were yet turbulent and barbarous, the art of maſonry was ſometimes more ſometimes leſs patroniſed; and of courſe the aſſembly more or leſs reſpected according to the reſpect which the art itſelf met with. The appellation of *ancient York maſons* is well known both in Ireland and Scotland; and the general tradition is, that they originated at Auldby near York; and as Auldby was a ſeat of Edwin, this tradition gives conſiderable confirmation to the above account. There is indeed great reaſon to believe that York was the original ſeat of maſonic government, no other place having claimed it, and the whole fraternity having at various times owned allegiance to the authority there eſtabliſhed; though we know not whether that allegiance be now given or not. Certain it is, that if ſuch a lodge was once eſtabliſhed there, of which there is no reaſon to doubt, we have no account of its being regularly moved from that place to any other part of the kingdom with conſent of its members. Many reſpectable meetings have indeed been held at different times in other parts of the kingdom, but there is no account of any other general meeting being held in another place than York till very lately.

While prince Edwin lived, the maſons were employed as formerly in building churches, monaſteries, &c. and repairing thoſe which had ſuffered by the ravages of the Danes; and after his death the order was patroniſed by king Athelſtane himſelf; but on his deceaſe the maſons were diſperſed, and remained in an unſettled ſtate till the reign of Edgar in 960. They were now collected by St Dunſtan, who employed them in works of the ſame kind: but as no permanent encouragement was given them, their lodges ſoon declined, and maſonry remained in a low ſtate for upwards of 50 years. It revived, however, in 1041, under Edward the Confeſſor, who ſuperintended the execution of ſeveral great works. By the aſſiſtance of Leofrick earl of Coventry, he rebuilt Weſtminſter Abbey, the earl being appointed ſuperintendant of the maſons; and by this architect many other magnificent ſtructures were likewiſe erected. After the Conqueſt, in 1066, Gundulph biſhop of Rocheſter and Roger de Montgomery earl of Shrewſbury, both of them excellent architects, became joint patrons of the maſons; and under their auſpices the Tower of London was begun, though finiſhed only in the reign of William Rufus, who likewiſe rebuilt London Bridge with wood, and in 1087 firſt conſtructed the palace and hall of Weſtminſter.

The maſons now continued to be patroniſed by the ſovereigns of England in ſucceſſion. The lodges aſſembled during the reign of Henry I. and during that of Stephen, the ſociety were employed in building a chapel at Weſtminſter, now the Houſe of Commons, and ſeveral other works; the preſident of the lodges being now Gilbert de Clare, the marquis of Pembroke. During the reign of Henry II. the lodges were ſuperintended by the grand-maſter of the Knights Templars, who employed them in building their temple in Fleet-Street in the year 1155. Maſonry continued under the patronage of this order till the year 1199, when John ſucceeded Richard I. in the throne of England, and Peter de Colechurch was then appointed grand-maſter. He began to rebuild London bridge with ſtone, which was afterwards finiſhed by William Alcmain in 1209. Peter de Rupibus ſucceeded Peter de Colechurch in the office of grand-maſter, and Geoffrey Fitz-Peter, chief ſurveyor of the king's works, acted as deputy under him; maſonry continued alſo to flouriſh under the auſpices of theſe two artiſts during this and the following reign. On the acceſſion of Edward I. in 1272, the ſuperintendence of the maſons was entruſted to Walter Giffard archbiſhop of York, Gilbert de Clare earl of Glouceſter, and Ralph lord of Mount Hermer, the progenitor of the family of the Montagues; and by theſe architects the abbey of Weſtminſter was finiſhed, after having been begun in 1220, during the minority of Henry II. During the reign of Edward II. the fraternity were employed in building Exeter and Oriel Colleges in Oxford, Clare-hall in Cambridge, &c. under the auſpices of Walter Stapleton biſhop of Exeter, who had been appointed grand-maſter of the maſons in 1307.

Edward III. was a great encourager of learning in general, and not only patroniſed the maſons, but applied very aſſiduouſly to the conſtitutions of the order, reviſed and meliorated the ancient charges, and added ſeveral uſeful regulations to the original code by which the fraternity had been governed. He patroniſed the lodges, and appointed five deputies under him to inſpect their proceedings; and at this period it appears from ſome old records, that the lodges were numerous, and that the fraternity held communications under the protection of the civil magiſtrates. William a Wykeham was continued grand-maſter on the acceſſion of

Richard II. and by him both the New College in Oxford and Wincheſter College were founded at his own expence. After the acceſſion of Henry IV. Thomas Fitz-Allan earl of Surrey was appointed grand-maſter, who, after the engagement at Shrewſbury, founded Battle-abbey and Fotheringay; the Guildhall at London being alſo built in this reign. On the acceſſion of Henry V. the fraternity were directed by Henry Chichely archbiſhop of Canterbury, under whom the lodges and communications of the fraternity were frequent. In 1425, however, during the reign of Henry VI. an act was made againſt the meetings of the chapters and congregations of maſons, becauſe it was ſaid, that by ſuch meetings "the good courſe and effect of the ſtatutes of labourers were openly violated and broken, in ſubverſion of the law, and to the great damage of all the commons." But this act was not put in force, nor did the fraternity ceaſe to meet as uſual under the protection of archbiſhop Chichely, who ſtill continued to preſide over them. The reaſon of this extraordinary edict is ſaid to have been as follows. The duke of Bedford, at that time regent of the kingdom, being in France, the regal power was veſted in his brother Humphrey duke of Glouceſter, who was ſtyled protector and guardian of the kingdom. The care of the young king's perſon and education was entruſted to Henry Beaufort biſhop of Wincheſter, the duke's uncle. This prelate being of an ambitious diſpoſition, and aſpiring at the ſole government, had continual diſputes with his nephew the protector; and by reaſon of the violent temper of that prince, gained frequent advantages over him. This animoſity increaſed to ſuch a degree, that the parliament was at length obliged to interpoſe. On the meeting of that aſſembly in the month of April 1425, however, the ſervants and followers of the peers came thither, armed with clubs and ſtaves; on which account it received the name of the *Bat Parliament*, and at this time the act againſt maſons was made. This was owing to the influence of the biſhop, who wiſhed to deſtroy the meetings of the fraternity on account of the ſecrecy obſerved in them. Dr Anderſon, in the firſt edition of the Book of Conſtitutions, makes the following obſervation upon this act: "It was made in ignorant times, when true learning was a crime, and geometry condemned for conjuration; but it cannot derogate from the honour of the ancient fraternity, who, to be ſure, would never encourage any ſuch confederacy of their working brethren. By tradition, it is believed that the parliament were then too much influenced by the illiterate clergy, who were not accepted maſons, nor underſtood architecture (as the clergy of ſome former ages), and were generally thought unworthy of this brotherhood. Thinking they had an indefeaſible right to know all ſecrets by virtue of auricular confeſſion, and the maſons never confeſſing any thing thereof, the ſaid clergy were highly offended; and at firſt, ſuſpecting them of wickedneſs, repreſented them as dangerous to the ſtate during that minority; and ſoon influenced the parliament to lay hold of ſuch ſuppoſed arguments of the working maſons for making an act that might ſeem to reflect diſhonour upon even the whole fraternity, in whoſe favour ſeveral acts had been made before that period, and were made after it."

The biſhop was ſoon after this diverted from his perſecution of the maſons by an affair of a more important kind. He had formed a deſign of ſurpriſing the city of London on the evening of St Simon and St Jude's day, that on which the Lord Mayor was inveſted with his office. But the plot having been diſcovered by the duke of Glouceſter, the Mayor was ſent for while at dinner, and ordered to keep a ſtrict watch for that night. The biſhop's party accordingly made an attempt to enter by the bridge about nine the next morning, but were repulſed by the vigilance of the citizens. At this the prelate was ſo much enraged, that he collected a numerous body of archers and men at arms, commanding them to aſſault the gate with ſhot. By the prudence of the magiſtrates, however, all violent meaſures were ſtopped; but no reconciliation could be procured betwixt the two parties, though it was attempted by the archbiſhop of Canterbury, and Peter duke of Coimbra, eldeſt ſon to the king of Portugal, with ſeveral other perſons of diſtinction. At laſt the biſhop wrote a letter to the duke of Bedford, urging his return to England, and informing him of the danger there was of a civil war, and reflecting upon the duke of Glouceſter. This letter had the deſired effect. The regent returned, and held a great council at St Albans on the 21ſt of February, but adjourned it to the 15th of March at Northampton, and to the 25th of June at Leiceſter. Bats and ſtaves were now prohibited at theſe meetings; but the parties aſſembled with weapons no leſs formidable, viz. with ſlings, ſtones, and leaden plummets. The duke of Bedford employed all his authority to reconcile the differences; and at laſt obliged the two rivals to promiſe before the aſſembly that they would bury all animoſities in oblivion. During the diſcuſſion of this matter five charges were exhibited by the duke of Glouceſter againſt the biſhop; one of which was, that "he had, in his letter to the duke of Bedford, at France, plainly declared his malicious purpoſe of aſſembling the people, and ſtirring up a rebellion in the nation, contrary to the king's peace." To this the biſhop anſwered, "That he never had any intention to diſturb the peace of the nation or raiſe a rebellion; but that he ſent to the duke of Bedford to ſolicit his return to England, to ſettle all thoſe differences which were ſo prejudicial to the peace of the kingdom: That though he had indeed written in the letter, 'That if he tarried, we ſhould put the land in adventure by a field, ſuch a brother you have here,' he did not mean it of any deſign of his own, but concerning the ſeditious aſſemblies of maſons, carpenters, tylers, and plaiſterers; who being diſtreſſed by the late act of parliament againſt the exceſſive wages of theſe trades, had given out many ſeditious ſpeeches and menaces againſt certain great men, which tended much to rebellion," &c.

Notwithſtanding this heavy charge, the duke of Glouceſter, who knew the innocence of the parties accuſed, took the maſons under his protection, and transferred the charge of ſedition and rebellion from them to the biſhop and his followers. By the intereſt of the latter, however, the king granted him a pardon for all offences; and though the duke drew up freſh articles of impeachment againſt him in 1442, and preſented them in perſon to the king, the council, being compoſed moſtly of eccleſiaſtics, proceeded ſo ſlowly in the buſineſs, that the duke, wearied out with the tediousneſs of the matter, dropped the proſecution entirely.

This conteſt terminated in the impeachment, impriſonment, and murder of the duke of Glouceſter himſelf. This event might have been attended with bad conſequence, had not their inveterate enemy, the prelate himſelf, been taken off by death in about two months after the duke. The maſons then continued not only to meet in ſafety, but were joined by the king himſelf. He was, that very year (1442) initiated into maſonry, and from that time ſpared no pains to become completely maſter of the art. He peruſed the ancient charges, reviſed the conſtitutions, and, with the conſent of his council, honoured them with his ſanction. The example of the ſovereign was followed by many of the nobility, who aſſiduouſly ſtudied the art. The king preſided over the lodges in perſon, nominating William Wanefleet biſhop of Wincheſter grand-maſter. This biſhop at his own expence built Magdalene college, Oxford, and ſeveral religious houſes. Eton-college near Windſor, and King's-college at Cambridge, were alſo founded during this reign. Henry himſelf founded Chriſt's-college, Cambridge, as his queen Margaret of Anjou did Queen's-college in the ſame univerſity.

About this time alſo, the maſons were protected and encouraged by James I. of Scotland, who, after his return from captivity, became a zealous patron of arts and learning of all kinds. He honoured the lodges with his royal preſence, and ſettled an annual revenue of four pounds Scots (an Engliſh noble) to be paid by every maſter-maſon in Scotland, to a grand-maſter choſen by the grand-lodge, and approved by the crown, one nobly born, or an eminent clergyman who had his deputies in cities and counties: ſomething was likewiſe paid him by every new brother at his entry. His office intitled him to regulate every thing in the fraternity which could not come under the juriſdiction of law-courts; and, to prevent law-ſuits, both maſon and lord, or builder and founder, appealed to him. In his abſence, they appealed to his deputy or grand-warden, who reſided next the premiſes.

The flouriſhing ſtate of maſonry was interrupted by the civil wars between the houſes of York and Lancaſter, which brought it almoſt totally into neglect. About 1471, however, it revived under the auſpices of Robert Beauchamp biſhop of Sarum, who had been appointed grand-maſter by Edward IV. and honoured with the title of *Chancellor of the Garter*, for repairing the caſtle and chapel of Windſor. It again declined during the reigns of Edward V. and Richard III.; but came once more into repute on the acceſſion of Henry VII. in 1485. It was now patroniſed by the maſter and fellows of the order of St John at Rhodes (now Malta); who aſſembled their grand-lodge in 1500, and choſe Henry for their protector. On the 24th of June 1502, a lodge of maſters was formed in the palace, at which the king preſided as grand-maſter; and having appointed John Iſlip abbot of Weſtminſter, and Sir Reginald Bray knight of the garter, his wardens for the occaſion, proceeded in great ſtate to the eaſt end of Weſtminſter abbey, where he laid the firſt ſtone of that excellent piece of Gothic architecture called *Henry the Seventh's Chapel.* The cape-ſtone of this building was celebrated in 1507. The palace of Richmond, as well as many other noble ſtructures, were raiſed under the direction of Sir Reginald Bray; and the colleges of Brazen-Noſe in Oxford, and Jeſus and St John's in Cambridge, were all finiſhed in this reign.

On the acceſſion of Henry VIII. Cardinal Wolſey was appointed grand-maſter; who built Hampton-court, Whitehall, Chriſt-church college, Oxford, with ſeveral other noble edifices; all of which, upon the diſgrace of that prelate, were forfeited to the crown in 1530. Wolſey was ſucceeded as grand-maſter in 1534 by Thomas Cromwell earl of Eſſex; who employed the fraternity in building St James's palace, Chriſt's hoſpital, and Greenwich caſtle. Cromwell being beheaded in 1540, John Touchet lord Audley ſucceeded to the office of grand-maſter, and built Magdalen college in Cambridge, and many other ſtructures. In 1547, the duke of Somerſet, guardian to the king, and regent of the kingdom, became ſuperintendant of the maſons, and built Somerſet-houſe in the Strand; which, on his being beheaded, was forfeited to the crown in 1552.

After the death of the duke of Somerſet, John Poynet biſhop of Wincheſter preſided over the lodges till the death of the king in 1553. From this time they continued without any patron till the reign of Elizabeth, when Sir Thomas Sackville accepted of the office of grand-maſter. Lodges, however, had been held during this period in different parts of England; but the general or grand lodge aſſembled in the city of York, where it is ſaid the fraternity were numerous and reſpectable.—Of the queen we have the following curious anecdote with regard to the maſons: Hearing that they were in poſſeſſion of many ſecrets which they refuſed to diſcloſe, and being naturally jealous of all ſecret aſſemblies, ſhe ſent an armed force to York to break up their annual grand-lodge. The deſign was prevented by the interpoſition of Sir Thomas Sackville, who took care to initiate ſome of the chief officers whom ſhe had ſent on this duty in the ſecrets of maſonry. Theſe joined in communication with their new brethren, and made ſo favourable a report to the queen on their return, that ſhe countermanded her orders, and never afterwards attempted to diſturb the meeting of the fraternity. In 1567, Sir Thomas Sackville reſigned the office of grand-maſter in favour of Francis Ruſſel earl of Bedford, and Sir Thomas Greſham an eminent merchant. The former had the care of the brethren in the northern part of the kingdom aſſigned to him, while the latter was appointed to ſuperintend the meetings in the ſouth, where the ſociety had conſiderably increaſed, in conſequence of the honourable report which had been made to the queen. The general aſſembly, however, continued to meet at York as formerly; and here all records were kept, and appeals made on every important occaſion to the aſſembly.

Sir Thomas Greſham abovementioned propoſed to erect a building in the city of London for the benefit of commerce, provided the citizens would purchaſe a ſpot proper for the purpoſe. Accordingly ſome

houſes

houſes between Cornhill and Threadneedle-ſtreet being pulled down, the foundation-ſtone of the building was laid on the 7th of June 1566, and with ſuch expedition was the work carried on, that the whole was finiſhed in November 1567. This building, which was conſtructed on the plan of the exchange of Antwerp, was called at firſt ſimply *the Bourſe*, but in January 1570, the queen having dined with Sir Thomas, returned through Cornhill, entered the Bourſe on the ſouth ſide, and having viewed every part of the building, particularly the gallery which extended round the whole ſtructure, and which was furniſhed with ſhops filled with all ſorts of the fineſt merchandize in the city; ſhe cauſed the edifice to be proclaimed, in her preſence, by herald and trumpet, the *Royal Exchange;* and on this occaſion, it is ſaid Sir Thomas appeared publicly in the character of grand-maſter.

The queen being now thoroughly convinced that the fraternity of maſons did not interfere in ſtate affairs, became quite reconciled to their aſſemblies, and from this time maſonry made a conſiderable progreſs; lodges were held in different parts of the kingdom, particularly in London and its neighbourhood, where the number of the brethren increaſed conſiderably. Several great works were carried on there under the auſpices of Sir Thomas Greſham, from whom the fraternity received every encouragement.

Sir Thomas was ſucceeded in the office of grand-maſter by Charles Howard earl of Effingham, who continued to preſide over the lodges in the ſouth till the year 1588, when George Haſtings earl of Huntingdon was choſen grand-maſter, and remained in the office till the deceaſe of the queen in 1603.

On the acceſſion of James I. to the crown of England, maſonry flouriſhed in both kingdoms, and lodges were held in both kingdoms. A number of gentlemen returned from their travels, with curious drawings of the old Greek and Roman architecture, as well as ſtrong inclination to revive a knowledge of it. Among theſe was the celebrated Inigo Jones, who was appointed general ſurveyor to the king. He was named grand-maſter of England, and was deputed by the king to preſide over the lodges (A). Several learned men were now initiated into the myſteries of maſonry, and the ſociety increaſed conſiderably in reputation and conſequence. Ingenious artiſts reſorted to England in great numbers; lodges were conſtituted as ſeminaries of inſtruction in the ſciences and polite arts after the model of the Italian ſchools; the communications of the fraternity were eſtabliſhed, and the annual feſtivals regularly obſerved. Under the direction of this accompliſhed architect, many magnificent ſtructures were raiſed; and among the reſt he was employed, by command of the ſovereign, to plan a new palace at Whitehall, worthy of the reſidence of the kings of England. This was executed; but for want of a parliamentary fund, no more of the plan was ever finiſhed than the banqueting-houſe. Inigo Jones continued in the office of grand-maſter till the year 1618, when he was ſucceeded by the earl of Pembroke; under whoſe auſpices many eminent and wealthy men were initiated, and the myſteries of the order held in high eſtimation.

After Charles I. aſcended the throne, Earl Pembroke was continued in his office till the year 1630, when he reſigned in favour of Henry Danvers earl of Danby. This nobleman was ſucceeded in 1633 by Thomas Howard earl of Arundel, the anceſtor of the Norfolk family. In 1635, Francis Ruſſel earl of Bedford accepted the government of the ſociety; but Inigo Jones having continued to patronize the lodges during his lordſhip's adminiſtration, he was re-elected the following year, and continued in office till the year of his death, 1646. The progreſs of maſonry, however, was for ſome time obſtructed by the breaking out of the civil wars; but it began to revive under the patronage of Charles II. who had been received into the order during his exile. Some lodges during this reign were conſtituted by *leave* of the *ſeveral* noble grand-maſters, and many gentlemen and famous ſcholars requeſted at that time to be admitted into the fraternity. On the 27th of December 1663, a general aſſembly was held, where Henry Jennyn earl of St Alban's was elected grand-maſter; who appointed Sir John Denham his deputy, and Mr Chriſtopher Wren, afterwards the celebrated Sir Chriſtopher Wren, and John Webb, his wardens. At this aſſembly ſeveral uſeful regulations were made, for the better government of the lodges; and the greateſt harmony prevailed among the whole fraternity. The earl of St Alban's was ſucceeded in his office of grand-maſter by earl Rivers in the year 1666, when Sir Chriſtopher Wren was appointed deputy, and diſtinguiſhed himſelf beyond any of his predeceſſors in promoting the proſperity of the lodges which remained at that time, particularly that of St Paul's, now the lodge of Antiquity, which he patronized upwards of 18 years. At this time he attended the meetings regularly; and during his preſidency made a preſent to the lodge of three mahogany candleſticks, which at that time were very valuable. They are ſtill preſerved, and highly valued as a teſtimony of the eſteem of the donor.

The fire which in 1666 deſtroyed ſuch a great part of London, afforded ample opportunity for the maſons to exert their abilities. After a calamity ſo ſudden and extenſive, however, it became neceſſary to adopt ſome regulations to prevent ſuch a cataſtrophe in time to come. It was now determined, that in all the new buildings to be erected, ſtone ſhould be uſed inſtead of timber. Wren was ordered by the king and grand-maſter to draw up the plan of a city with broad and regular ſtreets. Dr Chriſtopher Wren was appointed ſurveyor-general and principal architect for rebuilding the city, the cathedral of St Paul, and all the parochial churches enacted by parliament, in lieu of thoſe that were deſtroyed, with other public ſtructures. This gentleman, however, conceiving the charge to be too important for a ſingle perſon, ſelected for his aſſiſtant Mr Robert Hook profeſſor of geometry in Greſham college. The latter was immediately employed in meaſuring, adjuſting, and ſetting out the ground

---

(A) Mr Preſton obſerves, that the grand-maſter of the north bears the title of *grand-maſter of all England*, which (ſays he) may probably have been occaſioned by the title of *grand-maſter*.

ground of the private ſtreets to the ſeveral proprietors. The model and plan were laid before the king and houſe of commons, and the practicability of the whole ſcheme, without any infringement of private property: but unfortunately it happened, that the greater part of the citizens were totally averſe to leaving their old habitations, and building houſes in other places; and ſo obſtinate were they in their determinations, that they choſe rather to have their old city again under all its diſadvantages, than a new one upon the improved plan. Thus an opportunity was loſt of making the new city the moſt magnificent as well as the moſt convenient for health and commerce of any in Europe. Hence the architect, being cramped in the execution of his plan, was obliged to alter and abridge it, and to model the city after the manner in which it has ſince appeared.—In 1673 the foundation-ſtone of the cathedral of St Paul's was laid with great ſolemnity by the king in perſon, and the mallet which he uſed on this occaſion is ſtill preſerved in the lodge of Antiquity as a great curioſity.

During the time that the city was rebuilding, lodges were held by the fraternity in different places, and many new ones conſtituted, to which the beſt architects reſorted. In 1674, earl Rivers reſigned the office of grand-maſter in favour of George Villiers duke of Buckingham, who left the care of the fraternity to his wardens, and Sir Chriſtopher Wren who ſtill continued to act as deputy. In 1679, the duke reſigned in favour of Henry Bennet earl of Arlington: but this nobleman was too deeply engaged in ſtate affairs to attend to his duty as a maſon, though the lodges continued to meet under his ſanction, and many reſpectable gentlemen joined the fraternity. During the ſhort reign of James II. the maſons were much neglected. In 1685, Sir Chriſtopher Wren was elected to the office of grand-maſter, who appointed Gabriel Cibber and Mr Edward Strong his wardens: yet notwithſtanding the great reputation and abilities of this celebrated architect, maſonry continued in a declining way for many years, and only a few lodges were held occaſionally in different parts of the kingdom.

At the Revolution, the ſociety was in ſuch a low ſtate in the ſouth of England, that only ſeven regular lodges were held in London and its ſuburbs; and of theſe only two, viz. that of St Paul's and one at St Thomas's hoſpital, Southwark, were of any conſequence. But in 1695 king William having been initiated into the myſteries, honoured the lodges with his preſence, particularly one at Hampton-court, at which he is ſaid to have frequently preſided during the time that the new part of his palace was building. Many of the nobility alſo were preſent at a general aſſembly and feaſt held in 1697, particularly Charles duke of Richmond and Lenox, who was elected grand-maſter for that year; but in 1698 reſigned his office to Sir Chriſtopher Wren, who continued at the head of the fraternity till King William's death in 1702.

During the reign of Queen Anne, maſonry made no conſiderable progreſs. Sir Chriſtopher's age and infirmities drew off his attention from the duties of his office, the annual feſtivals were entirely neglected, and the number of maſons conſiderably diminiſhed. It was therefore determined that the privileges of maſonry ſhould not be confined to operative maſons, but that people of all profeſſions ſhould be admitted to participate in them, provided they were regularly approved and initiated into the order.

Thus the ſociety once more roſe into eſteem; and on the acceſſion of George I. the maſons, now deprived of Sir Chriſtopher Wren, reſolved to unite again under a grand-maſter, and revive the annual feſtivals. With this view, the members of the only four lodges at that time exiſting in London, met at the Apple-tree tavern in Charles-ſtreet, Covent Garden; and having voted the oldeſt maſter-maſon then preſent into the chair, conſtituted themſelves a grand-lodge *pro tempore*. It was now reſolved to renew the quarterly communications among the brethren; and at an annual meeting held on the 24th of June the ſame year, Mr Anthony Sayer was elected grand-maſter, inveſted by the oldeſt maſter-maſon there preſent, inſtalled by the maſter of the oldeſt lodge, and had due homage paid him by the fraternity. Before this time a ſufficient number of maſons, met together within a certain diſtrict, had ample power to make maſons without a warrant of conſtitution; but it was now determined, that the privilege of aſſembling as maſons ſhould be veſted in certain lodges or aſſemblies of maſons convened in certain places, and that every lodge to be afterwards convened, excepting the four old lodges then exiſting, ſhould be authorized to act by a warrant from the grand-maſter for the time, granted by petition from certain individuals, with the conſent and approbation of the grand-lodge in communication; and that without ſuch warrant, no lodge ſhould hereafter be deemed regular or conſtitutional. The former privileges, however, were ſtill allowed to remain to the four old lodges then extant. In conſequence of this, the old maſons in the metropolis veſted all their inherent privileges as individuals in the four old lodges, in truſt that they never would ſuffer the ancient charges and land-marks to be infringed. The four old lodges, on their part, agreed to extend their patronage to every new lodge which ſhould hereafter be conſtituted according to the new regulations of the ſociety; and while they acted in conformity to the ancient conſtitutions of the order, to admit their maſters and wardens to ſhare with them all the privileges of the grand-lodge, that of precedence only excepted.

Matters being thus ſettled, the brethren of the four old lodges conſidered their attendance on the future communications of the ſociety as unneceſſary; and therefore truſted implicitly to their maſters and wardens, ſatisfied that no meaſure of importance would be adopted without their approbation. It was, however, ſoon diſcovered, that the new lodges being equally repreſented with the old ones at the communications, would at length ſo far outnumber them, that by a majority they might ſubvert the privileges of the original maſons of England which had been centered in the four old lodges; on which account a code of laws was, with the conſent of the brethren at large, drawn up for the future government of the ſociety. To this the following was annexed, binding the grand-maſter for the time being, his ſucceſſors, and the maſter of every lodge to be hereafter conſtituted, to preſerve it inviolably; "Every annual grand-lodge has an an inherent power and authority to make new regulations, or to alter theſe for the real benefit of this ancient fraternity, provided always that the old landmarks be carefully preſerved: and that ſuch alterations and new regulations be propoſed and agreed to at the third quarterly communication preceding the annual grand feaſt; and that they be offered alſo to the peruſal of all the brethren before dinner, in writing, even of the youngeſt apprentice; the approbation and conſent of the majority of all the brethren preſent being abſolutely neceſſary to make the ſame binding and obligatory." To commemorate this circumſtance, it has been cuſtomary, ever ſince that time, for the maſter of the oldeſt lodge to attend every grand inſtallation; and, taking precedence of all preſent, the grand-maſter only excepted, to deliver the book of the original conſtitutions to the new inſtalled grand-maſter, on his promiſing obedience to the ancient charges and general regulations.

By this precaution the original conſtitutions were eſtabliſhed as the baſis of all ſucceeding maſonic juriſdiction in the ſouth of England; and the ancient *land-marks*, as they are called, or the boundaries ſet up as checks againſt innovation, were carefully ſecured from the attacks of any future invaders. No great progreſs, however, was made during the adminiſtration of Mr Sayer, only two lodges being conſtituted, though ſeveral brethren joined the old ones. In 1718 Mr Sayer was ſucceeded by Mr George Payne, who collected many valuable manuſcripts on the ſubject of maſonry, and earneſtly requeſted, that the fraternity would bring to the grand lodge any old writings or records concerning the fraternity, to ſhow the uſages of ancient times: and in conſequence of this invitation, ſeveral old copies of the Gothic conſtitutions were produced, arranged, and digeſted. Another aſſembly and feaſt were held on the 24th of June 1719, when Dr Deſaguliers was unanimouſly elected grand-maſter. At this feaſt the old, regular, and peculiar toaſts were introduced; and from this time we may date the riſe of free-maſonry on its preſent plan in the ſouth of England. Many new lodges were eſtabliſhed, the old ones viſited by many maſons who had long neglected the craft, and ſeveral noblemen initiated into the myſteries. In 1720, however, the fraternity ſuſtained an irreparable loſs by the burning of ſeveral valuable manuſcripts, concerning the lodges, regulations, charges, ſecrets, &c. (particularly one written by Mr Nicholas Stone, the warden under Inigo Jones). This was done by ſome ſcrupulous brethren, who were alarmed at the publication of the maſonic conſtitutions. At a quarterly communication it was this year agreed, that, for the future, the new grand-maſter ſhall be named and propoſed to the grand lodge ſome time before the feaſt; and if approved and preſent, he ſhall be ſaluted as grand-maſter elect: and that every grand-maſter, when he is inſtalled, ſhall have the ſole power of appointing his deputy and wardens according to ancient cuſtom.

In the mean time maſonry continued to ſpread in the north as well as the ſouth of England. The general aſſembly, or grand lodge at York, continued to meet as uſual. Several lodges met in 1705, under the direction of Sir John Tempeſt baronet, then grand-maſter; and many perſons of worth and character were initiated into the myſteries of the fraternity. The greateſt harmony ſubſiſted between the two grand lodges, and private lodges were formed in both parts of the kingdom under their ſeparate juriſdiction. The only diſtinction which the grand lodge in the north appears to have retained is in the title of the *Grand Lodge of all England;* while the other was only called the *Grand Lodge of England.* The latter, however, being encouraged by ſome of the principal nobility, ſoon acquired conſequence and reputation, while the other ſeemed gradually to decline; but, till within theſe few years, the authority of the grand lodge at York was never challenged; on the other hand, every maſon in the kingdom held that aſſembly in the higheſt veneration, and conſidered himſelf bound by the charges which originated from that aſſembly. It was the glory and boaſt of the brethren in almoſt every country where maſonry was eſtabliſhed to be accounted deſcendants of the original York maſons; and from the univerſality of the idea that maſonry was firſt eſtabliſhed at York by charter, the maſons of England have received tribute from the firſt ſtates in Europe. At preſent, however, this ſocial intercourſe is aboliſhed, and the lodges in the north and ſouth are almoſt entirely unknown to one another; and neither the lodges of Scotland nor Ireland court the correſpondence of the grand lodge at London. This is ſaid to have been owing to the introduction of ſome innovations among the lodges in the ſouth; but for the coolneſs which ſubſiſts between the two grand lodges another reaſon is aſſigned. A few brethren at York having, on ſome trivial occaſion, ſeceded from their ancient lodge, they applied to London for a warrant of conſtitution. Their application was honoured without any inquiry into the merits of the caſe; and thus, inſtead of being recommended to the mother-lodge to be reſtored to favour, theſe brethren were encouraged to revolt, and permitted, under the ſanction of the grand lodge in London, to open a new lodge in the city of York itſelf. This illegal extenſion of power juſtly offended the grand lodge at York, and occaſioned a breach which has never yet been made up.

The duke of Buccleugh, who in 1723 ſucceeded the duke of Wharton as grand-maſter, firſt propoſed the ſcheme of raiſing a general fund for diſtreſſed maſons. The duke's motion was ſupported by Lord Paiſley, Colonel Houghton, and a few other brethren; and the grand lodge appointed a committee to conſider of the moſt effectual means of carrying the ſcheme into execution. The diſpoſal of the charity was firſt veſted in ſeven brethren; but this number being found too ſmall, nine more were added. It was afterwards reſolved that 12 maſters of contributing lodges, in rotation with the grand officers, ſhould form the committee; and by another regulation ſince made, it has been determined that all paſt and preſent grand officers, with the maſters of all regular lodges which ſhall have contributed within 12 months to the charity, ſhall be members of the committee. This committee meets four times in the year by virtue of a ſummons from the grand maſter or his deputy. The petitions of the diſtreſſed brethren are conſidered at theſe meetings; and if the petitioner be conſidered as a deſerving object, he is immediately relieved with five pounds. If the circumſtances of the caſe are of a peculiar nature, his petition is referred to the next communication, where he is relieved with any ſum the committee may have ſpecified, not exceeding 20 guineas at one time. Thus the diſtreſſed have always found ready relief from this general charity, which is ſupported by the voluntary contributions of different lodges out of their private funds, without being burdenſome to any member in the ſociety. Thus has the committee of charity for free maſons been eſtabliſhed; and ſo liberally have the contributions been, that though the ſums annually expended for the relief of the diſtreſſed brethren have for ſeveral years paſt amounted to many thouſand pounds, there ſtill remains a conſiderable ſum.

The moſt remarkable events which of late has taken place in the affairs of maſonry, are the initiation of Omitul-Omrah Bahauder, eldeſt ſon of the nabob of the Carnatic, who was received by the lodge of Trinchinopoly in the year 1779. The news being officially tranſmitted to England, the grand lodge determined to ſend a congratulatory letter to his highneſs on the occaſion, accompanied with an apron elegantly decorated, and a copy of the book of Conſtitutions ſuperbly bound. The execution of this commiſſion was entruſted to Sir John Duy, advocate-general of Bengal; and in the beginning of 1780, an anſwer was received from his highneſs, acknowledging the receipt of the preſent, and expreſſing the warmeſt attachment and benevolence to his brethren in England. The letter was written in the Perſian language, and incloſed in an elegant cover of cloth of gold, and addreſſed to the grand-maſter and grand lodge of England. A proper reply was made; and a tranſlation of his highneſs's letter was ordered to be copied on vellum; and, with the original, elegantly framed and glazed, and hung up in the hall at every public meeting of the ſociety.

After ſuch a long hiſtory of the riſe and progreſs of maſonry, it muſt be natural to inquire into the uſes of the inſtitution, and for what purpoſe it has been patroniſed by ſo many great and illuſtrious perſonages. The profound ſecrecy, however, in which every thing relating to maſonry is involved, prevents us from being very particular on this head. The maſons themſelves ſay, in general, that it promotes philanthropy, friendſhip, and morality; that in proportion as maſonry has been cultivated, the countries have been civilized, &c. How far this can be depended upon, the fraternity themſelves beſt know. Another advantage, however, ſeems leſs equivocal, viz. that its ſigns ſerve as a kind of univerſal language, ſo that by means of them people of the moſt diſtant nations may become acquainted, and enter into friendſhip with one another. This certainly muſt be accounted a very important circumſtance; and conſidering the great number which have been, and daily are, admitted to the ſociety, and their inviolable attachment to the art, we muſt certainly conclude, that if it contains nothing of great importance to mankind at large, it muſt at leaſt be extremely agreeable, and even faſcinating to thoſe who are once initiated.

Egyptian Masonry, a new ſyſtem of maſonry taught by the celebrated impoſtor the Count Caglioſtro.—It is not known whether this ſyſtem was an invention of his own, or whether any ſuch thing really has an exiſtence among the ſuperſtitious Egyptians. The ſcheme was firſt put in execution in London; and by means of his pretended knowledge in the myſteries of this art, the Count procured great ſums of money, and attached to himſelf a vaſt number of followers. The following particulars concerning it were confeſſed by him before the inquiſition at Rome.

The Egyptian maſons are divided into ſeveral ſects, but there are two more eſteemed than the reſt. The firſt is that of the adepts, the members of which (ſay the inquiſitors) profeſs the moſt irreligious ſentiments, and employ magic in their operations; but their principal object is the deſtruction of the Catholic religion and of monarchy. The members of the other pretend to be occupied about the ſecrets of the hermetic art, and more eſpecially the philoſopher's ſtone. Caglioſtro owned that he was aſſociated in London with the ſecond of theſe ſects; that his wife was likewiſe a member, and received a diploma, which coſt five guineas. The lady was preſented with a ribbon, on which were embroidered the words *Union*, *Silence*, and *Virtue*; and ſhe was deſired to ſleep the following night with the ribbon attached to her thigh. When a male candidate is to be admitted, his courage muſt be tried in a number of ways. Caglioſtro himſelf ſubmitted to theſe trials; among which the following are mentioned in the account of his life. He was firſt hoiſted up to the cieling by means of a pulley, and, after ſuffering conſiderable pain, had his hand ſcorched by means of a candle. His eyes were then covered with a bandage, and he received an empty piſtol, with orders to charge it. This being done, he was ordered to diſcharge it againſt his head; and upon his refuſing to do ſo, the piſtol was taken from him with contempt, but returned after a number of ceremonies. This had ſuch an effect upon him, that without any regard to ſelf-preſervation, he drew the trigger, and got a ſmart ſtroke on the ſkull, which, however, produced no bad conſequence. At the initiation of other candidates, he diſcovered that the piſtol was changed, an unloaded one being put into the hands of the perſon when blind-folded, and that one of the aſſiſtants ſtruck him a ſmart blow on the head, to make him think himſelf wounded. The ceremony was concluded with his taking an oath of ſecrecy and obedience to the grand-maſter.

MASORA, a term in the Jewiſh theology, ſignifying a work on the Bible, performed by ſeveral learned rabbins, to ſecure it from any alterations which might otherwiſe happen.

Their work regards merely the letter of the Hebrew text, in which they have, firſt, fixed the true reading by vowels and accents: they have, ſecondly, numbered not only the chapters and ſections, but the verſes, words, and letters of the text: and they find in the Pentateuch 5245 verſes, and in the whole Bible 23206. The maſora is called, by the Jews, the *hedge or fence of the law*, becauſe this enumeration of the verſes, &c. is a means of preſerving it from being corrupted and altered. They have, thirdly, marked whatever irregularities occur in any of the letters of the Hebrew text; ſuch as the different ſize of the letters, their various poſitions and inverſions, &c. and they have been fruitful in finding out reaſons for theſe irregularities and myſteries in them. They are, fourthly, ſuppoſed to be be the authors of the Keri and Chetibh, or the marginal correction's of the text in our Hebrew Bibles.

The text of the ſacred books, it is to be obſerved, was originally written without any breaks or diviſions into chapters or verſes, or even into words; ſo that a whole book, in the ancient manner, was but one continued word: of this kind we have ſtill ſeveral ancient manuſcripts, both Greek and Latin. In regard, therefore, the ſacred writings had undergone an infinite number of alterations, whence various readings had ariſen, and the original was become much mangled and diſguiſed, the Jews had recourſe to a canon, which they judged infallible, to fix and aſcertain the reading of the Hebrew text; and this rule they call *maſora*, "tradition," from מסר, *tradidit*, as if this critique were nothing but a tradition which they had received from their forefathers. Accordingly they ſay, that when God gave the law to Moſes at Mount Sinai, he taught him, firſt, the true reading of it; and, ſecondly, its true interpretation; and that both theſe were handed down by oral tradition, from generation to generation, till at length they were committed to writing. The former of theſe, viz. the true reading, is the ſubject of the maſora; the latter, or true interpretation, that of the miſhna and gemara.

According to Elias Levita, they were the Jews of a famous ſchool at Tiberias, about 500 years after Chriſt, who compoſed, or at leaſt began, the maſora; whence they are called *maſorites*, and *maſoretic doctors*. Aben Ezra makes them the authors of the points and accents in the Hebrew text, as we now find it; and which ſerve for vowels.

The age of the maſorites has been much diſputed. Archbiſhop Uſher places them before Jerom; Capel, at the end of the fifth century; father Morin, in the tenth century. Baſnage ſays, that they were not a ſociety, but a ſucceſſion of men; and that the maſora is the work of many grammarians, who, without aſſociating and communicating their notions, compoſed this collection of criticiſms on the Hebrew text. It is urged that there were maſorites from the time of Ezra and the men of the great ſynagogue, to about the year of Chriſt 1030; and that Ben Aſher and Ben Naphtali, who were the beſt of the profeſſion, and who, according to Baſnage, were the inventors of the maſora, flouriſhed at this time. Each of theſe publiſhed a copy of the whole Hebrew text, as correct, ſays Dr Prideaux, as they could make it. The eaſtern Jews have followed that of Ben Naphtali, and the weſtern that of Ben Aſher; and all that has been done ſince is to copy after them, without making any more corrections, or maſoretical criticiſms.

The Arabs have done the ſame thing by their Koran that the maſorites have done by the Bible; nor do the Jews deny their having borrowed this expedient from the Arabs, who firſt put it in practice in the ſeventh century.

There is a great and little maſora printed at Venice and at Baſil, with the Hebrew text in a different character. Buxtorf has written a maſoretic commentary, which he calls *Tiberias*.

MASQUE, or Mask, a cover for the face, contrived with apertures for the eyes and mouth; originally worn chiefly by women of condition, either to preſerve their complexion from the weather, or out of modeſty to prevent their being known. Poppæa, wife of Nero, is ſaid to be the firſt inventor of the *maſque*; which ſhe did to guard her complexion from the ſun and weather, as being the moſt delicate woman, with regard to her perſon, that has been known.

Theatrical maſques were in common uſe both among the Greeks and Romans: Suidas and Athenæus aſcribe the invention of them to the poet Choerilus, a contemporary of Theſpis; Horace attributes them to Æſchylus; but Ariſtotle informs us, that the real inventor, and conſequently the time of their firſt introduction and uſe, were unknown. Brantome obſerves, that the common uſe of modern maſques was not introduced till towards the end of the ſixteenth century.

Masque is alſo uſed to ſignify any thing uſed to cover the face, and prevent a perſon's being known. The penitents of Lyons and Avignon hide their faces with large white veils, which ſerve them for maſques.

The Iron Masque (Maſque de Fer), or *Man with the iron maſque*, a remarkable perſonage ſo denominated, who exiſted as a ſtate priſoner in France during the latter part of the laſt century. As the circumſtances of this perſon form a hiſtorical problem which has occaſioned much inquiry, and given riſe to many conjectures, as well as of late, in conſequence of the deſtruction of the Baſtile, excited in a particular manner the curioſity of the public, it ſhall be endeavoured to condenſe in this article the ſubſtance of every thing material that has been publiſhed on the ſubject. We ſhall firſt relate ſuch particulars concerning this extraordinary priſoner as appear to be well authenticated; and ſhall afterwards mention the different opinions and conjectures that have been entertained with regard to his real quality, and the cauſes of his confinement.

I. The authenticated particulars concerning the *iron Maſque* are as follows:—A few months after the death of Cardinal Mazarine, there arrived at the iſle of Sainte Marguerite, in the ſea of Provence, a young priſoner whoſe appearance was peculiarly attracting: his perſon was above the middle ſize, and elegantly formed; his mien and deportment were noble, and his manners graceful; and even the ſound of his voice, it is ſaid, had in it ſomething uncommonly intereſting. On the road he conſtantly wore a maſk made with iron ſprings, to enable him to eat without taking it off. It was at firſt believed that this maſque was made entirely with iron; whence he acquired the name of "the Man with the iron maſk." His attendants had received orders to diſpatch him if he attempted to take off his maſque or diſcover himſelf.—He had been firſt confined at Pigneol, under the care of the governor M. de St Mars; and upon being ſent from thence to Sainte Marguerite, he was accompanied thither by the ſame perſon, who continued to have the charge of him. He was always treated with the moſt marked reſpect: he was ſerved conſtantly in plate; and the governor himſelf placed his diſhes on the table, retiring immediately after and locking the door behind him. He *tu-to'you* (thee'd and thou'd) the governor; who, on the other hand, behaved to him in the moſt reſpectful manner, and never wore his hat before him, nor ſat down in his preſence unleſs he was deſired. The Marquis de Louvoiſis, who went to ſee him at St Marguerite, ſpoke to him ſtanding, and with that kind of attention which denotes high reſpect.

During his reſidence here, he attempted twice, in an indirect manner, to make himſelf known. One day he wrote ſomething with his knife on a plate, and threw it out of his window towards a boat that was drawn on ſhore near the foot of the tower. A fiſherman picked it up and carried it to the governor. M. de St Mars was alarmed at the ſight; and aſked the man with great anxiety, whether he could read, and whether any one elſe had ſeen the plate? The man anſwered, that he could not read, that he had but juſt found the plate, and that no one elſe had ſeen it. He was, however, confined till the governor was well aſſured of the truth of his aſſertions.—Another attempt to diſcover himſelf proved equally unſucceſsful. A young man who lived in the iſle, one day perceived ſomething floating under the priſoner's window; and on picking it up, he diſcovered it to be a very fine ſhirt written all over. He carried it immediately to the governor; who, having looked at ſome parts of the writing, aſked the lad, with ſome appearance of anxiety, if he had not had the curioſity to read it? He proteſted repeatedly that he had not: but two days afterwards he was found dead in his bed.

The *Maſque de Fer* remained in this iſle till the year 1698, when M. St Mars being promoted to the government of the Baſtile, conducted his priſoner to that fortreſs. In his way thither, he ſtopt with him at his eſtate near Palteau. The Maſque arrived there in a litter, ſurrounded by a numerous guard on horſeback. M. de St Mars eat at the ſame table with him all the time they reſided at Palteau; but the latter was always placed with his back towards the windows; and the peaſants, who came to pay their compliments to their maſter, and whom curioſity kept conſtantly on the watch, obſerved that M. de St Mars always ſat oppoſite to him with two piſtols by the ſide of his plate. They were waited on by one ſervant only, who brought in and carried out the diſhes, always carefully ſhutting the door both in going out and returning. The priſoner was always maſked, even when he paſſed through the court; but the people ſaw his teeth and lips, and alſo obſerved that his hair was grey.—The governor ſlept in the ſame room with him, in a ſecond bed that was placed in it on that occaſion. In the courſe of their journey, the iron-maſk was, one day, heard to aſk his keeper whether the king had any deſign on his life? "No, Prince," he replied; "provided that you quietly allow yourſelf to be conducted, your life is perfectly ſecure."

The ſtranger was accommodated as well as it was poſſible to be in the Baſtile. An apartment had been prepared for him by order of the governor before his arrival, fitted up in the moſt convenient ſtyle; and every thing he expreſſed a deſire for was inſtantly procured him. His table was the beſt that could be provided; and he was ordered to be ſupplied with as rich clothes as he deſired: but his chief taſte in this laſt particular was for lace, and for linen remarkably fine. It appears that he was allowed the uſe of ſuch books as he deſired, and that he ſpent much of his time in reading. He alſo amuſed himſelf with playing upon the guitar. He had the liberty of going to maſs; but was then ſtrictly forbid to ſpeak or uncover his face: orders were even given to the ſoldiers to fire upon him if he attempted either; and their pieces were always pointed towards him as he paſſed through the court. When he had occaſion to ſee a ſurgeon or a phyſician, he was obliged, under pain of death, conſtantly to wear his maſk. An old phyſician of the Baſtile, who had often attended him when he was indiſpoſed, ſaid, that he never ſaw his face, though he had frequently examined his tongue, and different parts of his body; that there was ſomething uncommonly intereſting in the ſound of his voice; and that he never complained of his confinement, nor let fall from him any hint by which it might be gueſſed who he was. It is ſaid that he often paſſed the night in walking up and down his room.

This unfortunate prince died on the 19th of November 1703, after a ſhort illneſs; and was interred next day in the burying-place of the pariſh of St Paul. The expence of his funeral amounted only to forty livres. The name given him was *Marchiali:* and even his age, as well as his real name, it ſeemed of importance to conceal; for in the regiſter made of his funeral, it was mentioned that he was about forty years old; though he had told his apothecary, ſome time before his death, that he thought he muſt be ſixty.—It is a well known fact, that immediately after the priſoner's death, his apparel, linen, clothes matraſſes, and in ſhort every thing that had been uſed by him, were burnt; that the walls of his room were ſcraped, the floor taken up, evidently from the apprehenſion that he might have found means of writing any thing that would have diſcovered who he was. Nay ſuch was the fear of his having left a letter or any mark which might lead to a diſcovery, that his plate was melted down; the glaſs was taken out of the window of his room and pounded to duſt; the window-frame and doors burnt; and the ceiling of the room, and the plaſter of the inſide of the chimney, taken down. Several perſons have affirmed, that the body was buried without a head; and Monſieur de Saint Foix informs us †, that "a gentleman having bribed the ſexton, had the body taken up in the night, and found a ſtone inſtead of the head."

The reſult of theſe extraordinary accounts is, that the iron maſque was not only a perſon of high birth, but muſt have been of great conſequence; and that his being concealed was of the utmoſt importance to the king and miniſtry. We come now, therefore, to notice,

II. The opinions and conjectures that have been formed concerning the real name and condition of this remarkable perſonage. Some have pretended that he was the duke of Beaufort; others, that he was the Count de Vermandois, natural ſon to Louis XIV. by the ducheſs de la Valliere. Some maintain him to have been the duke of Monmouth, natural ſon of Charles II. of England by Lucy Walters; and others ſay, that he was Gerolami Magni, miniſter to the duke of Modena.

Beſides theſe conjectures, none of which poſſeſſes ſufficient probability to entitle them to conſideration, a fifth has been advanced; namely, That the Iron Maſque was a ſon of Anne of Auſtria, queen to Louis XIII. and conſequently that he was a brother of Louis XIV.; but whether a baſtard brother, a bro-

ther-

† In his E
*ſais Hiſt-
riques.*

ther-german, or a half brother, is a queſtion that has given riſe to three ſeveral opinions, which we ſhall ſtate in the order of time in which the reſpective tranſactions to which they allude happened.

1. The firſt opinion is, that the queen proved with child at a time when it was evident it could not have been by her huſband, who, for ſome months before, had never been with her in private. The ſuppoſed father of this child is ſaid by ſome to have been the duke of Buckingham, who came to France in May 1625, to conduct the princeſs Henrietta, wife of Charles I. to England. The private letters and memoirs of thoſe times ſpeak very ſuſpiciouſly of the queen and Buckingham: his behaviour at Amiens, whither the queen and queen-mother accompanied the princeſs in her way to Boulogne, *occaſioned much whiſpering:* notwithſtanding the pains that have been taken by La Porte in his *Memoires* to excuſe his miſtreſs, it appears that the king, on this occaſion, was extremely offended at her, and that it required all the influence and addreſs of the queen-mother to effect a reconciliation. It is ſaid, that this child was privately brought up in the country; that when Mazarin became a favourite, he was entruſted with the care of him; and that Louis XIV. having diſcovered the ſecret on the death of the cardinal, thought it neceſſary to confine him in the manner that has been related.

Hiſt. of the Baſtile, n° 6. p. 343.

But it may be obſerved, that this ſecret could ſcarcely have eſcaped the vigilance of the cardinal de Richlieu; and it is not improbable, that a miniſter ſo little ſcrupulous, if inclined to ſave the honour of a queen, would have removed a child, who, if he lived, might have been made uſe of to diſturb the tranquillity of the kingdom. After this ſuppoſed birth, the queen had frequent quarrels with the king, and, what was more dangerous, with the cardinal; who even uſed every means in his power to enquire into her moſt private tranſactions. It was on a memorable occaſion of this kind, that her ſervant La Porte was thrown into the Baſtile; and it can ſcarcely be imagined ſhe would have had the firmneſs ſhe then diſplayed, while conſcious of ſo much guilt, and under the riſk of having it diſcovered. The priſoner with the maſque appears, by ſeveral accounts, to have been a youth of a handſome figure in the year 1661; and in 1703, when he died, to have been above ſixty; but had he been a ſon of Buckingham, he would have been about thirty-ſix in 1661, when he could not be ſaid to have been a youth; and in November 1703, above ſeventy-eight.

2. The ſecond opinion is, that he was the twin-brother of Louis XIV. born ſome hours after him. This firſt appeared in a ſhort anonymous work publiſhed without date, and without the name of place or printer. It is therein ſaid, "Louis XIV. was born at St Germains en Laye, on the 5th of September 1638, about noon; and the illuſtrious priſoner, known by the appellation of the *Iron maſque*, was born the ſame day, while Louis XIII. was at ſupper. The king and the cardinal, fearing that the pretenſions of a twin-brother might one day be employed to renew thoſe civil wars with which France had been ſo often afflicted, cautiouſly concealed his birth, and ſent him away to be brought up privately. Having but an imperfect knowledge of the circumſtances that followed, I ſhall ſay nothing more, for fear of committing errors; but I firmly believe the fact I have mentioned; and time will probably prove to my reader, that I have ground for what I have advanced."

This opinion has been more noticed ſince the publication of a work called *Memoires du Marechal Duc de Richlieu*, written by the Abbé Soulavie; concerning which it may be proper to premiſe, that the preſent duke of Richlieu, ſon of the marechal, diſavows this work; while the Abbé Soulavie, who had been employed by the marechal, inſiſts on the authenticity of his papers (A). He informs us, that the duke of Richlieu was the lover of Mademoiſelle de Valois, daughter of the regent duke of Orleans, and afterwards ducheſs of Modena, who in return was paſſionately fond of him: that the regent had ſomething more than a paternal affection for his daughter; and that, though ſhe held his ſentiments in abhorrence, the duke of Richlieu made uſe of her influence with her father to diſcover the ſecret of the priſoner with the maſque: that the regent, who had always obſerved the moſt profound ſilence on this ſubject, was at laſt perſuaded to entruſt her with a manuſcript, which ſhe immediately ſent to her lover, who took a copy of it. This manuſcript is ſuppoſed to have been written by a gentleman on his death-bed, who had been the governor of the priſoner. The following is an extract of it, from what the Abbé Soulavie has told us.

"The birth of the priſoner happened in the evening of the 5th of September 1638, in preſence of the chancellor, the biſhop of Meaux, the author of the manuſcript, a midwife named Peronéte, and a ſieur Honorat. This circumſtance greatly diſturbed the king's mind; he obſerved, that the Salique law had made no proviſion for ſuch a caſe; and that it was even the opinion of ſome, that the laſt born was the firſt conceived, and therefore had a prior right to the other. By the advice of cardinal de Richlieu, it was therefore reſolved to conceal his birth, but to preſerve his life, in caſe by the death of his brother it ſhould be neceſſary to avow him. A declaration was drawn up, and ſigned and ſworn to by all preſent, in which every circumſtance was mentioned, and ſeveral marks on his body deſcribed. This document being ſealed by the chancellor with the royal ſeal, was delivered to the king; and all were commanded and took an oath never to ſpeak on the ſubject, not even in private and among themſelves. The child was delivered to the care of Madame Peronéte the midwife, to be under the direction of cardinal de Richlieu, at whoſe death the charge devolved to cardinal de Mazarin. Mazarin appointed the author of the manuſcript his governor, and entruſted to him the care of his education. But as the priſoner was extremely attached to Madame Peronéte, and ſhe equally ſo to him, ſhe remained with him till her death. His governor carried him to his houſe in Burgundy,

---

(A) A letter from the duke of Richlieu, and an anſwer from the Abbé Soulavie, appeared in the Journal de Paris.

gundy, where he paid the greateſt attention to his education.

“As the priſoner grew up, he became impatient to diſcover his birth, and often importuned his governor on that ſubject. His curioſity had been rouſed, by obſerving that meſſengers from the court frequently arrived at the houſe; and a box, containing letters from the queen and the cardinal, having one day been inadvertently left out, he opened it, and ſaw enough to gueſs at the ſecret. From that time he became thoughtful and melancholy, ‘which (ſays the author) I could not then account for. He ſhortly after aſked me to get him a portrait of the late and preſent king, but I put him off by ſaying that I could not procure any that were good. He then deſired me to let him go to Dijon; which I have known ſince was with an intention of ſeeing a portrait of the king there, and of going ſecretly to St John de Lus, where the court then was on occaſion of the marriage with the infanta. He was beautiful; and love helped him to accompliſh his wiſhes. He had captivated the affections of a young houſekeeper, who procured him a portrait of the king. It might have ſerved for either of the brothers; and the diſcovery put him into ſo violent a paſſion, that he immediately came to me with the portrait in his hand, ſaying, *Voila mon frere, et voila qui je ſuis*, ſhowing me at the ſame time a letter of the cardinal de Mazarin that he had taken out of the box.’ Upon this diſcovery his governor immediately ſent an expreſs to court to communicate what had happened, and to deſire new inſtructions; the conſequence of which was, that the governor and the young prince under his care were arreſted and confined.”

This memoir, real or fictitious, concludes with ſaying, “I have ſuffered with him in our common priſon: I am now ſummoned to appear before my Judge on high; and for the peace of my ſoul I cannot but make this declaration, which may point out to him the means of freeing himſelf from his preſent ignominious ſituation, in caſe the king his brother ſhould die without children. Can an extorted oath compel me to obſerve ſecrecy on a thing ſo incredible, but which ought to be left on record to poſterity.”

3. The third opinion is, that he was a ſon of the queen by the cardinal de Mazarin, born about a year after the death of her huſband Louis XIII.; that he was brought up ſecretly; and that ſoon after the death of the cardinal, which happened on the 9th of March 1661, he was ſent to Pignerol. To this account Father Griffet* objects, “that it was needleſs to maſque a face that was unknown; and therefore that this opinion does not merit diſcuſſion.” But in anſwer it has been obſerved, That the priſoner might ſtrongly reſemble Louis XIV. which would be a ſufficient reaſon to have him maſked. This opinion is ſuppoſed to have been that entertained by Voltaire, who aſſerts his thorough knowledge of the ſecret, though he declined being altogether explicit. The Abbé Soulavie, author of Memoirs of the Marechal de Richlieu, ſpeaking on this ſubject, ſays, “That he once obſerved to the Maréchal, that he certainly had the means of being informed who the priſoner was; that it even ſeemed that he had told Voltaire, who durſt not venture to publiſh the ſecret; and that he at laſt aſked him, whether he was not the elder brother of Louis XIV. born without the knowledge of Louis the XIII.? That the marechal ſeemed embarraſſed, but afterwards ſaid, that he was neither the baſtard brother of Louis the XIV. nor the duke of Monmouth, nor the count of Vermandois, nor the duke of Beaufort, as different authors had advanced; that their conjectures were nothing but reveries: but added, that they however had related many circumſtances that were true; that in fact the order was given to put the priſoner to death if he diſcovered himſelf; and that he finiſhed the converſation by ſaying, All I can tell you on the ſubject is, that the priſoner was not of ſuch conſequence when he died at the beginning of the preſent century as he had been at the beginning of the reign of Louis the XIV. and that he was ſhut up for important reaſons of ſtate.” The Abbé Soulavie tells us, that he wrote down what had been ſaid, and gave it to the Marechal to read, who corrected ſome expreſſions. The Abbé having propoſed ſome further queſtions, he anſwered, “Read what Voltaire publiſhed laſt on the ſubject of the priſoner with the maſque, eſpecially at the end, and reflect on it.”—The paſſage of Voltaire alluded to is as follows.

“The *man with the maſque* (ſays he) is an enigma of which every one would gueſs the meaning. Some have ſaid that it was the duke of Beaufort; but the duke of Beaufort was killed by the Turks in the defence of Candy in 1669, and the priſoner with the maſque was at Pignerol in 1661. Beſides, how could the duke of Beaufort have been arreſted in the midſt of his army, and brought to France, without any one knowing it? and why confine him? and why that maſk?—Others have dreamed that he was the count de Vermandois, natural ſon of Louis XIV. who died publicly at the army in 1683 of the ſmall-pox, and was buried at the little town of Aire and not Arras; in which Father Griffet was miſtaken, but in which to be ſure there is no great harm.—Others have imagined, that it was the duke of Monmouth, who was beheaded publicly in London in the year 1685. But for this he muſt have riſen again from the dead, and he muſt have changed the order of time, and placed the year 1662 in the room of the year 1685. King James, who never forgave any one, and who on that account deſerved all that happened to him, muſt have pardoned the duke of Monmouth, and got another to die in his ſtead, who perfectly reſembled him. This Soſia muſt firſt have been found, and then he muſt have had the goodneſs to let his head be cut off in public, to ſave the duke of Monmouth. It was neceſſary that all England ſhould be miſtaken; and that King James ſhould beg of Louis XIV. to be ſo obliging as to be his gaoler; that Louis XIV. after having ſhown this trifling piece of civility to King James, ſhould not have been wanting in the ſame attention to his friend King William and to Queen Anne (with both of whom he was engaged in war), and to pleaſe them, retained the dignity of gaoler, with which James had honoured him.

“All theſe illuſions being diſſipated, it then remains to know who this priſoner was, and at what age he died. It is clear, that if he was not permitted to croſs the court of the Baſtile, or to ſpeak to his phyſician, except covered with a maſque, it muſt have been from the apprehenſion that his features and countenance

---

* Traité de la Verite de l'Hiſtoire, p. 318. n.

nance might have diſcovered ſome reſemblance. He could ſhow his tongue, but not his face. He ſaid himſelf to the apothecary of the Baſtile, a few days before his death, that he believed he was about 60. Mr Marſoban, who was ſon-in-law to this apothecary, and ſurgeon to the marechal de Richlieu, and afterwards to the regent duke of Orleans, told me this frequently. Why give him an *ITALIAN* name?—They always called him *Marchiali*. He who writes this article perhaps knows more than Father Griffet, but he will ſay nothing farther."

This opinion has been lately reſumed, illuſtrated, and enforced, by M. de Saint Mihiel, in a work intitled *Le Veritable Homme*, &c. "The real Man with the Iron Maſque." The author, in ſupport of his idea, attempts to prove that Anne of Auſtria and Cardinal Mazarine were married. This, ſays he, the ducheſs of Orleans aſſures us of in three of her letters. In the firſt, dated Sept. 13. 1713, ſhe expreſſes herſelf as follows: "Old Beauvais, who was firſt lady of the bed-chamber to the queen-dowager, was acquainted with the ſecret of the ridiculous marriage; this rendered it neceſſary for the queen to do every thing that her confidant wiſhed; and this circumſtance has given riſe in this country to an extenſion of the rights of firſt ladies of the bedchamber." In the ſecond of theſe letters, dated Nov. 2. 1717, ſhe ſays, "The queen-mother, widow of Louis XIII. did worſe than love Cardinal Mazarine; ſhe married him, for he was not a prieſt: he was not even in orders; and who could have hindered her? He was moſt horribly tired of the good queen-mother, and lived on very bad terms with her, which is the reward that people deſerve for entering into ſuch marriages." In her third letter, dated July 2. 1719, ſpeaking of the queen, the ducheſs ſays, "She was perfectly eaſy reſpecting Cardinal Mazarine; he was not a prieſt, and therefore nothing could prevent their being married. The ſecret paſſage through which the Cardinal went every evening to the queen's apartment is ſtill to be ſeen at the Palais-Royal." Among other proofs beſides the above, which M. de St Mihiel brings to ſubſtantiate this marriage, he obſerves, that Mazarine held all councils of ſtate in his apartment whilſt he was ſhaving or dreſſing; that he never permitted any perſon to ſit down in his preſence, not even the chancellor nor marſhal de Villeroi; and that while they were deliberating with him on ſtate affairs he would be often playing with his monkey or linnet. What man (continues the author) would have ſubjected to ſuch humiliations a chancellor, who holds the firſt office in the kingdom ſince that of conſtable has been ſuppreſſed, and a marſhal who was governor to the king, had he not been in reality a ſovereign himſelf, in virtue of his being huſband to the queen-regent? He therefore concludes, that the man with the iron maſque was ſon to Anne of Auſtria and Cardinal Mazarine; and endeavours to juſtify this aſſertion by a variety of conjectural proofs. Of ſome of theſe we ſhall give a ſhort ſketch:

1. No prince, or perſon of any conſideration, after the year 1644, at which time the man with the iron maſque was born, until the time when his exiſtence was known, diſappeared in France. This perſonage, therefore, was not a prince or great lord of France known at that time.

2. The man with the iron maſque was not a foreigner; for foreigners, even of the higheſt diſtinction, did not at that period ſtudy the French language in ſuch a manner as to attain ſo great perfection in it as to paſs for Frenchmen. If this priſoner had ſpoken with the leaſt foreign accent, the officers, phyſicians, ſurgeons, apothecaries, confeſſors, and others employed in the priſons where he was, and eſpecially the priſoners with whom he converſed at St Margaret, would not have failed to diſcover it. From all this M. de St Mihiel infers that he muſt have been a Frenchman.

3. The exiſtence of the man with the iron maſque has been known for upwards of 90 years. Had any perſon of high rank diſappeared at an anterior period, his friends, relations, or acquaintances, would not have failed to claim him, or at leaſt to ſuppoſe that he was the man concealed by this maſque. But no one diſappeared, nor was any one claimed: the man with the iron maſque was therefore a perſon unknown.

4. This man was not torn away from ſociety on account of any criminal action; for when he was arreſted, it was foreſeen that he would cauſe much embarraſſment, and occaſion great expences. He was therefore not a criminal, elſe means would have been purſued to get rid of him; and conſequently all the importance of his being concealed was attached ſolely to his perſon.

5. This ſtranger muſt have been a perſon of very high birth; for the governor of the priſon St Mars behaved always to him with the greateſt reſpect.

6. Louis XIII. played on the guitar; Louis XIV. did the ſame in a very maſterly manner; and the man with the iron maſque played alſo on that inſtrument: which gives us reaſon to believe that his education was directed by the ſame perſons who had preſided over that of Louis XIV. and who appear to have been the particular choice of Anne of Auſtria.

7. This ſtranger died on the 19th of November 1703; and a few days before his death, he told the apothecary of the Baſtile, that he believed he was about 60 years of age. Suppoſing that he was then 59 and a half, he muſt have been born towards the end of May 1644; and if he was 60 wanting three months, he muſt have been born in the end of Auguſt, or the beginning of September, of the ſame year; a period when the royal authority was in the hands of Anne of Auſtria, but in reality exerciſed more by Mazarine than by her. "I have already proved (continues the author), that from the firſt day of the regency of Anne of Auſtria, the greateſt friendſhip, and even intimacy, ſubſiſted between this princeſs and the cardinal; that theſe ſentiments were changed into a mutual love; and that they were afterwards united by the bonds of marriage. They might, therefore, well have a ſon about the month of September 1644, as Louis XIII. had been then dead more than 15 months, having died on the 15th of May the year preceding. But nothing of what I have related, or of what has been written, and acknowledged as fact, reſpecting the man with the iron maſk, can be applied, except to a ſon of Mazarine and Anne of Auſtria. The man with the iron maſk was indebted, therefore, for his exiſtence to cardinal Mazarine, and the regent widow of Louis XIII."—To account for the

the manner in which the queen was able to conceal her pregnancy and delivery, Madame de Motteville is quoted; who relates, under the year 1644, that Anne of Auſtria quitted the Louvre, becauſe her apartments there diſpleaſed her: that ſhe went to reſide at the Palais-Royal, which Richlieu, when he died, bequeathed to the deceaſed king: that when ſhe firſt occupied this lodging, *ſhe was dreadfully afflicted with the jaundice:* that the phyſicians aſcribed this diſorder to her dejection and application to buſineſs, which gave her much embarraſſment: but that being cured of her melancholy, as well as of her malady, ſhe reſolved to think only of enjoying tranquillity; which ſhe did, by communicating to her miniſter the burden of public affairs. On this quotation, M. de St Mihiel aſks, “Is it not very ſingular, that the queen, who, during the 29 years of her former wedded ſtate, had always reſided in the Louvre, eſpecially from 1626, when Louis XIII. ceaſed to cohabit with her, until their re-union, which took place in the beginning of December 1637, ſhould have quitted it preciſely in 1644, becauſe ſhe was diſpleaſed with her apartments? How happened it that her apartments diſpleaſed her this year, and neither ſooner nor later? She might undoubtedly have had any kind of furniture there which ſhe deſired, and every alteration made according to her wiſhes, as ſhe was then abſolute miſtreſs: but the cauſe of her determination is plain; the apartments of the Palais-Royal, which front a garden, were much more convenient for her to be delivered in ſecret.”

8. As it is neceſſary that ſome name ſhould be given to every man, in order to diſtinguiſh him from another, that of *Marchiali* was given to the man with the iron maſk: a name which evidently ſhows, that it had been invented by an Italian. [Cardinal Mazarine was a native of Piſcina in the Abruzzo.]

9. Anne of Auſtria was remarkably delicate reſpecting every thing that touched her perſon. It was with great difficulty that cambric could be found fine enough to make ſhifts and ſheets for her. Cardinal Mazarine once rallying her on this ſubject, ſaid, *That if ſhe ſhould be damned, her puniſhment in hell would be to ſleep in Holland ſheets.* The predominant taſte of the man with the iron maſque, was to have lace and linen of the moſt extraordinary fineneſs. “Who (ſays the author) does not perceive, in this ſimilarity of taſtes, the maternal tenderneſs of Anne of Auſtria, who would have thought her ſon a great ſufferer had he not been indulged with fine linen?”

“Louis XIII. (continues M. de St Mihiel) was a huſband of a gloomy diſpoſition, and an enemy to pleaſure: while the queen, on the contrary, was fond of ſocial life; and introduced at the court of France, eſpecially after ſhe became free, that eaſe and politeneſs which diſtinguiſhed it under Louis XIV. from all the other courts of Europe. Louis XIII. had alſo a diſagreeable countenance, and a breath ſo offenſive, that it was a puniſhment for Richlieu to remain near him. It is clear, therefore, that ſhe could not be much pleaſed with ſuch a huſband. When ſhe became regent of the kingdom by the king's death, which happened on the 14th of May 1643, as ſhe had not enjoyed that happineſs which ariſes from a cloſe union of hearts, it will not appear extraordinary that ſhe ſhould indulge the affection ſhe entertained for cardinal Mazarine, and that ſhe ſhould marry him. Every circumſtance that could tend to favour ſuch a marriage will be found united in her ſituation. She was at a diſtance from her family; abſolute miſtreſs of all her actions; and had, beſides, a heart formed for love. Mazarine, though a cardinal, had never entered into orders; he gave out that he was deſcended from a great family; he was handſome and well made; he was of a mild, inſinuating diſpoſition, and remarkably engaging in converſation; and his office, as prime miniſter, afforded him every opportunity of viſiting and converſing with the queen whenever he thought proper. Is it, therefore, ſo very aſtoniſhing, that, with ſo many advantages, he was able to captivate the queen ſo far as to induce her to marry him? Such a marriage was not, indeed, according to the uſual courſe of things. Yet it was not without many precedents, particularly among ſovereigns of the other ſex, who had given their hands to perſons of inferior rank. Thus Chriſtian IV. of Denmark eſpouſed Chriſtina Monck; Frederick IV. eſpouſed Mademoiſelle Reventlau; James II. heir to the throne of England, married the daughter of a counſellor; Peter the Great raiſed to the throne Catharine I. the daughter of a poor villager, yet perhaps the moſt accompliſhed woman at that time between the Viſtula and the pole; and Louis XIV. eſpouſed the widow of a poet, but a woman poſſeſſed of the moſt extraordinary merit. As the women, however, are not forgiven ſo readily as the men for entering into ſuch marriages, Anne of Auſtria kept hers a ſecret from this motive, and becauſe ſhe would have been in danger of loſing the regency of the kingdom had it been known.”

The reaſoning of M. de St Mihiel is both ingenious and plauſible; though the probability of the account is ſomewhat diminiſhed by conſidering what muſt have been the queen's age at this period, after ſhe had been Louis's wife for 29 years before his death.—The account immediately preceding, without this objection, ſeems abundantly credible. But whether, upon the whole, either of them can be received as deciſive, or whether the myſtery of the iron maſk remains ſtill to be unravelled, we muſt leave to the reader to determine.

Masque, in architecture, is applied to certain pieces of ſculpture, repreſenting ſome hideous forms, croteſque, or ſatyrs faces, &c. uſed to fill up and adorn vacant places, as in friezes, the pannels of doors, keys of arches, &c. but particularly in grottos.

MASQUERADE, or Mascarade, an aſſembly of perſons maſqued or diſguiſed, meeting to dance and divert themſelves. This was much in uſe with us, and has been long a very common practice abroad, eſpecially in carnival time.

The word comes from the Italian *maſcarata*, and that from the Arabic *maſcara*, which ſignifies “raillery, buffoonery.” Granacci, who died in 1543, is ſaid to have been the firſt inventor of maſquerades.

MASRAKITHA, a pneumatic inſtrument of muſic among the ancient Hebrews, compoſed of pipes of various ſizes, fitted into a kind of wooden cheſt, open at the top, and ſtopped at the bottom with wood covered with a ſkin. Wind was conveyed to it from the lips, by means of a pipe fixed to the cheſt: the pipes were of lengths muſically proportioned to each other, and the melody was varied at pleaſure, by ſtopping and unſtopping with the fingers the apertures at the upper extremity. See Plate CCLXXIX.

MASS, in mechanics, the matter of any body cohering with it, *i. e.* moving and gravitating along with it. In which ſenſe, *maſs* is diſtinguiſhed from bulk, or volume, which is the expanſion of a body in length, breadth, and thickneſs.

The maſs of any body is rightly eſtimated by its weight. And the maſſes of two bodies of the ſame weight are in a reciprocal ratio of their bulks.

Mass, *Miſſa*, in the church of Rome, the office or prayers uſed at the celebration of the euchariſt; or in other words conſecrating the bread and wine into the body and blood of Chriſt, and offering them ſo tranſubſtantiated as an expiatory ſacrifice for the quick and the dead.

As the maſs is in general believed to be a repreſentation of the paſſion of our bleſſed Saviour, ſo every action of the prieſt, and every particular part of the ſervice, is ſuppoſed to allude to the particular circumſtances of his paſſion and death.

Nicod, after Baronius, obſerves that the word comes from the Hebrew *miſſach, (oblatum;)* or from the Latin *miſſa miſſorum;* becauſe in the former times, the catechumens and excommunicated were ſent out of the church, when the deacons ſaid, *Ite, miſſa eſt,* after ſermon and reading of the epiſtle and goſpel; they not being allowed to aſſiſt at the conſecration. Menage derives the word from *miſſio,* "diſmiſſing:" Others from *miſſa,* "miſſing, ſending;" becauſe in the maſs, the prayers of men on earth are ſent up to heaven.

The general diviſion of maſſes conſiſts in high and low. The firſt is that ſung by the choriſters, and celebrated with the aſſiſtance of a deacon and ſub-deacon; low maſſes are thoſe in which the prayers are barely rehearſed without ſinging.

There are a great number of different or occaſional maſſes in the Romiſh church, many of which have nothing peculiar but the name: ſuch are the maſſes of the ſaints; that of St Mary of the ſnow, celebrated on the fifth of Auguſt; that of St Margaret, patroneſs of lying-in women; that of the feaſt of St John the Baptiſt, at which are ſaid three maſſes; that of the Innocents, at which the gloria in excelſis and the hallelujah are omitted, and it being a day of mourning, the altar is of a violet-colour. As to ordinary maſſes, ſome are ſaid for the dead, and, as is ſuppoſed, contribute to fetch the ſoul out of purgatory: at theſe maſſes the altar is put in mourning, and the only decorations are a croſs in the middle of ſix yellow wax-lights; the dreſs of the celebrant, and the very maſs-book, are black; many parts of the office are omitted, and the people are diſmiſſed without the benediction. If the maſs be ſaid for a perſon diſtinguiſhed by his rank or virtues, it is followed with a funeral oration; they erect a *chapelle ardente,* that is, a repreſentation of the deceaſed with branches and tapers of yellow wax, either in the middle of the church, or near the deceaſed's tomb, where the prieſt pronounces a ſolemn abſolution of the deceaſed. There are likewiſe private maſſes ſaid for ſtolen or ſtrayed goods or cattle, for health, for travellers, &c. which go under the name of *votive maſſes.* There is ſtill a further diſtinction of maſſes denominated from the countries in which they were uſed; thus the Gothic maſs, or *miſſa moſarabum,* is that uſed among the Goths when they were maſters of Spain, and which is ſtill kept up at Toledo and Salamanca; the Ambroſian maſs is that compoſed by St Ambroſe, and uſed only at Milan, of which city he was biſhop; the Gallic maſs, uſed by the ancient Gauls; and the Roman maſs, uſed by almoſt all the churches in the Romiſh communion.

Mass of the Preſanctified, (miſſa præſanctificatorum), is a maſs peculiar to the Greek church, in which there is no conſecration of the elements; but after ſinging ſome hymns, they receive the bread and wine which was before conſecrated. This maſs is performed all Lent, except on Saturdays, Sundays, and the annunciation. The prieſt counts upon his fingers the days of the enſuing week on which it is to be celebrated, and cuts off as many pieces of bread at the altar as he is to ſay maſſes; and after having conſecrated them, ſteep them in wine, and then puts them in a box; out of which, upon every occaſion, he takes ſome of it with a ſpoon, and putting it on a diſh ſets it upon the altar.

MASSA, a town of Italy, in the kingdom of Naples, and in the Terra di Lavoro, with a biſhop's ſee; ſeated on a mountain near the ſea, in E. Long. 10. 0. N. Lat. 43. 5.

Massa, an ancient, populous, and handſome town of Italy, and capital of a ſmall territory of the ſame name, with the title of a principality, and a ſtrong caſtle. It is famous for its quarries of fine marble, and is ſituated in E. Long. 14. 23. N. Lat. 40. 40.

MASSACHUSETS colony, the principal ſubdiviſion of New England, having Hampſhire on the north, the Atlantic ocean on the eaſt and ſouth, and Connecticut and New York on the weſt. It is about 100 miles long, and 40 broad. See *New England.*

MASSACRE, a term uſed to ſignify the ſudden and promiſcuous butchery of a multitude. The moſt atrocious example of this kind upon record is that called the *Pariſian Massacre,* or *Maſſacre of St Bartholomew's Day.* The Pariſian maſſacre was carried on with ſuch deteſtable perfidy, and executed with ſuch a bloody cruelty, as would ſurpaſs all belief, were it not atteſted by the moſt undeniable evidence. In the year 1572, in the reign of Charles IX. many of the principal proteſtants were invited to Paris, under a ſolemn oath of ſafety, upon occaſion of the marriage of the king of Navarre with the French king's ſiſter, viz. the king of Navarre's mother, Coligni admiral of France, with other nobles. The queen-dowager of Navarre, a zealous proteſtant, was poiſoned by a pair of gloves before the marriage was ſolemnized; and on the 24th of Auguſt 1572, being Bartholomew's day, about day-break, upon the toll of the bell of the church of St Germain, the butchery began. The admiral was baſely murdered in his own houſe; and then thrown out of the window, to gratify the malice of the duke of Guiſe: his head was afterwards cut off, and ſent to the king and queen-mother; and his body, after a thouſand indignities offered to it, hung up by the feet on a gibbet. After this, the murderers ravaged the whole city of Paris, and butchered in three days above ten thouſand lords, gentlemen, preſidents, and people of all ranks. An horrible ſcene of things, ſays Thuanus, when the very ſtreets and paſſages reſounded with the noiſe of thoſe that met together for murder and plunder; the groans of thoſe who were dying, and the ſhrieks of ſuch as were juſt going to be butchered, were every where heard; the bodies of the ſlain thrown out of the windows; the courts and chambers of the houſes filled with them; the dead bodies of others dragged through the ſtreets, their blood running down the channels in ſuch plenty, that torrents ſeemed to empty themſelves in the neighbouring river: and, in a word, an innumerable multitude of men, women with child, maidens, and children, were all involved in one common deſtruction; and the gates and entrances of the king's palace all beſmeared with their blood.

From the city of Paris the maſſacre ſpread almoſt throughout the whole kingdom. In the city of Meaux they threw above two hundred into jail; and after they had raviſhed and killed a great number of women, and plundered the houſes of the proteſtants, they executed their fury on thoſe they had impriſoned, and calling them out one by one, they were killed, as Thuanus expreſſes, like ſheep in a market; the bodies of ſome were flung into ditches, and of others into the river Maine. In Orleans they murdered above five hundren men, women, and children, and enriched themſelves with their ſpoil. The ſame cruelties were practiſed at Angers, Troyes, Bourges, La Charité, and eſpecially at Lyons, where they inhumanly deſtroyed above eight hundred proteſtants; children hanging on their parents necks; parents embracing their children; putting ropes about the necks of ſome, dragging them through the ſtreets, and throwing them, mangled, torn, and half-dead, into the river.

It would be endleſs to mention the butcheries committed at Valence, Romaine, Rouen, &c. We ſhall, therefore, only add, that, according to Thuanus, above thirty thouſand proteſtants were deſtroyed in this maſſacre, or, as others with greater probability affirm, above one hundred thouſand.

Thuanus himſelf calls this a moſt deteſtable villainy; and, in abhorrence of St Bartholomew's day, uſed to repeat theſe words of P. Statius, Silv. v. iii. ver. 88. &c.

Excidat illa dies ævo, ne poſtera credant
Secula. Nos certe taceamus, et obruta multa
Nocte tegi propriæ patiamus crimina gentis.

In the words of Job, chap. iii. ver. 3. &c. "Let that day periſh; and let it not be joined unto the days of the year. Let darkneſs and the ſhadow of death ſtain it," &c. And yet, as though this had been the moſt heroic tranſaction, and could have procured immortal glory to the authors of it, medals were ſtruck at Paris in honour of it.

But how was the news of this butchery received at Rome, that faithful city, that holy mother of churches! How did the vicar of Chriſt, the ſucceſſor of Peter, and the father of the Chriſtian world, reliſh it? Let Thuanus tell the horrid truth. When the news, ſays he, came to Rome, it was wonderful to ſee how they exulted for joy. On the 6th of September, when the letters of the pope's legate were read in the aſſembly of the cardinals, by which he aſſured the Pope that all was tranſacted by the expreſs will and command of the king, it was immediately decreed that the pope ſhould march with his cardinals to the church of St Mark, and in the moſt ſolemn manner give thanks to God for ſo great a bleſſing conferred on the ſee of Rome and the Chriſtian world; and that on the Monday after, ſolemn maſs ſhould be celebrated in the church of Minerva; at which the pope, Greg. XIII. and cardinals were preſent; and that a jubilee ſhould be publiſhed throughout the whole Chriſtian world, and the cauſe of it declared to be, to return thanks to God for the extirpation of the enemies of the truth and church in France. In the evening the cannon of St Angelo were fired, to teſtify the public joy; the whole city illuminated with bonfires; and no one ſign of rejoicing omitted that was uſually made for the greateſt victories obtained in favour of the Roman church.

MASSAGETAE, an ancient people about whoſe ſeat there is as much doubt as about that of the Amazons: Tibullus and Ammian place them near Albania, beyond the Araxes, which ſometimes denotes the Oxus; it is probable they dwelt to the eaſt of Sogdiana. (Dionyſius Periegetes, Herodotus, Arrian).

MASSALIANS, a ſet of enthuſiaſts who ſprang up about the year 361, in the reign of the emperor Conſtantius, who maintained that men have two ſouls, a celeſtial and a diabolical, and that the latter is driven out by prayer.

MASSANIELLO, ſee *Hiſtory of* NAPLES.

MASSETER, in anatomy. See there, (*Table of the Muſcles*).

MASSICOT, ſee MASTICOT.

MASSIEU (William), a learned French writer, member of the academy of belles lettres, and of the French academy, was born at Caen in Normandy in 1665, and completed his ſtudies at Paris, when he entered amongſt the Jeſuits; but afterwards left them, that he might follow his inclination to polite literature with the greater freedom. In 1710 he was made Greek profeſſor in the royal college; and enjoyed that poſt till his death, which happened at Paris in 1722. He wrote, 1. Several curious diſſertations in the memoirs of the academy of inſcriptions. 2. A hiſtory of the French poetry, in 12mo, &c.

MASSILIA, (anc. geog.) a town of Gallia Narbonenſis, a colony of Phoceans, from Phocæa, a city of Ionia, and in confederacy with the Romans; univerſally celebrated, not only for its port, commerce, and ſtrength, but eſpecially for its politeneſs of manners and for its learning. According to Strabo, it was the ſchool for barbarians, who were excited by its means to a fondneſs for Greek literature, ſo that even their public and private tranſactions were all executed in that language. Strabo adds, "At this day the nobleſt Romans repair thither for ſtudy rather than to Athens." Now MARSEILLES, a city and port-town of Provence.

MASSILLON (Jean Baptiſte), ſon of a notary at Hieres in Provence, was born in 1663, and entered into the congregation of the oratory in 1681. He gained the affections of every perſon in the towns to which he was ſent, by the charms of his genius, the livelineſs of his character, and by a fund of the moſt delicate

Maſſillon.

delicate and affecting politeneſs. His firſt attempts in the art of eloquence were made at Vienne, while he was profeſſor of theology. His funeral oration on Henry de Villars, archbiſhop of that city, received univerſal approbation. This ſucceſs induced Father de la Tour, who was at that time general of the congregation, to call him to Paris. After he had been there for ſome time, he was aſked what he thought of the preachers who made a figure on that great theatre?— "I find them poſſeſſed of great genius and abilities (anſwered he); but if I preach, I will not preach like them." He in fact kept his word, and ſtruck out a new path in this great field of eloquence. P. Bourdaloue was excepted from the number of thoſe whom he propoſed not to imitate. If he did not take him for a model in every thing, the reaſon was, that his genius led him to a different ſpecies of eloquence.— His manner of compoſing, therefore, was peculiar to himſelf, and, in the opinion of men of taſte and judgement, was ſuperior to that of Bourdaloue. The affecting and natural ſimplicity of the father of the oratory, (ſaid a great man), appear fitter to bring home the truths of Chriſtianity to the heart than all the dialectics of the Jeſuit. We muſt ſeek for the logic of the goſpel in our own breaſts; and the moſt powerful reaſonings on the indiſpenſable duty of relieving the diſtreſſed, will make no impreſſion on that man who has beheld without concern the ſufferings of his brother. If logic is neceſſary, it is only in matters of opinion; and theſe are fitter for the preſs than for the pulpit, which ought not to be the theatre of learned diſcuſſions. The truth of theſe reflections was clearly perceived when he appeared at court. Upon preaching his firſt advent ſermon at Verſailles, he received this eulogium from the mouth of Louis XIV. "Father, when I hear others preach, I am very well pleaſed with them; but whenever I hear you, I am diſſatisfied with myſelf." The firſt time he preached his famous ſermon *on the ſmall number of the elect*, the whole audience were, at a certain place of it, ſeized with a ſudden and violent emotion, and almoſt every perſon half roſe from his ſeat by a kind of involuntary movement. The murmur of acclamation and ſurprize was ſo great, that it threw the orator into confuſion; but this only heightened the impreſſion of that pathetic diſcourſe What was moſt ſurpriſing in Maſſillon, was his deſcriptions of the world, which were ſo ſublime, ſo delicate, and ſo ſtriking in the reſemblance. When he was aſked whence a man, like him, whoſe life was dedicated to retirement, could borrow them? he anſwered, "From the human heart; however little we examine it, we will find in it the ſeeds of every paſſion. When I compoſe a ſermon (added he), I imagine myſelf conſulted upon ſome doubtful piece of buſineſs. I give my whole application to determine the perſon who has recourſe to me, to act the good and proper part. I exhort him, I urge him, and I leave him not till he has yielded to my perſuaſions." His declamation did not fail to be accompanied with ſucceſs. "We think we ſee him in our pulpits (ſay thoſe who had the pleaſure of hearing him), with the ſimple air, the modeſt carriage, the down-caſt and humble looks, the eaſy geſture, the affecting tone, and the countenance of a man deeply penetrated with his ſubject, conveying the cleareſt information to the underſtanding, and raiſing the moſt tender emotions in the heart." Baron, the famous comedian, having met him one day in a houſe which was open for the reception of men of letters, paid him this compliment: "Continue to deliver as you do. Your manner is peculiar to yourſelf; leave the obſervance of rules to others." When this famous actor came from hearing one of his ſermons, truth drew from him the following confeſſion, which is ſo humiliating to his profeſſion: "Friend (ſaid he to one of his companions who accompanied him), here is an *orator*; we are only *actors*."

Maſſillon.

In 1704 Maſſillon made his ſecond appearance at court, and diſplayed ſtill more eloquence than before. Louis XIV. after expreſſing his ſatisfaction to him, added, in the moſt gracious tone of voice, *Et je veux, mon pere, vous entendre tous les deux ans.* Theſe flattering encomiums did not leſſen his modeſty. When one of his fellows was congratulating him upon his preaching admirably, according to cuſtom, "Oh! give over, Father (replied he), the devil has told me ſo already, much more eloquently than you." The duties of his office did not prevent him from enjoying ſociety; and in the country he forgot that he was a preacher, but always without treſpaſſing againſt decency. One day when he was at the houſe of M. de Crozat, the latter ſaid to him, "Father, your doctrine terrifies me, but I am encouraged by your life." He was choſen, on account of his philoſophical and conciliatory diſpoſition of mind, to reconcile the cardinal de Noailles with the Jeſuits. All he gained by his attempts was the diſpleaſure of both parties; and he found that it was eaſier to convert ſinners than to reconcile theologians. In 1717, the regent, perſonally acquainted with his merit, appointed him to the biſhopric of Clermont. The next year, being deſtined to preach before Louis XV. who was only nine years of age, he compoſed in ſix weeks thoſe diſcourſes which are ſo well known by the name of *Petit Careme*. Theſe are the chef d'œuvre of this orator, and indeed of the oratorical art. They ought continually to be read by preachers as models for the formation of their taſte, and by princes as leſſons of humanity.

Maſſillon was admitted into the French academy a year afterwards, in 1719. The abbacy of Savigny becoming vacant, the cardinal du Bois, to whom he had been weak enough to give an atteſtation for being a prieſt, procured it for him. The funeral oration of the ducheſs of Orleans, in 1723, was the laſt diſcourſe he pronounced in Paris. He never afterwards left his dioceſe, where his gentleneſs, politeneſs, and kindneſs, had gained him the affection of all who knew him. He reduced the exorbitant rights of the epiſcopal roll to moderate ſums. In two years, he cauſed 20,000 livres to be privately conveyed to the Hotel-Dieu of Clermont. His peaceable diſpoſition was never more diſplayed than while he was a biſhop. He took great pleaſure in collecting the fathers of the oratory and the Jeſuits at his country-houſe, and in making them join in ſome diverſion. He died on the 28th of September 1742, at the age of 79. His name has become that of eloquence itſelf. Nobody ever knew better how to touch the paſſions. Preferring ſentiment to every thing elſe, he communicated to the ſoul that lively and ſalutary emotion which ex-

Maſſillon.

cites in us the love of virtue. What pathetic eloquence did his diſcourſes diſplay! what knowledge of the human heart! what conſtant diſcloſing of a mind deeply affected with his ſubject! what ſtrain of truth, philoſophy, and humanity! what imagination, at once the moſt lively, and guided by the ſoundeſt judgment! Juſt and delicate thoughts; ſplendid and lofty ideas; elegant, well choſen, ſublime, and harmonious expreſſions; brilliant and natural images; true and lively colouring; a clear, neat, ſwelling, and copious ſtyle, equally ſuited to the capacity of the multitude, and fitted to pleaſe the man of genius, the philoſopher, and the courtier, form the character of Maſſillon's eloquence, eſpecially in his *Petit Careme.* He could at once think, deſcribe, and feel. It has been juſtly obſerved concerning him, that he was to Bourdalone what Racine was to Corneille. To give the finiſhing ſtroke to his eulogium, Of all the French orators, he is the moſt eſteemed by foreigners.

An excellent edition of Maſſillon's works was publiſhed by his nephew at Paris in 1745 and 1746, in 14 vols. large 12mo, and 12 vols. of a ſmall ſize.—Among them we find, 1. Complete ſets of Sermons for Advent and Lent. It is particularly in his moral diſcourſes, ſuch as are almoſt all thoſe of his ſermons for Advent and Lent, that Maſſillon's genius appears. He excels, ſays M. d'Alembert, in that ſpecies of eloquence, which alone may be preferred to all others, which goes directly to the heart, and which agitates without wounding the ſoul. He ſearches the inmoſt receſſes of the heart, and lays open the ſecret workings of the paſſions, with ſo delicate and tender a hand, that we are hurried along rather than overcome. His diction, which is always eaſy, elegant, and pure, every where partakes of that noble ſimplicity, without which there can be neither good taſte nor true eloquence; and this ſimplicity is, in Maſſillon, joined to the moſt attractive and the ſweeteſt harmony, from which it likewiſe borrows new graces. In ſhort, to complete the charm produced by this enchanting ſtyle, we perceive that theſe beauties are perfectly natural; that they flow eaſily from this ſource, and that they have occaſioned no labour to the compoſer. There even occur ſometimes in the expreſſions, in the turns, or in the affecting melody of his ſtyle, inſtances of negligence which may be called happy, becauſe they completely remove every appearance of labour. By thus abandoning himſelf to the natural current of thought and expreſſion, Maſſillon gained as many friends as hearers. He knew, that the more anxious an orator appears to raiſe admiration, he will find thoſe who hear him the leſs diſpoſed to beſtow it. 2. Several Funeral Orations, Diſcourſes, and Panegyrics, which had never been publiſhed. 3. Ten diſcourſes, known by the name of *Petit Careme.* 4. The *Conferences eccleſiaſtiques*, which he delivered in the ſeminary of St Magloire upon his arrival at Paris; thoſe which he delivered to the curates of his dioceſe; and the diſcourſes which he pronounced at the head of the ſynods which he aſſembled every year. 5. Paraphraſes on ſeveral of the Pſalms. The illuſtrious author of theſe excellent tracts wiſhed that they had introduced into France a practice which prevails in England, of reading ſermons inſtead of preaching them from memory; a cuſtom which is very convenient, but by which all the warmth and fervour of eloquence are loſt. He, as well as two others of his brethren, had ſtopt ſhort in the pulpit exactly on the ſame day.—They were all to preach at different hours on Good-Friday, and they went to hear one another in ſucceſſion. The memory of the firſt failed; which ſo terrified the other two, that they experienced the ſame fate. When our illuſtrious orator was aſked, what was his beſt ſermon? he anſwered, "That which I am moſt maſter of." The ſame reply is aſcribed to Bourdaloue. The celebrated P. la Rue was of the opinion of Maſſillon, that getting by heart was a ſlavery which deprived the pulpit of a great many orators, and which was attended with many inconveniencies to thoſe who dedicated themſelves to it. The Abbé de la Porte has collected into 1 vol. 12mo the moſt ſtriking ideas, and the moſt ſublime ſtrokes, which occur in the works of the celebrated biſhop of Clermont. This collection, which is made with great judgment, appeared at Paris in 1748, 12mo, and forms the 15th volume of the large edition in 12mo, and the 13th of the ſmall in 12mo. It is entitled, *Penſées ſur differens ſujets de morale et de piete, tirées*, &c.

Maſſinger
||
Maſſon.

MASSINGER (Philip), an Engliſh dramatic poet, was born at Saliſbury about the year 1581, and was educated at Oxford. He left the univerſity without taking any degree; and went to London to improve his poetical genius by polite converſation. There he wrote many tragedies and comedies, which were received with vaſt applauſe; and were greatly admired for the economy of the plots and the purity of the ſtyle. He was at the ſame time a perſon of the moſt conſummate modeſty: which rendered him extremely beloved by the poets of his time, particularly by Fletcher, Middleton, Rowley, Field, and Decker, who thought it an honour to write in conjunction with him. He was as remarkable for his abilities as his modeſty. He died ſuddenly at his houſe on the Bank-ſide in Southwark, near the playhouſe; and was interred in St Saviour's church-yard, in the ſame grave with Mr Fletcher the poet.

MASSIVE, among builders, an epithet given to whatever is too heavy and ſolid: thus a maſſive column is one too ſhort and thick for the order whoſe capital it bears; and a maſſive wall is one whoſe openings or lights are too ſmall in proportion.

MASSON (Papirius), a French writer, was the ſon of a rich merchant, and born in the territory of Forez, May 1544. After ſtudying the belles lettres and philoſophy, and travelling to different places, he came to Paris, where he was made librarian to the chancellor of the duke of Anjou, in which place he continued ten years. In 1576, he was made an advocate of parliament; yet never pleaded but one cauſe, which, however, he gained with univerſal applauſe.—When the troubles of France were at an end, he married the ſiſter of a counſellor in parliament, with whom he lived thirty-four years, but had no iſſue by her.—The infirmities of age attacked him ſome time before his death, which happened Jan. 9. 1611. He wrote four books of French annals in Latin, firſt printed at Paris 1577, and afterwards in 1598, 4to. The ſecond edition, more enlarged than the firſt, deduces things from Pharamond to Henry II. Maſſon conſidered this as his principal performance; yet he is now chiefly known by his *Elogia virorum clariſſimorum*, although he publiſhed ſeveral other works.

Masson (John), a reformed miniſter in Holland ſome years ago. He was originally of France, but fled into England to enjoy that liberty in religion which his country refuſed him. He wrote, 1. *Hiſtoire critique de la republique des lettres*, from 1712 to 1717, in 15 vols. 12mo. 2. *Vitæ Horatii, Ovidii, et Plinii junioris*," 3 vols ſmall 8vo, and printed abroad, though dedicated to Engliſhmen of rank: the firſt at Leyden, 1708, to lord Harvey; the ſecond at Amſterdam, 1708, to Sir Juſtinian Iſham; the third at Amſterdam, 1709, to the biſhop of Worceſter. Theſe lives are drawn up in a chronological order, very learnedly and very critically; and ſerve to illuſtrate the hiſtory, not only of thoſe particular perſons, but of the times alſo in which they lived. 3. *Hiſtoire de Pierre Bayle & de ſes ouvrages*; Amſterdam, 1716, in 12mo. This at leaſt is ſuppoſed to be his, though at firſt it was given to M. la Monnoye.

Masson (Anthony), an eminent French engraver, who flouriſhed towards the concluſion of the laſt century, and reſided chiefly at Paris. It appears that he ſometimes amuſed himſelf with painting portraits from the life, ſome of which he alſo engraved. We have no account of the life of this extraordinary artiſt; nor are we even informed from what maſter he learned the principles of engraving. He worked entirely with the graver, and handled that inſtrument with aſtoniſhing facility. He ſeems to have had no kind of rule to direct him with reſpect to the turning of the ſtrokes; but twiſted and tirled them about, without the leaſt regard to the different forms he intended to expreſs, making them entirely ſubſervient to his own caprice. Yet the effect he has produced in this ſingular manner (Mr Strutt obſerves), is not only far ſuperior to what one could have ſuppoſed, but is often very pictureſque and beautiful. It was not in hiſtorical engraving that his greateſt ſtrength conſiſted. He could not draw the naked parts of the human figure ſo correctly as was neceſſary; but where the ſubject required the figures to be clothed, he ſucceeded in a wonderful manner. Among the moſt eſteemed works by this admirable artiſt, may be reckoned the following: The aſſumption of the Virgin, a large upright plate from Rubens; a holy family, a middling-ſized plate, lengthwiſe, from N. Mignard; Chriſt with the pilgrims at Emaus, a large plate, lengthwiſe, from Titian, the original picture of which is in the cabinet of the king of France. This admirable print is commonly known by the name of *the table-cloth*; for the cloth, with which the table is covered, is executed in a very ſingular ſtyle. Alſo the following portraits, among others: The comte de Harcourt, a large upright plate, reckoned a maſterpiece in this claſs of ſubjects; Guillaume de Briſacier, ſecretary to the queen of France; a middling-ſized upright plate: uſually known in England by the name of *the Grey-headed Man*, becauſe the hair in this print is ſo finely executed.

MASSUAH, a ſmall iſland in the Red Sea, near the coaſt of Abyſſinia, about three quarters of a mile long, and half as broad, one-third of which is occupied by houſes, another by ciſterns for receiving rain-water, and one reſerved for a burial place. It has an excellent harbour, with water ſufficiently deep for ſhips of any ſize to the very edge of the iſland; and ſo well ſecured, that they may ride in ſafety, let the wind blow from what quarter or with what degree of ſtrength it will. By the ancients it was called *Sebaſticum Os*, and was formerly a place of great conſequence on account of its harbour, from whence a very extenſive commerce was carried on, and poſſeſſed a ſhare of the Indian trade in common with other ports of the Red Sea near the Indian Ocean.—A very conſiderable quantity of valuable goods was alſo brought thither from the tract of mountainous country behind it, which in all ages has been accounted very unhoſpitable, and almoſt inacceſſible to ſtrangers. The principal articles of exportation were gold, ivory, elephants, and buffaloes hides; but above all ſlaves, who, on account of their perſonal qualifications, were more eſteemed than thoſe from any other quarter.—Pearls of a conſiderable ſize, and of a fine water, are likewiſe found along the coaſt; from the abundance of all which valuable commodities, the great defect, a want of water, was forgot, and the inhabitants cheerfully ſubmitted to ſuch a great inconvenience. The iſland of Maſſuah fell under the power of the Turks in the time of the emperor Selim, ſoon after the conqueſt of Arabia Felix by Sinan Baſha, and was for ſome time governed by an officer from Conſtantinople. From thence the conqueſt of Abyſſinia was for ſome time attempted, but always without ſucceſs. Hence it began to loſe its value as a garriſon for troops, as it had done in the commercial way after the diſcovery of the paſſage to India by the Cape of Good Hope.—Being thus deprived of it importance in every reſpect, the Turks no longer thought it worth while to ſend a baſhaw thither as formerly, but conferred the government upon the chief of a tribe of Mahometans named *Belowie*, who inhabit the coaſts of the Red Sea under the mountains of Habab, in the latitude of about 14° north. On this officer they conferred the title of *Naybe*; and on the removal of the baſhaw, he remained in fact maſter of the place, though, to ſave appearances, he pretended to hold it from the Ottomon Porte, by a firman from the Grand Signior for that purpoſe, and the payment of an annual tribute.

The Turks had originally put into the town of Maſſuah a garriſon of Janizaries; who, being left there on the withdrawing of the baſhaw, and intermarrying with the natives, ſoon became entirely ſubjected to the Naybe's influence. The latter, finding himſelf at a great diſtance from his protectors the Turks, whoſe garriſons were every where falling into decay, and that in conſequence of this he was entirely in the power of the emperor of Abyſſinia, began to think of taking ſome method of ſecuring himſelf on that ſide. Accordingly it was agreed that one half of the cuſtoms ſhould be paid to the Abyſſinian monarch; who in return was to allow him to enjoy his government unmoleſted. Having thus ſecured the friendſhip of the emperor of Abyſſinia, the Naybe began gradually to withdraw the tribute he had been accuſtomed to pay to the baſhaw of Jidda, to whoſe government Maſſuah had been aſſigned; and at laſt to pay as little regard to the government of Abyſſinia: and in this ſtate of in-

independence he was when Mr Bruce arrived there in 1769 on his way to Abyſſinia. This gentleman found both the prince and his people extremely unhoſpitable and treacherous; ſo that he underwent a variety of dangers during his reſidence there, nor was it without great difficulty that he could get away from thence at laſt.

The iſland of Maſſuah, as we have ſaid, is entirely deſtitute of water; nor can it be ſupplied with proviſions of any kind but from the mountainous country of Abyſſinia on the continent. Arkeeko, a large town in the bottom of the bay, has water, but is in the ſame predicament with regard to proviſions; for the adjacent tract of flat land, named *Samhar*, is a perfect deſart, inhabited only from the month of November to April by ſome wandering tribes, who carry all their cattle to the Abyſſinian ſide of the mountains when the rains fall there. Being thus in the territories of the Abyſſinians, it is in the power of the emperor of that country, or of his officer the Baharnagaſh, to ſtarve Maſſuah and Arkeeko, by prohibiting the paſſage of any proviſions from the Abyſſinian ſide of the mountains.

The houſes of Maſſuah are generally conſtructed of long poles and bent graſs, as is uſual with other towns of Arabia: only about 20 are of ſtone, and ſix or eight of theſe two ſtories high. The ſtones with which they are built have been drawn out of the ſea; and in them the bed of that curious muſcle found embodied in the ſolid rock at Mahon is frequently to be ſeen. Theſe are called *dattoli da mare*, or ſea-dates: but our author never ſaw any of the fiſh themſelves, though he has no doubt that they may be met with in the rocky iſlands of Maſſuah if they would take the trouble of breaking the rocks for them. All the neceſſaries of life are very dear in this place; and their quality is alſo very indifferent, owing to the diſtance from whence they muſt be brought, and the danger of carrying them through the deſart of Samhar, as well as to the extortions of the Naybe himſelf, who, under the name of *cuſtoms*, takes whatever part of the goods he thinks proper; ſo the profit left to the merchant is ſometimes little or nothing. All the money here is valued by the Venetian ſequin; and it is owing to the commercial intercourſe with the Arabian coaſt that any money at all is to be met with on this iſland or the eaſtern coaſt of Africa. Glaſs beads of all kinds and colours, whether whole or broken, paſs for ſmall money.

Though Maſſuah has now loſt very much of its commercial importance, a conſiderable trade is ſtill carried on from the place. From the Arabian ſide are imported blue cotton and ohter cloths; ſome of them from India being very fine. Other articles are Venetian beads, cryſtal, looking and drinking glaſſes, with cohol or crude antimony. Theſe three laſt articles come in great quantity from Cairo, firſt in the coffee-ſhips to Jidda, and then in ſmall barks to the port of Maſſuah. Old copper is alſo a valuable article of commerce. The Galla and all the various tribes to the weſtward of Gondar wear bracelets of this metal, which in ſome parts of that barbarous country is ſaid to ſell for its weight of gold. Here is alſo a ſhell, an univalve of the ſpecies of volutes, which ſells at an high price, and paſſes for money among the various tribes of Galla. The Banians were once the principal merchants of Maſſuah; but their number is now reduced to ſix, who are ſilver-ſmiths, and ſubſiſts by making ornaments for the women on the continent. They likewiſe eſſay gold, but make a poor livelihood.

MASSUET (Rene, or Renatus), a very learned Benedictine of the congregation of St Maur, was born at S. Owen de Macelles, in 1665. He is chiefly known for the new edition of St Irenæus, which he publiſhed in 1710. He conſulted ſeveral manuſcripts, which had never been examined, for that purpoſe, and made new notes and learned prefaces. He died in 1716, after having written and publiſhed ſeveral other works.

MAST, a long round piece of timber, elevated perpendicularly upon the keel of a ſhip, to which are attached the yards, the ſails, and the rigging. A maſt, with regard to its length, is either formed of one ſingle piece, which is called a *pole-maſt*, or compoſed of ſeveral pieces joined together, each of which retains the name of maſt ſeparately. The loweſt of theſe is accordingly named the *lower-maſt*, *a*, fig. 1. the next in height is the top-maſt, *b*, which is erected at the head of the former; and the higheſt is the top-gallant maſt, *c*, which is prolonged from the upper end of the top-maſt. Thus the two laſt are no other than a continuation of the firſt upwards.

Plate CCLXXXI

The lower-maſt is fixed in the ſhip by an apparatus, deſcribed in the articles HULK and SHEERS: the foot, or heel of it, reſts in a block of timber called the *ſtep*, which is fixed upon the *kelſon*: and the top-maſt is attached to the head of it by the *cap* and *the treſtle-trees*. The latter of theſe are two ſtrong bars of timber, ſupported by two prominences, which are as ſhoulders on the oppoſite ſides of the maſt, a little under its upper end: athwart theſe bars are fixed the *croſs-trees*, upon which the frame of the top is ſupported. Between the lower-maſt-head and the foremoſt of the croſs-trees, a ſquare ſpace remains vacant, the ſides of which are bounded by the two treſtle-trees. Perpendicularly above this is the foremoſt hole in the cap, whoſe after-hole is ſolidly fixed on the head of the lower-maſt. The top-maſt is erected by a tackle, whoſe effort is communicated from the head of the lower-maſt to the foot of the top-maſt; and the upper end of the latter is accordingly guided into and conveyed up through the holes between the treſtle-trees and the cap, as above-mentioned. The machinery by which it is elevated, or, according to the ſea-phraſe, *ſwayed up*, is fixed in the following manner: the top rope *d*, fig. 3. paſſing through a block *e*, which is hooked on one ſide of the cap, and afterwards through a hole, furniſhed with a ſheave or pulley *f*, on the lower end of the top-maſt, is again brought upwards on the other ſide of the maſt, where it is at length faſtened to an eye bolt in the cap *g*, which is always on the ſide oppoſite to the top-block *e*. To the lower end of the top-rope is fixed the top-tackle *h*, the effort of which being tranſmitted to the top-rope *d*, and thence to the heel of the top-maſt *f*, neceſſarily lifts the latter upwards, parallel to the lower-maſt. When the top-maſt is raiſed to its proper height, fig. 4. the lower end of it becomes firmly wedged in the ſquare hole above deſcribed, between the treſtle-trees. A bar of wood or iron called the *fid*, is then thruſt through a hole *i* in the heel of it, acroſs the treſtle-trees, by which the whole weight of the top-maſt is ſupported.

In the ſame manner as the top-maſt is retained at the head of the lower-maſt, the top-gallant-maſt is erected, and fixed at the head of the top-maſt.

Beſides the parts already mentioned in the conſtruction of maſts, with reſpect to their length, the lower-maſts of the largeſt ſhips are compoſed of ſeveral pieces united into one body. As theſe are generally the moſt ſubſtantial parts of various trees, a maſt, formed by this aſſemblage, is juſtly eſteemed much ſtronger than one conſiſting of any ſingle trunk, whoſe internal ſolidity may be very uncertain. The ſeveral pieces are formed and joined together, as repreſented in the ſection of a lower-maſt of this ſort, fig. 5. where *a* is the ſhaft, or principal piece into which the reſt are fixed, with their ſides or faces cloſe to each other. The whole is ſecured by ſeveral ſtrong hoops of iron, driven on the outſide of the maſt, where they remain at proper diſtances.

Plate CCLXXXI

The principal articles to be conſidered in equipping a ſhip with maſts are, 1ſt, the number; 2d, their ſituation in the veſſel; and, 3d, their height above the water.

The maſts being uſed to extend the ſails by means of their yards, it is evident, that if their number were multiplied beyond what is neceſſary, the yards muſt be extremely ſhort, that they may not entangle each other in working the ſhip, and by conſequence their ſails will be very narrow, and receive a ſmall portion of wind. If, on the contrary, there is not a ſufficient number of maſts in the veſſel, the yards will be too large and heavy, ſo as not to be managed without difficulty. There is a mean between theſe extremes, which experience and the general practice of the ſea have determined; by which it appears, that in large ſhips every advantage of ſailing is retained by three maſts and a bowſprit.

The moſt advantageous poſition of the maſts is undoubtedly that from whence there reſults an equilibrium between the reſiſtance of the water on the body of the ſhip on one part, and of the direction of their effort on the other. By every other poſition this equilibrium is deſtroyed, and the greateſt effort of the maſts will operate to turn the ſhip horizontally about its direction; a circumſtance which retards her velocity. It is counterbalanced indeed by the helm; but the ſame inconvenience ſtill continues; for the force of the wind, having the reſiſtance of the helm to overcome, is not entirely employed to puſh the veſſel forward. The axis of the reſiſtance of the water ſhould then be previouſly determined, to diſcover the place of the *main-maſt*, in order to ſuſpend the efforts of the water equally, and place the other maſts ſo as that their particular direction will coincide with that of the main-maſt. The whole of this would be capable of a ſolution if the figure of the veſſel were regular, becauſe the point, about which the reſiſtance of the water would be in equilibrio, might be diſcovered by calculation.

But when the real figure of the ſhip is conſidered, theſe flattering ideas will inſtantly vaniſh. This obſervation induced M. Saverien to employ a mechanical method to diſcover the axis of reſiſtance of the water, which he apprehended might be uſed with ſucceſs in the manner following:

Plate CCLXXXI.

When the veſſel is launched, before the places of the maſts are determined, extend a rope AB, fig. 6. from the head to the ſtern. To the extremities A and B attach two other ropes, AD, BC, and apply to the other ends of theſe ropes two mechanical powers, to draw the ſhip according to the direction BC, parallel to itſelf. The whole being thus diſpoſed, let a moveable tube Z, fixed upon the rope AB, have another rope ZR attached to it, whoſe other end communicates with a mechanical power R, equal to the two powers D and C. This laſt being applied to the ſame veſſel, in ſuch manner as to take off the effects of the two others by ſliding upon the rope AB, ſo as to diſcover ſome point Z, by the paralleliſm of the ropes AD, BC feebly extended with the rope ZR; the line ZR will be the axis of the equilibrium of the water's reſiſtance, and by conſequence the main-maſt ſhould be planted in the point Z.

The figures E, E, E, are three windlaſſes on the ſhore, by which this experiment is applied.

With regard to the ſituation of the other maſts, it is neceſſary, in the ſame manner, to diſcover two points; ſo that the direction of the two mechanical powers operating, will be parallel to the axis of reſiſtance RZ already found.

The exact height of the maſts, in proportion to the form and ſize of the ſhip, remains yet a problem to be determined. The more the maſts are elevated above the centre of gravity, the greater will be the ſurface of ſail which they are enabled to preſent to the wind; ſo far an additional height ſeems to have been advantageous. But this advantage is diminiſhed by the circular movement of the maſt, which operates to make the veſſel ſtoop to its effort; and this inclination is increaſed in proportion to the additional height of the maſt, an inconvenience which it is neceſſary to guard againſt. Thus what is gained upon one hand is loſt upon the other. To reconcile theſe differences, it is certain, that the height of the maſt ought to be determined by the inclination of the veſſel, and that the point of her greateſt inclination ſhould be the term of this height above the centre of gravity. See the article TRIM.

With regard to the general practice of determining the height of the maſts, according to the different rates of the ſhips in the royal navy, the reader is referred to the article SAIL.

In order to ſecure the maſts, and counterbalance the ſtrain they receive from the effort of the ſails impreſſed by the wind, and the agitation of the ſhip at ſea, they are ſuſtained by ſeveral ſtrong ropes, extended from their upper ends to the outſide of the veſſel, called *ſhrouds*, as repreſented in fig. 4. They are further ſupported by other ropes, ſtretched from their heads towards the fore-part of the veſſel.

The maſt, which is placed at the middle of the ſhip's length, is called the *main-maſt*; that which is placed in the forepart, the *fore-maſt*; and that which is towards the ſtern, is termed the *mizen-maſt*.

N. B. *Mizen* is applied to this maſt by all the nations of Europe, except the French, who alone call the fore-maſt *miſaine*.

MASTER, a title given to ſeveral officers and perſons of authority and command; particularly to the

the chiefs of the orders of knighthood, &c.—Thus we ſay the grand-maſter of Malta; of St Lazarus; of the golden fleece; of the free maſons, &c.

Master *(magiſter)*, was a title frequent among the Romans: they had their maſter of the people, *magiſter populi*, who was the dictator. Maſter of the cavalry, *magiſter equitum*, who held the ſecond poſt in an army after the dictator. Under the later emperors there were alſo maſters of the infantry, *magiſtri peditum*. A maſter of the cenſus, *magiſter cenſus*, who had nothing of the charge of a cenſor, or ſubcenſor, as the name ſeems to intimate; but was the ſame with the *præpoſitus frumentariorum*.

Master of the Militia (magiſter militiæ), was an officer in the lower empire, created, as it is ſaid, by Diocleſian, who had the inſpection and government of all the forces, with power to puniſh, &c. ſomewhat like a conſtable of France. At firſt there were two of theſe officers inſtituted, the one for the infantry, and the other for the cavalry; but the two were united into one under Conſtantine. Afterwards, as their power was increaſed, ſo was their number alſo; and there was one appointed for the court, another for Thrace, another for the Eaſt, and another for Illyria. They were afterwards called *comites*, *counts*, and *clariſſimi*. Their power was only a branch of that of the *præfectus prætorii*, who by that means became a civil officer.

Master of Arms (magiſter armorum), was an officer or comptroller under the maſter of the militia.

Master of the Offices (magiſter officiorum), had the ſuperintendance of all the officers of the court: he was alſo called *magiſter officii palatini;* ſimply *magiſter*; and his poſt *magiſteria*.—This officer was the ſame in the weſtern empire with the curopalates in the eaſtern.

Master at Arms, among us, is an officer appointed to teach the officers and crew of a ſhip of war the exerciſe of ſmall arms; to confine and plant centinels over the priſoners, and ſuperintend whatever relates to them during their confinement. He is alſo to obſerve that the fire and lights are all extinguiſhed as ſoon as the evening-gun is fired, except thoſe which are permitted by proper authority, or under the inſpection of centinels. It is likewiſe his duty to attend the gangway when any boats arrive aboard, and ſearch them carefully, together with their rowers, that no ſpirituous liquors may be conveyed into the ſhip unleſs by permiſſion of the commanding officer. In theſe ſeveral duties he is aſſiſted by proper attendants, called his *corporals*, who alſo relieve the centinels and one another at certain periods.

Master of Arts, the firſt degree taken up in foreign univerſities, but the ſecond in ours; candidates not being admitted to it till they have ſtudied in the univerſity ſeven years.

Master-Attendant, is an officer in the royal dock-yards, appointed to haſten and aſſiſt at the fitting out or diſmantling, removing, or ſecuring veſſels of war, &c. at the port where he reſides. He is particularly to obſerve, that his majeſty's ſhips are ſecurely moored, and for this purpoſe he is expected frequently to review the moorings which are ſunk in the harbour, and obſerve that they are kept in proper repair. It is alſo his duty to viſit all the ſhips in ordinary, and ſee that they are frequently cleaned and kept in order; and to attend at the general muſters in the dock-yards, taking care that all the officers, artificers, and labourers, regiſtered at the navy-books, are preſent at their duty.

Master of the Ceremonies, is an officer inſtituted by King James I. for the more ſolemn and honourable reception of ambaſſadors, and ſtrangers of quality, whom he introduces into the preſence.—The badge of this office is a gold chain and medal, having on one ſide an emblem of peace, with King James's motto; and on the reverſe the emblem of war, with *Dieu & mon droit*. He is always ſuppoſed to be a perſon of good addreſs, and a maſter of languages, and has an appointment of 300 l. a year: he is conſtantly attending at court, and hath under him an aſſiſtant-maſter, or deputy, at 6s. 8d. a day, who holds his place during the king's pleaſure.

There is alſo a third officer, called *marſhal of the ceremonies*, with 100l. a-year, whoſe buſineſs is to receive and diſtribute the maſter's orders, or the deputy's, for the ſervice; but without their order he can do nothing. This is the king's gift.

Masters of Chancery are uſually choſen out of the barriſters of the common law; and ſit in chancery, or at the rolls, as aſſiſtants to the lord chancellor and the maſter of the rolls. All theſe, ſo late as the reign of Queen Elizabeth, were commonly doctors of the civil law.—To them are alſo committed interlocutory reports, examination of bills in chancery, ſtating of accounts, taxing coſts, &c. and ſometimes, by way of reference, they are impowered to make a final determination of cauſes.

They have time out of mind had the honour to ſit in the lords houſe, though they have neither writs nor patent to impower them; but they are received as aſſiſtants to the lord chancellor and maſter of the rolls. They had anciently the care of inſpecting all writs of ſummons, which is now performed by the clerk of the petty-bag. When any meſſage is ſent from the lords to the commons, it is carried by the maſters of chancery. Before them alſo affidavits are made, and deeds and recognizances acknowledged.

Beſides theſe, who may be called *maſters of chancery ordinary* (being 12 in number, whereof the maſter of the rolls is reputed the chief), there are alſo maſters of chancery extraordinary, appointed to act in the ſeveral counties of England beyond 10 miles diſtance from London, by taking affidavits, recognizances, &c. for the eaſe of the ſuitors of the court.

Master of the Faculties, an officer under the archbiſhop of Canterbury, who grants licences and diſpenſations: he is mentioned in the ſtatute 22 and 23 Car. II. See *Court of Faculties*.

Master-Gunner. See Gunner.

Master of the Horſe is reckoned the third great officer of the court, and is an office of great honour and antiquity, and always (when not put in commiſſion) filled by noblemen of the higheſt rank and abilities. He has the management and diſpoſal of all the king's ſtables and bred horſes. He has authority over the equerries and pages, coachmen, footmen, grooms, riders of the great horſe, farriers, and ſmiths. He appoints all the other tradeſmen who work for the king's ſtables; and by his warrant to the avenor, makes them give an oath to be true and faithful. In ſhort, he is en-

entruſted with all the lands and revenues appropriated for the king's breed of horſes, the expences of the ſtable, and of the coaches, litters, &c. He alone has the privilege of making uſe of any of the king's horſes, pages, footmen, &c.; and at any ſolemn cavalcade he rides next the king, and leads a horſe of ſtate. His ſalary is L.1276 : 13 : 4 *per annum*. There is alſo a maſter of the horſe in the eſtabliſhment of her majeſty's houſehold, with a ſalary of 800l. a-year.

Master of the Houſehold, is an officer under the treaſurer of the houſehold, in the king's gift: his buſineſs is to ſurvey the accounts of the houſehold.—He has L. 66 : 13 : 4 a-year wages, and L. 433 : 6 : 8 board-wages.

Master of the Mint, was anciently the title of him who is now called *warden of the mint*; whoſe office is to receive the ſilver and bullion which comes to the mint to be coined, and to take care thereof. The office of maſter and worker is now diſtinct: and this officer is allowed for himſelf and three clerks 650l. a-year.

Master of the Ordnance. See Ordnance.

Master of the Revels, an officer with an appointment of 100l. a-year, whoſe buſineſs is to order all things relating to the performance of plays, maſques, balls, &c. at court. Formerly he had alſo a juriſdiction of granting licences to all who travel to act plays, puppet-ſhews, or the like diverſions; neither could any new play be acted at either of the two houſes till it had paſſed his peruſal and licence; but theſe powers were afterwards much abridged, not to ſay annihilated, by a ſtatute for regulating playhouſes, till the licenſing plays by the lord chamberlain was eſtabliſhed. This officer has a yeoman with L.46:11:8 a-year.

Master of the Rolls, a patent-officer for life; who has the cuſtody of the rolls and patents which paſs the great ſeal, and of the records of the chancery.

In the abſence of the lord chancellor or keeper, he alſo ſits as judge in the court of chancery; and is by Sir Edward Coke called his *aſſiſtant*.

At other times he hears cauſes in the rolls-chapel, and makes orders and decrees. He is alſo the firſt of the maſters of chancery, and has their aſſiſtance at the rolls: but all hearings before him are appealable to the lord chancellor.

He has alſo his writ of ſummons to parliament, and ſits next to the lord chief juſtice of England on the ſecond woolpack. He has the keeping of the parliament-rolls, and has the rolls-houſe for his habitation; as alſo the cuſtody of all charters, patents, commiſſions, deeds, and recognizances, which being made of rolls of parchment gave riſe to the name. Anciently he was called *clerk of the rolls*.

Concerning the authority of the maſter of the rolls to hear and determine cauſes, and his general power in the court of chancery, there were (not many years ſince) divers queſtions and diſputes very warmly agitated; to quiet which it was declared by ſtat. 3. Geo. II. cap. 30. that all orders and decrees by him made, except ſuch as by the courſe of the court were appropriated to the great ſeal alone, ſhould be deemed to be valid; ſubject nevertheleſs to be diſcharged or altered by the lord chancellor, and ſo as they ſhall not be inrolled till the ſame are ſigned by his lordſhip.

In his gift are the ſix clerks in chancery, the examiners, three clerks of the petty-bag, and the ſix clerks of the rolls-chapel where the rolls are kept. See Rolls, Clerk, &c.

The maſter of the rolls is always of the privy-council; and his office is of great profit, though much ſhort of what it has been.

Master of a Ship, an officer to whom is committed the direction of a merchant-veſſel, who commands it in chief, and is charged with the merchandiſes aboard.

In the Mediterranean the maſter is frequently called *patron*, and in long voyages *captain*.

It is the proprietor of the veſſel that appoints the maſter; and it is the maſter who provides the equipage, hires the pilots, ſailors, &c. The maſter is obliged to keep a regiſter of the ſeamen and officers, the terms of their contract, the receipts and payments, and, in general, of every thing relating to his commiſſion.

Master of a Ship of War, is an officer appointed by the commiſſioners of the navy, to take charge of navigating a ſhip from port to port under the direction of the captain. The management and diſpoſition of the ſails, the working of a ſhip into her ſtation in the order of battle, and the direction of her movements in the time of action, and in other circumſtances of danger, are alſo more particularly under his inſpection. It is likewiſe his duty to examine the proviſions, and accordingly to admit none into the ſhip but ſuch as are ſound, ſweet, and wholeſome. He is moreover charged with the ſtowage; and for the performance of theſe ſervices he is allowed ſeveral aſſiſtants who are properly termed *mates* and *quarter-maſters*.

Master of the Temple. The founder of the order of the templars, and all his ſucceſſors were called *magni templi magiſtri*; and ever ſince the diſſolution of the order, the ſpiritual guide and director of the houſe is called by that name. See Temple and Templar.

There were alſo ſeveral other officers under this denomination, as maſter of the wardrobe, with a ſalary of 2000l. a-year; maſter of the harriers, with 2000l. a-year; maſter of the ſtaghounds, with 800l. a-year; maſter of the jewel-office, &c. all now aboliſhed.

Master and Servant; a relation founded in convenience, whereby a man is directed to call in the aſſiſtance of others, where his own ſkill and labour will not be ſufficient to anſwer the cares incumbent upon him. For the ſeveral ſorts of ſervants, and how that character is created or deſtroyed, ſee the article Servant. In the preſent article we ſhall conſider, firſt, the effect of this relation with regard to the parties themſelves; and ſecondly, its effects with regard to others.

Blackſt. Comment.

1. The manner in which this relation affects either the maſter or ſervant. And, firſt, by hiring and ſervice for a year, or apprenticeſhip under indentures, a perſon gains a ſettlement in that pariſh wherein he laſt ſerved 40 days. In the next place, perſons ſerving ſeven years as apprentices to any trade have an excluſive right to exerciſe that trade in any part of England. This law, with regard to the excluſive part of

it, has by turns been looked upon as a hard law, or as a beneficial one, according to the prevailing humour of the times: which has occaſioned a great variety of reſolutions in the courts of law concerning it; and attempts have been frequently made for its repeal, tho' hitherto without ſucceſs. At common law every man might uſe what trade he pleaſed; but this ſtatute reſtrains that liberty to ſuch as have ſerved as apprentices: the adverſaries to which proviſion ſay, that all reſtrictions (which tend to introduce monopolies) are pernicious to trade; the advocates for it allege, that unſkilfulneſs in trades is equally detrimental to the public as monopolies. This reaſon indeed only extends to ſuch trades, in the exerciſe whereof ſkill is required: but another of their arguments goes much farther; viz. that apprenticeſhips are uſeful to the commonwealth, by employing of youth, and learning them to be early induſtrious; but that no one would be induced to undergo a ſeven years ſervitude, if others, tho' equally ſkilful, were allowed the ſame advantages without having undergone the ſame diſcipline: and in this there ſeems to be much reaſon. However, the reſolutions of the courts have in general rather confined than extended the reſtriction. No trades are held to be within the ſtatute, but ſuch as were in being at the making of it: for trading in a country village, apprenticeſhips are not requiſite, and following the trade ſeven years is ſufficient without any binding; for the ſtatute only ſays, the perſon muſt ſerve *as* an apprentice, and does not require an actual apprenticeſhip to have exiſted.

A maſter may by law correct his apprentice for negligence or other miſbehaviour, ſo it be done with moderation: though, if the maſter or maſter's wife beats any other ſervant of full age, it is good cauſe of departure. But if any ſervant, workman, or labourer, aſſaults his maſter or dame, he ſhall ſuffer one year's impriſonment, and other open corporal puniſhment, not extending to life or limb.

By ſervice all ſervants and labourers, except apprentices, become intitled to their wages: according to agreement, if menial ſervants; or according to the appointment of the ſheriff or ſeſſions, if labourers or ſervants in huſbandry: for the ſtatutes for regulation of wages extend to ſuch ſervants only; it being impoſſible for any magiſtrate to be a judge of the employment of menial ſervants, or of courſe to aſſeſs their wages.

2. Let us now ſee how ſtrangers may be affected by this relation of maſter and ſervant; or how a maſter may behave towards others on behalf of his ſervant, and what a ſervant may do on behalf of his maſter.

And, firſt, the maſter may *maintain*, that is, abet and aſſiſt, his ſervant in any action at law againſt a ſtranger: whereas, in general, it is an offence againſt public juſtice to encourage ſuits and animoſities, by helping to bear the expence of them, and is called in law *maintenance*. A maſter alſo may bring an action againſt any man for beating or maiming his ſervant: but in ſuch caſe he muſt aſſign, as a ſpecial reaſon for ſo doing, his own damage by the loſs of his ſervice; and this loſs muſt be proved upon the trial. A maſter likewiſe may juſtify an aſſault in defence of his ſervant, and a ſervant in defence of his maſter: the maſter, becauſe he has an intereſt in his ſervant, not to be deprived of his ſervice; the ſervant, becauſe it is part of his duty, for which he receives his wages, to ſtand by and defend his maſter. Alſo if any perſon do hire or retain my ſervant, being in my ſervice, for which the ſervant departeth from me and goeth to ſerve the other, I may have an action for damages againſt both the new maſter and the ſervant, or either of them: but if the new maſter did not know that he is my ſervant, no action lies; unleſs he afterwards refuſe to reſtore him upon information and demand. The reaſon and foundation upon which all this doctrine is built, ſeem to be the property that every man has in the ſervice of his domeſtics; acquired by the contract of hiring, and purchaſed by giving them wages.

As for thoſe things which a ſervant may do on behalf of his maſter, they ſeem all to proceed upon this principle, that the maſter is anſwerable for the act of his ſervant, if done by his command, either expreſsly given or implied: *nam qui facit per alium, facit per ſe.* Therefore, if the ſervant commit a treſpaſs by the command or encouragement of his maſter, the maſter ſhall be guilty of it: not that the ſervant is excuſed, for he is only to obey his maſter in matters that are honeſt and lawful. If an innkeeper's ſervants rob his gueſts, the maſter is bound to reſtitution; for as there is a confidence repoſed in him, that he will take care to provide honeſt ſervants, his negligence is a kind of implied conſent to the robbery; *nam, qui non prohibet, cum prohibere poſſit, jubet.* So likewiſe if the drawer at a tavern ſells a man bad wine, whereby his health is injured, he may bring an action againſt the maſter; for although the maſter did not expreſsly order the ſervant to ſell it to that perſon in particular, yet his permitting him to draw and ſell it at all is impliedly a general command.

In the ſame manner, whatever a ſervant is permitted to do in the uſual courſe of his buſineſs, is equivalent to a general command. If I pay money to a banker's ſervant, the banker is anſwerable for it: if I pay it to a clergyman's or a phyſician's ſervant, whoſe uſual buſineſs it is not to receive money for his maſter, and he imbezzles it, I muſt pay it over again. If a ſteward lets a leaſe of a farm, without the owner's knowledge, the owner muſt ſtand to the bargain; for this is the ſteward's buſineſs. A wife, a friend, a relation, that uſe to tranſact buſineſs for a man, are *quoad hoc* his ſervants; and the principal muſt anſwer for their conduct: for the law implies, that they act under a general command; and without ſuch a doctrine as this no mutual intercourſe between man and man could ſubſiſt with any tolerable convenience. If I uſually deal with a tradeſman by myſelf, or conſtantly pay him ready money, I am not anſwerable for what my ſervant takes up upon truſt; for here is no implied order to the tradeſman to truſt my ſervant: but if I uſually ſend him upon truſt, or ſometimes on truſt and ſometimes with ready money, I am anſwerable for all he takes up; for the tradeſman cannot poſſibly diſtinguiſh when he comes by my order and when upon his own authority.

If a ſervant, laſtly, by his negligence does any damage to a ſtranger, the maſter ſhall anſwer for his neglect:

gleƈt: if a ſmith's ſervant lames a horſe while he is ſhoeing him, an action lies againſt the maſter, and not againſt the ſervant. But in theſe caſes the damage muſt be done while he is actually employed in the maſter's ſervice; otherwiſe the ſervant ſhall anſwer for his own miſbehaviour. Upon this principle, by the common law, if a ſervant kept his maſter's fire negligently, ſo that his neighbour's houſe was burned down thereby, an action lay againſt the maſter; becauſe this negligence happened in his ſervice: otherwiſe, if the ſervant, going along the ſtreet with a torch, by negligence ſets fire to a houſe; for there he is not in his maſter's immediate ſervice, and muſt himſelf anſwer the damage perſonally. But now the common law is, in the former caſe, altered by ſtatute 6 Ann. c. 3. which ordains, that no action ſhall be maintained againſt any in whoſe houſe or chamber any fire ſhall accidentally begin; for their own loſs is ſufficient puniſhment for their own or their ſervant's careleſſneſs. But if ſuch fire happens through negligence of any ſervant (whoſe loſs is commonly very little), ſuch ſervant ſhall forfeit 100 l. to be diſtributed among the ſufferers; and, in default of payment, ſhall be committed to ſome workhouſe, and there kept to hard labour for 18 months. A maſter is, laſtly, chargeable if any of his family layeth or caſteth any thing out of his houſe into the ſtreet or common highway, to the damage of any individual, or the common nuiſance of his majeſty's liege people: for the maſter hath the ſuperintendance of all his houſehold. And this alſo agrees with the civil law; which holds, that the *pater familias*, in this and ſimilar caſes, *ob alterius culpam tenetur, ſive ſervi, ſive liberi.*

We may obſerve, that in all the caſes here put, the maſter may be frequently a loſer by the truſt repoſed in his ſervant, but never can be a gainer: he may frequently be anſwerable for his ſervant's miſbehaviour, but never can ſhelter himſelf from puniſhment by laying the blame on his agent. The reaſon of this is ſtill uniform and the ſame; that the wrong done by the ſervant is looked upon in law as the wrong of the maſter himſelf; and it is a ſtanding maxim, that no man ſhall be allowed to make any advantage of his own wrong.

Master-Load, in mining, a term uſed to expreſs the larger vein of a metal, in places where there are ſeveral veins in the ſame hill. Thus it often happens, that there are ſeven, ſometimes five, but more uſually three veins or loads, parallel to each other, in the ſame hill. Of theſe the middle vein is always much the largeſt. This is called the *maſter-load;* and the others which lie three, two, or one on each ſide of this, are called the *concomitants* of the maſter-load.

Master-Wort, in botany. See Imperatoria.

MASTICATION, the action of chewing, or of agitating the ſolid parts of our food between the teeth, by the motion of the jaws, the tongue, and the lips, whereby it is broken into ſmall pieces, impregnated with ſaliva, and ſo fitted for deglutition and a more eaſy digeſtion. See Anatomy, n° 104.

MASTICH, a kind of reſin exſuding from the lentiſcus tree; and brought from Chio, in ſmall yellowiſh tranſparent grains or tears, of an agreeable ſmell, eſpecially when heated or ſet on fire. See Pistachia.

This reſin is recommended in old coughs, dyſenteries, hæmoptoës, weakneſs of the ſtomach, and in general in all debilities and laxity of the fibres. Geoffroy directs an aqueous decoction of it to be uſed for theſe purpoſes: but water extracts little or nothing from this reſin. Rectified ſpirit almoſt entirely diſſolves it, and the ſolution is very warm and pungent. Maſtich is to be choſen in drops, clear, well-ſcented, and brittle.

We meet with a kind of cement ſometimes kept in the ſhops under the name of maſtich. It is compoſed of this gum, and ſeveral other ingredients, and is formed into cakes for uſe. This is intended for the ſervice of lapidaries, to fill up cracks in ſtones, &c. but is by no means to be uſed for any medicinal purpoſes.

MASTICOT, or YELLOW LEAD, is the calx or aſhes of lead, gently calcined, by which it is changed to a yellow or lighter or deeper teint, according to the degree of calcination. Maſticot is ſometimes uſed by painters, and it ſerves medicinally as a drier in the compoſition of ointments or plaſters. The maſticot which is uſed by the Dutch as the ground of their glazing, is prepared by calcining a mixture of one hundred weight of clean ſand, forty-four pounds of ſoda, ſold with us under the name of barilla, and thirty pounds of pearl-aſhes.

MASTIFF-DOG, or BAND-DOG, (*canis villaticus* or *catenarius)*, is a ſpecies of great ſize and ſtrength, and a very loud barker. Manwood ſays, that it derives its name from *maſe theſeſe*, being ſuppoſed to frighten away robbers by its tremendous voice. Great Britain was formerly ſo noted for its maſtiffs, that the Roman emperors appointed an officer in this iſland, with the title of *Procurator Cynegii*, whoſe ſole buſineſs was to breed, and tranſmit from hence to the amphitheatre, ſuch as would prove equal to the combats of the place. Strabo, lib. iv. tells us, that the maſtiffs of Britain were trained for war, and uſed by the Gauls in their battles. See Canis.

MASTIGADOUR, or SLABBERING-BIT, in the manege, a ſnaffle of iron, all ſmooth, and of a piece, guarded with paternoſters, and compoſed of three halfs of great rings, made into demi-ovals, of unequal bigneſs; the leſſer being incloſed within the greater, which ought to be about half a foot high.

MASULAPATAN, a populous town of Aſia in the Eaſt Indies, and on the coaſt of Coromandel, in the dominions of the Great Mogul. It carried on a great trade, and moſt nations in Europe had factories here; but the Engliſh have now left it, and even the Dutch themſelves have not above a dozen people here to carry on the chintz trade. The inhabitants are Gentoos, who will not feed on any thing that has life; and they had a famous manufacture of chintz, which is greatly decayed ſince the Engliſh left off buying. The Great Mogul has a cuſtom-houſe here; and the adjacent countries abound in corn, tobacco, and timber for building. It is ſeated on the weſt ſide of the Bay of Bengal, 200 miles north of fort St George. W. Long. 81. 25. N. Lat. 16. 30.

MATACA, or Mantaca, a commodious bay in America, on the north coaſt of the iſland of Cuba. Here the galleons uſually come to take in freſh water in their return to Spain. It is 35 miles from the Havannah. W. Long. 85. 6. N. Lat. 25. 0.

MATAMAN, a country of Africa, bounded by Benguela on the north, by Monomotopa on the eaſt, by Cafraria on the ſouth, and by the Atlantic Ocean on the weſt. There is no town in it, and the inhabitants live in miſerable huts, it being a deſart country, and but little viſited by the Europeans.

MATAN, or MACTAN, an iſland of Aſia in the Eaſt-Indian ſea, and one of the Philippines. The inhabitants have thrown off the yoke of Spain; and it was here that Magellan was killed in April 1521.

Cape MATAPAN, the moſt ſouthern promontory of the Morea, between the gulph of Coran and that of Colo-China.

MATARAM, a large town of Aſia, formerly the capital of an empire of that name in the iſland of Java. It is ſtrong by ſituation, and is ſeated in a very fertile, pleaſant, and populous country, ſurrounded with mountains. E. Long. 111. 25. S. Lat. 7. 55.

MATARO, a town of Spain, in Catalonia; ſeated on the coaſt of the Mediterranean, 15 miles north-eaſt of Barcelona, and 35 ſouth-weſt of Gironne. It is a ſmall town, but induſtrious and well-peopled; and the environs abound in vineyards, which produce wine much famed for its flavour. It likewiſe contains ſeveral manufactories, and is conſidered as one of the richeſt and moſt active towns in Catalonia. E. Long. 2. 35. N. Lat. 41. 30.

MATCH, a kind of rope ſlightly twiſted, and prepared to retain fire for the uſes of artillery, mines, fire-works, &c.

It is made of hempen-tow, ſpun on the wheel like cord, but very ſlack; and is compoſed of three twiſts, which are afterwards again covered with tow, ſo that the twiſts do not appear: laſtly, it is boiled in the lees of old wines. This, when once lighted at the end, burns on gradually and regularly, without ever going out till the whole be conſumed: the hardeſt and drieſt match is generally the beſt.

Quick-Match. See *Quick-Match.*

MATCHING, in the wine-trade, the preparing veſſels to preſerve wines and other liquors, without their growing ſour or vapid. The method of doing it is as follows: Melt brimſtone in an iron ladle, and when thoroughly melted, dip into it ſlips of courſe linen-cloth; take theſe out, and let them cool: this the wine-coopers call a *match.* Take one of theſe matches, ſet one end of it on fire, and put it into the bung-hole of a caſk; ſtop it looſely, and thus ſuffer the match to burn nearly out: then drive in the bung tight, and ſet the caſk aſide for an hour or two. At the end of this time examine the caſk, and you will find that the ſulphur has communicated a violent pungent and ſuffocating ſcent to the caſk, with a conſiderable degree of acidity, which is the gas and acid ſpirit of the ſulphur. The caſk may after this be filled with a ſmall wine which has ſcarce done its fermentation; and bunging it down tight, it will be kept good, and will ſoon clarify: this is a common and very uſeful method; for many poor wines could ſcarce be kept potable even a few months without it.

MATE *of a Ship of War*, an officer under the direction of the maſter, by whoſe choice he is generally appointed, to aſſiſt him in the ſeveral branches of his duty. Accordingly, he is to be particularly attentive to the navigation in his watch, &c. to keep the *log* regularly, and examine the line and glaſſes by which the ſhip's courſe is meaſured, and to adjuſt the ſails to the wind in the fore-part of the ſhip. He is to have a diligent attention to the cables, ſeeing that they are well *coiled* and kept clean when laid in the *tier*, and ſufficiently *ſerved* when employed to ride the ſhip. Finally, he is to ſuperintend and aſſiſt at the ſtowage of the hold, taking eſpecial care that all the ballaſt and proviſions are properly ſtowed therein.

Mate of a Merchant-Ship, the officer who commands in the abſence of the maſter thereof, and ſhares the duty with him at ſea; being charged with every thing that regards the internal management of the ſhip, the directing her courſe, and the government of her crew.

The number of mates allowed to ſhips of war and merchantmen is always in proportion to the ſize of the veſſel. Thus a firſt-rate man of war has ſix mates, and an Eaſt-Indiaman the ſame number; a frigate of 10 guns, and a ſmall merchant-ſhip, but only one mate in each; and the intermediate ſhips have a greater or ſmaller number, according to their ſeveral ſizes, or to the ſervices on which they are employed.

DURA *and* PIA MATER, the names given by anatomiſts to the two membranes which ſurround the brain. See ANATOMY, n° 129, 130.

MATERA, a conſiderable town of Italy, in the kingdom of Naples, and in the Terra d'Otranto, with a biſhop's ſee, ſeated on the river Canapro. E. Long. 16. 43. N. Lat. 40. 51.

MATERIA MEDICA,

Of Claſſification.

A GENERAL name for every ſubſtance uſed in medicine, and by ſome extended even to every article uſed as food or drink.

Thus the materia medica becomes exceedingly extenſive: however, before we enter upon any particular diſcuſſion of the ſubject, it appears proper to give ſome general idea of medicines and their operation.

A *medicine*, properly ſo called, is a ſubſtance which, when applied to the living human body, makes ſuch an alteration in it as either to prevent the approach of diſeaſe, or to remedy a morbid ſtate when already preſent. Such ſubſtances as may be uſed for theſe purpoſes without any great preparation are called *ſimple medicines*, or *ſimples*; and with theſe the writers on materia medica are chiefly converſant. In treatiſes written profeſſedly on this ſubject, it is common to give a particular deſcription of each article, the characteriſtic marks by which it may be diſtinguiſhed from all other ſubſtances, and the methods by which an adulteration or an imperfection may be diſcovered in it, together with the doſe in which it can ſafely be given: but as all theſe particulars are taken notice of in different parts of this work, it is only neceſſary here to mention the general claſſification, and enumerate the names of the various ſubſtances uſed in medicine, after giving, as hath been already promiſed, a brief and general account of their mode of operation.

Concerning the manner in which medicines act, phyſicians have greatly differed, and each has followed his own particular theory. The followers of Boerhaave have ſuppoſed their action to be directly upon the ſolids and fluids; while thoſe who build their theories on the hypotheſis of Hoffman have aſſerted, that all medicines act immediately upon the nervous ſyſtem, and from thence only in a ſecondary manner are their effects diffuſed over the ſolids and fluids. To diſcuſs this queſtion is not our buſineſs at preſent: neither indeed is it a matter of great conſequence whether it be diſcuſſed or not; ſeeing all parties muſt own, that certain effects follow the uſe of certain particular ſubſtances, whether theſe ſubſtances act firſt upon the nervous ſyſtem or upon the ſolids and fluids.

From their operations on the human body medicines are moſt uſually divided into claſſes. Some are found to have the property of rendering the ſolid parts of the body more lax than before, and are therefore called *relaxing* medicines: Others there are which have an effect directly contrary, and are therefore called *indurating* medicines: A third kind are found to excite inflammation in the part to which they are applied, and are therefore called *inflammatory* medicines: And, laſtly, a fourth kind are found remarkably either to increaſe or diminiſh the vigour of the body, or what is called the *tone* of the ſolids; and have therefore got the name of *tonics* if they increaſe, and *ſedatives* if they diminiſh, this tone.

Some medicines are ſuppoſed neither remarkably to increaſe nor diminiſh the tone of the ſolids; but to perform their office either by correcting ſome morbid matter in the body, or by evacuating it: in the former caſe they are called *alterants*, in the latter *evacuants*.

Theſe are the general diviſions or claſſes into which medicines are commonly divided; but when we begin more particularly to conſider their virtues, a great many inferior diviſions ariſe.—Of the relaxing medicines, ſome, when externally applied, are ſuppoſed only to ſoften the part; and in that caſe are called *emollients:* while others, which have a power of converting the humours ſtagnating in any inflamed part into pus, are called *maturants*, or *ſuppuratives*. Sedative medicines, externally applied, are ſometimes called *paregorics:* when taken internally, if they take off a ſpaſm then exiſting in the body, they are called *antiſpaſmodics;* if they mitigate pain, *anodynes;* if they produce a quiet ſleep, *hypnotics;* or if they produce a very deep and unnatural ſleep, together with a remarkable ſtupefaction of the ſenſes, they are then called *narcotics*.

Tonic medicines obtain the name of *corroboratives*, *analeptics*, or *nervine* medicines, when they ſlightly increaſe the contractile power of the ſolids; but of *aſtringents*, if they do this in a great degree, eſpecially if at the ſame time that they indurate the ſolids they alſo coagulate the fluids. Some of theſe medicines have received names from their ſuppoſed virtue of promoting the growth of the fleſh, conſolidating wounds, and ſtopping fluxes of blood: but it is now diſcovered that no medicines whatever are endowed with any ſuch powers; and therefore the diviſions into *ſarcotics traumatics*, or *vulneraries*, &c. are ſeldom uſed.—If aſtringent medicines are uſed with an intention to drive, by the conſtriction which they occaſion, any kind of matter from the ſurface towards the internal parts of the body, they are called *repellents;* but if they inſenſibly expel any kind of ſtagnating matter from the parts where it is contained, they are then called *diſcutients;* and laſtly, *ſtimulants*, or *attractives*, if they bring a greater flux of humours to the part to which they are applied.

As to medicines of the inflammatory kind, they are divided into *veſicatories* or bliſters, which by their application raiſe watery bladders on the ſkin; and *catheratics*, *eſcharotics*, or *corroſives*, if they eat into and deſtroy the ſubſtance of the ſolid parts themſelves. Another ſubdiviſion has been added, viz. that of *rubefactive* medicines, or ſuch as only induce a redneſs on the part to which they are applied; but theſe belong to the veſicatories, and what proves only *rubefactive* to one will frequently bliſter another.

The alterants are divided into *abſorbents*, ſuch as by their alkaline quality neutraliſe and deſtroy any acid matter which may be in the ſtomach; and *antiſeptics*, or thoſe which correct any putrid matter in it; *coagulants* when they thicken the humours, and *reſolvents* if they thin them; *heating* medicines when they increaſe the velocity of the blood, and *refrigerating* if they diminiſh it.

The evacuating medicines are divided according to the nature of the humour they evacuate. Thus, if they evacuate the contents of the ſtomach by vomiting, they are called *emetics;* if they induce purging, they are called *cathartics;* if they only evacuate the immediate contents of the inteſtines, they are named *eccoprotics;* or if a moderate evacuation is produced, without ſickneſs or pain, they are called *laxatives*.—The medicines which gently promote the expulſion of humours through the pores of the ſkin, are called *diaphoretics*. If they do this in great quantity and with violence, they are called *ſudorifics*. Such as excite urine, are called *diuretics*. Such as produce their evacuation by the glands of the palate, mouth, and ſalival ducts, are called *ſalivating* medicines; thoſe which promote the evacuation of mucus from the throat, are called *apophlegmatics;* while thoſe which evacuate by the noſe, are called *ptarmics*, *errhines*, *ſternutatories;* and thoſe which promote the menſtrual flux, *emmenagogues*.—To the order of evacuants alſo ſome reduce thoſe medicines which expel any unnatural bodies, as worms, ſtones, and flatus. Thoſe which deſtroy worms are called *anthelmintics;* thoſe which diſſolve the ſtone in the bladder, *lithontriptics;* and ſuch as expel flatus, *carminatives*.

According to theſe diviſions Mr Vogel claſſes the articles of his Materia Medica; but Dr Lewis chooſes to arrange them according to the natural qualities of the ſubſtances themſelves, and not their effects on the human body.

Writers on the materia medica (he obſerves) have taken great pains in arranging the various articles of which

Of Arrangement.

which it is compoſed, into different diviſions and ſubdiviſions, according to their real or reputed medicinal powers.

It has been imagined, that the whole materia medica is reducible under the three diſtinctions of *alteratives*, *evacuants*, and *reſtoratives:* the firſt comprehending all that has any power to alter the conſtitution, without ſenſibly increaſing or diminiſhing any of the natural evacuations; the ſecond, whatever viſibly promotes thoſe diſcharges; and the third, all that contributes to leſſen them, and make the increaſe greater than the waſte. Theſe diviſions being too general, they are broken into ſubdiviſions; and theſe again are further divided into different claſſes, under more reſtrained denominations, as cardiac, carminative, hyſteric, ſtomachic, &c.

Specious as this plan may appear to be, he imagines the execution of it, to any uſeful purpoſe, would require a far more extenſive knowledge of the nature and operation of medicines than has yet been attained to. A juſt and uſeful method of ſimples is ſcarcely to be expected, while thoſe properties on which the method is founded are imperfectly known, and in many articles only conjectural.

In all the arguments that have been hitherto contrived upon this plan, there appears a ſtriking incongruity among the ſeveral articles of which even the ultimate ſubdiviſions are compoſed; ſubſtances extremely diſſimilar being claſſed together, as cantharides and tea, tobacco and bran, hemlock and cowſlips, ſcurvy-graſs and raiſins, arum root and liquorice, wormwood and parſnips, cinnamon and nettles, raſberries and chalk, artichokes and alum, cloves and coffee, muſtard-ſeed and black cherries, &c. Nor are theſe incongruities to be laid always to the charge of the authors, the nature of the ſyſtem itſelf rendering them often unavoidable; for the particular effect which intitles a medicine to a particular claſs, may be produced by ſubſtances very diſſimilar, and even oppoſite, in their general powers: thus the alvine excretions are reſtrained by ſtarch, wax, tormentil-root, opium; among the capital diuretics are cantharides, nitre, ſalt, fixt alkaline ſalts, ſquills. It ſhould ſeem that the method of arrangement cannot be a juſt one which requires ſubſtances ſo diſcordant to be ranked together, and which further requires each of theſe ſubſtances to be ranked over again, in other claſſes, along with other ſubſtances to which they are equally diſcordant.

There is alſo a material imperfection in this ſcheme, even in the primary diviſions. Steel and its preparations act, in different circumſtances, both as evacuants and reſtoratives. Mercury and antimony afford, in their different preparations, both evacuants and alteratives; and there are many other drugs which are ſometimes uſed as alteratives, and ſometimes as evacuants; indeed, all evacuants, in diminiſhed doſes, ſeem to act merely as alteratives. It ſhould ſeem therefore, that "the diviſion of the whole materia medica into alteratives, evacuants, and reſtoratives," is a diviſion not founded in nature, even if there was no objection to the vague meaning of the appellations themſelves.

Cartheuſer has divided the materia medica on a plan which appears more rational. Inſtead of the operations of medicines in the human body, which are precarious, complicated, and greatly diverſified according to the doſe, the preparation, and the circumſtances of the patient, he takes for the baſis of his arrangement their more ſimple, obvious, and conſtant properties, as bitterneſs, ſweetneſs, aſtringency, acidity, &c. Having conſidered the nature of bitterneſs, for inſtance, in general, he examines what effects medicines poſſeſſed of this property are capable of producing in the body, and in what circumſtances they may be expected to be ſerviceable, and then proceeds to an account of the particular bitters.

This method is of real uſe, but its uſe is limited to a ſmall part of the materia medica. There are many of the medicinal ſimples, in which we can diſtinguiſh no prevailing qualities of this kind; there are many, in which different qualities are blended together; and many which, though ſimilar in theſe kinds of qualities, are very diſſimilar in their operations in the human body: thus though gentian and aloes agree in having a bitter taſte, and ſugar and manna in being ſweet, their medicinal virtues are reſpectively very different. Accordingly, the author is obliged in ſome caſes to depart from his general plan, and found the diviſion on the medicinal effects: he makes one claſs of purgatives and emetics, and another of vaporoſe inebriants and narcotics: this laſt claſs conſiſts of tobacco, elder-flowers, ſaffron, opium, and poppy-ſeeds, ſubſtances certainly very diſcordant in all their qualities that relate to medicinal intentions.

In this article, inſtead of attempting a medicinal diſtribution of the ſimples, which we apprehend not to be practicable to any good purpoſe, we ſhall, after Dr Lewis, adopt the alphabetical mode of arrangement, as poſſeſſing upon the whole a decided ſuperiority over every other. We ſhall, however, premiſe, from the ſame ingenious author, ſome general obſervations on certain claſſes of medicines, in Cartheuſer's manner; and thus preſerve the leſs exceptionable parts of his plan, with ſome amendments.

Acids.

Art. I. Acids.

Claſs 1. *Vegetable* { *native;* as ſorrel, wood-ſorrel, juice of lemon, oranges, barberries, and other fruits.
produced by fermentation; as vinegar and tartar.
Claſs 2. *Mineral:* the acids of vitriol, nitre, and common ſalt.

The medical effects of acids, duly diluted and given in proper doſes, are, to cool, quench thirſt, correct a tendency to putrefaction, and allay inordinate motions of the blood. By theſe qualities, in hot bilious temperaments and inflammatory diſorders, they frequently reſtrain immoderate hæmorrhages, and promote the natural ſecretions; in ſome kinds of fever, they excite a copious diaphoreſis, where the warm medicines, called *alexipharmic*, tend rather to prevent this ſalutary diſcharge.

Vegetable acids, particularly the native juices of certain plants and fruits, have ſome degree of a ſaponaceous quality; by means of which they attenuate

or

or diſſolve viſcid phlegm and deterge the veſſels, and thus prove ſerviceable in ſundry chronical diſorders. Inveterate ſcurvies have ſometimes yielded to their continued uſe, eſpecially when given in conjunction with medicines of the acrid or pungent kind: experience has ſhown, that the acrid antiſcorbutics have much better effects when thus managed than when exhibited by themſelves; hence in the *ſucci ſcorbutici* of our diſpenſatory, Seville orange juice is uſefully joined to that of the *cochlearia* and *naſturtium*.

The mineral acids inſtantly coagulate blood: the vegetable dilute it, even when inſpiſſated or thickened by heat; in which ſtate, watery liquors will not mingle with it. Hence, in ſome fevers, where water runs off by the kidneys almoſt as pale and inſipid as it was drank, vegetable acids render the urine of the due colour and quality. The mineral acids (the ſpirit of nitre in particular) combined with vinous ſpirits, have a like effect.

Acids are prejudicial in cold, pale, phlegmatic habits, where the veſſels are lax, the circulation languid, bile deficient, and the power of digeſtion weak. In theſe caſes, an acid is often generated in the ſtomach, from milk and moſt vegetable foods; which, whilſt it continues in the firſt paſſages, occaſions uneaſineſs about the ſtomach, flatulencies, ſometimes griping pains of the bowels, and vomitings.

ART II. INSIPID EARTHS *capable of* ABSORBING ACIDS.

- Oyſter-ſhells,
- Crabs claws and eyes ſo called,
- Coral, red and white,
- Pearls,
- Bezoar,
- Chalk,
- Some marles,
- Lime-ſtones,
- Marbles,
- Spars.

The virtues of theſe ſubſtances are, to abſorb or deſtroy acidities in the firſt paſſages, and conſequently to remove ſuch diſorders as proceed from that cauſe. The cordial, alexipharmic, antifebrile, and other like virtues attributed to theſe medicines, appear to have little foundation; or at beſt are only ſecondary ones. When united with the acid, they form a neutral ſaline compound, poſſeſſing ſome degree of an aperient and detergent quality, though too inconſiderable to be in general regarded.

The abſorbent earths were all ſtrangers to medicine in the earlier times; and their uſe does not ſeem to have been eſtabliſhed before the laſt century; when ſome practitioners, from an opinion that moſt kinds of diſeaſes proceeded from a preternatural acid, introduced a great variety of antacid bones, both of the earthy and ſaline kind, and very liberally exhibited them on almoſt every occaſion.

It is certain, that in children, and adults of a weak conſtitution, and whoſe food is chiefly of the vegetable aceſcent kind, ſundry diſorders are occaſioned by acidities; theſe readily diſcover themſelves by ſour eructations, the pale colour of the face, and in children by the ſour ſmell and green colour of the alvine fæces, which are ſometimes ſo manifeſtly acid as to raiſe a ſtrong effervеſcence with alkaline ſalts. In theſe caſes, and theſe only, the uſe of abſorbent earths is indicated.

If there are really no acid juices in the ventricle, theſe earths are apt to concrete with the mucous matter uſually lodged there, into hard indiſſoluble maſſes; which have ſometimes been thrown up by vomit, or found in the ſtomach upon diſſection. Hence indigeſtion, loſs of appetite, nauſea, vomiting, obſtructions of the bowels, and other diſorders. Sometimes the ſtomach and inteſtines have been found lined with a cruſt, as it were, of theſe earthy bodies, which muſt not only have prevented the ſeparation of the gaſtric liquor, but likewiſe have cloſed the orifices of the lacteal veſſels, ſo as to obſtruct the paſſage of the chyle into the maſs of blood.

Some ſuppoſe the earthy powders capable (without the concurrence of any acid) of paſſing the lacteals along with the chyle; and allege, in ſupport of this opinion, that, when triturated with water, they are in part taken up and carried with it through a filter of paper; the filtrated liquor leaving, upon evaporation, a portion of whitiſh earthy matter. This experiment (allowing the conſequence to be juſtly drawn from it) is itſelf erroneous: the reſiduum proceeds from the earth naturally contained in the water, not from that employed in the experiment; for if pure diſtilled water be made uſe of, it will leave no reſiduum, though long triturated or digeſted with the earth.

All theſe bodies, particularly thoſe of the animal kind, contain, beſides their purely alkaline earth, a portion of glutinous matter. An inſtance of this we have in crabs-eyes, which if macerated in the weaker acids, or in the ſtronger ſufficiently diluted with water, the earthy part will be diſſolved, and the animal-glue remain in form of a ſoft tranſparent mucilage. The glutinous ſubſtance increaſes their tendency to concrete in the ſtomach; and thence thoſe which contain leaſt thereof ſhould be preferred to the others. The mineral earths contain the leaſt of this kind of matter, and ſome of them are very eaſy of ſolution; chalk, for inſtance, which may therefore be given with greater ſafety than the animal-abſorbents. Theſe ſubſtances, diveſted of their conglutinating matter by means of fire, are reduced into acrimonious calces or limes, and thus become medicines of a different claſs.

The teeth, bones, hoofs, and horns of animals conſiſt of the ſame principles with the animal-abſorbents above mentioned, but combined in different proportions: the quantity of gelatinous matter is ſo large, as to defend the earthy part from the action of weak acids; whilſt the earth, in its turn, protects the gluten from being eaſily diſſolved by watery liquors. Hence theſe bodies in their crude ſtate, though recommended as poſſeſſing ſingular virtues, are not found to have any virtue at all.

Experiments have been made for determining the degree of ſolubility, or comparative ſtrength of theſe earths; the principal of which are arranged in the two following tables, one taken from Langius, and the other from Homberg.

TABLE of the quantity of Acid deſtroyed by different Abſorbents.

Ten grains of	Some kinds of Limeſtones	deſtroyed the acidity of	160	Drops of Spirit of Salt.
	Oyſter ſhells		120	
	Chalk		100	
	Shells of Garden-ſnails		100	
	Calcined Cray-fiſh		100	
	Pearls		80	
	Tooth of the Sea-horſe		80	
	Volatile Salts		80	
	Fixed Salts		60	
	Coral, red and white		60	
	Crabs-eyes		50	
	Egg-ſhells		50	
	Mother-of-Pearl		50	
	Crabs-claws		40	
	Jaw-bone of the Pike-fiſh		30	

TABLE of the quantity of Abſorbent Earths ſoluble in Acids.

576 grains of Spirit of Sált diſſolved of	Crabs-eyes	216
	Mother-of-Pearl	144
	Pearls	128
	Oyſter-ſhells	156
	Hartſhorn	165
	Coral	186
	Oriental Bezoar	118
	Occidental Bezoar	123
	Quick Lime	199
	Slacked Lime	193
576 grains of Spirit of Nitre diſſolved of	Crabs-eyes	277
	Mother-of-Pearl	202
	Pearls	219
	Oyſter-ſhells	236
	Hartſhorn	234
	Coral	233
	Oriental Bezoar	108
	Occidental Bezoar	144
	Quick Lime	180
	Slacked Lime	216

Theſe experiments do not ſufficiently aſcertain the point intended by them: in the firſt ſett, the quantity of acid is too vague and indetermined; in the ſecond, we are not told whether the acid was perfectly ſaturated; and in both, the acids made uſe of were ſo very different from any that can be ſuppoſed ever to exiſt in the human body, that little can be concluded from them with regard to the medical effects of theſe abſorbents. Trial ſhould have been made with the mild vegetable acids, as the juices of certain fruits, ſour fermented liquors, or rather with ſour milk. Nevertheleſs theſe tables, though not ſo perfect as could be wiſhed, have their uſe in the hands of ſuch as can make proper allowances.

ART. III. EARTHS *not* DISSOLUBLE *in Acids or other liquors.*

Theſe may be ranged in two claſſes.

Claſs 1. *Hard cryſtalline earths:* as the ruby, garnet, emerald, ſapphire, hyacinth, and other precious ſtones; cryſtal, flint, &c.

THESE kind of ſubſtances were introduced into medicine, and many fabulous virtues attributed to them by the ſuperſtition of the earlier ages. Some of them are ſtill preſerved in foreign pharmacopœias, but at length very juſtly expunged from ours, notwithſtanding what ſome late writers of repute ſpeak of their medical virtue. Theſe indiſſoluble hard bodies are not capable of producing any other effect, than by their rigid angular particles (which, though levigated with the utmoſt care, the microſcope ſtill diſcovers in them) to offend or wound the inteſtines. In levigation, they wear off ſo much from the hardeſt marble inſtruments, as will equal or exceed their own weight: from this circumſtance we may account for their having ſometimes appeared to act as abſorbents. Some of theſe ſtones, expoſed to a vehement fire, become in ſome meaſure friable; but nevertheleſs remain indiſſoluble. Moſt of the coloured ones by this treatment loſe their colour; and in this ſtate prove nearly of the ſame quality with common cryſtal: ſuch are, the ſapphire, emerald, amethyſt, and cornelian. Others melt into a blackiſh vitreous matter, from which a portion of iron is obtainable by proper fluxes; as the hyacinth and garnet. Geoffroy concludes from hence, that theſe ſtones really poſſeſs ſome medical virtues, depending upon their metallic part: but the quantity of metallic matter, ſufficient to give them a conſiderable tinct, is ſo exceedingly ſmall, and ſo incloſed in a ſtony matter not at all ſoluble by any of the known menſtrua, as ſcarce to admit of any poſſibility of its acting in the human body.

Claſs 2. *Softer earths;* the talky, gypſeous, and argillaceous.

THE talcs and gypſums have rarely been uſed as medicines. Some of the former, from their unctuous ſoftneſs and ſilver hue, ſtand recommended externally as coſmetics; and ſome of the latter, on little better foundation, internally as aſtringents. But they have long been deſervedly rejected by the judicious practitioners. They ſeem to poſſeſs the ill qualities of the alkaline earth (concreting with the mucus of the ſtomach, &c.), without any of their good ones.

Several of the clays, boles, and terræ ſigillatæ, were highly celebrated by the ancients as aſtringents and alexipharmics, and ſome of them ſtill continue in eſteem; though it is certain they have no great claim to the virtues that have been attributed to them. Their real effects are, to give a greater degree of conſiſtency to the fluids in the firſt paſſages, and in ſome meaſure defend the ſolids from their acrimony.

Moſt of theſe bodies contain, beſides the tenacious indiſſoluble earth, which is their principal characteriſtic, (1.) A portion of an earth ſoluble in acids ſimilar to thoſe of the firſt ſection. (2.) Of acid, ſeparable by diſtillation in a ſtrong fire: this acid is always of the ſame nature with that obtained from vitriol, ſulphur, and alum. (3.) The coloured ones contain likewiſe ſmall quantities of iron, reducible, by inflammable fluxes, into its metallic form. In conſequence of the firſt of theſe ingredients, theſe earths may be looked upon in ſome meaſure as abſorbent: the acid appears to be united with a part of the abſorbent earth into a ſaline compound, approaching to an aluminous nature; whence they have ſome degree of aſtrin-

Glutinous nd Unctuous ſubſtances.

gency: whether they receive any peculiar virtue from the iron, is greatly to be doubted; ſince it is in a very crude ſtate, and in quantity extremely ſmall.

Theſe earths unite with water into a turbid liquor, ſlippery and ſmooth to the touch, and remain for ſome time ſuſpended; the ſand, grit, or other groſſer matters, which are often found naturally mingled with them, ſubſiding. They may be freed by means of acids from their alkaline earth; by coction in water, from their ſaline matter; and the coloured ones from their iron by digeſtion in aqua-regis, the only menſtruum we are acquainted with that will extract the ferrugineous matter of argillaceous and bolar earths. This purified, they have all nearly the ſame appearance and qualities. Expoſed to a ſtrong fire, they loſe their ſoft glutinous quality, and are reduced into hard maſſes, indiſſoluble as at firſt.

Art. IV. Glutinous *Vegetable and Animal Subſtances.*

Claſs 1. *Vegetable.*

Pure gums:	Vegetables abounding with mucilage:
Tragacanth,	Orchis root,
Seneca,	Althæa root,
The gums of cherry, plum, and other European trees.	Quince-ſeeds, &c.

Gums and mucilages are glutinous vegetable productions, of no particular taſte or ſmell, ſoluble in water, but not in vinous ſpirits or in oils. They differ from one another only in degree of tenacity; the more tenacious are called *gums;* thoſe which are leſs ſo, *mucilages.* The firſt naturally exſude from certain trees and ſhrubs; the latter are extracted by art. Almoſt all vegetable ſubſtances contain ſome portion of theſe, which, after the reſinous part has been extracted by ſpirit, may be ſeparated from the remaining matter by means of water.

The general virtues of theſe kinds of ſubſtances are, to thicken the fluids, and defend the ſolids from them when grown ſharp or corroſive. Hence their uſe in a thin acrimonious ſtate of the juices, and where the natural mucus of the inteſtines is abraded.

Claſs 2. *Animal.*

Most animal ſubſtances (the fat excepted) contain a viſcous matter, in many reſpects ſimilar to the foregoing, and capable of being extracted by ſtrong coction in water.

Animal glues and gellies have the general qualities of the vegetable gums and mucilages; with this difference, that the former are more nutrimental, and apt to run into a putrid ſtate. Conſidered as the ſubjects of chemiſtry, the difference betwixt them is very great: thoſe of the animal kind are changed by fire into a volatile alkaline ſalt, and a fetid oil; the vegetable into an acid liquor, and a very ſmall portion of oily matter, conſiderably leſs fetid than the former.

Art. V. *Soft* unctuous *Subſtances.*

Claſs 1. *Inſipid vegetable oils; and ſubſtances abounding with them*; as almonds, and the kernels of moſt fruits; linſeed, and the medullary part of ſundry other ſeeds.

Claſs 2. *Animal fats;* as ſpermaceti.

Unctuous vegetables unite with water, by trituration, into a milky liquor; and give out their oil upon expreſſion.—Theſe kinds of oils and animal-fats diſſolve not in any menſtruum except alkaline ones; which change their quality, and reduce them into a ſoap, diſſoluble in water, but more perfectly in vinous ſpirits; from this compound, the oil may, by a ſkilful addition of acids, be recovered in a purer ſtate than before, and rendered ſoluble, like eſſential oils, in ſpirit of wine.

The medical virtues of theſe ſubſtances are, to obtund acrimonious humours, and to ſoften and relax the ſolids; hence their uſe internally in tickling coughs, heat of urine, pains, and inflammations; and externally in tenſion and rigidity of particular parts. The milky ſolutions, commonly called *emulſions,* though much leſs emollient than the oils themſelves or animal-fats, have this advantage, that they may be given in acute or inflammatory diſtempers, without danger of the ill conſequences which the others might ſometimes produce: fats and oils, kept in a degree of heat no greater than that of the human body, ſoon become rancid and acrimonious; whilſt emulſions tend rather to grow ſour.

Aſtringents.

Art. VI. Astringents.

Galls,
Tormentil-root,
Biſtort-root,
Balauſtines,
Terra Japonica,
Acacia, &c.

Astringent ſubſtances are diſtinguiſhed by a rough auſtere taſte; and changing ſolutions of iron, eſpecially thoſe made in the vitriolic acid, of a dark purple or black colour.

Aſtringents yield their virtues by infuſion both to water and vinous ſpirits, generally in greateſt perfection to the former. Oils extract nothing from them; nor do they give over any of their virtue in diſtillation: nevertheleſs their aſtringency is conſiderably abated by evaporating decoctions of them to the conſiſtence of an extract, and totally deſtroyed by long keeping.

The medical effects of theſe kinds of ſubſtances are, to conſtringe the fibres, and incraſſate or lightly thicken the juices. Their more experienced uſe is in diſorders proceeding from a debility or flaccid ſtate of the ſolids; in hæmorrhages, from a thinneſs of the blood, laxity or rupture of the veſſels; in preternatural diſcharges of other kinds, after the offending matter has been duly corrected or evacuated; and in external relaxations.

In ſome caſes, they produce the effects of aperients; the veſſels, conſtringed and ſtrengthened by them, being enabled to protrude the circulating juices with greater force.

A good deal of caution is requiſite in the uſe of theſe medicines, eſpecially thoſe of the more powerful kind. In plethoric habits, inveterate obſtructions, critical evacuations, and in all kinds of fluxes in general before the morbific matter has been expelled, or where there is any ſtricture or ſpaſmodic contraction of the veſſels, aſtringents prove eminently hurtful. Where critical dyſenteries or diarrhœas are reſtrained by ſtyptics, the acrimonious matter, now confined in the inteſtines, corrodes or enflames them; and ſometimes occaſions a gangrene of the parts.

Sweets and Acrids.

Art. VII. Sweets.

Sugar
Honey,
Raiſins,
Liquorice, &c.

The vegetable ſweets are a very numerous tribe; almoſt every plant that has been examined, diſcovering in ſome of its parts a ſaccharine juice. The bottoms of flowers, and moſt kinds of ſeeds and grain when they begin to vegetate, are remarkably ſweet.

Vegetable ſweets are extracted both by water and vinous ſpirits, moſt readily by the firſt, but in greateſt perfection by the latter. Nothing of their taſte ariſes in diſtillation with either of theſe liquors: nevertheleſs, by long boiling with water they become ſomewhat leſs agreeable; but are not much injured by being treated in the ſame manner with rectified ſpirit.

The purer ſweets, as ſugar, promote the union of diſtilled oils with watery liquors, and prevent the ſeparation of the butyraceous part from milk: from this quality, they are ſuppoſed to unite the unctuous part of the food with the animal juices. Hence ſome have concluded, that they increaſe fat: others, that they have a contrary effect, by preventing the ſeparation of the unctuous matter which forms the fat from the blood: and others, that they render the juices thicker and more ſluggiſh, retard the circulation and cuticular excretion, and thus bring on a variety of diſorders. But ſweets have not been found to produce any of theſe effects in any remarkable degree: common experience ſhows, that their moderate, and even liberal, uſe is at leaſt innocent; that they reconcile, not only to the palate, but to the ſtomach alſo, ſubſtances of themſelves diſguſtful to both; and thus render ſalutary what would otherwiſe be injurious to the body.

The unctuous and mucilaginous ſweets, as the impure ſugars, liquorice, &c. have a conſiderable degree of emollient and lubricating virtue.—Thoſe accompanied with a manifeſt acid, as in the juices of moſt ſweet fruits, are remarkably relaxing; and if taken immoderately, occaſion diarrhœas and dyſenteries, which ſometimes have proved fatal.

Art. VIII. Acrids.

Acrids are ſubſtances of a penetrating pungency. Applied to the ſkin, they inflame or exulcerate it: chewed, they occaſion a copious diſcharge of ſaliva: and ſnuffed up the noſe, they provoke ſneezing.

Theſe ſubſtances, conſidered as the ſubjects of pharmacy, may be divided into three claſſes,

Yielding their acrimony
- 1. In diſtillation with water: as horſe-radiſh, muſtard, ſcurvy-graſs, &c.
- 2. By infuſion only: as the greater celandine, pyrethrum, &c.
- 3. Neither to infuſion, nor diſtillation: as arum and dracunculus.

The general effects of acrid medicines are, to ſtimulate the veſſels, and diſſolve tenacious juices. In cold leucophlegmatic habits, ſtagnations of the fluids, and where the contractile power of the ſolids is weak, they prove powerful expectorants, deobſtruents, diuretics, and emmenagogues; and if the patient is kept warm, ſudorifics. In hot bilious conſtitutions, plethoric habits, inflammatory diſtempers, where there is already a degree of irritation, where the juices are too thin or acrimonious, or the viſcera unſound, theſe ſtimulating medicines prove highly prejudicial, and never fail to aggravate the diſeaſe.

Aromatics and Bitters

Certain acrid ſubſtances have been lately recommended in dry convulſive aſthmas: of the efficacy of the ſquill in particular, for the cure of this diſorder, ſeveral inſtances are related in the *Commercium Literarium* of Norimberg for the years 1737 and 1739. Cartheuſer thinks, that not the aſthma itſelf, but a particular effect of it, was removed by this medicine. He obſerves, that in all aſthmas the free circulation of the blood through the pulmonary veſſels is impeded; and hence, during every paroxyſm, the lungs are in a kind of œdematous ſtate: that if this œdema, becoming habitual, remains after the fit is over, it is either perpetually occaſioning freſh ones, or gives riſe to a dropſy of the breaſt: that acrid medicines, by removing the œdema, remove what was originally an effect of the aſthma, and in time a cauſe of its aggravation.

Art. IX. Aromatics.

Aromatics are ſubſtances of a warm pungent taſte, and a more or leſs fragrant ſmell. Some of the ſpices are purely aromatic, as cubebs, pepper, cloves; ſome ſubſtances have a ſweetneſs mixed with the aromatic matter, as angelica-root, aniſeed, fennel-ſeed; ſome an aſtringency, as cinnamon; ſome a ſtrong mucilage, as caſia lignea; ſome a bitterneſs, as orange-peel. The aromatic matter itſelf, contained in different ſubjects, differs alſo not a little in its pharmaceutic properties. It is extracted from all by rectified ſpirit of wine; from ſome in great part, from others ſcarcely at all, by water. The aromatic matter of ſome ſubjects, as of lemon-peel, riſes wholly in diſtillation both with ſpirit and water; that of others, as cinnamon, riſes wholly with water, but ſcarcely at all with ſpirit; while that of others, as pepper, is in part left behind after the diſtillation of water itſelf from the ſpice.

With regard to the general virtues of aromatics, they warm the ſtomach, and by degrees the whole habit; raiſe the pulſe, and quicken the circulation. In cold languid caſes, phlegmatic habits, and a weak flaccid ſtate of the ſolids, they ſupport the vis vitæ, and promote the ſalutary ſecretions. In hot bilious temperaments, plethoric habits, inflammatory indiſpoſitions, dryneſs and ſtrictures of the fibres, they are generally hurtful.

Art. X. Bitters.

Gentian root,
Hops,
Leſſer centaury,
Carduus, &c.

Bitters for the moſt part yield their virtue both to watery and ſpirituous menſtrua; ſome more perfectly to one, and others to the other. None of the ſubſtances of this claſs give over any thing conſiderable of their taſte in diſtillation, either to water or to ſpirit; their bitterneſs remaining entire, and frequently improved, in the extracts. Such as are accompanied with flavour, as wormwood, may by this proceſs be reduced into ſimple flavourleſs bitters.

Theſe ſubſtances participate of the virtues of aſtringents and aromatics. Their general effects are, to conſtringe the fibres of the ſtomach and inteſtines, to warm the habit, attenuate the bile and juices in the firſt paſſages, and promote the natural evacuations, particularly of ſweat and urine. In weakneſs of the ſtomach, loſs of appetite, indigeſtion, and the like diſorders, proceeding from a laxity of the ſolids, or cold ſluggiſh indiſpoſition of the juices, theſe kinds of medicines do good ſervice. Where the fibres are already too tenſe and rigid, where there is any immoderate heat or inflammation, bitters very ſenſibly increaſe the diſtemper; and, if their uſe is continued, communicate it to the kidneys: hence the urine becomes high-coloured, ſmall in quantity, and at length ſuppreſſed; a dropſy ſoon ſucceeding. If the kidneys were before ſo lax as to remain now uninjured, yet the other viſcera become gradually more and more rigid, and a tabes is at length brought on.

Bitter ſubſtances deſtroy inſects, and prevent putrefaction. Hence they are recommended as anthelmintic, and externally as antiſeptics.

Art. XI. Emetics *and* Cathartics.

Hellebore,
Julip,
Ipecacuanha,
Colocynth,
Scammony,
Gamboge, &c.

These ſubſtances conſiſt of a reſinous part, in which the purgative or emetic quality reſides: and a gummy ſaline one, which acts chiefly as a diuretic. The firſt is extracted or diſſolved by vinous ſpirits; the latter by water. Nothing ariſes in diſtillation from either.

The acrid reſins, exhibited by themſelves, tenaciouſly adhere to the coats of the inteſtines, by their ſtimulating power irritate and inflame them, and thus produce ſundry violent diſorders. Hoffman relates, that he has ſometimes obſerved convulſions, and a paralyſis of both ſides, from their uſe.

Theſe inconveniences may be avoided, by previouſly triturating them with ſubſtances capable of dividing their tenacious texture, and preventing their adheſion; by this means they become mild and ſafe, operate without diſturbance, and at the ſame time more effectually anſwer the purpoſes intended by them.

Some have endeavoured to correct the ill quality of the reſinous purgatives, by the addition of acids and aromatic oils. Acids weaken their power, but have no other effect than what a diminution of the doſe would equally anſwer. The pungent eſſential oils may ſerve to warm the ſtomach, make the medicine ſit eaſier, and thus prevent the nauſea which ſometimes happens; but as ſoon as the reſin begins to exert itſelf in the inteſtines, theſe oils, inſtead of correcting, increaſe its virulence; being themſelves apt to occaſion the inconveniences which they are here intended to prevent, an irritation and inflammation of the bowels. Alkaline ſalts or ſoaps have a better effect; as they diſpoſe the reſin to ſolution, and promote its operation.

The medicines of this claſs ſeem to act by liquefying the juices, and ſtimulating the coats of the ſtomach and inteſtines. If the irritation is ſtrong and ſudden, their action is quick and upwards: if ſlower, downwards. Cathartics given in a liquid form, or in very ſenſible habits, often prove emetic; and emetics, where mucus abounds, cathartic. They operate more violently in robuſt conſtitutions than in thoſe of a contrary temperament; the veſſels being in the former more tenſe and rigid, and conſequently leſs capable of of bearing an equal degree of irritation.

The action of theſe medicines is extended beyond the primæ viæ: This appears evident from the increaſe of the pulſe which always accompanies their operation; and from the common obſervation of children being purged by the milk, if the nurſe has taken a cathartic. Some of them, particularly hellebore, are ſaid to purge, if only applied externally in iſſue.—Purgatives, even of the more powerful kind, exhibited in ſuitable ſmall doſes, in conjunction with the milder aperients, may be introduced into the habit, ſo as to prove notable deobſtruents, diuretics, and diaphoretics, without acting ſenſibly by ſtool.

A CATALOGUE *of the* SIMPLES *uſed in the* MATERIA MEDICA, *exhibiting at one view their* TECHNICAL NAMES, ENGLISH NAMES, PARTS USED IN MEDICINE, VIRTUES, *and the different* PREPARATIONS FROM THEM.—*A particular account of the different articles of this liſt is given in the courſe of the alphabet, chiefly under the Linnæan names: And the method of making the preparations from them are ſhown under the article* PHARMACY. *The notes ſubjoined at the bottom of the following pages are intended to ſupply ſome particulars relating to a few of the detached articles already paſt.*

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Abies ruber (*Pinus abies*, Lin.)	The fir-tree.	The wood, tops, and cones.	Diuretic and diaphoretic.	A decoction.
Abrotanum fœmina (*Santolin chamæcypar*. Lin.)	Lavender cotton.	The leaves.	Stimulant, detergent, and anthelmintic.	Decoction, and ointment for cutaneous eruptions.
Abrotanum mas (*Artemiſia abrotanum*, Lin.)	Southernwood.	The leaves.	Stimulant, detergent, aperient, and ſudorific.	Decoction and tincture; alſo lotion and ointment for cutaneous eruptions.
Abſinthium maritimum (*Artemiſia maritima*, Lin.)	Sea wormwood.	The tops.	Stomachic.	An oil, extract, conſerve, and ſeveral diſtilled tincture-waters. They alſo enter the common fomentation and green oil.
Abſinthium vulgare (*Artemiſia abſinthium*, Lin.)	Common wormwood.	The leaves and flowering tops.	Stomachic.	

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Acacia Germanica (*Prunus ſpinoſa*, Lin.)	The ſloe.	Inſpiſſated juice.	Aſtringent.	
Acacia vera (*Mimoſa nilotica*, Lin.)	Acacia.	Inſpiſſated juice.	Aſtringent.	
Acetoſa (*Rumex acetoſ.* Lin.)	Sorrel.	Leaves.	Aſtringent and antiſcorbutic.	An eſſential ſalt for taking out ſpots in clothes. A decoction.
Acetoſella (*Oxalis acetoſel.* Lin.)	Wood ſorrel.	The leaves.	Aſtringent and antiſcorbutic.	A conſerve.
Acetum.	Vinegar.		Cordial, refrigerant, ſudorific, and antiſeptic.	A diſtilled ſpirit.
Aconitum (*A. napellus*, Lin.)	Wolf's-bane.	The herb and leaves.	Narcotic.	Tincture.
Acorus. See *Calamus arom.* infra.				
Adianthum verum (*Adianth. capill. Ven.* Lin.)	Maiden-hair.	The leaves.	Attenuating and aperient.	Decoction and ſyrup; its virtues beſt obtained from an infuſion of the herb ſweetened with ſugar and liquorice, and drank as tea.
Aer dephlogiſticus.	Dephlogiſticated air.		Suppoſed to be antiſeptic and corroborative.	
Aer mephiticus.	Fixed air.		Antiſeptic and lithontriptic.	
Aer nitroſus.	Nitrous air.		Very antiſeptic.	
Æs. See *Cuprum.*	Braſs. See *Copper.*			
Agaricus, (*Boletus pini laricis*, Lin.)	Agaric.		Cathartic.	An aqueous extract, but now much diſuſed.
Agaricus chirurgorum (*Boletus igniarius*, Lin.)	Female agaric, or agaric of the oak, touchwood, or ſpunk.		Styptic.	Pieces applied externally.
Agnus caſtus (*Vitex agnus caſtus*, Lin.)	The chaſte-tree.	The ſeeds.	Antaphrodiſiac.	
Agrimonia (*A. Eupator.* Lin.)	Agrimony.	The leaves.	Attenuant and tonic.	Digeſted in whey, it forms a diet-drink uſed by ſome in the ſpring.
Albumen ovi.	White of an egg.		Diſcutient.	
Alchemilla (*A. vulgaris*, Lin.)	Ladies-mantle.	The leaves.	Aſtringent.	
Alkekengi, (*Phyſalis alkakengi*, Lin.)	Winter-cherry.	The fruit.	Aperient and diuretic.	Dried and powdered. Inſpiſſated juice.
Alliaria (*Eryſimum allaria*, Lin.)	Sauce-alone, or Jack-by-the-hedge.	The leaves.	Sudorific and deobſtruent.	
Allium (*A. ſativum*, Lin.)	Garlic.	The roots.	Stimulant, attenuant, diſcutient, and diuretic.	A ſyrup and oxymel, ointment and poultice.
Alnus (*Betula alnus*, Lin.)	Alder.	Leaves and bark.	Aſtringent.	Decoction. The leaves chopt and heated, efficacious for diſperſing milk in the breaſts.
Aloes (*Aloe perfoliata*, Lin.)	Aloes.	Inſpiſſated juice.	Cathartic.	Ingredient in ſeveral tinctures and pills.
Alſine (*A. med.*) Lin.)	Chickweed.	The leaves.	Refrigerant.	

Althæa

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Althæa (*A. officinalis*, Lin.)	Marſhmallow.	The leaf and root.	Emollient.	A ſyrup and ointment.
Alumen.	Alum.	The whole.	Strongly aſtringent.	A ſtyptic powder, ſtyptic water, whey, &c.
Ambragriſea.	Ambergriſe.	The whole.	A high cordial.	A tincture or eſſence.
Ammi vulgaris.	Biſhop's weed.	The leaves.	Stimulant.	An ingredient in the theriaca.
Amomum verum.	True amomum.	The ſeeds.	Aromatic.	An ingredient in the theriaca.
Amomum vulgare (*Siſon*, Lin.)	Baſtard ſtone-parſley.	The ſeeds.	Carminative and diuretic.	
Ammoniacum. See *Gummi*.				
Amygdala (*Am. con.* Lin.)	Sweet and bitter almonds.	The fruit.	Relaxing.	Expreſſed oil and emulſion.
Amylum.	Starch.		Aſtringent.	
Anacardium occidentale, (Lin.)	Caſhew-tree.	The nuts.	Corroſive.	Oil outſide, but the kernels uſed as almonds; the gum inſtead of gum arabic.
Anagallis (*Arvenſis*, Lin.)	Pimpernel.	The leaves.	Sudorific and nervine.	Extract, or inſpiſſated juice.
Ananas (*Bromelia ananas*, Lin.)	The pine-apple.	The fruit.	Refrigerant.	
Anchuſa (*A. tinctoria*, Lin.)	Alkanet.	The root.	Only uſed for its colour.	
Anethum (*A. graveolens*, Lin.)	Dill.	The ſeeds.	Carminative.	Diſtilled oil, water, and ſpirituous extract.
Angelica (*A. Archangelica, and ſylveſtris*, Lin.)	Angelica.	The roots, ſtalks, leaves, and ſeeds.	Aromatic.	Several compound waters.
Anguſturæ cortex, (A)				
Aniſum (*Pimpinella aniſum*, Lin.)	Aniſe.	The ſeed.	Aromatic and tonic.	An eſſential oil, a ſpirituous compound water, &c.
Antimonium.	Antimony.		Diaphoretic, cathartic, emetic, or cauſtic.	A number of chemical preparations. See CHEMISTRY-*Index*, KERMES *Mineral*, and REGULUS *of Antimony*.
Aparine (*Gallium aparine*, Lin.)	Gooſegraſs, or clivers.	The leaves.	Aperient.	
Apium (*A. graveol.* Lin.)	Smallage.	The roots, leaves, and ſeeds.	Carminative.	Diet-drinks.
Aqua marina.	Sea-water.		Cathartic and alterative.	
Aquæ minerales.	Mineral waters.		Tonic and alterative.	
Aquæ ſulphureæ.	Sulphureous waters.		Alterative and anthelmintic.	
Argentina (*Potentill. argentin.* Lin.)	Silverweed.	The leaves.	Corroborant.	
Argentum vivum.	Quickſilver.		A moſt powerful alterant.	Several chemical preparations; ſee CHEMISTRY-*Index*. An ingredient in ſeveral other officinal preparations.

Ariſto-

(A) The Anguſtura bark was firſt imported from the Weſt Indies in 1788; but it is a native of Africa. Mr Bruce, who had been cured of a dyſentery in Abyſſinia by the bark of a plant called there *Wooginos*, brought the ſeeds from that country, and the plant is now cultivated in Kew garden and other places under the name of *Brucea antidyſenteria*, or *ferruginea*. He ſuppoſed the bark of this was the ſame with that of the Anguſtura; but Dr Duncan, in the Medical Commentaries for 1790, ſays that they are totally different when compared together. For an account of the Anguſtura bark, ſee *JESUIT's Bark*.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Ariſtolochia (*A. clematitis*, Lin.)	Birthwort.	The roots.	Attenuating, ſtimulant, and detergent.	
Armeniaca (*Prunus Armeniaca*, Lin.)	The plum-tree.	The fruit and gum.	The fruit refrigerant, and the gum demulcent.	
Arnica (*A. montana*, Lin.)	German leopard's bane.	The herb, flowers, and roots.	Antiſpaſmodic; emetic, cathartic.	A warm infuſion.
Arſenicum. (B)	Arſenic.		Corroſive.	
Artemiſia (*A. vulgaris*, Lin.)	Mugwort.	The leaves.	Antiſpaſmodic.	Infuſion.
Arum (*A. maculatum*, Lin.)	Wake-robin.	The root.	Stimulant.	A compound powder and conſerve (C).
Aſafetida. See *Gummi*, infra.				
Aſarum (*A. Europæum*, Lin.)	Aſarabacca.	The leaves.	Errhine, cathartic, and emetic.	A compound powder (D)
Aſparagus (*A. officinalis*, Lin.)	Aſparagus.	The roots.	Suppoſed diuretic, but uncertain.	
Aſperula.	Woodruff.	The flowers.	Attenuant and aperient.	

Aſphodelus,

(B) This pernicious mineral has ſome time ago been introduced into medicine as a certain remedy for cancers; but Mr Juſtamond, who publiſhed a treatiſe on this ſubject two or three years ago, informs us, that even the moſt guarded uſe of it in the external way, while it produces the happieſt effects in healing cancerous ulcers, yet occaſions ſuch diſagreeable ſymptoms of the paralytic kind, that it cannot be perſiſted in. The lateſt trials in London are likewiſe ſaid to confirm this account; notwithſtanding which, however, the internal uſe of it has ſince gained ground in a variety of diſorders, particularly in intermitting fevers, which are ſaid to be readily cured by it ſometimes after the bark and all other remedies had failed. A ſolution of the mineral is given by drops, from one ſixteenth to a ſixth part of a grain for a doſe, largely diluted in a warm aqueous liquid Dr Aikin recommends oil and milk as a certain remedy againſt this deſtructive poiſon. He quotes from Hoffman an inſtance where ſeveral perſons of diſtinction had taſted food mixed with arſenic inſtead of ſugar. All of them were ſeized with anxiety at the breaſt, pain at the ſtomach, tremor of the lips, and reachings. Milk and oil were given in great plenty, and they continued ſtrongly vomiting for half a day. Some vomited no leſs than 100 times; but all of them recovered. Some inſtances of a ſimilar kind have come within the Doctor's own knowledge. Sage in his Mineralogy relates, that the regulus is much leſs dangerous than the calx or glaſs: he ſays that on giving half an ounce to a cat, the animal only grew meagre for ſome time, but afterwards became fat again. He ſays that acids, particularly vinegar, are the antidotes to this poiſon; and that oils and emulſions do not ſo effectually obtund this poiſon as acids do. Of this he has had experience in brutes. He adds, that the regulus is not ſoluble in water, and that the founders are more afraid of fumes of lead than arſenic.

(C) Dr Aikin informs us, that the inſupportable pungency on the tongue, which has hitherto prevented it from being uſed in a freſh ſtate ſo as to exert its full virtues, is effectually covered by unctuous and gummy materials. The freſh root beaten into a ſmooth maſs, with the addition of a little teſtaceous powder which promotes the diviſion of it, may be either mixed with about an equal quantity of powdered gum arabic, and three or four times as much conſerve, ſo as to make them into an electuary; or rubbed with a thick mixture of mucilage of gum arabic and ſpermaceti, gradually adding any ſuitable watery liquors, and a little ſyrup in order to form an emulſion, two parts of the root, two of gum, and one of ſpermaceti, make an emulſion, which ſcarce impreſſes any degree of pungency upon the tongue though kept long in the mouth. In theſe forms our author has given the freſh root from ten grains to more than a ſcruple, three or four times a-day: it generally occaſioned a ſlight ſenſation of warmth, firſt about the ſtomach and then in the remoter parts; manifeſtly promoted perſpiration, and frequently produced a plentiful ſweat. Several obſtinate rheumatic pains have been removed by the uſe of this preparation, which our author therefore recommends to further trial.

(D) The leaves of this plant are by ſome ſuppoſed to be more powerful than the roots as emetics and cathartics, but they are milder as errhines. Geoffroy relates, that a ſingle doſe of the errhine of which this root is an ingredient has occaſioned a diſcharge for three days; and that he has known a palſy of the mouth and tongue cured by the ſame means. He recommends it in ſtubborn diſorders of the head proceeding from viſcid matters, in palſies, and lethargic diſtempers. During its operation the patient muſt carefully avoid cold; which is apt to produce puſtules, inflammations, ſwellings of the face, and ſometimes worſe ſymptoms than even theſe. The empirical herb-ſnuffs have the leaves of aſarum for their baſis, but ſometimes mixed with ingredients of a more dangerous nature.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Aſphodelus, (*A. fiſtulous*, Lin.)	Aſphodel, or king's ſpear.	The roots.	Emollient and ſuppurative.	
Atriplex (*Chenopodium vulvar.* Lin.)	Stinking orach.	The leaves.	Antiſpaſmodic.	A ſpirituous tincture, decoction, or conſerve, recommended by Tournefort and others.
Avena ſativa (*Lin.*)	Oats.	The grain.	Emollient.	Decoction.
Aura electrica.	Electricity.		A violent ſtimulant.	
Aurantium (*Citrus aurant.* Lin.)	The orange.	The leaves, fruit, and flowers.	Cordial, ſtomachic, and refrigerant.	An eſſential oil, a diſtilled water, and a conſerve.
Auricula Judæ, (*Tremell. verruc.* Lin.)	Jews-ears.	The whole.	Purgative, or aſtringent; uncertain.	
Auripigmentum.	Orpiment.		Corroſive, but leſs ſo than arſenic.	
Axungia porcina.	Hog's lard. }		Emollient.	
Axungia viperina.	Viper's fat. }			
Balauſtia (*Punica granat.* Lin.)	Balauſtine, or double-flowered pomegranate tree.	The flowers.	Aſtringent.	Ingredient in a powder.
Balſamita (*Tanacetum balſaminum*, Lin.)	Coſtmary.	The leaves.	Aromatic, antihyſteric.	Diſtilled water and ſpirituous tincture.
Balſamum Canadenſe (*Pinus balſamea*, Lin.)	Balſam of Canada.	The roſin.	Diuretic and tonic.	
Balſamum Copayvæ (*Copaifera officinalis*, Lin.)	Balſam of Copivi.	The roſin.	Diuretic and tonic.	An empyreumatic oil, and an ingredient in ſome tinctures (E).
Balſamum Gileadenſe (*Amyris Gileadenſis*, Lin.)	Opobalſam, or balm of Gilead.	The roſin.	Said to be a moſt extraordinary vulnerary.	
Balſamum Peruvianum (*Myroxylon peruiferum*, Lin.)	Balſam of Peru.	The roſin.	A fine warm aromatic.	An ingredient in many tinctures, and ſome ointments.
Balſamum Tolutanum (*Toluifera balſaminum*, Lin.)	Balſam of Tolu.	The roſin.	Aromatic and corroborant.	An ingredient in ſeveral tinctures, elixirs, and a kind of pectoral pills.
Bardana major, (*Arctium lappa*, Lin.)	Burdock.	The roots and ſeeds.	Aperient, diuretic, and ſudorific.	Decoction.
Barytes (F).				

Beccabunga,

(E) Balſam of Copivi has been employed empirically in hæmorrhoidal caſes; and Dr Cullen informs us, that he has known it give relief in ſuch caſes, in doſes from 20 to 40 drops once or twice a day, mixed with powdered ſugar. Fuller recommends it in conſumptions; but his practice is cenſured by Dr Fothergill in the 4th volume of London Medical Obſervations.

(F) *Barytes.* The ſolution of the aerated barytes, or terra ponderoſa, in ſpirit of ſalt, has been found capable of producing powerful effects on the human ſyſtem. Several trials of it were made in the year 1789 by Dr Crawford, in St Thomas's hoſpital; and it was found to be very efficacious in ſcrophulous complaints.—In ſome caſes of ſwelled glands, foul ulcers, enlarged joints, and general cachexy, ſingular relief was given by the muriated barytes, either alone or joined with mercurials, antimonials, and the bark. The medicine in a few caſes appeared to augment the cuticular ſecretion; in moſt it occaſioned an uncommon flow of urine, and almoſt univerſally improved the appetite and general health of the body. Few ſtomachs, however, could bear more than from ſix to ten drops of a ſaturated ſolution, nor did a continued uſe of the medicine reconcile the ſtomach to it, but rather the contrary. Sometimes it produced a vertigo, which probably aroſe from its nauſeating quality. Dr Crawford is of opinion, that this ſolution, when injudiciouſly managed, is capable of producing deleterious effects, by diſordering the nervous ſyſtem, and bringing on violent vomiting and purging. From ſome experiments made upon dogs, it appears that a large doſe would prove fatal.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Beccabunga (*Veronica beccabunga*, Lin.)	Brooklime.	The herb.	Attenuating, and antiſcorbutic.	
Bechen album, (*Centaurea bechen*, Lin.)		The root.	Stimulant.	
Bechen rubrum, (*Statice limon.* Lin.)		The root.	Stimulant.	
Belladona (*Atropa belladonna*, Lin.)	Deadly nightſhade.	The juice.	Narcotic.	An extract of the juice, decoction, infuſion, powders.
Bellis minor, (*Bell. peren.* Lin.)	Common daiſy.	The leaves.	Attenuant.	
Benzöe, (*Terminalia benzoin*, Lin.)	Benzoin.	The reſin.	Pectoral.	Ingredient in the paregoric elixir.
Berberis (*Berber. vulgar.* Lin.)	Barberry.	The bark and fruit.	Aſtringent.	A jelly.
Beta, (*B. vulgaris*, Lin.)	The beet.	The root and leaves.	Cathartic and errhine.	
Betonica (*B. officinalis*, Lin.)	Betony.	The leaves and flowers.	Corroborant.	
Betula (*B. alba*, Lin.)	The birch-tree.	The bark and ſap.	Antiſcorbutic and diuretic.	
Bezoar.	Bezoar-ſtone.		Many virtues falſely aſcribed to it; now found to be only an abſorbent.	
Bilis animalis.	The gall or bile of animals.		Cathartic.	
Biſtorta (*Polygonum biſtorta*, Lin.)	Biſtort or ſnakewort.	The roots.	Powerfully aſtringent.	An ingredient in a powder.
Boli.	Boles.		Aſtringent and ſlightly abſorbent.	Ingredients in ſeveral powders.
Bonus Henricus, (*Chenopidium bonus Hen.* Lin.)	Engliſh mercury, all-good, or good Henry.	The leaves.	Laxative.	
Borax.	Tincal, or borax.	The whole.	Diuretic and emmenagogue.	An ingredient in a powder, and a ſalt prepared from it. See CHEMISTRY-*Index*.
Branca urſina, (*Acanthus mollis*, Lin.)	Bear's-breech.	The root.	Emollient.	
Braſſica, (*B. oleracea*, Lin.)	Cabbage.	The leaves.	Refrigerant and laxative.	
Braſſica marina, (*Convolvulus ſoldanella*, Lin.)	Sea-coleworts, or ſoldanella.	The leaves.	A ſtrong cathartic.	Now rejected from practice.
Brucea antidyſenterica. See note (A), *ſupra*.				
Bryonia (*B. alba*, Lin.)	White briony,	The root.	Diſcutient and violently cathartic.	
Burſa paſtoris, (*Thlapſi burſa p.* Lin.)	Shepherd's purſe.	The leaves.	Aſtringent, but very doubtful.	
Cacao (*Theobroma cacao*, Lin.)	Chocolate tree.	The fruit.	Analeptic.	Chocolate.
Cajeput (*Maleleuca leucadendron*, Lin.)	Cajeput.	The fruit.	Stimulant, healing, carminative.	Diſtilled oil.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Calaminaris lapis.	Calamine ſtone.		Deſiccative, healing.	An ingredient in collyria, epulotic cerate, &c.
Calamintha (*Meliſſa calamintha,* Lin.)	Calamint.	The leaves.	Aromatic and ſtimulant.	
Calamus aromaticus (*acorus calamus*, Lin.)	Sweet-flag.	The roots.	Aromatic and ſtomachic.	
Calendula (*C. officinalis*, Lin.)	Garden marigold.	The flowers.	Attenuating and ſudorific, but very doubtful.	
Calx viva.	Quicklime.		A violent corroſive, and powerful alterant and abſorbent.	A medicated water.
Camphor (*Laurus camphora*, Lin.)	Camphire tree.	The concreted eſſential oil.	Refrigerant and diaphoretic, ſtimulant, antiſpaſmodic.	A ſolution in rectified ſpirit, in expreſſed and eſſential oils. Ingredient in many other compoſitions.
Canella alba (Lin.)	White cinnamon.	The bark.	Aromatic and ſtimulating.	An ingredient in ſeveral tinctures.
Cannabis (*C. ſativa*, Lin.)	Hemp.	The ſeeds.	Aperient and refrigerant, but doubtful.	Decoctions and infuſions.
Cantharis (*Meloe veſicatorius*, Lin.)	Spaniſh fly.		Violently ſtimulating and veſicatory.	A ſpirituous tincture, a plaſter, ointment, &c.
Caparis (*C. ſpinoſa*, Lin.)	Caper-buſh.	The bark of the root, and flower-buds.	Aperient and ſtomachic.	Pickled.
Cardamines (*C. pratenſis*, Lin.)	Cardamine.	The flowers.	Antiſpaſmodic.	Powder.
Cardamomum majus (*Amom. cardam.* Lin.)	Greater cardamom.	The ſeeds.	Aromatic and ſtimulant.	A ſpirituous water and tincture. Ingredient alſo in ſeveral officinal compoſitions.
Cardamomum minus (*Amom. repens*, Lin.)	Leſſer cardamom.	The ſeeds.	Aromatic and ſtimulant.	
Cardiaca (*Leonurus cardiaca*, Lin.)	Mother-wort.	The leaves.	Antiſpaſmodic.	
Carduus benedictus (*Centaurea benedicta,* Lin.)	Bleſſed-thiſtle.	The leaves and ſeed.	Stomachic.	An ingredient in a ſtomachic tincture. Infuſions.
Carica (*Ficus carica*, Lin.)	The fig.	The dried fruit.	Emollient, ſuppurative.	Ingredient in the pectoral decoction and lenitive electuary.
Carlina (*C. acaul.* Lin.)	Carline-thiſtle.	The root.	Diaphoretic.	
Carpobalſam (*Amyris Gileadenſis*, Lin.)	Carpobalſam.	The fruit.	Aromatic.	In ſubſtance applied warm as a cataplaſm.
Carthamus (*C. tinctorius*, Lin.)	Baſtard ſaffron.	The ſeeds.	Cathartic.	
Carvi (*Carum carvi*, Lin.)	Caraway.	The ſeeds.	Aromatic.	An eſſential oil, a ſpirituous water. Ingredient alſo in ſome officinal compoſitions.
Caryophylla rubra (*Dianthus carioph.* Lin.	Clove july-flower.	The flowers.	Cardiac and alexipharmac.	A ſyrup.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Caryophyllata, (*Geum urban.* Lin.)	Avens, or herb benet.	The root.	Aromatic.	An eſſential oil.
Caryophyllum (*C. aromaticus*, Lin.)	The clove-tree.	The flower-cups.	Strongly aromatic.	An eſſential oil. Ingredient alſo in many officinal compoſitions
Caſcarilla (*Croton caſcar*, Lin. *Croton eleutheria*, Swartz Prodr.	Caſcarilla.	The bark.	Aromatic and ſtimulant.	Infuſions.
Caſſia fiſtularis (*C. fiſtula*, Lin.)	Caſſia.	The fruit.	Purgative.	An ingredient in two electuaries.
Caſſia lignea (*Laurus caſſia*, Lin.)	Caſſia.	The bark and flower-buds.	Aromatic.	The baſis of a diſtilled water.
Caſſumunar.	Caſſumar.	The root.	Stomachic and carminative.	
Caſtoreum (*Caſtor fiber*, Lin.)	Caſtor.		Nervine and antiſpaſmodic.	A ſimple water; a ſpirituous water; a tincture. Ingredient in ſeveral officinal compoſitions.
Catechu (*Mimoſa catechu*, Lin.)	Catechu, *vulgo* Japan earth.		Aſtringent.	A tincture, troches, and confection, and an ingredient in ſeveral officinal compoſitions.
Celeri (*Apium graveolens*, Lin.)	Celery.	The leaves.	Laxative.	
Centaurium majus (*Centaurea centaurium*, Lin.)	Greater centaury.	The root.	Aſtringent, aperient, and vulnerary.	
Centaurium minus (*Gentiana centaur.* Lin.)	Leſſer centaury.	The tops.	Stomachic.	Tincture and infuſion.
Cepa (*Allium cepa*, Lin.)	The onion.	The root.	Attenuating and diuretic.	
Cera alba.	White wax.		Emollient.	Ingredient in many plaſters and ointments.
Cera flava.	Yellow wax.		Emollient.	Ingredient in almoſt all ointments.
Ceraſus (*Prunus ceraſus*, Lin.)	The cherry tree.	The fruit and gum.	Refrigerant; the gum partaking of the properties of gum-arabic.	
Cerefolium (*Sandix cerefol.* Lin.)	Chervil.	The juice.	Aperient and diuretic.	
Ceterach (*Aſplen. ceterach.* Lin.)	Spleenwort.	The leaves.	Diuretic (G).	
Cevadilla (*Veratrum album*, Lin.?)	Indian cauſtic barley.	The ſeeds.	Virulently cauſtic, (H).	
Chamædrys (*Teucrium chamædr.* Lin.)	Germander.	The leaves and tops with the ſeed.	Sudorific, diuretic, &c.	

(G) M. Morand relates, that theſe leaves have lately been diſcovered to have an admirable diuretic virtue; that they were uſed with great ſucceſs by Count d'Auteuil, a Spaniſh naval commander, for the gravel, with which he was violently tormented; and ſince that time they have come greatly into uſe at Paris, Verdun, and Grenoble. From obſervations made in thoſe places it appears, that they carry off ſand, cleanſe the kidneys, and mitigate pains in the urinary paſſages; that the method of uſing them is to drink infuſions of the leaves in the morning at tea, adding ſuch other medicines as may be judged proper.

(H) Theſe ſeeds appear to be the ſtrongeſt of all vegetable cauſtics. Monardes relates, that in putrid ver-

Cicuta major (*Conium maculat.* Lin.)	Hemlock (1).	The leaves and ſeeds.	Reſolvent and alterant.	Inſpiſſated juice of the leaves, and an extract from the ſeeds.

---

minous ulcers and gangrenes, they have the ſame effects as corroſive ſublimate, or the actual cautery; and that the way of uſing them is to ſprinkle a little of powdered ſeed upon the part; or, for the greater ſafety, to dilute it with watery liquors, and apply lint dipped in the mixture. In the *Amænitates Academicæ* of Linnæus, they are ſaid to be the moſt powerful of all medicines for deſtroying cutaneous inſects in children.

(1) It is ſuppoſed that the juice of this plant was the poiſon ſo much uſed among the Athenians for putting criminals to death; but from ſome late experiments this ſeems to be doubtful; or at leaſt that the remedy is very eaſy. Mr Haram, apothecary at Chartres, informs us, that a large ſpoonful of the juice given to a cat had no ſenſible effect; a ſecond produced a viſible *embarras* on the region of the reins: in a little time the animal ſtaggered, but did not fall. A quarter of an hour after, ſhe was found ſtretched out motionleſs, with her paws rigid. Half a drachm of theriaca, with two large ſpoonfuls of wine, were given without effect: but no ſooner was a large ſpoonful of lemon-juice ſwallowed than ſhe got up as if nothing had happened, and continued afterwards in good health. Other authors likewiſe inform us, that vinegar is an antidote againſt the poiſonous effects of this plant.

With regard to its medical virtues, Dr Monro, who has ſeen it tried in a great number of caſes, informs us, that he never ſaw it cure a confirmed cancer, whether ulcerated or not; that in a few caſes of ulcerated cancers it mended the diſcharge, and changed it from a thin ichor to an appearance of laudable pus; but, notwithſtanding this favourable appearance, the diſtemper at laſt terminated fatally.—In ſcrophulous caſes, ſome few ſmall tumours were thought to be diſcuſſed by it; but large hard ſwellings were never removed by it, tho' the remedy was continued for weeks and months. The diſcharge from ſcrophulous ſores of the extremities, however, was often mended by it; and in many caſes, it was found to be of more ſervice when joined with the bark than when given alone: the action of the bark and mercury was thought to be rendered more powerful by it. In the chincough it did not produce any remarkable effects. In ſome few inſtances, he imagined that it hurt the health of the patients; and in one or two, that it haſtened death. In this laſt caſe, indeed, the uſe of the cicuta had been laid aſide for ſome time, and the patients ſunk ſo gradually, that our author was in doubt what might have been the cauſe of their death.

The roots of hemlock have been ſuppoſed to be more active than the leaves, both when taken internally and when outwardly applied. Dr Stork relates, that on being cut, it yields a bitter acrid milk, of which a drop or two applied to the tip of the tongue occaſioned a rigidity, pain, and ſwelling of the part, ſo as to deprive him of the power of ſpeech. Theſe ſymptoms, however, diſappeared on waſhing the part with citron juice. When dried, it loſes its virulence; ſo that Dr Storck ſays, he has taken a grain or two of the powder without injury. Other authors give inſtances where 20 and 30 grains have been given with good effect in ſchirroſities of the liver, quartan agues, on the approach of a fit, and even in acute fevers. Dr Aikin informs us, that the freſh root ſeems not to be at all times of equal virulence; and that he has ſeen it chewed freely,

---

without any other effect than that ſweetiſhneſs obſervable in parſley roots or carrots. There are likewiſe inſtances, where the cicuta roots have been taken to the quantity of ſome drachms, or even ounces, without any bad conſequence.

The ſeeds have been recommended as demulcent, paregoric, and antaphrodiſiac; but little more (according to Dr Aikin) is yet known about them, but that they are innocent to ſome birds. Mr Ray ſays, that he found the crop of a thruſh full of them, and that at a ſeaſon when the corn was in full growth.

In the firſt volume of the Medical Commentaries, an extract prepared from hemlock-ſeeds is preferred to that made from the leaves; and in the laſt Edinburgh Pharmacopœia, an extract of this kind is ordered as an officinal.

(K) Dr Aikin informs us, that the expreſſed juice of the leaves has ſometimes proved ſucceſsful in dropſies, when other remedies had failed. For this purpoſe it is not depurated, but only freed by paſſing through a ſtrainer from the groſſer feculencies, and mixed with an equal quantity of white wine; three or four ſpoonfuls to be taken every morning and evening.—The following decoction (as we are informed by Dr Monro) was long kept a ſecret by a perſon at Andover, and is ſaid to have carried off the water from ſeveral people labouring under a dropſy. Take of artichoke leaves and ſtalks three handfuls; of bruiſed juniper-berries one quart; of ſcraped horſe-raddiſh one handful; of green fir-tops two handfuls; of bruiſed white muſtard-ſeed two table-ſpoonfuls; mix the whole, and boil them in two gallons of water to one, and ſtrain the whole thro' a cloth. Half a pint to be taken by a grown perſon morning and evening, adding a little ſyrup or ſugar to make it agreeable.

(L) This bark is reckoned a ſpecific in diarrhœas; the fine powder being made uſe of in an electuary formed with ſyrup of oranges, and given to the quantity of half a drachm or more four times a day, after a vomit has been given. The firſt day it is taken, the number of ſtools is generally increaſed, without any increaſe of the griping; the ſecond, the colour of the ſtools is meliorated; and, on the third or fourth, the conſiſtence approaches to the natural, when it makes a cure. It ſeldom fails in curing a recent diarrhœa, proceeding from irregularities in diet without fever; and it is frequently of ſervice in habitual diarrhœas.

Indian root. See *Radix Indica*, infra.				
Ipecacoanha (*Pſychatria emetica*, Lin.)	Ipecacuanha.	The root (N.)	Emetic and cathartic.	A vinous tincture, and a powder.

(N) A root has been ſometimes imported, under the name of white ipecacuanha (*viola ipecacuanha*, Lin.), which has little or nothing of the virtues of the true kind. More dangerous abuſes, however, have been practiſed by the ſubſtitution or mixture of the roots of a kind of *apocynum*, which have been found to operate with great violence both upwards and downwards, ſo as to prove fatal in ſome caſes. They may, however, eaſily be diſtinguiſhed by their colour, which is a deep reddiſh yellow, while the true ipecacuanha is pale coloured or greyiſh: the poiſonous roots are likewiſe larger, the fiſſures more diſtant, and the intermediate ſpaces ſmoother, than in the true ipecacuanha. This root is found to increaſe the purgative virtue of jalap remarkably. Dr Aikin informs us, that 15 grains of jalap, with two or three of ipecacuanha, purge more than twice the quantity of jalap by itſelf.

" Of late (ſays Dr Monro), a notion has prevailed, that the keeping up a nauſea by means of ſmall doſes of ipecacuanha, or of watery ſolution of emetic tartar, was of great ſervice in promoting the cure of fevers, as well as of fluxes, from a belief that they affected the nervous ſyſtem, and were capable of exciting the action of the extreme veſſels, and of increaſing the ſecretions by the ſkin, and of the internal organs. Hitherto I have not found this method to anſwer my expectations; and I have always obſerved, that ſuch a doſe of an emetic as emptied the ſtomach freely, and gave a ſhake to the whole frame, had a much better effect than

Lichen iſlandicus (*Lin.*)	Eatable liverwort.	The herb.	Nouriſhing, antiſeptic, and laxative.	

---

thoſe frequently repeated ſmall doſes, which kept the patient in a diſagreeable uneaſy ſituation for hours together; and I am perſuaded, that no practitioner of experience, who has attended large hoſpitals, where he has had an opportunity of trying and ſeeing the effects of different medicines, will ever recommend this nauſeating method for general practice in fevers, though it may be of uſe in ſome particular caſes."

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Lignum campechenſe (*Hæmatoxylum campech.* Lin.)	Logwood.	The wood.	Aſtringent.	An extract.
Lignum rhodium, (*Geniſta canarienſis*, Lin.)	Roſe-wood.	The wood.	Cordial.	An eſſential oil.
Liguſticum. See *Leveſticum*, ſupra.				
Lilium convallium, (*Conval. maial.* Lin.)	Lilly of the valley.	The root and flowers.	Cephalic and nervine.	
Lilium album, (*L. candidum*, Lin.)	White lily.	The root.	Emollient.	Poultice.
Limon, (*Citrus medica*, Lin.)	The lemon-tree.	The fruit.	Aromatic, antiſcorbutic, and cordial.	An eſſential oil; an ingredient in ſeveral compoſitions.
Linaria (*Antirrhinum linaria*, Lin.)	Toad-flax.	The leaves.	Diuretic and cathartic, but doubtful.	
Lingua cervina, (*Aſplenium ſcolopend.* Lin.)	Hart's tongue.	The leaves.	Aperient.	
Linum catharticum (*Euphorbia lathyrus*, Lin.)	Purging flax.	The leaves.	Cathartic.	Infuſion in whey. Dried powder.
Linum Sativum (*L. uſitatiſſimum*, Lin.)	Flax.	The ſeed.	Emollient.	An expreſſed oil. Cataplaſm.
Liquida ambra (*acernegundo*, Lin.)	Sweet gum, or ſtorax tree.	The reſinous juice.	Aromatic and cordial.	
Lithoſpermum (*L. officinale*, Lin.)	Gromwell.	The ſeeds.	Reſolvent; lithontriptic.	
Lobelia (*L. ſiphilitica*, Lin.)	Blue cardinal flower.	The root (o).	Alterant, and detergent.	Decoction.
Lujula, or wood-ſorrel. See *Acetoſella*, ſupra.				
Lumbrici et limaces terreſtres.	Earth worms and ſnails		Aperient and analeptic.	Decoction in milk.
Lupinus (*L. albus*, Lin.)	White lupines.	The ſeeds.	Anthelmintic.	
Lupulus (*Humul. lup.* Lin.)	Hops.	The looſe leafy heads which grow upon the tops of the ſtalks.	Diuretic and ſtomachic.	

Lycoperdon

(o) This root was long a famous ſecret among the North American Indians for curing the venereal diſeaſe. The ſecret was purchaſed by Sir William Johnſon, and has been publiſhed in the writings of Bartram, Kalm, &c. The following method of uſing it is, by Dr Aikin, recommended as the beſt: "A decoction is made of an handful of the roots in three meaſures of water. Of this half a meaſure is taken in the morning faſting, and repeated in the evening; and the doſe is gradually increaſed till its purgative effect becomes too violent, when the medicine is for a time to be intermitted, and then renewed till a perfect cure is effected. One doſe daily is ſufficient during the latter part of the treatment; and the regimen, during the whole proceſs, is to be equally ſtrict with that obſerved in a courſe of mercurial ſalivation. From the third day, the ulcers are to be well waſhed twice daily with the decoction; and it is ſaid, that when they are very deep and foul, the Indians ſprinkle them with powder of the internal bark of the ſpruce tree. By this method we are aſſured that inveterate venereal complaints are cured without the aid of mercury."

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Lycoperdon (*L. boviſta*, Lin.)	Puff-ball, or duſty muſhroom.	The whole.	Styptic.	
Macis. See *Nux Moſchata*, infra.				
Majorana (*Origanum majorana*, Lin.)	Sweet marjoram.	The leaves and flowers.	Aromatic and errhine.	An eſſential oil.
Malabathrum (*Laurus caſſia*, Lin.)	Indian leaf.		Aromatic.	An ingredient in mithridate and theriaca.
Malva (*M. ſylveſtris*, Lin.)	The mallow.	The leaves and flowers.	Emollient.	Ingredient in the decoction for glyſters, uſed alſo in cataplaſms and fomentations: formerly there was a conſerve of the flowers.
Malus (*Pyrus malus*, Lin.)	The apple-tree.	The fruit.	Refrigerant and laxative.	
Mandragora (*Atropa Mandrag.* Lin.)	The mandrake.	The leaves.	Narcotic.	
Manna (*Fraxinus ornus*, Lin.)	The manna aſh.	The concreted juice.	Laxative.	Gives name to an officinal lohoch, and enters ſeveral other compoſitions.
Marrubium (*M. vulgare*, Lin.)	White horehound.	The leaves.	Stomachic and aperient.	An ingredient in theriaca (p).
Marum Syriacum, (*Teucrium mar.* Lin.)	Syrian herb maſtich.	The leaves.	Aromatic and errhine.	An ingredient in ſome cephalic ſnuffs.
Maſtiche. See *Gum maſtic*, ſupra.				
Matricaria (*M. parthenium*, Lin.)	Feverfew.	The leaves and flowers.	Aperient and antiſpaſmodic.	
Mechoacanna, (*Convolvulus mechoac.* Lin.)	White jalap, or Mechoacan.	The root.	Cathartic.	
Mel.	Honey.		Aperient and detergent.	
Melampodium. See *Helleborus niger*, ſupra.				
Melilotus (*Trifolium melilot.* Lin.)	Melilot.	The leaves and flowers.	Emollient and carminative.	Gives name to a plaſter.
Meliſſa (*M. officin.* Lin.)	Balm.	The leaves.	Aromatic.	An eſſential oil, and an infuſion.
Melo (*Cucumis melo*, Lin.)	The melon.	The ſeeds.	Refrigerant and emollient.	
Mentha criſpa (*Lin.*)	Daniſh or German curled mint.	The herb.	Aromatic and cordial.	A diſtilled water, eſſential oil, and eſſence. An ingredient in ſeveral officinal preparations.
Mentha vulgaris, (*M. viridis*, Lin.)	Spearmint.	The herb.	Aromatic and cordial.	A diſtilled water, an eſſential oil, a ſpirit, and eſſence. An ingredient in ſeveral officinal preparations.

(p) The juices of horehound and plantain mixed are remedies of great repute in America againſt the bite of the rattleſnake. They are given by ſpoonfuls at ſhort intervals; while at the ſame time the wounded part is covered with a cataplaſm of the ſame herbs bruiſed. The good effects are ſaid to be ſpeedy, and the recovery of the patient complete and certain.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Mentha piperitis (*M. piperita*, Lin.)	Pepper-mint.	The herb.	Aromatic and cordial.	A diſtilled water, eſſential oil, and eſſence. An ingredient in ſeveral officinal preparations.
Mercurialis (*M. annua*, Lin.)	French mercury.	The leaves.	Emollient and laxative.	A ſyrup.
Meum (*Æthuſa meum*, Lin.)	Spignel.	The root.	Aromatic and carminative.	
Mezereon (*Daphne mezereum*, Lin.)	Mezereon, or ſpurge olive.	The bark of the root.	Violently cathartic.	Decoction and powder.
Millefolium ((*Achillea millefol.* Lin.)	Millefoil, or yarrow.	The leaves and flowers.	Mildly aſtringent and aromatic.	An eſſential oil.
Millepedæ (*Oniſcus aſellus*, Lin.)	Wood-lice, hog-lice, or ſlaters.		Diuretic.	The inſects dried and powdered; an infuſion in wine; alſo an ingredient in ſome other officinal preparations.
Minium. See *Plumbum*, infra.				
Morſus diaboli *Scabioſa ſucciſa*, Lin.)	Devil's bit.	The leaves and roots.	Diaphoretic.	
Morus nigra (*Lin.*)	The mulberry-tree.	The fruit and bark of the roots.	Refrigerant, aſtringent, and anthelmintic.	A ſyrup from the juice of the fruit.
Moſchus (*M. moſchiferus*, Lin.)	Muſk.		Diaphoretic and antiſpaſmodic.	A julep.
Myriſtica. See *Nux moſchata*, infra.				
Myrobalani (*Prunus myrobalanus*, Lin.)	Myrobalans.	The fruit.	Purgative.	
Myrrha. See *Gum myrrha*, ſupra.				
Myrrhia (*Siſon Canadenſe*, Lin.)	Sweet cicely.	The leaves and ſeeds.	Diuretic.	
Myrtillus (*Vaccinium myrtil.* Lin.)	Whortle-berry.	The leaves and berries.	Aſtringent.	
Myrtus (*M. communis*, Lin.)	The myrtle.	The berries.	Aſtringent.	
Napus (*Braſſica napus*, Lin.)	Sweet navew, or navew gentle.	The ſeeds.	Aromatic.	An ingredient in the theriaca.
Nardus Indica, (*Andrapogon nardus*, Lin.)	Indian nard.	The roots.	Stomachic and carminative.	Ingredient in the mithridate and theriaca.
Naſturtium aquaticum (*Siſymbrium naſturtium*, Lin.)	Water creſſes.	The leaves and juice.	Aperient and antiſcorbutic.	An ingredient in the ſucci ſcorbutici.
Naſturtium hortenſe (*Lepidium ſativum*, Lin.)	Garden creſſes.	The leaves and ſeeds.	Aperient and antiſcorbutic, but much weaker than the former.	
Nepeta (*N. cataria*, Lin.)	Nep, or catmint.	The leaves.	Aromatic and cordial.	
Nephriticum lignum (*Guilandina moringa*, Lin.)	Nephritic wood.	The wood in ſubſtance.	Diuretic, but uncertain.	
Nicotiana (*Nicotiana tabacum*, Lin.)	Tobacco.	The leaves.	Violently emetic, cathartic, and narcotic.	An extract recommended by Stahl and other German phyſicians.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Nigella (*Nigella ſativa*, Lin.)	Fennel-flower.	The ſeeds.	Aperient and diuretic, but uncertain.	
Nitrum.	Nitre or ſalt-petre.		Diaphoretic, diuretic, and refrigerant.	An acid ſpirit and fixed alkaline ſalt, an aqueous decoction or ſolution, troches. An ingredient in many other officinal preparations.
Nummularia (*Lyſimachia nummularia*, Lin.)	Moneywort, or herb twopence.	The leaves.	Antiſcorbutic.	
Nux moſchata (*Myriſtica aromatica*, Lin. *Myriſtica moſchata*, Act. Holm.)	The nutmeg-tree.	The fruit, and covering called *mace.*	An excellent aromatic, cordial, and ſtomachic.	An expreſſed oil, falſely called *oil of mace;* an eſſential oil; a ſimple water; a ſpirituous water; an ingredient in many officinal compoſitions.
Nux piſtachia (*Piſtachia vera*, Lin.)	The piſtachia-tree.	The fruit.	Emollient and analeptic.	
Nux vomica (*Strychnos nux vom.* Lin.)	Nux vomica.	The fruit.	Narcotic.	
Nymphæa alba (*Lin.*)	White water-lily.	The roots and flowers.	Aſtringent and corroborative.	
Ochra	Yellow ochre.		Aſtringent, but very weak.	
Oenanthe (*Oe. crocata*, Lin.)	Hemlock dropwort.	Leaves and root.	A virulent poiſon:	But the juice of the root, or the infuſion of the leaf, has been recommended in chronic eruptions. The latter has been alſo found uſeful as an emmenagogue.
Olibanum. See *Gum olibanum*, ſupra.				
Oliva (*Olea Europæa*, Lin.)	The olive-tree.	The fruit.	Emollient.	An expreſſed oil uſed in almoſt all ointments, plaſters, &c.
Ononis (*O. ſpinoſa*, Lin.)	Reſt-harrow, cammock, or pettywhin.	The root.	Aperient and diuretic.	
Opium (*Papaver Orientale*, Lin.)	The Aſiatic poppy.	The inſpiſſated juice.	A moſt excellent anodyne and cordial when properly applied, but a very fatal poiſon if taken in too great quantity.	Purified by ſtraining, called the *Thebaic extract;* a vinous and ſpirituous tincture, called *liquid laudanum.* Alſo a capital ingredient in many officinal preparations.
Opopanax. See *Gum opopanax*, ſupra.				
Origanum (*O. vulg.* Lin.)	Wild marjeram.	The leaves.	Aromatic.	An eſſential oil.
Oryza (*O. ſativa*, Lin.)	Rice.	The grain.	Emollient and refrigerant.	
Oxylapathum (*Rumex acutus*, Lin.)	Sharp-pointed dock.	The roots and leaves.	Alterant and laxative.	
Pæonia (*P. officinalis*, Lin.)	Male and female peony.	The roots, flowers, and ſeeds.	Emollient and antiſpaſmodic.	Ingredients in ſome anti-epileptic powders.
Palma (*Cocos butyracea*, Lin.)	The palm-tree.	The kernels of the fruit.	Emollient and anodyne.	An expreſſed oil uſed in ſtomachic plaſters.
Palma Chriſti. See *Ricinus*, infra.				

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Papaver album (*P. ſomniferum*, Lin.)	The white poppy.	The heads.	Anodyne.	A ſyrup.
Papaver erraticum (*P. rhœas*, Lin.)	Red poppy, or corn-roſe.	The flowers.	Valued chiefly for the colour they communicate.	A ſyrup.
Paralyſis (*Primula veris offic.* Lin.)	Cowſlip.	The flowers.	Corroborant and antiſpaſmodic.	A ſyrup.
Pareira brava (*Ciſſampelos pareira*, Lin.)	Pareira brava.	The root.	Attenuant, diuretic, and lithontriptic.	
Parietaria (*P. officinalis*, Lin.)	Pellitory of the wall.	The leaves.	Emollient and diuretic.	Ingredient in a nephritic decoction.
Paſtinaca (*P. ſativa*, Lin.)	Garden parſnip.	The roots and ſeeds.	Emollient and aromatic.	
Paſtinaca ſilveſtris (*Lin.*)	Wild parſnip.	The ſeeds.	Aromatic.	
Pentaphyllum (*Potentilla reptans*, Lin.)	Cinquefoil.	The root.	Aſtringent.	
Perſicaria urens (*Polygonum hydropiper*, Lin.)	Bitter arſmart, lake-weed, or water-pepper.	The leaves.	Diuretic and detergent when externally applied.	
Perſicaria mitis (*Polygonum perſic.* Lin.)	Spotted arſmart.	The leaves.	Antiſeptic and aſtringent.	
Perſica (*Amygdalus perſica*, Lin.)	The peach-tree.	The leaves, flowers, and fruit.	Laxative, anthelmintic, and refrigerant.	
Peruvianus cortex (*Cinchona officinalis*, Lin.)	The quinquina, or Jeſuit's-bark-tree.	The bark.	A moſt excellent corroborative.	An extract, a reſin, a ſpirituous tincture, a compound tincture, a tincture in volatile ſpirit; alſo an ingredient in the ſtomachic tincture.
Petaſites (*Tuſſilago petaſites*, Lin.)	Butterbur.	The root.	Aromatic, aperient, and deobſtruent.	
Petroleum.	Rock oil.		Anodyne and corroborative when applied externally.	
Petroleum Barbadenſe (*Bitumen petroleum*, Lin.)	Barbadoes tar.		Diſcutient, ſudorific, and corroborative.	
Petroſelinum (*Apium petroſelinum*, Lin.)	Common parſley.	The roots, leaves, and ſeeds.	Aperient and ſomewhat aromatic.	The ſeeds an ingredient in an electuary.
Peucedanum (*P. officinale*, Lin.)	Hog's-fennel, or ſulphur-wort.	The root.	Aperient, ſtimulating, and errhine.	
Pimenta (*Myrtus pimenta*, Lin.)	Pimento, Jamaica pepper, or allſpice.	The berry.	Aromatic and ſtimulant.	The baſis of a diſtilled water, a ſpirit, and an eſſential oil.
Pimpinella ſanguiſorba (*Sanguiſorba officinalis*, Lin.)	The greater wild burnet.	The leaves.	Aſtringent.	
Pimpinella ſaxifraga (*Lin.*)	Burnet ſaxifrage.	The root, leaves, and ſeeds.	Diaphoretic, diuretic, and antiſcorbutic.	
Pinus ſylveſtris (*Lin.*)	The pine-tree.	The kernels of its fruit or cones, and reſin.	The kernels emollient; for the reſin, ſee *Terebinthina*, infra.	

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Piper longum (*Lin.*)	Long pepper.		Highly aromatic and ſtimulant.	
Piper nigrum (*Lin.*)	Black pepper.			
Piper Jamaicenſe. See *Pimenta*, ſupra.				
Piper Indicum (*Capſicum annuum*, Lin.)	Guinea pepper.			A powder called *Cayenne pepper*.
Pix liquida (*Pinus ſylveſtris*, Lin.)	Tar.		Attenuant and ſtimulating.	An infuſion in water, and an ingredient in a kind of pectoral pills.
Pix Burgundica (*Pinus abies*, Lin.)	Burgundy pitch.		A warm adheſive reſinous ſubſtance.	Ingredient in ſeveral plaſters, ointments, and cerates.
Plantago latifolia, *P. major*, Lin.)	Common broad-leaved plantane.	The leaves.	Aſtringent.	
Plumbum.	Lead.		Aſtringent and refrigerating, but very dangerous.	Several chemical preparations. See CHEMISTRY-*Index*. A tincture and extract, or ſolution in vegetable acids; alſo an ingredient in ſeveral ointments, &c.
Polium montanum (*Teucrium polium*, Lin.)	Poley-mountain.	The tops.	Aromatic.	Ingredient in the Mithridate and theriaca.
Polygala amara (*Lin.*)	Milkwort.	The root.	Purgative.	
Polygala ſenega (*Lin.*)	Rattleſnake root.	The roots.	Stimulating, attenuant, and diuretic.	
Polypodium (*P. vulgare*, Lin.)	Polypody.	The root.	Laxative.	
Populus nigra, (*Lin.*)	Black poplar.	The buds.	Aromatic.	Uſed only in an ointment, but capable of being applied to better purpoſes.
Porrum (*Allium porrum*, Lin.)	The leek.	The root.	A ſtimulating diuretic.	
Portulaca (*P. oleracea*, Lin.)	Purſlane.	The ſeeds.	Refrigerant.	
Primula veris (*Lin.*)	Primroſe.	The herb and root.	Aromatic and ſtomachic.	An infuſion and diſtilled ſpirit.
Prunella (*P. vulgaris*, Lin.)	Self-heal.	The leaves.	Attenuant and detergent.	
Pruna Gallica *Prunus domeſtica*, Lin.)	French or common prunes.	The fruit.	Cooling and aperient.	
Prunus Sylveſtris. See *Acacia Germanica*, ſupra.				
Pſyllium (*Plantago pſyll.* Lin.)	Fleawort.	The ſeeds.	Emollient and laxative.	
Ptarmica (*Achillea ptarmica*, Lin.)	Sneezewort, or baſtard pellitory.	The root.	Errhine and ſtimulating.	
Pulegium (*Mentha puleg.* Lin.)	Pennyroyal.	The flower.	A warm aromatic.	A ſimple water, a ſpirituous water, an eſſential oil; and an ingredient in ſome other officinal compoſitions.
Pulmonaria maculoſa (*P. officinalis*, Lin.)	Spotted lung-wort, or ſage of Jeruſalem.	The leaves.	Said to be aperient and analeptic.	
Pulſatilla nigricans (*Anemone pratenſ.* Lin.)	Meadow anemone.	The herb and flower.	Emetic, diuretic, and cathartic.	An extract and diſtilled water, uſed in venereal complaints, and certain diſorders of the eye.

Liſt of Simples.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Pyrethrum (*Anthemis pyrethr.* Lin.)	Pellitory of Spain.	The root.	Promotes the ſalival flux.	
Quaſſia (*Q. Simaruba*, Lin.)	Simarouba.	The bark.	Antiſeptic; uſeful in dyſentery.	See *Ed. Phil. Tranſ.* vol. ii.
Quaſſia (*Q. amara*, Lin.)	Quaſſy.	The wood.	Stomachic and tonic.	An extract.
Quercus (*Q. robur.* Lin.)	Oak-tree.	The bark.	Strongly aſtringent.	
Quercus marina (*Fucus veſiculoſus*, Lin.)	Sea-wrack or Sea-oak.	The herb.	Aſtringent and detergent.	A powder of the burnt herb.
Radix Indica Lopeziana (*Gaub. Adverſ.*)	Indian or Lopez root.		Aſtringent.	
Raphanus ruſticanus (*Cochlearia armoracea*, Lin.)	Horſe-radiſh.	The root.	Stimulating and attenuant.	A compound water.
Rhabarbarum (*Rheum palmat.* Lin.)	Rhubarb.	The root.	Cathartic and ſtomachic.	Toaſted; a watery infuſion; vinous and ſpirituous tinctures; and an ingredient in ſeveral officinal compoſitions.
Rhamnus catharticus. See *Spina cervina*, infra.)				
Rhaponticum (*Rhæum rhapon.* Lin.)	Rhapontic.	The roots.	Laxative.	
Rhododendron chryſanthemum (*Lin.*)	Rhododendron.	The herb.	Powerfully ſedative.	Decoction and powder; lately found ſerviceable in the gout and rheumatiſm.
Ribes nigrum (*Lin.*)	The black-currant buſh.	The fruit.	Refrigerant and detergent.	A gelly.
Ribes rubrum (*Lin.*)	The red-currant buſh.	The fruit.	Ditto.	
Ricinus, (*R. communis*, Lin.)	Palma Chriſti.	The ſeed.	Laxative, anthelmintic.	Expreſſed oil.
Roſa damaſcena (*R. centafolia*, Lin.)	Damaſk roſe.	The flower.	Aromatic and gently laxative.	A diſtilled water and ſyrup.
Roſa rubra (*R. Gallica*, Lin.)	The red roſe.	The flower.	Aſtringent and corroborative.	A conſerve, honey, tincture, troches, vinegar, and ſyrup. An ingredient in ſeveral officinal compoſitions.
Roſmarinus hortenſis (*R. officinalis*, Lin.)	Roſemary.	The tops and flowers.	A fine aromatic and cordial.	An eſſential oil; a diſtilled ſpirit called *Hungary water.* An ingredient in many cordial and antiſpaſmodic medicines.
Rubia tinctorum, (*Lin.*)	Madder.	The root.	Aperient and detergent.	
Rubus idæus, (*Lin.*)	The raſp-berry buſh.	The fruit.	Refrigerant.	A ſyrup.
Rubus niger (*R. fruticoſ.* Lin.)	The bramble.	The leaves.	Aſtringent.	
Ruſcus (*R. aculeatus*, Lin.)	Butcher's-broom, or knee-holly.	The root.	Aperient.	Ingredient in diet-drinks.
Ruta (*R. graveolens*, Lin.)	Broad-leaved rue.	The leaves and ſeeds.	Powerfully ſtimulating, attenuating, and detergent.	An extract; and an ingredient in ſeveral compoſitions.

Sabadilla.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Sabadilla. See *Cevadilla*, ſupra.				
Sabina (*Juniperus ſabina*, Lin.)	Savin.	The leaves or tops.	A ſtimulating aperient.	An eſſential oil; a watery extract; and an ingredient in ſeveral officinal compoſitions.
Saccharum (*Arundo ſaccharifera*, Lin.) purificatum & non purificatum.	Sugar, refined and brown.		Emollient and laxative.	
Saccharum cantum, album & rubrum.	Sugar-candy, white and brown.			
Sagapenum (*Ferula orientalis*, Lin.)	Gum ſagapenum.		Aperient and deobſtruent.	An ingredient in ſeveral antiſpaſmodic medicines.
Sal alkali vegetabile.	Vegetable alkaline ſalt, or pearl-aſhes.		Aperient, diuretic, and cauſtic.	The baſis of a great number of neutral ſalts.
Sal alkali minerale.	Mineral alkali, ſalt of Soda, or baſis of ſea-ſalt.		Ditto.	Ditto.
Sal ammoniac. See *Ammoniac*.				
Sal catharticus amarus.	Epſom ſalt.		Cathartic.	Magneſia.
Sal commune.	Common ſalt.		In ſmall doſes ſtimulant, in large ones cathartic.	
Salicaria (*Lythrum Salicar*, Lin.)	Purple looſe-ſtrife.	The herb.	Aſtringent.	
Salix (*S. fragilis*, Lin.)	The crack-willow.	The bark.	Corroborant.	
Salvia (*S. officinalis*, Lin.)	Common ſage.	The leaves.	Moderately ſtimulating and aſtringent.	Infuſions.
Sambucus (*S. nigra*, Lin.)	Common black-berried alder.	The leaves, bark, flowers and berries.	Cathartic, aromatic, and aperient.	A rob for internal uſe from the berries, and an ointment and oil from the flowers and bark; the flowers are alſo ingredients in ſome compound waters.
Sanguis draconis, (*Calamus rotang*, *Dracena draco*, *Pterocarpus*, *draco*, &c. Lin.)	Dragon's-blood.		Aſtringent.	An ingredient in ſome officinal compoſitions.
Sanicula (*S. Europæa*, Lin.)	Sanicle.	The leaves.	Suppoſed to be corroborant.	
Santalum citrinum, (*S. album*. Lin.)	Yellow ſanders.	The wood.	Greatly recommended by Hoffman as a reſtorative.	Eſſential oil; extract.
Santalum rubrum (*Pterocarpus ſantolinus*, Lin.)	Red ſanders.	The wood.	Uſed only for its colour.	
Santonicum (*Artemiſia ſantonica*, Lin.)	Worm-ſeed.		Anthelmintic.	

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Sapo durus.	Hard Spaniſh ſoap.		Reſolvent and ſtimulating.	The firſt gives name to a plaſter, liniment, balſam, and pills; the ſecond is an ingredient in the milder cauſtic; and the third in an anodyne plaſter.
Sapo mollis.	Common ſoft ſoap.			
Sapo niger.	Black ſoap.			
Saponaria (*S. officinalis*, Lin.)	Soapwort or bruiſewort.	The herb and root.	Aperient, corroborant, and ſudorific.	Tincture; extract.
Sarcocolla (*Penæa ſarcoc.* Lin.)	Gum ſarcocol.		Suppoſed a vulnerary.	Ingredient in the pulvis ē ceruſſa.
Sarſaparilla (*Smilax ſarſap.* Lin.)	Sarſaparilla.	The root.	Alterant, and diaphoretic.	Infuſions and extract.
Saſſafras (*Laurus ſaſſafras*, Lin.)	Saſſafras.	The root.	Alterant, aperient, and corroborant.	An eſſential oil; an ingredient in ſome officinal preparations.
Satureia (*S. hortenſis*, Lin.)	Summer ſavory.	The leaves.	A very pungent warm aromatic.	
Satyrion mas (*Orchis maſcula*, Lin.)	Orchis.	The root.	Coagulant and corroborative.	Salep ſuppoſed to be a preparation from a root of this kind.
Saxifraga alba (*S. granulata*, Lin.)	White-flowered ſaxifrage.	The roots and leaves.	Suppoſed to be aperient, diuretic, and lithontriptic, but without juſt foundation.	
Saxifraga vulgaris, (*Peucedanum ſilaus*, Lin.)	Meadow ſaxifrage.	The leaves and ſeeds.		
Scabioſa (*S. arvenſis*, Lin.)	Scabious.	The leaves.	Aperient, ſudorific, and expectorant.	
Scammonium (*Convolvulus ſcam.* Lin.)	Scammony.	Roots.	Strongly cathartic.	Gives name to a powder, and is an ingredient in ſome officinal preparations.
Scilla (*S. maritima*, Lin.)	The ſquill, or ſea-onion.	The root.	Powerfully diuretic, ſtimulant, and expectorant.	A ſyrup, vinegar, oxymel, pills; the root dried, baked, and made into troches.
Scolopendrium. See *Lingua cervina*, ſupra.				
Scordium (*Teucrium ſcordium*, Lin.)	Water germander.	The leaves.	Deobſtruent, diuretic, and ſudorific, but doubtful.	An ingredient in mithridate, theriaca, and ſeveral other preparations.
Scorzonera (*S. hiſpanica*, Lin.)	Viper's graſs.	The root.	Cordial and ſtimulant, but doubtful.	
Scrophularia (*S. nodoſa*, Lin.)	Fig-wort.	The leaves and root.	Suppoſed corroborant, but doubtful.	
Sebeſten (*Cordia myxa*, Lin.)	Sebeſten plum.		Emollient.	
Sedum acre (Lin.)	Wall ſtone crop, or wall pepper.	The freſh plant.	Strongly purgative, emetic, and diuretic.	
Sedum majus (*S. album*, Lin.)	Greater houſeleek.	The leaves.	Refrigerant.	
Seneka. See *Polygala ſeneka*, ſupra.				
Senna (*Caſſia ſenna*, Lin.)	Senna.	The leaves.	Cathartic.	Infuſion, ſpirituous tinctures, compound powders, and an electuary.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Serpentaria Virginiana (*Ariſtolochia ſerpentar.* Lin.)	Virginian ſnake-weed.	The root.	A warm diaphoretic and diuretic.	A ſpirituous tincture; and an ingredient in a number of tinctures.
Serpyllum (*Thymus ſerpil.* Lin.)	Mother of thyme.	The herb.	Aromatic.	
Seſelis vulgaris, (*Tordylium offic.* Lin.)	Common hartwort.	The ſeeds.	Agreeable aromatics, but neglected. *Lewis.*	
Seſelis maſſilienſis (*Seſeli elatum*, Lin.)	Hartwort of Marſeilles.	The ſeeds.		
Sigillum Salomonis (*Convallaria polygon.* Lin.)	Solomon's ſeal.	The root.	Probably emollient.	
Simarouba. See *Quaſſia ſimarouba*, ſupra.				
Sinapi (*Sinapis alba & nigra*, Lin.)	Muſtard.	The ſeeds, black and white.	Strongly pungent and ſtimulant.	An expreſſed oil.
Sium (*S. nodiflorum*, Lin.)	Creeping ſkerrit, or water parſnip.	The herb.	The juice ſerviceable in ſome cutaneous diſorders.	
Solanum (*S. nigr.* Lin.)	Nightſhade.	The leaves.	Powerfully evacuant.	
Spermaceti (*Phyſeter macrocephalus*, Lin.)	Spermaceti.		A mild emollient.	Gives name to a lohoch.
Spigelia (*S. Marilandica*, Lin.)	Indian pink.	The root.	Anthelmintic.	
Spina cervina, (*Rhamnus catharticus*, Lin.)	Buckthorn.	The berries.	Strongly cathartic.	A ſyrup.
Spiritus vinoſi.	Vinous ſpirits.		Cordial and ſtimulant.	Uſed as menſtruums for tinctures, &c. in almoſt every preparation of that kind.
Spongia (*S. officinal.* Lin.)	Sponge.		Uſed as a tent for dilating ulcers, &c.	Burnt, recommended in ſcrophulous affections.
Stannum.	Tin.		Anthelmintic.	Powdered.
Staphiſagria (*Delphinium ſtaphiſagria*, Lin.)	Staveſacre.	The ſeeds.	A violent cathartic taken internally. Its external application deſtroys lice and other inſects.	
Stoechas (*Lavendula ſtoechas*, Lin.)	Arabian ſtoechas, or French lavender.	The flowers.	Aromatic.	An ingredient in mithridate and theriaca.
Stramonium (*Daturaſtramon.* Lin.)	Thorn-apple.	The herb.	Narcotic.	An extract.
Styrax calamita (*S. officinalis*, Lin.)	Storax.		Aromatic, ſtimulant, and nervine.	Ingredient in ſome tinctures and pills.
Styrax liquida (*Liquidamber ſtyraciflua*, Lin.)	Liquid ſtorax.			Ingredient in a mercurial plaſter.
Suber (*Quercus ſub.* Lin.)	The cork-tree.	The bark.	Aſtringent.	

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Succinum.	Amber.		Aſtringent and corroborant.	A tincture, balſam, eſſential oil, and an ingredient in ſeveral officinal preparations.
Sulphur.	Sulphur, and flowers of ſulphur.		Laxative, diaphoretic, and alterant.	Solutions in different kinds of oils called *balſams*, and an ingredient in ſome ointments.
Sumach (*Rhus coriaria*, Lin.)	Common ſumach.	The leaves and ſeeds.	Aſtringent.	
Tacamahac (*Populus balſamifera*, Lin.)	Tacamahac-tree.	The reſin.	Diſcutient, emollient, and ſuppurative.	An ingredient in ſeveral plaſters.
Tamarindus (*T. Indica*, Lin.)	Tamarinds.	The fruit.	Refrigerant and laxative.	Ingredients in ſome laxative electuaries.
Tamariſcus (*Tamarix Gallica*, Lin.)	The tamariſk-tree.	The leaves and bark.	Aſtringent.	
Tanacetum (*T. vulgare*, Lin.)	Tanſy.	The leaves, flowers, and ſeeds.	Stimulating, antiſpaſmodic, and anthelmintic.	
Taraxacum (*Leontodon tarax.* Lin.)	Dandelion.	The leaves and root.	Attenuating and reſolvent.	A diſtilled ſpirit, recommended by profeſſor Delius of England in aſthmatic and hydropic affections.
Tartarum.	Tartar.		Refrigerant and cathartic.	Purified from its earthy parts, and called *cream of tartar*, the baſis of ſome uſeful purging ſalts. An alkali is alſo prepared from it by fire.
Terebinthina Veneta (*Pinus larix*, Lin.)	Venice turpentine.		Warm ſtimulating diuretics and aperients.	
Terebinthina Argentoratenſis.	Straſburgh turpentine.			
Terebinthina Chia.	Chian, or Cyprus turpentine.			
Terebinthina communis.	Common turpentine.		Uſed chiefly in external applications.	An eſſential oil. The reſiduum forms the *reſina alba & nigra*, or white and black roſin of the ſhops, uſed in almoſt every ointment.
Terra Japonica. See *Catechu*, ſupra.				
Thapſus barbatus (*Verpaſcum thapſus*, Lin.)	Great white mullein.	The leaves and flowers.	Analeptic.	A ſpirituous extract from the flowers.
Thea bohea et viridis (*Lin.*)	Bohea and green tea.	The leaves.	Cordial, diuretic, and diaphoretic.	An infuſion.
Thlaſpi (*T. arvenſe*, Lin.)	Treacle, or mithridate muſtard.	The ſeeds.	Aromatic and ſtimulant.	Ingredient in theriaca.
Thus vulgare.	Common frankincenſe.		Suppoſed corroborative.	Ingredient in ſome warm plaſters.
Thymus citratus.	Lemon thyme.	The leaves.	An agreeable aromatic.	A diſtilled water and eſſential oil.
Thymus vulgaris.	Common thyme.	The leaves.	An agreeable aromatic.	A diſtilled water and eſſential oil.
Tilia (*T. Europæa*, Lin.)	The lime or linden tree.	The flowers.	Antiſpaſmodic.	Infuſion.
Tithymalus (*Euphorbia lathyrus*, Lin.)	The ſpurge.	The juice of the root.	Violently cathartic.	

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Tormentilla (*T. erecta*, Lin.)	Tormentil, or ſeptfoil.	The root.	Aſtringent.	An ingredient in ſeveral officinal compoſitions.
Trichomanes (*Aſplenium trich.* Lin.	Maidenhair.	The herb.	Pectoral.	Decoction and ſyrup.
Trifolium paludoſum (*Menyanthes trifoliata*, Lin.)	Marſh trefoil, or buck bean.	The leaves.	Laxative and alterant.	
Triticum (*T. hybernum*, Lin.)	Wheat.	The grain and flour.	Nutritive and glutinous.	Starch.
Turpethum (*Convolvulus turpethum*, Lin.)	Turbith.	The root.	Violently cathartic.	An extract.
Tuſſilago (*T. farfara*, Lin.)	Coltsfoot.	The leaves and flowers.	Emollient and mucilaginous.	An ingredient in pectoral decoctions.
Tutia.	Tutty.		Ophthalmic.	Ingredient in ſeveral ointments, and collyria.
Valeriana ſylveſtris (*Val. officinalis*, Lin.)	Wild valerian.	The root.	Antiſpaſmodic.	A tincture in proof ſpirit, and in volatile ſpirit; alſo an ingredient in ſeveral cephalic and anti-epileptic medicines.
Veratrum. See *Helleborus albus*, ſupra.				
Verbaſcum. See *Thapſus*, ſupra.				
Veronica mas (*V. officinalis*, Lin.)	Male ſpeedwell.	The leaves.	Aperient and pectoral.	Infuſions.
Vinum.	Wine.		Cordial and corroborant.	A menſtruum for a great number of medicinal ſubſtances.
Viola (*V. odorat.* Lin.)	The ſingle March violet.	The flowers.	Laxative.	A ſyrup.
Vipera (*Coluber berus*, Lin.)	The viper.	The fleſh and fat.	Reſtorative and emollient.	A vinous tincture; an ingredient in theriaca.
Vitis vinifera, *Lin.*)	The vine.	The leaves, ſap, flowers, and fruit.	Aſtringent, diuretic, aromatic, and pectoral.	Wine. The dried fruit or raiſins are ingredients in ſome pectoral and ſtomachic medicines.
Ulmus (*U. campeſtris*, Lin.)	The elm-tree.	The inner bark.	Aſtringent.	A decoction recommended by Dr Letſom in obſtinate cutaneous eruptions.
Winteranus cortex (*Wintera aromatica*, Lin.)	Winter's bark.		Aromatic.	
Urtica (*U. dioica*, Lin.)	The nettle.	The herb.	Rubefacient.	
Uva urſi (*Arbutus uva urſi*, Lin.)	Whortle-berry.	The leaves.	Aſtringent and lithontriptic.	
Zedoaria (*Kæmpferia rotunda*, Lin.)	Zedoary.	The root.	Stomachic and corroborant.	An extract with proof-ſpirit.
Zincum.	Zinc.		Suppoſed to be a good antiepileptic.	The metal reduced to a calx by fire. Calamine and tutty are a kind of ores of this metal. Theſe laſt are the baſis of two officinal ointments. A ſalt produced by its combination with the vitriolic acid. See CHEMISTRY-*Index*.
Zinziber (*Amomum zinzib.* Lin.)	Ginger.	The root.	Aromatic.	A ſyrup. Alſo an ingredient in ſeveral officinal compoſitions.

General Titles.

General TITLES *including ſeveral* SIMPLES.

- The five opening roots:
  - Smallage,
  - Aſparagus,
  - Fennel,
  - Parſley,
  - Butchers broom.
- The five emollient herbs:
  - Marſhmallows,
  - Mallows,
  - Mercury,
  - Pellitory of the wall,
  - Violets.
- The four cordial flowers:
  - Borage,
  - Bugloſs,
  - Roſes,
  - Violets.
- The four greater hot ſeeds:
  - Aniſe,
  - Caraway,
  - Cummin,
  - Fennel.
- The four leſſer hot ſeeds:
  - Biſhopſeed,
  - Stone parſley,
  - Smallage,
  - Wild carrot.
- The four greater cold ſeeds:
  - Water melons,
  - Cucumbers,
  - Gourds,
  - Melons.
- The four leſſer cold ſeeds:
  - Succory,
  - Endive,
  - Lettuce,
  - Purſlane.
- The four capillary herbs:
  - Maidenhair,
  - Engliſh maindenhair,
  - Wall rue,
  - Ceterach.
- The four carminative flowers:
  - Camomile,
  - Feverfew,
  - Dill,
  - Melilot.

The ſimples of each of the above claſſes have been often employed together under the reſpective general appellations. This practice has entirely ceaſed amongſt us; and accordingly theſe denominations are now expunged both from the London and Edinburgh pharmacopœias, and they are now retained in very few of the foreign ones. But as theſe articles are frequently mentioned under their general titles by writers of eminence, it was imagined that the above enumeration of them might be of ſome uſe.

GENERAL RULES *for the Collection and Preſervation of* SIMPLES.

ROOTS.

Annual roots are to be taken up before they ſhoot out ſtalks or flowers: Biennial ones, chiefly in the autumn of the ſame year in which the ſeeds were ſown: The perennial, when the leaves fall off, and therefore generally in the autumn. Being waſhed clean from dirt, and freed from the rotten and decayed fibres, they are to be hung up in a warm, ſhady, airy place, till ſufficiently dried. The thicker roots require to be ſlit longitudinally, or cut tranſverſely into thin ſlices. Such roots as loſe their virtues by exſiccation, or are deſired to be preſerved in a freſh ſtate, for the greater conveniency of their uſe in certain forms, are to be kept buried in dry ſand.

Collecti &c. of Simples

There are two ſeaſons in which the biennial and perennial roots are reckoned the moſt vigorous, the autumn and ſpring; or rather the time when the ſtalks or leaves have fallen off, and that in which the vegetation is juſt to begin again, or ſoon after it has begun; which times are found to differ conſiderably in different plants.

The college of Edinburgh, in the two firſt editions of their pharmacopœia, directed them to be dug in the ſpring, after the leaves were formed; in the third edition the autumn was preferred. The generality of roots appear, indeed, to be moſt efficacious in the ſpring: but as at this time they are alſo the moſt juicy, and conſequently ſhrivel much in drying, and are rather more difficultly preſerved, it is commonly thought moſt adviſable to take them up in autumn. No rule, however, can be given, that ſhall obtain univerſally: arum root is taken even in the middle of ſummer, without ſuſpicion of its being leſs active than at other ſeaſons; while angelica root is inert during the ſummer, in compariſon of what it was in the autumn, ſpring, or winter.

HERBS and LEAVES.

Herbs are to be gathered when the leaves have come to their full growth, before the flowers unfold; but of ſome plants the flowery tops are preferred. They are to be dried in the ſame manner as roots.

For the gathering of leaves, there cannot perhaps be any univerſal rule any more than for roots; for though moſt herbs appear to be in their greateſt vigour about the time of their flowering, or a little before, there are ſome in which the medicinal parts are more abundant at an earlier period.

Thus mallow and marſhmallow leaves are moſt mucilaginous when young, and by the time of flowering approach more to a woody nature. A difference of the ſame kind is more remarkable in the leaves of certain trees and ſhrubs: the young buds, or rudiments of the leaves, of the black poplar tree, have a ſtrong fragrant ſmell, approaching to that of ſtorax; but by the time that the leaves have come to their full growth, their fragrance is exhauſted.

Herbs are directed by moſt of the pharmaceutic writers to be dried in the ſhade; a rule which appears to be very juſt, though it has ſometimes been miſunderſtood. They are not to be excluded from the ſun's *heat*, but from the ſtrong action of the ſolar *light*; by which laſt their colours are more liable to be altered or deſtroyed than thoſe of roots. Slow drying of them in a cool place is far from being of any advantage: both their colours and virtues are preſerved in greateſt perfection llection, &c. of imples.

perfection when they are dried haſtily by the heat of common fire as great as that which the ſun can impart: the juicy ones, in particular, require to be dried by heat, being otherwiſe ſubject to turn black. Odoriferous herbs, dried by fire till they become friable, diſcover indeed, in this arid ſtate, very little ſmell; not that the odorous matter is diſſipated, but on account of its not being communicated from the perfectly dry ſubject to dry air; for as ſoon as a watery vehicle is ſupplied, whether by infuſing the plant in water, or by expoſing it for a little time to a moiſt air, the odorous parts begin to be extracted by virtue of the aqueous moiſture, and diſcover themſelves in their full force.

Of the uſe of heat in the drying of plants, we have an inſtance in the treatment of tea among the Chineſe. According to the accounts of travellers, the leaves, as ſoon as gathered, are brought into an apartment furniſhed with a number of little furnaces or ſtoves, each of which is covered with a clean ſmooth iron plate; the leaves are ſpread on the plates, and kept rolling with the hands till they begin to curl up about the edges; they are then immediately ſwept off on tables, on which one perſon continues to roll them, while another fans them that they may cool haſtily: this proceſs is repeated two or three times, or oftener, according as the leaves are diſpoſed to unbend on ſtanding.

Exsiccation of Herbs and Flowers.

Herbs and flowers are to be dried by the gentle heat of a ſtove or common fire, and only in that quantity at a time by which the exſiccation may be very ſoon finiſhed. By this means their ſtrength is beſt preſerved; and this is indicated in proportion as they retain their native colour.

But the leaves of hemlock, and ſome other herbs replete with a ſubtile volatile matter, are to be powdered immediately after the exſiccation, and preſerved in glaſs veſſels, well ſhut.

Flowers.

Flowers are to be gathered when moderately expanded, on a clear dry day, before noon. Red roſes are taken before they open, and the white heels clipped off and thrown away.

The quick drying, above recommended for the leaves of plants, is more particularly proper for flowers; in moſt of which both the colour and ſmell are more periſhable than in leaves, and more ſubject to be impaired by ſlow exſiccation. Of the flowers which come freſh into the apothecaries hands, the only ones employed dry in the London pharmacopœia are red roſes; and theſe, in all the compoſitions in which they are uſed in a dry ſtate, are expreſsly ordered to be dried haſtily. One of the moſt valuable aromatics of European growth, ſaffron, is part of a flower, dried on paper on a kind of kiln, with a heat ſufficient to make it ſweat, taking care only not to endanger the ſcorching of it.

It may here be obſerved, that the virtues of flowers are confined to different parts of the flower in different plants. Saffron is a ſingular production growing at the end of the ſtyle or piſtil. The active part of camomile flowers is the yellow diſk, or button in the middle: that of lilies, roſes, clove-july-flowers, violets, and many others, the petala or flower-leaves; while roſemary has little virtue in any of theſe parts, the fragrance admired in the flowers of this plant reſiding chiefly in the cups.

Collection, &c. of Simples.

Seeds and Fruits.

Seeds ſhould be collected when ripe, and beginning to grow dry, before they fall off ſpontaneouſly. Fruits are alſo to be gathered when ripe, unleſs otherwiſe ordered.

Of the fruits whoſe collection comes under the notice of the apothecary, there are few which are uſed in an unripe ſtate; the principal is the ſloe, whoſe virtue as a mild aſtringent is much diminiſhed by maturation. The fruit of the orange tree, raiſed in our gardens or green-houſes, is ſometimes gathered in a ſtate of much greater immaturity, ſoon after it is formed on the tree, before it has acquired its acid juice; at this time it proves an elegant aromatic bitter, nearly reſembling what are called *Curaſſao oranges*, which appear to be no other than the ſame fruit gathered at the ſame period in a warmer climate.

The rule for collecting ſeeds is more general than any of the others, all the officinal ſeeds being in their greateſt perfection at the time of their maturity. As ſeeds contain little watery moiſture, they require no other warmth for drying them than that of the temperate air in autumn: ſuch as abound with a groſs expreſſible oil, as thoſe commonly called the *cold ſeeds*, ſhould never be expoſed to any conſiderable heat; for this would haſten the rancidity, which, however carefully kept, they are very liable to contract. Seeds are beſt preſerved in their natural huſks or coverings, which ſhould be ſeparated only at the time of uſing; the huſk, or cortical part, ſerving to defend the ſeed from being injured by the air.

Woods and Barks.

The moſt proper ſeaſon for the felling of woods, or ſhaving off their barks, is generally the winter.

No woods of our own growth are now retained by the London or Edinburgh colleges. The only two which had formerly a place in the catalogues of ſimples were the juniper and the box; the firſt of which is never kept in the ſhops, or employed in practice; the other may be procured from the turner; and it is indifferent at what ſeaſon it has been cut down, being at all times ſufficiently fit for the only uſe to which it was applied, the yielding an empyreumatic oil by diſtillation in a ſtrong fire.

It may be doubted, whether barks are not generally more replete with medicinal matter in ſummer and ſpring than in winter. The barks of many trees are in ſummer ſo much loaded with reſin and gum as to burſt ſpontaneouſly, and diſcharge the redundant quantity. It is ſaid that the bark of the oak anſwers beſt for the tanners at the time of the riſing of the ſap in ſpring: and as its uſe in tanning depends on the ſame aſtringent quality for which it is uſed in medicine, it ſhould ſeem to be alſo fitteſt for medicinal purpoſes in the ſpring. It may be obſerved likewiſe, that it is in

Collection, &c. of Simples.

this laſt ſeaſon that barks in general are moſt conveniently peeled off.

ANIMAL SUBSTANCES.

Animal ſubſtances are to be choſen in their moſt perfect ſtate, unleſs they be ordered otherwiſe.

Collectio &c. o Simple

Whatever virtues theſe bodies may have, they are ſuppoſed to be beſt when they have attained to their common full growth.

Material || Mathematics.

MATERIAL, denotes ſomething compoſed of *matter*. In which ſenſe the word ſtands oppoſed to *immaterial*. See MATTER and METAPHYSICS.

MATERIALISTS, a ſect in the ancient church, compoſed of perſons who, being prepoſſeſſed with that maxim in the ancient philoſophy, *Ex nihilo nihil fit*, "Out of nothing nothing can ariſe," had recourſe to an internal matter, on which they ſuppoſed God wrought in the creation; inſtead of admitting God alone as the ſole cauſe of the exiſtence of all things. Tertullian vigorouſly oppoſes the doctrine of the materialiſts in his treatiſe againſt Hermogenes, who was one of their number.

Materialiſts is alſo a name given to thoſe who maintain that the ſoul of man is material; or that the principle of perception and thought is not a ſubſtance diſtinct from the body, but the reſult of corporeal organization: See METAPHYSICS. There are others, called by this name, who have maintained that there is nothing but matter in the univerſe; and that the Deity himſelf is material. See SPINOSISM.

MATHAM (Jaques), an engraver of conſiderable eminence, was born at Haerlem in 1571, and after the death of his father, Henry Goltzius, a celebrated painter and engraver, married his mother. From his father-in-law he learned the art of engraving. He went to Italy, to complete his ſtudies from the works of the greateſt maſters; and in that country he engraved a conſiderable number of plates. At his return, he worked under the eye of Goltzius, and produced many very valuable prints. Following the example of his father-in-law, he worked entirely with the graver, in a clear, free ſtyle; and though he never equalled him in point of taſte or correctneſs of drawing, eſpecially when confined to the naked parts of the human figure, moſt of his prints are greatly eſteemed.

MATHEMATICS, the ſcience of quantity; or a ſcience that conſiders magnitudes either as computable or meaſurable.

The word in its original, μαθησις, ſignifies *diſcipline*, or *ſcience* in the general; and ſeems to have been applied to the doctrine of quantity, either by way of eminence, or becauſe, this having the ſtart of all other ſciences, the reſt took their common name therefrom, See SCIENCE.

For the origin of the mathematics, Joſephus dates it before the flood, and makes the ſons of Seth obſervers of the courſe and order of the heavenly bodies: he adds, that, to perpetuate their diſcoveries, and ſecure them from the injuries either of a deluge or a conflagration, they had them engraven on two pillars, the one of ſtone, the other of brick; the former of which he ſays was ſtanding in Syria in his days. See ASTRONOMY.

Mathematics.

The firſt who cultivated mathematics after the flood were the Aſſyrians and Chaldeans; from whom, the ſame Joſephus adds, they were carried by Abraham to the Egyptians; who proved ſuch notable proficients, that Ariſtotle makes no ſcruple to fix the firſt riſe of mathematics among them. From Egypt, 584 years before Chriſt, they paſſed into Greece through the hands of Thales; who having learned geometry of the Egyptian prieſts, taught it in his own country. After Thales, comes Pythagoras; who, among other mathematical arts, paid a particular regard to arithmetic; fetching the greateſt part of his philoſophy from numbers: he was the firſt, as Laertius tells us, who abſtracted geometry from matter; and to him we owe the doctrine of incommenſurable magnitude, and the five regular bodies, beſides the firſt principles of muſic and aſtronomy. Pythagoras was ſeconded by Anaxagoras, Œnopides, Briſo, Antipho, and Hippocrates of Scio; who all applied themſelves particularly to the quadrature of the circle, the duplicature of the cube, &c. but the laſt with moſt ſucceſs: this laſt is alſo mentioned by Proclus, as the firſt who compiled elements of mathematics,

Democritus excelled in mathematics as well as phyſics; though none of his works in either kind are extant, the deſtruction of which ſome authors lay at Ariſtotle's door. The next in order is Plato, who not only improved geometry, but introduced it into phyſics, and ſo laid the foundation of a ſolid philoſophy. Out of his ſchool proceeded a crowd of mathematicians. Proclus mentions 13 of note; among whom was Leodamus, who improved the analyſis firſt invented by Plato; Theætetus, who wrote elements; and Archiates, who has the credit of being the firſt who applied mathematics to uſe in life. Theſe were ſucceeded by Neocles and Theon, the laſt of whom contributed to the elements. Eudoxus excelled in arithmetic and geometry, and was the firſt founder of a ſyſtem of aſtronomy. Menechmus invented the conic ſections, and Theudius and Hermotimus improved the elements.

For Ariſtotle, his works are ſo ſtored with mathematics, that Blancanus compiled a whole book of them: out of his ſchool came Eudemus and Theophraſtus; the firſt of whom wrote of numbers, geometry, and inviſible lines; the latter, a mathematical hiſtory. To Ariſteus, Iſidorus, and Hypſicles, we owe the books of ſolids; which, with the other books of elements, were improved, collected, and methodiſed by Euclid, who died 284 years before Chriſt.

An hundred years after Euclid, came Eratoſthenes and Archimedes. Cotemporary with the latter was Conon, a geometrician and aſtronomer. Soon after came Apollonius Pergæus; whoſe conics are ſtill extant. To him are likewiſe aſcribed the 14th and 15th books of Euclid, which are ſaid to have been contracted

thema-
tics

ted by Hypſicles. Hipparchus and Menelaus wrote on the ſubtenſes in a circle, the latter alſo on ſpherical triangles: Theodoſius's three books of ſpherics are ſtill extant. And all theſe, Menelaus excepted, lived before Chriſt.

A. D. 70. Ptolemy of Alexandria was born; the prince of aſtronomers, and no mean geometrician: he was ſucceeded by the philoſopher Plutarch, of whom we have ſtill extant ſome mathematical problems. After him came Eutocius, who commented on Archimedes, and occaſionally mentions the inventions of Philo, Diocles, Nicomedes, Sporus, and Heron, on the duplicature of the cube. To Cteſebes of Alexandria we owe our pumps; and Geminus, who came ſoon after, is preferred by Proclus to Euclid himſelf.

Diophantus of Alexandria was a great maſter of numbers, and the firſt inventor of algebra: among others of the ancients, Nicomachus is celebrated for his arithmetical, geometrical, and muſical works; Serenus, for his books on the ſections of the cylinder; Proclus, for his comments on Euclid; and Theon has the credit, among ſome, of being author of the books of elements aſcribed to Euclid. The laſt to be named among the ancients, is Pappus of Alexandria, who flouriſhed A. D. 400, and is celebrated for his books of mathematical collections ſtill extant.

Mathematics are commonly diſtinguiſhed into *pure and ſpeculative*, which conſider quantity abſtractedly; and *mixed*, which treat of magnitude as ſubſiſting in material bodies, and conſequently are interwoven every where with phyſical conſiderations.

Mixed mathematics are very comprehenſive; ſince to them may be referred aſtronomy, optics, geography, hydroſtatics, mechanics, fortification, navigation, &c. See the articles Astronomy, Optics, &c.

Pure mathematics have one peculiar advantage, that they occaſion no diſputes among wrangling diſputants, as in other branches of knowledge; and the reaſon is, becauſe the definitions of the terms are premiſed, and every body that reads a propoſition has the ſame idea of every part of it. Hence it is eaſy to put an end to all mathematical controverſies, by ſhowing, either that our adverſary has not ſtuck to his definitions, or has not laid down true premiſſes, or elſe that he has drawn falſe concluſions from true principles; and in caſe we are able to do neither of theſe, we muſt acknowledge the truth of what he has proved.

It is true, that in mixed mathematics, where we reaſon mathematically upon phyſical ſubjects, we cannot give ſuch juſt definitions as the geometricians: we muſt therefore reſt content with deſcriptions; and they will be of the ſame uſe as definitions, provided we are conſiſtent with ourſelves, and always mean the ſame thing by thoſe terms we have once explained.

Dr Barrow gives a moſt elegant deſcription of the excellence and uſefulneſs of mathematical knowledge, in his inaugural oration, upon being appointed profeſſor of mathematics at Cambridge.

The mathematics, he obſerves, effectually exerciſe, not vainly delude, nor vexatiouſly torment, ſtudious minds with obſcure ſubtilties; but plainly demonſtrate every thing within their reach, draw certain concluſions, inſtruct by profitable rules, and unfold pleaſant queſtions. Theſe diſciplines likewiſe enure and corroborate the mind to a conſtant diligence in ſtudy; they wholly deliver us from a credulous ſimplicity, moſt ſtrongly fortify us againſt the vanity of ſcepticiſm, effectually reſtrain us from a raſh preſumption, moſt eaſily incline us to a due aſſent, and perfectly ſubject us to the government of right reaſon. While the mind is abſtracted and elevated from ſenſible matter, diſtinctly views pure forms, conceives the beauty of ideas, and inveſtigates the harmony of proportions; the manners themſelves are ſenſibly corrected and improved, the affections compoſed and rectified, the fancy calmed and ſettled, and the underſtanding raiſed and excited to more divine contemplations.

MATHER (Dr Cotton), an eminent American divine, born at Boſton in New England in the year 1663. He was educated in Harward college, and in 1684 became miniſter of Boſton; in the diligent diſcharge of which office he ſpent his life, and promoted ſeveral excellent ſocieties for the public good: particularly one for ſuppreſſing diſorders, one for reforming manners, and a ſociety of peace-makers, whoſe profeſſed buſineſs it was to compoſe differences and prevent law-ſuits. His reputation was not confined to his own country: for in 1710, the univerſity of Glaſgow ſent him a diploma for the degree of doctor in divinity; and, in 1714, the Royal Society of London choſe him one of their fellows. He died in 1728; and is ſaid to have publiſhed in his life-time 382 pieces, including ſingle ſermons, eſſays, &c. yet ſeveral were of a larger ſize, among which was *Magnalia Chriſti Americana*, or an Eccleſiaſtical Hiſtory of New-England, from its firſt planting in 1620 to 1698, folio. But the moſt remarkable of all his works was that in which, like Glanville, he defended the doctrine of witchcraft. We ſhall content ourſelves with giving the title at large, which is as follows: "The wonders of the inviſible world; being an account of the trials of ſeveral witches lately executed in New-England, and of ſeveral remarkable curioſities therein occurring. Together with, 1. Obſervations on the nature, the number, and the operations of the devils. 2. A ſhort narrative of a late outrage committed by a knot of witches in Swedeland; very much reſembling, and ſo far explaining that under which New-England has laboured. 3. Some counſels directing a due improvement of the terrible things lately done by the unuſual and amazing range of evil ſpirits in New-England. 4. A brief diſcourſe upon the temptations which are the more ordinary devices of Satan. By Cotton Mather; publiſhed by the ſpecial command of his excellency the governor of the province of Maſſachuſet's Bay in New-England." Printed firſt at Boſton in New-England, and reprinted at London, in 1736, 4to.

MATLOCK, a town or village of Derbyſhire, near Wickſworth, ſituated on the very edge of the Derwent; noted for its bath, the water of which is milk-warm; and remarkable for the huge rocks in its environs, particularly thoſe called the *Torr*, on the eaſt ſide of the Derwent, over againſt it, which ſeem to be piled one upon another. It is an extenſive ſtraggling village, built in a very romantic ſtyle, on the ſteep ſide of a mountain, riſing irregularly from the bottom to nearly the ſummit. Near the bath are ſeveral ſmall houſes, whoſe ſituation is on the little natural horizontal parts of the mountain, a few yards above the road, and in ſome places the roofs of ſome almoſt touch the floors of others. There are excellent accommodations for company who reſort to the bath; and the poorer inhabitants are ſupported by the ſale of petrifactions, cryſtals, &c. and notwithſtanding the rockineſs of the ſoil, the cliffs produce an immenſe number of trees, whoſe foliage adds greatly to the beauty of the place.

MATRASS, Cucurbit, or Bolt-head, among chemiſts. See Chemistry, nº 579.

MATRICARIA, Feverfew, in botany: A genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, *Compoſitæ*. The receptacle is naked; there is no pappus; the calyx hemiſpherical and imbricated, with the marginal leafets ſolid, and ſomething ſharp. There are five ſpecies, but the only remarkable one is the parenthium or common feverfew. This hath very fibrous cluſtering roots, crowned with numerous compound leaves; upright ſtalks branching on every ſide two or three feet high; garniſhed with compound plain leaves of ſeven oval ſolioles, cut into many parts; and all the branches terminated by many compound radiated white flowers having a yellow diſk. There are varieties with double flowers, with ſemi-double flowers, with double fiſtular flowers, with a fiſtular diſc and plain radius, with ſhort-rayed flowers, with rayleſs flowers, with rayleſs ſulphur-coloured heads, and with finely curled leaves.—All theſe varieties flower abundantly in June, each flower being compoſed of numerous hermaphrodite and female florets; the former compoſe the diſk, the latter the radius or border, and which, in the double and fiſtulous kinds, are very ornamental in gardens, but of a diſagreeable odour; and are all ſucceeded by plenty of ſeed in autumn, by which they are eaſily propagated, as well as by parting the roots and cuttings.

Medical uſes. This plant has received a moſt extraordinary character in hyſteric and other affections of the nerves, as well as for being a carminative or warm ſtimulating bitter. Dr Lewis, however, thinks it inferior to camomile; with which he ſays it agrees in all its ſenſible qualities, only being ſomewhat weaker.

MATRICE, or Matrix. See Matrix.

Matrice, or matrix, in dyeing, is applied to the five ſimple colours, whence all the reſt are derived or compoſed. Theſe are, the black, white, blue, red, and yellow or root colour.

Matrice, or matrices, uſed by the letter-founders, are thoſe little pieces of copper or braſs, at one end whereof are engraven, dent-wiſe, or *en creux*, the ſeveral characters uſed in the compoſing of books. Each character, virgula, and even each point in a diſcourſe, has its ſeveral matrix; and of conſequence, its ſeveral puncheon to ſtrike it. They are the engravers on metal that cut or grave the matrices.

When types are to be caſt, the matrice is faſtened to the end of a mould, ſo diſpoſed as that when the metal is poured on it, it may fall into the creux or cavity of the matrice, and take the figure and impreſſion thereof. See *Letter-Foundery*.

Matrices, uſed in coining, are pieces of ſteel in form of dyes, whereon are engraven the ſeveral figures, arms, characters, legends, &c. wherewith the ſpecies are to be ſtamped. The engraving is performed with ſeveral puncheons, which being formed in relievo, or prominent, when ſtruck on the metal, make an indented impreſſion, which the French call *en creux*.

MATRICULA, a regiſter kept of the admiſſion of officers and perſons entered into any body or ſociety whereof a liſt is made. Hence thoſe who are admitted into our univerſities are ſaid to be matriculated. Among eccleſiaſtical authors, we find mention made of two kinds of matriculæ; the one containing a liſt of the eccleſiaſtics called *matricula clericorum*; the other of the poor ſubſiſted at the expence of the church, called *matricula pauperum*.

Matricula was alſo applied to a kind of almshouſe, where the poor were provided for. It had certain revenues appropriated to it, and was uſually built near the church; whence the name was alſo frequently given to the church itſelf.

MATRIMONY. See Marriage.

MATRIX, in anatomy, the womb, or that part of the female of any kind, wherein the fœtus is conceived and nouriſhed till the time of its delivery. See Anatomy, nº 108.

Matrix is alſo applied to places proper for the generation of vegetables, minerals, and metals. Thus the earth is the matrix wherein ſeeds ſprout; and marcaſites are by many conſidered as the matrices of metals.

The matrix of ores is the earthy and ſtony ſubſtances in which theſe metallic matters are inveloped: theſe are very various, frequently ſpar, quartz, fluors, or horn-blend.

MATRON, an elderly married woman.

Jury of Matrons. When a widow feigns herſelf with child in order to exclude the next heir, and a ſuppoſititious birth is ſuſpected to be intended, then, upon the writ *de ventre inſpiciendo*, a jury of women is to be impanelled to try the queſtion whether the woman is with child or not. So, if a woman is convicted of a capital offence, and, being condemned to ſuffer death, pleads in ſtay of execution, that ſhe is pregnant, a jury of matrons is impanelled to inquire into the truth of the allegation; and, if they find it true, the convict is reſpited till after her delivery.

MATRONA, (anc. geog.), a river ſeparating Gallia Celtica from the Belgica (Ceſar.) Now the Marne; which, riſing in Champaign near Langres, runs north-weſt, and then weſt, and paſſing by Meaux falls into the Siene at Charenton, two leagues to the eaſt of Paris.

MATRONALIA, a Roman feſtival inſtituted by Romulus, and celebrated on the kalends of March, in honour of Mars. It was kept by matrons in particular, and bachelors were entirely excluded from any ſhare in the ſolemnity. The men during this feaſt ſent preſents to the women, for which a return was made

made by them at the Saturnalia: And the women gave the ſame indulgence to their ſervants now which the men gave to theirs at the feaſt of Saturn, ſerving them at table, and treating them as ſuperiors.

MATROSSES, are ſoldiers in the train of artillery, who are next to the gunners, and aſſiſt them in loading, firing, and ſpunging the great guns. They carry firelocks, and march along with the ſtore-waggons, both as a guard, and to give their aſſiſtance in caſe a waggon ſhould break down.

MATSYS (Quintin), painter of hiſtory and portraits, was born at Antwerp in 1460, and for ſeveral years followed the trade of a blackſmith or farrier, at leaſt till he was in his 20th year. Authors vary in their accounts of the cauſe of his quitting his firſt occupation, and attaching himſelf to the art of painting. Some affirm, that the firſt unfolding of his genius was occaſioned by the ſight of a print which accidentally was ſhown to him by a friend who came to pay him a viſit while he was in a declining ſtate of health from the labour of his former employment, and that by his copying the print with ſome degree of ſucceſs, he was animated with a deſire to learn the art of painting. Others ſay, he fell in love with a young woman of great beauty, the daughter of a painter, and they allege that love alone wrought the miracle, as he could have no proſpect of obtaining her except by a diſtinguiſhed merit in the profeſſion of painting: for which reaſon he applied himſelf with inceſſant labour to ſtudy and practiſe the art, till he became ſo eminent as to be intitled to demand her in marriage, and he ſucceeded. Whatever truth may be in either of theſe accounts, it is certain that he appeared to have an uncommon genius; his manner was ſingular, not reſembling the manner of any other maſter, and his pictures were ſtrongly coloured and carefully finiſhed, but yet they have ſomewhat dry and hard. By many competent judges it was believed, when they obſerved the ſtrength of expreſſion in ſome of his compoſitions, that if he had ſtudied in Italy to acquire ſome knowledge of the antiques and the great maſters of the Roman ſchool, he would have proved one of the moſt eminent painters of the Low Countries. But he only imitated ordinary life; and ſeemed more inclined, or at leaſt more qualified, to imitate the defects than the beauties of nature. Some hiſtorical compoſitions of this maſter deſerve commendation; particularly a deſcent from the croſs, which is in the cathedral at Antwerp; and it is juſtly admired for the ſpirit, ſkill, and delicacy of the whole. But the moſt remarkable and beſt known picture of Matſys, is that of the two miſers in the gallery at Windſor. He died in 1529. He had a ſon, *John;* who painted in the ſame ſtyle and manner, but not with a reputation equal to his father; though many of his pictures are ſold to unſkilful purchaſers for the paintings of Quintin. His moſt frequent ſubject was the repreſentation of miſers counting their gold, or bankers examining and weighing it.

MATT, in a ſhip, is a name given to rope-yarn, junk, &c. beat flat and interwoven; uſed in order to preſerve the yards from galling or rubbing in hoiſting or lowering them.

MATTER, in common language, is a word of the ſame import with *body*, and denotes that which is tangible, viſible, and extended; but among philoſophers it ſignifies that ſubſtance of which all bodies are compoſed; and in this ſenſe it is ſynonymous with the word ELEMENT.

It is only by the ſenſes that we have any communication with the external world; but the immediate objects of ſenſe, philoſophers have in general agreed to term *qualities*, which they conceive as inhering in ſomething which is called their *ſubject* or *ſubſtratum*. It is this ſubſtratum of ſenſible qualities which, in the language of philoſophy, is denominated *matter;* ſo that *matter* is *not* that which we immediately ſee or handle, but the *concealed ſubject* or *ſupport* of viſible and tangible qualities. What the moderns term *qualities*, was by Ariſtotle and his followers called *form;* but ſo far as the two doctrines are intelligible, there appears to be no eſſential difference between them. From the moderns we learn, that body conſiſts of *matter* and *qualities;* and the Peripatetics taught the ſame thing, when they ſaid that body is compoſed of *matter* and *form*.

How philoſophers were led to analyſe body into matter and form, or, to uſe modern language, into matter and qualities; what kind of exiſtence they attribute to each; and whether *matter* muſt be conceived as ſelf-exiſtent or created—are queſtions which ſhall be conſidered afterwards (See METAPHYSICS). It is ſufficient here to have defined the term.

MATTHEW, *or Goſpel of St MATTHEW*, a canonical book of the New Teſtament.

St MATTHEW wrote his goſpel in Judæa, at the requeſt of thoſe he had converted; and it is thought he began in the year 41, eight years after Chriſt's reſurrection. It was written, according to the teſtimony of all the ancients, in the Hebrew or Syriac language; but the Greek verſion, which now paſſes for the original, is as old as the apoſtolical times.

St MATTHEW the Evangeliſt's Day, a feſtival of the Chriſtian church, obſerved on September 21ſt.

St MATTHEW, the ſon of Alpheus, was alſo called *Levi*. He was of Jewiſh original, as both his names diſcover, and probably a Galilean. Before his call to the apoſtolate, he was a publican or toll-gatherer to the Romans: an office of bad repute among the Jews, on account of the covetouſneſs and exaction of thoſe who managed it; St Matthew's office particularly conſiſting in gathering the cuſtoms of all merchandize that came by the ſea of Galilee, and the tribute that paſſengers were to pay who went by water. And here it was that Matthew ſat at the receipt of cuſtom, when our Saviour called him to be a diſciple. It is probable, that, living at Capernaum, the place of Chriſt's uſual reſidence, he might have ſome knowledge of him before he was called. Matthew immediately expreſſed his ſatisfaction in being called to this high dignity, by entertaining our Saviour and his diſciples at a great dinner at his own houſe, whither he invited all his friends, eſpecially thoſe of his own profeſſion, hoping, probably, that they might be influenced by the company and converſation of Chriſt. St Matthew continued with the reſt of the apoſtles till after our Lord's aſcenſion. For the firſt eight years afterwards, he preached in Judæa. Then he betook himſelf to propagating the goſpel among the

Gentiles, and choſe Ethiopia as the ſcene of his apoſtolical miniſtry; where it is ſaid he ſuffered martyrdom, but by what kind of death is altogether uncertain. It is pretended, but without any foundation, that Hyrtacus, king of Ethiopia, deſiring to marry Iphigenia, the daughter of his brother and predeceſſor Æglippus, and the apoſtle having repreſented to him that he could not lawfully do it, the enraged prince ordered his head immediately to be cut off. Baronius tells us, the body of St Matthew was tranſported from Ethiopia to Bithynia, and from thence was carried to Salernum in the kingdom of Naples in the year 954, where it was found in 1080, and where duke Robert built a church bearing his name.

St Matthew, a town of Spain, in the kingdom of Arragon, ſeated in a pleaſant plain, and in a very fertile country watered with many ſprings. W. Long. 0. 15. N. Lat. 40. 22.

Matthew of Paris. See Paris.

Matthew of Weſtminſter, a Benedictine monk and accompliſhed ſcholar, who wrote a hiſtory from the beginning of the world to the end of the reign of Edward I. under the title of *Flores Hiſtoriarum;* which was afterwards continued by other hands. He died in 1380.

St MATTHIAS, an apoſtle, was choſen inſtead of Judas. He preached in Judæa and part of Æthiopia, and ſuffered martyrdom. See the *Acts of the Apoſtles*, chap. i. There was a goſpel publiſhed under Matthias's name, but rejected as ſpurious; as likewiſe ſome traditions, which met with the ſame fate.

St Matthias's Day; a feſtival of the Chriſtian church, obſerved on the 24th of February. St Matthias was an apoſtle of Jeſus Chriſt, but not of the number of the twelve choſen by Chriſt himſelf. He obtained this high honour upon a vacancy made in the college of the apoſtles by the treaſon and death of Judas Iſcariot. The choice fell on Matthias by lot; his competitor being Joſeph called *Barſabas*, and ſirnamed *Juſtus*. Matthias was qualified for the apoſtleſhip, by having been a conſtant attendant upon our Saviour all the time of his miniſtry. He was, probably, one of the 70 diſciples. After our Lord's reſurrection, he preached the goſpel firſt in Judæa. Afterwards it is probable he travelled eaſtwards, his reſidence being principally near the irruption of the river Apſarus and the haven Hyſſus. The barbarous people treated him with great rudeneſs and inhumanity; and, after many labours and ſufferings in converting great numbers to Chriſtianity, he obtained the crown of martyrdom; but by what kind of death, is uncertain.—They pretend to ſhow the relics of St Matthias at Rome; and the famous abbey of St Matthias near Treves boaſts of the ſame advantage; but doubtleſs both without any foundation. There was a goſpel aſcribed to St Matthias; but it was univerſally rejected as ſpurious.

MATTIACÆ Aquæ, or Mattiaci Fontes, (anc. geog.), now Wiſbaden, oppoſite to Mentz, in the Weteravia. E. Long. 8. N. Lat. 50. 6.

MATTIACUM, or Mattium, (anc. geog.), a town of the Mattiaci, a branch of the Catti in Germany. Now Marpurg in Heſſe. E. Long. 8. 40. N. Lat. 50. 40.

MATTINS, the firſt canonical hour, or the firſt part of the daily ſervice, in the Romiſh church.

MATTHIOLUS (Peter Andrew), an eminent phyſician in the 16th century, born at Sienna, was well ſkilled in the Greek and Latin tongues. He wrote learned commentaries on Dioſcorides, and other works which are eſteemed; and died in 1577.

MATURANTS, in pharmacy, medicines which promote the ſuppuration of tumors.

MATY (Matthew), M. D. an eminent phyſician and polite writer, was born in Holland in the year 1718. He was the ſon of a clergyman, and was originally intended for the church; but in conſequence of ſome mortifications his father met with from the ſynod, on account of ſome particular ſentiments he entertained about the doctrine of the Trinity, turned his thoughts to phyſic. He took his degree of M. D. at Leyden; and in 1740 came to ſettle in England, his father having determined to quit Holland for ever. In order to make himſelf known, in 1749 he began to publiſh in French an account of the productions of the Engliſh preſs, printed at the Hague under the name of the *Journal Britannique.* This journal, which continues to hold its rank amongſt the beſt of thoſe which have appeared ſince the time of Bayle, anſwered the chief end he intended by it, and introduced him to the acquaintance of ſome of the moſt reſpectable literary characters of the country he had made his own. It was to their active and uninterrupted friendſhip he owed the places he afterwards poſſeſſed. In 1758 he was choſen fellow; and in 1765, on the reſignation of Dr Birch, who died a few months after and made him his executor, ſecretary to the royal ſociety. He had been appointed one of the under librarians of the Britiſh muſeum at its firſt inſtitution in 1753, and became principal librarian at the death of Dr Knight in 1772. Uſeful in all theſe poſts, he promiſed to be eminently ſo in the laſt, when he was ſeized with a languiſhing diſorder, which in 1776 put an end to a life which had been uniformly devoted to the purſuit of ſcience and the offices of humanity. He was an early and active advocate for inoculation; and when there was a doubt entertained that one might have the ſmall-pox this way a ſecond time, tried it upon himſelf unknown to his family. He was a member of the medical club (with the Drs Parſons, Templeman, Fothergill, Watſon, and others), which met every fortnight in St Paul's churchyard. He was twice married, *viz.* the firſt time to Mrs Elizabeth Boiſragon; and the ſecond to Mrs Mary Deners. He left a ſon and three daughters. He had nearly finiſhed the Memoirs of the Earl of Cheſterfield; which were completed by his ſon-in law Mr Juſtamond, and prefixed to that nobleman's Miſcellaneous Works, 1777, 2 vols 4to.

Maty (Paul Henry), M. A. F. R. S. ſon of the former, was educated at Weſtminſter and Trinity college Cambridge, and had their travelling fellowſhip for three years. He was afterwards chaplain to Lord Stormont at Paris in 17.., and ſoon after vacated his next fellowſhip by marrying one of the three daughters of Joſeph Clark, Eſq; ſiſter of the late Captain Charles Clark (who ſucceeded to the command on the death of Captain Cook). On his father's death in 1776, he ſucceeded to the office of one of the under librarians of

Maty || Maupertuis.

Maupertuis.

of the Britiſh muſeum, and was afterwards preferred to a ſuperior department, having the care of the antiquities, for which he was eminently well qualified. In 1776 he alſo ſucceeded his father in the office of ſecretary to the royal ſociety. On the diſputes reſpecting the reinſtatement of Dr Hutton in the department of ſecretary for foreign correſpondence 1784, Mr Maty took a warm and diſtinguiſhed part, and reſigned the office of ſecretary; after which he undertook to aſſiſt gentlemen or ladies in perfecting their knowledge of the Greek, Latin, French, and Italian claſſics. Mr Maty was a thinking conſcientious man; and having conceived ſome doubts about the articles he had ſubſcribed in early life, he never could be prevailed upon to place himſelf in the way of eccleſiaſtical preferment, though his connections were amongſt thoſe who could have ſerved him eſſentially in this point; and ſoon after his father's death he withdrew himſelf from miniſtering in the eſtabliſhed church, his reaſons for which he publiſhed in the 47th volume of the Gent. Magazine, p. 466. His whole life was thenceforwards taken up in literary purſuits. He received 100l. from the duke of Marlborough, with a copy of that beautiful work the *Gemmæ Marlburienſes*, of which only 100 copies were worked off for preſents; and of which Mr Maty wrote the French account, as Mr Bryant did the Latin. In January 1782 he ſet on foot a Review of publications, principally foreign, which he carried on, with great credit to himſelf and ſatisfaction to the public, for near five years, when he was obliged to diſcontinue it from ill health. He had long laboured under an aſthmatic complaint, which at times made great ravages in his conſtitution, and at laſt put a period to his life in Jan. 1787, at the age of 42; leaving behind him one ſon.—Mr Maty enjoyed a reſpectable rank in the republic of letters, and by his talents and attainments was fully intitled to it. He was eminently acquainted with ancient and modern literature, and particularly converſant in critical reſearches. The purity and probity of his nature were unqueſtionable; and his humanity was as exquiſite as it would have been extenſive, had it been ſeconded by his fortune.

MAUCAUCO, MACACO, or *Maki*, in zoology. See LEMUR, n° 4.

MAVIS, in ornithology, a ſpecies of turdus. See TURDUS.

MAUBEUGE, a town of the Netherlands, in Hainault, with an illuſtrious abbey of canoneſſes, who muſt be noble both by the father and mother's ſide. This place was ceded to France in 1678; and fortified after the manner of Vauban. It is ſeated on the river Sambre, in E. Long. 5. 0. N. Lat. 50. 15.

MAUNCH, in heraldry, the figure of an ancient coat ſleeve, borne in many gentlemens eſcutcheons.

MAUNDY THURSDAY, is the Thurſday in Paſſion week; which was called *Maundy* or *Mandate Thurſday*, from the command which our Saviour gave his apoſtles to commemorate him in the Lord's ſupper, which he this day inſtituted; or from the new commandment which he gave them to love one another, after he had waſhed their feet as a token of his love to them.

MAUPERTUIS (Peter Louis Morceau de), a celebrated French academician, was born at St Malo in 1698; and was there privately educated till he arrived at his 16th year, when he was placed under the celebrated profeſſor of philoſophy M. le Blond, in the college of la Marche, at Paris. He ſoon diſcovered a paſſion for mathematical ſtudies, and particularly for geometry. He likewiſe practiſed inſtrumental muſic in his early years with great ſucceſs; but fixed on no profeſſion till he was 20, when he entered into the army. He firſt ſerved in the Grey Muſqueteers; but in the year 1720, his father purchaſed him a company of cavalry in the regiment of La Rocheguyon. He remained but five years in the army, during which time he purſued his mathematical ſtudies with great vigour; and it was ſoon remarked by M. Freret and other academicians, that nothing but geometry could ſatisfy his active ſoul and unbounded thirſt for knowledge. In the year 1723, he was received into the Royal Academy of Sciences, and read his firſt performance, which was a memoir upon the conſtruction and form of muſical inſtruments, November 15. 1724. During the firſt years of his admiſſion he did not wholly confine his attention to mathematics; he dipt into natural philoſophy, and diſcovered great knowledge and dexterity in obſervations and experiments upon animals. If the cuſtom of travelling into remote climates, like the ſages of antiquity, in order to be initiated into the learned myſteries of thoſe times, had ſtill ſubſiſted, no one would have conformed to it with greater eagerneſs than M. de Maupertuis. His firſt gratification of this paſſion was to viſit the country which had given birth to Newton; and during his reſidence at London he became as zealous an admirer and follower of that philoſopher as of any one of his own countrymen. His next excurſion was to Baſil in Switzerland, where he formed a friendſhip with the famous John Bernouilli and his family, which continued to his death. At his return to Paris, he applied himſelf to his favourite ſtudies with greater zeal than ever: —And how well he fulfilled the duties of an academician, may be gathered by running over the memoirs of the academy from the year 1724 to 1736; where it appears that he was neither idle nor occupied by objects of ſmall importance. The moſt ſublime queſtions in geometry and the relative ſciences received from his hands that elegance, clearneſs, and preciſion, ſo remarkable in all his writings. In the year 1736, he was ſent by the king of France to the polar circle, to meaſure a degree in order to aſcertain the figure of the earth, accompanied by Meſſrs Clairault, Camus, Le Monnier, l'Abbé Outhier, and Celſius the celebrated profeſſor of aſtronomy at Upſal. This diſtinction rendered him ſo famous, that, at his return, he was admitted a member of almoſt every academy in Europe.

In the year 1740 Maupertuis had an invitation from the king of Pruſſia to go to Berlin; which was too flattering to be refuſed. His rank among men of letters had not wholly effaced his love for his firſt profeſſion, namely, that of arms. He followed his Pruſſian majeſty into the field, and was a witneſs of the diſpoſitions and operations that preceded the battle of Molwitz; but was deprived of the glory of being preſent, when victory declared in favour of his royal patron, by a ſingular kind of adventure. His horſe, during the heat of the action, running away with him, he fell into the hands of the enemy; and was at firſt

Maupertuis.

but roughly treated by the Auſtrian ſoldiers, to whom he could not make himſelf known for want of language; but being carried priſoner to Vienna, he received ſuch honours from their imperial majeſties as were never effaced from his memory. From Vienna he returned to Berlin; but as the reform of the academy which the king of Pruſſia then meditated was not yet mature, he went again to Paris, where his affairs called him, and was choſen in 1742 director of the academy of ſciences. In 1743 he was received into the French academy; which was the firſt inſtance of the ſame perſon being a member of both the academies at Paris at the ſame time. M. de Maupertuis again aſſumed the ſoldier at the ſiege of Fribourg, and was pitched upon by marſhal Cogny and the count d'Argenſon to carry the news to the French king of the ſurrender of that citadel.

He returned to Berlin in the year 1744, when a marriage was negotiated and brought about, by the good offices of the queen-mother, between our author and mademoiſelle de Borck, a lady of great beauty and merit, and nearly related to M. de Borck at that time miniſter of ſtate. This determined him to ſettle at Berlin, as he was extremely attached to his new ſpouſe, and regarded this alliance as the moſt fortunate circumſtance of his life.

In the year 1746, M. de Maupertuis was declared by his Pruſſian majeſty preſident of the royal academy of ſciences at Berlin, and ſoon after by the ſame prince was honoured with the order of Merit: However, all theſe accumulated honours and advantages, ſo far from leſſening his ardour for the ſciences, ſeemed to furniſh new allurements to labour and application. Not a day paſſed but he produced ſome new project or eſſay for the advancement of knowledge. Nor did he confine himſelf to mathematical ſtudies only: metaphyſics, chemiſtry, botany, polite literature, all ſhared his attention, and contributed to his fame. At the ſame time, he had, it ſeems, a ſtrange inquietude of ſpirit, with a dark atrabilaire humour, which rendered him miſerable amidſt honours and pleaſures. Such a temperament did not promiſe a very pacific life; and he was engaged in ſeveral quarrels. He had a quarrel with Koenig the profeſſor of philoſophy at Franeker, and another more terrible with Voltaire. Maupertuis had inſerted into the volume of Memoirs of the Academy of Berlin for 1746, a diſcourſe upon the laws of motion; which Koenig was not content with attacking, but attributed to Leibnitz. Maupertuis, ſtung with the imputation of plagiariſm, engaged the academy of Berlin to call upon him for his proof; which Koenig failing to produce, he was ſtruck out of the academy, of which he was a member. Several pamphlets were the conſequence of this; and Voltaire, for ſome reaſon or other, engaged againſt Maupertuis. We ſay, for ſome reaſon or other: becauſe Maupertuis and Voltaire were apparently upon the moſt amicable terms; and the latter reſpected the former as his maſter in the mathematics. Voltaire, however, exerted all his wit and ſatire againſt him; and on the whole was ſo much tranſported beyond what was thought right, that he found it expedient in 1753 to quit the court of Pruſſia.

Our philoſopher's conſtitution had long been conſiderably impaired by the great fatigues of various kinds in which his active mind had involved him; though from the amazing hardſhips he had undergone in his northern expedition, moſt of his future bodily ſufferings may be traced. The intenſe ſharpneſs of the air could only be ſupported by means of ſtrong liquors; which helped but to lacerate his lungs, and bring on a ſpitting of blood, which began at leaſt 12 years before he died. Yet ſtill his mind ſeemed to enjoy the greateſt vigour; for the beſt of his writings were produced, and moſt ſublime ideas developed, during the time of his confinement by ſickneſs, when he was unable to occupy his preſidial chair at the academy. He took ſeveral journeys to St Malo, during the laſt years of his life, for the recovery of his health: And though he always received benefit by breathing his native air, yet ſtill, upon his return to Berlin, his diſorder likewiſe returned with greater violence.—His laſt journey into France was undertaken in the year 1757; when he was obliged, ſoon after his arrival there, to quit his favourite retreat at St Malo, on account of the danger and confuſion which that town was thrown into by the arrival of the Engliſh in its neighbourhood. From thence he went to Bourdeaux, hoping there to meet with a neutral ſhip to carry him to Hamburgh, in his way back to Berlin; but being diſappointed in that hope, he went to Toulouſe, where he remained ſeven months. He had then thoughts of going to Italy, in hopes a milder climate would reſtore him to health; but finding himſelf grow worſe, he rather inclined towards Germany, and went to Neufchatel, where for three months he enjoyed the converſation of Lord Mariſchal, with whom he had formerly been much connected. At length he arrived at Baſil, October 16. 1758, where he was received by his friend Bernouilli and his family with the utmoſt tenderneſs and affection. He at firſt found himſelf much better here than he had been at Neufchatel: but this amendment was of ſhort duration; for as the winter approached, his diſorder returned, accompanied by new and more alarming ſymptoms. He languiſhed here many months, during which he was attended by M. de la Condamine; and died in 1759.

He wrote in French, 1. The figure of the earth determined. 2. The meaſure of a degree of the meridian. 3. A diſcourſe on the parallax of the moon. 4. A diſcourſe on the figure of the ſtars. 5. The elements of geography. 6. Nautical aſtronomy. 7. Elements of aſtronomy. 8. A phyſical diſſertation on a white inhabitant of Africa. 9. An eſſay on coſmography. 10. Reflections on the origin of languages. 11. An eſſay on moral philoſophy. 12. A letter on the progreſs of the ſciences. 13. An eſſay on the formation of bodies. 14. An eulogium on M. de Monteſquieu. 15. Letters, and other works.

MAUR (St), was a celebrated diſciple of St Benedict. If we can believe a life of St Maur aſcribed to Fauſtus his companion, he was ſent by Benedict on a miſſion to France. But this life is conſidered as apocryphal. In rejecting it, however, as well as the circumſtances of the miſſion, we muſt beware of denying the miſſion itſelf. It is certain that it was believed in France as early as the 9th century; and notwithſtanding the ſilence of Bede, Gregory of Tours, and others, there are ſeveral documents which prove this, or at leaſt render it extremely probable. A celebrated ſociety of benedictines took the name of *St Maur* in the beginning of the laſt century, and received the ſanction of Pope Gregory XV. in 1621. This ſociety was early diſtinguiſhed by the virtue and the knowledge of its members, and it ſtill ſupports the character. There are perhaps fewer eminent men in it than formerly; but this muſt be aſcribed to the levity of the age, and partly to the little encouragement for the reſearches of learned men. The chief perſons of ingenuity which this ſociety has produced are, the Fathers Menard, d'Acheri, Mabillon, Ruinart, Germain, Lami, Montfaucon, Martin, Vaiſſette, le Nourri, Martianay, Martenne, Maſſuet, &c. &c. See *L'Hiſtoire Letteraire de le Congregation de St Maur*, publiſhed at Paris under the title of *Bruſſels*, in 4to, 1770, by Dom. Taſſin.

MAURICEAU (Francis), a French ſurgeon, who applied himſelf with great ſucceſs and reputation to the theory and practice of his art for ſeveral years at Paris. Afterwards he confined himſelf to the diſorders of pregnant and lying-in women, and was at the head of all the operators in this way. His *Obſervations ſur la groſſeſſe* and *ſur l' accouchement des femmes, ſur leurs maladies, et celles des enfans nouveaux*, 1694, in 4to, is reckoned an excellent work, and has been tranſlated into ſeveral languages; German, Flemiſh, Italian, Engliſh: and the author himſelf tranſlated it into Latin. It is illuſtrated with cuts. He publiſhed another piece or two, by way of ſupplement, on the ſame ſubject; and died at Paris in 1709.

MAURICE (St) commander of the Theban legion, was a Chriſtian, together with the officers and ſoldiers of that legion, amounting to 6600 men.—This legion received its name from the city Thebes in Egypt, where it was raiſed. It was ſent by Diocleſian to check the Bagaudac, who had excited ſome diſturbances in Gaul. Maurice having carried his troops over the Alps, the emperor Maximinian commanded him to employ his utmoſt exertions to extirpate Chriſtianity. This propoſal was received with horror both by the commander and by the ſoldiers.—The emperor, enraged at their oppoſition, commanded the legion to be decimated; and when they ſtill declared that they would ſooner die than do any thing prejudicial to the Chriſtian faith, every tenth man of thoſe who remained was put to death. Their perſeverance excited the emperor to ſtill greater cruelty; for when he ſaw that nothing could make them relinquiſh their religion, he commanded his troops to ſurround them, and cut them to pieces. Maurice, the commander of theſe Chriſtian heroes, and Exuperus and Candidus, officers of the legion, who had chiefly inſtigated the ſoldiers to this noble reſiſtance, ſignalized themſelves by their patience and their attachment to the doctrines of the Chriſtian religion. They were maſſacred, it is believed, at Agaune, in Chablais, the 22d of September 286.—Notwithſtanding many proofs which ſupport this tranſaction, Dubordier, Hottinger, Moyle, Burnet, and Moſheim, are diſpoſed to deny the fact. It is defended, on the other hand, by Hickes an Engliſh writer, and by Dom Joſeph de Liſle a benedictine monk *de la congregation de Saint Vannes*, in a work of his, intitled, *Defence de la Verité du Martyre de la Legion Thebenne*, 1737. In defence of the ſame fact, the reader may conſult *Hiſtoria di S. Mauritie*, by P. Roſſignole a Jeſuit, and the *Acta Sanctorum* for the month of September. The martyrdom of this legion, written by St Eucherius biſhop of Lyons, was tranſmitted to poſterity in a very imperfect manner by Surius. P. Chifflet a Jeſuit, diſcovered, and gave to the public, an exact copy of this work. Don Ruinart maintains, that it has every mark of authenticity. St Maurice is the patron of a celebrated order in the king of Sardinia's dominions, created by Emmanuel Philibert duke of Savoy, to reward military merit, and approved by Gregory XIII. in 1572. The commander of the Theban legion muſt not be confounded with another *St Maurice*, mentioned by Theodoret, who ſuffered martyrdom at Apamea, in Syria.

MAURICE (Mauritius Tiberius), was born at Arabiſſus in Cappadocia, A. D. 539. He was deſcended from an ancient and honourable Roman family.—After he had filled ſeveral offices in the court of Tiberius Conſtantine, he obtained the command of his armies againſt the Perſians. His gallantry was ſo conſpicuous, that the emperor gave him his daughter Conſtantina in marriage, and inveſted him with the purple the 13th Auguſt 582. The Perſians ſtill continued to make inroads on the Roman territories, and Maurice ſent Philippicus, his brother-in-law, againſt them. This general conducted the war with various ſucceſs. At firſt he gained ſeveral ſplendid victories, but he did not continue to have a decided ſuperiority. As there was great uſe for ſoldiers in theſe unfortunate times, the emperor iſſued a mandate in 592, forbidding any ſoldier to become a monk till he had accompliſhed the term of his military ſervice. Maurice acquired much glory in reſtoring Choſroes II. king of Perſia, to the throne, after he had been depoſed by his ſubjects. The empire was in his reign haraſſed by the frequent inroads of the Arabian tribes. He purchaſed peace from them by granting them a penſion nearly equal to 100,000 crowns; but theſe barbarians took frequent opportunities to renew the war. In different engagements the Romans deſtroyed 50,000, and took 17,000 priſoners. Theſe were reſtored, on condition that the king of the Abari ſhould return all the Roman captives in his dominions. Regardleſs of his promiſe, he demanded a ranſom of 10,000 crowns. Maurice, full of indignation, refuſed the ſum; and the barbarian, equally enraged, put the captives to the ſword. While the emperor, to revenge this cruelty, was making preparations againſt the Abari, Phocas, who from the rank of a centurion had attained the higheſt military preferment, aſſumed the purple, and was declared emperor. He purſued Maurice to Chalcedon, took him priſoner, and condemned him to die. The five ſons of this unfortunate prince were maſſacred before his eyes; and Maurice, humbling himſelf under the hand of God, was heard to exclaim, *Thou art juſt, O Lord, and thy judgments are without partiality*. He was beheaded on the 26th November 602, in the 63d year of his age and 20th of his reign. Many writers have eſtimated the character of this prince by his misfortunes inſtead of his actions. They believed him guilty without evidence, and condemned him without reaſon. It cannot be denied, however, that he allowed Italy to be haraſſed, but he was a father to the reſt of the empire. He reſtored the military diſcipline, humbled the pride of his enemies, ſupported the Chriſtian religion by his laws, and piety by his example. He loved the ſciences, and was the patron of learned men.

Maurice, elector of Saxony, ſon of Henry le Pieux, was born A. D. 1521. He was early remarkable for his courage, and during his whole life he was engaged in warlike purſuits. He ſerved under the emperor Charles V. in the campaign of 1544 againſt France; and in the year following againſt the league of Smalkalde; with which, although a Proteſtant, he would have no manner of connection. The emperor, as a reward for his ſervices, in the year 1547, made him elector of Saxony, having deprived his couſin John Frederick of that electorate. Ambition had led him to ſecond the views of Charles, in the hope of being elector, and ambition again detached him from that prince. In 1551 he entered into a league againſt the emperor, together with the elector of Brandenburgh, the Count Palatine, the duke of Wirtemburg, and many other princes. This league, encouraged by the young and enterpriſing Henry II. of France, was more dangerous than that of Smalkalde. The pretext for the aſſociation was the deliverance of the Landgrave of Heſſe, whom the emperor kept priſoner. Maurice and the confederates marched, in 1552, to the defiles of Tirol, and put to flight the Imperial troops who guarded them. The emperor and his brother Ferdinand narrowly eſcaped, and fled from the conquerors in great diſorder. Charles having retired into Paſſau, where he had collected an army, brought the princes of the league to terms of accommodation. By the famous peace of Paſſau, which was finally ratified the 12th of Auguſt 1552, the emperor granted an amneſty without exception to all thoſe who had carried arms againſt him from the year 1546. The Proteſtants not only obtained the free exerciſe of their religion, but they were admitted into the imperial chamber, from which they had been excluded ſince the victory of Mulberg.—Maurice ſoon after united himſelf with the emperor againſt the Margrave of Brandenburg, who laid waſte the German provinces. He engaged him in 1553, gained the battle of Siverſhauſen, and died of the wounds he had received in the engagement two days after. He was one of the greateſt protectors of the Lutherans in Germany, and a prince equally brave and politic. After he had profited by the ſpoils of John Frederick, the chief of the Proteſtants, he became himſelf the leader of the party, and by theſe means maintained the balance of power againſt the emperor in Germany.

Maurice de Naſſau, prince of Orange, ſucceeded to the government of the Low Countries after the death of his father William, who was killed in 1584 by the fanatic Gerard. The young prince was then only eighteen years of age, but his courage and abilities were above his years. He was appointed captain general of the United Provinces, and he reared that edifice of liberty of which his father had laid the foundation. Breda ſubmitted to him in 1590; Zutphen, Deventer, Hulſt, Nimeguen, in 1591. He gained ſeveral important advantages in 1592, and in the year following he made himſelf maſter of Gertrudemburg. When he had performed theſe ſplendid ſervices, he returned to the Low Countries by the way of Zealand. His fleet was attacked by a dreadful tempeſt, in which he loſt forty veſſels, and he himſelf had very nearly periſhed. His death would have been conſidered by the Hollanders as a much greater calamity than the loſs of their veſſels. They watched over his ſafety with exceeding care. In 1594, one of his guards was accuſed of an intention to take away his life; and it was generally believed that he was bribed to this ſervice by the enemies of the republic. He fell a ſacrifice at Bruges, either to his own fanaticiſm or to the jealous anxiety of the friends of Maurice. The prince of Orange, increaſing in reputation, defeated the troops of the archduke Albert in 1597, and drove the Spaniards entirely out of Holland. In 1600 he was obliged to raiſe the ſiege of Dunkirk; but he took ample vengeance on Albert, whom he again defeated in a pitched battle near Newport. Before the action, this great general ſent back the ſhips which had brought his troops into Flanders: *My brethren* (ſaid he to his army), *we muſt conquer the enemy or drink up the waters of the ſea. Determine for yourſelves; I have determined I ſhall either conquer by your bravery, or I ſhall never ſurvive the diſgrace of being conquered by men in every reſpect our inferiors.* This ſpeech elevated the ſoldiers to the higheſt pitch of enthuſiaſm, and the victory was complete. Rhinberg, Grave, and Ecluſe, cities in Flanders, ſubmitted to the conqueror the following year. Maurice, however, not only laboured for the commonwealth, but alſo for himſelf. He coveted the ſovereignty of Holland, and was oppoſed in the proſecution of his deſign by the penſioner Barneveldt. The zeal and activity of this wiſe republican coſt him his life. He was an Arminian; and at this time Maurice defended Gomar againſt Arminius.—Taking advantage of the general odium under which the Arminians lay, he found means to get Barneveldt condemned in 1619. His death, wholly owing to the cruel ambition of the prince of Orange, made a deep impreſſion on the minds of the Hollanders. The truce with Spain being expired, Spinola laid ſiege to Breda in 1624, and in ſix months, by the proper direction of his great talents, though with great ſlaughter of his troops, he took the place. The prince of Orange, unſucceſsful in every attempt to raiſe the ſiege, died of vexation in 1625, aged 55 years, with the reputation of the greateſt warrior of his time.—"The life of this Stadtholder (ſays the Abbé Raynal) was almoſt an uninterrupted ſeries of battles, of ſieges, and of victories. Of moderate abilities in every thing elſe, he ſhone conſpicuous in his military capacity. His camp was the ſchool of Europe, and thoſe who received their military education in his armies augmented, perhaps, the glory of their maſter.—Like Montecuculi, he diſcovered inimitable ſkill in his marches and encampments; like Vauban, he poſſeſſed the talent of fortifying places, and of rendering them impregnable; like Eugene, the addreſs of finding ſubſiſtence for great armies, in countries barren by nature, or ravaged by war; like Vendome, the happy talent of calling forth, in the moment they became neceſſary, greater exertions from his ſoldiers than could reaſonably be expected; like Conde, that infallible quickneſs of eye which decides the fortune of battles; like Charles XII. the art of rendering his troops almoſt invincible to cold, hunger, and fatigue; like Turenne, the ſecret of making war with the leaſt poſſible expence of human blood." The Chevalier Folard maintains, that Maurice was the greateſt commander of infantry ſince the time of the Romans. He ſtudied the military art of the ancients, and applied their rules with great exactneſs in the various occurrences of war. He not only took advantage of the inventions of others, but he enriched the ſcience of war with ſeveral improvements. Teleſcopes were firſt uſed by him for a military purpoſe; and, beſides a kind of gallery in conducting a ſiege, and the plan of blockading a ſtrong place, which were of his invention, he greatly improved the whole art by his method of puſhing an attack with great vigour, and of defending, for the greateſt length of time, and in the beſt manner, a place beſieged. In ſhort, the many uſeful things which he practiſed or invented, placed him in the higheſt rank among men of a military character. On one occaſion, a lady of quality aſked him, *who was the firſt general of the age? Spinola* (replied he) *is the ſecond*. It was his conſtant practice, during ſleep, to have two guards placed by his bedſide, not only to defend him in caſe of danger, but to awake him if there ſhould be the leaſt occaſion. The war betwixt Spain and Holland was never carried on with greater keenneſs and animoſity than during his adminiſtration.—The Grand Signior, hearing of the vaſt torrents of blood ſhed in this conteſt, thought that a great empire muſt depend on the deciſion. The object of ſo many battles was pointed out to him on a map, and he ſaid coldly, *If it were my buſineſs, I would ſend my pioneers, and order them to caſt this little corner of earth into the ſea.* Maurice, like many great men, was impatient under contradiction, and too much devoted to women. He was ſucceeded by Frederic Henry his brother.

MAURITANIA, an ancient kingdom of Africa, bounded on the weſt by the Atlantic ocean, on the ſouth by Getulia or Lybia Interior, and on the north by the Mediterranean, and comprehending the greater part of the kingdoms of Fez and Morocco.—Its ancient limits are not exactly mentioned by any hiſtorian; neither can they now be aſcertained by any modern obſervations, theſe kingdoms being but little known to Europeans.

This country was originally inhabited by a people called *Mauri*, concerning the etymology of which name authors are not agreed. It is probable, however, that this country, or at leaſt a great part of it, was firſt called *Phut*, ſince it appears from Pliny, Ptolemy, and St Jerom, that a river and territory not far from Mount Atlas went by that name. From the Jeruſalem Targum it likewiſe appears, that part of the Mauri may be deemed the offspring of Lud the ſon of Miſraim, ſince his deſcendents, mentioned Geneſis x. are there called מרוטאי, *Mauri*, or *Mauritani*. It is certain, that this region, as well as the others to the eaſtward of it, had many colonies planted in it by the Phœnicians. Procopius tells us, that in his time two pillars of white ſtone were to be ſeen there, with the following inſcription in the Phœnician language and character, upon them: "We are the *Canaanites*, that fled from *Joſhua* the ſon of Nun, that notorious robber." *Ibnu Rachic*, or *Ibnu Raquig*, an African writer cited by Leo, together with Evagrius and Nicephorus Calliſtus, aſſert the ſame thing.

The Mauritanians, according to Ptolemy, were divided into ſeveral cantons or tribes. The *Metagonitæ* were ſeated near the ſtraits of Hercules, now thoſe of Gibraltar. The *Saccoſii*, or *Cocoſii*, occupied the coaſt of the Iberian ſea. Under theſe two petty nations the *Maſices*, *Verues*, and *Verbicæ* or *Vervicæ*, were ſettled. The *Saliſæ*, or *Salinſæ*, were ſituated lower, towards the ocean; and, ſtill more to the ſouth, the *Volubiliani*. The *Maurenſii* and *Herpiditani* poſſeſſed the eaſtern part of this country, which was terminated by the *Mulucha*. The *Angaucani* or *Jangacaucani*, *Nectiberes*, *Zagrenſii*, *Baniubæ*, and *Vacuntæ*, extended themſelves from the ſouthern foot of Ptolemy's Atlas Minor to his Atlas Major. Pliny mentions the *Baniuræ*, whom Father Hardouin takes to be Ptolemy's Baniubæ; and Mela the Atlantes, whom he repreſents as poſſeſſed of the weſtern parts of this diſtrict.

The earlieſt prince of Mauritania mentioned in hiſtory is Neptune; and next to him were Atlas and Antæus his two ſons, both famous in the Grecian fables on account of their wars with Hercules. Antæus, in his contention with that hero, ſeems to have behaved with great bravery and reſolution. Having received large reinforcements of Libyan troops, he cut off great numbers of Hercules's men. But that celebrated commander, having at laſt intercepted a ſtrong body of Libyans ſent to the relief of Antæus, gave him a total overthrow, wherein both he and the beſt part of his forces were put to the ſword. This deciſive action put Hercules in poſſeſſion of Libya and Mauritania, and conſequently of the riches of all theſe kingdoms. Hence came the fable, that Hercules, finding Antæus, a giant of an enormous ſize with whom he was engaged in ſingle combat, to receive freſh ſtrength as often as he touched his mother earth when thrown upon her, at laſt lifted him up in the air and ſqueezed him to death. Hence likewiſe may be deduced the fable intimating that Hercules took the globe from Atlas upon his own ſhoulders, overcame the dragon that guarded the orchards of the Heſperides, and made himſelf maſter of all the golden fruit there. Bochart thinks that the fable alluded chiefly to naval engagements, wherein Hercules, for the moſt part, was victorious; though Antæus from time to time received ſuccours by ſea. But at laſt Hercules, coming up with one of his ſquadrons which had a ſtrong reinforcement on board, made himſelf maſter of it, and thus rendered Antæus incapable for the future of making head againſt him. The ſame author likewiſe inſinuates, that the notion of Antæus's gigantic ſtature prevailing for ſo many centuries amongſt the Tingitanians, pointed out the ſize of the veſſels of which his fleets and ſquadrons were compoſed. As for the golden apples ſo frequently mentioned by the old mythologiſts, they were the treaſures that fell into Hercules's hands upon the defeat of Antæus; the Greeks giving the oriental word מאל, *riches*, the ſignification affixed to their own term αηλα, *apples*.

With regard to the age in which Atlas and Antæus lived, the moſt probable ſuppoſition ſeems to be that of Sir Iſaac Newton. According to that illuſtrious author, Ammon the father of Seſac was the firſt king of Libya, or that vaſt tract extending from the borders of Egypt to the Atlantic ocean; the conqueſt of which country was effected by Seſac in his father's life-time. Neptune afterwards excited the Libyans to a rebellion againſt Seſac, and ſlew him; and then invaded Egypt under the command of Atlas or Antæus, the ſon of Neptune, Seſac's brother and admiral. Not long after, Hercules, the general of Thebais and Ethiopia for the gods or great men of Egypt, reduced a ſecond time the whole continent of Libya, having overthrown and ſlain Antæus near a town in Thebais, from that event called *Antæa* or *Antæopolis*: this, we ſay, is the notion advanced by Sir Iſaac Newton, who endeavours to prove, that the firſt reduction of Libya, by Seſac, happened a little above a thouſand years before the birth of Chriſt, as the laſt, by Hercules, did ſome few years after. Now, though we do not pretend to adopt every particular circumſtance of Sir Iſaac Newton's ſyſtem, yet we cannot forbear obſerving, that it appears undeniably plain from ſcripture, that neither the weſtern extremity of Libya, nor even the other parts of that region, could poſſibly have been ſo well peopled before the time of David or Solomon, as to have ſent a numerous army to invade Egypt. For Egypt and Phœnicia, from whence the greateſt part of the anceſtors of the Libyans came, and which were much nearer the place from whence the firſt diſperſion of mankind was made, could not themſelves have been greatly overſtocked with inhabitants any conſiderable time before the reign of Saul. And that ſuch an invaſion happened in the reign of Neptune, or at leaſt of his ſon Antæus, has been moſt fully evinced by this moſt excellent chronologer.

From the defeat of Antæus, nothing remarkable occurs in the hiſtory of Mauritania till the times of the Romans, who at laſt brought the whole kingdom under their juriſdiction; for which ſee the article Rome. With regard to the cuſtoms, &c. of this people, it would ſeem, from what Hyginus inſinuates, that they fought only with clubs, till one Belus, the ſon of Neptune, as that author calls him, taught them the uſe of the ſword. Sir Iſaac Newton makes this Belus to have been the ſame perſon with Seſoſtris king of Egypt, who over-ran a great part of the then known world. 2. All perſons of diſtinction in Mauritania went richly attired, wearing much gold and ſilver in their clothes. They took great pains in cleanſing their teeth, and curled their hair in a curious and elegant manner. They combed their beards, which were very long, and always had their nails pared extremely cloſe. When they walked out in any numbers, they never touched one another, for fear of diſconcerting the curls into which their hair had been formed. 3. The Mauritanian infantry, in time of action, uſed ſhields made of elephants ſkins, being clad in thoſe of lions, leopards, and bears, which they kept on both night and day. 4. The cavalry of this nation was armed with broad ſhort lances, and carried targets or bucklers, made likewiſe of the ſkins of wild beaſts. They uſed no ſaddles. Their horſes were ſmall and ſwift, had wooden collars about their necks, and were ſo much under the command of their riders, that they would follow them like dogs. The habit of theſe horſemen was not much different from that of the foot above-mentioned, they conſtantly wearing a large tunic of the ſkins of wild beaſts. The Phutæi, of whom the Mauritanians were a branch, were eminent for their ſhields, and the excellent uſe they made of them, as we learn from Homer, Xenophon, Herodotus, and ſcripture. Nay, Herodotus ſeems to intimate, that the ſhield and helmet came from them to the Greeks. 5. Notwithſtanding the fertility of their ſoil, the poorer ſort of the Mauritanians never took care to manure the ground, being ſtrangers to the art of huſbandry; but roved about the country in a wild ſavage manner, like the ancient Scythians or Arabes Scenitæ. They had tents, or *mapalia*, ſo extremely ſmall, that they could ſcarce breathe in them. Their food was corn, herbage, &c. which they frequently did eat green, without any manner of preparation; being deſtitute of wine, oil, and all the elegancies as well as many neceſſaries of life. Their habit was the ſame both in ſummer and winter, conſiſting chiefly of an old tattered, though thick garment, and over it a coarſe rough tunic; which anſwered probably to that of their neighbours the Numidians. Moſt of them lay every night upon the bare ground; though ſome of them ſtrewed their garments thereon, not unlike the preſent African Kabyles and Arabs, who, according to Dr Shaw, uſe their hykes for a bed and covering in the night. 6. If the moſt approved reading of Horace may be admitted, the Mauritanians ſhot poiſoned arrows; which clearly intimates, that they had ſome ſkill in the art of preparing poiſons, and were excellent dartmen. This laſt obſervation is countenanced by Herodian and Ælian, who entirely come into it, affirming them to have been in ſuch continual danger of being devoured by wild beaſts, that they durſt not ſtir out of their tents or mapalia without their darts. Such perpetual exerciſe muſt render them exceedingly ſkilful in hurling that weapon. 7. The Mauritanians ſacrificed human victims to their deities, as the Phœnicians, Carthaginians, &c. did.

The country people were extremely rude and barbarous; but thoſe inhabiting cities muſt undoubtedly have had at leaſt ſome ſmattering in the literature of the ſeveral nations they deduced their origin from. That the Mauritanians had ſome knowledge in naval affairs, ſeems probable, not only from the intercourſe they had with the Phœnicians and Carthaginians, as well as the ſituation of their country; but likewiſe from Orpheus, or Onomacritus, who aſſerts them to have made a ſettlement at the entrance into Colchis, to which place they came by ſea. Magic, ſorcery, divination, &c. they appear to have applied themſelves to in very early times. Cicero and Pliny ſay, that Atlas was the inventor of aſtrology and the doctrine of the ſphere, i. e. he firſt introduced them into Mauritania. This, according to Diodorus Siculus, gave riſe to the fable of Atlas's bearing the heavens upon his ſhoulders. The ſame author relates, that Atlas inſtructed Hercules in the doctrine of the ſphere and aſtrology, or rather aſtronomy, who afterwards brought thoſe ſciences into Greece.

MAURITIA, the Ginkgo, or *Maiden-hair tree*: A genus of plants belonging to the natural order of Palmæ. The calyx of the male is monophyllous; the corolla monopetalous; with ſix ſtamina. It is a native of Japan, where it is alſo known by the names of *Ginan* and *Itſio*. It riſes with a long, erect, thick and branched ſtem, to the ſize of a walnut-tree. The

bark

bark is aſh-coloured, the wood brittle and ſmooth, the pith ſoft and fungous. The leaves are large, expanded from a narrow bottom into the figure of a maiden-hair leaf, unequally parted, ſtreaked, without fibres or nerves; both ſurfaces having the ſame appearance, and ſupported upon footſtalks, which are compreſſed upon the upper ſurface, and extended into the ſubſtance of the leaf. From the uppermoſt ſhoots hang the flowers in long catkins that are filled with the fertilizing powder; and to which ſucceeds the fruit, adhering to a thick fleſhy pedicle, which proceeds from the boſom of the leaves. This fruit is either exactly or nearly round, and of the appearance and ſize of a damaſk plum. The ſubſtance ſurrounding the fruit is fleſhy, juicy, white, very harſh, and adheres ſo firmly to the incloſed nut, as not to be ſeparated from it, except by putrefaction. The nut, properly termed *Gineau*, reſembles the piſtachia nut, eſpecially a Perſian ſpecies named *bergjes piſtai*; but is almoſt double in ſize, and of the figure of an apricot ſtone. The ſhell is ſomewhat white, woody, and brittle; and incloſes a white looſe kernel, having the ſweetneſs of an almond, along with a degree of harſhneſs. Theſe kernels taken after dinner are ſaid to promote digeſtion, and to give relief in ſurfeits; whence they never fail to make part of the deſert in great feaſts and anniverſary entertainments.—Many of theſe plants have been reared by Mr James Gordon at his nurſery near Mile-end. They ſeem to be very hardy, and thrive in this country in the open air.

MAURITIUS, or MAURICE, an iſland of Africa, about 400 miles eaſt of Madagaſcar, lying in the latitude of 20 and 21 degrees ſouth. In the beginning of the 16th century it was diſcovered by the Portugueſe, who, knowing that Pliny and other ancient writers had mentioned the iſland of Cerne in theſe ſeas, took it for granted that this muſt be it; and accordingly we find it ſtyled *Cerne* or *Sirne*, in their maps: but, notwithſtanding this, they did not think fit to ſettle it; and indeed their force was ſo ſmall, in compariſon of the vaſt dominions they graſped, that it was very excuſable. However, according to their laudable cuſtom, they put ſome hogs, goats, and other cattle upon it, that in caſe any of their ſhips either going to the Indies, or returning to Portugal, ſhould be obliged to touch there, they might meet with refreſhments. The Dutch, in the ſecond voyage they made to the Eaſt Indies under their admiral James Cornelius Vanneck, came together with five ſhips on the 15th of September 1568; anchored in a commodious port, to which they gave the name of *Warwick Haven*; and gave a very good account of the place in their journals. Captain Samuel Caſtleton, in the Pearl, an Engliſh Eaſt India ſhip, arrived there on the 27th of March 1612; and taking it to be an iſland undiſcovered before, beſtowed upon it the name of *England's Foreſt*, though others of his crew called it *Pearl-Iſland*, and in the account of their voyage, written by John Tatton the maſter of the ſhip, celebrated it as a place very convenient for ſhipping, either outward or homeward bound, to refreſh at. This they ſometimes accordingly did, and brought ſome cargoes of ebony and rich wood from thence, but without fixing any ſettlement.

At length, in 1638, the Dutch ſeated themſelves here; and it is highly remarkable, that at the very time they were employed in making their firſt ſettlement, the French ſent a veſſel to take poſſeſſion of it, who found the Dutch before-hand with them, and refuſed the aſſiſtance of an Engliſh Indiaman, wooding and watering in another port of the iſland, who very frankly offered it, to drive the Dutch from their half-ſettled poſts. They continued for ſome time in quiet poſſeſſion of the places they fortified in this iſland, to which they gave the name of *Mauritius*. But having engaged the French, who were ſettled on Madagaſcar, to ſteal 50 of the natives, and ſell them for ſlaves, for the improvement of the Dutch ſettlements here, this proved the ruin of both colonies: for the negroes ſurpriſed and maſſacred the French in Madagaſcar; and the ſlaves in Mauritius fled into the centre of the iſland; from whence they ſo much and ſo inceſſantly moleſted thoſe who had been formerly their maſters, that they choſe to quit a country where they could no longer remain in any tolerable degree of ſafety. The Eaſt India company, however, from motives of conveniency, and a very imperfect notion of its value, diſapproved this meaſure, and therefore ordered it to be reſettled; which was accordingly done, and three forts erected at the principal havens. Things now went on ſomewhat better than they did before; but they were ſtill very much diſturbed by the revolted negroes in the heart of the iſle, whom they could never ſubdue. One principal uſe that the company made of this place, was to ſend thither ſtate-priſoners, who, as they were not men of the beſt morals, quickly corrupted the reſt of the inhabitants, and rendered them ſuch a race of outrageous ſmugglers, the ſituation of the place concurring with their bad diſpoſitions, that, after various ineffectual attempts made to reform them, orders were at length given to abandon Mauritius a ſecond time, which, after ſome delays, were put in execution in the year 1710.

Two years after this, the French took poſſeſſion of it, and named it the *Iſle de France*. This name has obtained among themſelves, but the Europeans in general continue to call it Mauritius. It lies in S. Lat. 20. 15. E. Lon. 6. 15. The inconveniences ariſing from the want of a port at the iſland of Bourbon, induced the French to take poſſeſſion of Mauritius, it having two very good harbours, to fortify which no expence has been ſpared. That on the north-weſt is called *Port Louis*, that on the ſouth-eaſt ſide of the iſland is called *Port Bourbon*. The trade-wind from the ſouth-eaſt in theſe latitudes blows all the year round, excepting for a few days at the ſummer ſolſtice, when it is interrupted by hard gales and hurricanes from the north. The eaſe with which this wind enables ſhips to enter the port of Bourbon, cauſed the French, when they firſt took poſſeſſion of this ſpot, to eſteem it the beſt port in the iſland; but experience pointing out to them, that the ſame wind often rendered the paſſage out of the harbour ſo difficult, that a ſhip was ſometimes obliged to wait a conſiderable time before the weather admitted of her putting to ſea, this harbour is in a great meaſure abandoned, and the principal town and ſeat of government is now fixed at port Louis, which is nearly in the middle of the north ſide of the iſland, and its entrance is through a channel formed by two ſhoals, which advance about two miles into the

the ſea. When a ſhip arrives oppoſite to this channel, the ſouth-eaſt wind hinders her from entering the port under ſail, and ſhe muſt either warp in with cables or be towed in with boats. The neceſſity of this operation, joined to the extreme narrowneſs of the channel, which does not admit of two ſhips abreaſt of each other entering at the ſame time, is one of the beſt defences the harbour has againſt an attack by ſea; for, from theſe obſtacles, an enemy would find it a matter of the greateſt difficulty to force the port; and in addition to this natural ſtrength, they have built two forts and as many batteries, which are mounted with heavy cannon, and entirely command the approach to the harbour, ſhould ſhips preſume to force an entry under ſail. This port is capable of containing 100 ſail of ſhips, and is well provided with every requiſite for repairing and even building of ſhips. This port has proved of the greateſt advantage to France in the ſeveral wars which have been carried on between Great Britain and her; and has proved of great utility to the French Eaſt India company's commerce; for here their ſhips and crews were ſure to meet with all neceſſary refreſhment after a long voyage. The port of Bourbon is alſo fortified; and an army landed here would find it an extreme difficult taſk to paſs the mountains to the different parts of the iſland. There are ſeveral places between the north-eaſt extremity and port Louis where boats may land, but all theſe are defended by batteries; and the country behind them is a continued thicket: The reſt of the coaſt is inacceſſible. In the north-eaſtern quarter is a plain extending about 10 miles from eaſt to weſt, and in ſome places five miles inland from the northern coaſt. All the reſt of the iſland is full of high and ſteep mountains, lying ſo near to one another, and the intervals between them ſo narrow, that, inſtead of valleys, they rather reſemble the beds of torrents; and theſe are choaked with huge fragments of rocks which have fallen from the ſteep ſides of the impending mountains. On the ſummits of the mountains ice is frequently to be found, and they are covered with foreſts of ebony and other large trees. The ground they ſhade produces herbage, ſhrubs, and plants of various ſorts, from the common graſs to the ſtrongeſt thorn, and that in ſuch profuſion, that they form a thicket ſo cloſely interwoven, that no progreſs can be made but by means of a hatchet. Notwithſtanding theſe difficulties, plantations have been formed on theſe mountains, and very conſiderable progreſs has been made in the plains; but the productions, although moſtly of the ſame kind, are not only in leſs quantity, but of an inferior quality to thoſe produced at Bourbon iſland.

In a courſe of years, however, this ſettlement coſt ſo much, and was conſidered in every light worth ſo little, that it had been more than once under deliberation, whether, after the example of the Dutch, they ſhould not leave it again to its old negro inhabitants; which ſooner or later in all likelihood would have been its fate, if, in 1735, the famous M. de la Bourdonnais had not been ſent thither, with the title of *governor-general of the French iſlands.*

He found this iſle in the worſt ſtate poſſible, thinly inhabited by a ſet of lazy people, who equally hated induſtry and peace, and who were continually flattering this man to his face, and belying him wherever and as far as they durſt. He gave himſelf no trouble about this, having once found the means to make himſelf obeyed; he ſaw the vaſt importance of the iſland; he conceived that it might be ſettled to great advantage; and, without ſo much as expecting the thanks of thoſe for whom he laboured, he began to execute this great deſign. His firſt ſtep was to bring over black boys from Madagaſcar, whom he carefully trained up in good principles, and in continual exerciſe; by which he rendered them ſo good ſoldiers, that he very quickly obliged the Marones, or wild negroes, either to ſubmit or to quit the iſland: he taught the planters to cultivate their lands to advantage; he, by an aqueduct, brought freſh water to the ſea-ſide; and whereas they had not ſo much as a boat at his coming thither, he made a very fine dock, where he not only built ſloops and larger veſſels, but even a ſhip of the burden of 500 ton. However incredible it may ſeem, yet it is certainly fact, that in the ſpace of five years he converted this country into a paradiſe, that had been a mere wilderneſs for 5000; and this in ſpite of the inhabitants, and of the company, who being originally prejudiced by them, behaved ill to him at his return. He ſoon made the cardinal de Fleury, however, ſenſible of the true ſtate of things; and compelled the company to acknowledge, though they did not reward, his ſervices. He afterwards returned into the Indies, and perfected the work he had begun, and to him it is owing that the iſle of France was rendered one of the fineſt and moſt important ſpots upon the globe. Here no coffee is raiſed; but by the indefatigable induſtry of M. de Bourdonnais, ſugar, indigo, pepper, and cotton (which are not at Bourbon), came to be cultivated with ſucceſs. Since the departure of that moſt excellent governor, the plantations have been neglected, and are fallen off; but if a proper ſpirit of activity was raiſed among the inhabitants, they might ſoon be made to reſume their flouriſhing appearance. Mines of iron have been diſcovered in the mountains near the great plain, in the north-eaſt part of the iſland; and theſe mountains affording in great abundance the neceſſary fuel, forges have been erected: but the iron produced is of a very inferior quality, it being brittle, and only fit for making cannon-balls and bomb-ſhells. Black cattle, ſheep, and goats, are preſerved with difficulty; the firſt generally die before they have been a year in the iſland, and this occaſions frequent importations of them from Madagaſcar and other parts. Common domeſtic poultry breed in great plenty; and, with fiſh and turtle, furniſh a great part of the food of the European inhabitants.

The approach to the iſland is extremely dangerous, it being ſurrounded with ledges of rocks, and many of them covered by the ſea. The ſhore abounds with coral and ſhells. This iſland is ſaid to contain 60 rivers: ſome are conſiderable ſtreams, and moſt of them have their ſources from lakes, of which there are ſeveral in the middle part of the iſland. The rivers afford plenty of various kinds of fiſh, particularly eels. Theſe are of an enormous ſize, ſome having been found that were ſix feet long, and ſix inches in circumference, and ſo extremely voracious, that it is dangerous to bathe

bathe in thoſe parts of the river where they lie, as they will ſeize a man without fear, and have ſtrength ſufficient to keep him under water till he is drowned. Here is a great variety of birds, and bats as large as a young kitten: the inhabitants eſteem them a delicate morſel. The air is both hot and moiſt, but not unwholeſome. The place abounds with inſects, which are very troubleſome; but there are no ſerpents. It has been diſcovered, that off Port Louis the ſouth-eaſt wind generally blows with leaſt ſtrength about ſun-riſe; and it alſo happens, on four or five days, at intervals, in the courſe of a month, that early in the morning the wind ceaſes in the northern part of the iſland for an hour or two, when a breeze riſes, although but faintly, from the north-weſt; during which, a ſhip ſtationed at the entrance of the channel to avail herſelf of this breeze, may enter the harbour and attack the forts.

MAURUA, one of the Society-Iſlands in the South Sea. It is a ſmall iſland, entirely ſurrounded with a ridge of rocks, and without any harbour for ſhipping. It is inhabited; and its productions are the ſame with thoſe of the neighbouring iſlands. A high round hill riſes in the middle of it, which may be ſeen at the diſtance of 10 or 12 leagues.

MAUSOLEUM, a magnificent tomb or funeral monument. The word is derived from Mauſolus king of Caria, to whom Artemiſia his widow erected a moſt ſtately monument, eſteemed one of the wonders of the world, and called it, from his own name, *Mauſoleum*.

St MAWES, a town of Cornwall, in England, ſeated on the eaſt ſide of Falmouth haven, in W. Long. 5. 26. N. Lat. 50. 30. Though but a hamlet of the pariſh of St Juſt, two miles off, without a miniſter, or either church, chapel, or meeting-houſe, it has ſent members to parliament ever ſince 1562, who are returned by its mayor or portreve. It conſiſts but of one ſtreet, under a hill, and fronting the ſea, and its inhabitants ſubſiſt purely by fiſhing. King Henry VIII. built a caſtle here, over againſt Pendennis, for the better ſecurity of Falmouth haven. It has a governor, a deputy, and two gunners, with a platform of guns. Here is a fair the Friday after St Luke's day.

MAXENTIUS (Marcus Aurelius Valerius), a ſon of the emperor Maximianus Hercules, was, by the voluntary abdication of Diocleſian, and of his father, raiſed to the empire, A. D. 306. He afterwards incited his father to re-aſſume his imperial authority; and in a perfidious manner deſtroyed Severus, who had delivered himſelf into his hands, and relied upon his honour for the ſafety of his life. His victories and ſucceſſes were impeded by Galerius Maximianus, who oppoſed him with a powerful force. The defeat and voluntary death of Galerius ſoon reſtored peace to Italy; and Maxentius paſſed into Africa, where he rendered himſelf odious by his cruelty and oppreſſion. He ſoon after returned to Rome, and was informed that Conſtantine was come to dethrone him. He gave his adverſary battle near Rome, and, after he had loſt the victory, he fled back to the city. The bridge over which he croſſed the Tiber was in a decayed ſituation, and he fell into the river, and was drowned, A. D. 312. The cowardice and luxuries of Maxentius were as conſpicuous as his cruelties. He oppreſſed his ſubjects with heavy taxes, to gratify the cravings of his pleaſures, or the avarice of his favourites. He was debauched in his manners, and neither virtue nor innocence were ſafe whenever he was inclined to voluptuous purſuits. His body was deformed, and unwieldy. To viſit a pleaſure ground, or to exerciſe himſelf under a marble portico, or walk on a ſhady terrace, was to him a Herculean labour, which required the greateſt exertions of ſtrength and reſolution.

MAXILLA, the Jaw. See ANATOMY, n° 20—26.

MAXIM, an eſtabliſhed propoſition or principle; in which ſenſe it denotes much the ſame with axiom.

MAXIMILIAN I. emperor of Germany, ſignalized himſelf againſt the French while he was king of the Romans, and after he was emperor entered into the army of Henry VIII. of England as a volunteer againſt that nation: he was a protector of learned men, and aboliſhed an iniquitous tribunal, ſtyled *Judicium oculum Weſtphaliæ*: he compoſed ſome poems, and the memoirs of his own life. He died in 1519, aged 60.

MAXIMUM, in mathematics, denotes the greateſt quantity attainable in any given caſe.

If a quantity conceived to be generated by motion increaſes or decreaſes till it arrives at a certain magnitude or poſition, and then, on the contrary, grows greater or leſſer, and it be required to determine the ſaid magnitude or poſition, the queſtion is called a *problem de maximis et minimis*.

MAXIMUS, a celebrated Cynic philoſopher, and magician of Epheſus. He inſtructed the emperor Julian in magic; and, according to the opinion of ſome hiſtorians, it was in the converſation and company of Maximus that the apoſtacy of Julian originated. The emperor not only viſited the philoſopher, but he even ſubmitted his writings to his inſpection and cenſure. Maximus refuſed to live in the court of Julian, and the emperor, not diſſatisfied with the refuſal, appointed him high pontiff in the province of Lydia, an office which he diſcharged with the greateſt moderation and juſtice. When Julian went into the eaſt, the philoſopher promiſed him ſucceſs, and even ſaid that his conqueſts would be more numerous and extenſive than thoſe of the ſon of Philip. He perſuaded his imperial pupil, that, according to the doctrine of Metempſychoſis, his body was animated by the ſoul which once animated the hero whoſe greatneſs and victories he was going to eclipſe. After the death of Julian, Maximus was almoſt ſacrificed to the fury of the ſoldiers; but the interpoſition of his friends ſaved his life, and he retired to Conſtantinople. He was ſoon after accuſed of magical practices, before the emperor Valens, and beheaded at Epheſus, A. D. 366. He wrote ſome philoſophical and rhetorical treatiſes, ſome of which were dedicated to Julian. They are all now loſt.

MAXIMUS of Tyre, a Platonic philoſopher, went to Rome in 146, and acquired ſuch reputation there, that the emperor Marcus Aurelius became his ſcholar, and gave him frequent proofs of his eſteem. This philoſopher is thought to have lived till the reign of the emperor Commodus. There are ſtill extant 41 of his diſſertations; a good edition of which was printed by

Daniel Heinſius, in 1624, in Greek and Latin, with notes.

Maximus Marius. See *Marius*.

Maximus (St), an abbot and confeſſor of the 7th century, was of a noble family of Conſtantinople, and diſtinguiſhed himſelf by his zeal againſt the Monothelites, for which he was thrown into priſon, and died there on the 13th of Auguſt 1662. He wrote a Commentary on the books attributed to Dionyſius the Areopagite, and ſeveral other works, of which an edition has been publiſhed by father Combefis.

MAY, the fifth month in the year, reckoning from our firſt, or January; and the third, counting the year to begin with March, as the Romans anciently did. It was called Maius by Romulus, in reſpect to the ſenators and nobles of his city, who were named *majores*; as the following month was called *Junius*, in honour of the youth of Rome, *in honorem juniorum*, who ſerved him in the war; though ſome will have it to have been thus called from *Maia*, the mother of Mercury, to whom they offered ſacrifice on the firſt day of it; and Papias derives it from *Madius, eo quod tunc terra madeat*. In this month the ſun enters Gemini, and the plants of the earth in general begin to flower.—The month of May has ever been eſteemed favourable to love; and yet the ancients, as well as many of the moderns, look on it as an unhappy month for marriage. The original reaſon may perhaps be referred to the feaſt of the Lemures, which was held in it. Ovid alludes to this in the fifth of his Faſti, when he ſays,

Nec viduæ tædis eadem, nec virginis apta
Tempora; quae nupſit, non diuturna fuit;
Hac quoque de cauſa, ſi te proverbia tangunt,
Menſe malum Maio *nubere vulgus ait.*

May-dew. See Dew.

May-duke, a ſpecies of cherry. See Prunus.

May (Iſle of), a ſmall iſland at the mouth of the Frith of Forth, in Scotland, about a mile and an half in circumference, and ſeven miles from the coaſt of Fife, almoſt oppoſite to the rock called the *Baſs*. It formerly belonged to the priory of Pittenweem; and was dedicated to St Adrian, ſuppoſed to have been martyred in this place by the Danes; and hither, in times of Popiſh ſuperſtition, barren women uſed to come and worſhip at his ſhrine, in hopes of being cured of their ſterility. Here is a tower and lighthouſe built by Mr Cunningham of Barns, to whom king Charles I. granted the iſland in fee, with power to exact two-pence per ton from every ſhip that paſſes, for the maintenance of a light-houſe. In the middle of it there is a freſh-water ſpring, and a ſmall lake. The ſoil produces paſturage for 100 ſheep and 20 black cattle. On the weſt ſide the ſteep rocks render it inacceſſible; but to the eaſt there are four landing-places and good riding. It was here that the French ſquadron, having the chevalier de St George on board, anchored in the year 1708, when the vigilance of Sir George Byng obliged him to relinquiſh his deſign, and bear away for Dunkirk. The ſhores all round the iſland abound with fiſh, and the cliffs with water-fowl.

MAY (Thomas), an eminent Engliſh poet and hiſtorian in the 17th century, was born of an ancient but decayed family in Suſſex, educated at Cambridge, and afterwards removed to London, where he contracted a friendſhip with ſeveral eminent perſons, and particularly with Endymion Porter, Eſq; one of the gentlemen of the bed-chamber to king Charles I. While he reſided at court, he wrote the five plays now extant under his name. In 1622, he publiſhed a tranſlation of Virgil's Georgics, with annotations; and in 1635 a poem on king Edward III. and a tranſlation of Lucan's Pharſalia, which poem he continued down to the death of Julius Cæſar, both in Latin and Engliſh verſe. Upon the breaking out of the civil wars he adhered to the parliament; and in 1647, he publiſhed, "The hiſtory of the parliament of England, which began November the third MDCXL. With a ſhort and acceſſary view of ſome precedent years." In 1649, he publiſhed, *Hiſtoriæ parliamenti Angliæ Breviarium*, in three parts; which he afterwards tranſlated into Engliſh. He wrote the Hiſtory of Henry II. in Engliſh verſe. He died in 1652. He went well to reſt over-night, after a cheerful bottle as uſual, and died in his ſleep before morning: upon which his death was imputed to his tying his night-cap too cloſe under his fat cheeks and chin, which cauſed his ſuffocation; but the facetious Andrew Marvel has written a poem of 100 lines, to make him a martyr of Bacchus, and die by the force of good wine. He was interred near Camden, in Weſtminſter-Abbey; which cauſed Dr Fuller to ſay, that "if he were a biaſſed and partial writer, yet he lieth buried near a good and true hiſtorian indeed." Soon after the reſtoration, his body, with thoſe of ſeveral others, was dug up, and buried in a pit in St Margaret's church-yard; and his monument, which was erected by the appointment of Parliament, was taken down and thrown aſide.

MAYER (Tobias), one of the greateſt aſtronomers and mechanics this century has produced, was born at Maſpach, in the duchy of Wirtemberg 1723. He taught himſelf mathematics, and at the age of fourteen deſigned machines and inſtruments with the greateſt dexterity and juſtneſs. Theſe purſuits did not hinder him from cultivating the belles lettres. He acquired the Latin tongue, and wrote it with elegance. In 1750, the univerſity of Gottingen choſe him for their mathematical profeſſor; and every year of his ſhort life was thenceforward marked with ſome conſiderable diſcoveries in geometry and aſtronomy. He publiſhed ſeveral works in this way, which are all reckoned excellent; and ſome are inſerted in the ſecond volume of the "Memoirs of the univerſity of Gottingen." His labours ſeem to have exhauſted him; for he died worn out in 1762.

MAYERNE (Sir Theodore de), baron of Aulbone, was the ſon of Lewis de Mayerne, the celebrated author of The general hiſtory of Spain, and of the *Monarchie ariſto-democratique*, dedicated to the ſtates-general. He was born in 1573, and had for his godfather Theodore Beza. He ſtudied phyſic at Montpelier, and was made phyſician in ordinary to Henry IV. who promiſed to do great things for him provided he would change his religion. James I. of England invited him over, and made him firſt phyſician to himſelf and his queen, in which office he ſerved the whole royal family to the time of his death in 1655,

1655. His works were printed at London in 1700, and make a large folio, divided into two books; the firſt containing his *Conſilia, Epiſtolæ, & Obſervationes*; the ſecond his *Pharmacopœia variæque medicamentorum formulæ*.

MAYHEM. See Maim.

MAYNE (Jaſper), an eminent Engliſh poet and divine in the 17th century, who was bred at Oxford, and entered into holy orders. While his majeſty reſided at Oxford, he was one of the divines appointed to preach before him. He publiſhed in 1647 a piece intitled, ΟΧΛΟΜΑΧΙΑ, or, *The people's war examined according to the principles of reaſon and ſcripture, by Jaſper Mayne.* In 1648 he was deprived of his ſtudentſhip at Chriſt-church, and two livings he had; but was reſtored with the king, who made him his chaplain and archdeacon of Chicheſter; all which he held till he died. Dr Mayne was held in very high eſteem both for his natural parts and his acquired accompliſhments. He was an orthodox preacher, and a man of ſevere virtue and exemplary behaviour; yet of a ready and facetious wit, and a very ſingular turn of humour. From ſome ſtories that are related of him, he ſeems to have borne ſome degree of reſemblance in his manner to the celebrated Dr Swift; but if he did not poſſeſs thoſe very brilliant parts that diſtinguiſhed the Dean, he probably was leſs ſubject to that capricious and thoſe unaccountable whimſies which at times ſo greatly eclipſed the abilities of the latter. Yet there is one anecdote related of him, which, although it reflects no great honour on his memory, as it ſeems to carry ſome degree of cruelty with it, yet is it a ſtrong mark of his reſemblance to the Dean, and a proof that his propenſity for drollery and joke did not quit him even in his lateſt moments. The ſtory is this: The doctor had an old ſervant, who had lived with him ſome years, to whom he had bequeathed an old trunk, in which he told him he would find *ſomething that would make him drink after his death.* The ſervant, full of expectation that his maſter, under this familiar expreſſion, had left him ſomewhat that would be a reward for the aſſiduity of his paſt ſervices, as ſoon as decency would permit flew to the trunk; when behold, to his great diſappointment, the boaſted legacy proved to be a red herring. The doctor, however, bequeathed many legacies by will to pious uſes; particularly 50 pounds towards the rebuilding of St Paul's cathedral, and 200 pounds to be diſtributed to the poor of the pariſhes of Caſſington and Pyrton, near Wattington, of both which places he had been vicar. In his younger years he had an attachment to poetry; and wrote two plays, the latter of which may be ſeen in the tenth volume of Dodſley's collection, viz. 1. Amorous war, a tragicomedy. 2. The city-match, a comedy. He publiſhed a poem upon the naval victory by the duke of York over the Dutch, printed in 1665. He alſo tranſlated into Engliſh from the Greek part of Lucian's Dialogues.

MAYNOOTH, or Manooth, a poſt town in the county of Kildare, and province of Leinſter, in Ireland, near 12 miles from Dublin. Though not very large, it is regularly laid out, and conſiſts of good houſes. Here is a charter-ſchool, which was opened 27th July 1759.

MAYNWARING (Arthur), an eminent political writer in the beginning of the 18th century, ſtaid ſeveral years at Oxford, and then went to Cheſhire, where he lived ſome time with his uncle Mr Francis Cholmondley, a very honeſt gentleman, but extremely averſe to the government of king William III. to whom he refuſed the oaths. Here he proſecuted his ſtudies in polite literature with great vigour; and coming up to London, applied to the ſtudy of the law. He was hitherto very zealous in anti-revolutional principles, and wrote ſeveral pieces in favour of king James II.; but upon being introduced to the duke of Somerſet and the earls of Dorſet and Burlington, began to entertain very different notions in politics. His father left him an eſtate of near 800 l. a-year, but ſo incumbered, that the intereſt money amounted to almoſt as much as the revenue. Upon the concluſion of the peace he went to Paris, where he became acquainted with Mr Boileau. After his return he was made one of the commiſſioners of the cuſtoms, in which poſt he diſtinguiſhed himſelf by his ſkill and induſtry. He was a member of the kit-cat-club, and was looked upon as one of the chief ſupports of it by his pleaſantry and wit. In the beginning of queen Anne's reign, the lord treaſurer Godolphin engaged Mr Done to quit the office of auditor of the impreſts, and made Maynwaring a preſent of a patent for that office worth about 2000 l. a-year in a time of buſineſs. He had a conſiderable ſhare in the Medley, and was author of ſeveral other pieces. The Examiner, his antagoniſt in politics, allowed that he wrote wirh tolerable ſpirit, and in a maſterly ſtyle. Sir Richard Steele dedicated the firſt volume of the Tatler to him.

MAYO, one of the Cape de Verd iſlands, lying in the Atlantic ocean, near 300 miles from Cape Verd in Africa, about 17 miles in circumference. The ſoil in general is very barren, and water ſcarce; however, they have ſome corn, yams, potatoes, and plantains, with plenty of beeves, goats, and aſſes. What trees there are, grow on the ſides of the hills, and they have ſome figs and water-melons. The ſea round about the iſland abounds with fiſh. The chief commodity is ſalt, with which many Engliſh ſhips are loaded in the ſummer-time. The principal town is Pinoſa, inhabited by negroes, who ſpeak the Portugueſe language, and are ſtout, luſty, and fleſhy. They are not above 200 in number, and many of them go quite naked. W. Long. 21. 25. N. Lat. 15. 5.

Mayo, a county of Ireland, in the province of Connaught, having Sligo and the ſea on the north, Roſcommon on the ſouth, Leitrim and Roſcommon on the eaſt, and the Atlantic ocean on the weſt. It contains 724,640 Iriſh plantation acres, 73 pariſhes, 9 baronies, and one borough; and ſends four members to parliament. It gives title of earl to the family of Bourke. This county takes its name from an ancient city, built in 664; the ruins of the cathedral, and ſome traces of the ſtone walls which encompaſſed the city, yet remain on the plains of Mayo. It was a univerſity, founded for the education of ſuch of the Saxon youths as were converted to the Chriſtian faith: it was ſituated a little to the ſouth of Lough Conn; and is to this day frequently called *Mayo of the Saxons*, being celebrated for giving education to Alfred the great king of England. As this town has gone

gone to decay, Balinrobe is reckoned the chief town. The county by the ſea is mountainous; but inland has good paſtures, lakes, and rivers. It is about 57 miles long, and 48 broad. Caſtlebar is the aſſizes town.—Mayo was formerly a biſhop's ſee, which is now united to Tuam.

MAYOR, the chief magiſtrate of a city or town, choſen annually out of the aldermen. The word, anciently wrote *meyr*, comes from the Britiſh *miret*, i. e. *cuſtodire*, or from the old Engliſh *maier*, viz. *poteſtas*, and not from the Latin *major*. King Richard I. in 1189, changed the bailiff of London into a mayor, and from that example king John made the bailiff of King's Lynn a mayor anno 1204: Though the famous city of Norfolk obtained not this title for its chief magiſtrate till the ſeventh year of king Henry V. anno 1419; ſince which there are few towns of note but have had a mayor appointed for government.

Mayors of corporations are juſtices of peace *pro tempore*, and they are mentioned in ſeveral ſtatutes; but no perſon ſhall bear any office of magiſtracy concerning the government of any town, corporation, &c. who hath not received the ſacrament according to the church of England within one year before his election, and who ſhall not take the oaths of ſupremacy, &c.

If any perſon intrudes into the office of mayor, a *quo warranto* lies againſt him, upon which he ſhall not only be ouſted, but fined. And no mayor, or perſon holding an annual office in a corporation for one year, is to be elected into the ſame office for the next; in this caſe, perſons obſtructing the choice of a ſucceſſor are ſubject to 100 l. penalty. Where the mayor of a corporation is not choſen on the day appointed by charter, the next office in place ſhall the day after hold a court and elect one; and if there be a default or omiſſion that way, the electors may be compelled to chooſe a mayor, by a writ of mandamus out of the king's bench. Mayors, or other magiſtrates of a corporation, who ſhall voluntarily abſent themſelves on the day of election, are liable to be impriſoned, and diſqualified from holding any office in the corporation.

Mayor's Courts. To the lord mayor and city of London belong ſeveral courts of judicature. The higheſt and moſt ancient is that called the *huſtings*, deſtined to ſecure the laws, rights, franchiſes, and cuſtoms of the city. The ſecond is a court of *requeſt*, or of *conſcience*; of which before. The third is the court of the lord mayor and aldermen, where alſo the ſheriffs ſit: to which may be added two courts of ſheriffs and the court of the city orphans, whereof the lord mayor and aldermen have the cuſtody. Alſo the court of common council, which is a court or aſſembly, wherein are made all by-laws which bind the citizens of London. It conſiſts, like the parliament, of two houſes: an upper, conſiſting of the lord mayor and aldermen; and a lower, of a number of common council men, choſe by the ſeveral wards, as repreſentatives of the body of the citizens. In the court of common council are made laws for the advancement of trade, and committees yearly appointed, &c. But acts made by them are to have the aſſent of the lord mayor and aldermen, by ſtat. 11 Geo. I. Alſo the chamberlain's court, where every thing relating to the rents and revenues of the city, as alſo the affairs of ſervants, &c. are tranſacted. Laſtly, to the lord mayor belong the courts of coroner and of eſcheator; another court for the conſervation of the river Thames; another of gaol-delivery, held uſually eight times a year, at the Old Bailey, for the trial of criminals, whereof the lord mayor is himſelf the chief judge. There are other courts called *wardmotes* or meetings of the wards; and courts of halymote or aſſemblies of the ſeveral guilds and fraternities.

MAZA, among the Athenians, was a ſort of cake made of flour boiled with water and oil, and ſet, as the common fare, before ſuch as were entertained at the public expence in the common hall or *prytaneum*.

MAZAGAN, a ſtrong place of Africa, in the kingdom of Morocco, and on the frontiers of the province of Duguela. It was fortified by the Portugueſe, and beſieged by the king of Morocco with 200,000 men in 1562, but to no purpoſe. It is ſituated near the ſea. W. Long. 7. 45. N. Lat. 33. 5.

MAZARA, an ancient town of Sicily, and capital of a conſiderable valley of the ſame name, which is very fertile, and watered with ſeveral rivers. The town is a biſhop's ſee, and has a good harbour; is ſeated on the ſea coaſt, in E. Long. 12. 39. N. Lat. 37. 42.

MAZARINE (Julius), a famous cardinal and prime miniſter of France, was born at Piſcina in the province of Abruzzo, in Naples, in 1602. After having finiſhed his ſtudies in Italy and Spain, he entered into the ſervice of cardinal Sachetts, and became well ſkilled in politics, and in the intereſts of the princes at war in Italy; by which means he was enabled to bring affairs to an accommodation, and the peace of Queiras was ſhortly concluded. Cardinal Richelieu being taken with his conduct, did from thenceforward highly eſteem him; as did alſo cardinal Antonio, and Louis XIII. who procured him a cardinal's hat in 1641. Richelieu made him one of the executors of his will; and during the minority of Louis XIV. he had the charge of affairs. At laſt he became the envy of the nobility, which occaſioned a civil war; whereupon Mazarine was forced to retire, a price was ſet on his head, and his library ſold. Notwithſtanding he afterwards returned to the court in more glory than ever; concluded a peace with Spain, and a marriage treaty betwixt the king and the infanta. This treaty of peace paſſes for the maſterpiece of cardinal de Mazarine's politics, and procured him the French king's moſt intimate confidence: but at laſt his continual application to buſineſs threw him into a diſeaſe, of which he died at Vinciennes in 1661.—Cardinal Mazarine was of a mild and affable temper. One of his greateſt talents was his knowing mankind, and his being able to adapt himſelf, and to aſſume a character conformable to the circumſtances of affairs. He poſſeſſed at one and the ſame time the biſhopric of Metz, and the abbeys of St Arnauld, St Clement, and St Vincent, in the ſame city; that of St Dennis, Clugny, and Victor, of Marſeilles; of St Michael at Soiſſons, and a great number of others. He founded Mazarine-college at Paris, which is alſo called the *college of the four nations*. There has been publiſhed a collection of his letters, the moſt

Mazzuoli, Mead.

copious edition of which is that of 1745, in 2 vols duodecimo.

MAZZUOLI. See PARMIGIANO.

MEAD, a wholeſome, agreeable liquor, prepared of honey and water.

One of the beſt methods of preparing mead is as follows: Into twelve gallons of water ſlip the whites of ſix eggs; mixing theſe well together, and to the mixture adding twenty pounds of honey. Let the liquor boil an hour, and when boiled add cinnamon, ginger, cloves, mace, and a roſemary. As ſoon as it is cold, put a ſpoonful of yeſt to it, and tun it up, keeping the veſſel filled as it works; when it has done working, ſtop it up cloſe; and, when fine, bottle it off for uſe.

Thorley ſays, that mead not inferior to the beſt of foreign wines may be made in the following manner: Put three pounds of the fineſt honey to one gallon of water, and two lemon peels to each gallon; boil it half an hour, well ſcummed; then put in, while boiling, lemon peel: work it with yeſt; then put it in your veſſel with the peel, to ſtand five or ſix months, and bottle it off for uſe. If it is to be kept for ſeveral years, put four pounds to a gallon of water.

The author of the Dictionary of Chemiſtry directs to chooſe the whiteſt, pureſt, and beſt-taſted honey, and to put it into a kettle with more than its weight of water: a part of this liquor muſt be evaporated by boiling, and the liquor ſcummed, till its conſiſtence is ſuch, that a freſh egg ſhall be ſupported on its ſurface without ſinking more than half its thickneſs into the liquor; then the liquor is to be ſtrained, and poured through a funnel into a barrel; this barrel, which ought to be nearly full, muſt be expoſed to a heat as equable as poſſible, from 20 to 27 or 28 degrees of Mr Reaumur's thermometer, taking care that the bung-hole be ſlightly covered, but not cloſed. The phenomena of the ſpirituous fermentation will appear in this liquor, and will ſubſiſt during two or three months, according to the degree of heat; after which they will diminiſh and ceaſe. During this fermentation, the barrel muſt be filled up occaſionally with more of the ſame kind of liquor of honey, ſome of which ought to be kept a part, on purpoſe to replace the liquor which flows out of the barrel in froth. When the fermentation ceaſes, and the liquor has become very vinous, the barrel is then to be put into a cellar, and well cloſed; a year afterwards the mead will be fit to be put into bottles.

Mead is a liquor of very ancient uſe in Britain. See the article FEAST, p. 182, col. 1.

MEAD (Dr Richard), a celebrated Engliſh phyſician, was born at Stepney near London, where his father, the Reverend Mr Matthew Mead, had been one of the two miniſters of that pariſh; but in 1662 was ejected for nonconformity, but continued to preach at Stepney till his death. As Mr Mead had a handſome fortune, he beſtowed a liberal education upon 13 children, of whom Richard was the eleventh; and for that purpoſe kept a private tutor in his houſe, who taught him the Latin tongue. At 16 years of age Richard was ſent to Utrecht, where he ſtudied three years under the famous Grævius; and then chooſing the profeſſion of phyſic, he went to Leyden, where he attended the lectures of the famous Pitcairn on the theory and practice of medicine, and Hermon's botanical courſes. Having alſo ſpent three years in theſe ſtudies, he went with his brother and two other gentlemen to viſit Italy, and at Padua took his degree of doctor of philoſophy and phyſic in 1695. Afterwards he ſpent ſome time at Naples and at Rome; and returning home the next year, ſettled at Stepney, where he married, and practiſed phyſic, with a ſucceſs that laid the foundation of his future greatneſs.

Mead.

In 1703, Dr Mead having communicated to the Royal Society an analyſis of Dr Bonomo's diſcoveries relating to the cutaneous worms that generate the itch, which they inſerted in the Philoſophical Tranſactions; this, with his account of poiſons, procured him a place in the Royal Society, of which Sir Iſaac Newton was then preſident. The ſame year he was elected phyſician of St Thomas's hoſpital, and was alſo employed by the ſurgeons to read anatomical lectures in their hall, which obliged him to remove into the city. In 1707 his Paduan diploma for doctor of phyſic was confirmed by the univerſity of Oxford; and being patronized by Dr Radcliffe, on the death of that famous phyſician he ſucceeded him in his houſe at Bloomſbury-ſquare, and in the greateſt part of his buſineſs. In 1727 he was made phyſician to King George II. whom he had alſo ſerved in that capacity while he was prince of Wales; and he had afterwards the pleaſure of ſeeing his two ſons-in-law, Dr Nichols and Dr Wilmot, his coadjutors in that eminent ſtation.

Dr Mead was not more to be admired for the qualities of the head than he was to be loved for thoſe of his heart. Though he was himſelf a hearty whig, yet, uninfluenced by party-principles, he was a friend to all men of merit, by whatever denomination they might happen to be diſtinguiſhed. Thus he was intimate with Garth, with Arbuthnot, and with Freind; and long kept up a conſtant correſpondence with the great Boerhaave, who had been his fellow-ſtudent at Leyden: they communicated to each other their obſervations and projects, and never loved each other the leſs for being of different ſentiments. In the mean time, intent as Dr Mead was on the duties of his profeſſion, he had a greatneſs of mind that extended itſelf to all kinds of literature, which he ſpared neither pains nor money to promote. He cauſed the beautiful and ſplendid edition of Thuanus's hiſtory to be publiſhed in 1713, in ſeven volumes folio: and by his interpoſition and aſſiduity, Mr Sutton's invention of drawing foul air from ſhips and other cloſe places was carried into execution, and all the ſhips in his majeſty's navy provided with this uſeful machine. Nothing pleaſed him more than to call hidden talents into light; to give encouragement to the greateſt projects, and to ſee them executed under his own eye. During almoſt half a century he was at the head of his buſineſs, which brought him one year above ſeven thouſand pounds, and for ſeveral years between five and ſix thouſand: yet clergymen, and in general all men of learning, were welcome to his advice. His library conſiſted of 10,000 volumes, of which his Latin, Greek, and oriental manuſcripts, made no inconſiderable part. He had a gallery for his pictures and antiquities, which coſt him great ſums. His reputation, not only as a phyſician, but as a ſcholar, was ſo univerſally eſtabliſhed, that he correſponded with all the principal literati in Europe: even the king of Naples ſent to deſire a complete collection of his works; and in return made him a preſent of the two firſt volumes of Signior Bajardi, which may be conſidered as an introduction to the collection of the antiquities of Herculaneum. At the ſame time that prince invited him to his palace, that he might have an opportunity of ſhowing him thoſe valuable monuments of antiquity; and nothing but his great age prevented his undertaking a journey ſo ſuited to his taſte. No foreigner of learning ever came to London without being introduced to Dr Mead; and on theſe occaſions his table was always open, and the magnificence of princes was united with the pleaſures of philoſophers. It was principally to him that the ſeveral counties of England and our colonies abroad applied for the choice of their phyſicians, and he was likewiſe conſulted by foreign phyſicians from Ruſſia, Pruſſia, Denmark, &c. He wrote, beſides the above works, 1. A Treatiſe on the Scurvy. 2. *De variolis et morbillis diſſertatio.* 3. *Medica ſacra: ſive de Morbis inſignioribus, qui in Bibliis memorantur, Commentarius.* 4. *Monita et Præcepta medica.* 5. A Diſcourſe concerning peſtilential contagion, and the methods to be uſed to prevent it. The works he wrote and publiſhed in Latin were tranſlated into Engliſh, under the doctor's inſpection, by Thomas Stack, M. D. and F. R. S. This great phyſician, naturaliſt, and antiquarian, died on the 16th of February 1754.

MEADOW, in its general ſignification, means paſture or graſs-land, annually mown for hay: but it is more particularly applied to lands that are ſo low as to be too moiſt for cattle to graze upon them in winter without ſpoiling the ſward.

1
When the watering of meadows was firſt practiſed in England.

An improvement in agriculture by watering of meadows has of late come into much uſe, and been found of very conſiderable importance. In the Monthly Review for October 1788, the editors acknowledge the favour of a correſpondent, who informed them, that watering of meadows was practiſed during the reigns of Queen Elizabeth and James I. A book was written upon the ſubject by one Rowland Vaughan, who ſeems to have been the inventor of this art, and who practiſed it on a very extenſive plan in the Golden Valley in Herefordſhire. Till this note to the Reviewers appeared, the inhabitants of a village called South-Cerney in Glouceſterſhire had aſſumed the honour of the invention to themſelves, as we are informed in a treatiſe upon the ſubject by the reverend Mr Wright curate of the place. According to a received tradition in that village, watering of meadows has been practiſed there for about a century, and was introduced by one *Welladviſe*, a wealthy farmer in South-Cerney. His firſt experiment was by cutting a large ditch in the middle of his ground, from which he threw the water over ſome parts, and allowed it to ſtagnate in others: but finding this not to anſwer his expectations, he improved his method by cutting drains and filling up the hollows; and thus he ſucceeded ſo well, that his neighbours, who at firſt had called him a madman, ſoon changed their opinion, and began to imitate his example.

2
Advantage of watering.

The advantages which attend the watering of meadows are many and great; not only as excellent crops of graſs are thus raiſed, but as they appear ſo early, that they are of infinite ſervice to the farmers for food to their cattle in the ſpring before the natural graſs riſes. By watering we have plenty of graſs in the beginning of March, and even earlier when the ſeaſon is mild. The good effects of this kind of graſs upon all ſorts of cattle are likewiſe aſtoniſhing, eſpecially upon ſuch as have been hardly wintered; and Mr Wright informs us, that the farmers in his neighbourhood, by means of watering their lands, are enabled to begin the making of cheeſe at leaſt a month ſooner than their neighbours who have not the ſame advantage. Graſs raiſed by watering is found to be admirable for the nurture of lambs; not only thoſe deſigned for fattening, but ſuch as are to be kept for ſtore: For if lambs when very young are ſtopped and ſtinted in their growth, they not only become contracted for life themſelves, but in ſome meaſure communicate the ſame diminutive ſize to their young. The beſt remedy for preventing this evil is the ſpring feed from watered meadows; and Mr Wright is of opinion, that if the young of all kinds of farmer's ſtock were immediately encouraged by plenty of food, and kept continually in a growing ſtate, there would in a few years be a notable change both in the ſize and ſhape of cattle in general. Such indeed is the forwardneſs of graſs from watered meadows, that the feed between March and May is worth a guinea per acre; and in June an acre will yield two tons of hay, and the after-math is always worth twenty ſhillings; and nearly the ſame quantity is conſtantly obtained whether the ſummer be dry or wet. In dry ſummers alſo, ſuch farmers as water their meadows have an opportunity of ſelling their hay almoſt at any price to their neighbours.

3
Land conſtantly improves by watering.

Land treated in this manner is continually improving in quality, even though it be mown every year: the herbage, if coarſe at firſt, becomes finer; the ſoil, if ſwampy, becomes ſound; the depth of its mould is augmented, and its quality meliorated every year. "To theſe advantages (ſays Mr Boſwell in his treatiſe upon this ſubject) another may be addreſſed to the gentleman who wiſhes to improve his eſtate, and whoſe benevolent heart prompts him to extend a charitable hand to the relief of the induſtrious poor, and not to idleneſs and vice: almoſt the whole of the expence in this mode of cultivation is the actual manual labour of a claſs of people who have no genius to employ their bodily ſtrength otherwiſe for their own ſupport and that of their families; conſequently, when viewed in this light, the expence can be but comparatively ſmall, the improvement great and valuable."

4
Example of the produce of a watered meadow.

As a proof of the above doctrine, Mr Wright adduces an inſtance of one year's produce of a meadow in his neighbourhood. It had been watered longer than the eldeſt perſon in the neighbourhood could remember; but was by no means the beſt meadow upon the ſtream, nor was the preceding winter favourable for watering. It contains ſix acres and an half. The ſpring-feed was let for ſeven guineas, and ſupported near 200 ſheep from the 1ſt of March till the beginning of May: the hay being ſold for 30 guineas, and the after-math for ſix. Another and ſtill more remarkable proof of the efficacy of watering, is, that two of the moſt ſkilful watermen of that place were ſent to lay out a meadow of ſeven acres, the whole crop of which was that year ſold for two pounds. Though it was thought by many impoſſible to throw the water over it, yet the ſkill of the workmen ſoon overcame all difficulties; and ever ſince that time the meadow has been let at the rent of three pounds per acre. From manifold experience, our author informs us, that the people in that part of the country are ſo much attached to the practice of watering, that they never ſuffer the ſmalleſt ſpring or rivulet to be unemployed. Even thoſe temporary floods occaſioned by ſudden ſhowers are received into proper ditches, and ſpread equally over the lands until its fertilizing property be totally exhauſted. "Neceſſity (ſays he) indeed compels us to make the moſt of every drop; for we have near 300 acres in this pariſh, that muſt all, if poſſible, be watered; and the ſtream that affords the water ſeldom exceeds five yards in breadth and one in depth: therefore we may ſay, that a ſcarcity of water is almoſt as much dreaded by us as by the celebrated inhabitants of the banks of the Nile."

5
he prac-
ce of wa-
ering
ught to be
ore gene-
lly ex-
ended.

Conſidering the great advantages to be derived from the practice of watering meadows, and the many undoubted teſtimonies in its favour, Mr Wright expreſſes his ſurpriſe that it has not come into more general uſe, as there is not a ſtream of water upon which a mill can be erected but what may be made ſubſervient to the enriching of ſome land, perhaps to a great quantity. "I am confident (ſays he), that there are in each county of England and Wales 2000 acres upon an average which might be thus treated, and every acre increaſed at leaſt one pound in annual value. The general adoption therefore of watering is capable of being made a national advantage of more than 100,000l. per annum, beſides the great improvement of other land ariſing from the produce of the meadows and the employment of the induſtrious poor. Such an improvement, one would think, is not unworthy of public notice; but if I had doubled the ſum, I believe I ſhould not have exceeded the truth, though I might have gone beyond the bounds of general credibility. In this one pariſh where I reſide there are about 300 acres now watered; and it may be eaſily proved that the proprietors of the land reap from thence 1000l. yearly profit."

In Mr Boſwell's treatiſe upon this ſubject, publiſhed in 1790, the author complains of the neglect of the practice of improving the wet, boggy, and ruſhy lands, which lie at the banks of rivers, and might be meliorated at a very ſmall expence, when much larger ſums are expended in the improvement of barren uplands and large tracts of heath in various parts of the kingdom: and he complains likewiſe of the little information that is to be had in books concerning the method of performing this operation. The only author from whom he acknowledges to have received any information is Blyth; and even his method of watering is very different from that practiſed in modern times; for which reaſon he propoſes to furniſh an original treatiſe upon the ſubject; and of this we ſhall now give the ſubſtance.

6
and ca-
able of
eing wa-
ered.

The firſt thing to be conſidered is, what lands are capable of being watered. Theſe, according to Mr Boſwell, are all ſuch as lie low, near the banks of rivulets and ſprings, eſpecially where the water-courſe is higher than the lands, and kept within its bounds by banks. If the rivulet has a quick deſcent, the improvement by watering will be very great, and the expences moderate. On level lands the water runs but ſlowly, which is alſo the caſe with large rivers; and therefore only a ſmall quantity of ground can be overflowed by them in compariſon of what can be done in other caſes: but the water of large rivers is generally poſſeſſed of more fertilizing properties than that of rivulets. In many caſes, however, the rivers are navigable, or have mills upon them; both of which are ſtrong objections to the perfect improvement of lands adjacent to them. From theſe conſiderations, our author concludes, that the watering of lands may be performed in the beſt and leaſt expenſive manner by ſmall rivulets and ſprings.

There are three kinds of ſoils commonly found near the banks of rivers and rivulets, the melioration of which may be attempted by watering. 1. A gravelly or ſound warm firm ſoil, or a mixture of the two together. This receives an almoſt inſtantaneous improvement; and the faſter the water runs over it the better. 2. Boggy, miry, and ruſhy ſoils, which are always found by the banks of rivers where the land is nearly level. Theſe alſo are greatly improved by watering; perhaps equally ſo with thoſe already deſcribed, if we compare the value of both in their unimproved ſtate, this kind of ground being ſcarce worth any thing in its unimproved ſtate. By proper watering, however, it may be made to produce large crops of hay, by which horned cattle may be kept through the winter and greatly forwarded; though, in its uncultivated ſtate, it would ſcarce produce any thing to maintain ſtock in the winter, and very little even in ſummer. Much more ſkill, as well as expence, however, is requiſite to bring this kind of land into culture than the former. 3. The ſoils moſt difficult to be improved are ſtrong, wet, and clay ſoils; and this difficulty is occaſioned both by their being commonly on a dead level, which will not admit of the water running over them; and by their tenacity, which will not admit of draining. Even when the utmoſt care is taken, unleſs a ſtrong body of water is thrown over them, and that from a river the water of which has a very fertilizing property, little advantage will be gained; but wherever ſuch advantages can be had in the winter, and a warm ſpring ſucceeds, theſe lands will produce very large crops of graſs.

7
Springs and
rivulets
preferable
to large ri-
vers.

The advantage of uſing ſprings and rivulets for watering inſtead of large rivers is, that the expence of raiſing wares acroſs them will not be great; nor are they liable to the other objections which attend the uſe of large rivers. When they run through a cultivated country alſo, the land floods occaſioned by violent rains frequently bring with them ſuch quantities of manure as contribute greatly to fertilize the lands, and which are totally loſt where the practice of watering is not in uſe.

Springs may be uſeful to the coarſe lands that lie near them, provided the water can be had in ſufficient quantity to overflow the lands. "By ſprings (ſays our author), are not here meant ſuch as riſe out of poor heath or boggy lands (for the water iſſuing from them is generally ſo ſmall in quantity, and always ſo very lean and hungry in quality, that little if any advantage can be derived from it); but rather the head of rivulets and brooks riſing out of a chalky and

gravelly

gravelly ſound firm ſoil, in a cultivated country. Theſe are invaluable; and every poſſible advantage ſhould be taken to improve the ground near them. The author knows a conſiderable tract of meadow-land under this predicament; and one meadow in particular that is watered by ſprings iſſuing immediately out of ſuch a ſoil, without any advantage from great towns, &c. being ſituated but a ſmall diſtance below the head of the rivulet, and the rivulet itſelf is fed all the way by ſprings riſing out of its bed as clear as cryſtal. The ſoil of the meadow is a good loam ſome inches deep, upon a fine ſpringy gravel. Whether it is from the heat of the ſprings, or whether the friction by the water running over the ſoil raiſes a certain degree of warmth favourable to vegetation, or from whatever cauſe it ariſes, the fecundity of this water is beyond conception; for when the meadow has been properly watered and well drained, in a warm ſpring, the graſs has been frequently cut for hay within five weeks from the time the ſtock was taken out of it, having eat it bare to the earth: almoſt every year it is cut in ſix weeks, and the produce from one to three waggon loads to an acre. In land thus ſituated, in the mornings and evenings in the months of April, May, and June, the whole meadow will appear like a large furnace; ſo conſiderable is the ſteam or vapour which ariſes from the warmth of the ſprings acted upon by the ſun-beams: and although the water is ſo exceeding clear, yet upon its being thrown over the land only a few days in warm weather, by dribbling through the graſs, ſo thick a ſcum will ariſe and adhere to the blades of the graſs, as will be equal to a conſiderable quantity of manure ſpread over the land, and (it may be preſumed from the good effects) ſtill more enriching.

"It is inconceivable what 24 hours water properly conveyed over the lands will do in ſuch a ſeaſon: a beautiful verdure will ariſe in a few days where a parched ruſty ſoil could only be ſeen; and one acre will then be found to maintain more ſtock than ten could do before."

8 Explanation of the terms uſed in watering.

Mr Boſwell next proceeds to an explanation of the terms uſed in this art; of the inſtruments neceſſary to perform it; and of the principles on which it is founded. The terms uſed are:

1. A Ware. This is an erection acroſs a brook, rivulet, or river, frequently conſtructed of timber, but more commonly of bricks or ſtones and timber, with openings to let the water paſs, from two to ten in number according to the breadth of the ſtream; the height being always equal to the depth of the ſtream compared with the adjacent land. The uſe of this is occaſionally to ſtop the current, and to turn it aſide into the adjacent lands.

2. A Sluice is conſtructed in the ſame manner as a ware; only that it has but a ſingle paſſage for the water, and is put acroſs ſmall ſtreams for the ſame purpoſes as a ware.

3. A Trunk is deſigned to anſwer the ſame purpoſes as a ſluice; but being placed acroſs ſuch ſtreams as either cattle or teams are to paſs over, or where it is neceſſary to carry a ſmall ſtream at right angles to a large one to water ſome lands lower down, is for theſe reaſons made of timber, and is of a ſquare figure. The length and breadth are various as circumſtances determine.

4. A Carriage is made of timber or of brick. If of timber, oak is the beſt; if of brick, an arch ought to be thrown over the ſtream that runs under it, and the ſides bricked up: But when made of timber, which is the moſt common material, it is conſtructed with a bottom and ſides as wide and high as the main in which it lies. It muſt be made very ſtrong, cloſe, and well-jointed. Its uſe is to convey the water in one main over another, which runs at right angles to it; the depth and breadth are the ſame with thoſe of the main to which it belongs; and the length is determined by that which it croſſes. The carriage is the moſt expenſive inſtrument belonging to watering.

5. A Drain-Sluice, or *Drain-Trunk*, is always placed in the lower part of ſome main, as near to the head as a drain can be found; that is, ſituated low enough to draw the main, &c. It is made of timber, of a ſquare figure like a trunk, only much ſmaller. It is placed with its mouth at the bottom of the main, and let down into the bank; and from its other end a drain is cut to communicate with ſome trench drain that is neareſt. The dimenſions are various, and determined by circumſtances. The uſe of it is, when the water is turned ſome other way, to convey the leaking water that oozes through the hatches, &c. into the drain, that otherwiſe would run down into the tails of thoſe trenches which lie loweſt, and there poach and rot the ground, and probably contribute not a little to the making it more unſound for ſheep. This operation is of the utmoſt conſequence in watering; for if the water be not thoroughly drained off the land, the ſoil is rotted; and when the hay comes to be removed, the wheels of the carriages ſink, the horſes are mired, and the whole load ſometimes ſticks faſt for hours together. On the other hand, when the drain-trunks are properly placed, the ground becomes firm and dry, and the hay is ſpeedily and eaſily removed.

7. Hatches are beſt made of oak, elm, or deal; the uſe of them is to fit the openings of wares, trunks, or ſluices; and to keep back the water when neceſſary, from paſſing one way, to turn it another. They ought to be made to fit as cloſe as poſſible. When hatches belong to wares that are erected acroſs large ſtreams, or where the ſtreams ſwell quickly with heavy rains, when the hatches are in their places to water the meadows; they are ſometimes made ſo, that a foot or more of the upper part can be taken off, ſo that vent may be given to the ſuperfluous water, and yet enough retained for the purpoſe of watering the meadows. In this caſe, they are called *flood-hatches:* but Mr Boſwell entirely diſaproves of this conſtruction, and recommends them to be made entire, though they ſhould be ever ſo heavy, and require the aſſiſtance of a lever to raiſe them up. For when the water is very high, and the hatches are ſuddenly drawn up, the water falls with great force upon the bed of the ware, and in time greatly injures it: but when the whole hatch is drawn up a little way, the water runs off at the bottom, and does no injury.

8. A Head-Main, is a ditch drawn from the river, rivulet, &c. to convey the water out of its uſual current,

current, to water the lands laid out for that purpoſe, by means of leſſer mains and trenches. The head-main is made of various dimenſions according to the quantity of land to be watered, the length or deſcent of it, &c. Smaller mains are frequently taken out of the head one; and the only difference is in point of ſize, the ſecondary mains being much ſmaller than the other. They are generally cut at right angles, or nearly ſo with the other, though not invariably. The uſe of the the mains, whether great or ſmall, is to feed the trenches with water, which branch out into all parts of the meadow, and convey the water to float the land. By ſome, theſe ſmaller mains are improperly called *Carriages*.

9. A Trench is a ſmall ditch made to convey the water out of the mains for the immediate purpoſe of watering the land. It ought always to be drawn in a ſtraight line from angle to angle, with as few turnings as poſſible. It is never deep, but the width is in proportion to the length it runs, and the breadth of the plane between that and the trench-drain. The breadth tapers gradually to the lower end.

10. A Trench-Drain is always cut parallel to the trench, and as deep as the tail-drain water will admit, when neceſſary. It ought always, if poſſible, to be cut down to a ſtratum of ſand, gravel, or clay. If into the latter, a ſpade's depth into it will be of great advantage. The uſe of it is to carry away the water immediately after it has run over the panes from the trench. It need not be drawn up to the head of the land by five, ſix, or more yards, according to the nature of the ſoil. Its form is directly the reverſe of the trench; being narrower at the head, and growing gradually wider and wider until it empties itſelf into the tail-drain.

11. The Tail-Drain is deſigned as a receptacle for all the water that flows out of the other drains, which are ſo ſituated that they cannot empty themſelves into the river. It ſhould run, therefore, nearly at right angles with the trenches, though generally it is thought moſt eligible to draw it in the loweſt part of the ground, and to uſe it to convey the water out of the meadows at the place where there is the greateſt deſcent; which is uſually in one of the fence-ditches: and hence a fence-ditch is uſually made uſe of inſtead of a tail-drain, and anſwers the double purpoſe of fencing a meadow and draining it at the ſame time.

12 A Pane of ground, is that part of the meadow which lies between the trench and the trench-drain; and in which the graſs grows for hay. It is watered by the trenches, and drained by the trench-drains; whence there is a pane on each ſide of every trench.

13. A Way-Pane is that part of the ground which lies in a properly watered meadow, on the ſide of the main where no trenches are taken out, but is watered the whole length of the main over its banks. A drain for carrying off the water from this pane runs parallel to the main. The uſe is to convey the hay out of the meadows, inſtead of the teams having to croſs all the trenches.

14. A Bend is made in various parts of thoſe trenches which have a quick deſcent, to obſtruct the water. It is made, by leaving a narrow ſtrip of green ſward acroſs the trench where the bend is intended to be left; cutting occaſionally a piece of the ſhape of a wedge out of the middle of it. The uſe is to check the water, and force it over the trench into the panes; which, were it not for theſe bends, would run rapidly on in the trench, and not flow over the land as it paſſes along. The great art in watering conſiſts in giving to each part of the pane an equal proportion of water.

15. A Gutter is a ſmall groove cut out from the tails of theſe trenches where the panes run longer at one corner than the other. The uſe is to carry the water to the extreme point of the pane. Thoſe panes which are interſected by the trench and tail-drains, meeting in an obtuſe angle, require the aſſiſtance of gutters to convey the water to the longeſt ſide. They are likewiſe uſeful, when the land has not been ſo well levelled, but ſome parts of the panes lie higher than they ought: in which caſe, a gutter is drawn from the trench over that high ground, which otherwiſe would not be overflowed. Without this precaution, unleſs the flats be filled up (which ought always to be done when materials can be had to do it) the water will not riſe upon it; and after the watering ſeaſon is paſt, thoſe places would appear ruſty and brown, while the reſt is covered with beautiful verdure. Our author, however, is of opinion, that this method of treating water-meadows ought never to be followed; but that every inequality in water-meadows ſhould either be levelled or filled up. Hence the waterman's ſkill is ſhown in bringing the water over thoſe places to which it could not naturally riſe, and in carrying it off from thoſe where it would naturally ſtagnate.

16. A Catch-Drain is ſometimes made uſe of when water is ſcarce. When a meadow is pretty long, and has a quick deſcent, and the water runs quickly down the drains, it is cuſtomary to ſtop one or more of them at a proper place, till the water flowing thither riſes ſo high as to ſtrike back either into the tail-drains ſo as to ſtagnate upon the ſides of the panes, or till it flows over the banks of the drains and waters the grounds below, or upon each ſide. It is then to be conveyed over the land in ſuch quantity as is thought proper, either by a ſmall main, out of which trenches are to be cut with their proper drains, or by trenches taken properly out of it. In caſe of a ſtagnation, the deſign will not ſucceed; and it will then be neceſſary to cut a paſſage to let the ſtagnating water run off. Even when the method ſucceeds beſt, Mr Boſwell is of opinion, that it is not by any means eligible; the water having been ſo lately ſtrained over the ground, that it is ſuppoſed by the water-men not to be endowed with ſuch fertilizing qualities as at firſt; whence nothing but abſolute neceſſity can juſtify the practice.

17. A Pond is any quantity of water ſtagnating upon the ground, or in the tail-drain, trench-drains, &c. ſo as to annoy the ground near them. It is occaſioned ſometimes by the flats not having been properly filled up; at others, when the ware not being cloſe ſhut, in order to water ſome grounds higher up, the water is thereby thrown back upon the ground adjacent.

18. A Turn of water ſignifies as much ground as can be watered at once. It is done by ſhutting down

the hatches in all thoſe wares where the water is intended to be kept out, and opening thoſe that are to let the water through them. The quantity of land to be watered at once muſt vary according to circumſtances; but Mr Boſwell lays down one general rule in this caſe, viz. that no more land ought to be kept under water at one time than the ſtream can ſupply regularly with a ſufficient quantity of water; and if this can be procured, water as much ground as poſſible.

19. The HEAD of the meadow, is that part of it into which the river, main, &c. firſt enter.

20. The TAIL is that part out of which the river, &c. laſt paſſes.

21. The UPPER SIDE of a main or trench, is that ſide which (when the main or trench is drawn at right angles, or nearly ſo, with the river) fronts the part where the river entered. The lower ſide is the oppoſite.

22. The UPPER PANE in a meadow, is that which lies on the upper ſide of the main or trench that is drawn at right angles with the river: where the river runs north and ſouth, it enters in the former direction, and runs out in the ſouthern, the main and trenches running eaſt and weſt. Then all thoſe panes which lie on the north ſide of the mains are called *upper* panes; and thoſe on the ſouth ſide the *lower* panes. But when the mains, trenches, &c. run parallel to the river, there is no diſtinction of panes into upper and lower.

The inſtruments uſed in watering meadows are:

1. A *Water-Level.* The uſe of this is to take the level of the land at a diſtance, and compare it with that of the river, in order to know whether the ground can be overflowed by it or not. This inſtrument, however, is uſeful only in large undertakings; for ſuch as are on a ſmaller ſcale, the workmen diſpenſe with it in the following manner: In drawing a main, they begin at the head, and work deep enough to have the water follow them. In drawing a tail-drain, they begin at the lower end of it and work upwards, to let the tail-water come after them. By this method we obtain the moſt exact level.

2. The *Line*, *Reel*, and Breaſt-*Plough*, are abſolutely neceſſary. The line ought to be larger and ſtronger than that uſed by gardeners.

3. *Spades.* Thoſe uſed in watering-meadows are made of a particular form, on purpoſe for the work; having a ſtem conſiderably more crooked than thoſe of any other kind The bit is iron, about a foot wide in the middle, and terminating in a point: a thick ridge runs perpendicularly down the middle, from the ſtem almoſt to the point. The edges on both ſides are drawn very thin, and being frequently ground and whetted, the whole ſoon becomes narrow; after which the ſpades are uſed for trenches and drains; new ones being procured for other purpoſes. The ſtems being made crooked, the workmen ſtanding in the trench or drain are enabled to make the bottoms quite ſmooth and even.

4. *Wheel* and *Hand barrows.* The former are uſed for removing the clods to the flat places, and are quite open, without any ſides or hinder part. The latter are of ſervice where the ground is too ſoft to admit the uſe of wheel-barrows, and when clods are to be removed during the time that the meadow is under water.

5. *Three-wheeled carts* are neceſſary when large quantities of earth are to be removed; particularly when they are to be carried to ſome diſtance.

6. Short and narrow *Scythes* are made uſe of to mow the weeds and graſs, when the water is running in the trenches, drains, and mains.

7. *Forks*, and long *Crooks* with four or five tines, are uſed for pulling out the roots of ſedge, ruſhes, reeds, &c. which grow in the large mains and drains. The crooks ſhould be made light, and have long ſtems to reach wherever the water is ſo deep that the workmen cannot work in it.

8. Strong *Water-boots*, the tops of which will draw up half the length of the thigh, are indiſpenſably neceſſary. They muſt alſo be large enough to admit a quantity of hay to be ſtuffed down all round the legs, and be kept well tallowed to reſiſt the running water for many hours together.

9 Principl on which the practice of w tering de pends.

The principles on which the practice of watering meadows depend are few and eaſy.

1. Water will always riſe to the level of the receptacle out of which it is originally brought.

2. There is in all ſtreams a deſcent greater or ſmaller; the quantity of which is in ſome meaſure ſhown by the running of the ſtream itſelf. If it runs ſmooth and ſlow, the deſcent is ſmall; but if rapidly and with noiſe, the deſcent is conſiderable.

3. Hence if a main be taken out of the river high enough up the ſtream, water may be brought from that river to flow over the land by the ſide of the river, to a certain diſtance below the head of the main, although the river from whence it is taken ſhould, oppoſite to that very place, be greatly under it.

4. Water, ſunk under a carriage which conveys another ſtream at right angles over it, one, two, or more feet below its own bed, will, when it has paſſed the carriage, riſe again to the level it had before.

5. Water conveyed upon any land, and there left ſtagnant for any length of time, does it an injury; deſtroying the good herbage, and filling the place with ruſhes, flags, and other weeds.

6. Hence it is abſolutely neceſſary, before the work is undertaken, to be certain that the water can be thoroughly drained off.

10 Wright's method.

In Mr Wright's treatiſe upon this ſubject, the author conſiders a ſolution of the three following queſtions as a neceſſary preliminary to the operation of watering. 1. Whether the ſtream of water will admit of a temporary dam or ware acroſs it? 2. Can the farmer raiſe the water by this means a few inches above its level, without injuring his neighbour's land? 3. Can the water be drawn off from the meadow as quick as it is brought on?—If a ſatisfactory anſwer can be given to all theſe queſtions, he directs to proceed in the following manner.

Having taken the level of the ground, and compared it with the river, as directed by Mr Boſwell, cut a deep wide ditch as near the dam as poſſible, and by it convey the water directly to the higheſt part of the meadow; keeping the ſides or banks of the ditch of an equal height, and about three inches higher than the general ſurface of the meadow. Where the meadow

dow is large, and has an uneven ſurface, it will ſometimes be neceſſary to have three works in different directions, each five feet wide, if the meadow contains 15 acres, and if the higheſt part be fartheſt from the ſtream. A ditch of 10 feet wide and three deep will commonly water 10 acres of land. When there are three works in a meadow, and flood-hatches at the mouth of each, when the water is not ſufficient to cover the whole completely at once, it may be watered at three different times, by taking out one of the hatches, and keeping the other two in. In this caſe, when the water has run over one diviſion of the land for 10 days, it may then be taken off that and tumbled over to another, by taking up another hatch and letting down the former; by which means the three diviſions will have a proper ſhare of the water alternately, and each reap equal benefit. The bottom of the firſt work ought to be as deep as the bottom of the river, when the fall in the meadow will admit of it; for the deeper the water is drawn, the more mud it carries along with it. From the works, cut, at right angles, ſmaller ditches or troughs, having a breadth proportioned to the diſtance to which ſome part of the water is to be carried, their diſtance from each other being about 12 yards. A trough two feet wide and one foot deep, will water a ſurface 12 yards wide and 40 feet long. In each trough as well as ditch place frequent ſtops and obſtructions, eſpecially when the water is rapid, to keep it high enough to flow through the notches or over the ſides. Each ditch and trough is gradually contracted in width, as the quantity of water conſtantly decreaſes the farther they proceed. Between every two troughs, and at an equal diſtance from both, cut a drain as deep as you pleaſe parallel to them, and wide enough to receive all the water that runs over the adjacent lands, and to carry it off into the maſter-drain with ſuch rapidity as to keep the whole ſheet of water in conſtant motion; and if poſſible, not to ſuffer a drop to ſtagnate upon the whole meadow. "For a ſtagnation, ſays he, (though it is recommended by a Mr D. Young for the improvement of arable land), is what we never admit in our ſyſtem of watering; for we find that it rots the turf, ſoaks and ſtarves the land, and produces nothing but coarſe graſs and aquatic weeds.

"When a meadow lies cold, flat, and ſwampy, the width of the bed, or the diſtance between the trough and drain, ought to be very ſmall, never exceeding ſix yards: indeed, in this caſe, you can ſcarcely cut your land too much, provided the water be plentiful; for the more you cut, the more water you require. The fall of the bed in every meadow ſhould be half an inch in a foot: leſs will do, but more is deſirable; for when the draught is quick, the herbage is always fine and ſweet. The water ought never to flow more than two inches deep, nor leſs than one inch, except in the warm months."

11
Objections to his method anſwered.

Mr Wright proceeds now to anſwer ſome objections made by the Reviewers in their account of the firſt edition of his work. 1. That the Glouceſterſhire farmers uſe more water for their lands than is neceſſary. To this it is anſwered, That where water is plentiful, they find it advantageous to uſe even more water than he recommends; and when water is ſcarce, they chooſe rather to water only one half, or even a ſmaller portion of a meadow at a time, and to give that a plentiful covering, than to give a ſcanty one to the whole.

12
A repeated uſe of the ſame water is not eligible.

2. The Reviewers likewiſe recommend a repeated uſe of the ſame water upon different and lower parts of the ſame meadow, or to make each drain ſerve as a trough to the bed which is below it. But tho' this method is in ſome degree recommended by the celebrated Mr Bakewell, and taught by a ſyſtematic waterer in Staffordſhire, he entirely diſapproves of it; excepting where the great declivity of the land will not admit of any other plan. "This cannot (ſays he) be a proper mode of watering graſs-land in the winter-time; for it can be of no ſervice to the loweſt parts of the meadow, unleſs as a wetting in ſpring or ſummer. The firſt or higheſt part of a meadow laid out according to this plan will indeed be much improved; the ſecond may reap ſome benefit; but the third, which receives the exhauſted thin cold water, will produce a very unprofitable crop. Our farmers never chooſe more than a ſecond uſe in the ſame meadow, and that very ſeldom; they call even the ſecond running by the ſignificant name of *ſmall-beer;* which, they ſay, may poſſibly ſatisfy thirſt, but can give very little life or ſtrength to land (A). It is a much better method to have a meadow laid out ſo as to be watered at ſe-

---

(A) As by the concurrence of Mr Boſwell with this author, and likewiſe by the agreement of ſo many practical farmers, it ſeems eſtabliſhed as a fact, that water does really loſe its fertilizing properties by running over graſs, it may not here be amiſs to explain the principle on which it does ſo.

Under the article AGRICULTURE, we have ſhown at ſome length, that the true food of plants is the parts of animal and vegetable ſubſtances diſſolved and volatilized by putrefaction, in ſuch a manner that they can be abſorbed by the veſſels of other plants, and thus become part of their ſubſtance. There are two ways in which theſe effluvia may be diſſolved, viz. in air and in water; of conſequence, air and water are the two media by which the food of plants is applied to them, and by means of which they are augmented in bulk. From the analyſis of theſe two elements, it is known that both of them, at leaſt in their ordinary ſtate, contain a great quantity of volatilized earthy matter, which ſometimes ſtrikes our ſenſes very forcibly when firſt emitted by putrefying bodies; but on being thoroughly diſſolved by the atmoſphere, it totally eludes them, and becomes the PHLOGISTON concerning which ſuch violent diſputes have ariſen. This fine volatilized matter is abſorbed from the atmoſphere by the leaves of the plants, and from the water by their roots. Hence both elements, when loaded with vapours of this kind, are more favourable to vegetation than when in their pure ſtate. Thus plants will thrive very well in putrid air, while they languiſh and die in the pure dephlogiſticated kind. Juſt ſo it is with the element of water. When this is loaded with a great quantity of putrid matter, it readily parts with it not only to the roots of plants, but to the atmoſphere alſo; whence ſuch vegetables as it veral times, and to be at the expence of ſeveral ſmall flood-hatches, than to water the whole of it at once by means of catch-drains.

"Sometimes it is neceſſary, in a large meadow, to convey the water that has been uſed under the works and troughs; and then the water above is ſupported by means of boards and planks, which we call a *carry-bridge*. Sometimes, the better to regulate the courſe of the water on the ſurface, eſpecially in the ſpring, narrow trenches are dug, and the mould laid by the ſide of them, in order to be reſtored to its former place when the watering is finiſhed. The earth and mud thrown out in cleanſing and paring the ditches ſhould be carried to fill up the low hollow parts of the meadow, and be trodden down with an even ſurface; which will eaſily be done when the water is on, the waterman being always provided with a ſtrong pair of water-proof boots. If the mould thus uſed has upon it a turf that is tolerably fine, place it uppermoſt; but if it is ſedgy and coarſe, turn it under, and the water if it runs quick will ſoon produce a fine herbage upon it.

"The grounds that are watered in the eaſieſt and moſt effectual manner, are ſuch as have been ploughed and ridged up in lands about twelve yards wide. Here the water is eaſily carried along the ridge by means of a ſmall ditch or trough cut along its ſummit, and then, by means of the ſtops in it, is made to run down the ſides or beds into the furrows, by which it is carried into the maſter drain, which empties itſelf into the river. Every meadow, before it is well watered, muſt be brought into a form ſomething like a field that has been thus left by the plough in a ridged ſtate. Each ſide of the ridge ſhould be as nearly as poſſible an exact inclined plane, that the water may flow over it as equally as may be." Mr Wright does not, like Mr. Boſwell, diſapprove of the uſe of flood-hatches; he only gives the following hint, viz. that their baſis ſhould be deep and firmly fixed, well ſecured with ſtone and clay, that it be not blown up. The following directions are given for each month of watering:

13
Of cleaning and repairing the works.

In the beginning of November, all the ditches, troughs, and drains, are to be thoroughly cleanſed by the ſpade and breaſt-plough, from weeds, graſs, and mud; and well repaired, if they have received any injury from cattle.

14
Thick and muddy water to be uſed when it can be done.

After a ſhower, when the water is thick and muddy, turn over the meadow as much water as you can without injuring the banks of the works, eſpecially if the land be poor; as in this month, according to our author, the water contains many more fertilizing particles, which he calls *ſalts* and *richneſs*, than later in the winter. In defence of this poſition, of which it ſeems the Monthly Reviewers have doubted, our author urges, that though he is not able to prove it by any chemical analyſis, yet it ſeems evident, that "after the firſt waſhing of farm yards, various ſinks, ditches, and the ſurface of all the adjoining fields, which have lain dry for ſome time, the common ſtream ſhould then contain much more fatneſs than when the ſame premiſſes have been repeatedly waſhed." This is confirmed by the experience of the Glouceſterſhire farmers; who, if they can at this ſeaſon of the year procure plenty of muddy water to overflow their grounds for one week, look upon it to be equally valuable with what is procured during all the reſt of the winter. In ſupport of this, he quotes the following words of Mr Forbes, in a treatiſe on watering: "The water ſhould be let in upon the meadow in November, when the firſt great rains make it muddy, for then it is full of a rich ſediment, brought down from the lands of the country through which it runs, and is waſhed into it by the rain; and as the ſediment brought by the firſt floods is the richeſt, the carriages and drains of the meadow ſhould all be ſcoured clean and in order, before theſe floods come."

"In oppoſition (adds Mr Wright) to the opinion of practical waterers, that the muddineſs of the water is of little conſequence, I heſitate not to affirm, that the mud is of as much conſequence in winter-watering, as dung is in the improvement of a poor upland field. For each meadow in this neighbourhood is fruitful in proportion to the quantity of mud that it collects from the water. And, indeed, what can be conceived more enriching than the abundant particles of putrid matter which float in the water, and are diſtributed over the ſurface of the land, and applied home to the roots of the graſs. It is true, that any the moſt ſimple water thrown over a meadow in proper quantity, and not ſuffered to ſtagnate, will ſhelter it in winter, and in the warmth of ſpring will force a crop; but this unuſual force muſt exhauſt the ſtrength of the land, which will require an annual ſupply of manure in ſubſtance, or, in a courſe of years, the ſoil will be impaired rather than improved. The meadows in this county, which lie next below a market-town or village, are invariably the beſt; and thoſe which receive the water after it has been two or three times uſed, reap proportionably leſs benefit from it: For every meadow that is well laid out, and has any quantity of graſs upon its ſurface, will act as a fine ſieve upon the water, which, though it flow in ever ſo muddy, will be returned back to the ſtream as clear as it came from the fountain. This circumſtance, when there is a range of meadows to be watered, the property of different perſons, when water is ſcarce, creates vehement contentions and ſtruggles for the firſt uſe of it. The proprietors are therefore compelled to agree among themſelves, either to have the firſt uſe alternately, or for the higher meadows to dam up, and uſe only one half or a leſs portion of the river. Our farmers know

---

has acceſs to, arrive at the utmoſt luxuriance of growth. If the water is more pure, ſtill they will thrive very well; but the luxuriance of vegetation is leſs than in the former caſe. At laſt, however, when the water has parted with a certain quantity of phlogiſtic matter, the proceſs of vegetation is incapable of ſeparating any more; and therefore ſuch water, though applied to the roots of vegetables, cannot communicate to them any remarkable increaſe. Nay, it is by no means improbable, that after water has arrived at this ſtate, it will, inſtead of giving any freſh nouriſhment to the plants, again deprive them of the nouriſhment which they have already received; and this is probably what Mr Boſwell means, when, in the paſſage formerly quoted, he calls the water *hungry*.

know the mud to be of ſo much conſequence in watering, that whenever they find it collected at the bottom of the river or the ditches, they hire men whole days to diſturb and raiſe it with rakes made for the purpoſe, that it may be carried down by the water, and ſpread upon their meadows. One meadow in South Cerney, I think, is an inconteſtible proof of the conſequence of muddy water. It is watered by a branch of the common ſtream that runs for about half a mile down a public road. This water, by the mud on the road being continually diſturbed by carriages and the feet of cattle, becomes very thick, and when it enters the meadow is almoſt as white as milk. This field, which conſiſts of ſeven acres, was a few years ago let for 10 s. an acre, but is already become the richeſt land in the pariſh, and has produced at one crop eighteen loads of hay, and each load more than 25 hundred weight."

15 nce of good ts of dy wa-

16 Wim- s opi- upon ſub-

In further confirmation of what our author aſſerts, he quotes, from the Annals of Agriculture, the following words of Mr Wimpey: "As to the ſorts of water, little is to be found, I believe, which does not encourage and promote vegetation, even the moſt ſimple, elementary, and uncompounded fluid: heat and moiſture, as well as air, are the *ſine qua non* of vegetation as well as animal life. Different plants require different proportions of each to live and flouriſh; but ſome of each is abſolutely neceſſary to all. However, experience as well as reaſon univerſally ſhows, that the more turbid, feculent, and replete with putreſcent matter the water is, the more rich and fertilizing it proves. Haſty and impetuous rains, of continuance ſufficient to produce a flood, not only diſſolve the ſalts, but waſh the manure in ſubſtance off the circumjacent land into the rapid current. Such turbid water is both meat and drink to the land; and, by the unctuous ſediment and mud it depoſits, the ſoil is amazingly improved and enriched. The virtue of water from a ſpring, if at all ſuperior to pure elementary water,is derived from the ſeveral ſtrata or beds of earth it paſſes through, that, according to the nature of ſuch ſtrata, it may be friendly or otherwiſe to vegetation. If it paſſes through chalk, marle, foſſil ſhells, or any thing of a calcareous nature, it would in moſt ſoils promote the growth of plants; but if through metallic ores, or earth impregnated with the vitriolic acid, it would render the land unfertile, if not wholly barren. In general, the water that has run far is ſuperior to that which immediately flows from the ſpring, and more eſpecially that which is feculent and muddy, conſiſting chiefly of putrid animal ſubſtances waſhed down the ſtream."

17 irmed Ir For-

To the ſame purpoſe alſo ſays Mr Forbes: "There is great difference in the quality of water, ariſing from the particles of different kinds of matter mixed with them. Thoſe rivers that have a long courſe through good land are full of fine particles, that are highly fertilizing to ſuch meadows as are uſually overflowed by them; and this chiefly in floods, when the water is fulleſt of a rich ſediment: for when the water is clear, though it may be raiſed by art high enough to overflow the adjoining lands, and be of ſome ſervice to them, the improvement thus made is far ſhort of what is obtained from the ſame water when it is thick and muddy."

18 Mr Boſwell's opinion.

Mr Boſwell, though quoted by Mr Wright as an advocate for the doctrine juſt now laid down, ſeems, in one part of his work at leaſt, to be of a contrary opinion. This is in the 14th chapter of his book, where he remarks upon another publication on the ſame ſubject, the name of which he does not mention: "In page 4th of that pamphlet (ſays Mr Boſwell), the writer informs us, 'if the water uſed be always pure and ſimple, the effect will by no means be equal to the above; that is, of a ſtream that is ſometimes thick and muddy. We have a ſtriking inſtance of this in two of our meadows, which are watered immediately from ſprings that ariſe in the grounds themſelves. Their crops are early and plentiful, but not of a good quality, and the land remains unimproved after many years watering.'

"The writer of this treatiſe (Mr Boſwell), in a former edition, had aſſerted, and in this repeated, the contrary effects from a ſtream very near the ſpring-head, as clear as cryſtal.

"The gentleman (Mr Beverly of Keld) whom that writer mentions in his preface, made a ſhort viſit laſt ſpring into Dorſetſhire, to ſatisfy himſelf of the fact. The editor had the pleaſure to ſhow him the ſtream alluded to, which he traced almoſt to the fountain-head. It was perfectly clear, and the water was then immediately conveyed out of the ſtream upon the lands adjoining, ſome of which it was then running over; others it had been upon, and the verdure was then appearing. The gentleman expreſſed himſelf perfectly ſatisfied with the fact. To him the editor wiſhes to refer, &c. Mr George Culley of Fenton near Wooller in Northumberland, with a truly noble and public ſpirit that does him great honour as a friend to his country, ſent a very ſenſible young man from thence into Dorſetſhire, to learn the art of watering meadows, and to work the whole ſeaſon in thoſe meadows under different watermen. This man was often over thoſe meadows, and worked in ſome juſt below that were watered by the ſame ſtream. Might the editor preſume to offer his opinion upon this ſeeming contradiction, it is very probable that the ſoils, both the upper and under ſtrata, are very different, as well as thoſe through which the different ſprings run."

19 Advantages of land-floods.

From this paſſage, the latter part of which is not very intelligible, we might conclude that Mr Boſwell prefers clear to muddy water for overflowing meadows. In his chapter on land-floods, however, he expreſſes himſelf as follows: "They will (ſays he) always be found of great uſe where the ſweepings of towns, farm-yards, &c. are carried down by them; ſeldom any other erection is wanting beſides a ſluice or ſmall ware to divert and convey them over the lands. If the ſituation of the land happens to be on the ſide of a hill, catch-drains are abſolutely neceſſary for watering the lower part of the hill, after the water has been uſed upon the upper. In many parts of the kingdom, where there are large hills or extenſive riſing lands, great quantities of water run from them into the valleys after heavy rains: Theſe might with proper attention be collected together before they get to the bottom or flat ground, and from thence be diverted to the purpoſe of watering thoſe lands that lie below, with great advantage to the occupier, and at

20 Of converting arable land into paſture.

a ſmall expence. And ſhould the land thus ſituated be arable, yet it would be found a beneficial exchange to convert it into paſture; particularly if paſture-ground ſhould be a deſirable object to the occupier. The method of performing it is thus recommended. Obſerve the piece of land or field beſt adapted to the purpoſe, both for ſituation and ſoil. If it ſhould be arable, make it firſt very level; and with the crop of corn ſow all ſorts of hay ſeeds; and as ſoon as it has got a green ſward it may be laid out. In the loweſt part of the ground draw a deep ditch for the current to run in through it; and continue it into ſome ditch or low part in the lands below, that the water may be freely carried off, after it has been and while it is in uſe. Draw ditches above the field intended to be watered aſlant the ſides of the hill, in ſuch a manner that they may all empty themſelves into the head of the ditch above-mentioned, juſt where it enters the field to be watered: then erecting a ware acroſs this ditch, the field will be capable of being watered, according to the ſituation of the ditch in the middle or on the ſide of the field. It muſt then be conveyed by ſmall mains or trenches, and ſubdivided again by branch-trenches, according to the ſite of the field and the quantity of water that can be collected; trench-drains muſt be drawn, and the water conveyed into the ditch by means of tail-drains. A perſon unacquainted with water-meadows cannot conceive the advantage ariſing from water thus collected and conveyed over this ſpecies of water-meadow (if it may be ſo called), being generally a firm good ſoil; for the water running down from rich cultivated hills, eminences, &c. ſweeps away with it, when the rain falls very heavy, vaſt quantities of dung dropped by ſheep and other cattle, and the manure carried upon arable lands; all which being now diverted, and carried over the meadow with an eaſy deſcent, gives time for the particles of manure to ſubſide upon the ground at one ſeaſon, or of being filtered from it as it dribbles through the graſs at another; after which the warm weather puſhes on vegetation amazingly. Meadows thus ſituated would be vaſtly ſuperior to any other, if they had the advantage of a conſtant ſtream; but even as they are, taking the opportunity of watering them by every heavy rain or flood that happens, they will be found to be very valuable. The occupier of ſuch lands is ſtrenuouſly adviſed to let no time be loſt in appropriating them to this uſe; becauſe theſe lands are healthy for all kinds of cattle at almoſt all ſeaſons; and the expence of converting them into this kind of water-meadow is exceeding ſmall, the annual charges afterwards quite trifling, and the produce very conſiderable."

21 Mr Wright's directions for watering through the different months of the year.

Mr Wright, having diſcuſſed the ſubject of the quality of the water, proceeds to give directions for watering through the different months of the year:— "In December and January, the chief care conſiſts in keeping the land ſheltered by the water from the ſeverity of froſty nights. It is neceſſary, however, through the whole winter, every ten days or fortnight to give the land air, by taking the water off entirely, otherwiſe it would rot and deſtroy the roots of the graſs. It is neceſſary, likewiſe, that a proper perſon ſhould go over every meadow at leaſt twice every week, to ſee that the water is equally diſtributed, and to remove all obſtructions ariſing from the continual influx of weeds, leaves, ſticks, and the like. In February, a great deal depends upon care and caution. If you now ſuffer the water to remain on the meadow for many days without intermiſſion, a white ſcum is raiſed, very deſtructive to the graſs; and if you take off the water, and expoſe the land to a ſevere froſty night, without its being previouſly dried for a whole day, the greateſt part of the tender graſs will be cut off. The only ways to avoid both theſe injuries are, either to take the water off by day to prevent the ſcum, and to turn it over again at night to guard againſt the froſt; or, if this practice be too troubleſome, both may be prevented by taking the water entirely off for a few days and nights, provided the firſt day of taking off be a dry one; for if the graſs experience one fine drying day, the froſt at night can do little or no injury. The ſcum is generated chiefly by the warmth of the ſun, when the water is thin and uſed too plentifully. Towards the middle of this month we vary our practice in watering, by uſing only about half the quantity of water which is made uſe of earlier in the winter, all that is now required being to keep the ground in a warm moiſt ſtate, and to force vegetation.

"At the beginning of March, the crop of graſs in the meadows is generally ſufficient to afford an abundant paſturage for all kinds of ſtock, and the water is taken off for near a week, that the land may become dry and firm before the heavy cattle are turned in.—It is proper, the firſt week of eating off the ſpring-feed, if the ſeaſon be cold, to give the cattle a little hay each night."

22 Of eati off the ſp'ng with ew and lan

"It is a cuſtom (ſays Mr Wright) with ſome farmers in Hampſhire, to eat off the ſpring-graſs of their meadows with ewes and lambs, in the ſame manner that we do a field of turnips, by incloſing a certain portion each day with hurdles or ſtakes, and giving them hay at the ſame time. This is certainly making the moſt of the graſs, and an excellent method to fine and ſweeten the future herbage. In this month and April, you may eat the graſs as ſhort and cloſe as you pleaſe, but never later; for if you treſpaſs only one week on the month of May, the hay-crop will be very much impaired, the graſs will become ſoft and woolly, and have more the appearance and quality of an after-math than a crop. At the beginning of May, or when the ſpring feeding is finiſhed, the water is again uſed for a few days by way of wetting.

23 How tering occaſio the rot ſheep.

"It is rather remarkable, that watering in autumn, winter, or ſpring, will not produce that kind of herbage which is the cauſe of the rot in ſheep; but has been known to remove the cauſe from meadows, which before had that baneful effect. If, however, you uſe the water only a few days in any of the ſummer months, all the lands thus watered will be rendered unſafe for the paſturage of ſheep. Of this I was lately convinced from an experiment made by a friend. At the beginning of July, when the hay was carried off, and the water rendered extremely muddy and abundant by ſeveral days rain, he thought proper to throw it over his meadows for ten days, in which time a large collection of extremely rich manure was made upon the land. In about a month the meadow was covered with uncommon luxuriancy and blackneſs of herbage. Into this graſs were turned eight

eight ſound ewes and two lambs. In ſix weeks time the lambs were killed, and diſcovered ſtrong ſymptoms of rottenneſs; and in about a month afterwards one of the ewes was killed, and though it proved very fat, the liver was putrid and replete with the inſect called the *fluke* or *weevil:* the other ewes were ſold to a butcher, and all proved unſound. This experiment, however, convinces me, by the very extraordinary improvement made thereby in the meadow, that muddy water in the ſummer is much more enriching than it is in autumn or winter; and ought, therefore, to be uſed for a week at leaſt every wet ſummer, notwithſtanding its inconveniences to ſheep, the moſt profitable ſpecies of ſtock."

24
Mr Boſvell's geeral direcions for vatering.

Mr Boſwell, beſides his general directions for watering, gives many plans of the ditches, drains, &c. for particular meadows, ſome of them done from an actual ſurvey. But theſe being confined to particular ſituations, we ſhall here only ſpeak of his method in general. In his third chapter, intitled *A general Deſcription of Water-meadows*, he obſerves, that "lands capable of being watered, lie ſometimes only on one ſide and ſometimes on both ſides of the ſtream deſigned to ſupply them with water. In the former caſe, when they have a pretty quick deſcent, the land may be often watered by a main drawn out of the ſtream itſelf, without any ware; though he acknowledges that it is by far the beſt way to erect a ware, and to draw mains on each ſide, to diſpoſe of the water to the beſt advantage.

Boggy lands require more and longer continued watering than ſuch as are ſandy or gravelly; and the larger the body of water that can be brought upon them, the better. The weight and ſtrength of the water will greatly aſſiſt in compreſſing the ſoil, and deſtroying the roots of the weeds that grow upon it; nor can the water be kept too long upon it, particularly in the winter ſeaſon; and the cloſer it is fed, the better.

To improve ſtrong clay ſoils, we muſt endeavour to the utmoſt to procure the greateſt poſſible deſcent from the trench to the trench drain; which is beſt done by making the trench-drains as deep as poſſible, and applying the materials drawn out of them to raiſe the trenches. Then, with a ſtrong body of water, taking the advantage of the autumnal floods, and keeping the water ſome time upon them at that ſeaſon, and as often as convenient during the winter, the greateſt improvement on this ſort of ſoils may be made. Warm ſand or gravelly ſoils are the moſt profitable under the watering ſyſtem, provided the water can be brought over them at pleaſure. In ſoils of this kind, the water muſt not be kept long at a time, but often ſhifted, thoroughly drained, and the land frequently refreſhed with it: under which circumſtances the profit is immenſe. A ſpring-feeding, a crop of hay, and two aftermaths, may be obtained in a year; and this, probably, where in a dry ſummer ſcarce graſs enough could be found to keep a ſheep alive. If the ſtream be large, almoſt any quantity of land may be watered from it; and though the expence of a ware over it is great, it will ſoon be repaid by the additional crop. If the ſtream is ſmall, the expence will be ſo in proportion.

25
Method of improving a ſpringy water-meadow.

The following method of improving a water-meadow that was ſpringy has been tried by Mr Boſwell with ſucceſs. The meadow had been many years watered by a ſpring riſing juſt above it from a barren ſandy heath; the ſoil near the ſurface was in ſome places a gravelly ſand, in others a ſpongy cork, both upon a ſtrong clay and ſand mixture, which retained the draining of the lands above it. Whenever it had been watered, and left to drain itſelf dry, a yellowiſh-red water ſtood in many parts, and oozed out of others; the herbage being no other than a poor, miſerable, hairy graſs and ſmall ſedge. Chalk and aſhes had been thrown over it to very little purpoſe. It was then drained underground aſlant all the different deſcents, and all theſe drains carried into one large drain, which had been already cut for the purpoſe of carrying off the water when the meadow was overflowed. Theſe drains were cut quite through the mixture of clay and ſand, and as much deeper as the fall of the ground below would admit of; then, with chalk cut for the purpoſe, ſmall hollow drains were formed at the bottom of theſe; the drains were then filled up with the materials that came out.

This was done in the beginning of ſummer, and the work frequently examined through the ſeaſon; the ſoil was found firmer than before, and none of that naſty red water to be met with upon the ſurface, though it continually oozed into the drains. In autumn the meadow was again prepared for waterings, by repairing thoſe trenches and drains that were properly ſituated; cutting others where wanted, for the purpoſe of watering meadows. The water being then brought over it from the ſame ſpring as before, the event anſwered the moſt ſanguine wiſhes of the proprietor; the effects were viſible the firſt year, and the ground has been conſtantly improving ever ſince.

26
Of watering lands on the ſides of hills.

Mr Boſwell alſo informs us, that a gentleman in Scotland had applied to him for directions to water ſome lands lying on the ſides of hills, where the deſcent is quick; and of which there are many in this country, as well as in the north of England. It would be difficult to water ſuch lands by means of drains and trenches according to the directions already given; becauſe the bends in the trenches muſt be very near together and large, as the water muſt flow out of the trench *above* the bend to flow over the pane below it; the number and ſize would likewiſe be inconvenient, and greatly offend the eye.

Lands of this ſort are generally capable of being ploughed; in which caſe our author directs them to be once ploughed in the ſpring, and ſown with oats or any other kind of grain that will rot the ſward. When the grain is harveſted, plough the land acroſs; the laſt ploughing with the Kentiſh plough, which has a moveable mold-board, and is called a *turn-wriſt* plough. This turns the furrows down the ſide of the hill, the horſes going forwards and backwards in the ſame furrows. By this means the land is laid flat without any open furrows in it: dreſs it down in the ſpring very fine, and ſow it with oats, and mix with ſome kinds of graſs ſeeds very thick. Thus the ground will have but few irregularities; and as ſoon as the corn is carried off, or the following ſpring at fartheſt, the mains and drains may be cut out.

For watering coarſe lands that are firm enough to bear

bear the plough, and ſituated near a ſtream, our author gives the following directions.

27
Of watering coarſe lands.

“ Let the land thus ſituated be ploughed once in the ſpring, and ſown with any grain that will rot ſward. As ſoon as the crop is off, plough it again, and leave it rough through the winter. Work it down early in the ſpring, and plough it in the direction the trenches are to lie, making the ridges of a proper ſize for watering, ten or twelve yards wide for inſtance; work it fine; then gather the ridges up again in the ſame manner, making the laſt furrows of each ridge as deep as poſſible. If the land be not fine, dreſs it down again, and gather it up a ſecond time if neceſſary; and with a ſhovel throw the earth from the edges of the furrows to the tops of the ridges, to give the greateſt poſſible deſcent from the trench to the drain. Sow it with oats and graſs ſeeds very thick; and after the corn is carried off, the trenches may be formed upon the top of each ridge, diſperſing the furrows with a ſpade as much as the fall of the land will admit of for the drains; taking care to procure ſufficient fall at all events, to drain the lands after they have been watered. By this method the crops of corn will nearly pay all the expence, and the land will be in excellent order.

28
Of the management of meadows after watering.

After the work of watering a meadow is totally finiſhed, and the hay carried off, cattle may be let in to eat the after-math. When this is done, it will then be neceſſary to examine whether or not the mains have ſuffered any injury from their feet; whether there be quantities of mud or ſand collected at the angles, &c. all of which muſt be thrown out and the breaches repaired; by which means the trenches, drains, &c. will laſt three years, but otherwiſe not more than two. The roots, mud, &c. may be uſed in repairing the breaches, but never left upon the ſides of the trenches out of which they are taken. The tail-drains require to be cleanſed oftener than any of the other works, for this obvious reaſon, that the mud, &c. is carried down from all the others into them; where if it be allowed to accumulate, it occaſions a ſtagnation of water upon the meadow itſelf. In repairing the trenches, particular care ought to be taken that the workmen do not make them any wider than before, which they are very apt to do; neither are they to be allowed to throw the materials which they dig out in a ridge behind the edge of the trench, which both widens it and promotes weeds.

29
Of the times the water ſhould continue upon the meadows.

During the time of watering, it will be neceſſary to examine the meadow every two or three days in order to remove obſtructions, &c. If the drains ſhould be filled with water and run over, they ought to be made deeper; or if this cannot be done, they ſhould be widened. In the winter time a regular ſtrong water ſhould be kept, avoiding very ſtrong great floods. In this ſeaſon the water may be kept on the ground with ſafety for a month or even ſix weeks if the ſoil be corky or boggy or a ſtrong clay; but not quite ſo long if it be gravel or ſand. At the ſecond watering a fortnight or three weeks will be ſufficient; and after Candlemas a fortnight will be rather too long. At the third watering a week will be ſufficient, which will bring it to about the middle of March; by which time, if the weather be tolerably mild, the graſs will be long enough for the ewes and lambs, or fatting lambs; which may then be turned into the meadow with great advantage. Even in the end of February, if the winter has been very mild, the graſs will be long enough for them. Here they may be permitted to feed till the beginning of May, changing them into different meadows. As ſoon as they are taken out, the water muſt be turned in for a week, carefully examining every trench and drain for the reaſons already given. The water is then to be ſhifted into others, alternately watering and draining, leſſening the time the water remains upon it as the weather grows warmer; and in five, ſix, or ſeven weeks, the graſs will be fit to be mown for hay, and produce from one to two tons, or even more, an acre upon good ground.

Mr Boſwell directs, that about a week before the graſs is to be mown the water ſhould be let into the meadow for 24 hours; which, he ſays, will make the ground moiſt at the bottom, the ſcythe will go thro' it the more eaſily, and the graſs will be mown cloſer to the ground. This practice, however, is entirely diſapproved of by Mr Wright. “ Though it may prevail in Dorſetſhire (ſays he), it is very ſeldom adviſable, for the following reaſons: Water made to run through a thick crop of graſs, though it may appear ever ſo pure, will leave a certain quantity of adherent ſcum or ſediment, which can never be ſeparated from the hay, but will render it unpalatable, if not prejudicial, to the cattle that eat it. And this wetting of the land and graſs will impede the drying or making of the hay perhaps ſome days, which in difficult ſeaſons is of very great conſequence; and it will likewiſe make the turf too ſoft and tender to ſupport the wheels of a loaded waggon in carrying off the hay. Beſides, there is reaſon to believe that one day's wetting in the ſummer will, upon moſt meadows, endanger the ſoundneſs of every ſheep that feeds upon the aftermath.”

30
Of ſpring-feeding.

The ſpring-feeding ought never to be done by heavier cattle than ſheep or calves; for larger cattle do much hurt by poaching the ground with their feet, deſtroying the trenches, and ſpoiling the graſs. Mr Boſwell likewiſe greatly recommends a proper uſe of ſpring floods, from which he ſays much benefit may be derived; but if there is any quantity of graſs in the meadows not eaten, theſe floods muſt be kept out, otherwiſe the graſs will be ſpoiled; for they bring with them ſuch quantities of ſand and mud, which ſtick to the graſs, that the cattle will rather ſtarve than taſte it. Great quantities of egraſs or aftermath are frequently ſpoiled in flat countries by the floods which take place in the fall. In the winter-time, however, when the ground is bare, the ſand and mud brought down by the floods is ſoon incorporated with the ſoil, and becomes an excellent manure. The certain rule with regard to this matter is, ‘‘ Make uſe of the floods when the graſs cannot be uſed; avoid them when the graſs is long or ſoon to be cut.”

31
Of watering from the end of autumn to Candlemas.

“ It has often been a ſubject of diſpute (ſays Mr Boſwell), whether, from the latter end of autumn to Candlemas, the throwing a very ſtrong body of water, where it can be done, over the meadows, is of any eſſential ſervice or not? Thoſe who conſider it as advantageous, aſſert, that when the waters run rude and ſtrong over the ground, they beat down and rot the tufts

tufts

tufts of foggy or rough graſs, ſedge, &c. that are always to be found in many parts of coarſe meadow-ground; and therefore are of peculiar ſervice to them. On the other ſide it is alleged, that by coming in ſo large a body, it beats the ground (in the weak places particularly) ſo bare, that the ſward is deſtroyed; and alſo brings with it ſuch quantities of ſeeds of weeds, that at the next hay ſeaſon the land in all thoſe bare places bears a large burden of weeds, but little graſs.

“ The general opinion of the watermen upon this point is, that in water meadows which are upon a warm, ſandy, or gravelly ſoil, with no great depth of loam upon them, rude ſtrong watering, even in winter, always does harm without any poſſible eſſential ſervice. On the contrary, cold ſtrong clay land will bear a great deal of water a long time without injury; and boggy, corky, or ſpongy ſoil, will alſo admit of a very large and ſtrong body of water upon it; provided the drains are made wide and deep enough to carry it off, without forcing back upon the end of the panes, with great advantage for almoſt any length of time at that ſeaſon. The weight and force of the water vaſtly aſſiſts in compreſſing thoſe ſoils, which only want ſolidity and tenacity to make them produce great burthens of hay: nothing, in their opinion, corrects and improves thoſe ſoils ſo much as a very ſtrong body of water, kept a conſiderable time upon them at that ſeaſon.”

Notwithſtanding the above reaſons, however, Mr Boſwell informs us, That he has doubts upon the ſubject; nor can he by any means acquieſce in this opinion, unleſs by rude ſtrong waters he is permitted to underſtand only rather a larger quantity of water conveyed over the land at this early ſeaſon than ought to be uſed in the ſpring or ſummer: unmanageable waters he believes always hurtful.

“ It may be proper juſt to add (continues he), that as ſoon as the hay is carried off the meadows, cattle of any ſort except ſheep may be put to eat the graſs out of the trenches, and what may be left by the mowers. This perhaps will laſt them a week; when the water may be put into the meadows in the manner already deſcribed, taking care to mow the long graſs which obſtructs the water in the trenches; and this mowing is beſt done when the water is in them. Let the weeds, leaves, &c. be taken out and put in heaps, to be carried away into the farm-yards; examine the trenches, make up the breaches, &c. take particular care that the water only dribbles over every part of the panes as thin as poſſible, this being the warmeſt ſeaſon of the year. The firſt watering ſhould not be ſuffered to laſt longer than two or three days before it is ſhifted off (and if the ſeaſon be wet, perhaps not ſo long, as warmth ſeems to be the greateſt requiſite after the land is once wet to aſſiſt vegetation) to another part or meadow beat out by the cattle, by this time fit to take it. Do by this meadow exactly the ſame, and ſo by a third and fourth, if as many meadows belong to the occupier. Obſerve at all times, when the water is taken out of a meadow, to draw up the drain-ſluice hatches; as, without doing that, watering is an injury. By the time that three or four parts are thus regularly watered, the firſt will have an after-math, with ſuch rich and beautiful verdure as will be aſtoniſhing; and both quantity and quality will be beyond conception better than if the lands had not been watered.

“ Hence we ſee why every perſon ſhould if poſſible have three or four meadows that can be watered; for here, while the cattle are eating the firſt, the ſecond is growing, the third draining, &c. and the fourth under water. In this manner the after-math will in a mild ſeaſon laſt till Chriſtmas. A reaſon was given why the ſpring-graſs ſhould be fed only by ſheep or calves; a reaſon equally cogent may be given, why the after-graſs ought not to be fed by them, becauſe it will infallibly rot them. “ No ſheep (ſays our author), except thoſe which are juſt fat, muſt ever be ſuffered even for an hour in water-meadows except in the ſpring of the year; and even then care muſt be taken that every part of the meadows have been well watered, and that they are not longer kept in them than the beginning of May. Although at preſent it is unknown what is the occaſion of the rot, yet certain it is that even half an hour's feeding in unhealthy ground has often proved fatal. After a ſhort time they begin to loſe their fleſh, grow weaker and weaker: the beſt feeding in the kingdom cannot improve them after they once fall away; and when they die, animalcula like plaice are found in the livers. Scarcely any ever recover from a ſlight attack; but when farther advanced, it is always fatal. Guard by all means againſt keeping the water too long upon the meadow in warm weather; it will very ſoon produce a white ſubſtance like cream, which is prejudicial to the graſs, and ſhows that it has been too long upon the ground already. If it be permitted to remain a little longer, a thick ſcum will ſettle upon the graſs of the conſiſtence of glue, and as tough as leather, which will quite deſtroy it wherever it is ſuffered to be produced. The ſame bad effects ſeem to ariſe from rude waters; neither can the ſcum eaſily be got off.

32
Water ought not be kept too long upon meadows.

33
Advantage of rolling meadows.

“ Rolling meadows in the ſpring of the year is an excellent method. It ſhould be done after Candlemas, when the meadow has been laid dry a week. It ſhould be always rolled lengthwiſe of the panes, up one ſide of the trench and down the other. Rolling alſo contributes much to the graſs being cut cloſe to the ſurface when mown, which is no ſmall advantage; for the little hillocks, ſpewings of worms, ant-hills, &c. are by this means preſſed cloſe to the ground, which would otherwiſe obſtruct the ſcythe and take off its edge; and to avoid that inconvenience, the workmen always mow over them.”

MEAL, the flour of grain. The meal or flour of Britain is the fineſt and whiteſt in the world. The French is uſually browner, and the German browner than that. Our flour keeps well with us, but in carrying abroad it often contracts damp, and becomes bad. All flour is ſubject to breed worms; theſe are white in the white flour, and brown in that which is brown: they are therefore not always diſtinguiſhable to the eye; but when the flour feels damp, and ſmells rank and muſty, it may be conjectured that they are there in great abundance.

The colour and the weight are the two things which denote the value of meal or flour; the whiter and the heavier it is, other things being alike, the better it always is. Pliny mentions theſe two characters as the marks of good flour; and tells us, that Italy in his time produced the fineſt in the world. This country indeed was famous before his time for this produce; and the Greeks have celebrated it; and Sophocles in particular ſays, that no flour is ſo white or ſo good as that of Italy. The corn of this country has, however, loſt much of its reputation ſince that time; and the reaſon of this ſeems to be, that the whole country being full of ſulphur, alum, vitriol, marcaſites, and bitumens, the air may have in time affected them ſo far as to make them diffuſe themſelves through the earth, and render it leſs fit for vegetation; and the taking fire of ſome of theſe inflammable minerals, as has ſometimes happened, is alone ſufficient to alter the nature of all the land about the places where they are.

The flour of Britain, though it pleaſes by its whiteneſs, yet wants ſome of the other qualities valuable in flour; the bread that is made of it is brittle and does not hold together, but after keeping a few days becomes hard and dry as if made of chalk, and is full of cracks in all parts; and this muſt be a great diſadvantage in it when intended for the ſervice of an army or the like occaſions, where there is no baking every day, but the bread of one making muſt neceſſarily be kept a long time.

The flour of Picardy is very like that of Britain; and after it has been kept ſome time, is found improper for making into paſte or dough. The French are forced either to uſe it immediately on the grinding, or elſe to mix it with an equal quantity of the flour of Brittanny, which is coarſer but more unctuous and fatty; but neither of theſe kinds of flour keep well.

The flour of almoſt any country will do for the home conſumption of the place, as it may be always freſh ground; but the great care to be uſed in ſelecting it is in order to the ſending it abroad, or furniſhing ſhips for their own uſe. The ſaline humidity of the ſea-air ruſts metals, and fouls every thing on board, if great care be not taken in the preſerving them. This alſo makes the flour damp and mouldy, and is often the occaſion of its breeding inſects, and being wholly ſpoiled.

The flour of ſome places is conſtantly found to keep better at ſea than that of others; and when that is once found out, the whole caution needs only be to carry the flour of thoſe places. Thus the French find that the flour of Poitou, Normandy, and Guienne, all bear the ſea-carriage extremely well; and they make a conſiderable advantage by carrying them to their American colonies.

The choice of flour for exportation being thus made, the next care is to preſerve it in the ſhips: the keeping it dry is the grand conſideration in regard to this; the barrels in which it is put up ought to be made of dry and well-ſeaſoned oak, and not to be larger than to hold two hundred weight at the moſt. If the wood of the barrels have any ſap remaining in it, it will moiſten and ſpoil the flour; and no wood is ſo proper as oak for this purpoſe, or for making the bins and other veſſels for keeping flour in at home, ſince when once well dried and ſeaſoned it will not contract humidity afterwards. The beech-wood, of which ſome make their bins for flour, is never thoroughly dry, but always retains ſome ſap. The fir will give the flour a taſte of turpentine; and the aſh is always ſubject to be eaten by worms. The oak is preferable, becauſe of its being free from theſe faults; and when the ſeveral kinds of wood have been examined in a proper manner, there may be others found as fit, or poſſibly more ſo, than this for the purpoſe. The great teſt is their having more or leſs ſap. See FLOUR and WOOD.

MEAN, in general, denotes the middle between two extremes: thus we ſay the mean diſtance, mean proportion, &c.

MEARNS, or KINCARDINSHIRE, a county of Scotland, bounded on the north by Aberdeenſhire, on the eaſt by the Britiſh Ocean, and on the ſouth-weſt by Angusſhire. In form it reſembles a harp, having the lower point towards the ſouth. Its length alongſt the coaſt is ſcarce 30 miles; its greateſt breadth about 20. Some derive the firſt name from Mearns a valiant nobleman, who, ſubduing the country, received it in reward from his prince Kenneth II. Camden, with much probability, ſuppoſes it to retain part of the name of the old inhabitants, the Vernicones of Ptolemy, it being common for the Britons in diſcourſe to change the V into M. The other name is taken from its ancient capital *Kincardine*, now an inconſiderable village. The tract of country through which the Dee paſſes, and the plain along the ſea-coaſt, are well cultivated, and produce much corn and flax. The fields are in many places ſkreened by woods; and the heaths afford ſheep-walks and much good paſture for cattle. Near Stonehaven, to the ſouth, are the ruins of Dunotter caſtle, the ancient ſeat of the earls Mariſhal of Scotland, ſituated on a high perpendicular rock, almoſt ſurrounded by the ſea. In this neighbourhood is a precipitous cliff over-hanging the ſea, called *Fowl's Cleugh;* noted as the reſort of kittiwakes, the young of which are much ſought after in the hatching ſeaſon, being eſteemed a great delicacy.—At a little diſtance from Stonehaven, up the river, ſtands Urie, the birth-place of Barclay the famous apologiſt for the Quakers. The Quakers have here a burying ground; and in the vicinity are ſeen the traces of a Roman ſtation. The great valley called *Strathmore* commences here, and extends in a ſouth-weſt direction nearly as far as Benlomond in Stirlingſhire, bounded all along to the north-weſt by the Grampian mountains. —The village of Fordun, a little ſouth from the centre of the country, is ſuppoſed to be the birth-place of the celebrated author of the Scotichronicon. St Pady's church, or Paldy kirk in this neighbourhood, is famous for being the burial-place and reſidence of St Palladius; whoſe chapel is ſtill to be ſeen on the ſouth ſide of it, 40 feet by 18, now the burial-place of the Halkerton-family. Near the village, and along the river Bervie, the country is flat and well cultivated. The ſmall town of INVERBERVIE was made a royal borough by David Bruce, who landed there with his queen at Craig David after his long retreat into France. Near the village of *Fettercairn* was Den Finnel, the reſidence of Finella, daughter of a nobleman of large poſſeſſions in this country, or, as Major calls her, *counteſs of Angus*, who was acceſſary to the murder of Keneth II. About two miles from this place, on the road-ſide, is a cairn of a ſtupendous ſize and uncommon form, which probably might give name to the pariſh. About ſix miles weſt from Bervie, is ſituated *Laurencekirk*, which ſome years back was only an inſignificant village of ſix or ſeven houſes; but by the judicious and liberal exertions of its proprietor Lord Gardenſtone, has become a handſome little town, with a right to elect magiſtrates, and to hold an annual fair and a weekly market. He has eſtabliſhed here a flouriſhing and extenſive manufacture of lawn, cambric, linen, and various other articles. He has alſo freely renounced all the oppreſſive ſervices due by his tenants; ſervices which have been ſo long and ſo juſtly complained of as a check to agriculture in many parts of Scotland.—The north-weſt part of the ſhire, being mountainous, is more employed in paſture than in cultivation.

MEASLES, a cutaneous diſeaſe attended with a fever, in which there is an appearance of eruptions that do not tend to a ſuppuration. See (the *Index* ſubjoined to) MEDICINE.

MEASURE, in geometry, denotes any quantity aſſumed as one, or unity, to which the ratio of the other homogeneous or ſimilar quantities is expreſſed.

MEASURE, in a legal and commercial ſenſe, denotes a certain quantity or proportion of any thing, bought, ſold, valued, or the like.

It is neceſſary, for the convenience of commerce, that an uniformity ſhould be obſerved in weights and meaſures, and regulated by proper ſtandards. A foot-rule may be uſed as a ſtandard for meaſures of length, a buſhel for meaſures of capacity, and a pound for weights. There ſhould be only one authentic ſtandard of each kind, formed of the moſt durable materials, and kept with all poſſible care. A ſufficient number of copies, exactly correſponding to the principal ſtandard, may be diſtributed for adjuſting the weights and meaſures that are made for common uſe. There are ſeveral ſtandards of this kind both in England and Scotland. See the article *WEIGHTS and Meaſures*.

If any one of the ſtandards above-mentioned be juſtly preſerved, it will ſerve as a foundation for the others by which they may be corrected if inaccurate, or reſtored if entirely loſt. For inſtance, if we have a ſtandard foot, we can eaſily obtain an inch, and can make a box which ſhall contain a cubical inch, and may ſerve as a ſtandard for meaſures of capacity. If it be known that a pint contains 100 cubical inches, we may make a veſſel five inches ſquare, and four inches deep, which will contain a pint. If the ſtandard be required in any other form, we may fill this veſſel with water, and regulate another to contain an equal quantity. Standards for weights may be obtained from the ſame foundation; for if we know how many inches of water it takes to weigh a pound, we have only to meaſure that quantity, and the weight which balances it may be aſſumed as the ſtandard of a pound.

Again, if the ſtandard of a pound be given, the meaſure of an inch may be obtained from it: for we may weigh a cubical inch of water, and pour it into a regular veſſel; and having noticed how far it is filled, we may make another veſſel of like capacity in the form of a cube. The ſide of this veſſel may be aſſumed as the ſtandard for an inch; and ſtandards for a foot, a pint, or a buſhel, may be obtained from it. Water is the moſt proper ſubſtance for regulating ſtandards; for all other bodies differ in weight from others of the ſame kind; whereas it is found by experience that ſpring and river water, rain, and melted ſnow, and all other kinds, have the ſame weight; and this uniformly holds in all countries when the water is pure, alike warm, and free from ſalt and minerals.

Thus, any one ſtandard is ſufficient for reſtoring all the reſt. It may further be deſired to hit on ſome expedient, if poſſible, for reſtoring the ſtandards, in caſe that all of them ſhould ever fall into diſorder, or ſhould be forgotten, through the length of time, and the viſciſſitudes of human affairs. This ſeems difficult, as no words can convey a preciſe idea of a foot-rule, or a pound weight. Meaſures, aſſumed from the dimenſions of the human body, as a foot, a hand-breadth, or a pace, muſt nearly be the ſame in all ages, unleſs the ſize of the human race undergo ſome change; and therefore, if we know how many ſquare feet a Roman acre contained, we may form ſome judgment of the nature of the law which reſtricted the property of a Roman citizen to ſeven acres; and this is ſufficient to render hiſtory intelligible; but it is too inaccurate to regulate meaſures for commercial purpoſes. The ſame may be ſaid of ſtandards, deduced from the meaſure of a barley-corn, or the weight of a grain of wheat. If the diſtance of two mountains be accurately meaſured and recorded, the nature of the meaſure uſed will be preſerved in a more permanent manner than by any ſtandard; for if ever that meaſure fall into diſuſe and another be ſubſtituted in its place, the diſtance may be meaſured again, and the proportion of the ſtandards may be aſcertained by comparing the new and ancient diſtances.

But the moſt accurate and unchangeable manner of eſtabliſhing ſtandards is, by comparing them with the length of pendulums. The longer a pendulum is, it vibrates the ſlower; and it muſt have one preciſe length in order to vibrate in a ſecond. The ſlighteſt difference in length will occaſion a difference in the time; which will become abundantly ſenſible after a number of vibrations, and will be eaſily obſerved if the pendulum be applied to regulate the motion of a clock. The length of a pendulum which vibrates ſeconds in London is about 39$\frac{1}{5}$ inches, is conſtantly the ſame at the ſame place; but it varies a little with the latitude of the place, being ſhorter as the latitude is leſs. Therefore, though all ſtandards of weights and meaſures were loſt, the length of a ſecond pendulum might be found by repeated trials: and if the pendulum be properly divided, the juſt meaſure of an inch will be obtained; and from this all other ſtandards may be reſtored. See *Whitehurſt on Invariable* MEASURES.

Meaſures are various, according to the various kinds and dimenſions of the things meaſured.—Hence ariſe lineal or longitudinal meaſures, for lines or lengths; ſquare meaſures, for areas or ſuperfices; and ſolid or cubic meaſures, for bodies and their capacities: all which again are very different in different countries and in different ages, and even many of them for different commodities. Whence ariſe other diviſions of ancient and modern meaſures, domeſtic and foreign ones, dry meaſures, liquid meaſures, &c.

I. LONG *Meaſures, or Meaſures of Application.*

1.] The *Engliſh* and *Scotch* Standards.

The Engliſh lineal ſtandard is the yard, containing 3 Engliſh feet; equal to 3 Paris feet 1 inch and $\frac{1}{12}$

Meaſure.

of an inch, or $\frac{7}{9}$ of a Paris ell. The uſe of this meaſure was eſtabliſhed by Henry I. of England, and the ſtandard taken from the length of his own arm. It is divided into 36 inches, and each inch is ſuppoſed equal to 3 barley-corns. When uſed for meaſuring cloth, it is divided into four quarters, and each quarter ſubdivided into 4 nails. The Engliſh ell is equal to a yard and a quarter, or 45 inches, and is uſed in meaſuring linens imported from Germany and the Low-Countries.

The Scots *elwand* was eſtabliſhed by king David I. and divided into 37 inches. The ſtandard is kept in the council-chamber of Edinburgh, and being compared with the Engliſh yard, is found to meaſure $37\frac{1}{5}$ inches; and therefore the Scots inch and foot are larger than the Engliſh, in the proportion of 180 to 185; but this difference being ſo inconſiderable, is ſeldom attended to in practice. The Scots ell, though forbidden by law, is ſtill uſed for meaſuring ſome coarſe commodities, and is the foundation of the land-meaſure of Scotland.

Itinerary meaſure is the ſame both in England and Scotland. The length of the chain is 4 poles, or 22 yards; 80 chains make a mile. The old Scots computed miles were generally about a mile and a half each.

The reel for yarn is $2\frac{1}{2}$ yards, or 10 quarters, in circuit; 120 threads make a cut, 12 cuts make a haſp or hank, and 4 hanks make a ſpindle.

2.] The *French* Standard is the aune or ell, containing 3 Paris feet 7 inches 8 lines, or 1 yard $\frac{2}{7}$ Engliſh; the Paris foot-royal exceeding the Engliſh by $\frac{68}{1000}$ parts, as in one of the following tables. This ell is divided two ways, viz. into halves, thirds, ſixths, and twelfths; and into quarters, half-quarters, and ſixteenths.

This ell holds throughout the greateſt part of France; excepting at Troyes in Champagne, at Arc in the Barrois, and in ſome parts of Picardy and Burgundy, where the ell contains only 2 feet 5 inches 1 line; in Bretagne, where it contains 4 feet 2 inches 11 lines; and at St Genoux in Berry, where it exceeds the Paris ell by 8 lines. See Ell. But in Languedoc, particularly at Marſeilles, Montpelier, Thoulouſe in Provence, and in Guienne, they meaſure by the canna, which at Thoulouſe and in Guienne contains 5 Paris feet 5 inches and 6 lines; or one Paris ell and a half. But at Montpelier, and throughout the Lower Languedoc, as alſo in Provence and Avignon, and even Dauphine, the canna is 6 feet and 9 lines, or 1 Paris ell and $\frac{2}{3}$. See Canna.

We have lately had ſome accurate compariſons between ſome of the French weights and meaſures and thoſe of England, the reſult of which is, (1.) The Paris half toiſe, as ſet off on the ſtandard kept in the Royal Society; contains of Engliſh inches by the ſame ſtandard 38.355, whence it appears, that the Engliſh yard and foot is, to the Paris half toiſe and foot, nearly as 107 to 114; for as 107 to 1.14, ſo is 36 to 38.35514.

(2.) The Paris 2 marc, or 16 ounce weight, weighs Engliſh Troy grains 7560; whence it appears, that the Engliſh Troy pound of 12 ounces, or 5760 grains, is to the Paris 2 marc, or 16 ounce weight, as 16 to 21; that the Paris ounce weighs Engliſh Troy grains 472.5, and that conſequently, the Engliſh Troy ounce is to the Paris ounce as 64 is to 63.

(3). The Engliſh Avoirdupois pound weighs Troy grains 7004; whence the Avoirdupois ounce, whereof 16 make a pound, is found equal to 437.75 Troy grains.—And it follows, that the Troy pound is to the Avoirdupois pound as 88 to 107 nearly; for as 88 to 107, ſo is 5760 to 7003.636: that the Troy ounce is to the Avoirdupois ounce, as 80 to 73 nearly; for as 80 to 73, ſo is 480 to 438. And, laſtly, that the Avoirdupois pound and ounce is to the Paris two marc weight and ounce, as 63 to 68 nearly; for as 63 to 68, ſo is 7004 to 7559.873. See Weight. (4.) The Paris foot expreſſed in decimals, is equal to 1.0654 of the Engliſh foot, or contains 12.785 Engliſh inches. See Foot.

3.] The ſtandard in *Holland*, *Flanders*, *Sweden*, a good part of *Germany*, many of the Hans-towns, as *Dantzick*, and *Hamburgh*, and at *Geneva*, *Franckfort*, &c. is likewiſe the ell: but the ell, in all theſe places, differs from the Paris ell. In Holland, it contains one Paris foot eleven lines, or four ſevenths of the Paris ell. The Flanders ell contains two feet one inch five lines and half a line; or ſeven-twelfths of the Paris ell. The ell of Germany, Brabant, &c. is equal to that of Flanders.

4.] *The Italian* meaſure is the bracchio, brace, or fathom. This obtains in the ſtates of Modena, Venice, Florence, Lucca, Milan, Mantua, Bologna, &c. but is of different lengths. At Venice, it contains one Paris foot eleven inches three lines, or eight fifteenths of the Paris ell. At Boulogna, Modena, and Mantua, the brace is the ſame as at Venice. At Lucca it contains one Paris foot nine inches ten lines, or half a Paris ell. At Florence, it contains one foot nine inches four lines, or forty-nine hundredths of a Paris ell. At Milan, the brace for meaſuring of ſilks is one Paris foot ſeven inches four lines, or four-ninths of a Paris ell: that for woollen cloths is the ſame with the ell of Holland. Laſtly, at Bergama, the brace is one foot ſeven inches ſix lines, or five-ninths of a Paris ell. The uſual meaſure at Naples, however, is the canna, containing ſix feet ten inches and two lines, or one Paris ell and fifteen ſeventeenths,

5.] *The Spaniſh* meaſure is the vara or yard, in ſome places called the barra; containing ſeventeen twenty-fourths of the Paris ell. But the meaſure in Caſtile and Valencia is the pan, ſpan, or palm; which is uſed, together with the canna, at Genoa. In Arragon, the vara is equal to a Paris ell and a half, or five feet five inches ſix lines.

6.] *The Portugueſe* meaſure is the cavedos, containing two feet, eleven lines, or four-ſevenths of a Paris ell; and the varra, a hundred and ſix whereof make a hundred Paris ells.

7.] *The Piedmonteſe* meaſure is the ras, containing one Paris foot nine inches ten lines, or half a Paris ell. In Sicily, their meaſure is the canna, the ſame with that of Naples.

8.] *The Muſcovite* meaſures are the cubit, equal to one Paris foot four inches two lines; and the arcin, two whereof are equal to three cubits.

9.] *The Turkiſh* and *Levant* meaſures are the picq, containing two feet two inches and two lines, or three fifths of the Paris ell. The Chineſe meaſure, the cobre; ten whereof are equal to three Paris ells. In Perſia, and ſome parts of the Indies, the gueze, whereof there are two kinds; the royal gueze, called alſo the *gueze monkelſer*, containing two Paris feet ten inches eleven lines, or four-fifths of the Paris ell; and the ſhorter gueze, called ſimply *gueze*, only two thirds of the former. At Goa and Ormuz, the meaſure is the vara, the ſame with that of the Portugueſe, having been introduced by them. In Pegu, and ſome other parts of the Indies, the cando or candi, equal to the ell of Venice. At Goa, and other parts, they they uſe a larger cando, equal to ſeventeen Dutch ells; exceeding that of Babel and Balſora by ⅞ *per centum*, and the vera by 6¼. In Siam, they uſe the ken, ſhort of three Paris feet by one inch. The ken contains two ſoks, the ſok two keubs, the keub twelve nious or inches, the niou to be equal to eight grains of rice, i. e. to about nine lines. At Camboia, they uſe the haſter; in Japan, the tatam; and the ſpan on ſome of the coaſts of Guinea.

8. *Different Itinerary Meaſures.*

A French league is about	2¾	Engliſh miles
A German mile	4	ditto
A Dutch mile	3⅓	ditto
An Italian mile	11/12	ditto
A Spaniſh league	3⅔	ditto
A Ruſſian verſt	¾	ditto

II. Square, Superficial, or Land *Meaſure.*

1.] *Engliſh* ſquare meaſures are raiſed from the yard of 36 inches multiplied into itſelf, and thus producing 1296 ſquare inches in the ſquare yard; the diviſions of this are ſquare feet and inches; and the multiples, poles, roods, and acres. Becauſe the length of a pole is 5½ yards, the ſquare of the ſame contains 30¼ ſquare yards. A ſquare mile contains 640 ſquare acres. In meaſuring fens and woodlands, 18 feet are generally allowed to the pole, and 21 feet in foreſt lands.

A hide of land, frequently mentioned in the earlier part of the Engliſh hiſtory, contained about 100 arable acres; and 5 hides were eſteemed a knight's fee. At the time of the Norman conqueſt, there were 243,600 hides in England.

2.] *Scotch* ſquare or land meaſure is regulated by the Scotch ell: 36 ſquare ells = 1 fall, 40 falls = 1 rood, 4 roods = 1 acre.—The proportion between the Scotch and Engliſh acre, ſuppoſing the feet in both meaſures alike, is as 1369 to 1089, or nearly as 5 to 4. If the difference of the feet be regarded, the proportion is as 10,000 to 7869. The length of the chain for meaſuring land in Scotland is 24 ells, or 74 feet.—A huſband-land contains 6 acres of ſock and ſcythe land, that is, of land that may be tilled with a plough or mown with a ſcythe: 13 acres of arable land make one ox-gang, and 4 ox-gangs make a pound-land of old extent.

3.] *French* ſquare meaſures are regulated by 12 ſquare lines in the inch ſquare; 12 inches in the foot, 22 feet in the perch, and 100 perches in the arpent or acre.

Tables of Square *Meaſure.*

1. English.

Inches						
144	Feet					
1296	9	Yards				
3600	25	2 7/9	Paces			
39204	272¼	30¼	10.89	Poles		
1568160	10890	1210	435.6	40	Rood	
6272640	43560	4840	1743.6	160	4	Acre

2. *Grecian* ſquare meaſures were the plethron or acre, by ſome ſaid to contain 1444, by others 10,000 ſquare feet; and aroura the half of the plethron. The aroura of the Egyptians was the ſquare 100 cubits.

3. *Roman* ſquare meaſure reduced to Engliſh. The integer was the jugerum or acre, which the Romans divided like the libra or as: thus the jugerum contained

	ſquare feet.	ſcruples.	Eng. roods.	ſq. poles.	Square feet.

Note, Actus major was 14,400 ſquare feet, equal to a ſemis; clima, 3600 ſquare feet, equal to ſeſcuncia; and actus minimus equal to a ſextans.

III. CUBICAL *Meaſures*, or Meaſures of Capacity, for LIQUIDS.

1.] The *Engliſh* meaſures were originally raiſed from troy-weight: it being enacted by ſeveral ſtatutes, that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, ſhould weigh a gallon of wine meaſure, the diviſions and multiples whereof were to form the other meaſures; at the ſame time it was alſo ordered, that there ſhould be but one liquid meaſure in the kingdom: yet cuſtom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a ſecond ſtandard gallon adjuſted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter ſtandard are raiſed two ſeveral meaſures, the one for ale, the other for beer. The ſealed gallon at Guildhall, which is the ſtandard for wines, ſpirits, oils, &c. is ſuppoſed to contain 231 cubic inches; and on this ſuppoſition the other meaſures raiſed therefrom, will contain as in the table underneath: yet, by actual experiment, made in 1688, before the lord-mayor and the commiſſioners of exciſe, this gallon was found to contain only 224 cubic inches: it was however agreed to continne the common ſuppoſed contents of 231 cubic inches; ſo that all computations ſtand on their old footing. Hence, as 12 is to 231, ſo is $14\frac{12}{20}$ to $281\frac{1}{2}$ the cubie inches in the ale-gallon: but in effect the ale-quart contains $70\frac{1}{2}$ cubic inches, on which principle the ale and beer gallon will be 282 cubic inches. The ſeveral diviſions and multiples of theſe meaſures, and their proportions, are exhibited in the tables underneath.

The bariel for ale in London is 32 gallons, and the barrel for beer 36 gallons. In all other places of England, the barrel, both for ale and beer, is 34 gallons.

2.] *Scotch* liquid meaſure is founded on the pint. The Scotch pint was formerly regulated by a ſtandard jug of caſt metal, the cuſtody of which was committed to the borough of Stirling. This jug was ſuppoſed to contain 105 cubic inches; and though, after ſeveral careful trials, it has been found to contain only about $103\frac{1}{2}$ inches; yet, in compliance with eſtabliſhed cuſtom, founded on that opinion, the pint *ſtoups* are ſtill regulated to contain 105 inches, and the cuſtomary ale meaſures are about $\frac{1}{16}$ above that ſtandard. It was enacted by James I. of Scotland, that the pint ſhould contain 41 ounces Trone weight of the clear water of Tay, and by James VI. that it ſhould contain 55 Scots Troy ounces of the clear water of Leith. This affords another method of regulating the pint, and alſo aſcertains the ancient ſtandard of the Trone weight. As the water of Tay and Leith are alike, the Trone weight muſt have been to the Scots Troy weight as 55 to 41; and therefore, the pound Trone muſt have contained about $21\frac{1}{2}$ ounces Scots Troy.

4 gills = 1 mutchkin.
2 mutchkins = 1 chopin.
2 chopins = 1 pint.
2 pints = 1 quart.
4 quarts = 1 gallon.

The Scotch quart contains 210 inches; and is, therefore, about $\frac{1}{10}$ leſs than the Engliſh wine-gallon, and about $\frac{1}{4}$ leſs than the ale-gallon.

3]. As to the liquid meaſures of foreign nations, it is to be obſerved, that their ſeveral veſſels for wine, vinegar, &c. have alſo various denominations according to their different ſizes and the places wherein they are uſed. The woeders of Germany, for holding Rheniſh and Moſelle wines, are different in their gauges; ſome containing 14 aumes of Amſterdam-meaſure, and others more or leſs. The aume is reckoned at Amſterdam for 8 ſteckans, or 20 verges, or for $\frac{1}{6}$ of a ton of 2 pipes; or 4 barrels of French or Bourdeaux, which $\frac{1}{6}$ at this latter place is called *tiercon*, becauſe 3 of them make a pipe or 2 barrels, and 6 the ſaid ton. The ſteckan is 16 mingles, or 32 pints; and the verge is, in reſpect of the ſaid Rheniſh and Moſelle, and ſome other ſorts of wine, 6 mingles; but, in meaſuring brandy, it conſiſts of $6\frac{1}{6}$ mingles. The aume is divided into 4 anckers, and the ancker into 2 ſteckans, or 32 mingles. The ancker is taken ſometimes for $\frac{1}{24}$ of a ton, or 4 barrels; on which footing the Bourdeaux-barrel ought to contain at Amſterdam (when the caſk is made according to the juſt gauge) $12\frac{1}{2}$ ſteckans, or 200 mingles wine and lees; or 12 ſteckans, or 192 mingles racked wine; ſo that the Bourdeaux-ton of wine contains 50 ſteckans, or 800 mingles, wine and lees; and 48 ſteckans, or 768 mingles of pure wine. The barrels or poinçons of Nantes and other places on the river Loire, contain only 12 ſteckans Amſterſtam meaſure. The wine-ton of Rochelle, Cognac, Charente, and the Iſle of Rhe, differs very little from the ton of Bourdeaux, and conſequently from the barrels and pipes. A ton of wine of Chaloſſe, Bayonne, and the neighbouring places, is reckoned 60 ſteckons, and the barrel 15, Amſterdam-meaſure.

The muid of Paris contains 150 quarts, or 300 pints, wine and lees; or 280 pints clear wine; of which muids 3 make a ton, and the fractions are

The muid	containing	36 ſetiers
The ſetier		4 quarts
The quart		2 pints
The pint		2 chopins
The chopin		2 demi-ſetiers
The demi-ſetier		2 poiſſons.

The muid is alſo compoſed of pipes, or poinçons, quarteaux, queves, and demiqueves: thoſe poinçons of Paris and Orleans contain about 15 ſteckans Amſterdam meaſure, and ought to weigh with the caſk 666 lb. a little more or leſs. In Provence they reckon by milleroles, and the millerole of Toulon contains 66 Paris pints, or 100 pints of Amſterdam, nearly; and the Paris pint is nearly equal to the Engliſh wine-quart.

The butts or pipes from Cadiz, Malaga, Alicant, Benecarlo, Saloe, and Mataro, and from the Canaries, from Liſbon, Oporto, and Fayal, are very different in their gauges, though in affreightments they are all reckoned two to the ton.

Vinegar is meaſured in the ſame manner as wine; but the meaſures for brandies are different: theſe ſpirits from France, Spain, Portugal, &c. are generally ſhipped in large caſks called *pipes*, *butts*, and *pieces* according to the places from whence they are reported, &c. In France, brandy is ſhipped in caſks called *pieces* at Bourdeaux, and *pipes* at Rochelle, Cognac, the iſle of Rhé, and other neighbouring places,

places, which contain ſome more and ſome leſs, even from 60 to 90 Amſterdam verges or veertels, according to the capacity of the veſſels, and the places they come from, which being reduced into barrels will ſtand as follows, viz.

At Rochelle, Cognac, the Iſle of Rhé, and the country of Aunis	27 Veertels	per barrel.
At Nants, and ſeveral places of Bretagne and Anjou	29 Veertels	
At Bourdeaux, and different parts of Guienne	32 Verges	
At Amſterdam, and other cities of Holland	30 Veertels	
At Hamburgh and Lubeck	30 Verges	
At Embden	27 Verges	

In Provence and Languedoc, brandy is ſold by the quintal, the caſks included; and at Bruges in Flanders, the verges are called *ſiſters* of 16 ſtops each, and the ſpirit is ſold at ſo much per ſtop.

Olive oil is alſo ſhipped in caſks of various ſizes, according to the cuſtom of the places where it is embarked and the conveniency of ſtowage. In England it is ſold by the ton of 236 gallons; and at Amſterdam by the ton of 717 mingles, or 1434 pints. In Provence it is ſold by milleroles of 66 Paris-pints; from Spain and Portugal it is brought in pipes or butts, of different gauges; at the firſt place it is ſold by roves, whereof 40 go to the butt; and at the latter place by almoudas, whereof 26 makes a pipe. Train oil is ſold in England by the ton, at Amſterdam by the barrel.

IV. *Meaſures of Capacity for things Dry.*

1.] *Engliſh* dry or corn meaſure. The ſtandard for meaſuring corn, ſalt, coals, and other dry goods, in England, is the Wincheſter gallon, which contains 272¼ cubic inches. The buſhel contains 8 gallons, or 2178 inches. A cylindrical veſſel, 18½ inches diameter, and 8 inches deep, is appointed to be uſed as a buſhel in levying the malt-tax. A veſſel of theſe dimenſions is rather leſs than the Wincheſter buſhel of 8 gallons, for it contains only 2150 inches; though probably there was no difference intended. The denominations of dry meaſure commonly uſed, are given in the firſt of the ſubjoined tables. Four quarters corn make a chaldron, 5 quarters make a wey or load, and 10 quarters make a ton. In meaſuring ſea-coal, 5 pecks make a buſhel, 9 buſhels make a quarter or vatt, 4 quarters make a chaldron, and 21 chaldrons make a ſcore.

40 feet hewn timber make a load.
50 feet unhewn timber make a load.
32 gallons make a herring barrel.
42 gallons make a ſalmon barrel.
1 cwt. gun-powder makes a barrel.
256 lb. ſoap make a barrel.
10 dozen candles make a barrel.
12 barrels make a laſt.

2.] *Scotch* dry meaſure. There was formerly only one meaſure of capacity in Scotland; and ſome commodities were heaped, others *ſtraiked*, or meaſured exactly to the capacity of the ſtandard. The method of heaping was afterwards forbidden as unequal, and a larger

larger meaſure appointed for ſuch commodities as that cuſtom had been extended to.

The wheat-firlot, uſed alſo for rye, peaſe, beans, ſalt, and graſs-ſeeds, contains 21 pints 1 mutchkin, meaſured by the Stirling jug. The barley firlot, uſed alſo for oats, fruit, and potatoes, contains 31 pints. A different method of regulating the firlot was appointed, from the dimenſions of a cylindrical veſſel. The diameter for both meaſures was fixed at $19\frac{1}{8}$ inches, the depth $7\frac{1}{3}$ inches for the wheat-firlot, and $10\frac{1}{2}$ for the barley-firlot. A ſtandard conſtructed by theſe meaſures is rather leſs than when regulated by the pint; and as it is difficult to make veſſels exactly cylindrical, the regulation by the pint has prevailed, and the other method gone into diſuſe.

If the Stirling jug contain $103\frac{1}{2}$ inches, the wheat-firlot will contain 2109 inches; which is more than 2 *per cent.* larger than the legal malt-buſhel of England, and about 1 *per cent.* larger than the Wincheſter buſhel: and the barley-firlot will contain 3208 inches. The barley-boll is nearly equal to ſix legal malt buſhels.

In Stirlingſhire, 17 pecks are reckoned to the boll: in Invernesſshire, 18 pecks: in Ayrſhire, the boll is the ſame as the Engliſh quarter. And the firlots, in many places, are larger than the Linlithgow ſtandard.

3.] *French dry*, are, the litron, buſhel, minot, mine, ſeptier, muid, and tun. The litron is divided into two demilitrons, and four quarter-litrons, and contains 36 cubic inches of Paris. By ordonnance, the litron is to be three inches and a half high, and three inches 10 lines broad. The litron for ſalt is larger, and is divided into two halves, four quarters, eight demi-quarters, and 16 meſurettes. The French buſhel is different in different juriſdictions. At Paris it is divided into demi-buſhels; each demi-buſhel into two quarts; the quart into two half-quarts; and the half-quart into two litrons: ſo that the buſhel contains 16 litrons. By ordonnance the Paris buſhel is to be eight inches two lines and a half high, and ten inches broad, or in diameter within-ſide. The minot conſiſts of three buſhels, the mine of two minots or ſix buſhels, the ſeptier of two mines or 12 buſhels, and the muid of 12 ſeptiers, or an 144 buſhels. The buſhel of oats is eſtimated double that of any other grain; ſo that there go 24 buſhels to make the ſeptier, and 288 to make the muid. It is divided into four picotins, the picotin containing two quarts, or four litrons. The buſhel for ſalt is divided into two half-buſhels, four quarters, eight half-quarters, and 16 litrons; four buſhels make a minot, 16 a ſeptier, and 192 a muid. The buſhel for wood is divided into halves, quarters, and half-quarters. Eight buſhels make the minot, 16 a mine; 20 mines, or 320 buſhels, the muid. For plaſter, 12 buſhels make a ſack, and 36 ſacks a muid. For lime, three buſhels make a minot, and 48 minots a muid. The minot is by ordonnance to be 11 inches 9 lines high, and 14 inches 8 lines in diameter. The minot is compoſed of three buſhels, or 16 litrons; four minots make a ſeptier, and 48 a muid. The French mine is no real veſſel, but an eſtimation of ſeveral others. At Paris the mine contains ſix buſhels, and 24 make the muid; at Rouen the mine is four buſhels; and at Dieppe, 18 mines make a Paris muid. The ſeptier differs in different places: at Paris it contains two mines, or eight buſhels, and 12 ſeptiers the muid. At Rouen the ſeptier contains two mines or 12 buſhels. Twelve ſeptiers make a muid at Rouen as well as at Paris; but 12 of the latter are equal to 14 of the former. At Toulon the ſeptier contains a mine and a half; three of which mines make the ſeptier of Paris. The muid or muy of Paris conſiſts of 12 ſeptiers; and is divided into mines, minots, buſhels, &c. That for oats is double that for other grain, *i. e.* contains twice the number of buſhels. At Orleans the muid is divided into mines, but thoſe mines only contain two Paris ſeptiers and a half. In ſome places they uſe the tun in lieu of the muid; particularly at Nantes, where it contains 10 ſeptiers of 16 buſhels each, and weighs between 2200 and 2250 pounds. Three of theſe tuns make 28 Paris ſeptiers. At Rochelle, &c. the tun contains 42 buſhels, and weighs two *per cent.* leſs than that of Nantes. At Breſt it contains 20 buſhels, is equal to 10 Paris ſeptiers, and weighs about 2240 pounds. See Tun.

4.] *Dutch*, *Swediſh*, *Poliſh*, *Pruſſian*, and *Muſcovite*. In theſe places, they eſtimate their dry things on the foot of the *laſt*, *leſt*, *leth*, or *lecht*; ſo called according to the various pronunciations of the people who uſe it. In Holland, the laſt is equal to 19 Paris ſeptiers, or 38 Bourdeaux buſhels, and weighs about 4560 pounds; the laſt they divide into 27 mudes, and the mude into four ſchepels. In Poland, the laſt is 40 Bourdeaux buſhels, and weighs about 4800 Paris pounds. In Pruſſia, the laſt is 133 Paris ſeptiers. In Sweden and Muſcovy, they meaſure by the great and little laſt; the firſt containing 12 barrels, and the ſecond half as many. See Last. In Muſcovy, they likewiſe uſe the chefford, which is different in various places: that of Archangel is equal to three Rouen buſhels.

5.] *Italian*. At Venice, Leghorn, and Lucca, they eſtimate their dry things on the foot of the ſtaro or ſtaio; the ſtaro of Leghorn weighs 54 pounds: 112 ſtaros and ſeven-eighths are equal to the Amſterdam laſt. At Lucca, 119 ſtaros make the laſt of Amſterdam. The Venetian ſtaro weighs 128 Paris pounds: the ſtaro is divided into four quarters. Thirty-five ſtaros and one-fifth, or 140 quarters and four-fifths, make the laſt of Amſterdam. At Naples and other parts, they uſe the tomolo or tomalo, equal to one-third of the Paris ſeptier. Thirty-ſix tomoli and a half make the carro: and a carro and a half, or 54 tomoli, make the laſt of Amſterdam. At Palermo, 16 tomoli make the ſalma, and four mondili the tomolo. Ten ſalmas and three-ſevenths, or 171 tomoli and three-ſevenths, make the laſt of Amſterdam.

6.] *Flemiſh*. At Antwerp, &c. they meaſure by the viertel; 32 and one-half whereof make 19 Paris ſeptiers. At Hamburgh, the ſchepel; 90 whereof make 19 Paris ſeptiers.

7.] *Spaniſh and Portugueſe*. At Cadiz, Bilboa, and St Sebaſtian, they uſe the fanega; 23 whereof make the Nantes or Rochelle tun, or nine Paris ſeptiers and a half: though the Bilboa fanega is ſomewhat larger, inſomuch that 21 fanegas make a Nantes tun. At Seville, &c. they uſe the anagoras, containing a little more than the Paris mine; 36 anagoras make 19 Paris ſeptiers. At Bayonne, &c. the concha; 30 whereof are equal to nine Paris ſeptiers and an half. At Liſbon, the alquiver, a very ſmall meaſure, 240 whereof make 19 Paris ſeptiers, 60 the Liſbon muid.

eaſure.

Measure of Wood for Firing, is uſually the cord; four feet high, and as many broad, and eight long; this is divided into two half-cords, called *ways*, and by the French *membrures*, from the pieces ſtuck upright to bound them; or *voyes*, as being ſuppoſed half a waggon-load.

Measure for Horſes, is the hand, which by ſtatute contains four inches.

Measure, among botaniſts. In deſcribing the parts of plants, Tournefort introduced a geometrical ſcale, which many of his followers have retained They meaſured every part of the plant; and the eſſence of the deſcription conſiſted in an accurate menſuration of the whole.

As the parts of plants, however, are liable to variation in no circumſtance ſo much as that of dimenſion, Linnæus very rarely admits any other menſuration than that ariſing from the reſpective length and breadth of the parts compared together. In caſes that require actual menſuration, the ſame author recommends, in lieu of Tournefort's artificial ſcale, the following natural ſcale of the human body, which he thinks is much more convenient, and equally accurate.

The ſcale in queſtion conſiſts of 11 degrees, which are as follows: 1. A hair's-breadth, or the diameter of a hair, (*capillus.*) 2. A line, (*linea*), the breadth of the creſcent or white appearance at the root of the finger, (not thumb), meaſured from the ſkin towards the body of the nail; a line is equal to 12 hair-breadths, and is the 12th part of a Pariſian inch. 3. A nail, (*unguis*), the length of a finger-nail; equal to ſix lines, or half a Pariſian inch. 4. A thumb, (*pollex*), the length of the firſt or outermoſt joint of the thumb; equal to a Pariſian inch. 5. A palm, (*palmus*), the breadth of the palm excluſive of the thumb; equal to three Pariſian inches. 6. A ſpan, (*ſpithama*,) the diſtance between the extremity of the thumb and that of the firſt finger when extended; equal to ſeven Pariſian inches. 7. A great ſpan, (*dodrans*), the diſtance between the extremity of the thumb and that of the little finger, when extended; equal to nine inches. 8 A foot, (*pes*), meaſuring from the elbow to the baſis of the thumb; equal to 12 Pariſian inches. 9. A cubit, (*cubitus*), from the elbow to the extremity of the middle finger; equal to 17 inches. 10. An arm-length, (*brachium*), from the arm-pit to the extremity of the middle-finger; equal to 24 Pariſian inches, or two feet. 11. A fathom, (*orgya*), the meaſure of the human ſtature; the diſtance between the extremities of the two middle fingers, when the arms are extended; equal, where greateſt, to ſix feet.

Measure is alſo uſed to ſignify the cadence and time obſerved in poetry, dancing, and muſic, to render them regular and agreeable.

The different meaſures or metres in poetry, are the different manners of ordering and combining the quantities, or the long and ſhort ſyllables. Thus, hexameter, pentameter, iambic, ſapphic verſes, &c. conſiſt of different meaſures.

In Engliſh verſes, the meaſures are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleaſes. The moſt uſual are the heroic, generally conſiſting of five long and five ſhort ſyllables; and verſes of four feet; and of three feet and a cæſura, or ſingle ſyllable.

Meaſure, Meaſuring,

The ancients, by variouſly combining and tranſpoſing their quantities, made a vaſt variety of different meaſures. Of words, or rather feet of two ſyllables, they formed a ſpondee, conſiſting of two long ſyllables; a pyrrhic, of two ſhort ſyllables; a trochee, of a long and a ſhort ſyllable; and an iambic, of a ſhort and a long ſyllable.

Of their feet of three ſyllables they formed a moloſſus, conſiſting of three long ſyllables; a tibrach, of three ſhort ſyllables; a dactyl, of one long and two ſhort ſyllables; and an anepæſt, of two ſhort and one long ſyllable. The Greek poets contrived 124 different combinations or meaſures, under as many different names, from feet of two ſyllables to thoſe of ſix.

Measure in Muſic, the interval or ſpace of time which the perſon who beats time, takes between the raiſing and falling of his hand or foot, in order to conduct the movement, ſometimes quicker, and ſometimes ſlower, according to the kind of muſic, or the ſubject that is ſung or played.

The meaſure is that which regulates the time we are to dwell on each note. See Time.

The ordinary or common meaſure is one ſecond, or 60th part of a minute, which is nearly the ſpace between the beats of the pulſe or heart; the ſyſtole, or contraction of the heart, anſwering to the elevation of the hand; and its diaſtole, or dilatation, to the letting it fall. The meaſure uſually takes up the ſpace that a pendulum of two feet and an half long employs in making a ſwing or vibration. The meaſure is regulated according to the different quality or value of the notes in the piece; by which the time that each note is to take up is expreſſed. The ſemibreve, for inſtance, holds one riſe, and one fall; and this is called the *meaſure*, or *whole meaſure*; ſometimes the *meaſure-note*, or *time-note*; the minim, one riſe, or one fall; and the crotchet, half a riſe, or half a fall, there being four crotchets in a full meaſure.

Measure Binary or Double, is that wherein the riſe and fall of the hand are equal.

Measure Ternary or Triple, is that wherein the fall is double to the riſe; or where two minims are played during a fall, and but one in the riſe. To this purpoſe, the number 3 is placed at the beginning of the lines, when the meaſure is intended to be triple; and a C, when the meaſure is to be common or double. This riſing and falling of the hands was called by the Greeks ἄρσις and θέσις. St Auguſtine calls it *plauſus*, and the Spaniards *compas*. See Arsis and Thesis.

Powder Measures in Artillery, are made of copper, and contain from an ounce to 12 pounds: theſe are very convenient in a ſiege, when guns or mortars are loaded with looſe powder, eſpecially in ricochet firing, &c.

MEASURING, or Mensuration, is the uſing a certain known meaſure, and determining thereby the preciſe extent, quantity, or capacity of any thing.

Measuring, in the general, makes the practical part of geometry. From the various ſubjects whereon it is employed, it acquires various names, and conſtitutes various arts. See GEOMETRY, LEVELLING, TRIGONOMETRY, &c.

MEAT. See FOOD, DIET, DRINK, &c.

Amongſt the Jews, ſeveral kinds of animals were forbidden to be uſed as food. The fleſh with the blood, and the blood without the fleſh, were prohibited; the fat alſo of ſacrificed animals was not to be eaten. Roaſt meat, boiled meat, and ragouts, were in uſe amongſt the Hebrews, but we meet with no kind of ſeaſoning except ſalt, bitter herbs, and honey.—They never mingled milk in any ragout or haſh, and never eat at the ſame meal both meat and milk, butter or cheeſe. The daily proviſion for Solomon's table was 30 meaſures of fine wheat flour, 60 of common flour, 20 ſtalls of oxen, 20 paſture oxen, 100 ſheep, beſides veniſon and wild-fowl. See LUXURY.

The principal and moſt neceſſary food among the ancient Greeks was bread, which they called αρτος, and produced in a wicker baſket called κανεον. Their loaves were ſometimes baked under the aſhes, and ſometimes in an oven. They alſo uſed a ſort of bread called *Maza*. Barley meal was uſed amongſt the Greeks, which they called αγφιτον. They had a frequent diſh called θριον., which was a compoſition of rice, cheeſe, eggs, and honey, wrapped in fig-leaves. The Μυττωτον was made of cheeſe, garlic, and eggs, beaten and mixed together. Their bread, and other ſubſtitutes for bread, were baked in the form of hollow plates, into which they poured a ſauce. Garlic, onions, and figs, ſeem to have been a very common food amongſt the poorer Athenians. The Greeks, eſpecially in the heroical times, ate fleſh roaſted; boiled meat ſeldom was uſed. Fiſh ſeems not to have been uſed for food in the early ages of Greece. The young people only, amongſt the Lacedemonians, ate animal food; the men and the old men were ſupported by a black ſoup called μελα ζυμος, which to people of other nations was always a diſagreeable meſs. Graſshoppers and the extremities or tender ſhoots of trees were frequently eaten by the poor among the Greeks. Eels dreſſed with beet root was eſteemed a delicate diſh, and they were fond of the jowl and belly of ſalt-fiſh. Neither were they without their ſweet-meats: the deſert conſiſted frequently of fruits, almonds, nuts, figs, peaches, &c. In every kind of food we find ſalt to have been uſed.

The diet of the firſt Romans conſiſted wholly of milk, herbs, and roots, which they cultivated and dreſſed with their own hands; they alſo had a kind of gruel, or coarſe groſs pap, compoſed of meal and boiling water; this ſerved for bread: And when they began to uſe bread, they had none for a great while but of unmixed rye. Barley-meal was eaten by them, which they called *Polenta*. When they began to eat animal food, it was eſteemed a piece of luxury, and an indulgence not to be juſtified but by ſome particular occaſion. After animal food had grown into common uſe, the meat which they moſt frequently produced upon their tables was pork.

*Method of Preſerving Fleſh-*MEAT *without Spices, and with very little Salt.* Jones, in his *Miſcellanea Curioſa*, gives us the following deſcription of the Mooriſh *Elcholle*, which is made of beef, mutton, or camel's fleſh, but chiefly beef, and which they cut all in long ſlices, and let it lie for 24 hours in a pickle. They then remove it out of thoſe jars or tubs into others with water; and when it has lain a night, they take it out, and put it on ropes in the ſun and air to dry. When it is thoroughly dried and hard, they cut it into pieces of two or three inches long, and throw it into a pan or caldron, which is ready with boiling oil and ſuet ſufficient to hold it, where it boils till it be very clear and red when cut. After this they take it out, and ſet it to drain; and when all is thus done it ſtands to cool, and jars are prepared to put it up in, pouring upon it the liquor in which it was fried; and as ſoon as it is thoroughly cold, they ſtop it up cloſe. It will keep two years; will be hard, and the hardeſt they look upon to be the beſt done. This they diſh up cold, ſometimes fried with eggs and garlic, ſometimes ſtewed, and lemon ſqueezed on it. It is very good any way, either hot or cold

MEATH, commonly ſo called, or otherwiſe *Eaſt* Meath, to diſtinguiſh it from the county called *Weſt* Meath: A county of Ireland, in the province of Leinſter, bounded by the counties of Cavan and Louth on the north, the Iriſh channel on the eaſt, Kildare and Dublin on the ſouth, and Weſt Meath and Longford on the weſt. It is a fine champaign country, abounding with corn, and well inhabited. It returns 14 members to parliament; and gives title of earl to the family of Brabazan. It contains 326,480 Iriſh plantation acres, 139 pariſhes, 12 baronies, and ſix boroughs; chief town Trim. This diſtrict being the moſt ancient ſettlement of the Belgians in Ireland, the inhabitants were eſteemed the eldeſt and moſt honourable tribe: from which ſeniority their chieftains were elected monarchs of all the Belgæ; a dignity that was continued in the Hy-n-Faillian without intermiſſion, until the arrival of the Caledonian colonies, under the name of Tuath de Danan, when Conor-Mor, chieftain of theſe people, obtained, or rather uſurped, the monarchial throne, obliged Eochy Failloch, with ſeveral of his people, to croſs the Shannon, and eſtabliſh themſelves in the preſent county of Roſcommon, where Crothar founded the palace of Atha or Croghan, a circumſtance which brought on a long and bloody war between the Belgian and Caledonian races, which was not finally terminated until the cloſe of the 4th century, when the Belgian line was reſtored in the perſon of O'Nial the great, and continued until Briam Boromh uſurped the monarchial dignity, by depoſing Malachy O'Malachlin, about the year 1001 Tuathal Tetcthomar, by a decree of the Tarah aſſembly, ſeparated certain large tracts of land from each of the four provinces, where the borders joined together; whence, under the notion of adopting this ſpot for demeſne lands to ſupport the royal houſehold, he formed the county or kingdom of Meath, which afterwards became the peculiar inheritance of the monarchs of Ireland. In each of the portions thus ſeparated from the four provinces, Tuathal cauſed palaces to be erected, which might adorn them, and commemorate the name in which they had been added to the royal domain. In the track taken out of Munſter, he built the palace called Flachtaga, where the ſacred fire, ſo called, was kindled, and where all the prieſts and druids annually met on the laſt day of October; on the evening of which day it was enacted, that no other fire ſhould be be uſed throughout the kingdom, in order that all the fires might be derived from this, which being lighted up as a fire of ſacrifice, their ſuperſtition led them to believe would render all the reſt propitious and holy; and for this privilege every family was to pay threepence, by way of acknowledgment to the king of Munſter. The ſecond royal palace was erected in the proportion taken out of Connaught, and was built for the aſſembly called the convocation of Viſneach, at which all the inhabitants were ſummoned to appear on the 1ſt day of May, to offer ſacrifice to *Beal*, or *Bel*, the god of fire, in whoſe honour two large fires being kindled, the natives uſed to drive their cattle between them, which was ſuppoſed to be a preſervative for them againſt accidents and diſtempers, and this was called *Beal-Tinne*, or *Bel-Tine*, or the feſtival of the god of fire. The king of Connaught at this meeting claimed a horſe and arms from every lord of a manor or chieftain, as an acknowledgement for the lands taken from that province, to add to the territory of Meath. The third was that which Tailtean erected in the part taken from Ulſter, where the fair of that name was held, which was remarkable for this particular circumſtance, that the inhabitants brought their children thither, males and females, and contracted them in marriage, where the parents having agreed upon articles, the young people were joined accordingly; every couple contracted at this meeting, paid the king of Ulſter an ounce of ſilver by way of acknowledgement. The royal manſion of Tarah, formerly deſtroyed by fire, being re-built by Tuathal, on the lands originally belonging to the king of Leinſter, was reckoned as the fourth of theſe palaces; but as a fabric of that name had ſtood there before, we do not find that any acknowledgment was made for it to the king of Leinſter.

Meath, with *Clonmacnois*, is a biſhop's ſee, valued in the king's books at L. 373 : 7 : $0\frac{1}{2}$ Sterling, by an extent returned *anno* 28th Elizabeth; but, by a former extent taken *anno* 30th Henry VIII. the valuation amounts to L. 373, 12 s. which being the largeſt and moſt profitable for the king, is the meaſure of the firſt fruits at this day. This ſee is reputed to be worth annually L. 3400. There were formerly many Epiſcopal ſees in Meath, as Clonard, Duleek, Kells, Trim, Ardbraccan, Donſhaghlin, Slaine, and Foure, beſides others of leſs note; all theſe, except Duleek and Kells, were conſolidated, and their common ſee was fixed at Clonard, before the year 1152; at which time the diviſions of the biſhoprics in Ireland was made by John Paparo, cardinal-prieſt, entitled cardinal of St Lawrence in Damaſo, then legate from Pope Eugene III. to the Iriſh. This diviſion was made in a Synod held on the 6th of March in the abbey of Mellifont, or, as ſome ſay, at Kells; and the two ſees of Duleek and Kells afterwards ſubmitted to the ſame fate. The conſtitution of this dioceſe is ſingular, having no dean nor chapter, cathedral, or economy.— Under the biſhop, the archdeacon is the head officer, to whom, and to the clergy in general, the *congé d'elire* iſſued while biſhops were elective. The affairs of the dioceſe are tranſacted by a ſynod, in the nature of a chapter, who have a common ſeal, which is annually lodged in the hands of one of the body, by the appointment and vote of the majority. The dioceſe is divided into twelve rural deaneries.

Of Clonmacnois, *now annexed to Meath*: There is no valuation of this ſee in the king's books; but it is ſuppoſed to be included in the extent of the ſee of Meath, taken *anno* 30th Henry VIII. The chapter of this ſee conſiſted anciently of dean, chanter, chancellor, treaſurer, archdeacon, and twelve prebendaries, but moſt of the poſſeſſions of them have fallen into lay-hands. At preſent the deanery is the only part of the chapter which ſubſiſts, to which the prebend of Cloghran is annexed, and he hath a ſeal of office, which appears to have been the ancient Epiſcopal ſeal of this ſee. This ſee was founded by St Kiaran, or Ciaran, the younger, in 548 or 549; and Dermod, the ſon of Ceronill, king of Ireland, granted the ſite on which the church was built.

Weſt Meath. See Westmeith.

MEATUS auditorius. See Anatomy, nº 139.

MEAUX, an ancient town of France, in Brie, with a biſhop's ſee, ſeated in a place abounding in corn and cattle, on the river Marne, which divides it into two parts, and its trade conſiſts in corn, wool, and cheeſe. E. Long. 2. 58 N. Lat. 48. 58.

MECÆNAS, or Mecœnas (C. Cilnius), a celebrated Roman knight, deſcended from the kings of Etruria. He has rendered himſelf immortal by his liberal patronage of learned men and of letters; and to his prudence and advice Auguſtus acknowledged himſelf indebted for the ſecurity he enjoyed. His fondneſs for pleaſure removed him from the reach of ambition; and he preferred dying, as he was born, a Roman knight, to all the honours and dignities which either the friendſhip of Auguſtus or his own popularity could heap upon him. To the interference of Mecænas, Virgil owed the retribution of his lands; and Horace was proud to boaſt that his learned friend had obtained his forgiveneſs from the emperor, for joining the cauſe of Brutus at the battle of Philippi. Mecænas was himſelf fond of literature; and, according to the moſt received opinion, he wrote a hiſtory of animals, a journal of the life of Auguſtus, a treatiſe on the different natures and kinds of precious ſtones, beſides the two tragedies of Octavia and Prometheus, and other things, all now loſt. He died eight years before Chriſt; and on his death-bed he particularly recommended his poetical friend Horace to the care and confidence of Auguſtus. Seneca, who has liberally commended the genius and abilities of Mecænas, has not with-held his cenſure from his diſſipation, indolence, and effeminate luxury. From the patronage and encouragement which the princes of heroic and lyric poetry among the Latins received from the favourite of Auguſtus, all patrons of literature have ever ſince been called *Mecænates*. Virgil dedicated to him his Georgics, and Horace his odes.

MECCA, an ancient and very famous town of Aſia, in Arabia the Happy; ſeated on a barren ſpot, in a valley ſurrounded with little hills, about a day's journey from the Red-Sea. It is a place of no ſtrength, having neither walls nor gates, and the buildings are very mean. That which ſupports it is the reſort of a great many thouſand pilgrims annually, for the ſhops are ſcarcely open all the year beſides. The inhabitants are poor, very thin, lean, and ſwarthy. The hills about the town are very numerous; and conſiſt of a blackiſh rock, ſome of them half a mile in circumference. On the top of one of them is a cave, where they pretend Mahomet uſually retired to perform his devotions, and hither they affirm the greateſt part of the Alcoran was brought him by the angel Gabriel. The town has plenty of water, and yet little garden-ſtuff; but there are ſeveral ſorts of good fruits to be had, ſuch as grapes, melons, water-melons, and cucumbers. There are alſo plenty of ſheep brought thither to be ſold to the pilgrims. It ſtands in a very hot climate; and the inhabitants uſually ſleep on the tops of their houſes for the ſake of coolneſs. In order to protect themſelves from the heat through the day, they carefully ſhut the windows, and water the ſtreets to refreſh the air. There have been inſtances of perſons ſuffocated in the middle of the town by the burning wind called *Simoom.*

As a great number of the people of diſtinction in the province of Hedsjas ſtay in the city, it is better built than any other in Arabia. Amongſt the beautiful edifices it contains, the moſt remarkable is the famous *Kaba*, or *Caaba*, "The houſe of God," which was held in great veneration by the Arabs even before Mahomet's time.

No Chriſtian dare go to Mecca; not that the approach to it is prohibited by any expreſs law, or that the ſenſible part of the Mahometans have any thing to object to it; but on account of the prejudices of the people, who, regarding this ground as ſacred, think Chriſtians unworthy of ſetting their foot on it; it would be profaned, in the opinion of the ſuperſtitious, if it was trod upon by infidels. The people even believe, that Chriſtians are prevented from approaching by ſome ſupernatural power; and they tell the ſtory of an infidel, who having got ſo far as the hills that ſurround Mecca, all the dogs of the city came out, and fell upon him; and who, being ſtruck with this miracle, and the auguſt appearance of the Kaba, immediately became a muſſulman. It is therefore to be preſumed, that all the Europeans who deſcribe Mecca as eye-witneſſes, have been renegadoes eſcaped from Turkey. A recent example confirms this ſuppoſition. On the promiſe of being allowed to preſerve his religion, a French ſurgeon was prevailed on to accompany the Emir Hadsji to Mecca, in quality of phyſician; but at the very firſt ſtation, he was forced to ſubmit to circumciſion, and then he was permitted to continue his journey.

Although the Mahometans do not allow Europeans to go to Mecca, they do not refuſe to give them deſcriptions of the Kaba, and information with regard to that building; and there are perſons who gain their bread by making deſigns and little pictures of the Kaba, and ſelling them to pilgrims. See CAABA.

The Mahometans have ſo high an opinion of the ſanctity of Mecca, that they extend it to the places in the neighbourhood. The territory of that city is held ſacred to certain diſtances, which are indicated by particular marks. Every caravan finds in its road a ſimilar mark, which gives notice to the pilgrims when they are to put on the modeſt garb in which they muſt appear in thoſe ſacred regions. Every muſſulman is obliged to go once in his life, at leaſt, to Mecca, to perform his devotions there. If that law was rigourouſly enforced, the concourſe of pilgrims would be prodigious, and the city would never be able to contain the multitudes from all the countries where the Mahometan religion prevails. We muſt, therefore, ſuppoſe, that devotees alone perform this duty, and that the others can eaſily diſpenſe with it. Thoſe whoſe circumſtances do not permit a long abſence, have the liberty of going to Mecca by a ſubſtitute.—A hired pilgrim, however, cannot go for more than one perſon at a time; and he muſt, to prevent frauds, bring an atteſtation in proper form, from an Imam of Mecca, that he has performed the requiſite devotions on behalf of ſuch a perſon, either alive or dead; for, after the deceaſe of a perſon who has not obeyed the law during his life, he is ſtill obliged to perform the journey by proxy.

The caravans, which are not numerous, when we conſider the immenſe multitude of the faithful, are compoſed of many people who do not make the journey from purpoſes of devotion. Theſe are merchants, who think they can tranſport their merchandizes with more ſafety, and diſpoſe of them more eaſily; and contractors of every kind, who furniſh the pilgrims, and the ſoldiers who eſcort the caravans, with neceſſaries. Thus it happens, that many people have gone often to Mecca, ſolely from views of intereſt. The moſt conſiderable of thoſe caravans is that of Syria, commanded by the Pacha of Damaſcus. It joins at ſome diſtance the ſecond from Egypt, which is conducted by a Bey, who takes the title of Emir Hadsji. One comes from Yemen, and another, leſs numerous, from the country of Lachſa. Some ſcattered pilgrims arrive by the Red Sea from the Indies, and from the Arabian eſtabliſhments on the coaſts of Africa. The Perſians come in that which departs from Bagdad; the place of conductor to this laſt is beſtowed by the Pacha, and is very lucrative, for he receives the ranſoms of the heretical Perſians.

It is of conſequence to a pilgrim to arrive early at the holy places. Without having been preſent from the beginning at all the ceremonies, and without having performed every particular act of devotion, a man cannot acquire the title of Hadsji: this is an honour very much coveted by the Turks, for it confers real advantages, and makes thoſe who attain it to be much reſpected. Its infrequency, however, in the Mahometan dominions, ſhows how much the obſervation of the law commanding pilgrimages is neglected. A ſimilar cuſtom prevails among the Oriental Chriſtians, who are alſo exceedingly emulous of the title of Hadsji, or Mokdaſi, which is given to pilgrims of their communion. In order to acquire this title, it is not ſufficient that the perſon has made the journey to Jeruſalem; he muſt alſo have kept the paſſover in that city, and have aſſiſted at all the ceremonies of the holy weeks.

After all the eſſential ceremonies are over, the pilgrims next morning move to a place where they ſay Abraham went to offer up his ſon Iſaac, which is about two or three miles from Mecca: here they pitch their tents, and then throw ſeven ſmall ſtones againſt a little ſquare ſtone building. This, as they affirm, is performed in defiance of the devil. Every one then purchaſes a ſheep, which is brought for that purpoſe, eating ſome of it themſelves, and giving the reſt to the poor people who attend upon that occaſion. Indeed theſe are miſerable objects, and ſuch ſtarved creatures, that they ſeem ready to devour each other. After all, one would imagine that this was a very ſanctified place; and yet a renegado who went in pilgrimage thither, affirms there is as much debauchery practiſed here as in any part of the Turkiſh dominions. It is 25 miles from Jodda, the ſea-port town of Mecca, and 220 ſouth-eaſt of Medina. E. Long. 40. 55. N. Lat. 21. 45.

MECHANICAL, an epithet applied to whatever relates to mechanics: thus we ſay, mechanical powers, cauſes, &c. See the articles POWER, CAUSE, &c.

The mechanical philoſophy is the ſame with what is otherwiſe called *corpuſcular philoſophy*. See CORPUSCULAR.

This manner of reaſoning is much uſed in medicine; and, according to Dr Quincy, is the reſult of a thorough acquaintance with the ſtructure of animal bodies: for conſidering an animal body as a compoſition out of the ſame manner from which all other bodies are formed, and to have all thoſe properties which concern a phyſician's regard, only by virtue of its peculiar conſtruction; it naturally leads a perſon to conſider the ſeveral parts, according to their figures, contexture, and uſe, either as wheels, pullies, wedges, levers, ſcrews, cords, canals, ſtrainers, &c. For which purpoſe, continues he, it is frequently found helpful to deſign in diagrams, whatſoever of that kind is under conſideration, as is cuſtomary in geometrical demonſtrations.

For the application of this doctrine to the human body, ſee the article MEDICINE.

MECHANICAL, in mathematics, denotes a conſtruction of ſome problem, by the aſſiſtance of inſtruments, as the duplicature of the cube and quadrature of the circle, in contradiſtinction to that which is done in an accurate and geometrical manner.

MECHANICAL Curve, is a curve, according to Deſcartes, which cannot be defined by any algebraic equation; and ſo ſtands contradiſtinguiſhed from algebraic or geometrical curves.

Leibnitz and others call theſe mechanical curves *tranſcendental*, and diſſent from Deſcartes, in excluding them out of geometry. Leibnitz found a new kind of tranſcendental equations, whereby theſe curves are defined: but they do not continue conſtantly the ſame in all points of the curve, as algebraic ones do. See the article TRANSCENDENTAL.

MECHANICS,

IN the ſtrict ſenſe of the word, denotes the method of conſtructing machines to be ſet in motion, and to anſwer ſome uſeful purpoſes, by certain powers, either natural or artificial. According to this definition, the nature of the powers themſelves is not the object of mechanical inveſtigation, but rather the effect of them upon the paſſive bodies which we call *machines*; and the conſtructing of theſe in ſuch a manner, that the powers may act upon them with the leaſt poſſible obſtruction, and produce the intended effect to the greateſt advantage, is the perfection of MECHANICS.

It is uſual, in treatiſes upon this ſubject, to begin with an inveſtigation of the properties of *matter* itſelf, and of *central forces*; but the former is not to be inveſtigated by mechanical means, and the latter belong ſo much to aſtronomy, that very little needs to be ſaid upon them in this place; for which reaſon we refer to the articles ASTRONOMY, MATTER, and MOTION, for a diſcuſſion of theſe ſubjects. In treating of mechanics, therefore, we ſhall begin with a deſcription of what are commonly called the *mechanic powers*; and afterwards conſider the various ways in which they may be modified, in order to produce the effects expected from them.

SECT. I. *Of Material or Mechanical Power in general.*

§ 1. *Production of Motion and Reſt.*

IN mechanics every thing is called a power which is capable of acting upon a ſolid body; and every power which can act upon matter is ſuppoſed to be material, without regarding any abſtruſe ſpeculations concerning its nature. Hence the force of gravity, of electricity, of fire, of air, of water, the power of animals, of bodies preſſing or impinging with violence upon one another, are all accounted mechanical powers when applied to ſet machines in motion.

1 Reſt produced by the action of two oppoſite powers.

As any ſingle power, when applied to a material body, will ſet it in motion in proportion to its quantity, ſo the action of an oppoſite power upon the ſame body produces reſt. This may be eaſily conceived; for ſuppoſing two men to pull a log of wood with equal degrees of ſtrength in directions exactly oppoſite to one another, the log will remain immoveable. In like manner, if we put in a weight into one ſcale of a balance, motion will be produced; but reſt is the certain conſequence of counterpoiſing it with an equal weight in the oppoſite ſcale. When a weight is ſuſpended freely in the air, we are apt to imagine that it is acted upon by no force whatever; but we will ſoon diſcover our miſtake, by withdrawing the preſſure of the air from one ſide; for the body then, inſtead of remaining at reſt, will move with great violence to one ſide, and even contrary to the direction of gravity itſelf, unleſs it be extremely heavy. Whether reſt be in all caſes produced by the action of oppoſite powers upon the ſame ſubſtance, is a ſpeculation to be diſcuſſed under the article MOTION.

§ 2. *Of Reſiſtance.*

2 Ultimate cauſes of reſiſtance.

WHEN any moving power is ſtopped by a fixed obſtacle, ſo that it can proceed no farther, we ſay that it is *reſiſted* by that obſtacle. In this caſe we are apt to imagine that there is no force exerted by the reſiſting obſtacle; but it is found by experience, that *reſiſtance* is to all intents and purpoſes equivalent to a power equal and contrary to that which is impelled againſt the reſiſting obſtacle. This is exemplified in the caſe of a man ſtanding in a boat, and puſhing with a pole againſt the bank of a river or lake. In this caſe every one knows that the boat will go off in a direction contrary to that in which he puſhes; but if the boat be faſtened by means of a hook and rope to that part of the pole which is between the man's body and the bank, the boat will remain immoveable by reaſon of the equality betwixt the action of the man upon the pole forward, and of the boat upon the ſame pole backward. Thus, in fig. 1. when the man puſhes with the pole C againſt the bank D, in the direction CA, the boat B will be carried away from the bank in the direction AC; but if, by means of the rope E, the boat be faſtened to the pole AC, the recoil of the boat in the direction AC will be juſt equal to the puſh given by the man in the direction CA, ſo that no motion will enſue let him exert ever ſo much ſtrength. Hence we ſee, that by means of a reſiſting obſtacle a power may be made to counteract itſelf, ſo that a motion or tendency to it may be produced in any direction; and in this caſe, as well as in the former, reſt is produced by the oppoſition of two contrary forces.

Plate CCLXXXII.

The very ſame effect would follow, though we ſhould ſuppoſe the man in the boat not to puſh againſt the bank or any fixed obſtacle, but againſt another boat faſtened by means of a rope to his own. In this caſe both the boats will recede from each other till the rope be ſtretched; after which they will both remain immoveable, unleſs they be acted upon by ſome power external to both. If both boats be at liberty, they will mutually recede from each other till they get beyond the reach of the pole.

3
Reſiſtance equivalent to an oppoſing power.

Reſiſtance, whatever we may ſpeculate about it, ſeems ultimately to depend on the power of gravity joined with that of coheſion. Thus a weight of 100 pounds, even when ſuſpended in the freeſt manner we can imagine, will reſiſt much more than 20 pounds ſuſpended in the ſame manner; and though hard bodies reſiſt to a great degree, yet unleſs connected with ſome very heavy body, they are eaſily moved out of their place; and the immenſe gravitation of the whole globe of earth, we may juſtly ſuppoſe to be the ſource of all reſiſtance whatever to mechanical powers.

On the whole, therefore, we may conſider reſiſtance as an active power; but the action of which is confined to a very limited ſpace, or to the ſingle point of contact; though ſeveral experiments tend to ſhow, that even before actual contact bodies ſhow a very perceptible degree of reſiſtance.

§ 3. *Of the Communication of Power.*

This depends entirely upon that property of bodies which is called their *attraction of coheſion*, and the immobility of their particles among themſelves; for if the parts of a body are abſolutely moveable among themſelves, they can neither communicate motion by impulſe nor by preſſure. The moſt common method of communicating motion in the mechanical way is by preſſure, which is generally accompliſhed by means of the ſix mechanical powers to be afterwards deſcribed: colliſion being employed only in certain particular caſes, the moſt remarkable of which will be pointed out under the article Motion.

The motion, which by means of an hard inflexible body is communicated to any other, may be confined to a ſingle point, or it may be diffuſed over any aſſignable ſpace. Thus, in fig. 2. let us ſuppoſe that any aſſignable power is applied to the point E, urging it from E towards D; the whole of that force will reſt upon the point of contact betwixt the ball C and the line BD. The weight. if placed exactly perpendicular to the horizon, will remain upright, without inclining either to one ſide or other; for the power of reſiſtance in the line BD is exactly equal to the impulſe of the weight lying upon E; ſo that it is in the ſame ſituation with the man and boat in the firſt example, when he had the boat hooked to the pole with which he puſhed againſt the bank. If inſtead of oppoſing the end of the reſiſting body BD to the ball C, we place them in the poſition repreſented in fig. 3. then the whole of the power will reſt upon any point of the line BD we pleaſe. For if we ſuppoſe the line EC to drive the line BD before it in the poſition repreſented in the figure, it is plain that the whole force of that line will be diſcharged for a moment upon the line F, or upon any obſtacle we chooſe to put in its way in another part of the line; but if we place two ſupports or reſiſtances to the moving line BD, as F and G in fig. 4. it is equally plain, that one half of the power will reſt upon the one and one half upon the other. For the whole force urging forward the line BD is but a certain and determined quantity; and if divided betwixt two obſtacles, each of theſe muſt undoubtedly bear one half. In like manner, if, as in fig. 5. the power be oppoſed by four obſtacles, each of them will bear only one-fourth part; and ſo on if we ſuppoſe it oppoſed by ever ſo many. For reaſons afterwards to be aſſigned, however, it is abſolutely neceſſary that the force on E act in a line directly perpendicular upon BD; that the obſtacles be all at equal diſtances, comparatively ſpeaking, from C; as H and I, F and G, &c. likewiſe that they be of exactly the ſame height; for thus only the preſſure, and conſequently the motion, can be made uniform in all parts. On this principle depends in a great meaſure the perfection of printing preſſes, oil preſſes, and all other machines intended to produce a violent and uniform preſſure upon any broad and flat ſurface.

As the preſſure upon a ſingle point may thus be diffuſed over a broad ſurface, ſo may that upon a broad ſurface be concentrated upon a ſingle point or a ſurface of ſmall dimenſion, as in fig. 6. Here it is plain that whatever preſſure is applied to the line AB, or any pare of it in a perpendicular direction, muſt be ſuſtained by the point D; for if there was no reſiſtance, this point would be driven along with the line AB, and the moment it was ſtopped the power which urged it on muſt likewiſe be ſtopped. It is true, that unleſs the power act directly perpendicular to the point D, or the line CD be ſupported that it cannot move either to one ſide or to another, the impulſe will be but momentary; but of this we ſhall treat at large in the ſubſequent part of this article. On the principle juſt mentioned depends in a great degree the force of gimlets, augers, boring gimlets, &c.

§ 4. *Of changing the Direction of a Power into one directly oppoſite.*

THIS in all caſes is only to be accompliſhed by the application of a power greater than that of which we wiſh to change the direction. Thus, in fig. 2. ſuppoſe we wiſh to change the direction of the power at E from the direction AC to that of CA, we will find it impoſſible to do ſo by any other means than the application of a greater power from D towards C. If the two powers are equal, there will be no motion whatever; and the degree of motion produced at laſt will only be the difference betwixt the two powers. If it be wanted therefore to produce a power in the direction CA, equal and oppoſite to that in the direction AC, one muſt be applied in the direction CA double to the former. This principle is different from that firſt mentioned, in which motion is produced by puſhing againſt a fixed obſtacle while the moving power is not reſiſted on the oppoſite ſide; for here the power of gravity, or whatever we ſuppoſe to act upon E, reſiſts according to its quantity, and the whole is in the ſituation of the boat when hooked to the pole fig. 1. To produce motion, therefore, a new force muſt be applied, as if a perſon was to puſh from the bank D againſt the hooked pole of the boat in that figure. The principle juſt now laid down does not militate againſt the apparent *aſcent* of bodies by the action of gravity, or the repulſion of elaſtic balls from one another by what is called the *power* of elaſticity. In both caſes a greater power is applied than the ſimple force of gravity, and with the exceſs of this power the body aſcends, as ſhall be afterwards ſhown.

§ 5. *Of the Motion produced by two or more Powers acting upon a Body in directions oblique to each other.*

AS the action of two powers in direct oppoſition to each other is attended with the deſtruction of both if the powers are equal, and of one of them if they are unequal; ſo the action of powers directed obliquely upon one another is productive of motions in various directions, according to that of the acting powers.

The motion produced by the action of two powers is always in the diagonal of the parallelogram expreſſed by theſe powers. Thus, in fig. 7. let the body A be acted upon at once by two forces, one of which would carry it from A to B in the ſame time that the other would carry it from A to C. The body will then deſcribe AD, the diagonal of a ſquare, in the time that it would have deſcribed one of the ſides by a ſingle power applied to it. This is in conſequence of its obeying both forces; as it is evident that it has moved as far as from A to B, and likewiſe from A to C, which is preciſely the effect that the two powers would have had upon it ſeparately. In this caſe the body has acquired a greater power than it would have had from a ſingle power, but leſs than it would have acquired from the union of the two powers if they had acted directly in concert with each other; becauſe the diagonal of a ſquare is leſs than the ſum of the ſides, and the power with which any body moves is exactly proportioned to its velocity. If, inſtead of ſuppoſing the forces equal, we ſuppoſe one of them conſiderably greater than the other, then the greater force will carry the body farther in its own direction than the other, and the whole will be repreſented by a parallelogram, as in fig. 8. In this caſe it is evident that the body has moved exactly in conformity to the direction of both powers, *viz.* the whole length of AB, and the whole length of AC. In this caſe alſo the loſs of motion is leſs than in the former; becauſe the length of the oblong parallelogram approaches much nearer to the ſum of the ſides than the diagonal of a ſquare; and the greater inequality there is betwixt the ſides, the leſs power is loſt.

If, inſtead of acting at right angles to each other, the direction of the powers forms an acute angle, as in figs. 9, 10, 11, the power produced will be conſiderably greater than either of the original ones; and the more acute the angle is, the greater will be the augmentation, as is evident from an inſpection of the figures. The reaſon of this, though not quite ſo obvious, is the ſame with the former. Thus the body A in fig. 9. had it been acted upon by only one power, *viz.* that denoted by AB, would have been at B, or carried as far forward as E, the half of the diagonal; its oblique direction upward not being taken into the account. Had it been acted upon by the force AC alone, it would have been at C with an obliquity as far down as the other is up. As theſe obliquities, however, are in contrary directions, they muſt of neceſſity deſtroy one another; and therefore the body moves neither to one ſide nor another, but proceeds with the ſum of the direct forces of the powers, or thoſe by which they move in the ſtraight diagonal. But either of the two powers would have brought it forward as far as E; of conſequence both conjoined muſt carry it on to D, the whole length of the diagonal. Thus it appears, that when a body is acted upon by two powers which partly conſpire together, the power produced will be the exact ſum of them as far as they do conſpire, and the loſs ariſes entirely from the oppoſition betwixt them; for all powers which do not directly conſpire, oppoſe one another in a certain degree. Hence when the acting forces make an obtuſe angle with each other, as in figs. 12, 13, there is then a very great loſs of power, becauſe there is ſuch an oppoſition betwixt them; and it is only that ſmall part of their motion which acts in concert that can produce any in the body acted upon: but this, as in the former caſe, is exactly double to what it would be if only one of them acted upon the body. Thus, in fig. 12. the whole direction of the powers from E to B, and from B to C, is in abſolute oppoſition to each other; and therefore, ſuppoſing them equal, muſt be totally loſt. In the direction AD they conſpire; and therefore the body will move twice as far in that direction as is expreſſed by that of the lines in the figure; that is, from A to D, inſtead of only from A to E, which is the limit of each of the forces. In caſes of this kind, the more obtuſe the angle is at which the forces act, the greater is the loſs of power, as is evident from an inſpection of figs. 12, 13.

Plates
CCLXXXII.
CCLXXXIII.

4
Oppoſition betwixt two powers acting at right angles pointed out.

Some who are but beginning to the ſtudy of mechanics may be embarraſſed in their ideas how two forces acting at right angles to each other can in any manner of way oppoſe each other, as in fig. 7.; as we find that a body deſcending by the force of gravity may

may be puſhed to a ſide ſeemingly by the leaſt force imaginable. But this will eaſily be underſtood from fig. 14. which is only a ſquare turned into another poſture. Here it is plain that the powers AB and AC oppoſe each other as much as they conſpire; that is in the proportion of half the diagonal of the ſquare: this quantity therefore is totally loſt, and the body proceeds with the other half; which being doubled on account of each of the powers proceeding with one half of the diagonal, gives the whole diagonal for the total motion produced.

Plate CCLXXXIII.

5 Ultimate cauſe of this ſhown

But however plain this may appear from an inſpection of the figure, it is by no means ſo apparent when we come to try it by numbers. Thus, ſuppoſing each of the ſides AB and AC to be 5, the diagonal of the ſquare will be nearly 7.071; but if from the ſum of the ſides 10 we take this number, or half of it from each number, we will have only 2.919 for the whole motion, inſtead of the diagonal 7.071 which is the reality. From an inſpection of the figure alſo we plainly ſee, that if one diagonal is gained by the powers conſpiring together or acting in concert, another is loſt by their oppoſition. It is natural therefore to inquire, How can any two powers gain or loſe more than their own quantity; for the two powers taken together amount but to *ten*, but the two diagonals, one of which is gained and the other loſt, amount between them to upwards of *fourteen?* To ſolve this ſeeming paradox, we muſt conſider, that as the diagonal of the ſquare ABCD, fig. 14. is generated from the two ſides AB and CD, ſo theſe ſides themſelves may be accounted the diagonals of two other ſmaller ſquares *a*BAE and AE*b*C, fig. 15. each of the ſides of which is half the diagonal of the large one. From the ſum of the ſides of theſe ſquares, which to the large ſquare are the ſource of power, it is evident that a diagonal may be taken and another remain, becauſe each of the ſides is half a diagonal.

6 All powers are compounded of others.

Hence we not only ſee that every mechanical power we are acquainted with *may be* derived from two others, but have a demonſtration that it *actually is ſo*; not only becauſe this ſuppoſition explains the phenomena, but becauſe we are involved in an inexplicable contradiction if we ſuppoſe any thing elſe, for no power can loſe more than its own quantity; and if it loſes more than one half, it can never produce effects equivalent to another half; which we ſee muſt be the caſe, if we ſuppoſe any two *unoriginated* powers acting upon one another at right angles, or indeed any other way, though the ſuppoſition of their acting at right angles makes the matter more plain than any other. This leads to a very curious ſpeculation concerning the origin of mechanical motion, of which an account is given under the article Motion.

7 Experiment illuſtrating the truth of this doctrine.

Hitherto we have conſidered both the powers not only as equal at the beginning, but as continuing ſo throughout their whole courſe: but this is a ſuppoſition which ſcarcely exiſts in nature, unleſs the powers are kept from exerting themſelves otherwiſe than by ſimple preſſure. Thus, in fig. 16. ſuppoſing the body A pulled in the direction AB by the weight D of five pounds put over the fixed pin B, and pulled in the direction AC by C, another weight of five pounds faſtened to it by a ſtring; the whole will be kept in the poſition repreſented in the figure by a weight of 7.071 pounds faſtened to it by a ſtring, and put over the pin F, ſituated any where in the diagonal line FAG; and let us add ever ſo much weight, provided it be done to D and C in the proportion of five, and to E in that of 7.071, the body A will remain ſuſpended in the air without altering its poſition in the leaſt.

If, inſtead of making the weights equal, we make one exceed the other in any proportion, the weight neceſſary to counteract them will never be required equal to both, but will always be in proportion to the diagonal of the parallelogram of which the weights repreſent the ſides. Thus, in fig. 17. if we ſuppoſe the body A pulled in the direction AB by the weight G of four pounds, and in the direction AC by the weight H of three pounds, it will be kept ſuſpended by the weight F of five pounds put over the pin E, placed any where in the diagonal line EAD. For the diagonal AD is equal (by Prop. 47. Book 1. of Euclid) to the ſquare-root of the ſum of the ſquares of the ſides AB and AC, or CD and BD. But the ſquare of AB is $4\times4=16$ pounds, and that of AC is $3\times3=9$ pounds by the ſuppoſition; and $16+9=25$, the ſquare-root of which is 5; and theſe proportions will be found to hold invariably in whatever way we apply mechanical powers; though, when they act at oblique angles, the diagonals muſt be calculated by other methods.

8 Curvelin ar motion how produced.

If, however, we ſet any of the powers at liberty, we ſhall find that none of them will continue the ſame even for a moment. If we ſuppoſe any of them to be the power of gravity, which is the moſt conſtant and equable we are acquainted with, this is found to increaſe prodigiouſly; and, on the other hand, if we ſuppoſe one of them to be a projectile force, as of a ſtone thrown by the hand, we will find in like manner, that it will be diminiſhed to a great degree in a very little time. In all caſes, however, where a body is acted upon by two forces either increaſing or decreaſing, unleſs both increaſe or decreaſe exactly in proportion to their original quantity, the body acted upon will deſcribe a curve. Thus, in fig. 18. ſuppoſe the body A to be acted upon by two equal powers A*b* and A*c*; at the end of the firſt moment it will be at *d*, the end of the diagonal of the ſmall ſquare A*bcd*: but if now the force A*c* be increaſed to double what it was in the preceding moment, the body will at the end of the ſecond moment be at *g*, the extremity of the parallelogram *defg*; and by another increment of the ſame power, will be at the end of the third moment at *k*, and ſo on. This is ſimilar to the motion of falling bodies, of which we ſhall treat hereafter; but if one of the powers diminiſhes inſtead of increaſing, the phenomena will be different. Thus, in fig. 19. ſuppoſing the body at A to be actuated the firſt moment by the two forces A*b* and A*c*; at the end of that moment it will be at the extremity of the diagonal A*d*; but next moment, ſuppoſing the power A*c* to be diminiſhed one half, the other remaining the ſame, it will then be at *g*, and the third moment at *k*, thus deſcribing another kind of curve. If, while one of the powers decreaſes the other increaſes, a third kind of curve will be generated; and by proper management of theſe powers, the body may be made to deſcribe the ſegment of a circle, as in fig. 20; whereechanical Power.

where it is manifeſt that one power continually decreaſes while the other increaſes.

9 achine ſhow- the ion of lique wers. g. 21.

The following machine has been contrived to illuſtrate the operation of oblique powers upon each other. ABCD is a wooden ſquare, ſo contrived that the part BEFC may draw out from it or be puſhed back at pleaſure. To this is joined a pulley H, freely moving upon its axis, which will be at H when the piece is puſhed in, and at *h* when it is drawn out. To this part let the ends of a ſtraight wire *k* be fixed, ſo as to move along with it under the pulley; and let the ball G be made to ſlide eaſily upon the wire. A thread *m* is fixed to this ball, and goes over the pulley to I; by which means the ball may be drawn up on the wire parallel to the ſide AD, when the part BEFC is puſhed as far as it will go into the ſquare: but when this part is drawn out, the ball muſt be carried along with it parallel to the bottom of the ſquare DC. Thus the ball may be drawn either perpendicularly upward by pulling the thread *m*, or moved horizontally by pulling out the part BEFC, in equal times and through equal ſpaces, each power acting equally and ſeparately upon it. But if, when the ball is at G, the upper end of the thread be tied to the pin I, in the corner A of the fixed ſquare, and the moveable part BEFG be drawn out, the ball will then be acted upon by both the powers together: for it will be drawn up by the thread towards the top of the ſquare, and at the ſame time carried with its wire *k* towards the right hand BC, moving all the while in the diagonal line L, and will be found at *g* when the ſliding part is drawn out as far as it was before; which then will have cauſed the thread to draw up the ball to the top of the inſide of the ſquare, juſt as high as it was before when drawn up ſingly by the thread without moving the ſliding part.

10 bodies ed upon three ces.

If a body is acted upon by three forces, the inveſtigation becomes ſomewhat more complex, though it is ſtill eaſily explained on the foregoing principles. Thus, in fig. 22. let the body A be pulled ſidewiſe in oppoſite directions by the two equal weights G G put over the pins B and C, and directly downward by the weight H, the ſame with G. In this caſe it is plain, that each of the weights G and G ſuſtain one half of the weight H; and as both taken together are double in quantity to H, it might be ſuppoſed that they would be abundantly able to keep the body A in its poſition. The caſe, however, is very different. As each of the weights G ſuſtains only one half of H, it follows that H acts only with one half of its weight upon them. The body A, therefore, is pulled in the direction AC and AB by two powers, each of which is as 2, and in the direction AF by two, which are only as one. With the force AB, therefore, were it to act upon it ſingly, it would deſcribe the diagonal AD, and with that AC it would deſcribe the diagonal AE. Theſe two diagonals are in truth the forces by which it is now actuated, and the effect is preciſely according to the principles already laid down. By each of them taken ſeparately, the body would be brought down to F; their lateral action being in oppoſite directions deſtroys itſelf; and by their conjunct action, the body would be brought down to double the ſpace AF, that is to H, and conſequently would deſcribe the diagonal of the ſmall ſquare ADHE; which diagonal is equal to the ſide of the large one, and the very ſame that the body would have deſcribed though the two lateral weights had not been preſent.

Mechanical Power.

Hence it appears, that though we pull a body ever ſo ſtrongly by ſtrings in a direction oppoſite to each other, it will ſtill require an equal weight to retain it in equilibrio; that is, ſuppoſing the ſtrings to be perfectly flexible. There may indeed be a deception in making an experiment of this kind; for the body will never deſcend as far as H, nor near that diſtance; but then it muſt be obſerved, that when the ſtrings begin to bend in the middle, the weights G G act in a direction different from what they did originally, and pull the body upwards inſtead of laterally; in which caſe, it muſt either remain at reſt, as in fig. 23. or move upwards, as in fig. 24.

When the powers act in the direction AB and AC, fig. 23. one half of the weight H is ſuſtained by each of them. The body is therefore pulled in the directions AB and AC by two powers, each of which is as 2; and in the direction AF by other two, each of which is as 1. By the power AB it would be made to move in the diagonal AD of the parallelogram ABDF; and by the power AC, in the diagonal AE of the parallelogram ACFE; but theſe diagonals are equal and contrary to each other, and therefore deſtroy each other; of conſequence the body remains at reſt.

In fig. 24. the body A with the weight H appended to it is placed nearer to the point B than to C by one-third. Of conſequence, as will afterwards be explained, it bears two-thirds of the weight H, while C ſuſtains only one-third. The acting powers, therefore, are now the diagonals of two unequal parallelograms. One power draws the body in the direction AB with a force as 3, while the weight H draws it in the direction AH with a force as 2. By it, therefore, the body would be drawn in the direction of the diagonal AD of the parallelogram BDEA. On the other hand, it is acted upon by the power AC, which is likewiſe as 3, while the weight H draws it down with a force only as 1. By this, therefore, it would be drawn in the direction of the line AG, the diagonal of the parallelogram ACGF. We muſt now make theſe two diagonals the ſides of a third parallelogram ADIG; and in the diagonal AI of this parallelogram it will go, for the reaſons already given.

11 Of bodies acted upon by four or more forces.

If four or more forces act upon a body in different directions, the caſe becomes very complicated; and if many powers be employed, it will by no means be eaſy to determine *à priori* which way the body will tend. Caſes of this kind, however, ſeldom occur in practical mechanics; and when they do, it will be better to determine them by actual experiment than by a tedious inveſtigation, which, after all, may be liable to a miſtake. We forbear, therefore, to give more examples; though, if the reader inclines to exerciſe his ingenuity, he muſt proceed upon the plan already laid down, viz. by combining the different powers together; forming diagonals from theſe parallelograms; combining theſe diagonals into a third ſet of parallelograms; and the diagonals thence reſulting into a fourth ſet, &c. until at laſt a ſingle one is met with prevailing over all the reſt, or two deſtroying each other. If one prevails, the

Mechanical Power.

body will move in that direction ; but if two deſtroy each other, the body will remain at reſt.—It muſt alſo be obſerved, that in making drawings of this kind, the longeſt line always repreſents the greateſt power, and that without a ſingle exception to the contrary. By mere mechanical conſtruction, therefore, with ſcale and compaſs, we may be able to aſcertain the direction of oblique powers to as great accuracy as we can ever have occaſion for in practice.

12
Of the various ways in which powers may be produced.

We ſhall conclude this ſubject with obſerving, that as every power certainly *is* produced by the action of two others, ſo it *may be* by innumerable others. Thus, in fig. 25. the power AD may be produced by the two ſides of the ſquare ABDC ; by the ſides of the oblique-angled parallelogram A*a*D*b*, of the ſmaller parallelogram A*c*D*d* ; or of the large parallelogram AE, DF, &c. Hence it is eaſy to produce any power, whether ſtrong or weak, from the action of any two powers whoſe direction we have at our command, without regard to their quantity. If we make the generating powers conſpire together, a ſtrong one will be produced; or if they oppoſe each other to a certain degree, they will produce a weak one. The ſtrongeſt that can be produced by any two powers is when they act the ſame way in a direct line.

§ 6. *Of the Relation betwixt Velocity and Power.*

HITHERTO we have ſuppoſed the bodies to be moved not to make any reſiſtance to motion in any direction, unleſs oppoſed by a fixed obſtacle ; in which caſe, *velocity* and power would be the ſame thing ; and thus it always appears to be when we repreſent powers by lines upon paper. But when we come to practice, matters turn out very different. A ball of cork moving with any degree of velocity will not have an equal power with one of wood moving with the ſame velocity ; neither will a wooden ball have the ſame power with a metallic one. Among the metals themſelves, too, there is a difference ; for the lighter metals are inferior in power to the heavier ones. Gravity, therefore, muſt be accounted the power which gives to moving bodies what we call their *force* or *momentum* ; for according to the weight of a body, ſo will its impulſe always be, and that whether it moves upwards, downwards, ſidewiſe, or in a circle. The abſolute power of a body, therefore, muſt be meaſured by comparing the gravity of different bodies together, and denoting one of them by unity ; making the other 2, 3, 4, &c. according as it is twice, thrice, or four times, the ſpecific gravity of the former. Thus let an hollow ball of metal be filled with water ; if the ball be very thin, we may let its weight paſs unnoticed, or we may make allowance for it in the calculation. Suppoſing the weight of this ball then to be 1, if it moves with a velocity of 10 feet in a ſecond, its abſolute force or momentum will be $10 \times 1 = 10$; a ball of ſtone of equal ſize which weighs three times as much as the former, if moved with an equal velocity, will have a force of $10 \times 3 = 30$; a ball of tin which weighs 7 times as much, will have a momentum of 70 ; and a ball of gold or platina would have a momentum of 190 or 200.

This will alſo hold exactly, by increaſing the *quantity* of matter, where it is deficient in ſpecific gravity. Thus, if the hollow metallic ball be increaſed in diameter, ſo that it ſhall equal in weight the ball of ſtone or of metal, it will have the very ſame force with that ball ; and in like manner, it might be made to have a momentum equal to the metallic balls, though not without a very conſiderable increaſe of ſize.—Great maſſes of matter will therefore ſupply the place of great velocity : and hence Mr Atwood obſerves, that the battering-rams uſed by the ancients were no leſs powerful in beating down the walls of cities than the modern artillery. "The battering-rams of the ancients (ſays he) conſiſted of very large beams of wood terminated by ſolid bodies of braſs or iron ; ſuch a maſs being ſuſpended as a pendulum, and driven partly by its gravity and partly by the force of men againſt the walls of a fortification, exerted a force which, in ſome reſpects, exceeded the utmoſt effects of our battering cannon, though in others it was probably inferior to the modern ordnance. To compare the effects of the battering-ram, the metal extremity of which ſuppoſe equal to a 24 pounder with a cannon-ball of 24 pounds weight ; in order that the two bodies may have the ſame effect in cutting a wall or making a breach in it, the weight of the aries muſt exceed that of the cannon ball in the proportion of the ſquare of 1700, the velocity of the ball*, to the ſquare of the velocity with which the battering ram could be made to impinge againſt the wall expreſſed in feet. If this may be eſtimated at 10 feet in a ſecond, the proportion of the weights will be that of about 2,890,000 to 100, or of 28,900 to 1; the weight of the battering ram therefore muſt be 346 ton. In this caſe the battering-ram and the cannon-ball, moving with the velocities of 10 and 1700 feet reſpectively in a ſecond, would have the ſame effect in penetrating the ſubſtance of an oppoſed obſtacle : but it is probable that the weight of the aries never amounted to ſo much as is above deſcribed ; and conſequently the effects of the cannon-ball to cut down walls by making a breach in them, muſt exceed thoſe of the ancient battering-rams : but the momentum of theſe, or the impetus whereby they communicated a ſhock to the whole building, was far greater than the utmoſt force of cannon-balls ; for if the weight of the battering-ram were no more than 170 times greater than that of a cannon-ball, each moving with its reſpective velocity, the moments of both would be equal ; but as it is certain that the weight of theſe ancient machines was far more than 170 times our heavieſt cannon-balls, it follows, that their moment or impetus to ſhake or overturn walls, &c. was far ſuperior to that which is exerted by the modern artillery. And ſince the ſtrength of fortifications will in general be proportioned to the means which are uſed for their demolition, the military walls of the moderns have been conſtructed with leſs attention to their ſolidity and maſſy weight than the ancients thought a neceſſary defence againſt the aries; that ſort of coheſive firmneſs of texture which reſiſts the penetration of bodies being now more neceſſary than in ancient times : but it is manifeſt, that even now ſolidity or weight in fortifications alſo is of material conſequence to the effectual conſtruction of a wall or battery." This difference between the momentum and force of penetration is exemplified in knives, wedges, or

any ſharp inſtruments, where a ſudden blow will cauſe a much deeper penetration than a weight vaſtly greater than could be ſtirred from the earth by the force of the blow.

§ 7. *Of the Multiplication and Increaſe of Power.*

We have now ſeen that *power*, abſolutely ſo called, acts in a kind of double capacity, *viz.* either when it impreſſes a great velocity upon a ſmall quantity of matter, or when it impreſſes a ſmall velocity upon a great quantity of matter. It muſt, however, be remarked, that the matter we ſpeak of is always ſuppoſed ſubject to the laws of gravity; for what would be the conſequence of putting a body in motion which had no gravity we cannot poſſibly conceive, becauſe we never ſaw any ſuch body. Philoſophers indeed mention the *vis inertiæ* of matter as property diſtinct from gravity; but the arguments in favour of this property are now generally looked upon to be inconcluſive, and gravity and the *vis inertiæ* looked upon to be the ſame.

The two modes in which abſolute power acts, come preciſely to the ſame thing whether the velocity be great or ſmall: for it is evident, that when two pounds move with the velocity of 1, it is the ſame thing with one pound moving with the velocity of 2; the *velocities* as well as powers being exactly the ſame. But there is a third way in which power may be directed, in which it has not the relation to velocity already mentioned; and that is, by ſimple preſſure, where no motion is admitted. Thus may the ſmalleſt power be made to augment itſelf to an inconceivable degree, as in fig. 26. Here, ſuppoſe the body A to preſs directly downwards upon the line AB faſtened to the ſmall wheel B, moveable upon an axis. If we ſuppoſe the extremity of the line at A to be ſupported ſo that it ſhall not fall to a ſide, the wheel B will preſs downward with the whole of the weight A upon the line EF, and conſequently the line *g* muſt ſuſtain the whole of this weight. But if the line EF be ſupported ſo that it cannot move perpendicularly downwards to *g*, it will then roll along the line EF from B towards F; and this tendency to roll in the direction juſt mentioned will be exactly equivalent to the weight A. Any body therefore laid on the top of a ſtick ſet up at an angle of 45 degrees, will require a power double to its own weight to keep it ſteady at the foot, abſtracting from that which will be neceſſary to prevent it from falling to a ſide.

If now we ſuppoſe the wheel B to preſs laterally upon another C; and that other, by means of the line CD and wheel D, to preſs upon the two obſtacles *i* and *k*, both of which it touches at an angle of 45 degrees; it is plain that not only each of theſe obſtacles muſt bear the whole weight of the body A, but the reaction of the wheel D will preſs down the wheel C in the direction C*h* with the very ſame force that D is preſſed upwards. This is entirely ſimilar to the caſe of the man in the boat repreſented in fig. 1. Thus the weight A produces a preſſure equal to five times its own weight; and by multiplying the wheels and rods, we might increaſe the preſſure as much as we pleaſe. The caſe is ſimilar to that in hydroſtatics, where a little quantity of liquid may be made to burſt the ſtrongeſt veſſel.

Plate CCLXXXII.

Sect. II. *Of the Mechanical Powers.*

By theſe we underſtand ſuch ſimple machines as are uſeful for comparing the velocity of various bodies together, and impreſſing them with greater or ſmaller degrees of it at pleaſure; by which means we may either cauſe a ſmall weight overcome a great one, or by means of a great one we may make a ſmall weight move through a ſpace proportionably great. Thus by means of ſome of theſe powers, indeed by any of them, we may cauſe a weight of one pound, by moving through the ſpace of ten feet, raiſe another of ten pounds through one foot; or *vice verſa*, by a weight of ten pounds moving through the ſpace of one foot, we may make a ſingle pound move through the ſpace of ten feet; but by none of the powers will we be able, by moving a weight of ten pounds through one foot, to move a ſingle pound through 11 feet; nor by a ſingle pound moving through a ſpace of nine feet will we be able to raiſe a weight of ten pounds through the ſpace of one foot. None of the mechanic powers, as they are called, therefore, can make any abſolute increaſe of the power applied; all that they can do is to alter the velocity of the power applied, and thus transfer it either to a larger or ſmaller body at pleaſure; and upon this principle depends the whole practical part of mechanics. The mechanical powers are ſix in number, *viz.* the *lever*, *wheel in axis* or *axis in peritrochio*, the *pulley*, *inclined plane*, *wedge*, and *ſcrew*, of all which we ſhall now treat particularly.

§ 1. *Of the Lever.*

14
Firſt kind of lever.
Plate CCLXXXIII.

This is the moſt ſimple of all the mechanical powers, and is uſually no other than a ſtraight bar of wood or iron ſupported by a prop, as in fig. 27. The weight to be raiſed is ſuſpended at the ſhort arm of the lever A; and exactly in the inverſe proportion of the diſtance of the weight from the fulcrum or prop C, is the quantity of the weight at B neceſſary to keep it in equilibrio. Thus if the weight at A be diſtant one foot or one inch, it ſignifies nothing which, from the prop, it will require an equal weight placed at the ſame diſtance on the other ſide, as at 1, to balance it; but if the latter be placed at 2, then only half the weight ſuſpended at A will balance it: if the ſmall weight is placed at 3, then only one third will be neceſſary; if at 4, only one-fourth, &c. and if, as in the figure, it be removed to 10, then only one-tenth part will be required to make a balance. It muſt ſtill be remembered, however, that if the lever is put in motion, the ſmall weight muſt move through a ſpace ten times as great as that through which the large one moves; ſo that in fact there is not any acquiſition of power by means of the lever, though it is one of the inſtruments moſt commonly uſed in mechanics, and very ſerviceable in looſening ſtones in quarries, or raiſing great weights to a ſmall diſtance from the ground; after which they may be raiſed to greater heights by other machines.

In making experiments with this kind of lever, it is neceſſary either to have the ſhort arm much thicker than the long one, ſo that it may exactly balance the latter, or a weight muſt be appended to it juſt ſufficient to keep it *in equilibrio*, otherwiſe no accuracy can be be expected. This lever is the foundation of balances of all kinds, whether of the common kind or of that called the *Roman ſtatera* or ſteel-yard. The latter is no other than the lever repreſented in fig. 27. For if a ſcale is appended to the end A of the lever, and a weight, ſuppoſe of one pound, uſed as a counterpoiſe to the body which is to be put in the ſcale, it will ſhow exactly the weight of that body, by putting it at a proper diſtance from the fulcrum upon the long arm. Thus if the weight when placed at the diviſion 5 counterpoiſes that placed in the ſcale, it ſhows that the body weighs exactly five pounds: if it balances at 6, then it ſhows that the body weighs ſix pounds, &c. But for a more particular account of this inſtrument, ſee the article *Steel-Yard*. To this kind of lever may be reduced ſeveral kinds of inſtruments, as ſciſſars, ſnuffers, pincers, &c.

15 Of the ſteel-yard.

In levers of this kind, the fulcrum C muſt ſupport both the weight to be raiſed and likewiſe that which raiſes it; ſo that the weight upon C muſt be the greater in proportion as the arm CB of the lever is ſhorter. Thus, if the arms are both equal, the fulcrum C muſt bear double the weight at A: if the one arm is double the length of the other, then it has only to bear the weight to be raiſed, and one half more; becauſe any weight at 2 will balance one double to itſelf at 1; but if removed to 10, the fulcrum will only have 1$\frac{1}{10}$ to bear.

16 Second kind of lever.

In ſome caſes, the weight to be raiſed is placed between the acting power and the fulcrum, as in fig. 28. This lever is more powerful than the other, and is likewiſe more eaſily ſupported, becauſe only part of the weight to be raiſed, and none of that which raiſes it, lies upon the fulcrum. Thus in fig. 28. let the extremity A of the lever AB reſt upon a fulcrum at *o*, and let the ſmall weight 1, by means of a ſtring put over the wheel or pin C, pull up the other extremity; this weight 1 will then counterpoiſe the large one 10, and very little additional force will be required to raiſe it up. It is alſo plain, that the whole weight to be raiſed being 10, the fulcrum ſuſtains only 9 of it, for the other 1 is ſuſtained by the ſtring BC. It is plain alſo, that a lever of this kind only ten feet long will raiſe as great a weight as another of the former kind eleven feet in length; nevertheleſs there is not any abſolute gain of power, becauſe the ſmall weight 1 muſt move through ten times as much ſpace as the large one; and thus the quantity of motion is exactly equal in both. To this kind of lever we may reduce oars, doors turning upon hinges, cutting knives fixed at the point of the blade, &c. From it alſo we ſee the reaſon why two men carrying a burden upon a pole may bear unequal ſhares of the weight; for the nearer any one of them is to the burden, the greater ſhare he bears; and if he goes directly under it, he muſt bear the whole. Hence, if two perſons of uneqal ſtrength are to carry a burden in this manner, the weaker ſhould always be placed at the greateſt diſtance from it.

17 Third kind of lever.

If in this lever the moving power be put in the place of the weight, it acts at a great diſadvantage; and a very great power will be requiſite to overcome a ſmall weight. The reaſon of this is plain from an inſpection of fig. 28; for it is the ſame thing whether we ſuppoſe the body 10 to be the moving power, or the weight to be raiſed; in either caſe, nine-tenths of it are ſpent upon the fulcrum at *o*; and the other tenth part at 10 will be able to do no more than balance the weight 1. Levers of this kind are only made uſe of when we wiſh to give a conſiderable degree of velocity to bodies: and hence the flys of clocks, millſtones, &c. may be accounted levers of this kind; for in theſe the moving power is applied to a pinion near the centre of motion, and acts at a great diſadvantage; the muſcles of the arms or legs of a man, by their inſertion near the joints, likewiſe act as levers of this kind; and hence the power exerted by a muſcle is always much greater than the force it has to overcome.

18 In what manner a power applied to a lever acts to the greateſt ad vantage. Plate CCLXXXIV.

In all caſes in which the lever is applied, it is neceſſary, in order to give it the greateſt advantage, that the moving power act in a direction exactly perpendicular to the lever itſelf. If this be not the caſe, it will be neceſſary to lengthen the lever in proportion to the obliquity. Thus in fig. 29. ſuppoſe the ſtraight lever AB to reſt on the fulcrum C, ſo that a weight of one pound may counteract 10; if the lever be bent in the direction AD, it will then be neceſſary to lengthen it ſomewhat in order to produce the ſame effect. If bent in the direction CE, it muſt be farther lengthened, and ſtill farther if bent in the direction CF. The reaſon of this is, that when the weight acts on the bended lever ACF, ACE, and ACD, a part of its force is ſpent in giving, or attempting to give, a lateral motion to the fulcrum C; and the part thus loſt is exactly equal to the advantage gained by the greater length of the lever. To make a lever of a determinate length act always with the ſame power, it will be neceſſary to have ſome contrivance by which the moving power may act always perpendicularly to it; as by having two circular pieces of wood or other ſolid matter faſtened to the ends of it, round which the ropes may wrap themſelves when it is put in motion, ſuch as are repreſented by *ab* and BG in the figure.

19 Fourth kind of lever.

Fig. 30. ſhows a kind of lever bent ſo that one part of it may form a right angle with the other. Here the prop or centre of motion is at the angular point C. P is a power acting upon the longer arm AC at F, by means of the cord DE going over the pulley G; and W is a weight of reſiſtance acting upon the end B of the ſhorter arm BC. If the power be to the weight as BC is to CF, they will remain in equilibrio. Thus ſuppoſe W to be five pounds acting at the diſtance of one foot from the centre of motion C, and P to be one pound acting at F five feet from the centre C, the power and weight will juſt balance each other. A hammer drawing a nail is a lever of this kind. In this lever the preſſure upon the fulcrum downwards is juſt equal to the weight to be raiſed; but there is likewiſe a lateral preſſure equal to the weight P; ſo that the centre of motion muſt have a double ſupport, otherwiſe the whole lever with the weight would be drawn towards the ſide in the direction BC.

20 Fifth kind of lever.

If, as in fig. 31. and 32. the lever be bent ſo as to form two ſides of a ſquare, the weight to be raiſed will always be equal to that upon the fulcrum, in whatever place the fulcrum may be put; but both will vary according to the diſtance from the angular point. Thus, if as in fig. 31. the fulcrum be placed at the angular point A, the weight F appended to the extremity B of of the arm AB will juſt counterpoiſe an equal weight E by means of the ſtring CDE put over the pin D, and drawn laterally by the arm AC. But if, as in fig. 32. the fulcrum be placed nearer to the extremity of the arm AC, as at 3, the caſe will then be very much altered, and one pound ſuſpended at the extremity B of the arm AB will counterpoiſe four at the extremity C of the other arm: the preſſure on the fulcrum will likewiſe be equal to the weight to be raiſed. Was the fulcrum placed at 2, then a weight of one pound at B would only counterpoiſe two pounds acting at C; and if it was placed at 1, then a weight of three pounds at B would be requiſite to counterpoiſe 4 at C.

21
evers of
ie fifth
ind can-
ot be ba-
nced by
ny other.

It is worth notice, that levers of this kind cannot be exactly counterpoiſed by the power of ſtraight levers. Thus, in fig. 33. let any weight, as C, be appended to B, the extremity of the aim of the bent lever BA4. Let DE be a ſtraight lever, the force of which we deſign to oppoſe to that of the crooked lever. For this purpoſe let another weight F act upon the extremity D of this ſtraight lever by means of a ſtring put over the pin G. Let the two levers be connected together by means of the ſtring *h*3, and let a piece of wood or iron E4 be put between their two extremities: the two weights being now allowed to act, it is evident that the levers will be pulled in different directions, the ſtring *h*3 will be tightened, and the extremity E of the ſtraight lever DE will be preſſed towards 4, while the extremity 4 of the crooked lever will be preſſed towards E; by which means the two levers will oppoſe one another in every point of their action. There is not, however, any weight whatever applied to the ſtraight lever which can be made to counterbalance that at C, in ſuch a manner as to keep the bent lever ſteady. Let us firſt ſuppoſe the weights to be each one pound, and the ſtring to be placed as in the figure at *h*3. In this caſe the weight C pulls the crooked lever from *h* towards 3, with a force equal to 4, and the extremity 4 will be preſſed towards E with an equal degree of force. But in the ſtraight lever, though the point *h* be pulled in the direction 3*h* by a force of four pounds, the extremity E is preſſed the contrary way by a force equivalent only to three. Thus the weight C muſt preponderate, and that at F will aſcend. Let us next add to the weight F one third of a pound; by which means the preſſure from E towards 4 will be augmented to 4, and the two extremities of the levers will counteract each other: but now the preſſure in the direction 3*h* will be greater by one-third of a pound than it is in the direction *h*3; and of conſequence the weight F will prevail, the arm AB of the crooked lever and the weight appended to it being raiſed. If we attempt to mend matters by augmenting the weight F by not quite a third part, the extremities of the two levers will not balance each other, the preſſure from 4 to E will be greater than from E to 4; and in like manner the preſſure from 3 to *h* will be greater than from *h* to 3. Hence both levers will be pulled in a direction from D towards G, and the weight F will deſcend if the weights be properly adjuſted without any aſcent of the other. In ſhort, let us alter the weights as we will, or let us alter the poſition of the fulcrum as we will, it is eaſy to ſee that there is an abſolute impoſſibility that the two levers can counteract each other; becauſe the preſſure upon the fulcrum of the crooked lever will always be equal to that by its extremity 4; but in the ſtraight lever the preſſure upon the fulcrum muſt neceſſarily be greater than that of the extremity.

22
Dr Hamilton's demonſtration of the properties of the lever.

Theſe are all the varieties of the lever which can be ſuppoſed; it remains now only to ſhow the reaſon of its action, or why a ſmall weight when at reſt ſhould counterpoiſe a great one; motion or velocity being here to appearance out of the queſtion, as we cannot attribute any degree of motion to two bodies abſolutely at reſt. To do this in a clear and diſtinct manner has puzzled ſome of the greateſt mathematicians: that of Dr Hamilton profeſſor of philoſophy in Dublin, founded upon the reſolution of forces, ſeems to be the moſt readily underſtood, and leaſt liable to objection. ‘The moſt noted theorem in mechanics (ſays he) is this, “When two heavy bodies counterpoiſe each other by means of any machine, and are then made to move together, the quantities of motion with which one deſcends and the other aſcends perpendicularly will be equal.” An equilibrium always accompanying this equality of motions, bears ſuch a reſemblance to the caſe wherein two moving bodies ſtop each other when they meet together with equal quantities of motion, that many writers have thought that the cauſe of an equilibrium in the ſeveral machines might be immediately aſſigned, by ſaying, that ſince one body always loſes as much motion as it communicates to another, two heavy bodies counteracting each other muſt continue at reſt, when they are ſo circumſtanced that one cannot deſcend without cauſing the other to aſcend at the ſame time, and with the ſame quantity of motion. For then, ſhould one of them begin to deſcend, it muſt inſtantly loſe its whole motion by communicating it to the other. This argument, however plauſible it may ſeem, I think is by no means ſatisfactory; for when we ſay that one body communicates its motion to another, we muſt neceſſarily ſuppoſe the motion to exiſt firſt in the one, and then in the other; but in the preſent caſe, where the two bodies are ſo connected that one cannot poſſibly begin to move before the other, the deſcending body cannot be ſaid to communicate its motion to the other, and thereby make it aſcend: But whatever we ſhould ſuppoſe cauſes one body to deſcend, muſt be alſo the immediate cauſe of the other's aſcending: ſince from the connection of the bodies, it muſt act upon them both together as if they were really but one. And therefore, without contradicting the laws of motion, I might ſuppoſe the ſuperior weight of the heavier body, which is in itſelf more than able to ſuſtain the lighter, would overcome the lighter, and cauſe it to aſcend with the ſame quantity of motion with which the heavier deſcends; eſpecially as both their motions, taken together, may be leſs than what the difference of the weights, which is here ſuppoſed to be the moving force, would be able to produce in a body falling freely.

‘However, as the theorem above-mentioned is a very elegant one, it ought certainly to be taken notice of in every treatiſe of mechanics, and may ſerve as a very good index of an equilibrium in all machines; but I do not think that we can from thence, or from any one general principle, explain the nature and effects of all the mechanic powers in a ſatisfactory manner;

manner; becauſe ſome of theſe machines differ very much from others in their ſtructures, and the true reaſon of the efficacy of each of them is beſt derived from its particular ſtructure.

‘ The lever is conſidered as an inflexible line, void of weight, and moveable about a fixed point called its *fulcrum* or prop. The property of the lever, expreſſed in the moſt general term, is this: “ When two weights, or any two forces, act againſt each other on the arms of a lever, and are in equilibrio, they will be to each other inverſely as the perpendicular or ſhorteſt diſtances of their lines of direction from the fulcrum.”

‘ This propoſition contains two caſes; for the directions of the forces may either meet in a point, or be parallel to each other. Moſt writers begin their demonſtration of this propoſition with the ſecond caſe, which ſeems to be the ſimpleſt, and from which the other may be deduced by the reſolution of forces. Archimedes, in his demonſtration, ſets out with a ſuppoſition, the truth of which may reaſonably be doubted: for he ſuppoſes, that if a number of equal weights be ſuſpended from the arm of a lever, and at points equidiſtant from each other, whether all theſe points be at the ſame ſide of the fulcrum, or ſome of them on the oppoſite ſide, theſe weights will have the ſame force to turn the lever as they would have were they all united and ſuſpended from a point which lies in the middle between all the points of ſuſpenſion, and may be conſidered as the common centre of gravity of all the ſeparate weights. Mr Huygens, in his *Miſcellaneous obſervations on mechanics*, ſays, that ſome mathematicians have endeavoured, by altering the form of this demonſtration, to render its defects leſs ſenſible; though without ſucceſs. He therefore propoſed another proof, which is extremely tedious and prolix, and alſo depends on a poſtulatum, that, I think, ought not to be granted on this occaſion: it is this; “ When two equal bodies are placed on the arms of a lever, that which is furtheſt from the fulcrum will prevail and raiſe the other up.” Now, this is taking it for granted, in other words, that a ſmall weight placed further from the fulcrum, will ſuſtain or raiſe a greater one. The cauſe and reaſon of which fact muſt be derived from the demonſtration that follows, and therefore this demonſtration ought not to be founded on the ſuppoſed ſelf-evidence of what is partly the thing to be proved.

‘ Sir Iſaac Newton's demonſtration of this propoſition is indeed very conciſe; but it depends on this ſuppoſition, that when from the fulcrum of a lever ſeveral arms or radii iſſue out in different directions, all lying in the ſame vertical plane, a given weight will have the ſame power to turn the lever from which-ever arm it hangs, provided the diſtance of its line of direction from the fulcrum remains the ſame. Now it muſt appear difficult to admit this ſuppoſition, when we conſider that the weight can exert its whole force to turn the lever only on that arm which is the ſhorteſt, and is parallel to the horizon, and on which it acts perpendicularly; and that the force which it exerts, or with which it acts perpendicularly, on any one of the oblique arms, muſt be inverſely as the length of that arm, which is evident from the reſolution of forces.

‘ Mr Maclaurin, in his *View of Newton's Philoſophy*, after giving us the methods by which Archimedes and Newton prove the property of the lever, propoſes one of his own, which, he ſays, appears to be the moſt natural one for this purpoſe. From equal bodies, ſuſtaining each other at equal diſtances from the fulcrum, he ſhows us how to infer that a body of one pound (for inſtance) will ſuſtain another of two pounds at half its diſtance from the fulcrum; and from thence that it will ſuſtain one of three pounds at a third part of its diſtance from the fulcrum: and going on thus, he deduces, by a kind of induction, what the proportion is in general between two bodies that ſuſtain each other on the arms of a lever. But this argument, were it otherwiſe ſatisfactory, yet as it cannot be applied when the arms of the lever are incommenſurable, it cannot conclude generally, and therefore is imperfect.

‘ There are ſome writers on mechanics, who, from the compoſition of forces, demonſtrate that caſe of the general propoſition relating to the lever, in which the directions of the forces are oblique to each other, and meet in a point: but I do not find that they have had any other way of proving the ſecond caſe, in which the directions of the forces are parallel, but by conſidering theſe directions as making an angle with each other, though an infinitely ſmall one, or as meeting at an infinite diſtance; which way of reaſoning is not to be admitted in ſubjects of this kind, where the proof ſhould always ſhow us, directly from the laws of motion, why the concluſion muſt be true, in ſuch manner that we might ſee clearly the force of every ſtep from the firſt principles down to the concluſion, which we are prevented from doing when any ſuch arbitrary and inconſiſtent ſuppoſition is introduced.

‘ From thus conſidering the various proofs that have been given of this fundamental propoſition in mechanics, we may ſee the reaſon why many ſubſequent writers have appeared diſſatisfied with the former demonſtrations, and have looked for new ones: I ſhall now propoſe two methods of demonſtrating it, merely from the compoſition and reſolution of forces. The propoſition may be expreſſed as follows.

“ When three forces act upon an inflexible line, whether ſtraight or crooked, and keep it in equilibrio, any two of them will be to each other inverſely as the perpendicular diſtances of their lines of direction from that point to which the third force is applied.”

‘ Let the three forces E, G, F, (fig. 34.) act upon three points A, B, D, in an inflexible line; and firſt let the directions of the forces E and F (which act on the ſame ſide of the line) meet in the point C. Then it is evident that the force, which is compounded of theſe two, muſt act upon the line A B D in the direction of a right line that paſſeth through the point C; conſequently the force G, which ſuſtains this compounded force, muſt be equal thereunto, and muſt act in a contrary direction; therefore the force G muſt act in the direction of the line C B. From the point B draw B H and B K perpendicular to the directions of the forces E and F, and draw B M and B N parallel to theſe directions, forming the parallelogram B M C N; then, ſince theſe three forces are in equilibrio, they muſt be to each other reſpectively as the ſides and diagonal of this parallelogram to which their directions are parallel; therefore E is to F as CM to CN or MB, that is, (becauſe the ſides of a triangle are as the ſines of the oppoſite angles) as the ſine of the angle MBC, or its alternate one BCN, to the ſine of the angle BCM; but making CB the radius, BK is the ſine of the former angle, and BH of the latter; therefore E is to F as BK to BH; ſo that the forces E and F are to each other inverſely as the perpendicular diſtances of their lines of direction from the point B, on which the third force G acts. Now to compare the forces F and G together: From the point A, on which the third force acts, draw AB and AL perpendicular to the directions of the forces G and F; then, as was ſaid before, F is to G as MB is to CB; but MB is to CB as AB to AL; becauſe, making CA the radius, AB is the ſine of the angle MCB, and AL is the ſine of the angle MCN, or CMB its ſupplement, to two right ones; therefore the forces F and G are to each other inverſely as the perpendicular diſtances of their lines of direction from the point A, on which the third force E acts; and thus the firſt caſe of the propoſition is proved, in which the forces act againſt each other in oblique directions.

‘ We muſt now conſider what parts of the forces E and F act againſt the force G in directions parallel to GC; for it is ſuch parts only that really oppoſe the force G, and keep it in equilibrio; and from thence we ſhall ſee what proportion two forces muſt have to each other when they are in equilibrio, and act in parallel directions. Let the three forces act upon the points A, B, and D, (fig. 35.); let them be in equilibrio, and their lines of direction meet in the point C, as in the preceding caſe; then, if the points A, B, and D, are not in a right line, draw the line AD meeting BC in P, and from P draw PN and PM parallel to the directions of the forces E and F; through the points A and D draw parallel lines to BC; and through B draw a perpendicular to theſe lines, meeting them in H and K; from the point M draw MO parallel to AD, and meeting BC in O. Now the three forces E, G, and F, that are in equilibrio, will be to each other reſpectively as the ſides of the triangle CMP, as in the preceding caſe; but the force E, which is denoted by the line MC, may be reſolved into two forces acting in the directions MO and OC, the former of theſe only urges the point A towards D, and the latter acts in direct oppoſition to the force G; in like manner the force F, which is denoted by the line PM, may be reſolved into two forces acting in the directions OM and PO, the former of which only urges the point D towards A, and the latter acts in direct oppoſition to the force G; now it is evident that the force G, which is denoted by the line PC, is ſuſtained only by thoſe parts of the forces E and F which act againſt it, in directions parallel to BC, and are denoted by the lines OC and PO, which, taken together, are equal to PC; for the other parts of the forces E and F, which are denoted by MO, are loſt, being equal, and contrary to each other: if, therefore, inſtead of the forces F and E, we ſuppoſe two other forces, R and L, to act on the points D and A, in directions parallel to BC, and to keep the force G in equilibrio, it follows, from what has been proved, that R and L taken together will be equal to G, and that theſe three forces will be to each other reſpectively as the lines PO, OC, and PC; therefore R will be to L as PO to OC, (that is, as AM to MC, or as AP to PD, or) HB to BK; conſequently the forces R and L are to each other inverſely as the perpendicular diſtances of their lines of direction from the point B, to which the third force is applied. Now to compare the forces R and G together; ſince the forces R and L may be denoted by BH and BK, and are both together equal to G, that force will be denoted by the whole line KH, and therefore R will be to G as BH to KH; ſo that theſe forces are alſo to each other inverſely as the perpendicular diſtances of their lines of direction from the line of direction of the third force L; and thus the ſecond caſe of the propoſition is proved, in which the forces act againſt each other in parallel directions. If the point in the inflexible line, to which one of the forces is applied, ſhould become a fixed point, or *fulcrum*, round which the line may turn, it is evident that the other two forces will continue in equilibrio, as they were before; and therefore the property of the lever, in all caſes, is manifeſtly proved by this propoſition.

‘ The centre of gravity of a body is ſaid to be that point which being ſuſtained, or prevented from deſcending, the body will continue at reſt. From hence it follows, that when a body hangs freely from a ſingle point and continues at reſt, its centre of gravity will lie perpendicularly under the point of ſuſpenſion; for in that ſituation only it will be ſuſtained, and can deſcend no lower.

‘ From this property, which agrees likewiſe to the common centre of gravity of two bodies joined together by an inflexible right line, and which may then be conſidered as one, I ſhall ſhow that their centre of gravity is a point in the line that joins them together, ſo ſituated that the diſtances of the two bodies from it are to each other inverſely as their weights. This theorem concerning the poſition of the common centre of gravity of two bodies, which is a very noted one in mechanics, I have never ſeen demonſtrated otherwiſe than by inferring it from the general property of the lever: but I think the method I ſhall now propoſe of deducing it directly from the definition of the centre of gravity, is the moſt conciſe as well as the moſt natural, and beſides it will afford us a very eaſy way of demonſtrating the property of the lever.

‘ Let the two bodies A and B (fig. 36.) be joined by an inflexible right line paſſing through their centres of gravity, and let them be ſuſpended from the fixed point or pin at P, by the threads AP and BP, ſo that they may hang freely in ſuch a poſition as their joint gravity will give them. When theſe bodies continue at reſt, their common centre of gravity muſt lie directly under the point of ſuſpenſion, or in the perpendicular line PL, conſequently it muſt be at the point C, the interſection of the lines PL and AB; the poſition of which point, in the line AB, will be determined by finding out the proportion between the ſegments CA and CB. If the inflexible line was not interpoſed between theſe bodies, they would move till their threads coincided with the perpendicular line PL; ſince therefore they are kept aſunder by this line, they muſt urge it with certain forces in oppoſite directions; and theſe urging forces muſt be equal, ſince the line on which they act continues at reſt: and therefore the force with which each body urges the other in the direction of this line, may be denoted by the ſame letter U, and we may denote the weights of the two bodies reſpectively by the letters A and B. Now the body A is acted upon by three forces, viz. by its weight A in the direction PC, by the force U with which the other body urges it in the direction CA, and by the reaction of the pin in the direction AP; and ſince theſe three forces are in equilibrio, and keep the body at reſt, they are to each other reſpectively as the ſides of the triangle PCA; therefore A is to U, as PC to CA. In like manner, the body B is urged by three forces, *viz.* its weight B in the direction PC, the urging force U in the direction CB, and the reaction of the pin in the direction BP, which forces are to each other as the ſides of the triangle PCB; therefore U is to B, as CB to PC; and therefore *(ex æquo perturbate)* A is to B, as CB to CA; conſequently the weights of the bodies A and B are to each other directly as their diſtances from the point C, which lies directly under the point of ſuſpenſion, and is therefore their common centre of gravity.

'When two bodies are connected by an inflexible line, and this line is ſupported by a prop ſo that their centre of gravity cannot deſcend, the bodies muſt continue to reſt, and will be in equilibrio. Therefore it is eaſy to ſee how, from the theorem now demonſtrated, we may prove the property of the lever in that caſe where the directions of the forces are parallel; and from thence the other caſe, in which the directions are oblique to each other, may be deduced by the reſolution of forces, as is uſually done. And this is the ſecond method by which I ſaid the general property of the lever might be ſtrictly demonſtrated.

'The lever is the moſt ſimple of all the mechanic powers; and to it may be reduced the balance and the *axis in peritrochio*, or axle and wheel: Though I do not conſider the balance as a diſtinct mechanic power, becauſe it is evidently no other than a lever fitted for the particular purpoſe of comparing the weights of bodies, and does not ſerve for raiſing great weights or overcoming reſiſtances as the other machines do.'

23 Another demonſtration.

Though this demonſtration will no doubt be abundantly clear to mathematical readers, yet to others leſs verſed in that ſcience its appearance will no doubt be ſomewhat obſcure and perplexed. The following we ſubjoin as leſs intricate.

Let AB, fig. 37, repreſent a ſtraight rod of wood or iron, faſtened at the extremity A, at right angles to another piece of the ſame, and kept ſteady by two pins C and D. If a weight be put upon the extremity H of the upright rod AH, it will preſs down that, and along with it the horizontal rod AB, ſo that every point in the rod will move with the whole force of the weight. Thus, whether we ſuppoſe an obſtacle to be placed at the extremity B, at the point 2, or at 1, in the horizontal rod AB, it will have exactly the force of the weight placed at H to overcome.—Suppoſing then that the weight would make the whole deſcend from A to E in one ſecond; then it is plain that the whole power exerted by the rod in its deſcent would be expreſſed by the parallelogram ABEF. But if, inſtead of ſuppoſing the line AB to be the full length repreſented in the figure, we ſuppoſe it to be only half that length, and cut off at 1, then the power of the weight would be repreſented by the parallelogram A 1 E 1. Were it ſtill farther ſhortened, by being cut off at 2, then the power would be repreſented by the parallelogram A 2 E 2; and each of theſe parallelograms, however unequal they may be as repreſented upon paper, would in reality be equal when the experiment was made, becauſe in no caſe could the weight deſcend with a greater force than its own. Suppoſe next the weight to be taken off from H, and put upon B, and the rod AB to be moveable upon the centre A; the whole power of the weight then would be expreſſed by the triangle ABG, equal to the parallelogram ABEF; but as every point of the lever muſt bear the whole impulſe of the weight as before, it is plain, that as we approach towards the centre, that power is compreſſed into leſs and leſs ſpace. Thus, when the weight has deſcended from B to G, though the large triangle ABG be equal to the parallelogram ABEF, yet the ſmaller triangle A 1 1 is equal only to one half of the parallelogram A 1 E 1, which repreſents the power. The whole power being therefore compreſſed into half the ſpace, muſt of neceſſity be double to what it was in the former caſe. In like manner, the triangle A 2 *b*, is only equal to one half of the parallelogram A 2 *a b*; and this parallelogram itſelf is only half the ſpace repreſenting the whole power of the weight. In this caſe, therefore, the power is confined within one fourth part of the ſpace which it naturally has, and for that reaſon muſt be four times as great.

§ 2. *Of the Wheel and Axle, or Axis in Peritrochio.*

THIS power acts entirely on the principles of the lever, and has therefore ſometimes been called a perpetual lever. In it the power is applied to the circumference of a wheel by means of a rope or otherwiſe, the weight to be raiſed being faſtened to a rope which winds round the axis. It is repreſented fig. 38, where AB is the wheel, EDF its axis, P the moving power, and W the weight to be raiſed by means of the rope K coiling itſelf about the axis. It is plain then from an inſpection of the figure, that when the large wheel has made one revolution, the weight P will have deſcended through a ſpace equal to the circumference, and as much of the cord I, by which it is ſuſpended, will be wound off. On the other hand, the weight W will have aſcended only through a ſpace equal to the circumference of the axle, and juſt ſo much of the rope K will be wound up upon it. As the circumference of the wheel, therefore, is to that of the axis, ſo will the velocity of the moving power be to that of the weight to be raiſed, and of conſequence ſuch will be the force of the machine: thus, if the circumference of the wheel be eight, ten, twelve, or any number of times as large as that of the axle, one pound applied to the circumference will counterbalance eight, ten, twelve, or more pounds, applied to the axle, and a ſmall addition will raiſe it up.

24 Of the e gines call cranes.

The engines called *cranes*, for raiſing great weights, are no other than wheels of this kind. Sometimes they are moved by handles S, S, &c. placed on the circumference of the wheel, which is turned by mens hands, as is ſhown fig. 38. Sometimes the wheel is hollow, and furniſhed with ſteps, on which a man, who is incloſed in the wheel, continually ſets his feet, as if he was aſcending a ſtair; and thus the wheel yielding to his weight turns round, and coils up the rope which raiſes the weight about its axis. When the crane is to be turned by mens hands, it may advantageouſly have cogs all round the circumference, in which a ſmall trundle may be made to work and be turned by a winch.—Thus the power of the man who works it will be greatly increaſed; for his ſtrength will be augmented as many times as the number of revolutions of the winch exceeds that of the axle D, when multiplied by the exceſs of the length of the winch above the length of the ſemidiameter of the axle, added to the ſemidiameter or half the thickneſs of the rope K, by which the weight is drawn up. Thus, ſuppoſe the diameter of the rope and axle taken together to be 12 inches, and conſequently half their diameters to be 6 inches, ſo that the weight W will hang at ſix inches perpendicular diſtance from below the centre of the axle; let us ſuppoſe the wheel AB, which is fixed on the axle, to have 80 cogs, and to be turned by means of a winch ſix inches long, fixed on the axis of a trundle of eight ſtaves or rounds, working in the cogs of the wheel. Here it is plain that the winch and trundle would make ten revolutions for one of the wheel AB, and its axis D, on which the rope K winds in raiſing the weight W: and the winch being no longer than the ſum of the ſemidiameters of the great axle and rope, the trundle could have no more power on the wheel than a man could have by pulling it round by the edge, becauſe the winch would then have no greater velocity than the edge of the wheel has, which is ſuppoſed to be ten times the velocity of the riſing weight; ſo that in this caſe the acquiſition of power would be as 10 to 1. But if the length of the winch be 12 inches, the power gained will be as 20 to 1; if 18 inches, which is a ſufficient length for any man to work with, the acquiſition of power will be as 30 to 1; becauſe the velocity of the handle would be 30 times as great as that of the riſing weight, and the abſolute force of any machine is exactly in proportion to the velocity of the weight raiſed by it. We muſt always remember, whoever, that juſt as much time is loſt in working the machine as there is power gained by it; for none of the mechanical powers are capable of gaining both power and velocity at the ſame time.

In all cranes, it is neceſſary to have a racked wheel, repreſented by G, on one end of the axle, with a catch H to fall into its teeth; which will at any time ſupport the weight, and keep it from deſcending, if the workman ſhould happen to let ſlip his hold. For want of this precaution, terrible accidents have ſometimes happened to people incloſed in cranes, by their inadvertently miſſing a ſtep.

§ 3. *Of the Pulley.*

The pulley is a ſingle wheel of wood, braſs, or iron, moveable upon an axis, and incloſed in a kind of caſe called its *block*, which admits of a rope to paſs freely over the circumference of the pulley, in which alſo there is uſually a groove to keep the rope from ſliding, the axis being generally fixed in the block. In ſome pulleys the block is fixed; in others moveable, and riſes with the weight. Both theſe kinds are repreſented, fig. 39. AA ſhows a fixed pulley, with its block *b*. Over the wheel a ſtring BB paſſes, to the extremities of which are fixed the two weights W and P. This pulley, however, though it changes the direction of a power, yet does not gain any advantage; for one of the weights muſt always deſcend as much as the other aſcends, of conſequence their velocities muſt always be equal; and when this is the caſe, there can be neither increaſe nor decreaſe of power. A ſingle fixed pulley, therefore, though it may compare the weight of two bodies together, cannot be accounted in any reſpect a mechanical power. But if with a fixed pulley we combine a moveable one, or one in which the block ariſes along with the wheel, we gain an increaſe of one half. Thus if a weight W hangs at the lower end of the moveable block P of the pulley D, and the cord GF goes under the wheel, it is plain that the half G of the cord bears one half of the weight W, and the half F the other. The hook H, therefore, which ſuſtains the half G of the cord, muſt therefore bear one half of the weight; and if the cord at F be drawn up, ſo that the pulley may be raiſed from D to C, the ſtring will be extended to its whole length, all but that which goes under the wheel of the pulley D; but the weight or power P by which the ſtring is thus drawn up, will have moved twice as far as the weight W which is drawn up: whence we ſee that only one pound at P will be requiſite to counterpoiſe two pounds at W. If the upper and fixed block contain two pulleys, and the lower one U contain alſo two, the advantage gained by this combination will be as 4 to 1. Thus, if one end of the ſtring KMOQ be fixed to a hook at I, and the ſtring paſſes over the pulleys N and R, and under thoſe L and P, the weight T of one pound will balance a weight W of four pounds, ſuſpended by a hook from the moveable block, making allowance for the weight of the block itſelf. In like manner will the pulleys give an advantage of 4 to 1 when diſpoſed as at X and Y; but in all caſes the ſame relation between velocity and power is preſerved as in the lever and axis in peritrochio, viz. if the power balances twice its own weight, it muſt move or have a tendency to move through twice the ſpace; if it balances four times its weight, then it muſt have a tendency to move through four times the ſpace that the other does.

25
Advantages and diſadvantages of pulleys.

Pulleys are of great uſe in practical mechanics, as by their means great weights may be raiſed to any height much more expeditiouſly than by any other method, and the ſmallneſs of their weight makes them very convenient for carriage. At ſea they are uſed for hoiſting the ſails and yards, ſtraitening ropes, &c. Archimedes, by means of a machine compoſed of pulleys, is ſaid to have drawn a ſhip along the ſtrand, in the preſence of Hiero king of Syracuſe; but this is ſcarcely to be credited, on account of the great friction which attends this kind of machines.—The friction ariſes from three cauſes: 1. The diameter of the axis bearing a conſiderable proportion to that of the wheels. 2. Their rubbing againſt their blocks, or againſt one another. 3. The ſtiffneſs of the rope that goes over and under them. All theſe cauſes muſt neceſſarily be augmented, in proportion to the weight we have to overcome: and when we conſider the immenſe reſiſtance which a ſhip muſt make, with the ſtrength and ſtiffneſs of the ropes neceſſary to overcome it, we can ſcarce ſuppoſe the ſtrength of any individual equal to the taſk. Pulleys have often been uſed by inhuman tyrants, in conſtructing machines for torturing the objects of their cruelty.

26
Reaſon of the effects of the pulley.

The pulley has by ſome writers been reduced to the lever as well as the wheel and axis; in which method they conſider the fixed pulleys as a lever of the firſt, and the moveable pulley as one of the ſecond kind: but it is juſtly obſerved by Profeſſor Hamilton, that the pulley cannot be with any propriety reduced to a lever; becauſe, though both the moveable and immoveable pulleys ſhould be taken away, the ropes would have to ſuſtain the ſame weight that they do with the pulleys; nay, the very ſame advantages would be gained by the mere uſe of pins, without any wheels, were not the friction very great even upon the ſmootheſt pins that could be made uſe of. It is, indeed, merely to avoid this reſiſtance on the pins that wheels are made uſe of at all. The beſt method of computing the power, and explaining the reaſon of the effects of pulleys, is by conſidering that every moveable pulley hangs by two ropes equally ſtretched, each of which bears one half of the weight; and therefore, when the ſame rope goes round a number of fixed and moveable pulleys, ſince all its parts on each ſide of the pulleys are equally ſtretched, the whole weight muſt be equally divided amongſt all the ropes by which the moveable pulleys hang; conſequently, if the power which acts on one rope be equal to the weight divided by the number of ropes, that power will ſuſtain the weight.

27
Mr White's patent pulley.
Plate CCLXXXVII.

A very conſiderable improvement in the conſtruction of pulleys has been made by Mr James White, who has obtained a patent for his invention, and of which the following deſcription is given by the inventor. Fig. 68 ſhows the machine, conſiſting of two pulleys Q and R, one fixed and the other moveable. Each of theſe has ſix concentric grooves, capable of having a line put round them, and thus acting like as many different pulleys, having diameters equal to thoſe of the grooves. Suppoſing then each of the grooves to be a diſtinct pulley, and that all their diameters were equal, it is evident that if the weight 144 were to be raiſed by pulling at S till the pulleys touched each other, the firſt pulley muſt receive that length of line as many times as there are parts of the line hanging between it and the lower pulley. In the preſent caſe, there are 12 lines, b, d, f, &c. hanging between the two pulleys, formed by its revolution about the ſix upper and ſix lower grooves. Hence as much line muſt paſs over the uppermoſt pulley as is equal to twelve times the diſtance of the two. But, from an inſpection of the figure, it is plain, that the ſecond pulley cannot receive the full quantity of line by as much as is equal to the diſtance betwixt it and the firſt. In like manner, the third pulley receives leſs than the firſt by as much as is the diſtance between the firſt and third; and ſo on to the laſt, which receives only one twelfth of the whole. For this receives its ſhare of line *n* from a fixed point in the upper frame, which gives it nothing; while all the others in the ſame frame receive the line partly by turning to meet it, and partly by the line coming to meet them.

Suppoſing now theſe pulleys to be equal in ſize, and to move freely as the line determines them, it appears evident, from the nature of the ſyſtem, that the number of their revolutions, and conſequently their velocities, muſt be in proportion to the number of ſuſpending parts that are between the fixed point above-mentioned and each pulley reſpectively. Thus the outermoſt pulley would go twelve times round in the time that the pulley under which the part *n* of the line, if equal to it, would revolve only once; and the intermediate times and velocities would be a ſeries of arithmetical proportionals, of which, if the firſt number were 1, the laſt would always be equal to the whole number of terms. Since then the revolutions of equal and diſtinct pulleys are meaſured by their velocities, and that it is poſſible to find any proportion of velocity on a ſingle body running on a centre, viz. by finding proportionate diſtances from that centre, it follows, that if the diameters of certain grooves in the ſame ſubſtance be exactly adapted to the above ſeries (the line itſelf being ſuppoſed inelaſtic, and of no magnitude), the neceſſity of uſing ſeveral pulleys in each frame will be obviated, and with that ſome of the inconveniencies to which the uſe of the pulley is liable.

In the figure referred to, the coils of rope by which the weight is ſupported are repreſented by the lines *a*, *b*, *c*, &c.; *a* is the *line of fraction*, commonly called the fall, which paſſes over and under the proper grooves, until it is faſtened to the upper frame juſt above *n*. In practice, however, the grooves are not arithmetical proportionals, nor can they be ſo; for the diameter of the rope employed muſt in all caſes be deducted from each term; without which the ſmaller grooves, to which the ſaid diameter bears a larger proportion than to the larger ones, will tend to riſe and fall faſter than they, and thus introduce worſe defects than thoſe which they were intended to obviate.

The principal advantage of this kind of pulley is, that it deſtroys lateral friction, and that kind of ſhaking motion which are ſo inconvenient in the common pulley. "And leſt (ſays Mr White) this circumſtance ſhould give the idea of weakneſs, I would obſerve, that to have pins for the pulleys to run on, is not the only nor perhaps the beſt method; but that I ſometimes uſe centres fixed to the pulleys, and revolving on a very ſhort bearing in the ſide of the frame, by which ſtrength is increaſed, and friction very much diminiſhed; for to the laſt moment the motion of the pulley is perfectly circular: and this very circumſtance is the cauſe of its not wearing out in the centre as ſoon as it would, aſſiſted by the ever increaſing irregularities of a gullied bearing. Theſe pulleys, when well executed, apply to jacks and other machines of that nature with peculiar advantage, both as to the time of going and their own durability; and it is poſſible to produce a ſyſtem of pulleys of this kind of ſix or eight parts only, and adapted to the pockets, which, by means of a ſkain of ſewing ſilk, or a clue of common thread, will raiſe upwards of an hundred weight.

§ 4. *Of the Inclined Plane.*

Plate CCLXXXIV.

THIS power is repreſented fig. 40; and the advantage gained by it is exactly in the proportion of the length of the plane to the perpendicular height of it. Thus, let AB be a plane parallel to the horizon, and CD one inclined to it; ſuppoſe alſo the whole length CD to be three times as great as the perpendicular height G*f*F; in this caſe, the cylinder E will be ſupported upon the plane CD, and kept from rolling down upon it, by one-third part of its weight. Were the length of the plane four times its height, it would be prevented from rolling down by one-fourth part of its weight. The force with which a rolling body deſcends upon an inclined plane will be to that with which it would deſcend by the power of gravity, as the height of the plane is to the length of it.—For, ſuppoſe the plane AB (fig. 41.) to be parallel to the horizon, the cylinder C will keep at reſt upon any part of the plane on which it is laid. If the plane be ſo elevated as in fig. 42. that its perpendicular height D be equal to one half of its length AB, then the cylinder will roll down with half its weight; for it would require a power (acting in the direction AB) equal to half its weight to keep it from rolling. If the plane be elevated ſo as to be perpendicular to the horizon, as in fig. 43. the cylinder C will deſcend with its whole force of gravity, becauſe the plane contributes nothing to the ſupport or hinderance of it; for which reaſon, it muſt require a power equal to the whole force of its gravity to keep it from deſcending.

If, as in fig. 44. the cylinder C be made to turn upon ſlender pivots in the frame D, which is furniſhed with a hook, with a line G faſtened to it; if this line go over the fixed pulley H, and have its other end tied to the hook in the weight I; if the weight of the body I be to the weight of the cylinder C, added to that of its frame D, as the perpendicular height of the plane LM is to its length AB; the weight will juſt ſupport the cylinder, and a ſmall force will make it either aſcend or deſcend. In the time that the cylinder moves from A to B, it muſt riſe through the whole height of the plane ML, and the weight will deſcend from H to K, through a ſpace equal to the whole length of the plane AB. If the plane be now made to move upon rollers or wheels as in fig. 45. and the cylinder be ſupported upon it, the ſame power will draw the cylinder up the plane, provided the pivots of the wheels be ſmall, and the wheels themſelves pretty large. For let the machine ABC, equal in height and length to ABM, fig. 44. be furniſhed with four wheels, of which two are ſeen at D and E, the third being under C, while the fourth is concealed by the board *a*. Let the cylinder F be laid upon the lower end of the inclined plane CB, and the line G be extended from the frame of the cylinder about ſix feet, parallel to the plane CB, and fixed in that direction to a hook in the wall, which will keep the cylinder from rolling off the plane. Let one end of the line H be tied to a hook at C in the machine, and the other to a weight K, the ſame which drew the cylinder up the plane before. If this line be put over the fixed pulley I, the weight K will draw the machine along the horizontal plane L, and under the cylinder F; and when the machine has been drawn the whole length CB, the cylinder will be raiſed to *d*, equal to the perpendicular height AB above the horizontal part at A.

28
Reaſon of the effects of the inclined plane.

The inclined plane, conſidered as a mechanical power, may eaſily be reduced to the lever; for the power acquired by it is always in the proportion of the length to the height, in the ſame manner as the power acquired by a lever is in the proportion of the long arm to the ſhort one. To compute, or ſhow the reaſon of the power of an inclined plane, therefore, we have only to conſtruct a lever, the long arm of which is equal to the length of the plane, and the ſhort arm to the height of it; then, whatever weight put upon the long arm counterpoiſes another put upon the ſhort one, will alſo keep the ſame weight from rolling down the inclined plane.

To the inclined plane belong alſo the wedge, and all cutting inſtruments which act as wedges, as knives, hatchets, &c. From the theory of the inclined plane alſo combined with that of falling bodies, we deduce ſome of the moſt remarkable properties of the pendulum. See PENDULUM.

§ 5. *Of the Wedge.*

Plate CCLXXXV.

This may be conſidered as two equally inclined planes DEF and CEF, fig. 46. joined together at their baſes e EFO: DC is the whole thickneſs of the wedge at its back ABCD, where the power is applied; EF is the depth or height of the wedge; DF the length of one of its ſides, equal to CF the length of the other ſide; and OF is its ſharp edge, which is entered into the wood or other matter to be ſplit, by the force of a hammer or mallet ſtriking perpendicularly upon its back. Thus, AB fig. 47. is a wedge driven into the cleft CED of the wood FG.

When the wood does not cleave at any diſtance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the reſiſtance of the wood acting againſt the two ſides of the wedge: if the power be to the reſiſtance as half the thickneſs of the wedge at its back is to either of its ſides, and if the power be increaſed ſo as to overcome the friction of the wedge, and the reſiſtance ariſing from the coheſion of the wood, the wedge will be driven in, and the wood ſplit. But when the wood ſplits, as it commonly does, before the wedge, the power impelling the latter will not be to the reſiſtance of the wood as half the thickneſs of the wedge is to one of its ſides, but as half its thickneſs is to the length of the other ſide of the cleft, eſtimated from the top or acting part of the wedge; for if we ſuppoſe the wedge to be lengthened down to the bottom of the cleft at E, the ſame proportion will hold; namely, that the power will be to the reſiſtance, as half the thickneſs of the wedge is to the length of either of its ſides; or, which is the ſame thing, as the whole thickneſs of the wedge is to the length of both its ſides.

To prove this, let us ſuppoſe the wedge is divided lengthwiſe into two equal parts; in which caſe, it will become two equally inclined planes, one of which, as *abc* fig. 48. may be made uſe of for ſeparating the moulding *cd* from the wainſcot AB. It is evident, that when this half wedge has been driven its whole length *ac* between the wainſcot and mouldings, its inſide *ac* will

be

be at *cd*, and the moulding will be ſeparated to *fg* from the wainſcot. But, from what has been already ſhown concerning the inclined plane, it appears, that, to have an equilibrium between the power impelling the half wedge and the reſiſtance of the moulding, the former muſt be to the latter as *ab* to *ac*, that is, as the thickneſs of the back which receives the ſtroke is to the length of the ſide againſt which the moulding acts. Since, therefore, the power upon the half wedge is to the reſiſtance againſt its ſide as the half back *ab* is to the whole ſide *ac*, it is plain that the power upon the whole wedge, where the whole thickneſs is double the half-back, muſt be to the reſiſtance of both its ſides as the thickneſs of the whole back is to the length of both ſides of the cleft, when the wood ſplits at any diſtance before the wedge: For when the wedge is driven quite into the wood, and the latter ſplits at ever ſo ſmall a diſtance before it, the top of the wedge then becomes the acting part, becauſe the wood does not touch it any where elſe. And ſince the bottom of the cleft muſt be conſidered as the place where the whole reſiſtance is accumulated, it is plain from the nature of the lever, that the farther the power is from the reſiſtance, the greater advantage it acts with.

29
Reaſon of the effects of the wedge.

Some have ſuppoſed, that the power of the wedge was in the proportion of the thickneſs of it to the length of one of its ſides; but from what has already been advanced, it is plain that this cannot be the caſe. The wedge, as has already been ſhown, is compoſed of two inclined planes, each of which has a perpendicular height of only one half the thickneſs of the wedge. As the power of the inclined plane therefore is always as the length to its perpendicular height, it is evident that the power of each of theſe inclined planes of which the wedge is compoſed muſt be as the length of one ſide to half the thickneſs; and conſequently the power of both muſt be as the length of both ſides is to the whole thickneſs.

The power of the wedge is exceedingly great, inſomuch that not only wood but rocks may be ſplit by it, which could ſcarce be done by any of the other powers: but in this it is aſſiſted by percuſſion of the hammer which drives it, and ſhatters the ſtone in a manner that could ſcarcely be done by any ſimple preſſure.—Wedges as well as pulleys have alſo been uſed as inſtruments of torture.

§ 6. *Of the Screw.*

THIS is the ſtrongeſt of all the mechanical powers, though it cannot be accounted a ſimple one, as no ſcrew can be made uſe of without a lever or winch to aſſiſt in turning it. We may ſuppoſe it made by cutting a piece of paper into the form of an inclined plane or half wedge, and then wrapping it round a cylinder, as in fig. 49. From this figure it is evident, that the winch which turns the cylinder muſt move once round in the time that the paper deſcribes one ſpiral; and conſequently if any weight or greater power of reſiſtance were applied, the winch muſt turn once round in the time that the weight would move from one ſpiral thread to another, from d to e for inſtance. Hence the force of the ſcrew will be as the circumference of the circle defined, by the lever or winch by which it is turned, is to the diſtance between the threads of the ſcrew itſelf. Thus, ſuppoſing the diſtance of the threads to be half an inch, and the length of the winch twelve inches, the circle deſcribed by the extremity of it where the power acts will be nearly 76 inches, or about 152 times the diſtance between the threads; whence a ſingle pound acting at the end of ſuch a winch would balance 152 at the extremity of the ſcrew; and as much more as can overcome the friction would turn the winch and raiſe up the weight.

30
Machine for exhibiting the force of the ſcrew.

Fig. 50. repreſents a machine for exhibiting the force of the ſcrew. Let the wheel C have upon its axis a ſcrew *ab*, working in the teeth of the wheel D, which ſuppoſe to be 48 in number. It is plain that every time the ſcrew *ab* and wheel C are turned round by the winch A, the wheel D will be moved one tooth by the ſcrew; and therefore in 48 revolutions of the winch, the wheel D will be turned once round. If then the circumference of a circle deſcribed by the handle of the winch A be equal to the circumference of a groove *e* round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Conſequently if the line G goes round the groove *e*, and has a weight of 48 pounds hung to it below the pedeſtal EF, a power of one pound at the handle will balance that weight. If the line G goes round the axle I inſtead of the groove of the wheel D, the force of the machine will be as much increaſed as the circumference of the groove *e* is greater than that of the axle; which, ſuppoſing to be ſix times, then one pound at H will balance 288 pounds ſuſpended by the line at the axle.

31
Mr Hunter's improvement on the ſcrew.

The ſcrew is of very extenſive uſe in mechanics, its great power rendering it more eligible for compreſſing bodies together than any of the reſt, and the great diſparity betwixt the velocity of the handle and that of the threads of the ſcrew, rendering it proper for dividing ſpace into an almoſt infinite number of parts. Hence, in the conſtruction of many mathematical inſtruments, ſuch as teleſcopes, where it is neceſſary to adjuſt the focus to the eyes of different people, the ſcrew is always made uſe of in order to move the eyeglaſs a very little nearer or farther away from the object glaſs. In the 71ſt volume of the Philoſophical Tranſactions, a new method of applying the ſcrew, ſo as to make it act with the greateſt accuracy, is deſcribed by Mr Hunter ſurgeon. The following are the general principles upon which this method depends.

1. That the ſtrength of the ſeveral parts of the engine be adjuſted in ſuch a manner to the force they are intended to exert, that they ſhall not break under the weight they ought to counteract, nor yet encumber the motion by a greater quantity of matter than is neceſſary to give them a proper degree of ſtrength.

2. That the increaſe of power by means of the machine be ſo regulated, that while the force we can exert is thereby rendered adequate to the effect, it may not be retarded in procuring it more than is abſolutely neceſſary.

3. That the machine be as ſimple as is conſiſtent with other conditions.

4. It ought to be as portable, and as little troubleſome as poſſible in the application.

5. The moving power muſt be applied in ſuch a manner as to act to the greateſt advantage; and that the

the motion ultimately produced may have that direction and velocity which is moſt adapted to the execution of the ultimate deſign of the machine.

6. Of two machines, equal in other reſpects, that deſerves the preference in which the friction leaſt diminiſhes the effect propoſed by the whole.

To attain all theſe advantages in any machine is perhaps impoſſible; but in the application of the ſcrew, the following method promiſes to be attended with ſeveral of them.

Let AB (fig. 51.) be a plate of metal, in which the ſcrew C D plays, having a certain number of threads in an inch, ſuppoſe 10. Within the ſcrew CD there is a female ſcrew*, which receives the ſmaller ſcrew DE of 11 threads in an inch. This ſcrew is kept from moving about with the former by means of the apparatus at A F G B. But if the handle C K L be turned ten times round the ſcrew, C D will advance an inch upwards; and if we ſuppoſe the ſcrew D E to move round along with C D, the point E will advance an inch. If we now turn the ſcrew D E ten times backward, the point E will move downwards $\frac{10}{11}$ths of an inch, and the reſult of both motions will be to lift the point E $\frac{1}{11}$th of an inch upwards. But if, while the ſcrew C D is turned ten times round, D E be kept from moving, the effect will be the ſame as if it had moved ten times round with C D, and been ten times turned back; that is, it will advance $\frac{1}{11}$ of an inch. At one turn, therefore, it will advance upwards $\frac{1}{11}\times\frac{1}{10}=\frac{1}{110}$ of an inch. If now the handle be ſix inches long, the power to produce an equilibrium muſt be to the weight as 1 to 110×6.2832×6=4146.912. Thus the force of Mr Hunter's ſcrew is greatly ſuperior to that of the common one; for in order to have as great a power on the plan of the latter, it muſt have 110 threads in an inch, which would render it too weak to reſiſt any conſiderable violence.

With regard to the ſecond general maxim above laid down, Mr Hunter conſiders both kinds of ſcrews as equally applicable, only that the more complicated ſtructure, and conſequently greater expence of his ſcrew, renders it convenient to uſe the common ſcrew where only a ſmall increaſe of power is neceſſary, and his improved one where a great power is wanted. By ſhortening the handle alſo, the whole machine is rendered more portable and leſs troubleſome in the uſing.

To anſwer the fifth intention, both ſeem to be equally proper; but for the ſixth, the preference muſt be given to ſuch as beſt anſwer the particular purpoſe propoſed. Thus if the ſcrew DE be deſigned to carry an index which muſt turn round at the ſame time that it riſes upward, the common ſcrew is preferable; though our author alſo propoſes a method by which his ſcrew may anſwer the ſame purpoſe: With this view a ſtill ſmaller ſcrew ought to play within the ſcrew D E, and be connected with the ſcrew C D, ſo as to move round along with it. It muſt have, according to the foregoing proportions, 111 threads in an inch; and they muſt lie in a contrary direction to thoſe of C D; ſo that when they are both turned together, and C D moves upwards, this other may move downwards. At one turn this will move upwards $\frac{1}{12210}$th part of an inch, and at the ſame time will move in a circular direction; but the accuracy required in conſtructing ſuch ſcrews, even though made with fewer threads than thoſe juſt mentioned, would probably be too great for practice. In many caſes, however, ſcrews upon Mr Hunter's principles may be of conſiderable uſe.

32
Theory of the ſcrew.

The theory of the ſcrew is eaſily deduced from that of the inclined plane and lever; for the threads of the ſcrew in fact form a continued inclined plane, the height of which is the diſtance betwixt the two threads, and the length is the circumference of the cylinder. Hence, without any lever, the ſcrew would have a conſiderable power, were it not for the great friction of the parts upon one another; and this friction would be much more increaſed by the perpendicular action of a weight on the top of the cylinder than by the horizontal action of a lever.

§ 7. *Other methods of accumulating power, which do not properly come under the denomination of any of the mechanical powers already deſcribed.*

From the account already given of the ſix mechanical powers, it is evident, that they can do no more than accumulate, or, if we may uſe the expreſſion, *compreſs*, any degree of velocity into a ſmall ſpace. The velocity thus compreſſed, becomes what we call *power*, and is capable of again impreſſing the original degree of velocity upon a body of an equal or nearly equal ſize to the firſt which originally impreſſed it; but in every caſe the abſolute quantity of motion, or of power, remains the ſame without a poſſibility of augmentation or diminution by levers, ſcrews, pulleys, or wedges. It follows, therefore, that if by any method we can preſerve for a certain time a ſmall quantity of motion, that will at the end of the time ſpecified amount to an aſtoniſhing power, which we could ſcarce at firſt have imagined to proceed from ſo ſmall a cauſe. Thus, though a man cannot raiſe a ton weight from the ground at once, he is eaſily capable of raiſing 100 pounds at once from the ground, and this for a conſiderable number of times in ſucceſſion. It is plain, therefore, that in a very ſhort time a man could in this manner raiſe the ton weight, if it were divided into 20 parts, as effectually as by a lever or other machine; though the fatigue conſequent upon ſtooping down and raiſing up his body ſo often would no doubt make the toil much greater. Even by means of a lever, however, before a man could raiſe a ton weight one foot from the ground, with the trouble of exerting a force equal to 100 pounds, he muſt have a lever 20 or 21 feet in length; and exert a conſtant force of 100 pounds, while he goes up through a ſpace of 20 feet, or pulls down a rope through that ſpace. The lever, therefore, only accumulates the power exerted in pulling or carrying the weight of 100 pounds through 20 feet, and diſcharges it all upon the ſpace of one foot; whence it is plain, that any other thing which could do this would raiſe the ton weight as effectually as the lever.

One method of accumulating a great power is by ſuſpending a very heavy body by a chain or ſtrong rope of conſiderable length. This body may be put in motion by a very ſmall degree of power more than is requiſite for bending the rope, and will acquire a vibratory motion like a pendulum; by continuing the impulſe as the body returns, it will continually acquire greater and greater force, the arches through which

it

---

* See the rticle *crew.*

it moves becoming continually larger, until at laſt it might be made to overcome almoſt any obſtacle: and upon this principle the battering rams of old were conſtructed, the power of which has been already mentioned; nevertheleſs the power of one ſtroke of this engine never could exceed the accumulated power of the impulſes given to it in order to produce that ſtroke, or even quite equal it, becauſe the ſtiffneſs of the rope, and the reſiſtance of the air, muſt always take off ſomething from it.

Another method of accumulating force is by means of a very heavy wheel or cylinder, moveable about an axis. A ſmall force will be ſufficient to put this wheel in motion; and, if long continued, will accumulate in ſuch a manner as to produce ſuch effects in raiſing weights and overcoming reſiſtances, as could not by any means be accompliſhed by the application of the original moving force. On this ſubject Mr Atwood has demonſtrated, that a force of 20 pounds applied for 37 ſeconds to the circumference of a cylinder of 10 feet radius, and weighing 4713 pounds, would, at the diſtance of one foot from the centre, give an impulſe to a muſket-ball equivalent to what it receives from a full charge of gun-powder. The ſame effect would be produced in ſix minutes and ten ſeconds by a man turning the cylinder with a winch one foot long, in which he conſtantly exerted a force of 20 pounds. In this caſe, however, as well as the former, there is not any abſolute accumulation of power; for the cylinder has no principle of motion in itſelf, and cannot have more than it receives.

33
Of the uſe of flies in various machines.

This accumulation of motion, however, in heavy wheels, is of great ſervice in the conſtruction of machines for various purpoſes, rendering them greatly more powerful and eaſy to be worked by animals, as well as more regular and ſteady, when ſet in motion by water, or any inanimate power. Hence the uſe of flys, ballaſt-wheels, &c. which are commonly ſuppoſed to increaſe the power of a machine, though in reality they take ſomething from it, and act upon a quite different principle.—In all machines in which flys are uſed, a conſiderably greater force muſt at firſt be applied than what is neceſſary to move the machine without it, or the fly muſt have been ſet in motion ſome time before it is applied to the machine. It is this ſuperfluous power which is collected by the fly, and ſerves as a kind of reſervoir from which the machine may be ſupplied when the animal ſlackens his efforts. This, we muſt obſerve, will always be the caſe with animals, for none are able to exert a great power with abſolute conſtancy; ſome intervals of reſt, even though almoſt imperceptible, are requiſite, otherwiſe the creature's ſtrength would in a ſhort time be entirely exhauſted. When he begins to move the machine he is vigorous, and exerts a great power; in conſequence of which he overcomes not only the reſiſtance of the machine itſelf, but communicates a conſiderable degree of power to the fly. The machine, when moving, yields for a time to a ſmaller impulſe; during which time the fly itſelf acts as a moving power, and the animal recovers the ſtrength he had loſt. By degrees, however, the motion of the machine decreaſes, and the animal is obliged to renew his efforts. The velocity of the machine would now be conſiderably increaſed, were it not that the fly now acts as a reſiſting power, and the greateſt part of the ſuperfluous motion is lodged in it, ſo that the increaſe of velocity in the machine is ſcarcely perceptible. Thus the animal has time to reſt himſelf until the machine again requires an increaſed impulſe, and ſo on alternately.—The caſe is the ſame with a machine moved by water, or by a weight; for tho' the ſtrength of theſe does not exhauſt itſelf like that of an animal, yet the yielding of the parts of the machine renders the impulſe much leſs after it begins to move: hence its velocity is accelerated for ſome time, until the impulſe becomes ſo ſmall that the machine requires an increaſe of power to keep up the neceſſary motion. Hence the machine ſlackens its pace, the water meets with more reſiſtance, and of conſequence exerts its power more fully, and the machine recovers its velocity. But when a fly is added to the other parts, this acts firſt as a power of reſiſtance, ſo that the machine cannot acquire the velocity it would otherwiſe do. When it next begins to yield to the preſſure of the water, and the impulſe of courſe to ſlacken, the fly communicates part of its motion to the other parts; ſo that if the machine be well made, there is very little difference in the velocity perceptible.—The truth of what is here advanced will eaſily be ſeen, from conſidering the inequality of motion in a clock when the pendulum is off, and how very regularly it goes when regulated by the pendulum, which here act as a fly.

34
Of the weight of flies.

Flies are particularly uſeful in any kind of work which is done by alternate ſtrokes, as the lifting of large peſtles, pumping of water, &c. In this caſe the weight of the wheel employed is a principal object; and the method of calculating this is to compare it with the weight to be raiſed at each ſtroke of the machine. Thus, ſuppoſe it required to raiſe a peſtle 30 pounds weight to the height of one foot 60 times in a minute: Let the diameter of the fly be ſeven feet, and ſuppoſe the peſtle to be lifted once at every revolution of the fly; we muſt then conſider what weight paſſing through 22 feet in a ſecond will be equivalent to 30 pounds moving through one foot in a ſecond. This will be $30 \div 22$ or $1\frac{4}{11}$ pounds. Were a fly of this kind to be applied, therefore, and the machine ſet a going, the fly would juſt be able to lift the peſtle once after the moving power was withdrawn; but by increaſing the weight of the fly to 10, 12, or 20 pounds, the machine when left to itſelf would make a conſiderable number of ſtrokes, and be worked with much leſs labour than if no fly had been uſed, though no doubt at the firſt it would be found a conſiderable incumbrance to the motion. This is equally applicable to the action of pumps; but the weight which can be moſt advantageouſly given to a fly has never yet been determined by mechanics. It is certain, however, that the fly does not communicate any abſolute increaſe of power to the machine; for if a man or other animal is not able to ſet any mechanical engine in motion without a fly, he will not be able to do it though a fly be applied, nor will he be able to keep it in motion though ſet a-going with a fly by means of a greater power. This may ſeem to be contradicted by the example of a common clock; for if the pendulum be once ſtopped, the weight is not able to ſet it in motion again, though it will keep it going when once put in motion by an external power. This, however, depends

depends not upon any inſufficiency of the weight, but on the particular mechaniſm of the crown wheel; which is ſuch, that when once the pendulum is ſtopped, it would require a much greater weight than that commonly applied to ſet it in motion; and if the uſual weight was to act fairly, it would be more than ſufficient to move all the machinery, and make the pendulum vibrate alſo with much greater force than it does.

§ 8. *Of Friction.*

The doctrine of friction, according to Mr Ferguſon, may be ſummed up in the following manner: 1. When one body inſiſts on another upon a horizontal plane, it preſſes it with its whole weight; which being equally reacted on, and conſequently the whole effect of its gravity deſtroyed by the plane, it will be abſolutely free to move in any horizontal direction by any the leaſt power applied thereto, provided both the touching ſurfaces be perfectly ſmooth. 2. But ſince we find no ſuch thing as perfect ſmoothneſs in the ſurfaces of bodies, but an evident roughneſs or unevenneſs of the parts in their ſurface, ariſing from their poroſity and peculiar texture, it is eaſy to underſtand, that, when two ſuch ſurfaces come together, the prominent parts of one will in ſome meaſure fall into the concave parts of the other; and therefore, when an horizontal motion is attempted in one, the fixed prominent parts of the other will give more or leſs reſiſtance to the moving ſurface, by holding and detaining its parts; and this is what we call *friction*. 3. Now ſince any body will require a force proportional to its weight to draw it over a given obſtacle, it follows, that the friction ariſing to the moving body will always be in proportion to its weight only, and not the quantity of the ſurface by which it bears upon the reſiſting plane or ſurface. Thus, if a piece of wood four inches wide and one thick be laid upon another fixed piece of the ſame wood, it will require the ſame weight to draw it along, whether it be laid on its broad or narrow ſide. 4. For though there be four times the number of touching particles on the broad ſide *(cæteris paribus)*, yet each particle is preſſed with but $\frac{1}{4}$th of the weight that thoſe are on the narrow ſide; and ſince four times the number, multiplied by $\frac{1}{4}$th of the weight, is equal to $\frac{1}{4}$th of the number multiplied by four times the weight, it is plain the reſiſtance is equal in both caſes, and ſo requires the ſame force to overcome it. 5. The reaſon why friction is proportional to the weight of the moving body is, becauſe the power applied to move the body muſt raiſe it over the prominent parts of the ſurface on which it is drawn; and this motion of the body, as it is not upright, ſo it will not require a power equal to its whole weight; but being in the nature of the motion on an inclined plane, it will require only a part of its own weight, which will vary with the various degrees of ſmoothneſs and aſperity. 6. It is found by experiment, that a body will be drawn along by nearly $\frac{1}{3}$d of its weight; and if the ſurfaces be hard and well poliſhed, by leſs than a third part; whereas if the parts be ſoft or ragged, it will require a much greater weight. Thus alſo the cylinder of wood AB, if very ſmooth, and laid on two well poliſhed ſupporters CD (having been firſt oiled or greaſed), and then charged with the weight of two pounds in the two equal balls GH, it will require an additional weight *x*, equal to about a third part of the two pounds, to give motion to or overcome the friction of the ſaid cylinder. 7. Now this additional weight, as it cauſes a greater weight of the cylinder, will likewiſe increaſe the friction; and therefore require the addition of another weight *y*, equal to the third part of its own weight; for the ſame reaſon, the weight *y* will require another *z*, a third part leſs; and ſo on *ad infinitum*. Hence, ſuppoſing the friction to be preciſely a third of the weight, the firſt weight with all the additional ones, *viz.* 2, $\frac{2}{3}$, $\frac{2}{9}$, $\frac{2}{27}$, &c. will be a ſeries of numbers in geometrical progreſſion decreaſing. Now the ſum of all theſe terms, except the firſt, is found, by a well-known theorem in arithmetic, to be equal to one pound. So that if the weight of the cylinder be inconſiderable, the readieſt way to overcome the friction would be to double the power G, or H, at once. 8. But though we may, at a medium, allow a third part of the weight with which any ſimple machine is charged for the friction ariſing from thence, yet this is very precarious, and ſeldom is the caſe: for if ABCD be a piece of braſs of ſix ounces, and EFGH be alſo a plate of braſs, and both the ſurfaces well ground and poliſhed, the weight P of near two ounces will be required to draw along the body AC alone; but if AC be loaded with 6, 8, or 10lb. then a ſixth part of the weight will be ſufficient to draw it along the plane. On the other hand, if the plane be covered with a linen or woollen cloth, then a third or half part, and ſometimes more, will be requiſite to draw it along on the plane. 9. Yet notwithſtanding the difficulty and uncertainty attending the eſtimation of the quantity of friction, it is ſtill a moſt uſeful and neceſſary inquiry, how and by what means the friction of any machine may be diminiſhed? In order to this, we muſt conſider friction mechanically, or as a force acting againſt a power applied to overcome it. Thus ſuppoſe AB an upright ſtem or ſhaft, turning freely in the ſocket B fixed in the table or plane IKLM; and AC, DE, two arms fixed in the ſaid ſhaft, the latter of which, DE, has three pins going into a ſocket in the middle of heavy weights, F, G, or H, in ſuch a manner, that when a power applied at C moves the lever AC, it cauſes the lever DE to protrude or thruſt along the weights at F, G, or H, in a circular manner upon the table. 10. Now ſince we ſuppoſe the weight, all the while it is in motion, is freely and wholly ſupported by the plane, it follows, that all the reſiſtance it can give to the power applied to C, is only what ariſes from its friction on the plane. What this friction is, will be found by applying the weight at G, ſo that BG be equal to AC; for then the power applied to C, acting in a tangent to the circle CRS, that ſhall juſt move the weight G, will be equal to its friction. But if the weight be applied at F, becauſe BF is greater than AC, the ſame power at C, as before, will not move it, by reaſon its force is here increaſed, by having a greater velocity than the power; as, on the other hand, if placed at H, a leſs power at C ſhall move it, becauſe of its having there leſs velocity than the power, as is evident from the properties of the lever. 11. Hence we underſtand, that though the

54.

Fig. 55.

Fig. 56.

weight of a machine remains the ſame; yet the friction may be diminiſhed, by contriving that the parts on which it moves and rubs ſhall have leſs velocity than the power which moves it: thus, if the cylinder AB (fig. 54.) were to move on the two ſmall pins or gudgeons E, F, the friction would be abated in the proportion of the diameter of the cylinder to that of the pins. 12. The friction on theſe gudgeons is ſtill farther diminiſhed by cauſing them to move on the circumference of a wheel: thus, let F be the gudgeon of the cylinder, revolving on the wheel CDE (fig. 57.), the velocity of the wheel's circumference will be the ſame with that of the gudgeon; but the velocity of the wheel's axis AB (which is now to be conſidered as the rubbing part) is leſs than that of the wheel, in proportion as its diameter is leſs than that of the wheel: for example, if the friction of the cylinder moving on its ſurface be $_{3}$d part of the weight, and the gudgeon be to the cylinder as 1 : 10, they will reduce the friction to $\frac{1}{30}$th part; and if, again, the axis of the wheel be to the wheel as 1 : 10, the wheel will reduce the friction to $\frac{1}{300}$th part; and if the axis of this wheel be laid on the perimeter of another wheel, the friction will be reduced to a ſtill leſſer part of the weight; ſo that you may proceed in this manner to diminiſh the friction *ad infinitum;* and wheels applied in this manner are called *friction-wheels.* 13. Beſides what has been already ſaid, ſomewhat farther is neceſſary to diminiſh the friction of wheel-carriages. It was before obſerved, that friction aroſe chiefly by lifting the body over the prominent parts of the plane on which it is moved: now if we can contrive to move the body along without lifting or ſuſtaining its weight, we ſhall move it without much friction; and this may be done by laying the body on any moveable circular ſubject, as rollers, wheels, &c.: becauſe the aſperities of its ſurface will lay hold on thoſe of the roller, and move it likewiſe; and it is as evident, that when the body is drawn againſt the prominent parts of the roller, they immediately give way, and make no reſiſtance. By this circular motion of the roller, its prominent parts below do only deſcend and move upon or over, and are not drawn againſt, the fixed prominent parts of the plane, and ſo receive no reſiſtance from them. Hence the body is conveyed along without being lifted up, in the ſame manner as a wheel is moved by a pinion without any conſiderable reſiſtance.

SECT. III. *Of the Combinations of the Mechanical Powers.*

FROM what has been already laid down concerning the mechanical powers in particular, we have ſeen that none of them is capable of augmenting the abſolute force of any acting ſubſtance; and from thence we may juſtly conclude, that no combination of them can do ſo. In fact, theſe combinations are very often detrimental, and occaſion a great loſs of power by friction. This is the great obſtacle in mechanics, and muſt always be greater in complex than in ſimple machines; and therefore the latter are always to be preferred, excepting where conveniency requires ſome degree of complication. The lever being the ſimpleſt machine, and that attended with leaſt friction, is always to be uſed where it is requiſite to raiſe weights for a ſmall way. It may likewiſe be uſed with propriety where bodies are to undergo a long continued degree of preſſure, and where they yield but little. For this purpoſe the lever ought to be of the ſecond kind, repreſented fig. 28. where one end being fixed at A, a weight may be put upon the other extremity B, and the body to be preſſed put at 1, 2, or any of the intermediate diviſions, according to the degree of preſſure it is deſigned to undergo. This has the advantage of giving a long and very equable preſſure, and is a very advantageous method of preſſing cheeſe or other things which do not require a very great exertion of force. Where this is requiſite we muſt employ wedges or ſcrews; but both theſe have the diſadvantage of ſlackening their preſſure on the leaſt yielding of the materials to be preſſed. Wedges therefore require to be almoſt conſtantly driven, and ſcrews to be turned by a lever, in order to produce a conſtant preſſure. In oil mills the preſſure is produced by wedges, which are conſtantly driven by great mallets lifted up by the force of the mill. Oil of ſweet almonds is made by apothecaries in a preſs driven by a ſcrew, and turned by a long lever aſſiſted by a capſten.

Plate CCLXXXIII.

Where it is neceſſary to have a conſiderable weight raiſed to ſome height, the pulley is the moſt uſeful power, but the friction is extremely great; the axis in peritrochio combined with a ſingle pulley will anſwer the purpoſe extremely well, and with leſs friction than any machine compoſed of pulleys alone. The machines called *cranes* are generally combinations of theſe two; and are very much uſed, eſpecially by the commercial people, for raiſing goods out of ſhips, drawing them up into warehouſes, and for lowering them down. In theſe operations we muſt obſerve, that lowering goods is much more dangerous than raiſing them, on account of the vaſt increaſe of velocity which bodies acquire every moment by the power of gravity. In the conſtruction of cranes, therefore, it is abſolutely neceſſary to attend to this circumſtance, and to guard againſt accidents. The following are recommended by Mr Ferguſon: Fig. 52. ſhows one crane well calculated for the purpoſes juſt mentioned. When the rope H is hooked to the weight K, a man turns the winch A, on the axis whereof is the trundle B, which turns the wheel C, on whoſe axis D is the trundle E, which turns the wheel F with its upright axis G, on which the great rope HH winds as the wheel turns; and going over a pulley I, at the end of the arm *d* of the gib *ccde*, it draws up the heavy burden K; which being raiſed to a proper height, as from a ſhip to the quay, is then brought over the quay by pulling the wheel Z round by the handles *z*, *z*, which turns the gib by means of the half wheel *b* fixed on the gib-poſt *cc*, and the ſtrong pinion *a* fixed on the axis of the wheel Z. This wheel gives the man that turns it an abſolute command over the gib, ſo as to prevent it from taking any unlucky ſwing, ſuch as often happens when it is only guided by a rope tied to its arm *d;* and people are frequently hurt, ſometimes killed, by ſuch accidents.

35
Beſt method of conſtructing cranes.

Plate CCLXXXV.

The great rope goes between two upright rollers *i* and *k*, which turn upon gudgeons in the fixed beams *f* and *g;* and as the gib is turned towards either ſide, the rope bends upon the roller next that ſide. Were it not for theſe rollers, the gib would be quite unmanageable; for the moment it were turned ever ſo little towards any ſide, the weight K would begin to deſcend, becauſe the rope would be ſhortened between the pulley I and axis G; and ſo the gib would be pulled violently to that ſide, and either be broken to pieces or break every thing that came in its way. Theſe rollers muſt be placed ſo that the ſides of them round which the rope bends may keep the middle of the bended part directly even with the centre of the hole in which the upper gudgeon of the gib turns in the beam *f*. The truer theſe rollers are placed, the eaſier the gib is managed, and the leſs apt to ſwing either way by the force of the weight K.

A ratchet-wheel Q is fixed upon the axis D, near the trundle E; and into this wheel falls the catch or click R. This hinders the machine from running back by the weight of the burden K, if the man who raiſes it ſhould happen to be careleſs, and to leave off working at the winch A ſooner than he ought to do.

When the burden K is raiſed to its proper height from the ſhip, and brought over the quay by turning the gib about, it is let down gently upon the quay, or into a cart ſtanding thereon, in the following manner: A man takes hold of the rope *tt* (which goes over the pulley *v*, and is tied to a hook at S in the catch R), and ſo diſengages the catch from the ratchet-wheel Q; and then, the man at the winch A turns it backward, and lets down the weight K. But if the weight pulls too hard againſt this man, another lays hold of the handle V, and by pulling it downward draws the gripe U cloſe to the wheel Y, which by rubbing hard againſt the gripe hinders the too quick deſcent of the weight; and not only ſo, but even ſtops it at any time if required. By this means, heavy goods may be either raiſed or let down at pleaſure, without any danger of hurting the men who work the engine.

When part of the goods are craned up, and the rope is to be let down for more, the catch R is firſt diſengaged from the ratchet-wheel Q, by pulling the cord *t*; then the handle *q* is turned half round backward, which, by the crank *n n* in the piece *o*, pulls down the frame *h* between the guides *m* and *m* (in which it ſlides in a groove), and ſo diſengages the trundle B from the wheel C: and then the heavy hook β at the end of the rope H deſcends by its own weight, and turns back the great wheel F with its trundle E and the wheel C; and this laſt wheel acts like a fly againſt the wheel F and hook β, and ſo hinders it from going down too quick; whilſt the weight X keeps up the gripe U from rubbing againſt the wheel Y, by means of a cord going from the weight over the pulley *w* to the hook W in the gripe; ſo that the gripe never touches the wheel unleſs it be pulled down by the handle V.

When the crane is to be ſet at work again for drawing up another burden, the handle *q* is turned half round forwards; which, by the crank *nn*, raiſes up the frame *h*, and cauſes the trundle B to lay hold of the wheel C; and then, by turning the winch A, the burden of goods K is drawn up as before.

The crank *nn* turns pretty ſtiff in the mortiſe near *c*, and ſtops againſt the farther end of it when it has got juſt a little beyond the perpendicular; ſo that it can never come back of itſelf: and therefore the trundle B can never come away from the wheel C until the handle *q* be turned half round.

The great rope runs upon rollers *pp* in the lever LM, which keep it from bending between the axle at G and the pulley I. This lever turns upon the axis N by means of the weight O, which is juſt ſufficient to keep its end L up to the rope; ſo that, as the great axle turns, and the rope coils round it, the lever riſes with the rope, and prevents the coilings from going over one another.

The power of this crane may be eſtimated thus: Suppoſe the trundle B to have 13 ſtaves or rounds, and the wheel C to have 78 ſpur-cogs; the trundle E to have 14 ſtaves, and the wheel F 56 cogs: then, by multiplying the ſtaves of the trundles, 13 and 14, into one another, their product will be 182; and by multiplying the cogs of the wheels, 78 and 6, into one another, their product will be 4368; and dividing 4368 by 182, the quotient will be 24: which ſhows that the winch A makes 24 turns for one urn of the wheel F and its axle G, on which the great rope or chain HIH winds. So that if the length or radius of the winch A were only equal to half the diameter of the great axle G, added to half the thickneſs of the rope H, the power of the crane would be as 24 to 1: but the radius of the winch being double the above length, it doubles the ſaid power, and ſo makes it as 48 to 1: in which caſe, a man may raiſe 48 times as much weight by this engine as he could do by his natural ſtrength without it, making proper allowance for the friction of the working parts. Two men may work at once, by having another winch on the oppoſite end of the axis of the trundle under B, and ſo make the power ſtill double.

If this power be thought greater than what may be generally wanted, the wheels may be made with fewer cogs in proportion to the ſtaves in the trundles; and ſo the power may be of whatever degree is judged to be requiſite. But if the weight be ſo great as will require yet more power to raiſe it (ſuppoſe a double quantity), then the rope H may be put under a moveable pulley, as δ, and the end of it tied to a hook in the gib at ε; which will give a double power to the machine, and ſo raiſe a double weight hooked to the block of the moveable pulley.

When only ſmall burdens are ſo raiſed, this may be quickly done by men puſhing the axle G round by the handſpokes *y*, *y*, *y*, *y*; having firſt diſengaged the trundle B from the wheel C: and then, this wheel will only act as a fly upon the wheel F; and the catch R will prevent its running back, if the men ſhould inadvertently leave off puſhing before the burden be unhooked from β.

Laſtly, when very heavy burdens are to be raiſed, which might endanger the breaking of the cogs in the wheel F; their force againſt theſe cogs may be much abated by men puſhing round the handſpokes *y*, *y*, *y*, *y*, whilſt the man at A turns the winch.

We have only ſhown the working parts of this crane, without the whole of the beams which ſupport them; knowing that theſe are eaſily ſuppoſed, and that if they had been drawn, they would have hid a great deal of the working parts from ſight, and alſo confuſed the figure.

Another very good crane is made in the following manner:

manner: AA (fig. 53) is a great wheel turned by men walking within it at H. On the part C, of its axle BC, the great rope D is wound as the wheel turns; and this rope draws up goods in the ſame way as the rope HH does in the above-mentioned crane, the gib-work here being ſuppoſed to be of the ſame ſort. But theſe cranes are very dangerous to the men in the wheel; for if any of the men ſhould chance to fall, the burden will make the wheel run back and throw them all about within it; which often breaks their limbs, and ſometimes kills them. The late ingenious Mr Padmore of Briſtol (whoſe contrivance the fore-mentioned crane is), obſerving this dangerous conſtruction, contrived a method for remedying it, by putting cogs all around the outſide of the wheel, and applying a trundle E to turn it; which increaſes the power as much as the number of cogs in the wheel is greater than the number of ſtaves in the trundle: and by putting a ratchet-wheel F on the axis of the trundle (as in the above-mentioned crane), with a catch to fall into it, the great wheel is ſtopt from running back by the force of the weight, even if all the men in it ſhould leave off walking. And by one man working at the winch I, or two men at the oppoſite winches when needful, the men in the wheel are much aſſiſted, and much greater weights are raiſed, than could be by men only within the wheel. Mr Padmore put alſo a gripe-wheel G upon the axis of the trundle, which being pinched in the ſame manner as deſcribed in the former crane, heavy burdens may be let down without the leaſt danger. And before this contrivance, the lowering of goods was always attended with the utmoſt danger to the men in the wheel; as every one muſt be ſenſible of who has ſeen ſuch engines at work. And it is ſurpriſing that the maſters of wharfs and cranes ſhould be ſo regardleſs of the limbs, or even lives of their workmen, that, excepting the late Sir James Creed of Greenwich, and ſome gentlemen at Briſtol, there is ſcarce an inſtance of any who has uſed this ſafe contrivance.

36 Another crane.

37 Mr Gottlieb's new crane.

We ſhall deſcribe here four new cranes invented and made by Mr Gottlieb of Hounſditch, London, who communicates them to the public as quite new in their principles, and more ſimple and uſeful than any hitherto contrived. Fig. 59. is a repreſentation of a crane adapted for a large warehouſe, where heavy goods are wanted to be drawn up from a cart or quay. One of this conſtruction has lately been erected in Mr Camden's ſugar-houſe, Old Gravel-Lane, London. Its operation is as follows: The horſe yoked below at A turns the upright axis and the wheel B, which is about 6 feet in diameter; this turns a 3 feet wheel C, having an upright axis D through the floor turning with it, and carrying a 3 feet wheel E with perpendicular cogs. The wheel E turns two pinions F and G, the former of 8 inches in diameter, and the latter of 5 inches diameter, both fixed upon one axis. The pinion G turns a 3 feet wheel H, to which is fixed the barrel I and wheel W. The rope K winds round the barrel, and comes over the ſheiff-wheel L in the upper ſtory, and the pulley M in the gib-head drawing up the goods ſuſpended at the hook N.

Plate CCLXXXVI.

By a mark made upon the rope at I, the man ſuperintending the crane knows when the goods are raiſed enough for landing into the room: he then immediately puſhes aſide the upright piece O, diſengages the lever P from it; and by putting it downwards, the action of the quarter pinion at Q raiſes up the pinion at G, and thereby unconnects it with the wheel H. To prevent the machinery now from running backwards, a ratchet-wheel R is fixed upon the wheel H, into which a click-catch S falls. This effectually prevents the wheels going backwards by the weight at N while the man above is employed in landing the goods. When the goods are brought into the ſtore-room, the hook N is thrown out, and the man below, from the uſual call, runs to the handle U, ſlides the pinion T into the wheel H, then turns back the ratchet-wheel R, and puſhes back the click S, then ſlides back again the pinion T; and the wheel H and barrel I being thus at liberty, the hook N and rope run down by their own gravity, and freſh goods are attached; then again, from the uſual call, the man puſhes up the lever P, fixes it at O, places the click S into the teeth of the ratchet-wheel; and the whole machinery is again in action from the horſe below, that keeps conſtantly going without being ſtopped at every ſhort interval of the landing, ſtoring, &c.

When the goods are to be carted off, and required to be let down only, it is performed without the horſe, and in the following manner: The pinion G is diſengaged from the wheel H by the lever P as before, and the pinion V of the fly-wheel is ſlipped into the teeth of the 2 feet wheel W. The goods being ſuſpended at N, will act by the rope upon the wheel W and pinion V, thereby turning round the fly-wheel X: while the goods are thus deſcending, the man preſſes upon the lever Y, and bears againſt the wheel, making ſuch a reſiſtance as to be ſufficient to allow the goods to deſcend with as gentle a degree of motion as may be neceſſary,

The hook N being taken from the goods, the man goes to the wheel W, and with his hands turns it round, which winds up the cord and hook in readineſs for more goods, and ſo on as before. The pinions T and V in this caſe are ſlipped out of the wheels H and W.

As the horſe at A may likewiſe be uſed to turn other mill-work from a connection made with the main-wheel, and ſuppoſing that the crane is not wanted at the ſame time, it is readily diſengaged by turning of the winch at Z; which, by the pinion *a* below, working into the teeth of the bar, and the wheel C which turns upon it, quite unconnects the wheel C from the crane.

It is therefore evident from what has been deſcribed, that this crane can be managed by two men only, and occaſionally without a horſe, when very heavy goods are not raiſed. All the neceſſary beams for fixing the machinery by, could not be repreſented in the figure without obſcurity and confuſion; but theſe being omitted, will not to the moſt ordinary mechanic render the general conſtruction of the crane difficult to underſtand.

38 New cellar crane.

A new portable cellar crane is repreſented in fig. 60. which is very uſeful to wine-merchants, brewers, &c. in drawing up and letting down caſks full of wine, beer, &c. It ſaves the trouble and inconvenience of horſes, and in many places can be uſed where horſes could not. AA are two wooden props about 6 feet in height, and

and jointed together like a ruler at E. They are connected to each other by an iron round bar C and wooden bar at the bottom D. The iron prongs EE faſten the uprights ſteadily to the edge of the cellar; F is the axis round which two ropes are coiled, the ends of which are faſtened to the two clamps GG. On the axis F is fixed the iron wheel H of 3 feet in diameter: in the teeth of this works the pinion I of about 6 or 7 inches in diameter, and is turned by the handle at K.

It is evident, by a bare inſpection of the figure, that when the two ropes are ſlipt over the ends upon the barrel, either at the top or bottom of the cellar, that by turning of the winch K towards or from you, the barrel can be ſafely and expeditiouſly taken out or lowered down.

When the crane is done with, it ſhuts up by unſcrewing the nut at B, taking the wheel and axis away out of the loops at L, and folding the ſides at A together like a jointed rule; it may then be taken away in the cart or dray, or taken in the mens hands.

39 Portable tone- rane.

Fig. 61. repreſents a portable ſtone-crane mounted in a wooden frame and ſtage, which is judged to be very uſeful for loading and unloading carts with large heavy ſtones. It is moveable to any part of a ſtone-yard or ground; the frame is ſufficiently wide for a cart to draw under the crane, and at any time it may be taken to pieces.

The frame AAAA is made of wood, is about 9 or 10 feet high, and about 9 feet ſquare. The wheels BB are of iron, and are about 3 feet in diameter, and the pinion D, that is fixed to the axis of the firſt wheel B, 8 inches in diameter, on the axis of the ſecond wheel B, the axis round which the rope-coils is fixed.

Now the ſtones being corded and hooked at the end of the rope, it is very evident that the man at C will either raiſe or lower them as may be neceſſary, according as he turns the winch towards or from him, and in a ſafe and very eaſy manner.

40 Crane car- iage.

Fig. 62. is a repreſentation of a crane-carriage which Mr Gottlieb conceives to be very uſeful in moving large ſtones in quarries, where carts and horſes cannot be conveniently or at all managed. Its principle is evidently clear from a bare view of the figure. It conſiſts only of two ſets of crane-wheels applied to the two ſets of wheels belonging to the carriage; ſo that two men, one at each winch AA, turning the pinions and wheels round, ſhall act upon the carriage-wheels and move it along. By their both turning forwards or backwards, the carriage goes accordingly; but if they turn contrary-ways, the carriage will be turned round, or partly ſo, as may be wanted.

The pinion B is 6 inches in diameter, which turns the wheel C of 3 feet diameter, on the axis of which is fixed the pinion D of 1 foot diameter, which works into 2 wheels E, E, of 3 feet 6 inches diameter, that are fixed upon the carriage-wheels, and give motion to the whole machine.

The friction of the axle-trees of theſe machines may be conſiderably diminiſhed, by applying an improved axle-tree invented by Mr Gottlieb, which he calls the *anti-attrition axle-tree*, and for which he has a patent. It is formed from a ſteel-roller, from 4 to 6 inches long, turning within a groove cut in the iron part of the axle; and the advantages diſcovered by experiments made by Mr Gottlieb will be ſeen by the ſmall table ſubjoined. A ſection of this axle-tree is repreſented in fig. 65. where *a* is the axle-tree, *b* the groove, *c* the roller, *d* the cavity between the lower part of the tree and the box *e*. In figs. 66, 67, *f* repreſents the oil-veſſel ſupplying it with oil, *g* the tube to convey the oil by, *h* the ſtraps of ditto, *i* the faſtening ſcrews. Figs. 63, 64, give a ſide view of the axle.

One general maxim to be kept in mind by all mechanics is, that whatever a machine gains in power it loſes in time, even ſuppoſing friction were entirely out of the queſtion. It muſt likewiſe be remembered, that in almoſt all caſes where a machine gains by complication, it will loſe one third by mere friction, unleſs its parts are made with an accuracy not to be expected. In ſome caſes, however, a great power muſt be had; and in theſe we muſt have recourſe to the moſt ſimple machines, which will loſe only time, and but little power by friction; for the complicated ones waſte both time and power to a great degree. There is not perhaps a better method of procuring a very great power than by combining a ſcrew with a toothed wheel which acts as an axis in peritrochio, as is repreſented fig. 50; for by making the threads of the ſcrew pretty cloſe, and the diameter of the wheel large, we may increaſe the power almoſt to any degree we pleaſe, without any conſiderable increaſe of friction. In this caſe, where it can conveniently be done, it is better to increaſe the diameter of the wheel than to add another, for this augments the power without any ſenſible augmentation of the friction; and it is abſolutely neceſſary to have the axle as ſmall as can be made of ſufficient ſtrength to bear the weight. Archimedes is ſaid to have boaſted, that he could move the earth provided he could find a place to ſtand on; and Biſhop Wilkins, that he could pull the ſtrongeſt oaks up by the roots by means of a ſingle horſe-hair. But abſtracting from the impoſſibility in the caſe of Archimedes, it does not appear that the biſhop could more eaſily have fulfilled his taſk, on account of the immenſe friction of the machine he muſt have employed, and the ſtiffneſs of the great ropes which muſt have been bent in order to accompliſh his purpoſe. To perform feats of this kind, a lever ſeems more likely than any thing; but the vaſt room it takes up, and the exceſſive length requiſite to make it act with ſufficient force, together with the vaſt weight it muſt neceſſarily have if made of the requiſite ſtrength, muſt eaſily convince us that all ſuch extravagant boaſts are vain, and that wherever great effects are to be accompliſhed, a great power muſt originally be applied.

Plate CCLXXXV.

Sect. IV. *Of Wheel-carriages.*

Wheel-carriages in general ſignify all kinds of machines furniſhed with wheels, for drawing great weights by means of the ſtrength of animals or otherwiſe.

41 Sledges uſed before wheel-carriages.

It is very probable, that in the infancy of the arts, ſledges were uſed before wheels were invented, or at leaſt before the application of them became very general. Homer mentions them as employed in bringing wood for the funeral of Patroclus; though it is not to be doubted that the Greeks at that time were acquainted with the uſe of wheels, as the ſame poet mentions them on all occaſions when ſpeaking of the war chariots of his heroes. It is poſſible, therefore, that by the country people, for inferior purpoſes, the ſledge might be employed, while wheel-carriages were confined to thoſe of ſuperior rank, or uſed only for war-chariots. It is not long ago indeed ſince ſledges were uſed for certain purpoſes in our own country, notwithſtanding the number of wheel-carriages uſed in it from time immemorial. In ſome of the cold countries, where ice is met with in great quantity, and the ground is covered with frozen ſnow for a great part of the year, ſledges are ſtill uſed, and run upon the ſmooth ſurfaces of theſe bodies with as great eaſe as wheels run upon the ordinary ground. Upon very ſmooth ice, indeed, or upon any body perfectly ſmooth, wheels would not turn at all; for the only reaſon why they turn in the ordinary way, is the continual inequality they meet with. If we ſuppoſe the wheels to be carried in the air, it is plain that they would not turn, there being nothing to put any part in motion more than another; and the ſame would be the caſe if we could ſuppoſe ice, or any other body, to be ſo ſmooth that it would give as little reſiſtance as air. On common roads, however, the wheels meet with obſtructions at the bottom, which retard that part; and in conſequence of this the upper part moves forward, and a circulating motion immediately begins to take place. By means of this circulatory motion the friction becomes very much leſs than what it would be if the weight were drawn along the ground upon a ſledge, inſomuch that, according to the computation of Dr Helſham, a four-wheeled carriage may be drawn with five times as much eaſe as one that ſlides upon the ſame ſurface as a ſledge.

42 Obſtacles which occur to the motion of carriages.

The ſtructure of wheel-carriages is ſo generally known, that it is needleſs to deſcribe them. In the conſtruction of them, however, there are ſeveral particulars to be obſerved, which may render one method of conſtruction preferable to another, though there may be a general ſimilarity between one carriage and another. In order to aſcertain the moſt proper method for conſtructing them, it will firſt be neceſſary to conſider the obſtacles which occur to their motion. Theſe are,

1. The *vis inertiæ* of matter.—This, though for a conſiderable time ſuppoſed to be a principle of mere *inactivity*, or *reſiſtance* to any change of ſtate from motion to reſt in material bodies, is now almoſt exploded. Mr Anſtice, in a late treatiſe on wheel-carriages, ſuppoſes the philoſophers who maintain the exiſtence of ſuch a principle, to have miſtaken Sir Iſaac Newton and other great men. According to him, they meant no more by the *vis inertiæ* of matter than a mere paſſiveneſs in it, by which it was diſpoſed to abide in that ſtate, either of reſt or motion, in which it originally was; "whereby it alters not its ſtate but in proportion to the quantity of power exerted againſt it. Thus, ſhould a body of any given weight or quantity of matter, moving with a certain degree of velocity, ſtrike another body at reſt of the ſame weight, it would communicate half its motion to that body, and they would move together with the ſame velocity as the firſt; but this proceeds from no principle of the body at reſt to reſiſt motion, it does not deſtroy in the other more than it receives from it; therefore no motion is loſt, it is only divided; and the two after diviſion have a power equal to that of the one before it, with the whole velocity of motion. Indeed when we conſider that the leaſt degree of motion in any body, however ſmall, will communicate ſome degree of it to the largeſt in the univerſe; and that, on the contrary, none but an equal degree of impetus can deprive a body of actual motion, and that immediately oppoſed to it: add to this, that ſince all matter within the reach of our obſervation, and by analogy we have reaſon to think it is in actual and rapid motion, impreſſed on it by its great Creator, and co-exiſtent with it; we may conclude, that if matter do not affect, it is more liable to motion than to reſt."

2. *Friction.* By this is meant the quantity of motion deſtroyed by bodies ſliding over one another, and which is in proportion to the weights laid upon them. See Sect. II. § 8.

Friction depends not only upon the preſſure made on the moving bodies, but on the inequalities on the ſurfaces upon which they move. For as the ſurfaces of even the moſt highly poliſhed bodies have ſome inequalities, whenever two of them are preſſed together, the inequalities of the one muſt enter, and in ſome degree accommodate themſelves, to thoſe of the other; and as the forms of theſe inequalities are of infinite variety, it is impoſſible to give any general deſcription which can exactly anſwer to every one of them.

Mr Anſtice ſuppoſes the varieties only to be of two kinds, which he thinks may not be very diſſimilar to any that occur. 1. Let us imagine two ſliding ſurfaces, when viewed through a microſcope, to preſent ſuch an appearance as is repreſented in fig. 69. in which A is the ſliding body to be moved in the direction C D over the fixed body B. To effect this, it is evident, that either the teeth muſt be violently broken off, or a power applied to them ſufficient to make them ſlide upon each other on the principles of the inclined plane; in which caſe the friction muſt always be in proportion to the weight of the ſlider, and that with which it is loaded, without regard to the length or breadth of the bearing ſurface: for if only one pound reſted upon one tooth, there would be no more but that pound to be lifted. If the pound reſted upon two teeth, there would only be half a pound to be lifted over each, and ſo on to any number; but if we ſuppoſe the teeth to be of ſuch a ſhape, that they cannot act as inclined planes, let them be ever ſo ſtrong, we muſt calculate the friction in a different manner.

Plate CCLXXXVII.

Let ſurfaces of this kind be repreſented by fig. 70. In which caſe it is evident, that inſtead of depending on the weight or preſſure only, it will be in proportion to the number and ſtrength of the teeth ſo locked together; or, in other words, on the length and breadth of the rubbing ſurfaces. On this ſuppoſition the weight of the ſlider will have little or no effect in breaking the teeth, or hindering its being done by the power applied in the longitudinal direction; but if one tooth is to be broken, it will be neceſſary to apply twice that power to break two, thrice the power to break three, &c. Hence it is evidently impoſſible to form any general rule concerning the friction which takes place on this principle. As experience, however, has ſhown that two bricks, or other bodies of that kind, are almoſt as eaſily drawn along a table when placed ſide by ſide, as when laid upon each other, it ſeems probable that ſuch a locking of parts ſeldom occurs; and when it does, the obſtacles are ſoon broken down. Yet it is certain, that ſome ſuch thing muſt take place on all occaſions, otherwiſe the wearing of bodies which rub upon one another could not happen.

From what has been ſaid it muſt appear plain, that if a ſlider be laid upon an horizontal plane, it muſt remain at reſt; though by a very ſmall force, ſuch as is barely ſufficient to overcome the friction, it will be ſet in motion: becauſe, on a plane quite horizontal, the motion of any body does not remove it in the leaſt farther from the point to which it is attracted by the force of gravity. If the plane be inclined to the horizon, then, beſides the power neceſſary to overcome the friction, it will be neceſſary to have one ſufficient alſo to overcome that of gravity, by which it is determined to roll down the plane; the proportion of which is aſcertained under Sect. II. § 4. The difficulty of raiſing great weights in this manner, however, where the aſcent is ſteep, and the ways rough, muſt neceſſarily be ſo great, that ſledges could not be uſed with any advantage, and therefore wheels are indiſpenſable.

The advantage of wheels over ſledges may be further underſtood from the following conſiderations. 1. A ſledge, in ſliding over a plane, ſuffers a friction equivalent to the diſtance through which it moves; but if we apply to it an axle, the circumference of which is ſix inches, and that of the wheels eighteen feet, it is plain, that moving the carriage eighteen feet over the plane, the wheels will make but one revolution; and as there is no ſliding of parts between the plane and the wheels but only a mere change of ſurface, no friction can take place there, the whole being transferred to the nave acting on the axle, ſo that the only ſliding of parts has been betwixt the inſide of the nave and the axle; which, if they fit one another exactly, is no more than ſix inches: and hence it is plain, that the friction muſt be reduced in the proportion of one to thirty-ſix. Another advantage is alſo gained, by having the ſurfaces confined to ſuch a ſmall extent; by which means they may be more eaſily kept ſmooth, and fitted to each other. The only inconvenience is the height of the wheel, which muſt in all caſes be added to that of the carriage itſelf.

It has been a matter of no little conſideration, whether the wheels of a carriage ought to be ſmall or large; and this ſubject Mr Anſtice has treated in a very particular manner. He obſerves, that in the overcoming of ſuch obſtacles as are commonly met with in roads, wheels act as mechanical powers, and therefore the ſize of the wheel muſt be regulated upon the principles of theſe powers. Thus, let the circle O T A G L, fig. 71, repreſent a wheel of four feet diameter, placed on the level P Q, and oppoſed in that line by the obſtacle O, which is ſuppoſed to be 7.03 inches in height; the line in which the carriage is drawn being C T, parallel to the plane P Q. In this caſe the effort applied to the carriage is communicated to the nave of the wheel where it touches the axle. This part, therefore, repreſents the part of the lever to which the power is applied, and is the point C in the figure. As the turning point is that where the wheel touches the obſtacle, that muſt repreſent the fulcrum of the lever; whence that arm of the lever will be repreſented by C O, which may be ſuppoſed a ſpoke of the wheel: and as the upright ſpoke C L is in the line which bears the whole weight from the axle, and in which it is to be lifted; hence that part of the circumference of the wheel which is between the fulcrum and the upright ſpoke bearing on it, muſt repreſent the arm of the lever which is to raiſe the weight. In this caſe neither the weight nor the power act at right angles to their reſpective arms of the lever; ſo that we muſt repreſent their powers by the imaginary lines MO and ON. As the length of OM, therefore, is to that of ON; ſo is the proportion required to the weight to balance it on the obſtacle, when riſing over it; and in this caſe the arms are equal, it is plain that the powers muſt be ſo likewiſe. Every obſtacle, therefore, exceeding this height, which is as 7.03 to 48, will require a power acting parallel to the plane greater than the weight drawn; and every obſtacle whoſe height bears a ſmaller proportion to that of the nave, muſt be overcome by a ſmaller power.

Again, let a wheel of four feet diameter be repreſented by the circle in fig. 72, and ſuppoſed to be moved along the plane PQ, and an obſtacle of twelve inches height be placed before it, the real lever will then be repreſented by the lines L O C; which being reduced to the imaginary ones MON, ſhows that the power is greater than the weight. By the ſame rule, if an obſtacle of three inches be placed in the way of a wheel, as in fig. 73, the power required to move the wheel will be conſiderably leſs than the weight, though it is plain that the proportion of power muſt always be according to the ſize of the wheel, the height of the obſtacle, and the direction in which the carriage is drawn. For inſtance, if the line of traction in fig. 73. be raiſed into the direction CS, the power required to move the carriage over it will be to the real weight as the line CO is to the line ON; and in conſequence of thus altering the direction, we gain as much as the length of the line CO exceeds that of CN.

43
Whether large or ſmall wheels are preferable.

This view of the manner in which the wheels of carriages act, will ſerve to elucidate the queſtion, whether large or ſmall wheels are preferable for carriages? Let the circle fig. 74. repreſent a wheel of two feet diameter, and the obſtacle in its way 7 03 inches in height; then will the true lever be repreſented by the lines COL, to be reduced to the imaginary ones MON. In this caſe, the power required to draw the carriage muſt be to its weight as NO is to OM, which is more than double; and thus the advantage of large wheels over ſmall ones is evident. In this, however, as in all other caſes where wheels act as mechanical powers, we muſt remember, that the ſame doctrine applies to them as to the powers themſelves when uſed in any other manner, viz. that as much as we gain in power we loſe in time; and therefore, though a wheel of twice the diameter may be raiſed over an obſtacle of any given height with twice the eaſe that would be required for one of once the diameter, yet the large wheel would require twice the time to move over it that the ſmall one does.

Hitherto we have conſidered the carriage as being drawn in a direction parallel, or nearly ſo, to the plane on which the wheels move, which line is ſuppoſed to be horizontal: but the caſe will be different when we ſuppoſe them to move upon an inclined plane; for then, even though the line of traction be parallel to the aſcending plane, and though the wheels act as levers, we ſhall find that the action of the weight will increaſe with the power gained by the increaſe of ſize in the wheels; and conſequently, that the increaſed ſize of the latter will be of no farther uſe than that of diminiſhing the friction, in the ſame manner as is done upon horizontal planes.

To illuſtrate this, ſuppoſe the larger circle in fig. 75. to repreſent a wheel of four feet diameter, and the ſmaller circle a wheel of only two, both of which are made to aſcend the inclined plane LM, by powers applied in the directions GI and ES parallel to the elevation of the plane, which is 45 degrees; it will then be found, that by deſcribing the lever as in the former caſe, though the arm of the lever to which the power is applied be double the length in the large wheel that it is in the ſmall, the other is augmented in the ſame proportion. Neither will the powers be augmented by varying the direction of the line of traction; for while theſe are kept parallel to one another, their relative powers muſt always keep the ſame proportion to one another. The reaſon is obvious, viz. that when wheels of any dimenſion aſcend or deſcend inclined planes of any regular elevation, the fulcrum of the lever contained in the wheels muſt be determined by that part of the wheel which touches the plane, and which muſt always be of a proportionate height both in large and ſmall wheels. It is otherwiſe, however, with the fulcrum marked out by perpendicular or irregular obſtacles upon the plane itſelf; for large wheels will always have the advantage over ſmall wheels when theſe are preſented, for the reaſons already given. Indeed, when the wheel impinges perpendicularly upon an obſtacle as high as the line of traction, it is plain that it cannot be drawn over it by any power whatever, unleſs the direction of the latter be altered.

44
General concluſions concerning the motion of carriages.

From theſe conſiderations, our author draws the following concluſions: 1. That in a carriage placed upon an horizontal plane, nothing more is required to produce motion than to overcome the friction which takes place between it and the plane. 2. By the application of wheels to a carriage, the friction is leſſened in the proportion of the diameters of the axles and hollow parts of the naves to thoſe of the wheels. 3. In the draught of a carriage without wheels up a regular plain aſcent, the friction muſt not only be overcome, but there is a power likewiſe to be applied ſufficient to lift ſuch a proportion of the weight of the carriage as the perpendicular part of the aſcending plane bears to that portion of the plane. 4. If wheels of any ſize be applied to the carriage in ſuch circumſtances, they have only the advantage of leſſening the friction; for though they really act as levers, yet as each arm of the lever is lengthened in proportion to the increaſe of ſize in the wheels, the power can be no farther augmented than as the aſcent may act as a mechanical power for raiſing up the wheels, carriage, &c. to the top. 5. Large wheels have the advantage over ſmall ones in overcoming obſtacles, becauſe they act as levers in proportion to their various ſizes. 6. The line of traction, or that in the direction of which the carriage is drawn, ſhould always, if poſſible, be parallel to that in which the plane lies; for when this is the caſe, the arm of the lever to which the power is applied will bear the longeſt proportion poſſible to the other. This always takes place when the line of traction is perpendicular to that ſpoke of the wheel which points to the obſtacle. As it may not always be poſſible, however, to alter the direction of the line of traction to this poſition, it will be moſt proper to fix upon ſome medium betwixt that which commonly occurs and that which requires the greateſt exertion to overcome the obſtacle; that is, betwixt a level line and one riſing perpendicular to the ſpoke of the wheel which points to the obſtacle it is likely to meet with. The greater attention ought to be paid to this laſt, that all wheels, but eſpecially ſmall ones, are liable to ſink into the ground over which they paſs, and thus produce a conſtant obſtacle to their own progreſs. The line of traction, it muſt alſo be obſerved, is not an imaginary one drawn from that part of the animal to which the traces or chains are attached to the axle of the wheel, but the real direction of the traces to whatever part of the carriage they are attached; for the effort will be inſtantly communicated in the ſame direction from one part of the carriage to all the reſt, by reaſon of the whole being faſtened together and in one piece.

Hitherto we have conſidered the whole weight of the carriages as bearing perpendicularly againſt the axles of the wheels: but as this cannot be done in chairs, carts, and other carriages having only two wheels, it will be neceſſary to have their centres, or tranſverſe lines of gravity, as near to the ground as poſſible. To underſtand this, it muſt be premiſed, that the centre of gravity is that point of any body which if ſuſpended will keep all the parts of the body at reſt, let the body be placed in any ſituation we pleaſe. Thus the centre of gravity in a wheel or circle is the centre of the circumference, provided the ſubſtance of it be equably ponderous throughout. In like manner, the real centre of a globe coincides with the centre of gravity, provided the matter of which it is compoſed be equably ponderous. In a ſquare, whether ſuperficial or ſolid, the centre of gravity will be a point equally diſtant from all its ſides; ſo that if the ſubſtance be equably heavy, it will be impoſſible to turn it into any poſition in which there will not be as much matter upon one ſide of the centre as upon the other: and in like manner, every figure, however irregular, has ſome point round which, if it be turned, as much matter will always be upon one ſide as on the other.

If now any body be ſupported by a tranſverſe line paſſing not through the centre of gravity itſelf, but either

either above or below it, the body can only be kept in equipoiſe while that line remains directly above or below the point ; for if the body is moved forwards, as in two-wheeled carriages moving down hill, a greater part of the weight will be thrown forwards over the line of ſuſpenſion than what remains behind it ; and conſequently this ſuperfluous part muſt be borne by the animal which draws it. In aſcending any height, juſt the reverſe takes place ; for thus a portion of the weight is thrown backwards, and will tend to lift up the animal altogether. The conſequence of this is, not only that the creature muſt proceed with great pain, but that the friction on the nave and axle will be augmented by laying upon them a part of the animal's weight alſo. If the body be ſuſpended above the centre of gravity, the effect, though the ſame in the main, will be reverſed in the aſcent and deſcent of hill, as long as the body is firmly attached to the ſhafts ; but ſhould the whole weight be ſuſpended under the axle, independent of the ſhafts altogether, then it will always, whether aſcending, deſcending, or moving horizontally, have the ſame effect as if hung directly by it.

45
uſpend- carri- above elow centre ravity.

Our author next proceeds to treat of a generally received opinion, that the diſadvantages attending carriages ſuſpended either above or below the centre of gravity are augmented by the height of the wheels. The reaſon given for this opinion is, that the hinder part of the load in aſcending an hill, being thrown back, will overhang that part of a large wheel which touches the plane, much more than when a ſmaller wheel is uſed. Mr Anſtice, however, obſerves, that all the diſadvantage, in either caſe, is expreſſed by the weight which, from its action upon the axle, tends to lift the animal, which muſt always be the ſame whether the wheels are high or low. Thus, in fig. 76. let a carriage be repreſented with two wheels of four feet diameter, aſcending a plane of 35° elevation from the level LE. Let fig. 77. repreſent a carriage exactly in the ſame circumſtances with the former, only that the wheels are ſix feet in diameter. Let C be the centre of gravity, and SP the line of gravity parallel to the central line AR, the line of ſupport or ſuſpenſion ; in each of theſe the body is thrown ſo far back by its poſition, that the ſpace GS and AR is taken from before the line of gravity, and added to the part behind it. Hence a certain part of the animal's weight muſt be exerted upon the ſhafts, in order to balance that of the carriage, which is thus thrown back, and which, as is evident from the figures, muſt be the ſame in both carriages, though the wheels of the one ſo much exceed thoſe of the other in ſize, and the point T, where the wheel touches the plane, is much farther from the line of ſuſpenſion in the large wheel than in the ſmall one.

To remedy the inconvenience which muſt ariſe from placing the centre of gravity in the carriage low enough with reſpect to the wheels, it will be beſt to apply three or four wheels, placing them in ſuch a manner that the line of gravity may always fall between the wheels, in whatever ſituation the carriage may probably be placed. Thus if the body A, fig. 78, be placed on four wheels, the axles of which are at B and C, it will be entirely ſupported between them, though more by C than B, even though the carriage ſhould be aſcending an hill as ſteep as HI, viz. 50 degrees, which cannot ever happen in practice. Even in this caſe the animal would have no occaſion to make exertions for preſerving the balance of the carriage, though, had it been ſupported only by the axles of two wheels at S, far the greater part of the weight of the carriage would have been thrown behind, and the equilibrium could not have been preſerved without the greateſt difficulty. Hence it is plain, that the greater the diſtance betwixt the axles of three or four wheels applied to a carriage, the leſs liable will it be to have the line of gravity thrown out of its proper direction ; but as this diſtance greatly augments the difficulty in turning a carriage, ſome medium is to be obſerved in this as well as other things.

46
Of preventing a carriage from being overturned.

What has been juſt now obſerved with regard to the preſerving the balance of a carriage longitudinally, applies equally to the preventing it from being overturned laterally upon uneven roads, or ſuch as have one ſide much higher than the other. In order to this, we muſt take care to keep the line of gravity ſo far within the body of the carriage that it cannot be thrown out of it by any ordinary declivity of the road upon one ſide more than another. In the preſent caſe, however, as the wheels are not moveable on an axle in a lateral direction, we muſt conſider the points of ſuſpenſion to be thoſe where the wheels touch the ground. Thus, let fig. 79. repreſent the croſs ſection of a carriage moving upon two wheels ; let C be its centre of gravity : it is plain, that in the poſition there repreſented, each of the points A and B ſuſtains an equal ſhare of the weight, and muſt do ſo as long as the carriage moves upon level ground : but if it be drawn along a road one ſide of which is higher than the other, ſuch as is repreſented fig. 80. then the centre of gravity, and conſequently the whole weight of the carriage, will bear upon the point of the wheel B, with this additional inconvenience, that the preſſure does not lie perpendicularly but ſomewhat obliquely, by which the wheel is in great danger of being broken. To avoid inconveniences of this kind, the points of bearing upon the wheels are removed to a greater diſtance than the exact perpendicular, and this is called *diſhing* the wheels ; the good effects of which are evident from the figure. The wheels are diſhed by inſerting the ſpokes into the naves in ſuch a manner that they may decline every way from the carriage. Some diſadvantage, however, attends this contrivance, for the carriage thus takes up more room upon the road, which makes it more unmanageable ; and when it moves upon plain ground, the ſpokes not only do not bear perpendicularly, by which means their ſtrength is leſſened, but the friction upon the nave and axle is made unequal, and the more ſo the more that the wheels are diſhed. To obviate theſe inconveniences, ſome have bent downwards the ends of the axles ; but thus the good effects of the diſh is entirely loſt, for the wheels are thereby thrown erect, and the breadth of the diſh doubly increaſed on the upper part of the carriage.

The practice of bending forward the ends of the axle is ſtill worſe ; for thus the wheels are thrown out of that parallel direction which they ſhould always preſerve on the ground, and likewiſe increaſes the friction both on the ſhoulders of the axles, and likewiſe

wiſe on the ground; for the wheels, by rolling in this poſition, would ſoon come together if not prevented by the ſhoulders of the axles; whence in every revolution they muſt rub with conſiderable force upon the ground.

47
How the power of wheels may be augmented.

The power of wheels can only be augmented in two ways. 1. By increaſing the length of that arm of the lever to which the power is applied; and, 2. By diminiſhing the friction betwixt the nave and axle. The former is only a temporary expedient in caſe of any obſtacle which cannot be ſurmounted in the ordinary way. It is accompliſhed, by transfering the action of the animal's power from the centre to the upper part of the circumference of the wheel: thus the power of the lever will be nearly doubled, as is ſhown from fig. 71. for if the power be applied to the wheel at A, then the arm of the lever would be repreſented by the dotted line AO inſtead of CO; and the former being nearly twice as long as the latter, their powers muſt be in the ſame proportion. It is evident, however, that this mode of applying the animal's power can only be uſeful in any ſudden emergency; for were we to attempt to reduce it into practice by winding a rope or chain about the circumference of the wheel, the animal muſt move twice as faſt as the carriage. See this alſo exemplified in Plate CCLXXXV. fig. 58, where the moving power is repreſented by the weight P; the wheel EF turning between two toothed planes AB and CD. Here it is evident, that while one of the ſmall diviſions *ca*, *ae*, &c. moves forward its own length, the plane A muſt do the ſame, while the centre, by the motion of which only that of the wheel can be meaſured, moves but through half the ſpace.

48
Of friction-wheels.

2. With reſpect to friction-wheels or rollers, the caſe is different; and we may apply theſe in as great numbers, and in as great a variety of ways as we pleaſe, without fear of inconvenience. The beſt method of applying them, according to Mr Anſtice, is to have the wheels and axle fixed to one another, ſo that both may turn together. Two friction wheels a little overlapping each other, muſt then be fixed on each ſide of the body of the carriage, ſo that it may bear on the axle in the interſection of the wheels, as is repreſented in fig. 81. Here ABCD repreſents the body of the carriage, the large circle one of the wheels fixed to the axle E. The circumference of each of the friction-wheels F and G is ſuppoſed to be three feet, and that of their axles three inches. As the large wheel then revolves by the motion of the carriage, and thus transfers the friction from its circumference to its axle; ſo the friction of the axle itſelf is now transferred from the circumference of the friction-wheels to their axles. Every revolution of the great wheel, therefore, during which it paſſes over 18 feet of ground by means of the motion of the axle, puts the leſſer wheels round one ſixth part of their circle; and conſequently their axles are moved through the ſame part of their circumference, the friction being thus reduced to that upon this ſmall part; which being no more than half an inch, becomes 432 times leſs than it would have been on the large wheel without any motion on an axle, and 12 times leſs by means of the friction-wheels than without them. The axles on both ſides indeed are in motion, but the calculation muſt be made as if only one moved; for the greater number of wheels there are, the more will the friction be divided among them.

Plate CCLXXXVII.

An objection of conſiderable weight ariſes to this method of fixing the wheels and axles together, that thus the wheels are prevented from moving with different velocities as they ought to do, when the carriage moves out of a right line; but this may be obviated by leaving the friction wheels looſe upon their axles, by which means they will be at liberty to move with different velocities, at the ſame time that they will have the advantages of friction-wheels always as to one wheel of the carriage, and generally as to both.—The whole contrivance, however, ſeems likely to be entirely ſuperſeded by the following one of Mr Gamett of Briſtol, who has obtained a patent for it. The general principle on which he proceeds is this. Between the axle and nave a hollow ſpace is left to be filled up by ſolid equal rollers nearly touching each other. Theſe are furniſhed with axles inſerted into a circular ring at each end, by which their relative diſtances are preſerved; and they are kept parallel by means of wires faſtened to the rings between the rollers, and which are rivetted to them.

49
Mr Ga-mett's m thod of ſtroying friction.

To underſtand the effect of this machinery we muſt conſider, that if, when plane ſurfaces move with a roller between them, if the under one be fixed, the upper plane will put the rollers forward but with half the quantity of its own motion. This is owing to the reaction of the ſtationary plane, which cauſes the roller to move backward upon itſelf as much as the other cauſes it to move forward upon itſelf. Thus, let CD, fig. 82. be a fixed ſurface, and AB a moveable one, with a roller E between them; if B be moved forward to G, it will cauſe the roller to move to F, which is but half the diſtance that AB has moved; becauſe it has rolled in a retrograde direction as far againſt the ſurface BA as it has gone forward upon the other. This is entirely owing to the reſiſtance it meets with from CD; for if it did not touch that ſurface, but was attached by any other means to AB, it would be carried along with it through the whole ſpace without any rolling motion. Hence it is clear, that if a roller be placed between the axle and nave of a wheel, and the latter be turned round, the roller will move with a retrograde motion upon the axle; and in order to carry it quite round, the nave muſt be turned as much beyond a whole revolution as is equal on its inner circumference to the whole circumference of the axle. To exemplify this, let ABCD, fig. 83. repreſent the nave of the wheel E, the inner circumference of which is 18 inches, and the axle ſo ſmall that it may be conſidered as a point. Let F and G be two rollers cloſely fitted between them: if then the wheel be turned round, the rollers will alſo be carried along with it round the point which we conſider as an axle; for there can neither be rolling nor friction againſt a mere point. But if the axle be of any ſenſible ſize, for inſtance one inch circumference, then muſt each roller move round by the motion of the nave againſt it, and the reſiſtance of the angle on the oppoſite ſide. But in order to do this, it muſt roll in a retrograde direction upon the nave, and conſequently the latter muſt go as far beyond a revolution as is equal to the circumference of the axle upon it, before the roller can go once round the axle, which in this caſe is by

Plate CCLXXXV

heel-
riages.

one 18th part of the circumference. Should the circumference of the axle be nine inches, and that of the inner part of the nave remain as before, the wheel muſt perform one revolution and an half before the roller could be moved once round, and ſo on in the ſame proportion: but as the circumference of an axle muſt always be leſs than the inner part of a nave turning upon it with rollers between them, it never can amount to two revolutions of the wheel round the axle, however nearly it may approach to it; for no ſegment of a circle can ever be a ſtraight line.

It will now be apparent, that if ſeveral rollers be placed all round between the nave and axle, whichever way the wheel be turned there cannot be any real friction, but merely a rolling of the rollers. If likewiſe theſe rollers be all of one ſize, and very nicely fitted to the cavity, they will keep their places without ſhifting, and very effectually anſwer the purpoſe of deſtroying friction. As ſuch rollers, however, were very liable to be diſplaced by accident, the uſe of them was neglected, till Mr Gamett ſuggeſted the improvement already mentioned, and which is repreſented in fig. 84. Here ABCD repreſents a piece of metal to be inſerted into the nave of a wheel, of which E is the axle, and 1, 1, 1, &c. rollers of metal having axes inſerted into the braſen circle which paſſes thro' their centres; and both circles being rivetted together by means of bolts paſſing between the rollers from one ſide of the nave to the other; and thus they are always kept ſeparate and parallel. By this method, indeed, ſome friction unavoidably takes place betwixt the axles of the rollers and their ſockets in the braſs-rings; but as the quantity of friction depends principally on the force by which the rubbing ſurfaces are preſſed upon each other, and as in this caſe there is but the ſlight preſſure occaſioned by thoſe accidental circumſtances which would bring the rollers together, the friction muſt be too trifling to be noticed.

Thus far with regard to wheel-carriages in general. We muſt now make ſome remarks on the methods of drawing them, and the conſtruction of particular carriages.—Men, by reaſon of their upright form, are by no means fitted for horizontal draughts; but animals who go upon all fours are remarkably ſo. In Britain horſes are commonly made uſe of; but mules, oxen, ſheep, and dogs, in other parts of the world. In all animals, however, the capacity for drawing a load depends upon their weight as well as their abſolute ſtrength. Thus it may happen, that a very heavy horſe will draw a load, which a lighter though ſtronger one could not move; and this will always happen, when the weaker horſe exceeds the other in weight more than he is exceeded by him in ſtrength. It is well known that the weight, as far as it goes, reacts upon the horſe, and pulls him back as much as he pulls it forward, until the exertions of the muſcles of the animal reſiſted, by the ſolid ground, overcome the reſiſtance of the load upon the moveable wheels, and it goes forward in proportion to the exceſs of the one power over the other. If the horſe were put upon a moveable plane, and attempted to draw a load upon the ſolid ground, inſtead of pulling it forward he would pull himſelf back.—The horſe has two ſources of power in drawing a load, viz. his ſtrength and weight. The former is the ſource of velocity; and as we find the actual power of any inanimate body in motion by multiplying the velocity into its quantity of matter, ſo do we find the power of a horſe to draw a load, by conſidering his weight as well as abſolute ſtrength. There are even many inſtances in common practice, where it is uſeful to increaſe the weight of an horſe or other animal; and therefore when horſes are employed to draw mills, it is uſual to put a ſmall load upon their backs in order to increaſe their abſolute momentum. Where the animals are equal in ſtrength and momentum, however, the only difference that can take place in the weights they draw muſt ariſe from the convenience or inconvenience of the carriages to which they are yoked, or of the roads upon which they walk. A load breaſt-high is much more eaſily drawn than one which is dragged along the ground, becauſe the power of the animal is then exerted directly againſt it; and this holds good whether the horſes go up or down hill. In deſcending, indeed, as the load is then higher with regard to the horſe than when it is on a plane, he will conſequently pull it with the greater force; but in this caſe, its own gravity conſpires with the draught, and will likewiſe help the load to deſcend; ſo that in this caſe the animal has an opportunity of exerting his greateſt power when there is the leaſt neceſſity, nay, when it is often inconvenient.

Wheel-
carriages.

In all carriages with four wheels the two fore ones are made of a much ſmaller ſize than the hind ones, both for the ſake of turning more eaſily, and likewiſe that there may be no danger of cutting the braces; but were both the fore and hind wheels to be of the ſame height, the carriage would be drawn with much greater eaſe. It is imagined indeed by the drivers of carriages, that the high hind wheels puſh on the fore-wheels: but this is evidently abſurd; for the fore-wheels muſt turn as many times round oftener than the large ones as the latter exceed them in ſize. Thus, if we ſuppoſe the circumference of the large wheels to be 18 feet, and that of the ſmall ones only *ſix*, it is evident that the latter muſt turn round three times for once that the large ones turn round. Suppoſing the carriage therefore to be loaded equally on both axles, it is plain that by the greater friction upon the fore-axle than the other, it muſt wear out much ſooner, and that as much as the fore-wheels are ſmaller than the hind ones. But it is the univerſal practice of thoſe converſant in loading and driving carriages, to put a much greater load upon the fore than the back axle. Thus the friction not only becomes greateſt where it ought to be leaſt, but the ſmall wheels muſt neceſſarily ſink deeper into the ground than the large ones, which they are at any rate inclined to do from their ſize. The only danger in laying the greateſt load upon the hind axle is, when the carriage goes up a very ſteep aſcent; but in the few caſes in which this may happen, a ſmall temporary weight laid upon the pole betwixt the horſes would prevent all danger of overſetting.

To confirm theſe reaſonings by experiment, let a ſmall model of a waggon be made, with its fore-wheels $2\frac{1}{2}$ inches in diameter, and its hind-wheels $4\frac{1}{2}$; the whole model weighing about 20 ounces. Let this little carriage be loaded any how with weights, and have a ſmall cord tied to each of its ends, equally high from the ground it reſts upon; and let it be drawn along a horizontal board, firſt by a weight in a ſcale hung to the cord at the fore-part; the cord going over a pulley at the end of the board to facilitate the draught, and the weight juſt ſufficient to draw it along. Then turn the carriage, and hang the ſcale and weight to the hind-cord, and it will be found to move along with the ſame velocity as at firſt: which ſhows that the power required to draw the carriage is all the ſame, whether the great or ſmall wheels are foremoſt; and therefore the great wheels do not help in the leaſt to puſh on the ſmall wheels in the road.

Hang the ſcale to the fore-cord, and place the fore-wheels (which are the ſmall ones) in two holes, cut three eight parts of an inch deep in the board; then put a weight of 32 ounces into the carriage over the fore-axle, and an equal weight over the hind-one: this done, put 44 ounces into the ſcale, which will be juſt ſufficient to draw out the fore-wheels: but if this weight be taken out of the ſcale, and one of 16 ounces put into its place, if the hind-wheels are placed in the holes, the 16 ounce weight will draw them out; which is little more than a third part of what was neceſſary to draw out the fore-wheels. This ſhows, that the larger the wheels are, the leſs power will draw the carriage, eſpecially on rough ground.

Put 64 ounces over the axle of the hind-wheels, and 32 over the axle of the fore-ones, in the carriage; and place the fore-wheels in the holes: then put 38 ounces into the ſcale, which will juſt draw out the fore-wheels; and when the hind-ones come to the hole, they will find but very little reſiſtance, becauſe they ſink but a little way into it.

But ſhift the weights in the carriage, by putting the 32 ounces upon the hind-axle, and the 64 ounces upon the fore-one; and place the fore-wheels in the holes: then, if 76 ounces be put into the ſcale, it will be found no more than ſufficient to draw out theſe wheels; which is double the power required to draw them out when the lighter part of the load was put upon them; which is a plain demonſtration of the abſurdity of putting the heavieſt part of the load in the fore-part of the waggon.

Every one knows what an outcry was made by the generality, if not the whole body, of the carriers, againſt the broad-wheel act; and how hard it was to perſuade them to comply with it, even though the government allowed them to draw with more horſes, and carry greater loads than uſual. Their principal objection was, that as a broad wheel muſt touch the ground in a great many more points than a narrow wheel, the friction muſt of courſe be juſt ſo much the greater; and conſequently there muſt be ſo many more horſes than uſual to draw the waggon. It is believed that the majority of people were of the ſame opinion; not conſidering, that if the whole weight of the waggon and load in it bears upon a great many points, each ſuſtains a proportionably leſs degree of weight and friction, than when it bears only upon a few points: ſo that what is wanting in one is made up in the other; and therefore will be juſt equal under equal degrees of weight, as may be ſhown by the following plain and eaſy experiment.

Let one end of a piece of pack-thread be faſtened to a brick, and the other end to a common ſcale for holding weights: then, having laid the brick edgewiſe on a table, and let the ſcale hang under the edge of the table, put as much weight into the ſcale as will juſt draw the brick along the table. Then taking back the brick to its former place, lay it flat on the table, and leave it to be acted upon by the ſame weight in the ſcale as before, which will draw it along with the ſame eaſe as when it lay upon its edge. In the former caſe, the brick may be conſidered as a narrow wheel on the ground; and in the latter, as a broad wheel. And ſince the brick is drawn along with equal eaſe, whether its broad ſide or narrow edge touches the table, it ſhows that a broad wheel might be drawn along the ground with the ſame eaſe as a narrow one (ſuppoſing them equally heavy), even though they ſhould drag, and not roll, as they go along.

50 Of broad and narr wheels.

As narrow wheels are conſtantly ſinking into the road, they not only prove very deſtructive to the highways over which the carriages move, but by reaſon of this very ſinking, they muſt be accounted as going continually up hill in ſome degree, even when drawn upon plain ground. Theſe inconveniences are obviated by the uſe of broad wheels; and indeed the utility of theſe is ſo obvious, that it ſeems ſurpriſing how the uſe of narrow wheels is on any occaſion permitted by the legiſlature. The wheels ordinarily uſed for waggons are nine inches broad; but of late a practice has been introduced of uſing rollers 16 inches broad; by which the inconveniencies of the narrow wheels are removed, and the greateſt weights may be drawn over the very worſt roads, not only without making them worſe, but greatly to their improvement. It has been objected, that broad wheels ſoon accumulate in clayey roads ſo much matter that it would ſoon equal an ordinary load; but, not to mention that ſuch roads ought to have no exiſtence in a country where ſuch ſums are annually paid for their reparation, it is evident, that paſſing heavy rollers over them is the only method to give that firmneſs to clay which is neceſſary for its ſupporting the animals who walk over it; and indeed many of the roads in this country, by reaſon of the continual poaching by wheels and feet of horſes, &c. become throughout a great part of the year almoſt impaſſable by people on foot. The legiſlature appear to be very ſenſible of the advantages derived from theſe rollers, and accordingly allow ſuch carriages as are furniſhed with them to go toll-free.

51 Mr Edg worth's periment on carriages.

In the tranſactions of the Royal Iriſh Academy for 1788, we meet with ſome curious obſervations on the ſubject of wheel-carriages, by Mr Lovell Edgeworth. This gentleman informs us, that he was preſent in London in 1773, at a ſet of experiments tried in order to determine the comparative advantages of low and high wheels. The apparatus for theſe experiments was conſtructed with the greateſt accuracy. The carriages themſelves were made by the beſt workmen in London, and they were drawn along a ſmooth table by ſilk ſtrings of ſmall diameters put over a pulley nicely conſtructed, and fitted up in ſuch a manner as to have ſcarce any friction. On applying a weight to the end of the ſtring which paſſed over the pulley, little difference appeared in the velocities with which the carriages paſſed along the table, whether the wheels were high or low; but what appeared ſurpriſing was, that when obſtacles were put in their way, ſometimes the high and ſometimes the low wheels had the advantage, according to the different ſhapes and ſizes of the obſtacles. “ It appears at firſt view (ſays Mr Lovell), that the force which drew theſe carriages was employed only in overcoming the friction of the axle-tree, or in lifting the weight over the obſtacle. But I ſuſpected at the time, and have ſince been convinced, that an obſtruction of another ſort exiſted more conſiderable than either of theſe which I have mentioned, and which has not to my knowledge been taken notice of by any writer upon mechanics.”

52 uppoſed roof of the *vis inertiæ*, ndepen- ent of gra- ity.

This obſtruction is no other than the *vis inertiæ* of matter, which has ſo much engaged the attention of philoſophers, and the non-entity of which, in diſtinction from the power of gravity, ſeems now to be pretty generally admitted. The argument uſed for its exiſtence by Mr Edgeworth is as follows: “ After a carriage has been once ſet in motion upon a ſmooth road with any given velocity, its motion, ſo long as that velocity is continued, is neither retarded nor promoted by the *vis inertiæ*; but whenever it paſſes over any height, not only the weight of the carriage muſt be lifted up, but the *vis inertiæ* of that weight muſt be overcome in a new direction; and as much velocity muſt be communicated to it in that new direction as will enable it to riſe to the height of the obſtacle while it paſſes over its baſe. When an obſtacle is of ſuch a ſize and ſhape that a wheel of ſix feet diameter muſt ſtrike the top of it at once, and not roll from the bottom upwards, and when its ſhape will permit a ſmaller wheel to touch it during its whole aſcent, as there is more time allowed for overcoming the *vis inertiæ* of its weight in the latter caſe than in the former, the ſmaller wheel may be drawn forward by a leſs power than the larger, notwithſtanding the advantage of a lever, which is in favour of the larger wheel.”

To determine this, our author made uſe of an inclined plane five or ſix feet long and one foot high, placed on a ſmooth horizontal floor. He then aſſumed the diſtance to which the carriage was driven on the floor by the velocity acquired in deſcending the plane, as a meaſure of the force with which it could overcome any obſtacle placed in its way; and conſequently the diminution of the diſtance was the meaſure of the reſiſtance itſelf. Not ſatisfied with this apparatus, however, he ſcrewed a circle of iron three feet three inches in diameter upon a ſolid floor. In the centre of this circle he erected an upright axis or roller upon two pivots, one reſting in a ſocket of braſs upon the floor, the other in a bridge raiſed acroſs the machine. Around the axis was wound a ſmall ſilk cord, with a ſcale and weights faſtened to it, which paſſed over a pulley into an adjoining ſtair-caſe, and turned the axis with a determined velocity. An horizontal arm of wood extended from the axis to the circumference of the inner circle, and to the extremity of the arm was faſtened a piece of ſteel in form of the axle-tree of a carriage, having a wheel upon it, which by the motion of the axis was carried round upon its edge like the ſtone of a tanner's mill. The arm was furniſhed with an hinge, by means of which the wheel could riſe up and paſs over any obſtacle which ſtood in its way. Above this was another arm, having on its extremity a tin vane, which by its reſiſtance to the air regulated the motion of the machine. On putting weights into the ſcale, it was found that eight or ten turns were neceſſary to give the wheel an uniform velocity, which was preſerved in all the experiments, any reſiſtance thrown in the way being overcome by an addition of weight, and conſequently this addition being always an accurate meaſure of the reſiſtance.

On loading the wheel ſo as to weigh about four pounds, it acquired a velocity of ten feet in a ſecond by nearly five pounds and an half; but on placing in its way an obſtacle only a quarter of an inch high, ſix pounds and an half were required to cauſe the wheel paſs over it. Two ſuch obſtacles required fourteen and an half pounds; but on ſubſtituting two obſtacles of the ſame height, but making an inclined plane three quarters of an inch long, it required only two pounds to overcome their reſiſtance. “ The difference therefore (ſays he) between two and fourteen, muſt be attributed to the *vis inertiæ*; for the velocities of the carriage and the heights of the obſtacles remaining the ſame, the only difference that exiſts is, that in the one caſe the wheel has much more time to ſurmount the obſtacle than in the other, and conſequently had much leſs *vis inertiæ*.”

On this piece of reaſoning, however, it is impoſſible to avoid making the following remark, *viz*. that nothing happens but what ought to do ſo upon the common principles of mechanics. One obſtacle, when upright, required ſix pounds and an half to overcome it; but when an inclined plane three times the length was added to it, it ought then to have been overcome by a third part of the power, that is, by ſomething more than two pounds; and the reaſon why ſomething leſs than the third part was required, ſeems to have been the advantage the wheel had by acting as a lever; as has been already obſerved on the principles of Mr Anſtice. There is not therefore the leaſt occaſion to apply to a *vis inertiæ*, or any obſcure principle, for a ſolution of what may ſo eaſily be ſolved upon the common principles of mechanics and gravity.

53 Uſe of ſprings in carriages.

Mr Edgeworth concludes his obſervations with ſome remarks on the uſe of ſprings, which are found greatly to facilitate the draught of carriages. “ Whatever (ſays he) permits the load to riſe gradually over an obſtacle without obſtructing the velocity of the carriage, will tend to facilitate its draught; and the application of ſprings has this effect to a very conſiderable degree: the ſame weight of four pounds being drawn over the ſame obſtacles, when ſprings were put between the load and the carriage, by four pounds inſtead of 14. This remarkable difference points out the great advantage of ſprings in rough roads; an advantage which might be obtained for heavy waggons, as well as for other carriages, by a judicious application of the ſame means.

“ It appears from the Memoirs of the French academy, that the idea of applying ſprings to carriages had occurred to M. Thomas in the year 1703; who has given a drawing of a carriage conſtructed upon this principle many years before it was attempted to be put in execution. So little expectation had he of ſucceſs, that he expreſsly mentions it as a theory which could not be reduced to practice: he had, however, no notion of applying ſprings to facilitate the draught, but

but merely for the convenience of the rider; and I apprehend that it is not at preſent commonly imagined that ſprings are advantageous for this purpoſe; nor would it at firſt ſight apppear credible, that, upon a rough paved road, ſuch as are common in Cheſhire and other parts of England, a pair of horſes could draw a carriage mounted upon ſprings with greater eaſe and expedition than four could draw the ſame carriage if the ſprings and braces were removed, and the carriage bolted faſt down to the perch."

54
On high and low carriages.

Mr Lovell made alſo ſome experiments with high and low, long and ſhort, carriages, in order to determine which was the moſt advantageous, but could not recollect the particular reſults of each experiment. He was, however, aſſured, that the preference lately given in England to high carriages is ill-founded; and that, though in ſmooth roads, the height of the carriage is a matter of indifference, yet in rough roads it is very diſadvantageous. The length of carriages alſo, if their weight be not increaſed, is a matter of indifference, except in very uneven roads, and where there are deep ruts; long carriages being preferable in the former caſe, and ſhort ones in the latter.

The reaſon why ſprings ſo much facilitate the draught of carriages ſeems to be, not only that they allow the wheels to paſs more gradually over the obſtacles, as Mr Edgeworth ſays, but that by their elaſticity they make the carriage bound upwards every moment for a ſmall way. Thus its gravity is for that moment in a great meaſure counteracted, and the progreſſive motion which it has already acquired is at liberty to act more freely in puſhing it forward; for were it poſſible very ſuddenly to take away the horſes from a carriage mounted on ſprings, and moving with conſiderable velocity, it would continue for ſometime to move of itſelf; the weight in this caſe acting as a fly upon any mechanical engine, by means of which the machine accumulates a certain quantity of power, and will keep itſelf in motion for a conſiderable time after the hand is taken away from it. The weight of all carriages indeed has ſome effect of this kind, otherwiſe the draught would require an intolerable exertion of ſtrength; and it is to be obſerved, that this tendency to proceed in the direction in which it is once ſet a-going, is remarkable in all great quantities of matter, and very perceptible even when weights are pulled directly upward; for in raiſing great weights by a crane, the burden is lifted with conſiderably more eaſe when near the top than at bottom, even after making every neceſſary allowance for the weight of the rope, &c.

55
A carriage to go without any other force than what it receives from the paſſengers.
Fig. 85.

By means of wheels, ſome people have contrived carriages to go without horſes, or any other moving power than what was given by the paſſengers, by the wind, &c. One of theſe is repreſented by ABCD. It is moved by the footman behind it; and the fore-wheels, which act as a rudder, are guided by the perſon who ſits in the carriage (A).

Between the hind-wheels is placed a box, in which is concealed the machinery that moves the carriage. AA (fig. 86.) is a ſmall axis fixed into the box. B is a pulley, over which runs a rope, whoſe two ends are faſtened to the ends of the two levers or treddles CD, whoſe other ends are fixed in ſuch manner in the piece E, which is joined to the box, that they can eaſily move up and down. F, F, are two flat pieces of iron that are joined to the treddles, and take the teeth of the two wheels H, H, which are fixed on the ſame axis with the hind-wheels of the carriage, I, I.

It is evident, that when the footman behind preſſes down one of the treddles, ſuppoſe C, with his foot, he muſt bring down one of the pieces of iron F, and conſequently turn the wheel H that is next to it; and at the ſame time, by means of the rope that goes over the pulley, he muſt raiſe the other treddle D, together with its piece F, which being thruſt down will turn the other wheel H; and ſo alternately: and as the great wheels are fixed on the ſame axis, they muſt neceſſarily move at the ſame time.

It is eaſy to conceive, that if the ends of the treddles next E, inſtead of being placed behind the carriage, were turned the oppoſite way, ſo as to come under the feet of the perſon who ſits in it, he might move it with equal, or even greater facility, than the footman, as it would then be charged with the weight of one perſon only.

A machine of this kind will afford a ſalutary recreation in a garden or park, or on any plain ground; but in a rough or deep road muſt be attended with more pain than pleaſure.

56
To ſail as faſt, with a fair wind, by land, as by water.
Fig. 87.

Another contrivance for being carried without draught, is by means of a ſailing chariot or boat fixed on four wheels, as AB; which is driven before the wind by the ſails CD, and guided by the rudder E. In a chariot of this kind, the wheels ſhould be farther aſunder, and the axle-trees longer, than in other carriages, to prevent overturning.

A machine of this ſort was conſtructed in the laſt century by Stephinus, at Scheveling in Holland, and is celebrated by many writers. Its velocity with a ſtrong wind is ſaid to be ſo great, that it would carry eight or ten perſons from Scheveling to Putten, which is 42 Engliſh miles diſtant, in two hours.

Carriages of this kind are ſaid to be frequent in China; and in any wide, level country, muſt be ſometimes both pleaſant and profitable. The great inconvenience attending this machine is, that it can only go in the direction the wind blows, and even not then unleſs it blow ſtrong: ſo that, after you have got ſome way on your journey, if the wind ſhould fail, or change, you muſt either proceed on foot or go back. Some remedy for this inconvenience will be found in the next contrivance. The Hollanders have, or had, ſmall veſſels, ſomething of this kind, that carry one or two perſons on the ice, having a ſledge at bottom inſtead of wheels: and being made in the form of a boat, if the ice break the paſſengers are ſecured from drowning.

57
To ſail by land againſt the wind.
Fig. 88.

To ſail againſt the wind: Let ABCD be the body of a ſailing chariot: M the maſt, to which are fixed the wings or ſails EFGH; the two firſt of which, EF, are here ſuppoſed to be expanded by the wind; R is the rudder by which it is guided. Therefore the wind driving

---

(A) This machine was invented by M. Richard, a phyſician of Rochelle, and was exhibited at Paris in the laſt century. It is deſcribed by M. Ozanam in his *Recreations Mathematiques*.

driving the ſails round, with the maſt M, and the cog-wheel K, take the teeth placed perpendicular to the ſides of the two fore-wheels of the carriage, and conſequently keep it in continual motion.

The body of this machine ſhould not be large, nor placed very high, not only to prevent overturning, but that its motion may not be thereby impeded; for the velocity will be in proportion to the force of the wind on the ſails to that on the body of the machine. Therefore, if they be both equal, it will ſtand ſtill; or if the force on the body be greateſt, it will go backwards; unleſs there be a contrivance to lock the wheels. The upper part of the machine next A, may be made to take off when the wind is contrary; and there may be another ſet of ſails placed between the two hind-wheels, which will conſiderably increaſe its velocity. But after all, for general uſe, a common carriage muſt be preferable: for this cannot be expected to go up a moderate aſcent without great difficulty; nor down a declivity, when there is a ſtrong wind, without danger; and even on level ground, if the road be in any degree rough, its progreſs muſt be very ſlow, attended both with difficulty and danger. In an open country, however, where there is a large tract of level and ſmooth ground, and frequent ſtrong winds, a machine of this ſort will certainly be very convenient; and in moſt countries, when made of a ſmall ſize, may be uſeful to young people, by affording them a pleaſant and healthful exerciſe.

58 The uninvertible carriage. Fig. 89.

A carriage, the body of which is incapable of being overturned, may be made as follows. The body muſt conſiſt of a regular hollow globe, as AB, at the bottom of which is to be an immoveable weight, and which muſt be proportioned to the number of perſons or the load the machine is intended to carry. Round the globe muſt go two horizontal iron circles D, E, and two others F, G, that are perpendicular to the former. All theſe circles muſt be made exactly to fit the globe, that it may move freely in every direction. The two horizontal circles are to be joined on each ſide by a perpendicular bar, one of which is expreſſed in the figure by HI. All theſe irons ſhould be lined with leather, to prevent unneceſſary friction. The body of the carriage may be either of leather or hard wood; but the latter will be moſt elegible, as leaſt liable to wear. The wheel on each ſide is to be faſtened to the perpendicular bar by means of a handle K that keeps it ſteady.

Now the body of this machine moving freely in the iron circles every way, the centre of gravity will always lie at C; therefore, in whatever poſition the wheels are, or even if they overturn, the body of the carriage will conſtantly remain in the ſame perpendicular direction.

At L is placed a pin, round which is a hollow moveable cylinder: this pin moves up and down in the groove MN, that it may not impede the perpendicular motion of the circles, at the ſame time that it prevents the body of the machine from turning round in a horizontal direction. O is one of the windows, P the door, and QR the ſhafts to this machine.

When a carriage of this ſort is intended for a ſingle perſon, or a light weight, it may be hung on ſwivels, in the ſame manner as the rolling lamp or the ſea-compaſs, which will make its horizontal motion ſtill more regular: and when it is deſigned to carry ſeveral perſons, by adding another perpendicular bar on each ſide, between the two horizontal circles, it may be placed on four wheels. The body of this machine ſhould be frequently oiled or greaſed, not only to prevent any diſagreeable noiſe that may ariſe from its rubbing againſt the circles, but to prevent unneceſſary wear in the ſeveral parts.

This carriage is not intended for ſmooth roads, or a regular pavement; there certainly, thoſe of the common conſtruction are much preferable; nor ſhould a carriage totally free from irregular motion be ſought after by thoſe who are in perfect health: but there are many perſons, ſubject to different diſorders, who by being obliged to travel over rough roads in the common carriages, ſuffer tortures of which the healthful have no idea; to all theſe, therefore, and to every one who is forced to travel through dangerous roads, a carriage of this ſort muſt doubtleſs be highly deſirable.

As this deſign may appear to ſome perſons, on a ſuperficial view, impracticable, we ſhall here inſert an account of a ſimilar carriage, which we have taken from the firſt volume of the Abridgement of the Philoſophical Tranſactions, by Lowthorp. There is not, however, any deſcription of the manner in which that machine was conſtructed. The account is as follows: "A new ſort of calaſh deſcribed by Sir R. B. This calaſh goes on two wheels; carries one perſon; is light enough. Though it hangs not on braces, yet it is eaſier than the common coach. A common coach will overturn if one wheel go on a ſuperficies a foot and a half higher than the other; but this will admit of the difference of three feet and one-third in height of the ſuperficies, without danger of overturning. We choſe all the irregular banks, and ſides of ditches, to run over; and I have this day ſeen it, at five ſeveral times, turn over and over, and the horſe not at all diſordered. If the horſe ſhould be in the leaſt unruly, with the help of one pin you diſengage him from the calaſh without any inconvenience *(a contrivance of this ſort may be eaſily added to the foregoing deſign)*. I myſelf have been once overturned, and knew it not till I looked up and ſaw the wheel flat over my head: and if a man went with his eyes ſhut, he would imagine himſelf in the moſt ſmooth way, though at the ſame time there be three feet difference in the height of the ground of each wheel."

SECT. V. *Of Mills.*

MILL, in the proper ſenſe of the word, ſignifies a machine for grinding corn, though, in a more general ſenſe, it is applied to all machines which have an horizontal circulatory motion. Mills are diſtinguiſhed by particular names, ſometimes taken from the powers by which they are moved, and ſometimes from the uſes to which they are applied. Hence they are called hand-mills, horſe-mills, water-mills, fulling-mills, wind-mills, corn-mills, levigating mills, boring-mills, &c.

59 A hand-mill.

The moſt ſimple of theſe is the *hand mill*, repreſented fig. 90, where A and B repreſent the two ſtones between which the corn is ground, and of which the upper one A turns round, but the lower one (B) remains

mains fixed and immoveable. The upper ſtone is five inches thick, and 21 inches broad; the lower one ſomewhat broader. C is a cog-wheel, having 16 or 18 cogs, which go into the trundle F, having nine ſpokes fixed to the axis G, the latter being firmly inſerted into the upper ſtone A, by means of a piece of iron. H is the hopper into which the corn is put; I the ſhoe to carry it by little and little through a hole at K, in betwixt the ſtones, where being ground into meal, it comes out through the eye at L. Both ſtones are incloſed in a circular wooden caſe, of ſuch a ſize as will admit the upper one to run freely within it.—The under ſurface of the upper ſtone is cut into grooves, as repreſented at Q, which enable it to throw the meal out at the eye L more perfectly than could be done if it was quite plain. Neither of them are entirely flat, the upper one being ſomewhat concave, and the under one convex. They nearly touch at the edges, but are at ſome diſtance in the middle, in order to let the corn go in between them. The under ſtone is ſupported by ſtrong beams, not repreſented in the figure; the ſpindle G ſtands on the beam MN, which lies upon the bearer O. One end of this bearer reſts upon a fixed beam, and the other has a ſtring fixed to it, and going round the pin P, by the turning of which the timbers O and MN may be raiſed or lowered, and thus the ſtones put nearer, or removed farther from each other, in order to grind fine or coarſe. When the corn is to be ground, it muſt be put into the hopper by little at a time. A man turns the handle D, and thus the cog-wheel and trundle are carried round alſo together with the ſtone A. The axis G is angular at K; and, as it goes round, ſhakes the ſhoe I, and makes the corn fall gradually through the hole K. The upper ſtone going round grinds it, throwing out the meal, as already ſaid, at the eye L. Another handle, if thought proper, may be put at the other end of the handle E. The ſpindle muſt go through both ſtones, in order to reach the beam MN, and the hole through which it paſſes is faſtened with leather or wood, ſo that no meal can paſs through. Mr Emerſon, from whom this account is taken, obſerves, that "it is a pity ſome ſuch mills are not made at a cheap rate, for the ſake of the poor, who are much diſtreſſed by the roguery of the millers."

60
Horſe-mill.

The conſtruction of a horſe-mill differs not from that of the hand-mill juſt deſcribed, excepting that inſtead of the handle D, the ſpindle is furniſhed with a long horizontal lever and cogged wheel, which turns the trundle and ſtones, as already mentioned.—The ſtones are much heavier than in the hand-mill.

61
Water-mills.

The mills moſt commonly in uſe for grinding corn are water-mills, the conſtruction of which is not eſſentially different from that of the hand or horſe-mills.—The lower mill-ſtone, as already mentioned, is fixed, but the upper one moveable upon a ſpindle. The oppoſite ſurfaces of the two ſtones are not flat, but the one convex and the other concave, though in a very ſmall degree. The upper ſtone, which is ſix feet in diameter, is hollowed only about an inch in the middle, and the other riſes three quarters of an inch. They approach much nearer each other at the circumference, and the corn begins to be ground about two thirds of the radius diſtant from the circumference, and there it makes the greateſt reſiſtance, the ſpace between the two ſtones being in that place only about two-thirds or three-fourths of the thickneſs of a grain of corn; but as theſe ſtones, as well as thoſe of the hand-mill or horſe-mill, can be ſeparated a little from each other, the meal may be made fine or coarſe in them, as well as in the two former mills.

In order to cut and grind the corn, both the upper and under ſtones have furrows cut in them, as is obſerved in the hand-mill. Theſe are cut perpendicularly on one ſide, and obliquely upon the other, by which means each furrow has a ſharp edge, and by the turning of the ſtones, the furrows meet like a pair of ſciſſars, and by cutting the corn, make it grind the more eaſily. They are cut the ſame way in both ſtones when they lie upon their backs, by which means they run croſswiſe to each other when the upper one is inverted and turned round; and this greatly promotes the grinding of the corn, great part of which would be driven onward in the lower furrows, without being ground at all, if both lay the ſame way.—When the furrow becomes blunt and ſhallow by wearing, the running ſtone muſt be taken off, and the furrows cut deeper in both by means of a chiſſel and hammer. Thus, however, by having the furrows cut down a great number of times, the thickneſſes of both ſtones are greatly diminiſhed; and it is obſerved, that in proportion to the diminution of the thickneſs of the upper ſtone, the quantity of flour alſo diminiſhes.

By means of the circular motion of the upper ſtone, the corn is brought out of the hopper by jerks, and recedes from the centre towards the circumference by the centrifugal force; and being entirely reduced to flour at the edges when the ſtones nearly touch one another, it is thrown at laſt out at the hole called the eye, as already mentioned. In Scotland, it is frequent to have the ſtones without any furrows, and only irregularly indented with ſmall holes, by means of an iron inſtrument. Stones of this kind laſt a much ſhorter time than thoſe with furrows, the latter being fit for uſe for 30 or 40 years, while the former ſeldom or never laſt more than ſeven. The under millſtone is conſiderably thicker than the upper; and therefore, when both have been conſiderably worn by uſe, the lower one is frequently taken up, and the upper one put in its place, the former being converted into a running-ſtone.

62
Of water-mills.
Plate CCLXXXIX.

Fig. 91 ſhows the conſtruction of a common water mill, where AA is the large water-wheel, commonly about 17 or 18 feet diameter from a, the extremity of any float-board, to b the extremity of the oppoſite one. This wheel is turned round by the falling of the water upon the boards from a certain height, and the greater the height, provided the water runs in an uninterrupted ſtream, the ſmaller quantity will be ſufficient to turn the mill. This wheel is without the mill-houſe, but the wheel has an axle BB of conſiderable length, which paſſes through a circular hole in the wall, and has upon it a wheel D, of eight or nine feet diameter, having 61 cogs, which turn a trundle E of ten ſtaves or ſpokes; by which means the trundle, and conſequently the mill-ſtone, will make ſix revolutions, and one-tenth for every revolution of the wheel. The odd cog, commonly called the *hunting* cog, is added, that as every one comes to the trundle it may take the ſtaff behind that one which it took at the laſt revolution;

tion; and thus all the parts of the cogs and rounds which work upon one another will wear equally, and to equal diſtances from another, in a little time; by which means a true uniform motion will be produced through the whole work. The trundle is fixed upon an iron axis called the ſpindle, the lower end of which turns in a braſs pot fixed at F in the horizontal beam ST, called the *bridge-tree;* and the upper part of the ſpindle turns in a wooden buſh, fixed into the lower mill-ſtone, which lies upon beams in the floor YY. The top part of the ſpindle above the buſh is ſquare, and goes into a ſquare hole in a ſtrong iron croſs *abcd*, fig. 92, called the *rynd;* under which, and cloſe to the buſh, is a round piece of thick leather upon the ſpindle, which it turns round at the ſame time that it does the rynd. The latter enters into the grooves in the under ſurface of the running mill-ſtone G, fig. 91, and thus turns it round along with the trundle E, by means of the cog-wheel D. In the middle of the upper mill-ſtone is a large hole called the *eye*, through which the middle part of the rynd and upper part of the ſpindle may be ſeen; the ends being hid in the grooves below the ſtone. The end T of the bridge-tree TS, which ſupports the upper mill-ſtone G upon the ſpindle, is fixed into a hole in the wall; and the end S is let into the beam QR called the *brayer;* one end R of which remains fixed in a mortiſe, while the other end Q hangs by a ſtrong iron rod P, which goes through the floor YY, and has a ſcrew-nut on its top O; by the turning of which nut the end Q of the brayer is raiſed or depreſſed at pleaſure, along with the bridge-tree TS and upper mill-ſtone. Thus the upper mill-ſtone may be raiſed as high from the under one, or let down as cloſe to it, as the miller pleaſes; by which means the meal or flour is made either coarſe or fine at pleaſure. The upper mill-ſtone G is incloſed in a round box H, which leaves a vacant ſpace of about an inch all round. On the top of this box ſtands a frame for holding the hopper *k k*, at which hangs the ſhoe I, by two lines faſtened to the hinder part of it, fixed upon hooks in the hopper, and by one end of the ſtring K to the fore part of it at *i*, the other end being twiſted round the pin L. As the pin is turned one way, the ſtring draws up the ſhoe cloſer to the hopper, and ſo leſſens the aperture between them; and as the pin is turned the other way, it lets down the ſhoe, and widens the aperture. If it be drawn quite up to the hopper, no corn can fall out from the latter into the mill, and the quantity will be greater or leſs as the ſhoe is farther from the hopper or nearer to it. This happens by reaſon of the hopper being open at bottom, and the ſhoe at the forepart towards the end *i* over the middle of the eye of the mill-ſtone. There is alſo a ſquare hole in the top of the ſpindle, in which is put the feeder *e*, fig. 92. Thus the ſhoe is jogged three times in each revolution, and the corn runs conſtantly down from the hopper through the ſhoe into the eye of the mill-ſtone, where it falls upon the top of the rynd, and, by the motion of that and of the leather beneath, is introduced betwixt the ſtones, and by the violent motion of the upper one acquires a centrifugal force; and proceeding gradually from the eye of the mill-ſtone towards the circumference, is thrown at laſt out in flour, at the hole called the eye of the mill.

Some degree of nicety is requiſite in feeding the mill; for if too great a quantity be poured into it, the ſtones are ſeparated from each other more than they ought to be, and their motion is alſo impeded; while, on the other hand, if it be fed too ſlowly, the ſtone moves with too great velocity, and the attrition of the two is apt to make them ſtrike fire. This matter is regulated by turning the pin L backwards or forwards as the miller thinks proper.

Sometimes, where plenty of water can be had, there are two trundles applied to the cog-wheel by means of a ſingle large one turned immediately by the perpendicular cog-wheel, and carrying round with it an horizontal cogged wheel; on each ſide of which are placed the ſmaller trundles above-mentioned carrying the ſtones. In like manner, the water-wheel may be made to drive fanners, boulting-mills, &c. but it muſt always be remembered, that by complicating machinery to a great degree, it becomes more ready to give way; and the frequent reparation of which it ſtands in need, will, by the delay of buſineſs, be found at laſt more expenſive than if ſeparate machines had been uſed.

The wind-mill is furniſhed with an apparatus ſimilar to the water-mill, but neceſſarily differs in the external apparatus for applying the power. This is done by means of the two arms AB and CD, fig. 93, interſecting each other at right angles in E, and paſſing through the axis EF, and about 32 feet in length.—On theſe yards are placed two ſails or vanes, in the ſhape ſometimes of parallelograms, and ſometimes of trapeziums, with parallel baſes; the greater whereof HI is about ſix feet, and the length of the ſmaller FG is determined by radii drawn from the centre E to I and H.

As the direction of the wind is very uncertain, it becomes neceſſary to have ſome contrivance for turning the ſails towards it, in order to receive its force in whatever way it may turn; and for this purpoſe two general methods are in uſe. In the one, the whole machine is ſuſtained upon a moveable arbor or axis, perpendicular to the horizon, and which is ſupported by a ſtrong ſtand or foot very firmly fixed in the earth; and thus by means of a lever the whole machine may be turned round as occaſion requires. In the other method, only the roof, which is circular, can be turned round by means of a lever and rollers, upon which the circular roof moves. This laſt kind of wind-mill is always built of ſtone, in the form of a round turret, having a large wooden ring on the top of it, above which the roof, which muſt likewiſe be of wood, moves upon rollers, as has been already mentioned. To effect this motion the more eaſily, the wooden ring which lies on the top of the building is furniſhed with a groove, at the bottom of which are placed a number of braſs truckles at certain diſtances, and within the groove is placed another ring, by which the whole roof is ſupported. The beams *ab* and *ae* are connected with the moveable ring, and a rope is faſtened to the beam *ab* in *b*, which at the other extremity is fitted to a windlaſs or axis in peritrochio; and this rope being drawn through the iron hook G, and the windlaſs turned round, the ſails and roof will be turned round alſo, in order to catch the wind in any direction. Both theſe methods of conſtruction have their advantages and diſadvantages. The former is the leaſt expenſive, as the whole may be made of wood, Mills.

wood, and of any form that is thought proper; while the other requires a coſtly building of ſtone: and the roof being round, the building muſt alſo be ſo, while the other can be made of any form, but has the inconvenience of being liable to be carried off altogether by a very high wind, of which an inſtance occurred not long ago in Eſſex.

Fig. 94. ſhows the internal mechaniſm of a windmill. AHO is the upper room; H *o* Z the lower one; AB the axle-tree paſſing through the mill; STVW the ſails covered with canvas ſet obliquely to the wind, and turning round in the order of the letters. CD is the cog-wheel, having about 48 cogs *a a a*, &c. which carry round the lantern EF, having eight or nine trundles *c c c*, &c. along with the axis GN. IK is the upper mill-ſtone, LM the lower one; QR is the bridge ſupporting the axis or ſpindle GN, which reſts upon the beams *c d*, XY, wedged up at *c*, *d*, and X: ZY is the lifting tree, which ſtands upright; *ab* and *ef* are levers, having Z and *e* as centres of motion; *fghi* is a cord, with a ſtone *i* wound about the pins *g* and *h*, and which thus ſerves as a balance or counterpoiſe. The ſpindle *t* N is fixed to the upper mill-ſtone IK by means of a piece of iron called the rynd, and fixed in the lower ſide of the ſtone, the whole weight of which reſts upon a hard ſtone fixed in the bridge QR at N. The trundle EF and axis G may be taken away; for it reſts its lower part by *t* in a ſquare ſocket, and the top runs in the edge of the beam *w*. By bearing down the end of the lever *fe* we raiſe *b*, which raiſes alſo ZY, and this raiſes YX, which lifts up the bridge QR, with the axis NG, and the upper ſtone IK; ſo that by this contrivance the ſtones may, as in a water-mill, be ſet at any diſtance. The lower ſtone is fixed upon ſtrong beams, and is broader than the upper one; the flour being conveyed through the tunnel *n o* into a cheſt. P is the hopper into which the corn is put, and which runs along the ſpout *r* into the hole *t*, and ſo falls between the ſtones, where it is ground. The ſquare axis G *t* ſhakes the ſpout *r* as it turns round, and makes the corn run out; *r* is a ſtring going round the pin *s*, which ſerves to bring the ſpout nearer or let it go farther from the axis, and thus makes the corn to run faſter or ſlower according to the velocity of the wind. If the wind be very ſtrong, only part of the ſails S, T, V, W, is covered, or perhaps only one half of the two oppoſite ſails. Another cog-wheel B is placed towards the end B of the axle tree, with a trundle and mill-ſtones like thoſe already deſcribed; ſo that when the wind is ſtrong, the mill may do twice the buſineſs it ordinarily does. When only one pair is to grind, the trundle EF and axis G *t* are taken out from the other: *xyl* is a girt of pliable wood, fixed at the end *x*; and the other end *l* is tied to the lever *km*, moveable about *k*; and the end *m* being put down, draws the girt *xyl* cloſe to the cog-wheel; and thus the motion of the mill may be ſtopped at pleaſure: *pq* is a ladder for aſcending to the higher part of the mill; and the corn is drawn up by means of a rope rolled about the axis AB

63 A threſhing mill.

Beſides theſe mills for grinding corn, one has lately been invented by a Mr Winlaw for threſhing it out, and for which he has obtained a patent. It is repreſented fig. 95. A A A A repreſents the frame of the mill, B the cone, C a large iron wheel, D a regulating ſcrew, E a pinion, G the top curb ſurrounding the nut, H the fly.

Before the corn is put into this mill, it muſt undergo the operations of combing the bottoms of the ſheaves, and ſtripping the ears from the ſtraw. The former is performed by means of an hand-comb. The uſe is obvious, viz. to take out all the looſe ears, and ſtraw laid irregularly, which would otherwiſe be loſt, or impede the ſtripping of the ears. The comb for ſtripping the ears is made in the form of a croſs. The teeth are of an angular form, and ſet at convenient diſtances, ſo as to ſtrip the ears clean. If ſet too wide, they will paſs through without effect; and if too near together, they will not admit the ſtraw to go between them.

The grain is ſeparated from the chaff and ſtraw of the ear by the motion of the inner nut within the outward cone. The diſtance betwixt theſe is adjuſted by the regulating ſcrew D at the bottom; for if this be ſcrewed up too far, the grain will be bruiſed, if too far lowered down, the grain will not be ſeparated. The dart marked upon the fly ſhows the direction in which the handle is to be turned, it being pointed as the handle is to be turned.

This mill was tried in the month of June 1785, in the preſence of a number of gentlemen, with great ſatisfaction to the ſpectators; and ſince that time has been uſed by a number of others, though it has not as yet come into general uſe. At the firſt trial there paſſed through the mill one buſhel of heads per minute, with very moderate labour to the man who turned it; and by experiment it was found, that four buſhels of ears yielded one buſhel of clean grain. Hence it appears, that the difference betwixt the expedition of the mill and the labour of the threſher is immenſely great; for allowing that a man will threſh ſix buſhels per day at eight hours work, the mill will clear that quantity in 24 minutes, and that to much greater perfection than can be done by the flail, as it ſeparates every grain from the ear, which cannot but be accounted a very great ſaving; while much corn flies off by the flail, and a great deal is loſt by foul threſhing, either when performed by taſk or day-work. But by the uſe of the mill, all fraudulent practices muſt be prevented, the ſtraw preſerved in its original reed, and thus anſwer the purpoſes of thatching, &c. much better than when bruiſed under the flail; and every other purpoſe equally well. The ears may alſo be combed out with great expedition, as a lad without having practiſed was found to comb out a buſhel of ears in 20 minutes, which is at the rate of ſix buſhels of clean corn per day.—The ſaving by the uſe of this mill is calculated at 2½d. per buſhel. On a ſmaller ſcale the mill anſwers equally well for clover-ſeed, the flowers being firſt combed off from the ſtems; after which it will do as much work in three hours, as a man in the ordinary way can perform in a week; for a man cannot clean much above a buſhel in that time, which is the great reaſon of the high price of clover-ſeed. The mill will likewiſe anſwer for flax, canary, or any other ſeeds, or for ſeparating the huſks from rice, which in the preſent mode cannot be done without great labour and expence.

In all mills it is neceſſary that a conſiderable power be be employed in order to accomplish the intended purpoſe.---Water is the moſt common power, and indeed the beſt, as being the moſt conſtant and equable; while wind comes at ſometimes with great violence, and at others is totally gone. Mills may alſo be moved by the force of ſteam, as were the Albion-mills at London; but the expence of fuel muſt undoubtedly prevent this mode of conſtructing mills from ever becoming general. In all caſes it is abſolutely neceſſary to make the moſt of the power that we can, by making it act to the greateſt advantage. Hence the beſt methods of conſtructing water and wind-mills have been inveſtigated by thoſe who were moſt converſant in the principles of mechanics; and ſo difficult has been the inveſtigation, that the principles are not yet ſettled abſolutely without diſpute.

64 erent s of

The water-mills are of three kinds: *Breaſt-mills*, *Underſhot-mills*, and *Overſhot-mills*. In the former, the water falls down upon the wheel at right angles, to the float-boards or buckets placed all round the wheel to receive it: if float-boards are uſed, it acts only by its impulſe; but if buckets, it acts alſo by the weight of water in the buckets in the under quarter of the wheel, which is conſiderable. In the underſhot wheel float-boards only are uſed, and the wheel is turned merely by the force of the current running under it, and ſtriking upon the boards. In the overſhot-wheel the water is poured over the top, and thus acts principally by its weight; as the fall upon the upper part of the wheel cannot be very conſiderable. leſt it ſhould daſh the water out of the buckets. Hence it is evident, that an underſhot-mill muſt require a much larger ſupply of water than any other; the breaſt-mill the next, unleſs the fall is very great; and an overſhot mill the leaſt. Dr Deſaguliers found, that a well-made overſhot mill would perform as much work as an underſhot one with one tenth part of the quantity of water required by the other.

65 aton's rva- s on ls.

In the 51ſt volume of the Philoſophical Tranſactions, Mr Smeaton has conſidered at great length the beſt methods of conſtructing all theſe mills from machines and models made on purpoſe: but conſcious of the inferiority of *models* to actual practice, did not venture to give his opinion without having ſeen them actually tried, and the truth of his doctrines eſtabliſhed by practice.

Having deſcribed the machines and models uſed for making his experiments, he obſerves, that, with regard to power, it is moſt properly meaſured by the raiſing of a weight; or, in other words, if the weight raiſed be multiplied by the height to which it can be raiſed in a given time, the product is the meaſure of the power raiſing it; and, of conſequence, all thoſe powers are equal whoſe products made by ſuch multiplication are equal: for if a power can raiſe twice the weight to the ſame height, or the ſame weight to twice the height in the ſame time that another can, the former power will be double the latter; but if a power can only raiſe half the weight to double the height, or double the weight to half the height, in the ſame time that another can, the two powers are equal. This, however, muſt be underſtood only of a ſlow and equable motion, without acceleration or retardation; for if the velocity be either very quickly accelerated or retarded, the *vis inertiæ*, in our author's opinion, will produce an irregularity.

To compute the effects of water-wheels exactly, it is neceſſary to know in the firſt place what is the real velocity of the water which impinges on the wheel. 2. The quantity of water expended in a given time: and, 3. How much of the power is loſt by the friction of the machinery.

1. With regard to the velocity of the water, Mr Smeaton determined by experiments with the machinery deſcribed in the volume referred to, that with a head of water 15 inches in height, the velocity of the wheel is 8.96 feet in a minute. The area of the head being 105.8 inches, this multiplied by the weight of a cubic inch of water equal to .579 of an ounce avoirdupoiſe, gives 61.26 ounces for the weight of as much water as is contained in the head upon one inch in depth: and by further calculations derived from the machinery made uſe of, he computes that 264.7 pounds of water deſcend in a minute through the ſpace of 15 inches. The power of the water, therefore, to produce mechanical effects in this caſe will be 264.7×15, or 3970. From the reſult of the experiment, however, it appeared that a vaſt quantity of the power was loſt; the effect being only to raiſe 9.375 pounds to the height of 135 inches; ſo that the power was to the effect as 3970 to $9.375 \times 135 = 1266$, or as 10 to 3.18.

This, according to our author, muſt be conſidered as the greateſt ſingle effect of water upon an underſhot-wheel, where the water deſcends from an height of 15 inches; but as the force of the current is not by any means exhauſted, we muſt conſider the true proportion betwixt the power and effect to be that betwixt the quantity of water already mentioned and the ſum of all the effects producible from it. This remainder of power, it is plain, muſt be equal to that of the velocity of the wheel itſelf multiplied into the weight of the water. In the preſent experiment, the circumference of the wheel moved with the velocity of 3.123 feet in a ſecond, which anſwers to a head of 1.82 inches (A); and this height being multiplied by 264.7, the quantity of water expended in a minute gives 481 for the power of the water after it has paſſed the wheel; and hence the true proportion betwixt the power and the effect will be as 3849 to 1266; or as 11 to 4.

As the wheel revolved 86 times in a minute, the velocity of the water muſt be equal to 86 circumferences of the wheel; which, according to the dimenſions of the apparatus uſed by Mr Smeaton, was as 86 to 30, or as 20 to 7.—The greateſt load with which the wheel would move was 9 lb. 6 oz.; and by 12 lb. it was entirely ſtopped. Whence our author concludes,

---

(A) Theſe calculations are founded upon the known maxim in hydroſtatics, that the velocity of ſpouting water is nearly the ſame with that which an heavy body would acquire by fallinig from an height equal to that of the reſervoir, and is proved by the riſing of jets nearly to the height of their reſervoirs.

cludes, that the impulſe of the water is more than than double of what it ought to be according to theory: but this he accounts for by obſerving, that in his experiment the wheel was placed not in an open river, where the natural current, after it has communicated its impulſe to the float, has room on all ſides to eſcape, as the theory ſuppoſes, but in a conduit, to which the float being adapted, the water cannot otherwiſe eſcape than by moving along with the wheel. It is obſervable, that a wheel working in this manner, as ſoon as the water meets the float, receiving a ſudden check, it riſes up againſt the float like a wave againſt a fixed object, inſomuch that when the ſheet of water is not a quarter of an inch thick before the float, yet this ſheet will act upon the whole ſurface of a float whoſe height is three inches: and conſequently, was the float no higher than the thickneſs of the ſheet of water, as the theory alſo ſuppoſes, a great part of the force would have been loſt by the water daſhing over the float.

Mr Smeaton next proceeds to give tables of the velocities of wheels with different heights of water; and from the whole deduces the following concluſions.

1. The virtual, or effective head, being the ſame, the effect will be nearly as the quantity of water expended.

2. The expence of water being the ſame, the effect will be nearly as the height of the virtual or effective head.

3. The quantity of water expended being the ſame, the effect is nearly as the ſquare of the velocity.

4. The aperture being the ſame, the effect will be nearly as the cube of the velocity of the water. Hence, if water paſſes out of an aperture in the ſame ſection, but with different velocities, the expence will be proportional to the velocity; and therefore, if the expence be not proportional to the velocity, the ſection of the water is not the ſame.

5. The *virtual* head, or that from which we are to calculate the power, bears no proportion to the head water; but when the aperture is larger, or the velocity of the water leſs, they approach nearer to a coincidence: and conſequently, in the large openings of mills and ſluices, where great quantities of water are diſcharged from moderate heads, the head of water, and virtual head determined from the velocity, will nearly agree, which is alſo confirmed by experience.

6. The moſt general proportion betwixt the power and effect is that of 10 to 3; the extremes 10 to 3.2, and 10 to 2.8. But as it is obſervable, that where the power is greateſt, the ſecond term of the ratio is greateſt alſo; whence we may allow the proportion ſubſiſting in great works to be as three to one.

7. The proportion of velocity between the water and wheel is in general about 5 to 2.

8. There is no certain ratio between the load that the wheel will carry at its *maximum*, and what will totally ſtop it; though the proportions are contained within the limits of 20 to 19, and 20 to 15; but as the effect approaches neareſt to the ratio of 20 to 15, or of 4 to 3 when the power is greateſt either by increaſe of velocity or quantity of water, this ſeems to be the moſt applicable to large works: but as the load that a wheel ought to have, in order to work to the beſt advantage, can be aſſigned by knowing the effect that it ought to produce, and the velocity it ought to have in producing it, the exact knowledge of the greateſt load it will bear is of the leaſt conſequence in practice.

Mr Smeaton, after having finiſhed his experiments on the underſhot mills, reduced the number of floats, which were originally 24, to 12; which cauſed a diminution in the effect, by reaſon that a greater quantity of water eſcaped between the floats and the floor than before; but on adapting to it a circular ſweep of ſuch a length, that one float entered into the curve before the other left it, the effect came ſo near that of the former, as not to give any hopes of advancing it by increaſing the number of floats beyond 24 in this particular wheel.

Our author next proceeds to examine the power of water when acting by its own gravity in turning an overſhot wheel: "In reaſoning without experiment (ſays he,) one might be led to imagine, that however different the mode of application is, yet that, whenever the ſame quantity of water deſcends through the ſame perpendicular ſpace, the natural effective power would be equal, ſuppoſing the machinery free from friction, equally calculated to receive the full effect of the power, and to make the moſt of it: for if we ſuppoſe the height of a column of water to be 30 inches, and reſting upon a baſe or aperture of one inch ſquare, every cubic inch of water that departs therefrom will acquire the ſame velocity or momentum from the uniform preſſure of 30 cubic inches above it, that one cubic inch let fall from the top will acquire in falling down to the level of the aperture; one would therefore ſuppoſe that a cubic inch of water let fall through a ſpace of 30 inches, and there impinging upon another body, would be capable of producing an equal effect by colliſion, as if the ſame cubic inch had deſcended through the ſame ſpace with a ſlower motion, and produced its effects gradually. But however concluſive this reaſoning may ſeem, it will appear in the courſe of the following deductions, that the effect of the gravity of deſcending bodies is very different from the effect of the ſtroke of ſuch as are non-elaſtic, though generated by an equal mechanical power."

Having made ſuch alterations in his machinery as were neceſſary for overſhot wheels, our author next gives a table of experiments with the apparatus ſo altered. In theſe the head was 6 ſix inches, and the height of the wheel 24 inches; ſo that the whole deſcent was 30 inches: the quantity of water expended in a minute was $96\frac{2}{3}$ pounds; which multiplied by 30 inches, gives the power $=2900$: and after making the proper calculations, the effect was computed at 1914; whence the ratio of the power to it comes to be nearly as 3 to 2. If, however, we compute the power from the height of the wheel only, the power will be to the effect nearly as 5 to 4.

From another ſet of experiments the following concluſions were deduced.

1. The effective power of the water muſt be reckoned upon the whole deſcent; becauſe it muſt be raiſed to that height in order to be able to produce the ſame effect a ſecond time. The ratios between the powers

powers ſo eſtimated and the effects at a *maximum*, differ nearly from 4 to 3, and from 4 to 2. Where the heads of water and quantities of it expended are the leaſt, the proportion is nearly from 4 to 3; but where the heads and quantities are greateſt, it comes nearer to that of 4 to 2; ſo that by a medium of the whole the ratio is nearly as 3 to 2. Hence it appears, that the effect of overſhot wheels is nearly double to that of underſhot ones; the conſequence of which is, that non-elaſtic bodies, when acting by their impulſe or colliſion, communicate only a part of their original impulſe, the remainder being ſpent in changing their figure in conſequence of the ſtroke. The ultimate concluſion is, that the effects as well as the powers are as the quantities of water and perpendicular heights multiplied together reſpectively.

2. By increaſing the head, it does not appear that the effects are at all augmented in proportion; for by raiſing it from 3 to 11 inches, the effect was augmented by leſs than one-ſeventh of the increaſe of perpendicular height. Hence it follows, that the higher the wheel is in proportion to the whole deſcent, the greater will be the effect; becauſe it depends leſs upon the impulſe of the head, and more upon the gravity of the water in the buckets: and if we conſider how obliquely the water iſſuing from the head muſt ſtrike the buckets, we ſhall not be at a loſs to account for the little advantage that ariſes from the impulſe thereof, and ſhall immediately ſee of how little conſequence this is to the effect of an overſhot wheel. This, however, as well as other things, muſt be ſubject to limitation; for it is neceſſary that the velocity of the water ſhould be ſomewhat greater than the wheel, otherwiſe the latter will not only be retarded by the ſtriking of the buckets againſt the water, but ſome of the power will be loſt by the daſhing of the water over the buckets.

3. To determine the velocity which the circumference of the wheel ought to have in order to produce the greateſt effect, Mr Smeaton obſerves, that the more ſlowly any body deſcends by the force of gravity when acting upon any piece of machinery, the more of that force will be ſpent upon it, and conſequently the effect will be the greater. If a ſtream of water falls into the bucket of an overſhot wheel, it will be there retained till the wheel diſcharges it by moving round; and of conſequence, the ſlower the wheel moves, the more water it will receive; ſo that what is loſt in velocity is gained by the greater preſſure of water upon the buckets. From the experiments, however, it appears, that when the wheel made about 20 turns in a minute the effect was greateſt; when it made only $18\frac{1}{4}$ the motion was irregular; and when loaded ſo as not to admit its turning 18 times, the wheel was overpowered with the load. When it made 30 turns, the power was diminiſhed by about $\frac{1}{20}$th, and when the number of turns was increaſed to 40, it was diminiſhed by one-fourth. Hence we ſee, that in practice the velocity of the wheel ſhould not be diminiſhed farther than what will procure ſome ſolid advantage in point of power; becauſe, *ceteris paribus*, the buckets muſt be larger as the motion is ſlower; and the wheel being more loaded with water, the ſtreſs will be proportionably increaſed upon every part of the work. The beſt velocity for practice therefore will be that when the wheel made 30 turns in a minute, which is little more than three feet in a ſecond. This velocity is applicable to the higheſt overſhot wheels as well as the loweſt. Experience however determines, that high wheels may deviate further from this rule before they will loſe their power, by a given aliquot part of the whole, than low ones can be permitted to do; for a wheel of 24 feet high may move at the rate of 6 feet *per* ſecond; while our author has ſeen one of 33 feet high move very ſteadily and well with a velocity of little more than two feet. The reaſon of this ſuperior velocity in the 24 feet wheel, may probably be owing to the ſmall proportion that the head requiſite to give the proper velocity to the wheel bears to the whole height.

4. The maximum load for an overſhot wheel is that which reduces the circumference of the wheel to its proper velocity; which is known by dividing the effect it ought to produce in a given time by the ſpace intended to be deſcribed by the circumference of the wheel in the ſame time: the quotient will be the reſiſtance overcome at the circumference of the wheel, and is equal to the load required, including the friction and reſiſtance of the machinery.

5. The greateſt velocity that an overſhot wheel is capable of, depends jointly upon the diameter or height of the wheel and the velocity of falling bodies; for it is plain that the velocity of the circumference can never be greater than to deſcribe a ſemi-circumference, while a body let fall from the top deſcribes the diameter, nor even quite ſo great; as the difference in point of time muſt always be in favour of that which falls through the diameter. Thus, ſuppoſing the diameter of the wheel to be 16 feet and an inch in diameter, an heavy body would fall through this ſpace in one ſecond; but ſuch a wheel could never arrive at this velocity, or make one turn in two ſeconds, nor could an overſhot wheel ever come near it; becauſe, after it has acquired a certain velocity, great part of the water is prevented from entering the buckets, and part is thrown out again by the centrifugal force: and as theſe circumſtances have a conſiderable dependence upon the form of the buckets, it is impoſſible to lay down any general rule for the velocity of this kind of wheels.

6. Though in theory we may ſuppoſe a wheel to be made capable of overcoming any reſiſtance whatever, yet as in practice it is neceſſary to make the wheel and buckets of ſome certain and determinate ſize, we always find that the wheel will be ſtopped by ſuch a weight as is equal to the effort of the water in all the buckets of a ſemi-circumference put together. This may be determined from the ſtructure of the buckets themſelves; but in practice, an overſhot wheel becomes unſerviceable long before this time; for when it meets with ſuch an obſtacle as diminiſhes its velocity to a certain degree, its motion becomes irregular; but this never happens till the velocity of the circumference is leſs than the two feet *per* ſecond, when the reſiſtance is equable.

7. From the above obſervations, we may eaſily deduce the force of water upon breaſt-wheels, &c. But in general, all kinds of wheels where the water cannot deſcend through a given ſpace unleſs the wheel moves with it, are to be conſidered as overſhot wheels; and

thoſe

thoſe which receive the impulſe or ſhock of the water, whether in an horizontal, oblique, or perpendicular direction, are to be conſidered as underſhots. Hence a wheel in which the water ſtrikes at a certain point below the ſurface of the head, and after that deſcends in the arch of a circle, preſſing by its gravity upon the wheel, the effect of ſuch a wheel will be equal to that of an underſhot whoſe head is equal to the difference of level between the ſurface of the water in the reſervoir and the point where it ſtrikes the wheel, added to that of an overſhot, whoſe height is equal to the difference of level between the point where it ſtrikes the wheel and the level of the tail-water.

66
Diſpute concerning Sir Iſaac Newton's doctrine of motion conſidered.

In the 66th volume of the Tranſactions, our author conſiders ſome of the cauſes which have produced diſagreements and diſputes among mathematicians upon this ſubject. He obſerves, that ſoon after Sir Iſaac Newton had given his definition, "that the quantity of motion is the meaſure of the ſame, ariſing from the velocity and quantity of matter conjointly," it was controverted by his cotemporary philoſophers. They maintained, that the meaſure of the quantity of motion ſhould be eſtimated by taking the quantity of matter and the ſquare of the velocity conjointly. On this ſubject he remarks, that from equal impelling powers acting for equal intervals of time, equal augmentations of velocity are acquired by given bodies when they are not reſiſted by a medium. Thus a body deſcending one ſecond by the force of gravity, paſſes through a ſpace of 16 feet and an inch; but at the end of that time it has acquired a velocity of 32 feet 2 inches in a ſecond; at the end of two ſeconds, it has acquired one that would carry it through 64 feet 4 inches in a ſecond. If, therefore, in conſequence of this equal increaſe of velocity, we define this to be a double quantity of motion generated in a given time in a certain quantity of matter, we come near to Sir Iſaac's definition: but in trying experiments upon the effects of bodies, it appears, that when a body is put in motion by whatever cauſe, the impreſſion it will make upon an uniformly reſiſting medium, or upon uniformly yielding ſubſtances, will be as the maſs of matter of the moving body multiplied by the ſquare of its velocity. The queſtion therefore properly is, whether thoſe terms, the *quantity of motion*, the *momenta*, or *forces* of bodies in motion, are to be eſteemed equal, double, or triple, when they have been generated by an equable impulſe acting for an equal, double, or triple time? or that it ſhould be meaſured by the effects being equal, double, or triple, in overcoming reſiſtances before a body in motion can be ſtopped? For according to the meaning we put upon theſe words, the momenta of equal bodies will be as the velocities or ſquares of the velocities of the moving bodies.

Though by a proper attention to the terms employed, however, we will find both theſe doctrines to be true; it is certain that ſome of the moſt celebrated writers upon mechanics have fallen into errors by neglecting to attend to the meaning of the terms they make uſe of. Deſaguliers, for inſtance, after having been at pains to ſhow that the diſpute, which in his time had ſubſiſted for 50 years, was a diſpute merely about words, tells us, that both opinions may be eaſily reconciled in the following caſe, viz. that the wheel of an underſhot water-mill is capable of doing quadruple work when the velocity of the water is doubled, inſtead of double work only: "For (ſays he) the adjutage being the ſame, we find, that as the water's velocity is double, there are twice the number of particles that iſſue out, and therefore the ladle-board is ſtruck by twice the matter; which matter moving with twice the velocity that it had in the firſt caſe, the whole effect muſt be quadruple, though the inſtantaneous ſtroke of each particle is increaſed only in a ſimple proportion of the velocity." In another place, the ſame author tells us, that though "the knowledge of the foregoing particulars is abſolutely neceſſary for ſetting an underſhot wheel to work, yet the advantage to be reaped from it would be ſtill gueſswork; and we ſhould be at a loſs to find out the utmoſt that it could perform, had it not been for an ingenious propoſition of that excellent mechanic M. Parent of the Royal Academy of Sciences, who has ſhowed, that an underſhot wheel can do the moſt work when its velocity is equal to the third part of that of the water; becauſe then two-thirds of the water is employed in driving the wheel, with a force proportionable to the ſquare of the velocity. By multiplying the ſurface of the adjutage or opening by the height of the water, we ſhall have the column of water that moves the wheel. The wheel thus moved will ſuſtain on the oppoſite ſide only four-ninths of that weight which will keep it in equilibrio; but what it can move with the velocity it has, is only one-third of the equilibrium." This concluſion is likewiſe adopted by Mr Maclaurin.

67
Enormous miſtakes of Belidor and others.

Underſhot wheels had been greatly preferred by M. Belidor to thoſe of any other conſtruction. He had even concluded, that water applied in this way will do more than ſix times the work of an overſhot wheel; while Dr Deſaguliers, in overthrowing Belidor's propoſition, determined that an overſhot wheel would do 10 times the work of an underſhot wheel with an equal quantity of water. Between theſe two celebrated authors, therefore, there is a difference of no leſs than 60 to 1.

In conſequence of ſuch monſtrous diſagreement, Mr Smeaton began the experiments of which we have already given an account. From them, beſides the poſitions already deduced, it appears, that where the velocity of water is double, the adjutage or aperture of the ſluice remaining the ſame, the effect is eight times; that is, not as the ſquare, but as the cube of the velocity. In the other concluſion of Deſaguliers and Maclaurin, the error was no leſs; for from thence it would follow, that by means of the wheel only $\frac{4}{27}$ths of the water expended would be raiſed back again to the height of the reſervoir from which it deſcended, excluſive of the friction, which would ſtill diminiſh the quantity: but from Mr Smeaton's experiments it appears, that in ſome caſes upwards of one-fourth had been raiſed. In large works the effects had been ſtill greater, approaching in an underſhot wheel to one half, and in an overſhot one to the whole; which would be the limit, if it were poſſible, to remove the friction and reſiſtance of the air. The velocity of the wheel alſo, which, according to the concluſions of M. Parent and Dr Deſaguliers, amounted to no more than one-third of the velocity of the water, varies, according to Mr Smeaton, between one-third and one-half. But in all great works the maximum lieth much nearer to one-half than a third; the former appearing to be the true maximum, if all friction, reſiſtance of the air, and ſcattering of water, could be avoided.

To make theſe matters plain to mechanics, and to prevent them from running into practical errors in conſequence of a fallacious theory, Mr Smeaton, in the year 1759, inſtituted another ſet of experiments; the immediate object of which was, to determine what proportion or quantity of mechanical power is expended in giving the ſame body different degrees of velocity. Having conſtructed a proper apparatus for the purpoſe, and with it made a number of experiments, he concludes, "that time, properly ſpeaking, has nothing to do with the production of mechanical effects otherwiſe than as by equally flowing it becomes a common meaſure; ſo that whatever mechanical effect is found to be produced in a given time, the uniform continuance of the action of the ſame mechanical power will, in a double time, produce twice that effect. A mechanical power, therefore, properly ſpeaking, is meaſured by the whole of its mechanical effects produced, whether that effect be produced in a greater or leſſer time: thus, having treaſured up 1000 tuns of water, which I can let out upon the overſhot wheel of a mill, and deſcending through a perpendicular of 20 feet; this power, applied in a proper manner, will grind a certain quantity of corn in an hour: but ſuppoſing the mill to be capable of receiving a greater impulſe with as great advantage as a leſſer; then, if the corn be let out twice as faſt, the ſame quantity of water will be ground in half an hour, the whole of the water being likewiſe expended in that time. What time has therefore to do in the caſe is this: let the rate of doing the buſineſs or producing the effect be what it will; if this rate is uniform, when I have found by experiment what is done in a given time, then, proceeding at the ſame rate, twice the effect will be produced in twice the time, on ſuppoſition that I have a ſupply of mechanic power to go on with. Thus, 1000 tons of water deſcending through 20 feet perpendicular, being, as has been ſhown, a given mechanic power, let it be expended at what rate it will; if, when this is expended, we are to wait another hour till an equal quantity can be procured, then we can only expend 12 ſuch quantities in 24 hours. But if, while the thouſand tons of water are expending in one hour, the ſame quantity is renewed, we can then expend 24 ſuch in the 24 hours, or go on without intermiſſion. The product or effect will then be in proportion to time, which is the common meaſure; but the quantity of mechanic power ariſing from the flow of the two rivers, compared by taking an equal portion of time, is double in the one to the other; though each has a mill that, when going, will grind an equal quantity of corn in an hour."

Mr Ferguſon, in his directions to mill-wrights, has adopted the maxim which Mr Smeaton condemns as erroneous, viz. that when the velocity of the wheel is but one-third of that of the water, it then acts to the greateſt advantage. He adds, that the millſtone ought to make about 60 turns in a minute; for when it makes only 40 or 50 turns it grinds too ſlowly; and when more than 70, it heats the meal too much, and cuts the bran ſo ſmall, that a part of it mixes with the meal and cannot be ſeparated from it by any means. The utmoſt perfection of mill-work, therefore, according to this author, lies in making the train ſo that the mill-ſtone ſhall make about 60 turns in a minute, when the wheel moves with one-third of the velocity of the water. To accompliſh this he lays down the following rules. 1. Meaſure the perpendicular height of the fall of water above the middle of the aperture, where it is let out to act by impulſe againſt the float-boards on the lower ſide of the underſhot wheel. 2. Multiply this conſtant number 64.2882 by the height of the fall in feet, and extract the ſquare-root of the product, which will give the number of feet that the water moves in a ſecond. 3. The velocity of the floats of the wheel is equal to one-third of the velocity of the water juſt now found. 4. Divide the circumference of the wheel by the velocity of its floats, and the quotient will be the number of ſeconds in one turn of the great water-wheel, on whoſe axis the cog-wheel that turns the trundle is fixed. 5. Divide 60 by the number of ſeconds in a turn of the water-wheel, and the quotient will be the number of turns it makes in a minute. 6. By this number of turns divide 60, the number of times that a mill-ſtone ought to have in a minute; the quotient is the number of turns that the mill-ſtone ought to make for every one of the large wheel. 7. Then as the number of turns required of the mill-ſtone in a minute is to the number of turns of the cog-wheel in a minute; ſo muſt the number of cogs in the wheel be to the number of ſtaves in the trundle on the axis of the mill-ſtone, in the neareſt whole number that can be found.

On theſe principles Mr Ferguſon has conſtructed the following table, for the ſake of ſuch as have occaſion to conſtruct mills, and are not willing to take the trouble of particular calculations.

The Mill-wright's Table.

Height of the fall of water.	Velocity of the fall of water per ſecond.		Velocity of the wheel per ſecond.		Revolutions of the wheel per minute.		Revolution of the millſtone for one of the wheel		Cogs in the wheel, and ſtaves in the trundle.		Revolutions of the millſtone per minute by theſe ſtaves and cogs.

68
Imiſon's practical rules for the conſtruction of mills.

For the practical conſtruction of water-mills, Mr Imiſon hath laid down the following rules.

1. To find the velocity or force of any moderate ſtream of water; let it be obſtructed by a dam in ſuch a manner as to force the whole ſtream into a ſpout by which it may be conveyed into a large veſſel or reſervoir. Meaſure then the quantity of water which falls into the reſervoir in one ſecond or minute; and multiplying by the number of ſeconds or minutes in an hour, we have the whole force of the ſtream of water *per* hour. In ſtreams which are too large to be meaſured in this way, the velocity is determined (though we muſt own in a vague manner) by that of ſtraw or other light body floating down it; and calculations may be made accordingly.

Mr Imiſon differs very materially from Mr Ferguſon in the number of revolutions which a mill-ſtone ought to make in a minute; the latter, as has been already mentioned, being of opinion, that 60 revolutions of a mill-ſtone in a minute are ſufficient, while Mr Imiſon requires 120; though he agrees with him that the velocity of the wheel ſhould be only one-third of that of the water. The mill-ſtone, according to Mr Ferguſon, ought to be five feet in diameter; but Mr Imiſon makes it only four feet and an half.

To conſtruct a mill by this table, find the height of the fall of water in the firſt column, and againſt that height in the ſixth column you have the number of cogs in the wheel and ſtaves in the trundle for cauſing the millſtone 4 feet 6 inches diameter to make about 120 revolutions in a minute, as near as poſſible, when the wheel goes with one-third part of the velocity of the water. And it appears by the 7th column, that the number of cogs in the wheel and ſtaves in the trundle are ſo near the truth for the required purpoſe, that the leaſt number of revolutions of the mill-ſtone in a minute is 118, and the greateſt number never exceeds 121; which, according to our author, is the velocity of the beſt mills he had ſeen.

With regard to the mere mechanical part, our author obſerves, that an overſhot wheel acts with greater power than a breaſt or underſhot wheel; ſo that where there is a conſiderable deſcent, and only a ſmall quantity of water, the overſhot wheel ought always to be made uſe of. Where the water runs only upon a little declivity, it can act but ſlowly upon the under part of the

the wheel; in which caſe, the motion of the wheel will be very ſlow: the float-boards therefore ought to be very long, though not high, that a large body of water may act upon them; ſo that what is wanting in velocity may be made up in power: in which caſe, the cog wheel may have a greater number of cogs in proportion to the ſtaves of the trundle, in order to give the mill-ſtone a ſufficient degree of velocity.

For the conſtruction of the different parts of mills, Mr Imiſon gives the following general directions:

The method for ſetting out a ſpur-wheel and wallower.—Draw the pitch lines A1, B1, A2, 2B; then divide
g.96. them into the number of teeth or cogs required, as *abc*.

Divide one of thoſe diſtances, as *bc*, into ſeven equal parts, as 1, 2, 3, 4, 5, 6, 7: three parts allow for the thickneſs of the cogs, as 1, 2, 3, in the cog *a*, and four for the thickneſs of the ſtave, of the wallower (one reaſon for allowing three parts for the cog and four for the ſtave, is, the wallower is in general of leſs diameter than the wheel, therefore ſubject to more wear in proportion of the number of cogs to the number of ſtaves; but if there is the ſame number of ſtaves as of cogs, they may be of equal thickneſs), as 1, 2, 3, 4, in the ſtave *m*, fig. 97. the height of the cog is equal to four parts; then divide its height into five equal parts, as 1, 2, 3, 4, 5, in the cog C; allow three for the bottom to the pitch line of the cog; the other two parts for epicycloid, ſo as to fit and bear on the ſtave equally. The mill-wrights in general put the point of a pair of compaſſes in the dot 3, of the cog *a*, and ſtrike the line *de*; then remove the point of the compaſſes to the point *d*, and ſtrike the curve line 3*f*, which they account near enough the figure of the epicycloid.

The method for a face-wheel is thus: Divide the pitch line AB into the number of cogs intended, as *abc*; divide the diſtance *bc* into ſeven equal parts; three of thoſe parts allow for the thickneſs of the cogs, as 1, 2, 3, in the cog *a*, four for the height and four for the width, as *de*, and four for the thickneſs of the ſtave *m*; draw a line through the centre of the cog, as the line AI at S: and on the point 5 deſcribe the line *de*; remove the compaſſes to the point A, and draw the line *fg*, which forms the ſhape of the cog; then ſhape the cog on the ſides to a cycloid, as *defg*. But this method of ſetting out the ſhape of a cog is variable, according to the cycloid in different diameters of wheels.

In common ſpur-nuts, divide the pitch line A into twice as many equal parts as you intend teeth, as *a*, *b*, *c*, *d*, *e*, fig. 98.; with a pair of compaſſes opened to half the diſtance of any of thoſe diviſions, from the points *a*1, *c*3, *e*5, draw the ſemicircles *a*, *c*, and *e*, which will form the ends of the teeth. From the points 2, 4, and 6, draw the ſemicircles *ghi*, which will form the hollow curves for the ſpaces; but if the ends of the teeth were epicycloids, inſtead of ſemicircles, they would act much better.

The principle of bevel geer,—conſiſts in two cones,
ig. 99. rolling on the ſurface of each other, as the cone A and B revolving on their centres *ab*, *ac*; if their baſes are equal, they will perform their revolutions in one and the ſame time, or any other two points equally diſtant from the centre *a*, as *d*1, *d*2, *d*3, &c. will revolve in the ſame time as *f*1, *f*2, *f*3, &c. In the like manner, if the cones *afde* be twice the diameters at the baſe Plates CCLXXXIX, CCXC. fig. 100, 101. *de*, as the cones *afe* are; then if they turn about their centres, when the cone *afd* has made one revolution, the cone *ade* will have made but half a revolution; or when *afd* has made two revolutions, *ade* will have made but one, and every part equally diſtant from the centre *a*, as *f*1, *f*2, *f*3, &c. will have made two revolutions to *e*1, *e*2, *e*3, &c. and if the cones were fluted, or had teeth cut in them, diverging from the centre *a* to the baſes *dc*, *ef*, they would then become bevel geer. The teeth at the point of the cone being ſmall and of little uſe, may be cut off at E and F, figs. 102, 103. as ſeen by Plate CCXC. fig. 104. where the upright ſhaft *ab*, with the bevel wheel *cd*, turns the bevel wheel *ef* with its ſhaft *bg*, and the teeth work freely into each other, as *ab*, fig. 105. The teeth may be made of any dimenſion, according to the ſtrength required; and this method will enable them to overcome a much greater reſiſtance, and work ſmoother than a face wheel and wallower of the common form can poſſibly do; beſides, it is of great uſe to convey a motion in any direction, or to any part of a building, with the leaſt trouble and friction.

The method of conveying motion in any direction, and proportioning or ſhaping the wheels thereto, is as follows: let the line *ab* repreſent a ſhaft coming from Fig. 106.
a wheel; draw the line *ed* to interſect the line *ab*, in the direction that the motion to be conveyed is intended, which will now repreſent a ſhaft to the intended motion.

Again, ſuppoſe the ſhaft *ed* is to revolve three times, whilſt the ſhaft *ab* revolves once, draw the parallel line *ii*, at any diſtance not too great, ſuppoſe one foot by a ſcale; then draw the parallel line *kk* at three feet diſtance, after which draw the dotted line *w*X, through the interſection of the ſhafts *ab* and *ed*, and likewiſe through the interſection of the parallel lines *ii* and *kk*, in the points X and *y*; which will be the pitch line of the two bevel wheels, or the line where the teeth of the two wheels act on each other, as may be ſeen fig. 107. where the motion may be conveyed in any direction.

The univerſal joint, as repreſented fig. 108. may be applied to communicate motion inſtead of bevel geer, where the ſpeed is to be continued the ſame, and where the angle does not exceed 30 or 40 degrees, and the equality of motion is not regarded; for as it recedes from a right line, its motion becomes more irregular. This joint may be conſtructed by a croſs, as repreſented in the figure; or with four pins faſtened at right angles upon the circumference of a hoop or ſolid ball. It is of great uſe in cotton-mills, where the tumbling ſhafts are continued to a great diſtance from the moving power. But by applying this joint, the ſhafts may be cut into convenient lengths, by which it will be enabled to overcome greater reſiſtance.

To deſcribe the cycloid and epicycloid, of uſe in ſhaping the teeth of wheels, &c.—If a point or pencil *a* on the Fig. 109.
circumference of the circle B proceeds along the plane *a*C in a right line, and at the ſame time revolves round its centre, it will deſcribe a cycloid.

And if the generating circle D moves along the Fig. 110.
circumference of another circle E, and at the ſame time turns round its centre, the point of contact will deſcribe an epicycloid.

In the conſtruction of wind-mills, Mr Smeaton has been at no leſs pains to explain the principles than in thoſe which go by water. For this purpoſe he conſtructed a machine, of which a particular deſcription is given in the 51ſt volume of the Philoſophical Tranſactions. The general principle of this was, that by means of a determinate weight it carried round an axis with an horizontal arm, upon which were four ſmall moveable ſails. Thus the ſails met with a conſtant and equable blaſt of air; and as they moved round, a ſtring with a weight affixed to it was wound about their axis, and thus ſhowed what kind of ſize or conſtruction of ſails anſwered the purpoſe beſt.

With this machine a great number of experiments were made; the reſults of which were as follow.

1. The ſails ſet at the angle with the axis, propoſed as the beſt by M. Parent and other geometricians, *viz.* 55°, was found to be the worſt proportion of any that was tried.

2. When the angle of the ſails with the axis was increaſed from 72° to 75°, the power was augmented in the proportion of 31 to 45; and this is the angle moſt commonly in uſe when the ſails are planes.

3. Were nothing more requiſite than to cauſe the ſails acquire a certain degree of velocity by the wind, the poſition recommended by M. Parent would be the beſt. But if the ſails are intended with given dimenſions, to produce the greateſt effects poſſible in a given time, we muſt, if planes are made uſe of, confine our angle within the limits of 72 and 75 degrees.

4. The variation of a degree or two, when the angle is near the beſt, is but of little conſequence.

5. When the wind falls upon concave ſails, it is an advantage to the power of the whole, though each part ſeparately taken ſhould not be diſpoſed of to the beſt advantage.

6. From ſeveral experiments on a large ſcale, Mr Smeaton has found the following angles to anſwer as well as any. The radius is ſuppoſed to be divided into ſix parts; and $\frac{1}{6}$th, reckoning from the centre, is called 1, the extremity being denoted 6.

N°	Angle with that axis.	Angle with the plane of motion.
1	72°	18°
2	71	19
3	72	18 middle
4	74	16
5	77½	12½
6	83	7 extremity.

7. Having thus obtained the beſt method of *weathering* the ſails, *i. e.* the moſt advantageous manner in which they can be placed, our author's next care was to try what advantage could be derived from an increaſe of ſurface upon the ſame radius. The reſult was, that a broader ſail requires a large angle; and when the ſail is broader at the extremity than near the centre, the figure is more advantageous than that of a parallelogram. The figure and proportion of enlarged ſails, which our author determines to be moſt advantageous on a large ſcale, is that where the extreme bar is one-third of the radius or whip (as the workmen call it), and is divided by the whip in the proportion of 3 to 5. The triangular or loading ſail is covered with board from the point downward of its height, the reſt as uſual with cloth. The angles above mentioned are likewiſe the moſt proper for enlarged ſails; it being found in practice, that the ſails ſhould rather be too little than too much expoſed to the direct action of the wind.

Some have imagined, that the more ſail the greater would be the power of the windmill, and have therefore propoſed to fill up the whole area; and by making each ſail a ſector of an ellipſis, according to M. Parent's method, to intercept the whole cylinder of wind, in order to produce the greateſt effect poſſible. From our author's experiments, however, it appeared, that when the ſurface of all the ſails exceeded ſeven-eighths of the area, the effect was rather diminiſhed than augmented. Hence he concludes, that when the whole cylinder of wind is intercepted, it cannot then produce the greateſt effect for want of proper interſtices to eſcape.

"It is certainly deſirable (ſays Mr Smeaton), that the ſails of windmills ſhould be as ſhort as poſſible; but it is equally deſirable, that the quantity of cloth ſhould be the leaſt that may be, to avoid damage by ſudden ſqualls of wind. The beſt ſtructure, therefore, for large mills, is that where the quantity of cloth is the greateſt in a given circle that can be: on this condition, that the effect holds out in proportion to the quantity of cloth; for otherwiſe the effect can be augmented in a given degree by a leſſer increaſe of cloth upon a larger radius, than would be required if the cloth was increaſed upon the ſame radius.

8. The ratios between the velocities of windmill ſails unloaded, and when loaded to their maximum, turned out very different in different experiments, but the moſt common proportion was as 3 to 2. In general it happened, that where the power was greateſt, whether by an enlargement of the ſurface of the ſails, or an increaſed velocity of the wind, the ſecond term of the ratio was diminiſhed.

9. The ratios between the leaſt load that would ſtop the ſails and the maximum with which they would turn, were confined betwixt that of 10 to 8 and 10 to 9; being at a medium about 10 to 8.3, and 10 to 9, or about 6 to 5; though on the whole it appeared, that where the angle of the ſails or quantity of cloth was greateſt, the ſecond term of the ratio was leſs.

10. The velocity of windmill ſails, whether unloaded or loaded, ſo as to produce a maximum, is nearly as the velocity of the wind, their ſhape and poſition being the ſame. On this ſubject Mr Ferguſon remarks, that it is almoſt incredible to think with what velocity the tips of the ſails move when acted upon by a moderate wind. He has ſeveral times counted the number of revolutions made by the ſails in 10 or 15 minutes; and from the length of the arms from tip to tip, has computed, that if an hoop of the ſame ſize was to run upon plain ground with an equal velocity, it would go upwards of 30 miles in an hour.

11. The load at the maximum is nearly, but ſomewhat leſs, than as the ſquare of the velocity of the wind; the ſhape and poſition of the ſails being the ſame.

12. The effects of the ſame ſails at a maximum are nearly, but ſomewhat leſs, than as the cubes of the velocity of the wind.

13. The load of the ſame ſails at a maximum is nearly

nearly as the ſquares, and the effect as the cubes of their number of turns in a given time.

14. When ſails are loaded ſo as to produce a maximum at a given velocity, and the velocity of the wind increaſes, the load continuing the ſame; then the increaſe of effect, when the increaſe of the velocity of the wind is ſmall, will be nearly as the ſquares of theſe velocities; but when the velocity of the wind is double, the effects will be nearly as 10 to 27½; and when the velocities compared are more than double of that where the given load produces a maximum, the effects increaſe nearly in a ſimple ratio of the velocity of the wind. Hence our author concludes, that windmills, ſuch as the different ſpecies for draining water, &c. loſe much of their effect by acting againſt one invariable oppoſition.

15. In ſails of a ſimilar figure and poſition, the number of turns in a given time will be reciprocally as the radius or length of the ſail.

16. The load at a maximum that ſails of a ſimilar figure and poſition will overcome, at a given diſtance from the centre of motion, will be as the cube of the radius.

17. The effects of ſails of ſimilar poſition and figure are as the ſquare of the radius. Hence augmenting the length of the ſail without augmenting the quantity of cloth, does not increaſe the power; becauſe what is gained by the length of the lever is loſt by the ſlowneſs of the motion. Hence alſo if the ſails are increaſed in length, the breadth remaining the ſame, the effect will be as the radius.

18. The velocity of the extremities of the Dutch ſails, as well as of the enlarged ſails, either unloaded or even when loaded to a maximum, is conſiderably greater than that of the wind itſelf. This appears plainly from the obſervations of Mr Ferguſon already related concerning the velocity of ſails, and is more fully treated of under the article Wind.

19. From many obſervations of the comparative effects of ſails of various kinds, Mr Smeaton concludes, that the enlarged ſails are ſuperior to thoſe of the Dutch conſtruction.

Having thus diſcuſſed the ſubject of the common windmills with oblique vanes, our author next proceeds to the conſideration of thoſe called *horizontal* windmills, in which it is attempted to make the wind impinge directly upon the wheel, as in the caſe of water-mills. To ſet the probable advantage of this ſcheme in its proper point of view, Mr Smeaton proceeds in the following manner: "Let AB, fig. 111. be the ſection of a plane, in which let the wind blow in the direction CD, with ſuch a velocity as to deſcribe a given ſpace BE, in a given time, ſuppoſe one ſecond; and let AB be moved parallel to itſelf in the direction CD. Now, if the plane AB moves with the ſame velocity as the wind; that is, if the point B moves through the ſpace BE in the ſame time that a particle of air would move through it, it is plain, that in this caſe there can be no preſſure or impulſe of the wind upon the plane; but if the plane moves ſlower than the wind, ſo that the point B may move to F, while a particle of air ſetting out from B would reach E, then BF will expreſs the velocity of the plane; and the relative velocity of the wind and plane would be expreſsed by the line FE. Let the ratio of FE to BE be given, ſuppoſe 2 to 3; let the line AB repreſent the impulſe of the wind upon the plane AB when acting with its whole velocity BE; but when acting with its relative velocity FE, let its impulſe be denoted by ſome aliquot part of AB, as for inſtance $\frac{4}{9}$; then will $\frac{4}{9}$ths of the parallelogram AF repreſent the mechanical power of the plane, that is, $\frac{4}{9}$ths $AB \times \frac{1}{3} BE$.

"2. Let IN be the ſection of a plane inclined in ſuch a manner, that the baſe IK of the right angled triangle IKN may be equal to AB; and the perpendicular NK=BE: let the plane IN be ſtruck by the wind in the direction LM, perpendicular to IK; then, according to the known rules of oblique forces, the impulſe of the wind upon the plain IN, tending to move it according to the direction LM or NK, will be denoted by the baſe IK; and that part of the impulſe tending to move it, according to the direction IK, will be expreſſed by the perpendicular NK. Let the plane IN be moveable in the direction of IK only; that is, the point I in the direction of IK, and the point N in the direction NQ parallel thereto. Now it is evident, that if the point I moves through the line IK, while a particle of air, ſetting forwards at the ſame time from the point N, moves through the line NK, they will both arrive at the point K at the ſame time; and conſequently there can be no preſſure or impulſe of the particle of air upon the plane IN. Now let IO be to IK as BF to BE; and let the plane IN move at ſuch a rate, that the point I may arrive at O, and acquire the poſition OQ, in the ſame time that a particle of air would move through the ſpace NK; as OQ is parallel to IN, by the properties of ſimilar triangles, it will cut NK in the point P in ſuch a manner, that NP will be equal to BF, and PK to FE. Hence it appears, that the plane IN, by acquiring the poſition OQ, withdraws itſelf from the action of the wind, by the ſame ſpace NP that the plane AB does by acquiring the poſition FG; and conſequently, from the equality of PK to FE, the relative impulſe of the wind PK upon the plane OQ will be equal to the relative impulſe of the wind upon the plane FG: and ſince the impulſe of the wind upon AB, with the relative velocity FE, in the direction BE, is repreſented by $\frac{4}{9}$ AB; the relative impulſe of the wind upon the plane IN in the direction NK will in like manner be repreſented by $\frac{4}{9}$ IK; and the impulſe of the wind upon the plane IN, with the relative velocity PK, in the direction IK will be repreſented by $\frac{4}{9}$ NK: and conſequently the mechanical power of the plane IN in the direction IK will be repreſented by $\frac{4}{9}$ of the parallelogram IQ; that is, $\frac{1}{3} IK \times \frac{4}{9} NK$: that is, from the equality of IK to AB, and NK to BE, we ſhall have $\frac{4}{9} IQ = \frac{1}{3} AB \times \frac{4}{9} BE = \frac{4}{9} AB \times \frac{1}{3} BE = \frac{4}{9}$ the area of the parallelogram AF.

"Hence we deduce this general propoſition; that all planes, however ſituated, that intercept the ſame ſection of the wind, and having the ſame relative velocity in regard to the wind, when reduced into the ſame direction, have equal powers to produce the ſame mechanical effects. For what is loſt by the obliquity of the impulſe, is gained by the velocity of the motion.

"Hence it appears, that an oblique ſail is under no diſadvantage in reſpect of power, compared with a direct one; except what ariſes from a diminution of its breadth,

breadth, in regard to the ſection of the wind; the breadth IN being by obliquity reduced to IK.

“ The diſadvantage of horizontal windmills therefore does not conſiſt in this, that each ſail, when directly expoſed to the wind, is capable of a leſs power than an oblique one of the ſame dimenſions; but that in an horizontal windmill little more than one ſail can be acting at once: whereas, in the common windmill, all the four act together; and therefore, ſuppoſing each vane of an horizontal windmill to be of the ſame ſize with that of a vertical one, it is manfeſt that the power of a vertical mill will be four times as great as that of an horizontal one, let the number of vanes be what we will. This diſadvantage ariſes from the nature of the thing; but if we conſider the further diſadvantage that ariſes from the difficulty of getting the ſails back again againſt the winds, &c. we need not wonder if this kind of mill is in reality found to have not above one-eighth or one-tenth of the power of the common ſort; as has appeared in ſome attempts of this kind.”

Notwithſtanding what is here advanced, it ſeems that the ideas of Mr Smeaton have not been very generally received, as premiums are ſtill held forth for the beſt methods of conſtructing horizontal wind-mills. Indeed, conſidering the clearneſs and perſpicuity of the above reaſoning, it ſeems ſurpriſing that public encouragement ſhould continue to be given to attempts which muſt certainly prove abortive. The principal inconvenience in wind-mills is their exceſſive irregularity and difficulty of being managed when the wind is high, owing to the great extent of the ſails and bulk of the machinery. But were it poſſible to make a number of ſmall wind-mills exert their power upon one object, theſe would be much more eaſily managed than one large one. Perhaps if a number of theſe were to be employed in pumping up water to a certain height from a lake or reſervoir, ſo as to produce a conſtant ſtream of water to turn a common mill, it might be more advantageous than to employ them directly. Wind-mills are commonly erected upon eminences for the ſake of receiving the wind to more advantage; and there are few eminences which do not afford a ſmall ſupply of water at no great diſtance from their ſummit. This ſupply being collected in a reſervoir, might be drawn up to the top by pumps worked by wind-mills; where being collected in another reſervoir, it might be let down to the former, turning a water-mill in its way, and being again drawn up by the pumps as before.

Some projectors, conſidering the great power of oblique vanes in wind-mills, have attempted to improve water-mills by giving them oblique vanes, but with as little ſucceſs. The power of the ſame ſection of a ſtream of water is not greater when acting upon an oblique vane than on a direct one; and any advantage which can be made of intercepting a greater ſection of water, which ſometimes may be done in the caſe of an open river, muſt be counterbalanced by the ſuperior reſiſtance that ſuch vanes would meet with by moving at right angles to the current: whereas the common floats always move with the water nearly in the ſame direction.

Mr Smeaton concludes his diſſertation upon this ſubject, with giving a reaſon why one angle ſhould be preferable to another in ſetting the ſails of a wind-mill. “ It is to be obſerved (ſays he), that if the breadth of the ſail IN is given, the greater the angle KIN, the leſs will be the baſe IK; that is, the ſection of the wind intercepted will be leſs. On the other hand, the more acute the angle KIN, the leſs will be the perpendicular KN; that is, the impulſe of the wind in the direction IK being leſs, and the velocity of the ſail greater, the reſiſtance of the medium will be greater alſo. Hence, therefore, as there is a diminution of the ſection of the wind intercepted on one hand, and an increaſe of reſiſtance on the other, there is ſome angle where the diſadvantage ariſing from theſe cauſes upon the whole is the leaſt of all; but as the diſadvantage ariſing from reſiſtance is more of a phyſical than geometrical conſideration, the true angle will beſt be aſſigned by experiment.”

Sect. VI. *Of the Motion of Bodies in Straight Lines and Curves; the Acceleration, Accumulation, and Retardation, of Motion in various Circumſtances.*

To underſtand this ſubject, it is neceſſary to keep in mind what has been ſaid concerning the *momentum* or quantity of motion in any moving body, *viz.* that it is compounded of the velocity multiplied into the quantity of matter. Thus, ſuppoſe there are two bodies, one containing twice the quantity of matter contained in the other, but moving with thrice its velocity, the quantities of matter will be expreſſed by any numbers in the proportion of 2 to 1, and their velocities by any others in the proportion of 3 to 1. Multiplying therefore the quantity of matter in the firſt (2) by its velocity (3), the product is 6; and multiplying the quantity of matter (1) by its velocity (1), the product is only 1; whence it appears that the momenta or abſolute forces of theſe bodies are to one another as 6 to 1.

As ſome bodies are elaſtic and others non-elaſtic, the effect of motion communicated from one to another becomes very different, according to this circumſtance. The motion is likewiſe very different, according to the manner in which one body acts upon another, and according to which it will be driven forward in a rectilinear direction, or deſcribe curves of various kinds, revolving on its axis, &c. Theſe different kinds of motion have been conſidered by different authors, but by none more particularly than Mr G. Atwood, who has publiſhed a large octavo volume upon the rectilinear motion and rotation of bodies. The fundamental laws of motion aſſumed by this author as axioms are three.

1. Every body perſeveres in its ſtate of reſt or uniform motion in a right line, until a change is effected by the agency of ſome external force.

2. Any change effected in the quieſcence or motion of a body is in the direction of the force impreſſed, and is proportional to it in quantity.

3. Action and reaction are equal, and in contrary directions.

From theſe three ſimple axioms, the truth of which muſt, from what has been already ſaid, be abundantly evident, our author proceeds to demonſtrate the moſt difficult problems concerning the impulſe and motion of

Motion of Bodies.

Motian of Bodies.

of bodies in every poſſible direction, beginning from the moſt ſimple and eaſy deductions. For the more eaſy comprehending this ſubject, however, we ſhall premiſe what our author has ſaid in his ſecond ſection concerning the properties of *ratios* or proportions.

1. Two mathematical quantities of the ſame kind, as two lines, two ſurfaces, two angles, &c. conſtitute a ratio. Thus, ſuppoſe one line two feet in length and another four; theſe are to one another in the ratio of 4 to 2, or of 2 to 1; but a line cannot be ſaid to bear any ratio to a ſurface, becauſe they are not quantities of the ſame kind, and therefore cannot be compared.

2. We may compare the ratio of two quantities of one kind with the ratio of two quantities of a different kind. Thus, when two bodies move uniformly, for an equal time, but with different velocities, the ratio of the ſpaces paſſed over may be compared with that of the velocities, though ſpace and velocity are accounted different quantities.

3. If any quantity be divided by another of the ſame kind, the quotient becomes abſolute number. Thus, if we divide a velocity of four feet in a ſecond by one of two feet in a ſecond, the quotient will be 2; and in all caſes the quotient will be to 1 as the greater quantity is to the leſſer.

4. The ratio of any mathematical quantities may be expreſſed by two numbers, if both terms of the ratio be divided by the conſequent or by the antecedent. Thus, let the antecedent be 8 and the conſequent 4; let both be divided by 4, and the ratio will then be 2 to 1; or let both be divided by 8, and it will be 1 to 0.5, which is the ſame.

5 Any ratio may be repreſented by a fraction, the numerator of which is the antecedent, and the denominator the conſequent. Thus the ratio of 8 to 4 is repreſented by the fraction $\frac{8}{4}$; and hence we may add and ſubtract ratios by the addition and multiplication of fractions. Thus, ſuppoſing two bodies to move uniformly, one at the rate of 8 feet in a ſecond and the other 4; ſuppoſing them alſo to move the former for four, and the latter for two ſeconds, the ſpaces paſſed over will be 32 and 8, their ratio $\frac{32}{8}$, or at length $32:8:4\times8:2\times4$; or $\frac{32}{8}=\frac{4}{2}\times\frac{8}{4}$. Here it is to be obſerved, that when the mark of equality is interpoſed betwixt heterogeneous quantities, the only equality meant is that which ſubſiſts between the ratios there expreſſed; and when the mark of multiplication is interpoſed between heterogeneous quantities, it means the addition of two ratios, the antecedents of which are the terms expreſſed, and the conſequents are unity.

6. If there are three ratios, conſiſting of variable terms, and the relation of the quantities to each other be ſuch, that when the third ratio becomes unity the other two become equal; or when the ſecond becomes unity, the firſt and third are equal; then in all caſes, whatever be the magnitudes, we have the firſt ratio = the 2d×3d. Thus let the three ratios be $\frac{5}{2}$, $\frac{7}{3}$, and $\frac{2}{1}$, diminiſhing the numbers by 1, we have $\frac{4}{2}$, $\frac{6}{3}$, and $\frac{1}{1}$, it is evident that $\frac{4}{2}=\frac{6}{3}\times\frac{1}{1}$: the ſame will be the caſe if we place them in a different order, as $\frac{5}{2}$, $\frac{2}{1}$, and $\frac{7}{3}$; for then, diminiſhing as before, we have $\frac{4}{2}$, $\frac{1}{1}$, and $\frac{6}{3}$, in which caſe $\frac{4}{2}\frac{1}{1}=\frac{1}{1}\times\frac{6}{3}$.

7. In comparing the ratios which obtain between mathematical quantities of any ſort, the ſtandard to which each of thoſe quantities is referred may be taken =1. Thus, ſuppoſing we compare the weight, magnitude, and denſity, of any ſubſtance with water, we may take a cubic inch of that element for a ſtandard, and call the weight, magnitude, and denſity of it =1; by which means we may readily compare the weight, magnitude, or denſity, of any quantity, however large, of another ſubſtance with water.

We now proceed to that part of the work which treats directly of the motion of bodies acted upon by any external impulſe.

8. Any force acting continually upon a body in the ſame direction, will produce a continual acceleration or retardation of the motion. Thus, if a body deſcends by the force of gravity, its motion is continually accelerated; or if it be thrown up againſt the force of gravity, the motion will be continually retarded nntil it be totally deſtroyed.

9. If, while a body moves, equal quantities of motion be communicated to it, or taken from it in equal ſpaces of time, the force is ſaid to be conſtant, and equally accelerated or retarded.

10. When unequal velocities are generated or deſtroyed in equal ſpaces of time, the force is ſaid to be variable.

11. When a body is acted upon by a conſtant force, we muſt conſider the ſpace through which it moves, the time it takes to move through it, the velocity it acquires, and the force which produces it; any two of which being given, we may from them find the other two. Here we muſt obſerve, that the force mentioned relates only to the communication of the velocity, without any regard to the quantities of matter moved. As it is proportioned to the velocity generated in a given time, it is thence called the *accelerating* force. That which relates to the quantity of matter moved, as well as the velocity communicated, is called the *moving* force; being proportional to the quantity of motion produced in a given time.

12. The moving forces which communicate the ſame velocity in a given time to different bodies, will be as the quantities of matter contained in the bodies moved. This will appear from a conſideration of what has already been ſaid concerning the momenta of bodies. For if one body contains ten times the quantity of matter that another does, it will of courſe require ten times as much force to move it with an equal degree of velocity; for the former is equivalent to ten ſuch bodies, and it is the ſame thing whether they be ſeparate or altogether.

13. The moving forces which act upon bodies, and the degrees of velocity communicated to them in a certain time, are proportional to the quantities of matter moved and the velocities communicated jointly: for, by the laſt propoſition, when the velocity communicated in a certain time is the ſame, the moving force is as the quantity of matter moved. Thus, if a ball of ten pounds weight is made to move at the rate of 10 feet in a ſecond, and another of one pound is made to move at the ſame rate, the moving forces will be in proportion to the quantities of matter; that is, as 10 to 1. Hence we may eaſily perceive, that when the quantity of matter is given, the moving force will be as the velocity. Thus, if two balls of ten pounds each

each are cauſed to move, one with the velocity of ten feet in a ſecond, and the other with a velocity of five feet in the ſame time, the forces will be as the velocities; that is, as 10 to 5, or as 2 to 1; and hence, when both the quantities of matter and velocities are different, the moving forces will be according to theſe jointly. Thus if a ball of ten pounds is moved with a velocity of ten feet in a ſecond, and a ball of one pound moves with a velocity of five feet in a ſecond, the moving forces will be as 10×10 or 100 is to 1×5, or as 20 to 1.

Here our author takes occaſion to deny that there is any ſuch thing as a communication of motion by an inſtantaneous impulſe or ſtroke, as has commonly been ſuppoſed. Every degree of motion, according to him, is the effect of acceleration. "The latter way (ſays he) viz. the communication by inſtantaneous impulſe, can obtain only in bodies perfectly hard and inflexible, which exiſt not in nature; and even in the abſtract conſideration of theſe as well as of other caſes in mechanics, when metaphyſical poſſibilities inſtead of the natural ſtate of bodies are attended to, difficulties ariſe hardly explicable by any method of reaſoning: but it is certain, that when finite velocity is communicated to any natural body, the time in which it is communicated muſt be finite alſo; ſo that when the body acted upon begins to move from quieſcence, it muſt, during the action of the force, poſſeſs all the intermediate degrees of velocity between 0 and the velocity ultimately communicated.

"To exemplify this further, let it be ſuppoſed that a ſoft and flexible ball of clay impinges againſt another of the ſame ſort, in the direction of a line joining the centres of the balls. At the firſt inſtant of the impact, the body ſtruck will begin to move, and will proceed with a velocity inferior to that of the impinging body, the velocity of which will continue to decreaſe, and that of the other body to increaſe, as long as the impinging force cauſes a change in the figure of the two bodies; that is, till they have both acquired a common velocity; at which inſtant all acceleration ceaſes if the bodies be perfectly non-elaſtic. If the bodies be of ſuch a kind, as, after having received impreſſion from any impact, poſſeſs a power of reſtoring their changed figure with a force equal to that of the impact, it is manifeſt, that whatever velocity was communicated during the change of figure, an equal quantity will be ſuperadded during the reſtoration of it. In this caſe, after the acceleration ariſing from the impact during the change of the figure of the bodies has ceaſed, the bodies having then acquired a common velocity, a new acceleration will begin, being cauſed by the elaſtic force of the balls, which, acting in a direction of the lines joining their centres, tends to ſeparate them, accelerating the ball ſtruck, and retarding the other.

"From theſe conſiderations it appears, that in whatever degree the hardneſs of perfectly elaſtic bodies may differ, the effects of their impact will be the ſame, the weights and velocities before the ſtroke being given. For the figures of the ſtriking and of the other body continually change, till they have acquired a common velocity, which depends only on the velocity of bodies and their impact, and is determined by the rules for the colliſion of non-elaſtic bodies. Moreover, the reſtoration of the changed figures, how great or how ſmall ſoever may have been the change, muſt cauſe an addition of velocity in the ball ſtruck equal to that received from the impact.

"It follows alſo, that the effect will be the ſame, whether the bodies be both perfectly elaſtic, or whether one of them be perfectly elaſtic and the other perfectly hard; every thing elſe being given for the figure of the elaſtic body muſt change until the bodies have obtained a common velocity, which depends on the weights and velocities before the ſtroke only; and will be the ſame as if the bodies were non-elaſtic: the reſtoration of the figure will in this, as well as in the former caſe, cauſe an increaſe of velocity in the ball ſtruck, equal to that before communicated. Although no ſubſtance in nature poſſeſſes perfect elaſticity, or is entirely deſtitute of it, yet there are ſeveral elaſtic and non-elaſtic bodies ſubject to experimental trials, wherein the laws relating to colliſion are found to agree with fact to a conſiderable degree of exactneſs."

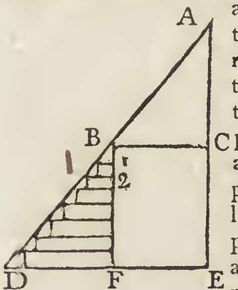
14. The accelerating forces which communicate velocity to bodies are directly as the moving forces, and inverſely as the quantity of matter moved; for ſince, by prop. 11. the accelerating force is as the velocity generated in a given time; and by prop. 13. the moving force is as the quantity of matter and velocity generated in a given time, it follows, that the moving force is as the accelerating force and quantity of matter moved jointly: that is, the accelerating force is as the moving force directly, and the quantity of matter moved inverſely. Thus, let a maſs of matter, equal to four ounces, be impelled by a force equal to three ounces; then the force which accelerates the maſs of four ounces will be three-fourths when the acceleration of gravity is 1; or in other words, it will generate, in a given time, three parts in four of the velocity which gravity generates during any given time.

15. In bodies impelled in a rectilinear direction by forces acting uniformly, the velocities generated are as the forces and times in which they act, conjointly. Thus, ſuppoſe a force equal to ten acting upon a ball of ten pounds, and another alſo equal to ten acting upon a ball of equal weight, the former for one ſecond, and the latter for two; it is plain that the velocity generated in the latter will be double to that generated in the former. But if we ſuppoſe the latter ball to be acted upon by a force equal only to five, then will both the velocities be equal, though the latter ſhould continue for two ſeconds and the former only for one. In all practical inquiries of this kind, however, it muſt be remarked, that a ſtandard velocity is to be obtained from obſerving what degree of velocity is generated by the force of gravity during a given time; one ſecond, for inſtance.

16. If a quieſcent body be impelled by any conſtant force acting upon it for a given time, the ſpace deſcribed will be to the ſpace deſcribed in the ſame time by a body moving uniformly with the laſt acquired velocity, in the ratio of one to two. In order to underſtand this, we muſt ſuppoſe the time to be divided into ſuch ſmall parts that the acceleration during any one of them is imperceptible: then it is evident, that at the end of two moments, the impulſe continuing the ſame, it will have gained double the velocity it did the firſt moment; and this is

is manifeſt from the phenomena of falling bodies, which having deſcended for one ſecond, acquire then a velocity twice as great as that which they had during the firſt ſecond. That this propoſition may be true, however, it is neceſſary that the velocity of the impelling power ſhould be *infinite* with reſpect to that which the body itſelf can acquire; for whenever the body moved comes to acquire a velocity in any degree proportional to that of the moving power, then that proportion muſt be deducted from the acceleration; and when both come to be equal, no farther acceleration can take place. With regard to falling bodies, indeed, as far as our obſervations can go, were it not for the reſiſtance of the air, this acceleration would go forward till the body had acquired a velocity much ſuperior to any that we can now communicate, either by that or any other method. In all artificial accelerations, however, the velocity of the body moved ſoon becomes equal to that of the moving power, and then the motion goes on uniformly, which otherwiſe would continually increaſe.

17. The ſpaces which bodies deſcribe from reſt, by the action of conſtant forces, are in a compound ratio of the velocities laſt acquired and the times of motion: For the ſpaces deſcribed by the laſt acquired velocities continued uniform, are as thoſe velocities, and the times of motion jointly; and the ſpaces deſcribed by the accelerating forces acting conſtantly for equal reſpective times, are half the former ſpaces by prop. 16. This will perhaps appear more intelligible from the annexed figure; in which the motion of a body, by an accelerated force, is repreſented by a triangle; for ſuppoſing the body to begin its motion from the point A, and to be uniformly accelerated until it arrived at the point C, it is plain that the velocity acquired would then be properly repreſented by the triangle ABC; but if the acceleration was then to ceaſe, the velocity, and conſequently the ſpace paſſed over, would be repreſented by the parallelogram BCFE, double the triangle ABC. But let us ſuppoſe the acceleration ſtill to go on, as is repreſented in the triangle BDF; it is plain that the ſpace paſſed over in every ſmall moment of time will be compoſed of a parallelogram formed by the velocity laſt acquired, and a triangle formed by the acceleration during that moment, which is entirely in terms of the propoſition, that the ſpaces are in a compound ratio of the velocities laſt acquired, and the times of motion.



18. Conſtant forces which accelerate bodies, cauſe them to deſcribe, from reſt, ſpaces which are as the forces and ſquares of the times wherein they act jointly. For the ſpaces deſcribed are as the velocities laſt acquired, and the times of motion. This will be evident, from an inſpection of the former figure; for in the triangle BDF, let B 1 repreſent the time in which a body acquires a certain velocity; then when it has attained the length of 2, the ſpace paſſed over will be repreſented by a ſmall ſquare, being that of the firſt moment, and of a triangle repreſenting the additional force the ſecond moment.

19. The conſtant forces which accelerate bodies from a ſtate of reſt, are in a direct duplicate ratio of the velocities generated, and in an inverſe ratio of the ſpaces deſcribed. Hence the following corollary is deduced, viz. that the laſt acquired velocities are in a ſubduplicate ratio of the accelerating forces, and a ſubduplicate ratio of the ſpaces deſcribed jointly.

20. If bodies unequal in quantity of matter be impelled from reſt through equal ſpaces, by the action of moving forces which are conſtant, theſe forces are in a duplicate ratio of the laſt acquired velocities, and the ratio of the quantity of matter jointly.

In his obſervations on this propoſition, our author takes occaſion to conſider the theory of thoſe who inſiſt, contrary to the opinion of Sir Iſaac Newton that the abſolute force of bodies is compounded of the quantity of matter and *ſquare* of the velocity, inſtead of the velocity itſelf. "In the experiments (ſays he) which have been made on the force of bodies, the loſs of motion from reſiſtance has been more attended to than the communication of it by acceleration; and the reaſon probably aroſe from a want of adequate methods of ſubjecting accelerating forces, velocities acquired, and quantities of matter moved, to experimental trials; whereas the impact of bodies on ſubſtances which they penetrate, by affording convenient opportunity for obſerving the depths to which bodies ſink before all motion is deſtroyed, regard being had to the velocities of impact, and the weight and form of the impinging body, has ſeemed a more eligible method, however imperfect, of inveſtigating the principles of motion.—When a body deſcends for three ſeconds by the force of gravity, it acquires, by a force of acceleration, a velocity of $96\frac{1}{2}$ feet in a ſecond: alſo, if a body be projected perpendicularly upward, with a velocity of $96\frac{1}{2}$ feet in a ſecond, the whole velocity will be deſtroyed in three ſeconds; and in like manner, every other property demonſtrated concerning accelerated motions is found to belong to retarded ones, provided we attend to the following circumſtances: If in any propoſition relating to accelerated motion, the force is conſtant, it follows, that when this is applied to retarded motion, the retardation muſt alſo be conſtant. Moreover, ſince in accelerated motions the ſpaces are eſtimated from quieſcence, ſo in retarded motions the bodies are ſuppoſed to move to quieſcence; that is, till all motion is deſtroyed by retardation: in whatever concerns motions of this kind, therefore, we muſt conſider the retarding force to be directly as the force of reſiſtance, and inverſely as the quantity of matter.

"In order to illuſtrate this ſubject, it is to be obſerved, that if a body projected with different initial velocities be retarded by any conſtant given force, the whole ſpaces which the body deſcribes are in a duplicate ratio of the initial velocities, which follows from what has been already demonſtrated; and converſely, ſince when bodies are impelled by an accelerating force through various ſpaces, if theſe ſpaces are always as the ſquares of the laſt acquired velocities, it follows that the force of acceleration is conſtant: ſo when a given body is projected with different velocities, and is retarded by a given force, if the whole ſpaces deſcribed be always in a duplicate ratio of the initial velocities, it is concluded, that the force of retardation is conſtant. It is from this argument inferred, that the force whereby blocks of wood, banks of earth, &c. reſiſt the penetration of bodies impinging on them, is conſtant; for it is obſerved, that the depths to which military projectiles of a given magnitude and weight, ſtriking againſt a body of this kind, enter its ſubſtance, are in a duplicate ratio of the initial velocities, which has been ſufficiently proved by Mr Robins, who firſt aſcertained the velocities of military projectiles, and applied his method, among other uſeful purpoſes, to the diſcovery of the retardation which bodies ſuffer by paſſing through reſiſting ſubſtances.

" The forces of reſiſtance, which are oppoſed to the motion of bodies impinging on ſubſtances which they penetrate, being granted conſtant, the propoſitions concerning acceleration already demonſtrated may be applied to explain the motion of bodies, which, having been projected with given initial velocities, are interrupted by ſuch obſtacles as blocks of wood, banks of earth, or others of a ſimilar kind.—For example, it has been demonſtrated, that bodies moving from reſt by the acceleration of conſtant forces, deſcribe ſpaces which are as the accelerating forces and ſquares of the times jointly. By applying this propoſition to retarded motions, we ſhall have the whole ſpaces or depths to which bodies impinging on the ſubſtances penetrate, as the forces of retardation and ſquares of the times wherein the bodies move, jointly. Moreover, it has been demonſtrated, that if different quantities of matter be impelled from reſt through equal ſpaces, the moving forces will be in a ratio compounded of the duplicate ratio of the velocities laſt acquired, and the ratio of the quantities of matter moved. It is from hence inferred, that in retarded motions alſo, if different quantities of matter be projected againſt any of the ſubſtances above deſcribed, with different initial velocities, and the whole depths to which the bodies penetrate are equal, the forces whereby the bodies reſiſt the progreſs of the impinging bodies will be in a duplicate ratio of the initial velocities of impact and the quantities of matter jointly.

" By this propoſition we may examine ſome of the experiments concerning the force of moving bodies, and the concluſions deduced from them by Bernoulli, Leibnitz, Poleni, &c. againſt the meaſure of force delivered by Sir Iſaac Newton, which he deſcribed in the following definitions:

" The quantity of motion is meaſured by the quantity of matter in a moving body and its velocity jointly.

" The moving forces whereby bodies tend towards centres of attraction are as the quantities of motion generated in a given time.

" It follows, then, from theſe definitions, that the moving forces, acting for a given time, will be proportional to the quantities of matter moved, and velocities generated, jointly: ſo that if the ratio of the moving forces be known, and we can find by experiment what velocities are generated in given bodies by the action of them for the ſame time; the quantities of motion generated in the bodies may be eſtimated according to Sir Iſaac Newton's definition. Moreover, ſince it is allowed that the effects of a reſiſting force to deſtroy are the ſame as thoſe of an equal force to generate motion in a given time; it follows, that if the ratio of two reſiſting forces be known, the quantities of matter in bodies which impinge on ſubſtances, and penetrate them, and the velocities deſtroyed in a given time, will give the ratio of the quantities of motion deſtroyed, according to Sir Iſaac Newton's definition.

" In many of the experiments alluded to, which have been greatly varied and multiplied, the reſiſting forces were made equal, by cauſing ſpheres equal in magnitude to impinge on a given ſubſtance which they penetrated; and the ſpheres being of given denſities, it was obſerved in experiments, that whenever the denſities or weights of thoſe equal ſpheres were in an inverſe duplicate ratio of their velocities, the depths to which they penetrated would be equal. The concluſions were theſe: the quantities of matter diſplaced by the moving bodies were equal, the depths to which the equal ſpheres penetrated were the ſame. Moreover, the whole motions which had been communicated to the bodies were deſtroyed; that is, the whole motion of the impinging bodies muſt have been as the ſquares of the velocities into the quantities of matter. But it plainly appears, that this concluſion is not applicable to the Newtonian definition, according to which the moving force generates motion in bodies: and it follows by what has preceded, that the reſiſting force by which the motion of bodies is deſtroyed, is proportional to the quantities of motion generated or deſtroyed in a given time reſpectively; and conſequently, to eſtimate the quantity of motion deſtroyed, the time wherein reſiſting forces act ſhould be equal. If, therefore, the times wherein the bodies in the experiment deſcribe the equal ſpaces can be proved different, this will plainly ſhow that the quantities of motion deſtroyed cannot be inferred from the experiment, the different times of the bodies deſcribing the depths to which they ſink not being taken into the account: this will be eaſily proved, ſince from propoſition 17. it appears, that the ſpaces deſcribed are univerſally as the velocities and ſpaces laſt deſcribed jointly; and from what has been ſaid, the converſe of this propoſition when applied to retarded motions muſt alſo be true. The ſpaces therefore being given as in the experiment, the times will be inverſely as the initial velocities; which velocities being unequal from the experiment, it follows that the times are unequal. This being the caſe, it is manifeſt that no concluſion can be drawn from theſe experiments concerning the quantity of motion deſtroyed, tending to prove any inconſiſtency between the Newtonian eſtimation of force and matter of fact.

" It is next to be ſhown, that the experiments are ſtrictly conſiſtent with the Newtonian meaſure, and with the theory in general.—It has already been proved, that in accelerated motions the ſpaces deſcribed are in a duplicate ratio of the velocities laſt acquired, and the quantities of matter moved, and an inverſe ratio of the moving forces. This propoſition being applied to retarded motions, it will follow, that the whole ſpaces or depths to which the impinging bodies ſink, are in a duplicate ratio of the quantities of matter, and an inverſe ratio of the reſiſting forces; whence alſo the depths to which the bodies penetrate muſt be equal when ſpheres of equal diameters are projected againſt a given ſubſtance, the weights being in an inverſe duplicate

plicate ratio of the initial velocities, which we find entirely correſpondent to experiment. It ſeems indeed rational to ſuppoſe, independent of all theory, that, in eſtimating the quantities of motion generated or deſtroyed by given moving or reſiſting forces, regard muſt be had to the times wherein the forces act; becauſe moving forces, or thoſe of reſiſtance, may be equal, and may generate or deſtroy quantities of motion varying in any aſſignable degree. For it is manifeſt, that a ſmall reſiſtance, oppoſed to a moving body for a longer time, may deſtroy more motion than a greater force acting for a ſhorter time; which ſufficiently ſhows, that the times wherein the moving and reſiſting forces act, muſt either be equal, or muſt be taken into the account in eſtimating the quantities of motion generated or deſtroyed.

21. The moving forces which communicate, and the forces of reſiſtance which deſtroy, the motion of bodies in the ſame time, will be in a compound ratio of the quantities of matter in the moving bodies and velocities generated or deſtroyed.—This and the preceding propoſitions have been fully illuſtrated and confirmed by experiments. From them we deduce the following facts: 1. When muſket-balls, equal in weight and magnitude, impinge on a block of wood with different velocities, the reſiſting force being conſtant, we ſhall have the whole ſpaces through which the balls move in the wood as the ſquares of the velocities. 2. If balls of equal diameters, but different weights, impinge againſt a block with the ſame velocity, we have the depths to which they penetrate the block as the weights. 3. If balls of the ſame kind of ſubſtance, that is, of the ſame denſity, but of different diameters, impinge againſt a given block of wood or the ſame bank of earth with equal velocities, the depths to which they penetrate will be directly as the diameters of the balls.

When the force of reſiſtance is not uniform, the ſame principle obtains in degree, though the laws are then various; for greater bodies always ſuffer leſs by retardation than ſmaller ones of the ſame denſity, moving through the ſame reſiſting medium, and projected with a given initial velocity: becauſe, though the force of reſiſtance increaſes with the increaſe of the body's magnitude, yet the weight in moſt bodies increaſes in a greater proportion. Thus, in cannon-balls, and other ſolid bodies, though the reſiſtance of the air increaſes as the ſquare of the ball's diameter, yet the weight increaſes as the cube. Thus, if a ball two inches in diameter is projected from the mouth of a piece, it is reſiſted by the atmoſphere four times leſs than one four inches in diameter; but the weight of the latter, being *eight* times greater, makes the reſiſtance leſs upon the whole in the large ball than in the ſmall one. It is otherwiſe when the weight does not increaſe in this manner; for then the ſmaller the body is, the leſs reſiſtance it meets with, and the faſter it goes. This is manifeſt from aeroſtatical experiments; for ſmall air-balloons always outſtrip the larger ones: and the ſame thing is obſervable in boats; for the ſmaller ones, if they have the ſame advantages in proportion to their bulk, will always ſail faſter than the larger ones.

22. If bodies, projected with the ſame velocity, be retarded by different conſtant forces, theſe forces will be in an inverſe ratio of the whole ſpaces deſcribed by the projected bodies, until all motion is deſtroyed.—For example, let a body be projected on an inclined plane, in a direction contrary to that in which gravity acts in the plane, and with a velocity of 144.467 inches in a ſecond. Suppoſe the body then projected, aſcending along the plane, to deſcribe 216 inches before its motion is deſtroyed; let it be required to aſcertain the retarding force which oppoſes its aſcent, that is, the proportion of it to the force of gravity. If the body were projected perpendicularly upward, with the given velocity of 144.467 inches in a ſecond, it would riſe only to 27 inches, as follows in Prop. 19. And ſince it aſcends along the plane 216 inches, the retarding force on the plane will be to that of gravity as 27 to 216, or as 1 to 8; which is alſo the proportion of the height of the plane to the length of it.

From this propoſition, having given the depth to which a body impinging againſt another penetrates it, the proportion of the retarding force of gravity may be determined. For example, Mr Robins found that a leaden ball of $\frac{3}{4}$ of an inch, or $\frac{1}{16}$ of a foot in diameter, impinging on a block of elm with a velocity of 1700 feet in a ſecond, penetrated it to the depth of five inches, or $\frac{5}{12}$ of a foot; wherefore, ſince a body projected upwards with a velocity of 1700 feet in a ſecond, would riſe, if the atmoſphere made no reſiſtance, to the height of 44922 feet, we have the force by which elm retards the ball to the force of gravity as 44922 to $\frac{5}{12}$; or as 107.813 to 1.

On this theory it may further be obſerved, that the reſiſtances oppoſed to ſpherical bodies, which impinge on a block of wood, a bank of earth, &c. depend not only on the tenacity or denſity of the parts, of which the penetrated ſubſtances are compoſed, but upon the diameters of the impinging ſpheres: ſo that, although the reſiſting and retarding forces be determined in any ſubſtance for a ſingle caſe; yet when the diameters and weights of the impinging bodies vary, the forces of reſiſtance and retardation oppoſed to the impact on the ſame ſubſtance will be different. By the preceding propoſition, however, we may be enabled, from a ſingle experiment made on the retardation of any ſubſtance oppoſed to a ſphere, the weight and diameter of which are known, to infer the retardation in any other caſe, however the weights and diameters may vary.

23. If ſpheres of different diameters and different ſpecific gravities impinge perpendiculary on fixed obſtacles, the reſiſting forces of which are conſtant, but of different quantities, the forces which retard the progreſs of the impinging ſpheres will be in a direct ratio of the abſolute forces of reſiſtance, and the joint inverſe ratio of the diameters and ſpecific gravities of the ſpheres. No abſolute concluſion can be drawn from this propoſition concerning any matter of fact, unleſs an experiment be firſt made on the retarding and reſiſting force of ſome ſubſtance which is to be conſidered as a ſtandard.

24. The whole ſpaces or depths to which ſpheres, impinging on different reſiſting ſubſtances, penetrate, are in the ratio compounded of the duplicate ratio of the velocities of impact, the joint ratios of the diameters and ſpecific gravities of the ſpheres, and an inverſe ratio of the abſolute forces whereby the ſubſtances reſiſt the progreſs of the ſpheres.

Mr Atwood concludes this ſection with ſome problems relative chiefly to military projectiles; and in his next ſection (the 4th) conſiders the rectilinear motion of bodies acted upon by forces which vary in ſome ratio of the diſtances from a fixed point. This ſection chiefly relates to the powers of gravity and projection, by which the celeſtial bodies are actuated, and which conſequently chiefly regards aſtronomy and the motion of pendulums; though there are likewiſe ſome curious particulars relating to the action of compreſſed air, the vibration of muſical ſtrings, and the undulation of fluids. The fifth ſection conſiders the motion of bodies immerſed in fluids; but the ſixth treats of a ſubject which properly belongs to mechanics, viz. the communication of motion to bodies revolving round an axis.

69 **Of rotatory motion.**

In treating this ſubject Mr Atwood obſerves, that in the former part of his work he had ſuppoſed the accelerating, as well as reſiſting, forces, to act upon the body in a ſtraight line paſſing through the centre of gravity of the moving; in which caſe every particle of the body muſt partake of the ſame degree of velocity, being equal to that with which the common centre of gravity moves. "But (ſays he) it frequently happens, that a body, or ſyſtem of bodies, is ſo conſtituted, that when any force is impreſſed upon it, no motion can be produced except round a fixed axis; ſo that the velocity of the particles which compoſe the ſyſtem will be greater or leſs according as theſe particles are farther from the common axis or nearer it. Theſe circumſtances ſhould be attended to, in order to aſcertain the motion of revolving bodies; the preceding principles of acceleration being not wholly of themſelves ſufficient for that purpoſe.

"In this inveſtigation two things muſt be attended to. 1. The moving force by which the revolving motion is generated; and, 2. The inertia of the parts of which the ſyſtem is compoſed. The moving force exerted on any given particle of the ſyſtem, as well as its inertia, depends on its diſtance from the axis of motion, every thing elſe being the ſame; and if both theſe be aſcertained, the abſolute acceleration of the particle will be determined, and conſequently the abſolute velocity generated in a certain time. The methods therefore of determining theſe forces in any given circumſtance ſhould next be deſcribed.

"Let AFGH (fig. 112.) repreſent the circumference of a wheel which turns in its own plane round an horizontal axis, paſſing through its centre; and let a weight P, fixed at the extremity of a line AP, communicate motion to the wheel. Moreover, let the whole weight of the wheel be Q; and ſuppoſe this weight to be collected uniformly into the circumference AFGH; then, during the deſcent of the weight P, each point of the circumference muſt move with a velocity equal to that with which P deſcends; and conſequently, ſince the moving force is the weight P, and the maſs moved P+Q, the force which accelerates P in its deſcent will, by Prop. 14. be that part of the accelerating force of gravity which is expreſſed by the fraction $\frac{P}{P+Q}$. The velocity, therefore, which is generated in P in any given time, is found from the rules before demonſtrated. Thus, ſuppoſing Q to be equal to P, then will $\frac{P}{P+Q}=\frac{1}{2}$; and the weight P will be accelerated by a power which is to that of gravity as 1 to 2; and ſince gravity generates in bodies which deſcend for one ſecond of time near the earth's ſurface a velocity of $32\frac{1}{6}$ feet in a ſecond; it follows, that the weight P will in the ſame time have acquired a velocity of $16\frac{1}{12}$ feet in a ſecond only.

"The parts of the weight Q which are uniformly diſpoſed over the circumference AFGH, balance each other round the common centre of gravity S; their weight therefore is of no effect in accelerating or retarding the deſcent of P: and this will be the caſe whenever the axis of motion paſſes through the common centre of gravity. But in order to render the properties of rotatory motions more obvious, it will be convenient to diſpoſe the parts of the revolving ſyſtem ſo that the axis of motion ſhall not neceſſarily paſs through the common centre of gravity: thus, inſtead of having the weight Q uniformly dipoſed over the circumference AFGH, let it be collected into any point Q. Here it is manifeſt, that if the maſs Q be acted upon by gravity, the force which communicates motion to the ſyſtem round S will be variable, it being the greateſt when SQ is horizontal, and gradually diminiſhing till Q has arrived at its loweſt point. But as we ſhould begin with the moſt ſimple caſes, the moving force muſt be conſtant. This will be effected by ſuppoſing the maſs which is collected in Q to be deſtitute of weight, and to poſſeſs inertia only. It follows therefore, that during the revolution of Q round S as an axis, the moving force will be conſtantly equal to P, and the maſs moved $=P+Q$. Conſequently the force which accelerates the deſcending weight, or any point in the circumference, will be that part of gravity which is expreſſed by the fraction $\frac{P}{P+Q}$ as before.

"In theſe caſes, the force which communicates motion to the ſyſtem has been ſuppoſed a weight or body acted upon by the earth's gravity, and conſequently conſtitutes a part of the maſs moved, at the ſame time that it acts as a moving force: but motion may be communicated by a force which ſhall add nothing to the inertia of the matter moved: and it will be convenient in many demonſtrations to aſſume the force of this kind; and in this caſe we have not to take the inertia into the account. Thus if any number of bodies without gravity collected into the points F, H, Q, (fig. 112.) are cauſed to revolve round the axis S, by a moving force P, the force which accelerates theſe bodies in their revolution will be $\frac{P}{F+H+Q}$; provided the bodies F, H, Q, be diſpoſed at a diſtance from the axis of motion equal to the radius of the circle AFGH, at the circumference of which the moving force P is applied.

"In the preceding example, F, H, Q, &c. have been ſuppoſed to move with the ſame velocity; but when bodies revolve at unequal diſtances from the axis, their velocities of motion being different, other rules will be neceſſary to determine the force whereby any given point of the ſyſtem is accelerated. In demonſtrating the properties of rotatory motion, the revolving

ving ſyſtem may be ſuppoſed to conſiſt of one or more of the bodies A, B, C: the magnitude of theſe may be ſuppoſed evaneſcent; becauſe, were the contrary ſuppoſition adopted, the particles in each body would be impelled by different moving forces, and exert different degrees of inertia in oppoſition to the communication of motion. But the force which impels each individual particle, and the effects of its inertia in different circumſtances, muſt be known before the acceleration of the whole ſyſtem can be determined.

“ The bodies A, B, and C, which may be termed, according to the ideas juſt deſcribed, material points, are imagined to be connected together by ſome perfectly rigid ſubſtance, ſo as always to poſſeſs the ſame ſituation in reſpect to each other: and conſequently no motion can be produced in any of them, excepting that all revolve at the ſame time round the common axis of motion.

“ All the points in this imaginary ſubſtance, by which the parts of the ſyſtem are connected together, partake of the ſame angular motion, deſcribing circles round the common axis S. A force P therefore being applied to any point in the plane of its motion, and in the direction of any line in that plane which paſſes not through the axis, will communicate an equal angular motion to the whole. Thus let B (fig. 113.) repreſent a material point moveable about an axis of motion paſſing through S. With the radius SD deſcribe a circle DGH. Now if B be connected with every point in the area of this circle, which is an inflexible ſubſtance, no force can be applied to move the circle but what muſt communicate the ſame angular motion to B. Let the force be applied at the point D; it is manifeſt, that in order to render its effects conſtant, the inclination of its direction to SD muſt be always the ſame, and in a given plane; and the moſt obvious method of effecting this, either in conſidering the ſubject theoretically, or in the practical illuſtration of it, is by applying a thin and flexible line GHDP round the circumference of the circle DGH, and ſtretching this line by a given moving force P. Here it is plain, that in whatever part the point D is ſituated, the effects of the force P will be the ſame as if it were directly applied to D in the direction of the plane of motion, and perpendicular to SD, and the point B will revolve with the ſame abſolute and angular velocity in both caſes.

“ Let now ABC (fig. 114.) be a ſyſtem of bodies of evaneſcent magnitude and without gravity, moveable about an axis of motion which paſſes through S; it muſt be obſerved, that the imaginary ſubſtance by which the parts of the ſyſtem ABC are connected, muſt contribute nothing either by its weight or inertia to accelerate or retard the motion of the material points A, B, C, which are cauſed to revolve by the action of the given and conſtant force P, applied at the diſtance from the axis SD. The abſolute force of P to move D, or any point of the circumference, will be P; but the communication of motion to this point D is reſiſted by the inertia of the bodies A, B, C; which being moved with different velocities, and acted on by different moving forces, their inertia will not be eſtimated by their quantities of matter only, according to the laws obſerved in rectilinear motion: the force which accelerates D, therefore, cannot be obtained by dividing P by A+B+C; but if an equivalent maſs, or a quantity of matter, can be aſſigned, which being collected into any points of the circumference *a*, *b*, *c*, will cauſe an inertia or reſiſtance to the motion of D equal to that exerted by the particles A, B, C, when revolving at their reſpective diſtances, the force which accelerates the circumference or any point in it D will be determined. Thus, let the maſs Q, when collected into *a*, be ſuch as will be equivalent in its inertia to A, when revolving at the diſtance SA; alſo let R be the maſs collected into *b*, which is equivalent to B when revolving at the diſtance SB; and let T, the maſs collected into C, be equivalent to C when revolving at the diſtance SC; then will the maſs moved by the force P be Q+R+T; and the force which accelerates the circumference $=\frac{P}{Q+R+T}$, being equal to that by which the circumference or any point in it is accelerated when the point conſiſts of A and B and C, revolving at the reſpective diſtances from the axis of motion SA, SB, SC.”

70
Of revolving bodies.

Our author now proceeds particularly to inveſtigate the motion of revolving bodies in almoſt all poſſible circumſtances, deducing from his propoſitions many concluſions very uſeful in practical mechanics. Many of theſe regard the pendulum, and are therefore taken notice of under that article; others more immediately relate to the parts of mechanics particularly treated of in this article: the principal of which follow.

1. The force which accelerates the centre of gravity of a ſphere, while it rolls down an inclined plane, is to the force by which it would be accelerated were it to ſlide in the ratio of five to ſeven. As our limits will not admit of inſerting at length the demonſtration of this and other propoſitions, we ſhall in this only obſerve, that when a wheel or a ſphere *rolls*, the circumference goes backward, while the centre moves forward; which retrograde motion muſt of neceſſity make the other ſlower than it would otherwiſe be: and this retardation Mr Atwood has determined to be in the proportion above-mentioned.

From this propoſition the following corollaries are deduced. 1. The abſolute force whereby motion is generated in the circumference of a ſphere in ſuch a ſituation, is expreſſed by a fraction conſiſting of twice the weight of the ſphere divided by ſeven, and multiplied into another fraction conſiſting of the height of the plane divided by its length; that is, ſuppoſe the weight of the ſphere to be repreſented by *w*, the height of the plane by *h*, and its length by *l*, the force by which the circumference of the ſphere is impelled will be repreſented by $\frac{w}{7}\times\frac{h}{l}$. 2. In the ſame manner, let a cylinder roll down an inclined plane, keeping the axis always horizontal, and the force which accelerates the axis will be repreſented by the fraction $\frac{2}{3}\times\frac{h}{l}$.

2. Let AB (fig. 115.) repreſent a ſtraight lever moveable round an horizontal axis of motion, which paſſes through S. Let the arms be SB, SA. Suppoſe a weight W to be affixed to the extremity of the

ſhorter arm, and to be raiſed by the weight P applied at the extremity of the longer arm, when the lever is horizontal. Required to determine the time in which W will be raiſed through any given height, the weight and inertia of the lever itſelf not being conſidered.

"When there is an equilibrium (ſays Mr Atwood) on any mechanic power, the proportion of the weight ſuſtained to the power ſuſtaining it, will, in all caſes, be aſſigned from having given the dimenſions of the mechanic power. An equilibrium having been once formed, the ſmalleſt addition of weight will cauſe the body to which it is applied on either ſide to preponderate. In this caſe a certain degree of motion is generated; and ſince the uſes of the mechanic powers are not only to ſuſtain forces in equilibrio, but to raiſe weights and overcome reſiſtances, it is a problem of principal conſequence to aſſign the abſolute quantity of motion generated by a known moving force in given circumſtances." The general ſolution of the problem is as follows:

"Let AB be the lever, W the weight moved by the power P; each acting in a direction perpendicular to the horizon. Let G be the common centre of gravity of the whole ſyſtem, including the weights P and W with the lever itſelf; and o the centre of oſcillation *, when AB vibrates round the axis S; the force which accelerates B when the lever is horizontal $=\frac{SG\times SB}{SG\times SO}=\frac{SB}{SO}$ (c). If this be put $=F$, the time wherein P deſcends through a perpendicular ſpace x, and conſequently wherein W aſcends through the correſponding ſpace; then $x\times\frac{SA}{SB}=\sqrt{\frac{x}{lF}}$ (D). $\times\overline{\frac{1+x^2}{SB^2 2.5}}$, &c. $=\sqrt{\frac{x}{l}\times\frac{SO}{SB}\times 1+\frac{x^2}{SB^2 2.5}}$, &c.

* See *Pendulum.*

73 On the wheel-axle. Plate CCXCI.

3. Let ABC (fig. 116.) repreſent a wheel and axle, its weight w, and let the axis be horizontal; having a given weight Q applied to the circumference of the axle, and P applied to the circumference of the wheel in order to raiſe Q. Required to aſſign the ſpace deſcribed by the elevated weight Q in any given time. The ſolution of this problem, without attending to the demonſtration, is this. Having found the accelerating power, which here is $\frac{P\times SD-Q\times SA\times SA}{w\times SR^2\,\text{(E.)}+p\times SD^2+Q\times SA^2}$ All this he puts $=F$; and then l being $=193$ inches as before, the ſpace deſcribed by Q in any number of ſeconds will be = the ſquare of that number of ſeconds multiplied into lF. On this propoſition our author makes the following obſervations.

"Whenever motion is communicated to a body, a certain reſiſtance muſt have been overcome by the moving force. This reſiſtance is of various kinds. 1. The inertia of the maſs moved, whereby it endeavours to perſevere in its ſtate of quieſcence, or of uniform motion in a right line. 2. That of a weight or other abſolute force oppoſed to the action of the moving power. 3. Obſtacles upon which the moving body impinging is retarded in its progreſs: ſuch, for example, is the reſiſtance which ariſes from the particles of a fluid thro' which a body moves. The eſtimation of theſe reſiſtances, and their effects in retarding the motion of bodies acted on by a given force, are deducible from the laws of motion, and conſtitute a part of the ſolution of almoſt all problems relating to the motion of bodies.

"The moving forces alſo are of various kinds, viz. The power of gravity, muſcular power, the impact of bodies, ſolid and fluid, &c. It has been ſhown, that the effects of theſe moving forces which are exerted on bodies in order to create motion, excluſive of the reſiſtance oppoſed to them, depend on the various circumſtances of the time in which they act, and on the ſpaces through which the bodies moved are impelled, &c.

"Theſe conſiderations are urged, to ſhow, that from the great variety of undetermined conditions which may enter into mechanical problems, there muſt of courſe be various methods of producing the ſame mechanical effect: and it is a very material part of the art, conſidered either in a theoretical or practical view, to proportion the means to the end, and to effect this with all the advantages which the nature of the caſe is capable of. It is the due obſervation of theſe particulars which contributes to render mechanic inſtruments complete, and the neglect of them defective, in their conſtruction. This proper choice of means to produce mechanical effects, is frequently the reſult of long continued experience independent of all theory; the knowledge of which, however, when applied to practice, would ſave the artiſt much time and trouble, as well as would be productive of other advantages, which experience alone muſt be deſtitute of."

4. ABC (fig. 116.) is a wheel and axis moveable round an horizontal axis, which paſſes through S. Suppoſe a given weight Q, which is applied to the circumference of the axle; let it be required to aſſign the proportion of the radii of the wheel and axle, ſo that the time in which the weight Q aſcends through any given ſpace ſhall be the leaſt poſſible. In this caſe, ſuppoſing the radius of the wheel to be 10 inches, and its weight 20 ounces; let the radius of the axle SA = 1 inch, the weight to be raiſed thro' any given ſpace to be 100 ounces, the moving force by which it is raiſed to be 33 ounces; then the diſtance of the centre of gyration from the axis is $\sqrt{50}$ inches; and the length of the radius ſought is 9.55 inches.—If, inſtead of raiſing the weight perpendicularly, it be required to draw it horizontally, and to aſſign the diſtance SD, at which, if a given force P be applied, the time of deſcribing a given ſpace ſhall be the leaſt, and the moment of q the greateſt poſſible, we have the following concluſion. "Let the quantity of matter to be drawn along the plane be four times greater than that which is contained in the moving

---

(c) This he had formerly proved when treating of pendulums.

(D) l is here put for 193 inches, the ſuppoſed velocity of the weight P.

(E) R is the centre of gyration of the wheel.

Motion of Bodies,

ving force; the radius of the axle SA being given; in order that it may be impelled with the greateſt velocity poſſible and with the greateſt moment, the radius of the wheel ſhould be double that of the axle when the inertia of the wheel is not conſidered.

5. Let ARCH (fig. 117.) be a ſyſtem of bodies moveable round a vertical axis which paſſes through the common centre of gravity of the ſyſtem. Suppoſe DEG to be a wheel, the axis of which is vertical, and coincident with that of the ſyſtem; let motion be communicated by means of a line going round this wheel, the ſtring DP being ſtretched by a given weight P; let it be required to aſſign the radius of the wheel EGD, ſo that the angular velocity communicated to the ſyſtem may be the greateſt poſſible. Here, ſuppoſing the moving force to be one-fourth of the weight of the ſyſtem, it ſhould be applied at a diſtance from the axis equal to twice the diſtance of the centre of gyration, in order to produce the greateſt poſſible angular velocity in a given time.

"In order (ſays Mr Atwood) to increaſe the action of a moving force againſt a weight to be raiſed, or reſiſtance to be overcome, a combination of two or more mechanic powers is frequently made uſe of. Let *p* (fig. 118.) be a power applied by means of a line to the vertical wheel C: ſuppoſe the circumference of the axle K to be in contact with the circumference of any other vertical wheel B; ſo that the circumference of the wheel B may always move equally faſt with that of the axle which belongs to C; let alſo the axle of B communicate motion to a vertical wheel A, to the axle of which a weight *q* is ſuſpended, ſo as to act in oppoſition to *p*; moreover, let the ratio of *lmn* to 1 be the ſum of the ratios of the radius of each wheel to that of its axle: then, if $plmn = q$, the two weights *p* and *q* will ſuſtain each other in equilibrio; but if *plmn* be at all greater than *q*, the equilibrium will be deſtroyed;" and our author gives a method of calculating the quantity of motion communicated in certain circumſtances.

Our author next goes through a ſet of ſimilar propoſitions relating to the pulley and wedge; after which he treats of the accumulation of power in ponderous cylinders, and the uſe of balaſt-wheels in machines, of which mention has already been made; and having diſcuſſed theſe ſubjects, he next comes to treat of the action of a ſtream of water upon a wheel revolving round an horizontal axis.

6. Let ABC (fig. 119.) repreſent a water-wheel which revolves round an horizontal fixed axis, paſſing through its centre S. Suppoſe DEF to be the axle of this wheel, and that a weight W is affixed to a line DW, ſo wound round the axle, that while the wheel is driven round its own plane by the force of the water impinging at I, the weight W may be raiſed in a vertical line: having given the area of the boards II, againſt which the ſtream impinges perpendicularly, and the altitude from which the water deſcends, it is required to aſſign the greateſt velocity with which the wheel can revolve.

"When a ſtream of any fluid (ſays he) impinges perpendicularly againſt a plain and quieſcent ſurface, the exact quantity of the moving force is equal to the weight of a column of the fluid, the baſe of which is the area upon which the fluid impinges, and the altitude that from which a body muſt deſcend freely from reſt by gravity, in order to acquire that velocity. This will be the moving force which impels the body when quieſcent or juſt beginning to move: but after it has acquired ſome motion, the impulſive force of the body will be diminiſhed; being the ſame as if the body were quieſcent, and the water impinged upon it with the difference of the former velocities. Wherefore the altitude of the column of the fluid, which is equal to its impelling force, will be always as the difference between the velocity of the impact and that of the body itſelf; and ſince the altitudes from which bodies fall from reſt are in a duplicate ratio of the velocities acquired, it follows, that the force of the impact will be in a duplicate ratio of the difference between the velocity of the wheel and that of the impact." The following is the concluſion drawn by Mr Atwood concerning the velocity: Putting A for the weight of the column of water when the wheel is quieſcent; V the velocity with which it impinges on the boards II, &c. and *y* the velocity of the circumference ſought; W the weight of the wheel; then $y = V - V \times \sqrt{\frac{W}{A} \times \frac{SD}{SI}}$.

Motion of Bodies.

7. Every other thing remaining the ſame, let the weight W be varied; and let it be required to aſſign the weight W, ſo that when the wheel has acquired its uniform velocity, the moment of W may be the greateſt poſſible. Here the weight $= \frac{4A \times SI}{9SD.}$

8. Having given a weight W to be raiſed by the action of the ſtream of water, the force of which is $= A$ againſt a quieſcent ſurface; let it be required to aſſign what muſt be the proportion between the radius of the wheel and that of the axle; ſo that the uniform velocity of the aſcending weight may be the greateſt poſſible. Here the length of the radius $= \frac{9W \times SD}{4A}$. Hence he concludes, that if the velocity with which the water impinges againſt the boards be doubled, the greateſt moment communicated to a weight aſcending uniformly, will be increaſed in the proportion of 8 to 1.

71
Atwood's obſervations on water-mills.

"The force (ſays Mr Atwood) which communicates motion to water-wheels, and the reſiſtances which are occaſioned by friction, tenacity, and various other cauſes, render the application of the theory of mechanics to practice, in theſe caſes, extremely difficult. It is probably from this reaſon, that the conſtruction of machines moved by the force of water, &c. has been almoſt wholly practical, the beſt improvements having been deduced from continued obſervation of the reſults produced in given circumſtances; whereby the gradual correction of error, and varied experience of what is moſt effectual, have ſupplied the place of a more perfect inveſtigation from the laws of motion.

"This ſeems to be the beſt method, as far as regards the practical conſtruction of theſe machines, the nature of the caſe will admit of; for although there may be two ways leading ultimately to the ſame truths, *i. e.* a direct inveſtigation from the laws of motion and long continued obſervation, independent of theory, the latter is frequently the moſt eaſy and intelligible, although leſs direct and leſs ſcientific; the former being inacceſſible to thoſe who poſſeſs the elementary

mentary parts of mechanics only. It is in vain to attempt the application of the theory of mechanics to the motion of bodies, except every cauſe which can ſenſibly influence the moving power and the reſiſtance to motion be taken into account: if any of theſe be omitted, error and inconſiſtency in the concluſions deduced muſt be the conſequence. It was at one time ſuppoſed, from this inadequate application of the theory, that the ſame laws of motion would not extend to all branches of mechanics, but that different principles were to be accommodated to different kinds of motion. If this were truly the caſe, the ſcience of mechanics would fall ſhort of that ſuperior excellence and extent which it is generally allowed to poſſeſs. For it is probable, that there is no kind of motion but what may be referred to three eaſy and obvious propoſitions, the truth of which it is impoſſible to doubt: and if we are not enabled to inveſtigate the effects from the data in all caſes, the deficiency muſt not be imputed to the ſcience of mechanics, but to the want of methods of applying mathematics to it.

Fig. 119.

"This may be illuſtrated by an example, in order to ſhow that the motion communicated to water-wheels, however complicated the data may be, is equally referable to the laws of motion, with the effects of the moſt uncompounded force. If a ſtream of water falls perpendicularly on a plain ſurface, the moving force ariſing from the impact only is equal to the weight of a column of water, the baſe of which is the ſurface upon which the water impinges, and altitude that through which a body muſt fall to acquire the velocity of impact. If the inclination of the ſtream to the ſurface ſhould be changed, the force exerted in a direction perpendicular to the plane will be diminiſhed in a duplicate ratio of the radius to the ſine of inclination; the ſurface on which the water impinges remaining. Now, when the water falls on the boards of a water-wheel, the direction of the ſtream makes different angles with the planes of thoſe boards; for ſince the particles of water deſcend in curve lines, they will ſtrike any plain ſurface in the direction of a tangent to the curve on the point of impact. Moreover, the water will ſtrike the higher boards TT with leſs velocity, and in a direction more inclined to their planes, than the lower ones II; it is alſo to be conſidered, that the ſtream will impinge on the boards at different diſtances from the axis of motion: all which circumſtances muſt be taken into account, to find the force which tends to communicate motion to the wheel when quieſcent; and when motion has been communicated, the force of the ſtream to turn the wheel will be determined in the manner already mentioned. But this is not the only conſideration which affects the moving force: The force hitherto conſidered has been ſuppoſed to proceed from the impact of the particles only; in which caſe, each particle after it has ſtruck the board is imagined to be of no other effect in communicating motion: but this is not wholly the caſe; for after the particle has impinged on the board, it will continue ſome time to operate by its weight; and this time will be longer or ſhorter according to the different conſtructions of the wheel. In the overſhot wheel, the continuance of the preſſure, ariſing from the weight of the water, will be longer than in the underſhot, the force which ariſes from the impact of the water being nearly the ſame in each caſe. The whole moving force, therefore, will conſiſt of the impact determinable as above, and of the weight of the water deſcending along with the circumference, and communicating additional motion to it: this entire moving force being determined either by theory or experience, may be denoted by A. After the moving force which impels the circumference has been determined, the reſiſtance to this force muſt be found; for on the proportion between the moving force and the reſiſtance, the acceleration of the machine will depend. This reſiſtance is of various kinds: 1. That of inertia. 2. If the machine is of that kind which raiſes weights, ſuch for inſtance as water; the weight raiſed, allowing for its mechanical effect on the point of which we deſire to know the acceleration, muſt be ſubducted from the moving force before found; and this will be a conſtant quantity. There are other reſiſtances alſo homogeneal to weight, viz. thoſe of friction and tenacity, &c. which are variable in ſome ratio of the machine's velocity: and in order to proceed with the inveſtigation, the exact quantity of weight which the friction is equal to, when the wheel moves with a given velocity, muſt be conſidered, as well as the variation of the reſiſtances in reſpect to the velocities; which circumſtances muſt be determined by experiment. If the force equivalent to the friction, &c. be ſubducted from the moving force, the remainder will give the moving power, by which the circumference is impelled upon the whole: this being divided by the inertia of the maſs moved, will give the force which accelerates the circumference.

72
His apparatus for experiments on motion.

The following apparatus has been invented by Mr Atwood, for illuſtrating his doctrines concerning accelerated motion, and has been found to anſwer the purpoſe more completely than any other we have heard of; diſcovering at once the quantity of matter moved, the force which moves it, the ſpace deſcribed from reſt, the time of deſcription, and the velocity acquired.

1. *Of the maſs moved.*—In order to obſerve the effects of the moving force, which is the object of any experiment, the interference of all other forces ſhould be prevented: the quantity of matter moved, therefore, conſidering it before any impelling force has been applied, ſhould be without weight; for although it be impoſſible to abſtract the natural gravity or weight from any ſubſtance whatever, yet the weight may be ſo counteracted as to be of no ſenſible effect in experiments. Thus in the inſtrument conſtructed to illuſtrate this ſubject experimentally, A, B, fig. 120. repreſent two equal weights affixed to the extremities of a very fine and flexible ſilk line: this line is ſtretched over a wheel or fixed pulley *abcd*, moveable round an horizontal axis: the two weights A, B, being preciſely equal and acting againſt each other, remain in equilibrio; and when the leaſt weight is ſuperadded to either (ſetting aſide the effects of friction), it will preponderate. When AB are ſet in motion by the action of any weight *m*, the ſum $A+B+m$ would conſtitute the whole maſs moved, but for the inertia of the materials which muſt neceſſarily be uſed in the communication of motion; theſe materials conſiſt of,

Motion of Bodies.

1. The wheel *abcd*, over which the line ſuſtaining A and B paſſes. 2. The four friction wheels on which the axle of the wheel *abcd* reſts: the uſe of theſe wheels is to prevent the loſs of motion, which would be occaſioned by the friction of the axle if it revolved on an immoveable ſurface. 3. The line by which the bodies A and B are connected, ſo as when ſet in motion to move with equal velocities. The weight and inertia of the line are too ſmall to have ſenſible effect on the experiments; but the inertia of the other materials juſt mentioned conſtitute a conſiderable proportion of the maſs moved, and muſt be taken into account. Since when A and B are put in motion, they muſt neceſſarily move with a velocity equal to that of the circumference of the wheel *abcd* to which the line is applied; it follows, that if the whole maſs of the wheels were accumulated in this circumference, its inertia would be truly eſtimated by the quantity of matter moved; but ſince the parts of the wheels move with different velocities, their effects in reſiſting the communication of motion to A and B by their inertia will be different; thoſe parts which are furtheſt from the axis reſiſting more than thoſe which revolve nearer in a duplicate proportion of thoſe diſtances. If the figures of the wheels were regular, from knowing their weights and figures, the diſtances of their centres of gyration from their axes of motion would become known, and conſequently an equivalent weight, which being accumulated uniformly in the circumference *abcd*, would exert an inertia equal to that of the wheels in their conſtructed form. But as the figures are wholly irregular, recourſe muſt be had to experiment, to aſſign that equivalent quantity of matter, which being accumulated uniformly in the circumference of the wheel *abcd*, would reſiſt the communication of motion to A in the ſame manner as the wheels.

In order to aſcertain the inertia of the wheel *abcd*, with that of the friction wheels, the weights AB being removed, the following experiment was made.

A weight of 30 grains was affixed to a ſilk line (the weight of which was not ſo much as $\frac{1}{4}$th of a grain, and conſequently too inconſiderable to have ſenſible effect in the experiment); this line being wove round the wheel *abcd*, the weight 30 grains by deſcending from reſt communicated motion to the wheel, and by many trials was obſerved to deſcribe a ſpace of about $38\frac{1}{2}$ inches in 3 ſeconds. From theſe data the equivalent maſs or inertia of the wheels will be known from this rule:

Let a weight P (fig. 121.) be applied to communicate motion to a ſyſtem of bodies by means of a very ſlender and flexible line going round the wheel SLDIM, through the centre of which the axis paſſes (G being the common centre of gravity, R the centre of gravity of the matter contained in this line, and O the centre of oſcillation). Let this weight deſcend from reſt through any convenient ſpace s inches, and let the obſerved time of its deſcent be t ſeconds; then if l be the ſpace through which bodies deſcend freely by gravity in one ſecond, the equivalent weight ſought $=$

$$\frac{W\times SR\times SO}{SD^2}=\frac{P\times t^2 l}{s}-P.$$

Here we have $p=30$ grains, $t=3$ ſeconds, $l=193$ inches, $s=38.5$ inches; and $\frac{P\times t^2 l}{s}-P=\frac{30\times 9\times 193}{385}-30=1323$ grains, or $2\frac{3}{4}$ ounces.

This is the inertia equivalent to that of the wheel *abcd*, and the friction wheels together: for the rule extends to the eſtimation of the inertia of the maſs contained in all the wheels.

The reſiſtance to motion therefore ariſing from the wheel's inertia, will be the ſame as if they were abſolutely removed, and a maſs of $2\frac{3}{4}$ ounces were uniformly accumulated in the circumference of the wheel *abcd*. This being premiſed, let the boxes A and B be replaced, being ſuſpended by the ſilk line over the wheel or pulley *abcd*, and balancing each other: ſuppoſe that any weight m be added to A ſo that it ſhall deſcend, the exact quantity of matter moved, during the deſcent of the weight A, will be aſcertained; for the whole maſs will be $A+B+m+2\frac{3}{4}$ oz.

Fig. 120.

In order to avoid troubleſome computations in adjuſting the quantities of matter moved and the moving forces, ſome determinate weight of convenient magnitude may be aſſumed as a ſtandard, to which all the others are referred. This ſtandard weight in the ſubſequent experiments is $\frac{1}{4}$ of an ounce, and is repreſented by the letter m. The inertia of the wheels being therefore $=2\frac{3}{4}$ ounces, will be denoted by $11\,m$. A and B are two boxes conſtructed ſo as to contain different quantities of matter, according as the experiment may require them to be varied: the weight of each box, including the hook to which it is ſuſpended, $=1\frac{1}{2}$ oz. or according to the preceding eſtimation, the weight of each box will be denoted by $6\,m$; theſe boxes contain ſuch weights as are repreſented by fig. 122. each of which weighs an ounce, ſo as to be equivalent to $4\,m$; other weights of $\frac{1}{2}$oz.$=2m$, $\frac{1}{4}=m$, and aliquot parts of m, ſuch as $\frac{1}{2}m$, $\frac{1}{4}m$, may be alſo included in the boxes, according to the conditions of the different experiments hereafter deſcribed.

If $4\frac{3}{4}$ oz. or $19\,m$, be included in either box, this with the weight of the box itſelf will be $25m$; ſo that when the weights A and B, each being $25m$, are balanced in the manner above repreſented, their whole maſs will be $50\,m$, which being added to the inertia of the wheels $11\,m$, the ſum will be $61\,m$. Moreover, three circular weights, ſuch as that which is repreſented at fig. 123. are conſtructed; each of which $=$ $\frac{1}{4}$ oz. or m: if one of theſe be added to A and one to B, the whole maſs will now become $63m$, perfectly in equilibrio, and moveable by the leaſt weight added to either (ſetting aſide the effects of friction), in the ſame manner preciſely as if the ſame weight or force were applied to communicate motion to the maſs $63m$, exiſting in free ſpace and without gravity.

2. *The moving Force.* Since the natural weight or gravity of any given ſubſtance is conſtant, and the exact quantity of it eaſily eſtimated, it will be convenient here to apply a weight to the maſs A as a moving force: thus, when the ſyſtem conſiſts of a maſs $=63m$, according to the preceding deſcription, the whole being perfectly balanced, let a weight $\frac{1}{4}$oz. or m, ſuch as is repreſented in fig. 124. be applied on the maſs A; this will communicate motion to the whole ſyſtem: by adding a quantity of matter m to the former maſs $63m$, the whole quantity of matter moved will now become

become $64m$; and the moving force being $=m$, this will give the force which accelerates the deſcent of A $=\frac{m}{64m}$, or $\frac{1}{64}$ part of the accelerating force by which the bodies deſcend freely towards the earth's ſurface.

By the preceding conſtruction, the moving force may be altered without altering the maſs moved; for ſuppoſe the three weights m, two of which are placed on A, and one on B to be removed, then will A balance B. If the weights $3m$ be all placed on A, the moving force will now become $3m$, and the maſs moved $64m$ as before, and the force which accelerates the deſcent of $A=\frac{3m}{64m}=\frac{3}{64}$ parts of the force by which gravity accelerates bodies in their free deſcent to the ſurface.

Suppoſe it were required to make the moving force $2m$, the maſs moved continuing the ſame. In order to effect this, let the three weights, each of which $=m$, be removed; A and B will balance each other; and the whole maſs will be $61m$: let $\frac{1}{2}m$, fig. 124. be added to A, and $\frac{1}{2}m$ to B, the equilibrium will ſtill be preſerved, and the maſs moved will be $62m$; now let $2m$ be added to A, the moving force will be $2m$, and the maſs moved $64m$, as before; wherefore the force of acceleration $=\frac{1}{32}$ part of the acceleration of gravity. Theſe alterations in the moving force may be made with great eaſe and convenience in the more obvious and elementary experiments, there being no neceſſity for altering the contents of the boxes A and B: but the proportion and abſolute quantities of the moving force and maſs moved may be of any aſſigned magnitude, according to the conditions of the propoſition to be illuſtrated.

3. *Of the ſpace deſcribed.* The body A, fig. 120, deſcends in a vertical line; and a ſcale about 64 inches in length graduated into inches and tenths of an inch is adjuſted vertical, and ſo placed that the deſcending weight A may fall in the middle of a ſquare ſtage, fixed to receive it at the end of the deſcent: the beginning of the deſcent is eſtimated from o on the ſcale, when the bottom of the box A is on a level with o. The deſcent of A is terminated when the bottom of the box ſtrikes the ſtage, which may be fixed at different diſtances from the point o; ſo that by altering the poſition of the ſtage, the ſpace deſcribed from quieſcence may be of any given magnitude leſs than 64 inches.

4. *The time of motion* is obſerved by the beats of a pendulum, which vibrates ſeconds; and the experiments, intended to illuſtrate the elementary propoſitions, may be eaſily ſo conſtructed that the time of motion ſhall be a whole number of ſeconds: the eſtimation of the time, therefore, admits of conſiderable exactneſs, provided the obſerver takes care to let the bottom of the box A begin its deſcent preciſely at any beat of the pendulum; then the coincidence of the ſtroke of the box againſt the ſtage, and the beat of the pendulum at the end of the time of motion, will ſhow how nearly the experiment and the theory agree together. There might be various mechanical devices thought of for letting the weight A begin its deſcent at the inſtant of a beat of the pendulum W; let the bottom of the box A, when at o on the ſcale, reſt on a flat rod, held in the hand horizontally, its extremity being coincident with o, by attending to the beats of the pendulum; and with a little practice, the rod which ſupports the box A may be removed at the moment the pendulum beats, ſo that the deſcent of A ſhall commence at the ſame inſtant.

4. *Of the velocity acquired.* It remains only to deſcribe in what manner the velocity acquired by the deſcending weight A, at any given point of the ſpace through which it has deſcended, is made evident to the ſenſes. The velocity of A's deſcent being continually accelerated will be the ſame in no two points of the ſpace deſcribed. This is occaſioned by the conſtant action of the moving force; and ſince the velocity of A at any inſtant is meaſured by the ſpace which would be deſcribed by it, moving uniformly for a given time with the velocity it had acquired at that inſtant, this meaſure cannot be experimentally obtained, except by removing the force by which the deſcending body's acceleration was cauſed.

In order to ſhow in what manner this is affected particularly, let us again ſuppoſe the boxes A and B $=25m$ each, ſo as together to be $=50m$; this with the wheel's inertia $11m$ will make $61m$; now let m, fig. 122, be added to A, and an equal weight m to B, theſe bodies will balance each other, and the whole maſs will be $63m$. If a weight m be added to A, motion will be communicated, the moving force being m, and the maſs moved $64m$. In eſtimating the moving force, the circular weight $=m$ was made uſe of as a moving force: but for the preſent purpoſe of ſhowing the velocity acquired, it will be convenient to uſe a flat rod, the weight of which is alſo $=m$. Let the bottom of the box A be placed on a level with o on the ſcale, the whole maſs being as deſcribed above $=63m$, perfectly balanced in equilibrio. Now let the rod, the weight of which $=m$, be placed on the upper ſurface of A; this body will deſcend along the ſcale preciſely in the ſame manner as when the moving force was applied in the form of a circular weight. Suppoſe the maſs A, fig. 125, to have deſcended by conſtant acceleration of force of m, for any given time, or through a given ſpace: let a circular frame be ſo affixed to the ſcale, contiguous to which the weight deſcends, that A may paſs centrally through it, and that this circular frame may intercept the rod m by which the body A has been accelerated from quieſcence. After the moving force m has been intercepted at the end of the given ſpace or time, there will be no force operating on any part of the ſyſtem which can accelerate or retard its motion: this being the caſe, the weight A, the inſtant after m has been removed, muſt proceed uniformly with the velocity which it had acquired that inſtant: in the ſubſequent part of its deſcent, the velocity being uniform will be meaſured by ſpace deſcribed in any convenient number of ſeconds.

Other uſes of the inſtrument. It is needleſs to deſcribe particularly, but it may not be improper juſt to mention the further uſes of this inſtrument; ſuch as the experimental eſtimation of the velocities communicated by the impact of bodies elaſtic and nonelaſtic; the quantity of reſiſtance oppoſed by fluids, as well as for various other purpoſes. Theſe uſes we ſhall not inſiſt on; but the properties of retarded motion being a part of the preſent ſubject, it may be neceſſary to ſhow in what manner the motion of bodies reſiſted by conſtant forces are reduced to experiment by means of the inſtrument above deſcribed, with as great eaſe and preciſion as the properties of bodies uniformly accelerated. A ſingle inſtance will be ſufficient: Thus, ſuppoſe the maſs contained in the weights A and B, fig. 125. and the wheels to be 61 m, when perfectly in equilibrio; let a circular weight m be applied to B, and let two long weights or rods, each $=m$, be applied to A, then will A deſcend by the action of the moving force m, the maſs moved being 64 m: ſuppoſe that when it has deſcribed any given ſpace by conſtant acceleration, the two rods m are intercepted by the circular frame above deſcribed, while A is deſcending through it, the velocity acquired by that deſcent is known; and when the two rods are intercepted, the weight A will begin to move on with the velocity acquired, being now retarded by the conſtant force m; and ſince the maſs moved is 62 m, it follows, that the force of retardation will be $\frac{1}{62}$ part of that force whereby gravity retards bodies thrown perpendicularly upwards. The weight A will therefore proceed along the graduated ſcale in its deſcent with an uniformly retarded motion, and the ſpaces deſcribed, times of motion, and velocities deſtroyed by the reſiſting force, will be ſubject to the ſame meaſures as in the examples of accelerated motion above deſcribed.

In the foregoing deſcriptions, two ſuppoſitions have been aſſumed, neither of which are mathematically true: but it may be eaſily ſhown that that are ſo in a phyſical ſenſe; the errors occaſioned by them in practice being inſenſible.

1. The force which communicates motion to the ſyſtem has been aſſumed conſtant; which will be true only on a ſuppoſition that the line, at the extremities of which the weights A and B, fig. 120. are affixed, is without weight. In order to make it evident, that the line's weight and inertia are of no ſenſible effect, let a caſe be referred to, wherein the body A deſcends through 48 inches from reſt by the action of the moving force m, when the maſs moved is 64 m; the time wherein A deſcribes 48 inches is increaſed by the effects of the line's weight by no more than $\frac{312}{100000}$th parts of a ſecond; the time of deſcent being 3.9896 ſeconds, when the ſtring's weight is not conſidered, and the time when the ſtring's weight is taken into account $=$ 4.0208 ſeconds; the difference between which is wholly inſenſible by obſervation.

2. The bodies have alſo been ſuppoſed to move in vacuo, whereas the air's reſiſtance will have ſome effect in retarding their motion: but as the greateſt velocity communicated in theſe experiments, cannot much exceed that of about 26 inches in a ſecond (ſuppoſe the limit 26.2845), and the cylindrical boxes being about $1\frac{3}{4}$ inches in diameter, the air's reſiſtance can never increaſe the time of deſcent in ſo great a proportion as that of 240 : 241; its effects therefore will be inſenſible in experiment.

The effects of friction are almoſt wholly removed by the friction wheels; for when the ſurfaces are well poliſhed and free from duſt, &c. if the weights A and B be balanced in perfect equilibrio, and the whole maſs conſiſts of 63 m, according to the example already deſcribed, a weight of $1\frac{1}{2}$ grains, or at moſt 2 grains, being added either to A or B, will communicate motion to the whole; which ſhows that the effects of friction will not be ſo great as a weight of $1\frac{1}{2}$ or 2 grains. In ſome caſes, however, eſpecially in experiments relating to retarded motion, the effects of friction become ſenſible; but may be very readily and exactly removed by adding a ſmall weight 1.5 or 2 grains to the deſcending body, taking that the weight added is ſuch as is in the leaſt degree ſmaller than that which is juſt ſufficient to ſet the whole in motion, when A and B are equal and balance each other before the moving force is applied.

MECHOACAN, a province of Mexico, or New Spain, in America, bounded on the north by Panuco and Gaudalajara, on the eaſt by Panucs and Mexico Proper, on the ſouth by the Pacific Ocean, and on the weſt by Guadalajara and the South Sea. The ſoil is exceedingly fertile; and the climate ſo wholeſome, that the Spaniards imagine it to be poſſeſſed of ſome peculiarly reſtorative quality; for which reaſon the ſick and infirm flock to it from all quarters. The commodities are ſulphur, indigo, ſarſaparilla, ſaſſafras, cacao, vanelloes, ambergriſe, hides, wool, cotton, ſilk, ſugar, the root mechoacan or white jalap, and ſilver. This province formed an independent kingdom at the time Mexico was reduced by Cortez. The ſovereign had long been the inveterate enemy of the Mexicans, and was conſidered, next to the republic of Tlaſcala, as the moſt formidable barrier againſt the extenſion of the imperial frontier. However, he ſubmitted to Cortez without ſtriking a blow, being intimidated by the wonders he had performed with a handful of men; and thus Mechoacan became a province of the Spaniſh empire, and a valuable addition to Mexico. The country at that time was exceedingly populous, but the natives are now much thinned; and that rather by the luxury and effeminacy introduced by the Spaniards, than by their tyranny. The capital of the province is alſo called *Mechoacan* by the natives, but *Valladolid* by the Spaniards.

MECHOACAN, or *White Jalap*, in the materia medica, the root of an American ſpecies of convolvulus brought from Mechoacan, a province of Mexico, in thin ſlices like jalap, but larger, and of a whitiſh colour. It was firſt introduced into Europe about the year 1524, as a purgative univerſally ſafe, and capable of evacuating all morbific humours from the moſt remote parts of the body: but as ſoon as jalap became known, mechoacan gradually loſt its reputation, which it has never ſince been able to retrieve. It is nevertheleſs by ſome ſtill deemed an uſeful cathartic; it has very little ſmell or taſte, and is not apt to offend the ſtomach; its operation is ſlow, but effectual and ſafe. Geoffroy affirms, that there is ſcarce any purgative accompanied with fewer inconveniences. It ſeems to differ from jalap only in being weaker; the reſins obtained from both have nearly theſ ame qualities, but jalap yields five or ſix times as much as mechoacan; hence it is found neceſſary to exhibit the latter in ſix times the doſe of the former to produce the ſame effects.

MECKLENBURG, a duchy of Germany, containing thoſe of Schwerin and Guſtro, is bounded by Pomerania on the eaſt, by part of the marquiſate of Brandenburg and the duchy of Lunenburg on the ſouth, the Baltic on the north, and Holſtein and Saxe-Lawenburg on the weſt. Their greateſt length is about 120 miles, and greateſt breadth upwards of 60. With reſpect to the ſoil, much cannot be ſaid in favour of it, as it conſiſts in general, either of ſand, or large and deſolate heaths, interſperſed with moors, woods, fens, and lakes. It yields very little wheat, and not a great deal of oats, rye, and barley; but breeds a conſiderable number of ſheep and cattle, has plenty of fiſh, with ſtone-quarries, ſalt-ſprings, alum, iron, and ſome copper. The principal rivers here are the Elde and Stor, which fall into the Elbe as it glides along the borders of this country to the ſouth-weſt; the Reckenitz, which diſcharges itſelf into the Baltic; as do the Peene, the Warno, and the Stopenitz. This country has only one harbour on the Baltic, namely that of Roſtock. In both duchies, excluſive of Roſtock, are 45 great and ſmall cities, with three convents, and a great number of manors and farms, belonging either to the duke, the nobility, or convents. The peaſants are in a ſtate of villainage; but the nobility enjoy very conſiderable privileges. The ſtates are compoſed of the nobility and towns; and the diets, which are ſummoned annually, are held alternately at Sternberg and Malehin. The duchy of Schwerin appoints four provincial counſellors, and that of Guſtro as many; who rank according to ſeniority with the duke's actual privy-counſellors, as their marſhals do with the colonels. The leſſer committee repreſents the whole body of the nobility and commons, by whom the members are choſen freely and without controul, and no edict relative to the whole country can be publiſhed without their conſent, or in prejudice of their rights. The inhabitants of this country are moſtly Lutherans, under their ſuperintendants. There are alſo ſome Calviniſts and Roman Catholics. Beſides the grammar-ſchools in the towns, there is an univerſity at Roſtock. The commodities of the duchy are corn, flax, hemp, hops, wax, honey, cattle, butter, cheeſe, wool, and wood, a part of which is exported, but hardly any manufactures.

Of the houſe of Mecklenburg, there are two lines ſtill ſubſiſting, viz. that of Schwerin and that of Strelitz. The latter commenced in duke Adolphus Frederick II. younger brother of the duke of Schwerin, and grandfather of the preſent duke of Strelitz, Adolphus Frederick IV. who entered on the government in 1752, and whoſe family hath lately received a great additional luſtre by his Britannic majeſty's taking his ſecond ſiſter for his conſort, and by her own great merit and noble deportment in that high ſtation. Beſides the duchy of Strelitz, to this duke belong the principality of Ratzeburg, with the lordſhip of Stargard, the ancient commanderies of Miro and Nemero, and a yearly penſion of 9000 dollars out of the Boitzenburgh toll. The title aſſumed by both the dukes is *duke of Mecklenburg, prince of Wenden, Schwerin, and Ratzburg, count of Schwerin and the country of Roſtock, and lord of Stargard.* By the agreement concluded at Wittſtock in 1442, the elector of Brandenburg, on the extinction of the male-line of the dukes of Mecklenburg, is entitled to their whole ſucceſſion. The duke of Schwerin has two votes both in the diet of the empire and that of the circle. The matricular aſſeſſment for the duchies of Schwerin and Guſtro is 40 horſe and 67 foot, or 748 florins monthly, including what is paid by Sweden for Wiſmar, and the bailiwics of Poll and Neukloſter. To the chamber of Wetzlar, theſe two duchies pay each 243 rix-dollars, 43 kruitzers. For the government of Mecklenburg, the adminiſtration of juſtice, and the management of the revenue, there is the privy council of regency, the demeſne-chamber, the high and provincial court of juſtice, to which appeals lie in moſt cauſes, both from the conſiſtory and the inferior civil courts, and which are common to both the dukes. As to the revenues, thoſe of the Schwerin line muſt be very conſiderable, thoſe ariſing from the demeſne-bailiwics and regalia alone amounting to 300,000 rix-dollars per annum. There is a tax on land that produces no contemptible ſum, and that called the *princeſs's tax* is fixed at 20,000 rix-dollars: beſides all theſe, there are alſo free-gifts. The whole revenues of the Strelitz branch are eſtimated at 120,000 rix-dollars. Each of theſe princes maintains a body of troops.

MECONIUM, the excrement contained in the guts of an infant at its birth. If this matter is not ſoon purged off, it occaſions gripes, &c. A tea-ſpoonful of true caſtor oil is an excellent purge in this caſe; but the firſt milk from the mother's breaſt is uſually ſufficient, if it flows in due time.

Meconium, in pharmacy, the extract of Britiſh poppies. It has all the virtues of foreign opium, but in a ſomewhat lower degree.

END OF THE TENTH VOLUME.

DIRECTIONS FOR PLACING THE PLATES OF VOL. X.

Plate	Page	Plate	Page

In all, 22 Plates.

ERRATA.

Page 121. col. 1. line 30. For “ *Lord* Napier, Baron of Merchiſton,” read “ *John* Napier, Baron,” &c. And for “ *Lord* Napier,” in different other places in the courſe of the article, read “ *Baron* Napier.” The ſame error has been fallen into by ſeveral former writers, when treating of the invention of Logarithms. *John*, above mentioned, the real author of that invention, was, according to the cuſtom of Scotland in his time, called The Baron of Merchiſton; *Baron* being an appellation then given to all the great landholders, but which did not confer or imply the title of *Lord*. The firſt Lord Napier was *Archibald*, eldeſt ſon of the illuſtrious inventor of the Logarithms.

P. 309. col. 1. l. 8. For *paternas*, read *paternos*.
413. col. 2. line 26. For *Goetic*, read *Geotic*.
537. col. 2. l. 16. from bottom. For CASIA, read CASSIA.
651. in the Title of the Catalogue of Simples. For *method*, read *methods*.
