THE JOURNAL

OF THE

American Medical Association

A MEDICAL JOURNAL CONTAINING THE

OFFICIAL RECORD OF THE PROCEEDINGS OF THE ASSOCIATION, AND THE PAPERS READ AT THE ANNUAL MEETING, IN THE SEVERAL SECTIONS, TOGETHER WITH THE

MEDICAL LITERATURE OF THE PERIOD

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES

BY

GEORGE H. SIMMONS, A.M., M.D.

VOLUME XXXIII

JULY — DECEMBER

1899

396638
36.9A1

CHICAGO
AMERICAN MEDICAL ASSOCIATION PRESS.

1899

"The American Medical Association, though formally accepting and publishing the reports of the various Standing Committees (and Sections), holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except otherwise decided by special resolution."—TRANSACTIONS, 1851.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1899-1900

GENERAL OFFICERS

PRESIDENT—W. W. KEEN	Philadelphia.
FIRST VICE-PRESIDENT—CHARLES A. WHEATON	St. Paul.
SECOND VICE-PRESIDENT—E. D. FERGUSON	Troy, N. Y.
THIRD VICE-PRESIDENT—J. M. ALLEN	Liberty, Mo.
FOURTH VICE-PRESIDENT—WILLIAM D. MIDDLETON	Davenport, Iowa.
TREASURER—HENRY P. NEWMAN	100 Washington St., Chicago.
SECRETARY—GEORGE H. SIMMONS	61 Market St., Chicago.
ASSISTANT SECRETARY—J. A. JOY	Atlantic City, N. J.
LIBRARIAN—GEORGE W. WEBSTER	Chicago.
CHAIRMAN COM. OF ARRANGEMENTS—PHILIP MARVEL	Atlantic City, N. J.

BOARD OF TRUSTEES.

Joseph Eastman, 197 N. Delaware St., Indianapolis, 1900.
 J. T. Priestley, 707 E. Louis St., Des Moines, Iowa, 1900.
 Truman W. Miller, 100 State St., Chicago, 1900.
 Alonzo Garcelon, Lewiston, Maine (President), 1901.
 T. J. Happel, Trenton, Tenn., 1901.
 I. N. Love, 4661 Maryland Ave., St. Louis, 1901.
 E. E. Montgomery, 1715 Walnut St., Philadelphia, 1902.
 H. L. E. Johnson, 1400 L St. N.W., Washington, D. C., 1902.
 C.A. L. Reed, Seventh and Race Sts., Cincinnati, 1902.

JUDICIAL COUNCIL.

Term expires 1900: D. W. Crouse, Iowa; R. C. Moore, Nebraska; T. D. Crothers, Connecticut; G. B. Gillespie, Tennessee; W. T. Bishop, Pennsylvania; C. H. Hughes, Missouri; Ida J. Heiberger, District of Columbia. Term expires 1901: S. Bailey, Iowa; D. R. Brower, Illinois; N. S. Davis, Illinois; H. D. Didama, New York; D. Mason, Washington; F. T. Rogers, Rhode Island; Milo B. Ward, Missouri. Term expires 1902: J. D. Griffith, Kansas City, Mo.; P. H. Bailhache, Marine Hospital Service; J. E. Cook, Cleveland; J. P. Lewis, Topeka, Kan.; F. H. Wiggin, New York City; J. W. Irwin, Louisville; Walter Wynn, Washington, D. C.

SECTION OFFICERS

Officers of Section, 1899-1900.

Practice of Medicine—George Dock, Ann Arbor, Mich., Chairman; T. B. Fitcher, Baltimore, Secretary.
 Surgery and Anatomy—H. O. Walker, Detroit, Mich., Chairman; Ramon Gutiérrez, New York City, Secretary.
 Obstetrics and Diseases of Women—W. E. B. Davis, Birmingham, Ala., Chairman; F. F. Lawrence, Columbus, Ohio, Secretary.
 Materia Medica, Pharmacy and Therapeutics—Leon L. Solomon, Louisville, Ky., Chairman; J. W. Walnwright, New York City, Secretary.
 Ophthalmology—H. V. Würdemann, Milwaukee, Chairman; C. F. Clarke, Columbus, Ohio, Secretary.
 Laryngology and Otology—Christian R. Holmes, Cincinnati, Chairman; J. A. Stucky, Lexington, Ky., Secretary.
 Diseases of Children—Edwin Rosenthal, Philadelphia, Chairman; Louis Fischer, New York City, Chairman.
 Physiology and Dietetics—Elmer Lee, New York City, Chairman; R. Harvey Cook, Oxford, Ohio, Secretary.
 Neurology and Medical Jurisprudence—Hugh T. Patrick, Chicago, Chairman; F. S. Pearce, Philadelphia, Secretary.
 Cutaneous Medicine and Surgery—L. Duncan Bulkley, New York City, Chairman; R. R. Campbell, Chicago, Secretary.
 State Medicine—W. C. Woodward, Washington, D. C., Chairman; Armand Ravold, St. Louis, Secretary.
 Stomatology—M. H. Fletcher, Cincinnati, Chairman; Eugene S. Talbot, Chicago, Secretary.

General Business Committee, 1899-1900.

Practice of Medicine—J. H. Musser, Philadelphia; S. A. Fiske, Denver; Frank Billings, Chicago.
 Surgery and Anatomy—Reginald Sayre, New York City; W. L. Rodman, Philadelphia; W. J. Mayo, Rochester, Minn.
 Obstetrics and Diseases of Women—Milo B. Ward, Kansas City; Joseph Price, Philadelphia; A. H. Cordier, Kansas City.
 Materia Medica, Pharmacy and Therapeutics—T. H. Stucky, Louisville, Ky.; John V. Shoemaker, Philadelphia; Warren B. Hill, Milwaukee.
 Ophthalmology—G. E. de Schweinitz, Philadelphia; Harold Gifford, Omaha; Casey A. Wood, Chicago.
 Laryngology and Otology—William E. Casselberry, Chicago; B. Alexander Randall, Philadelphia; Emil Mayer, New York City.
 Diseases of Children—A. C. Cotton, Chicago; J. P. Crozer Griffith, Philadelphia; H. E. Tuley, Louisville, Ky.
 Physiology and Dietetics—A. P. Clarke, Cambridge, Mass.; Randall Hunt, Shreveport, La.; James Weir, Jr., Owensboro, Ky.
 Neurology and Medical Jurisprudence—W. J. Herdman, Ann Arbor, Mich.; Chas. H. Hughes, St. Louis; Frederick Peterson, New York City.
 Cutaneous Medicine and Surgery—A. Ravogll, Cincinnati; A. W. Bratton, Indianapolis; W. T. Corlett, Cleveland.
 State Medicine—Elmer Lee, New York City; Arthur R. Reynolds, Chicago.
 Stomatology—John S. Marshall, Chicago; A. E. Baldwin, Chicago; G. V. I. Brown, Milwaukee.
 Executive Council—W. J. Herdman, Ann Arbor, Mich., Chairman; W. T. Mayo, Rochester, Minn., Vice-Chairman; J. H. Musser, Philadelphia; H. E. Tuley, Louisville, Ky.

GENERAL INDEX.

*Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings, e. g., brain, cerebral, tumors, etc.; heart and cardiac; cirrhosis, liver and hepatic; child, children and infant; gland, thyroid, etc. Often, too, writers treat of the eye, ear, nose and throat under one head, etc., and the titles do not always permit of indexing under the several headings. The "General Index" contains only titles of articles, editorials, society reports, and miscellaneous matter appearing in the Journal, the book notices, deaths, discussions, authors, and titles of articles mentioned in the "Current Medical Literature" department being indexed and arranged under their separate headings instead of in the body of the "General Index." The * preceding the page reference in the "Index of Authors" indicates that the article appeared in full in the Journal. In the case of titles included in the Index of Titles, only those of articles given in abstract in the "Current Medical Literature" department from week to week appear also in the "General Index." Societies are indexed under Association, College, Conference, Congress and Society.*

- Abbott, E. H., breech presentation, 338
 Abdomen (see cancer, echinococcosis, operations).
 injury to without external wounds, 746
 gunshot wounds of, 1549
 Abdominal (see aorta, arthritis, colon, contusions, fat-necrosis, fibroma, fibrosarcoma, hernia, hysterectomy, incisions, injuries, lavage, operations, pain, palpitations, pregnancy, sections, surgery, sutures, tumors).
 exploration, 1605
 Aborigines, filaria in blood of, 98
 Abortion, artificial, and induced labor, 568
 Insanity from, 1413
 to prevent, 504
 with no vagina, 494
 Abrams, A., treatment of consumption, 915
 Abscesses (see brain, cerebellar, epiglottitis, liver, lung, sinus), cerebellar, 535
 double poas, 1602
 of paracarditis, 279
 hepatic, 276
 orbital, points in diagnosis, 1409
 otitic brain, 470
 peritonissilar, 343
 post-appendicial, 344
 prostatic, and urethritis, 1228
 tonsillar, abscesses following, 1187
 Abscesses, palmar, 474
 tonsillar, 971
 Abt, I. A., complications of diphtheria, 1190
 Academia de Med. of Brazil, 604
 Acad. of Med. and Surg. Sci., St. Louis, 1494
 of Med. and Surg., Topeka, 354
 918, 1560
 of Med., Cal., 161, 227, 414, 462, 732, 1101, 1425
 of Med., Chicago, 347, 415, 483, 606, 1167, 1226, 1489
 of Med., Cincinnati, 192, 794, 917, 1294, 1422, 1495
 of Med., Detroit, 983, 1040, 1362, 1617.
 of Med., Minn., 1040
 of Med., N. Y., 1292, 1355, 1422
 of Ky. Surg., Am., 604, 1041
 Accident, unusual, 1351
 Accutimid as substitute for drugs, 332
 habit, 33
 in ear supuration, 1033
 in typhoid, cases, 582
 poisoning, 32
 Acetoneuria and fatty acids, 160
 pathologic, 975
 Acetoneuria, 357
 Acid (see arsenious, boric, cacodylic, camphoric, carbolic, citraconic, citric, hydrochloric, lactic, osmic, oxybutyric, phenic, picric, sulphuric, etc.)
 Acetic fatty, acetoneuria and, 160
 Acne, iodid of potash in, 1285
 nature and treatment, 1412
 necrotic, 1607
 Acne, 494
 anesthetic in subconjunctival injections, 1210
 Acromioclavicular, 110
 Acromioclavicular, pathogenesis of, 674
 symptomatology of, 1418
 Acromioclavicular, 101, 343, 1035
 Act, Illinois Medical practice, 450
 medical practice, Ill., 1435
 Actinomycetes, examining pus for, 476
 Actinomycosis hominis, 1030, 1039
 Action, study of cumulative, 1288
 Adams, J. G., bovine tuberculosis, 621
 J. G., latent infection, etc., 1509, 1572
 Adams, E. P., gouty diathesis, 1585
 E. P., skin grafting, 102
 Addison's disease, 41
 Address, 93
 Am. Public Health Assn., 1223
 Cal. State Med. Soc., 21
 in laryngology, 307
 in neurology, 308
 in state medicine, 540
 Ky. State Med. Soc., 156
 of president, 418
 on medicine, 2
 on nasal disorders, 340
 on otitis, 340
 on recent war, 541
 on stomatology, 57
 on surgery, 243
 of surgeons, Canadian Med. Assn., 621
 Address, change of, 56, 176, 180, 242, 304, 320, 341, 478, 502, 624, 626, 750, 816, 874, 932, 996, 1056, 1118, 1184, 1244, 1312, 1380, 1444, 1508, 1568, 1636
 Adenasthenia gastrica, for, 901
 Adenitis, cervical tubercular, 1481
 tuberculous, 1090
 Adenocarcinoma (see nose).
 Adenoïd infections, hemorrhage after, 273
 Adenoïds (see infectious diseases, post-pharynx, tonsils).
 in adult, 541
 in ear diseases, 1577
 nasopharyngeal, treatment of, 1291
 results of operations for, 1039
 Adenoma of urethra, 2211
 Adenomas, rectal, 1650
 Adenomata, rectal, 38
 Adenomata of sexual apparatus, 863
 Adhesions, intestinal, in pelvic disease, 913
 in urethra, 1645
 Adult defect (see childhood), disease, relations of, 415, 416
 disease, school strain and, 485
 Adulteration of foodstuffs, 1562
 Advertising, medical, 660, 1179
 method of, 1311
 in interdict period, treatment of, 1653
 Aged, plea for, 1136
 pneumonia of, 458
 Aggritation by red corpuscles, 911
 Aikin, J. M., cerebral hemorrhage, 1464
 Air (see liquid), entrance into circulation, 1285
 in lungs, 152
 liquid, 276, 538
 superheated, in articular disease, 1621
 Albumin in urine, estimation of, 762
 Albuminuria (see hydrophobia, donkey), accidental or spurious, 764
 handicapping, influence of, 478
 in apparently healthy, 1651
 Albuminuria, functional, 113
 with lymphatic disposition, 1548
 Albumose peptone, 1481
 485
 Alcohol (see blindness, endometriosis, longevity, night sweats), amaurosis, methyl, 1653
 an antidote for carbolic acid, 424
 and legal responsibility, 747
 and misrepresentation, 1365
 as a beverage, 1235
 as a stimulant, 1164
 evils of, 1650
 food value of, 46
 in medicine, 341
 narcosis, 1652
 narcosis, theory of, 279
 tobacco and, 95
 Alcoholic (see neuritis, polyneuritis), pathology of, 534
 Aldrich, C. J., cerebrospinal meningitis, 42
 cord lesions, 1169
 T. E., chloroform, 777
 Alexander's operation, 804
 Alimentary canal in anemia, 975
 canal, wounds of, 730
 tract, and, anastomosis of, 969
 Alimentation, artificial, 411
 Alkalies, use of, 557
 Alkalinization, effects of, 747
 Alshen, J. B., growth of pylorus, 978
 J. E., pyroelectric, 1338
 Allen, D. P., exophary of bladder, 258, 337
 W. H., Sanitation in England, 1291
 S. E., Dyspnea from glands, 795
 S. E., Mastoid disease, 795
 F. S., Otitis media purulenta, 1143
 J. M., Diabetes mellitus, 1070
 Alliance of America, medical, 871
 Allison, C. C., Tubercular pelvic peritonitis, 24
 Alloxalic, 1596, 1621
 of jaw, 37
 Alloxalic bodies, method of determining, 60
 arentia, 788
 Allport, C., eyes of employees, 1528
 Altitude (see arteriosclerosis, blood, heart, hemoglobin, phthisis)
 Amaurosis from dynamite gases, 537
 methyl alcohol, 1653
 Amberg, E., Anatomy of temporal bone, 984
 Amherst, P., Serotherapy, 64
 Amblyopia, tobacco, 155
 toxic, 1157
 Amnion, rupture in disease, 971, 987
 dysenteric, liver abscess, 34
 Amenorrhœa with Raynaud's disease and tuberculosis, 728
 Letourneau, for, 1538
 American, development of, 611, 1368, 904
 Anemia, 904
 Amputated parts, not responsible for, 685
 Amputation by bands, 103
 of limb, in chronic, 76
 in ages, 795
 intrascapulo-thoracic, 784
 not found to have, 494
 Amputation, stumps, after treatment of, 1547
 technic for stumps after, 859
 tenotomy preliminary to, 340
 vs. excision of elbow, 1407
 Anacidity, gastric, hydrochloric acid in, 492
 Anastomosis, end-to-end, 1193
 forceps, 1649
 intestinal, invagination method of, 602
 Intestinal, LaFage forceps, 850
 intestinal, research in, 1163
 of bladder and rectum, 132
 ureteral, 306
 vesicorectal, 976
 Anatomy, visceral, study of, 1603
 Anchylostomiasis, 538
 Anders, J. M., gall-stone crepitus, J. M., pancreatic hemorrhage, 1391
 Andrew, A. H., tongue-depressor, 1242
 E. M., select use of words, 1237
 Anemia from toxic sera, 543
 headache from, 238
 pernicious, 152, 1575
 pernicious, etiology of, 1500, 1572
 pernicious, modifications in, 975
 secondary to malarial infection, 731
 serotherapy, 1335, 1336
 aplenic, diabetes and, 1641
 vascular changes after, 541
 Anesthesia, 1350
 and anesthetics, surgical, 1541
 blood examination in, 215
 by chloroform and ether, 670
 editorial oversight on, 489
 ether, preceded by morphia, etc., 87
 first exhibition of, 465
 infiltration, 684
 local, 786
 oxygen with ether for, 93
 surgical, 356
 surgical, apparatus for, 1441
 Anesthetics (see acolin, beta-cuculin, chloroform, chloroform, ether, kidneys, obstetric, paralytic, sickness), 1483
 administration of, 1542
 comparative safety of, 908
 how to give, 160
 Aneurysm (see aorta), electrolysis in, 1494
 of arch, 1543
 popliteal, 160, 918
 popliteal, extirpation of, 629
 vomiting due to, 1287
 Anesthesia, operative treatment of, 974
 Angina pectoris, 22
 pectoris, gravest, for, 781
 pectoris, treatment, 300
 Angiocholitis (see cholecystitis), Angioma, multiple cavernous, 470
 of larynx, treatment, 476
 of nose, enzymes for, 1146
 Angioplasty, 1284
 Anisotropia, high, management of, 1184
 Ankylosis of spine, chronic, 302
 of stapes, treatment, 412
 temporo-maxillary, excision for, 1666
 Ankylosis-ostitis, liver and spleen in, 793
 Anly, F. L., early conception, 1114
 Anonim, 1602
 Anthemon, the, 359

- Antihistaminic**, bacillus does not form
-als, 712
-bacillus, injections of, 1546
in Ontario, 1505
on man, 347
- Antiphlogistic**, in asylums, scheme
for, 345
- Antiphlogistic mixture**, 594
- Antipode** (see alcohol, num vom-
-ica, 727)
for gas, 1149
universal, 1117
- Antiseptic mixtures**, 655
- Antiseptics in fever**, 1292
- Antipyria** (see dysentery, intoxication)
- Antisepsis of mouth**, 1546
-technic and, 805
- Antisepsis**, intestinal, 1352
in cholera, 848
intestinal, in typhoid, 1159
Intestiprocic (see serum)
- Antitoxin** (see diphtheria, paral-
-ysis), 1158
in diphtheric laryngitis, 1114
in disease, 421
intracerebral injections in tetanus, 220, 221
origin of, 340
state and, 653
statistics, indication of, 1521
tetanus treated with, 342
treatment of diphtheria, 1004
- Antitoxic**, what are? 718
- Antivaccination delusion**, 1175
- Antivivisection**, 91
bill, concerning, 1615
in Congress, 1556
Antidiseases, 95
- Antrum, drainage-tube in**, 125
empyema of, 151
empyema of, age and sex in,
122
etiology and management,
empyema of, etiology and
etiology of, malignant etiology
of, 126
of Highmore, catarrh of, 1485
of Highmore, diseases of, 771
purulent accumulation in, 1201
Aorta, abdominal, elastic ligature
of, 872
aneurysm of, 968
aneurysm of, dissecting, 1287
aneurysm of, in situ, 1353
aneurysm of, head jerks, 911
- Aorticitis**, 217
abdominal, sign of, 1038
malaria, 345, 540
- Apathia and willis**, 1498
- Aphasia**, hysterical, 345, 361
-pneumonia (see poisoning)
- Apoplexy**, cause and prevention,
221
prephylaxis and management,
285
treatment of, 964
- Appendical**, of appendicular? 179
- Appendicitis**, leaving adherent, 117
- Appendicitis** (see gastrostomy,
peritonitis, 728, 853, 1354, 1041, 1042,
1414, 1479, 1481, 1544
and disease of ovary and tube,
192
cases at Angustana Hospital,
196
causes, prevention and treat-
-ment, 315
collateral consideration, 1493
country doctor and, 216
diagnosis and treatment, 311
diagnosis of, differential, 601
drainage in, 1161
features of, 978
gastrostomy stimulating, 1615
hernia following operations for,
111
in classic literature, 369
in Fuzland, rarity of, 369
in the tuberculous, 476
its great mortality, 1404
its etiology, 376
lymphatic count in, 852
medicinally treated, 978
pathogenesis of, 1415
suppurative, 918
theories, criticism of, 118
the term, 216
treatment, 216, 535
treatment of, 117, 1229
- Appendicular subjects**, future of,
928

 position of, 407
 Women doctors in Russia, 747
 examination of for insurance,
 1655
 Women's diseases, prolonged
 standing and, 856
 Wood, A. C., brain tumor, 983
 C. A., alcohol amaurosis, 1653
 C. A., ophthalmic section, 1
 Woodbury vs. Eddy, 1173
 Wood-sorrel, is it poisonous? 477
 nephritis fatal from, 346
 Woodward, W. C., malpractice,
 1295
 W. C., vaccination, 1291
 Wood and won, 1441
 Woolen, G. V., intranasal surgery,
 1641
 Word blindness, congenital, 1649
 Words, correct use of, 1237
 Work, H., toxic causes of insan-
 ity, 482
 Work, scientific research, still a,
 929
 Wounds, treatment of, new
 methods, 720
 Wright, F. W., contagious dis-
 eases, 1290
 J. W., diseases of eye, 1001
 J., nose and throat diseases, 84
 Wüdemann, H. V., high myopia,
 1467
 Wyeth's life of Forrest, 1234
 Wynan, H. C., appendicitis, 978
 H. C., tuberculosis of periton-
 eum, 983
 Wynekoop, F. E., diagnosis of
 diphtheria, 1100
 Wynn, F. B., exhibits at meetings,
 1436
 XANTHOMATA, nature of, 217
 X-ray and head injuries, 1482
 examinations in children, 219
 examination, one, enough, 175
 X-rays (see chest, laryngology,
 Roentgen, stomach),
 diagnostic utility of, 1498
 in lupus, 530
 in medical diagnosis, 1207, 1661
 renal calculi and, 470
 YEAST and levirin in furunculo-
 sis, 176
 Yellow fever, 361, 401, 474, 676,
 968, 1090, 1218
 Yellow fever (see marine-hospital
 reports, serum, Sanarelli),
 fever a controllable disease, 421
 fever and digestive tract, 554
 fever, arsenious acid a prevent-
 ive, 221
 fever at Soldiers' Home, 421
 fever, bacillus teteroides in, 537
 fever, bacteriologic study of, 36
 fever, bacteriology of, 1543
 fever, divided authority in, 89
 fever, fat in urine of, 239
 fever in Cuba, 96
 fever in Cuba, suppression of,
 1607
 fever in New Orleans, 787
 fever, localization of, 1289
 fever, microbe of, 672
 fever, nature and cause, 559
 fever, papers on, 1222
 fever, Sanarelli's serum in, 471
 fever, specific cause of, 725
 fever, symptoms and anatomy,
 367
 fever, treatment of, 97, 1285
 Young, A. G., formaldehyde in
 milk, 1290
 W. H., hypertrophied prostate,
 1360
 ZIEMANN'S method, 1055
 Zinc chloride in uterus, death, 684
 Zöpphilism and degeneracy, 735

INDEX OF DEPARTMENTS

BOOK NOTICES.

Abbott, A. C. Hygiene of Transmissible Diseases 619, 993	Abdominal Brain and Automatic Visual Ganglia 1242	Albuminuria and Bright's Disease 301	Albutt, F. C. System of Medicine 301	Allen, C. W. Handy Book of Medical Progress 993	American Pocket Medical Dictionary 926	Anders, J. M. Text-Book of the Practice of Medicine 1440	Annual and Analytical Cyclopaedia of Practical Medicine 1631	Archives of Neurology and Psychopathology 745	Asthma, Recent Developments in Its Treatment 926, 1307	Atlas of Diseases of Skin 42	Atlas of External Diseases of Eye 427	Baker, W. M. Kirke's Handbook of Physiology 1565	Barker, I. F. Nervous System and Its Constituent Neurons 1241, 1307	Bellini, A. Ingiene Della Pelle 1440	Bernard, C. Masters of Medicine 744	Bernard, O. Manual Hoepfli 1440	Books and Pamphlets Received 52, 301, 619, 1241	Bradford, E. H. Treatise on Orthopedic Surgery 1440	Brain in Relation to Mind 926	Brown, H. D. Brain and Other Scalp Affections: Their Cause and Cure 1241	Browne, J. L. Throat and Nose and Their Diseases 426	Bulletin of Ohio Hospital for Epileptics 745	Chirurgie De La Plevre Et Poupon 1307	Christian, J. Brain in Relation to Mind 926	Clinical Lectures on Neuroanatomy 1565	Cockley, C. G. Nose and Throat 926	Coblenz, V. Newer Remedies 426	Collins, H. D. Physiology 1565	Compend of Gynecology 1242	of the Diseases of Eye and Refraction 926	of Practice of Medicine 926, 1440	Crook, J. K. Mineral Waters of U. S. and Their Uses 302, 994	Cushny, A. R. Text-Book of Pharmacology and Therapeutics 620	Cyclopaedia of Diseases of Children 426	de M. S. Annual and Analytical Cyclopaedia of Practical Medicine 1631	Denver, E. Surgical Anatomy 993	Donders, F. C. Essay on Nature and Consequences of Anomalies of Refraction 1307	Electro-Hemostasis in Surgery 301	Elements of Vital Statistics 301	Enlargement of Prostate, Its Treatment and Radical Cure 926, 1631	Essay on Nature and Consequences of Anomalies of Refraction 1307	Fitzgerald, J. P. Prorrhea Alveolaris 302, 992	Fractures and Dislocations 1632	Fullerton, A. M. Surgical Nursing 926	General Pathology 619, 1182	Gordini, H. G. Minute Anatomy of Central Nervous System 619, 744	Gould, G. M. Compend of Diseases of Eye and Refraction 926	Gowers, S. Manual of Diseases of Nervous System 744	Grardin, E. H. Text-Book on Practical Obstetrics 426	Gross and Minute Anatomy of Central Nervous System 619, 744	Haab, O. Atlas of External Diseases of Eye 427	Hall, W. S. Text-Book of Physiology 1241, 1631	Halphide, A. C. Mind and Body. Hypnotism and Suggestion Applied in Therapeutics and Education 619	Handy Book of Medical Progress 993	Hardin, W. L. Rise and Development of Liquefaction Gases 926, 1307	Harrison, R. Paper on Stone, Prostate and Other Urinary Disorders 619	Heisler, J. C. Text-Book on Embryology for Students of Medicine 1631	Heitzmann, L. Diagnosis and Prognosis 426	Helfrich, H. Fractures and Dislocations 1632	Hedges, D. E. Compend of Practice of Medicine 926, 1440	Hygiene of Transmissible Diseases 619, 993	Ingiene Della Pelle 1440	International Clinica 620, 1241	Directory of Ophthalmologists and Otologists 426	Medical Annual and Practitioner 426	Introduction to Dermatology 1242, 1565	Text-Book of Surgery 1242	Intertrigo and So-Called Pyorrhea Alveolaris 619, 992	of Differential Diagnosis with Clinical Memoranda 1242, 1631	Kingscope, E. Asthma: Recent Developments in Its Treatment 926, 1307	Kirke's Hand-Book of Physiology with Clinical Memoranda 926, 1565	Knopf, A. Pulmonary Tuberculosis 301, 1182	Kyle, D. B. Text-Book of Dislocation of Nose and Throat 619	Laboratory Manual of Physiological Chemistry 1242, 1566	Work in Bacteriology 426	Lake, R. International Directory of Laryngologists and Otologists 426	Lane, L. C. Surgery of Head and Neck 427	Les Pteses Viserales 682	Lewis, W. B. Text-Book of Mental Diseases 175	Lovelness 1241	Lovatt, R. W. Treatise on Orthopedic Surgery 1440	Malvern, G. E. Practice of Medicine 1241	Manual Hoepfli 1440	Manual of Bacteriology 301, 1182	of Diseases of Nervous System 744	Material Medical Therapeutics. Medical Pharmacy. Prescription Writing, and Medical Law 1565	Massage and Original Swedish Movements: Their Application to Diseases of Body 426	Masters of Medicine 744	Mechanics of Surgery 301, 683	Medical Directory of New York, New Jersey and Connecticut 1565	Mind and Body. Hypnotism and Suggestion Applied in Therapeutics and Education 619	Minerals Waters of U. S. and Their Uses 302, 994	Minor Surgery and Bandaging 1226, 1565	Moullin, C. M. Enlargement of Prostate, Its Treatment and Radical Cure 926, 1631	Mracek, F. Atlas of Diseases of Skin 52	Muir on Herbs. Manual of Bacteriology 1182	Musser, J. H. Practical Treatise on Medical Diagnosis for Students and Physicians 1631	Nervous System: Its Constituent Elements 1241, 1307	Newer Remedies 426	Nevelme, A. Elements of Vital Statistics 1307	Notes on Modern Treatment of Fracture 1565	Novy, F. G. Laboratory Work in Bacteriology 426	Ostrum, K. W. Massage and Original Swedish Movements, Their Application to Diseases of Body 426	Over 1000 Prescriptions 1242	Pamphlets Received 1242	Paperson Stone, Prostate and Other Urinary Disorders 619	Phelps, E. S. Loveliness 1241	Physiology of the Body 1565	Poisonous Plants of U. S. 302	Practical Anatomy 620, 1565	Material Medica for Assays 426	Urinalysis and Urinary Diagnosis 1182	Practical Treatise on Medical Diagnosis for Students and Physicians 1631	Prescription Book of Infant and Children 1242	Modification of Milk 926	Progressive Medicine 426	Fryor, Wm. R. Treatment of Pelvic Inflammation Through Vagina 682	Pulmonary Tuberculosis 301, 1182	Purdy, J. W. Practical Urinary Diagnosis 1182	Pyorrhea Alveolaris 992	of the Teeth and Its Relations to Medicine 302, 992	Ringworm and Other Scalp Affections: Their Cause and Cure 1241	Rise and Development of Liquefaction of Gases 926, 1307	Ritchie, J. E. (See Muir and Ritchie.)	Roberts, J. R. Notes on Modern Treatment of Fracture 1565	Robinson, W. M. Diseases of Brain and Automatic Visual Ganglia 1242	Rockwood, E. W. Laboratory Manual of Physiological Chemistry 1422, 1566	Saville, T. D. Clinical Lectures on Neuroanatomy 1565	Schell, W. M. Medica and Therapeutics 926, 1565	Schott Methods of Treatment of Nervous Diseases of Heart 1242	Skene, A. J. J. Electro-Hemostasis in Surgery 301	Smith, H. W. Diseases of Infants and Children 926	F. J. Introduction to Outlines of Principles of Differential Diagnosis with Clinical Memoranda 1242, 1631	Sobel, J. Handy Book of Medical Progress 993	Spach, A. B. Prescription Book of Infant Diets for Home Modification of Milk 242	Stall, S. What a Young Husband Ought to Know 993	Stoney, E. A. M. Practical Material Medica 426	Summers, J. E., Jr. Treatment of Wounds 1440	Surgery of Head and Neck 427	Surgical Anatomy 993	Nursing 926	Talbot, E. S. Intertrigo and So-Called Pyorrhea Alveolaris 619, 992	Tarrier, F. Chirurgie de la Plevre et Du Poupon 1307	Text-Book of Diseases of Nose and Throat 426	of Pharmacology and Therapeutics 175	of Physiology 1241, 1631	on Embryology for Students of Medicine 1631	on Practical Obstetrics 426	of Practice of Medicine 1440	Thorne, W. E. Schott Methods of Treatment of Chronic Diseases of the Heart 1242	Throat and Nose, and Their Diseases 426	Tirard, N. Albuminuria and Bright's Disease 301	Transactions of American Microscopical Soc. 619, 745	of Indiana State Medical Society 1631	of Iowa State Medical Society 1632	of Soc. Surg. and Gyn. of Women 619, 745	Treatment of Pelvic Inflammation Through Vagina 682	Treatise on Orthopedic Surgery 1440	of Gergers 926	Tranax, Chas. Mechanics of Surgery 301, 683	Tuttle, G. M. Diseases of Children 1242	Twentieth Century Practice 682	Urinary Analysis and Diagnosis 426	Walker, N. Introduction to Dermatology 1242, 1565	Wasting Diseases of Infants and Children 926	Wells, W. H. Compend of Gynecology 1242	Wharton, H. R. Minor Surgery and Bandaging 926, 1565	What a Young Husband Ought to Know 993	Ziegler, E. General Pathology 619, 1182

INDEX OF TITLES OF AMERICAN MEDICAL LITERATURE.

- Abdomen, colloid cancer of. 1030
 injuries to from blunt force 533
 pistol-shot wound of. 850
 preparation for operation 1154
- Abdominal (see aneurysm, cancer, celiotomy, contusions, dress, electrode, fibroid, pregnancy, sections, surgery, symptoms.)
- Abdomino-perineal pectosigmoidectomy 850
- Abortion (see also abscess), 902, 1410
 and insanity. 1411
 criminal. 338
 justifiable, when indicated 1214
 missed, case of. 323
 sequene and treatment. 902
 tubal, case. 850
 with "dying declaration" 1252
- Abscess (see appendix, encephalitis, hip disease, ossification, pectoraria, peritonsillar, perityphilitis, thrombophlebitis).
 abscess of pyosalpinx after abortion 1214
 antrals, asthma from. 902
 brain, acute bilateral. 850
 brain, with peculiar symptoms 850
 cerebellar, case. 532
 cerebral in child, complicated 339
 cerebral, in new-born. 1347
 hepatic, etiology, diagnosis, treatment. 272
 ischio-rectal, case. 902
 hip, fourteen cases. 1155
 mammary 783
 of sigmoiditis 1155
 of lung. 1282
 of uterine wall. 1648
 otitic brain, operation 469
 of parotid gland. 150
 palmar, operations in. 469
 pelvic, after abortion. 1214
 pelvic, in woman. 150
 pelvic, peptonuria in. 492
 peritonsillar 339
 perityphilitic, case. 1281
 pharyngeal following tonsillotomy 903
 psos, open method in. 1601
 subphrenic 1281
 temporal, removed through attic. 272
 tonsillar and circumtonsillar 902
 tubercular, of cheek. 1539
- Accident, remarkable. 1087
 unusual 1347
- Acetabular head of femur in middle epiphyseal fracture 1020
- Acholia (see bile).
- Acid, acetic (see cellulitis, maorold, poisoning, scarlet fever).
 hydrochloric and starch digestion 1282
 Acme, lodid of potash in. 92
 nature and treatment of 1410
 vulgaris, treatment. 1155
- Acid. 339
 case. 93
 case and eye symptoms. 1030
- Actinomyosis in man. 1029
 in man, in America. 1281
- Action, physical, equivalents 783
- Addison's disease, case. 150
 disease in infancy, etc. 1029
 disease, suprarenal extract in. 903
- Address. 92, 721, 902, 1649
 Am. Laryng. and Rhinol. and Otol. Soc. 338
 Am. Neur. and Surg. Assn. before Charity Hosp. Alumni Assn. 468
 Canadian Med. Assn. 967, 1214
 chairman's 656
 commencement. 28
 Confer. Med. Col. 902
 delectate 902
- Address, historian's. 92
 in medicine. 967
 Kingston M. S. S. Soc. 1214
 Med. Soc. of Colo. 272
 Socio-Chir. Col. 1347
 Soc. of Med. Sci. 469
 N. Mo. Med. Assn. 469
 of welcome. 28
 Ohio, State Med. Soc. 92
 President's M. S. Soc. 20, 151
 president's, Am. Derm. Assn. 656
 president's A. M. S. 28, 469
 272, 468, 469
 to Col. of P. & S. 338
- Adenitis, tuberculous, remarks on. 1088
 cervical, tubular. 1478
- Adenocarcinoma (see nose).
 Adenoids (see diphtheria, ear trouble, hemorrhage, respiration, tonsils).
 influences of. 402
 neglected, and results. 1410
 Adenomas, rectal. 1649
- Adenosarcoma (see septum) in ngress. 1539
- Adhesions, intrapelvic. 1154
 intestinal, in pelvic dissection. 1478
- Advertising, medical, policy, ethics, etc. 656
- Africa, life in west. 29
 aged, diseases of. 1153
 Agnaphia, case of. 1478
 Agr, entrance into circulation. 1282
 hot dry, therapeutical of. 903, 1411
 liquid, clinical uses of. 533
 liquid, in medicine and surgery at. 272
 Air-passages, foreign body in 595, 902
- Albumin (see urine).
 quantitative determination of. 656
- Albumins, test for. 1539
- Albumuria (see eye, hemorrhage, nephritis, pregnancy, diagnostic symptom. 783
 febrile. 1539
 observations on. 1154
 Albumose peptone, value of. 1478
 Albumosuria (see urine).
 Alcohol (see usefulness, action and alcoholism).
 drinking of. 1649
 is condemnation just. 338
 on the mind. 1281
 operations without. 1087
 (see amblyopia, blindness, congress, epilepsy, schools).
- Alcoholism. 1155
 and mortality. 522
 pathology of. 502
- Alexander's method of technique of. 532
 operation on uterus. 1601
- Allergic, problems of. 783
 Allergoids and curacy. 907
- Allopecia arcata, two epidermic 783
 circumscribed. 92
- Altitude, see blood changes, consumptive, heart disease.
- Amalgam fillings and mercurial poisoning. 1215
- Amanorosis after use of dynamite 595
- Amblyopia, locomotor, case. 150
 from methyl alcohol. 150
 locomotor, railroad employes. 1154
 Ameba, ciliata in disease. 903
 ciliata in disease. 907
 Amenorrhoea. 1347
- Ametropia and heterophoria, prevalence of. 52
 significance of. 902
- Amputation, 783
 of the term abolished. 29
 tenotomy preferred to. 378
- Amrygdalitis, bacillary acid in. 1088
- Anal surgery, rectal, progress in. 1540
- Anastomoses of alimentary tract. 967
- Anastomoses, vesico-rectal. 1030, 1155, 1601
- Anatomy teaching, defects of our 1214
 visceral, study of. 1601
- Anemia (see arthritis, spine).
 in form of. 656
 iron in. 1410
 pernicious, blood examination in. 272
 pernicious, cases. 1154
 progressive pernicious. 1411
 Anemias of intestinal origin. 902
 Anemic conditions, peptomangan in. 1411
 Anesthetics. 721
 Anesthesia. 1347
 and anesthetics. 1281, 1601
 and anesthetics, surgical. 1539
 by suggestion. 305
 local 783
 nitrous oxid, ether, etc. 492, 92
 oxygen with ether for. 92
 paralysis following. 1088
 Schleich, in 110 operations. 1601
 technic of. 1468
- Anesthetic, beta-eucin as 1088, 1347
 ethyl bromid as. 657
 ethyl chlorid as. 902
- Anesthetics, comparative safety of. 903
 comparative of. 1539
 discussion on. 1478
 effects on kidneys. 903, 1347, 1478
 eighty-six cases of. 1601
 how to give. 29
 in obstetrics. 903
- Anesthetization, blood examination and. 214
 Aneurysm 967
 abdominal. 1087
 arteriovenous in Scarpia's hernatoma simulating. 1088
 of arch, early diagnosis. 1539
 of aorta. 721, 967, 1601
 of aorta, retracted. 1154
 of aorta, unusual. 28
 of coronary artery. 721
- Angina, Ludwig's and cervical suppuration 967
 Ludwig's, cases. 150
 pericarditis, aortitis and. 1214
 Antidotes, 1281
- Animal doctors and patients. 595
 Anriods, total, cases of. 1649
- Ankylosis of hip-joint. 721
 Anomia and paranoimia. 1601
- Anthonem, the. 595
- Anthrax affecting man. 1087
 in Ontario. 1214
- Antinosis (see nosoph, ulcers).
 Antipyretics in children. 272
- Antisepsis, gastro-intestinal. 214
 Antisepsis in peptic practice 656
 intestinal. 1214

 Theriac in typhoid 903
 Thermometer, fever 272
- Thialion, clinical experience 902
- Thiocal in pulmonary tuberculosis 902
 colitis 902
 Thiostramin 1347
- Thomson's method, in uvergio 29
- Three Board Systems, influence of 656
- Throat, acute, non-infectious, faucial, in treatment 533
 bacteriologic examination 1601
 nose, ear and family physician 1347
 affections, nonophen, etc. 505
 cut, case 150
 foreign bodies in 93
 membranous sore 1087
 syphilitic 902
- Thrombophlebitis with peritonitis, fibrillar abscess 1029
 thrombosis after colotomy 92
 of cavernous sinuses 150
 of lateral sinus, new symptom of 850
 of sigmoid sinus, operation in 92
 words, spelling use of 721
- Thrombus neonatorum 1410
- Thyroid (see gland, zoster, toxic, obesity)
- extract in cerebral neoplasia 402
 extract in 1030 insanity 1347
 extract, use of 1478
 gland, typhoid complicating 1649
- Tibia, restoration of 1029
 specific necrosis of 903
- Tibial tubercles, enlargement 533
- Tinea capitis 92, 1347
- Tissue builder, a good 595
- Tissues, method of preserving 1087
- Tobacco and amblyopia 150
 are its uses detrimental? 402
 its detrimental to mankind 1030
 its history and effects 1411
 toxicity of 1281
 using and intemperance 92
- Toulinid-blue and ocular inflammations 850
 blue in eye diseases 650, 902
- Tones and murmurs from oral cavity 967
 Tongue in disease 1155
 Tongue (see fibropoloma, sarcoma) and adenoid removal 338, 1214
 clippings, some 372
 pharyngeal, hyperplasia of 468
 ruffiness of 1478
- Tonsillar (see abscess) 1478
 inflammation, epidemic 1410
 ring hypertrophies in 1411
- Tonsillitis apthous 1478
 chronic, case of 338
 in infant of five months 532
 treatment and prophylaxis 1215
- Tonsils, false 216
 faucial, suppurative processes in 967
 Touth in nasal cavity 214
- Tooth plate, c. s. pharyngitis for impacted 783
- Toxemia, importance of recognition 273
 malarial 505
 recognition of 215
 with convulsions 656
- Toxic (see serum)
- Trachea, foreign bodies in 1029
 diagnosis of foreign bodies 1029
- Tracheal sound, Wintrich's value of 967
- Tracheitis and laryngitis, case of 505
- Tracheotomy for croup 1281
- Trachoma 902
- Trachomatous eyes, retraction of 92, 1154
- Training, effects of 657
- Transactions, journalizing the 532
- Pennsylvania University, his- tory of 532
- Trauma and cerebral arterio- sclerosis 1029
- Treatment, medical and surgical 850
 Trendelenburg 1087
- Trendelenburg (see posture)
- Trephining for epilepsy 967
- Trichinosis, without eosinophilia 1539
- Triphenlin, therapeutic action of 214, 272
- Troops in West Indies, care of 656
 dental sequelae in 1154
- Trusts, a force of 468
- True Crookes', excitation of 1155
- Tubercular (see hemoptysis, meningitis, osteomyelitis, peritonitis)
- tubercle in animals 902
- Tuberculosis in tuberculous 783, 1281
 test, notes on 402
- Tuberculosis, treatment, of 1087
 fistula, glands, immunity, negroes, typhoid 1478
 and insurance 1214
 an indication for nephrectomy 469
 art, reason of 1088
 bovine and man 657, 721
 bovine in Canada 1539
 compulsory reporting of 850
 diagnosis and 1087
 duties of the hour 1539
 early diagnosis 903
 early sign of 1540
 etiology 721
 etiology from biologic standpoint 932
 finally snail-like for 1530
 following typhoid 902
 hip-joint, surgical aspect 272
 home 902
 and prevention of 902
 in childhood, morbid anatomy 1088
 in children 1688
 in children 783
 inhalation treatment 1088, 1154, 1411
- in monkeys 214
 joint, diagnosis 402
 large 656
 modern idea of 281
 necessity for state aid 1348
 nuclei in four cases 402
 blood-vessels, etc. character of 150
- Tuberculosis of bones and joints, treatment 1155
 of breast 468
 of intestine, localized 533
 of kidney, diagnosis of 649
 of mamma, coexistence with carcinoma 150
 of pleura, case of 1281
 of pleura, without other involvement 29
 of throat 967
 of ureter 967
 prevention of 850
 primary lesions of 967
 pulmonary 656
 pulmonary, case of 532
 pulmonary, early diagnosis, nosos, etc. 402, 532
 pulmonary, blood in 967
 renal 721
 reasonable control of 1410
 Roentgen ray in 783
 sanatoria for 967
 spread of 532
 sterilization of lung tissue 402
 struggle against 850
 subacute miliary 29
 surgical 849
 treatment 721, 850
 vagaries in 339
 vexed questions on 468
 watery extract of bacilli 402
- Widal reaction in 1087
- Tuberculous (see adenitis, lrisitis, pleurisy, peritonitis)
- plea for 902
- Process in children, three steps in 92
- Tumor, (see also pharynx, pituitary)
- brain, optic neuritis a 1539
 of nasopharynx 1062
- Tumor, brain, exploratory operation 214
 sign of 1155
- colon and intra-abdominal 656
 dermoid of conjunctiva and cornea 92
 fibroid and ovarian 656
 fibrous, early operations for 595
 laryngeal, case 1154
 of conjunctiva, ciliated, 1154
 of labium 1050
 of nasopharynx 1602
 ovarian, prolapse through phantom 468
 phantoms 1087
- Tumors (see also neoplasms), benign laryngeal 1030
 cerebral, treatment of 1088
 hepatic, 76 cases of liver resection for 1539
 in spinal canal, treatment 967
 lecture on 1029, 1539
 of breast, malignant 849
 of childhood, congenital 1281
 of eye, malignant 1539
 of fingers, congenital 1215
 of gigantic size 1411
 of the brain 656, 1061
 of mamma and 1155
 of oblongata 721
 ovarian 92
 ovarian 1154
 cystic 849
 phantoms, relation of colon to 532
 renal, diagnosis 967
 retro-peritoneal, case and specimen of 1478
 woman with 1087
- Turbinal, offending middle 967
- Twin birth, peculiar case 150
- Twins, something rare in 783
- Typhanic cavity, therapy of 339
- Typhoid, treatment of 656
- Typhoid (see aphasia, copper eruptions, the term, hospital, users) 28,
 address on 92, 469
 advance in knowledge of 1281
 among our soldiers 150
 arterial 178
 and malarial fevers, case 273
 and pneumonia with tuberculosis 150
 and stricture of esophagus 1155
 bacilli from coll. to dis- tinguish 030
 bacillus isolated after 18 years 902
 bacilli in urine of patients 238
 bacillus meningitis due to 1347

VOL. XXXIII

CHICAGO, ILLINOIS, JULY 1, 1899.

No. 1

Addresses.

THE OPHTHALMIC SECTION.*

HOW MAY IT DO THE MOST EFFECTIVE WORK?

CHAIRMAN'S ADDRESS.

BY CASEY A. WOOD, M.D.

CHICAGO.

As you are well aware, the By-Laws of the ASSOCIATION direct that the chairman of each Section shall prepare an address on recent advancements in the particular department of medicine over which he has been elected to preside, or to make suggestions in regard to possible improvements in methods of work. I have this year chosen to address you on the second of these subjects, because it occurs to me that while the story of the last year's progress in ophthalmology is a tale oft told by numerous journals, text-books and monographs, and readily accessible to all of you, the experiences of your executive committee, secretary and chairman in providing for a continuance of the successful meetings held in the past may be new to most of you and well worth recounting. It is in the hope that a frank recital of these will issue in the consideration of some means whereby improvements, not only in the methods, but in the quality, of the work done by this Section, may be brought about.

It must not be inferred from this that the scientific and practical value of the papers read before this branch of the ASSOCIATION can be justly regarded as inferior to those presented to similar societies elsewhere. On the contrary, it is rather with an embarrassment of riches in this respect that we have to deal. For example, under the able and discriminating leadership of my distinguished predecessor, Dr. Harold Gifford, fifty-six titles were placed on the program. This year we have fifty-eight, and I believe I am well within the mark when I state that quite seventy-five papers, ranking well above the average in interest and value, might have readily been obtained for this meeting. The latest official roll-call of the ASSOCIATION shows that there are about 375 members who are especially interested in ophthalmology, and it is not too much to claim that one-fifth of these are as competent to observe, as capable of giving and as willing to furnish us with the valuable results of their studies, as any similar body in the whole realm of ophthalmology. I will freely confess, however, that I regard fifty-eight (or even fifty) as too large a number of papers for one meeting. In the first place, a superabundance of material necessarily limits the time allowed for the presentation of each paper. The number of hours for the scientific portion of the program being strictly prescribed by the By-Laws, the time possible for each reader is in inverse ratio to the number of contributions. You will remember that at the previous meeting it was considered necessary, and I think properly so, to restrict each reader to ten minutes, without regard

to the character of his paper. A report of a case or two that might, with propriety, occupy that amount of time, or less, was placed on a par with essays dealing with subjects that in their very nature require at least twenty minutes or half an hour for intelligent delivery. With an ever-increasing membership (at least 400 this year) the problem of arranging future programs becomes a most serious matter and while this may well continue to be the particular task of your chairman, the whole Section is vitally interested in, and will be greatly affected by, the manner in which it is done. In any event, we have come to the parting of the ways. Henceforth, it will be physically impossible—and very probably undesirable even if it were possible—to read and discuss all the papers that, in the ordinary course of events, will be offered to this Section. How, then, shall the program be filled, and whose is to be the responsibility of selecting some and rejecting others? In the absence of any definite instructions from the Section on this point, the chairman's work must grow more difficult and embarrassing every year. Judging from my own experience, I am sure that your executive officers would be glad to receive and carry out the suggestions of the majority. After giving the matter much thought, and in the light of my own investigations, I would suggest that the papers be limited to forty, of which fifteen be contributed by members, on invitation of the chairman, while the remaining twenty-five be volunteer contributions, selected by the executive or other committee—with the chairman and secretary as ex-officio members—from the titles sent in before a certain date. This plan has proved successful in other representative societies. It is vital to the carrying out of this plan that the Section should grant its executive power to allow, at his discretion, an extension of the time for reading some particular paper to the limit permitted by the ASSOCIATION By-Laws, the number of minutes so allowed to be printed on the program with the title.

By no means the least valuable portion of our program is the discussion that is expected to follow the reading of the papers. If the title of a paper was always a sufficient indication of its contents, members interested in the subject would require nothing more to enable them, at the proper time, to confirm the experiences or controvert the opinions therein expressed. As it is, we are usually left in the dark as to the subject really under discussion until the paper is read to the Section. Few of us possess such phenomenal memories that we can at once recall the details of cases—stored in case-book and note-book—bearing on the matter at issue. I have long believed that each contributor to our program, should, as early as possible, send a brief extract of his paper to the secretary. Copies of this should be made and forwarded, not only to members appointed to discuss the paper, but to any others who may ask for them. In this way the value of the proceedings will be much enhanced—to the reader, to the critic, and to the audience.

*Presented to the Section on Ophthalmology at the Fiftieth Annual Meeting of the American Medical Association, held in Columbus, Ohio, June 6-9, 1899.

Intelligent limitation of the number of papers will not only prevent needless haste in the presentation of the papers, and allow of reasonable time for their discussion, but it will make possible such variations in the usual program as may, from time to time, seem desirable. For instance, I have this year, after consultation with your executive committee, invited a distinguished French ophthalmologist to address you on a subject with which he is peculiarly competent to deal. In the same way, at my invitation, two American gentlemen equally well known to us, have consented to give addresses on topics of much interest. Personally, I am much in favor of joint discussions with some other Section of subjects of common interest, and this year, at the suggestion of Dr. Mayer, have helped to arrange a symposium with the Section on Laryngology and Otolaryngology. By no means the least valuable of the results that flow from such an arrangement is the emphasis thus placed on the fact—by some forgotten—that ophthalmology is not a science apart from, but is merely one branch of the tree of, medical learning.

It has been suggested to me that, instead of the ordinary symposia, a subject of importance should be announced for general discussion at the close of one session, to be taken up the following year. This plan has been adopted by our sister society, the British Medical Association, and may well have our consideration.

Another project, to the accomplishment of which I have given much thought, might, perhaps, profitably receive some of the attention and occupy a portion of the time at our disposal. I refer to the investigation by the Section of the value of those remedies, methods of examination, etc., which are so frequently recommended by ophthalmologists here and elsewhere. The virtues of many of these are often heralded by a flourish of trumpets, and sometimes promoted by publications in the medical press and by makers of medical instruments or wholesale drug houses having a commercial interest in their successful sale. I do not say that such agents are necessarily without virtue, but statements concerning them, thus exploited, may well be received *cum grano salis*. Even sincere partisans of new methods of treatment are oftentimes led to overestimate the value of the remedies in question. On the other hand, we know that not a few useful additions to our pharmacopœia long remained in undeserved obscurity, mainly because their virtues were not early and sufficiently put to the test. In the midst of such uncertainty, how shall the individual observer find the truth? It certainly seems as if this Section possesses qualities that eminently fit it for the task of separating the wheat from the mass of therapeutic and other chaff yearly offered to us. It is a truly representative body, of wide influence, of vigorous growth and, moreover, comprises members with the most conservative as well as the most radical leanings. It would be difficult to obtain at the hands of committees appointed at each meeting unbiased reports on the efficacy of such agents, remedial and other, as at the time appear to be worthy of investigation. As a few examples of these that seem to me to call for such investigation, may be mentioned protargol, argentamin, suprarenal capsule, McGowan's method of ripening and extracting immature cataract, the relative merits—as local anæsthetics—of eucain (alpha and beta), holocain and cocaine, the removal of the tarsus in the treatment of deep-seated trichoma, the value of portable ophthalmopneumatic fields, for instance—and the sidroscope of Auer. Reports, from proper committees representing a year's work in hospital and private practice, would not

only be of the greatest value to every member of the Section, but would command respect from ophthalmologists everywhere. They would not only add to the prestige of our Section and increase its influence, but they might well form one answer to that vague insinuation, occasionally made by those who do not know us, that Americans are so prone to cast side glances at the financial aspect of medicine, that they fail to maintain a steady gaze upon the more important landmarks of our profession—that we are "practical" rather than scientific. Evidence of the American's ability to hold his own in the field of scientific research connected with ophthalmology continually multiplies about us, and there is no reason why the ASSOCIATION, to which we are proud to belong, should not do its fair part in the friendly strife for pre-eminence.

PRACTICE OF MEDICINE SECTION.*

CHAIRMAN'S ADDRESS.

BY FRANK BILLINGS, M.D.
CHICAGO.

The officers of your Section present you with a program, the chief fault of which is its length, and an attempt has been made this year, and we believe the first of its kind in any of the Sections of the AMERICAN MEDICAL ASSOCIATION, to present synopses of the papers which will be read.

It has been difficult to obtain these abstracts, but I think we may feel that the attempt has been successful enough to show its desirability and to establish it as a custom in this Section. No one will deny the importance of the publication of the synopses of the papers which are to be read, inasmuch as the members thus have an opportunity to acquaint themselves with the subject-matter of the papers and may prepare themselves for the discussion. One of the chief advantages of the presentation of papers before a body of medical men is the discussion which is elicited. It is difficult for any man to discuss with full intelligence and clearness a paper on a subject or on conditions which may be brought out by the writer immediately after the reading of such a paper, unless he shall have had the opportunity to become acquainted with the chief points which the writer discusses.

We have succeeded in presenting fifty-four abstracts of the eighty-three papers on the program, and these synopses were published with the program in the JOURNAL more than two weeks ago, so it is probable that every one in attendance on this Section has had an opportunity to read an epitome of most of the papers which will be presented to you. We have reprints of the program with the abstracts of the papers for distribution during the meeting, which will, we hope, still further stimulate a discussion of the important subjects to be brought before you.

This Section should adopt a rule requiring every member who desires to present a paper at any future meeting to prepare and send to the officers of the Section a short synopsis of the paper, which may be printed in the JOURNAL, with the program, not later than the first week of May of each year. The great length of this program is a fault which, under the present rules of the ASSOCIATION, it is not within the power of the officers to correct.

Every member of the ASSOCIATION enjoys the priv-

*Presented to the Section on Practice of Medicine, at the Fiftieth Annual Meeting of the American Medical Association, held in Columbus, Ohio, June 6-9, 1929.

ilege of presenting a paper before the Section on any medical topic, provided it is within the scope of this Section. This is a rule which is without doubt a fair one, but it must work to the disadvantage of the Section, inasmuch as a program which is too long will not allow a discussion upon the important subjects which they demand. It seems to me that a modification of this rule should be adopted which will give the officers of the Section the discretionary power of limiting the number of papers which may be read at any meeting. To give all an opportunity to present papers which may be published in the JOURNAL, by the recommendation of the officers of the Section, a rule which is in existence in other societies, and which could be adopted, would allow members to present papers, to be read by title only.

It seems to me also desirable that a certain class of papers should be favored. Original research should be stimulated, and especially in the direction of clinic work. Reports of cases with full reports on the clinic findings, and, when possible, supported by thorough post-mortem examinations, will be of greater value than papers on general subjects more or less theoretic in character.

This ASSOCIATION is composed of an immense body of medical men made up of the best talent of the country. There is no reason why the work done in the ASSOCIATION should not be equal to or better than the work of any other medical body. The large membership and its necessarily unwieldy nature must make it difficult to attain an ideal state, but if the program is carefully made up of selected papers, and if abstracts are required of all who read papers, it will finally become what it should be—the leading medical association of the country.

I appreciate fully the honor conferred on me in appointing me to the position of chairman of this Section, and I desire to express my thanks to you.

The innovation presented in the program and the recommendations which the chairman has taken the liberty to present to you in this short address are not given to you in any dogmatic spirit, but with the belief that the principles involved are important and that a great majority of the members of the Section are in sympathy with them.

In closing, I wish to add a word of public thanks to the secretary of the Section, who has been indefatigable in his efforts to formulate a program and to stimulate the co-operation of members everywhere to present papers to the Section.

100 State St.

THE CLEVELAND (Ohio) City Council, on June 19, passed an ordinance, "to prevent and limit the spread of certain dangerous infectious diseases in and by street-cars." It provides that any person or persons, while riding in or upon any street-car within the city, who shall expectorate or in any way deposit upon the floor, seats, or other parts of any street-car in use for transporting passengers any secretion, excretion, or discharge from the lungs, throat, mouth or nose shall be deemed guilty of a misdemeanor." The penalty for each offense is a fine of not less than \$1 nor more than \$10 with costs of prosecution. It is hoped that, in addition to ridding the street-cars of that intolerable and disgusting nuisance—the American expectorator—this legislation will have an educating influence on the public in regard to the care necessary to avoid the needless of infectious diseases.

ACTION BY TOXIC AGENTS.

WHAT ARE THE PHYSIOLOGIC PROCESSES OR TENDENCIES THAT IMPART TO THE LIVING HUMAN BODY ITS VITAL RESISTANCE OR IMMUNITY AND HOW CAN THEY BE AIDED BY THERAPEUTIC AGENTS.

BY N. S. DAVIS, M.D.
CHICAGO.

One of the important aphorisms of Hippocrates declares that "the physician is a servant, not a teacher of nature," and that in the treatment of diseases he should "follow nature." His declarations have been repeated and their wisdom extolled by all the more philosophic and learned members of our profession, from his time to the present. Therefore, we are reminded of the curative achievements of nature or of the *vis medicatrix nature*, in almost every medical work relating to diseases and their treatment. If, however, we are to follow Nature for the purpose of aiding her in resisting the influence of toxic agents, we must have some definite conception of what is meant by Nature in this connection; or at least, a correct knowledge of the processes she employs in resisting the impression of toxic agents and of expelling them after they have gained access and established the phenomena of disease. It is evident that the word Nature, so freely used in medical literature, is simply intended to personify the natural forces or functions by which a living body resists the impressions of foreign or toxic agents, and thereby prevents the development of disease or disorder; or after disorder has been established, still neutralizes or expels the disturbing agents and restores health. Just what these natural forces or functions are, but few practical writers attempt to explain. They simply claim that nature does this and that in preventing or curing disease.

Biologists, with the aid of modern facilities for minute and exact investigations, have resolved all living organized bodies into one essential prominent element, called by some persons bioplasm and by others protoplasm. The anatomist, with the aid of his microscope, finds this bioplasm segregated into minute organized bodies or cells, each capable of responding to the presence of food material by appropriating it to its own growth or multiplication; and of oxygen by yielding to disintegration or waste. We thus find the primary and distinctive function of all bioplasm to be a constant change in the atoms of which it is composed, produced by an affinity for such material as by addition constitutes nutrition or growth on the one hand, and, on the other, a similar affinity for oxygen, by which oxidation and disintegration are constantly taking place.

These constant changes in the bioplasm show that all animal life involves changes in the matter of which the living body is composed. They show, also, that these changes, which have been styled metabolism, take place under the guidance or control of laws or forces peculiar to living or vitalized matter—laws or forces derived from previous living bodies. Thus each cell or aggregation of bioplasm of which the living body is composed has been developed from a preceding cell and inherited the properties or forces of the parent cell from which it originated. It is by these properties that each bioplasmic cell is enabled to attract to itself and appropriate in definite positions such matter as is necessary for its nutrition or

*Presented to the Section on Practice of Medicine, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

growth, and to reject all other materials. And it is this ability of organized bioplasm to appropriate or reject materials with which it comes in contact that constitutes one of the most important natural functions or processes for resisting the action of toxic agents of all kinds. In the lower and simpler animal organizations, it would seem to be the only means for perpetuating a normal existence. But when the bioplasmic cells are aggregated in such a way as to constitute a variety of forms or structures, each having some special function, as in the more complex or higher animal organizations, each added special function brings with it some additional influence or mode by which toxic materials may be developed within or imbibed from without, and also additional means for their neutralization or expulsion.

Thus the mass of bioplasm that we call the germ or cell, if kept in contact with a proper temperature and food material, will simply maintain those metabolic changes that pertain to its own nutrition and growth. It simply imbibes what it needs and refuses or excretes all else. It has neither power of locomotion, variety of structures, nor complexity of function. In man, the most complex of animal organizations, however, we find the cell bioplasm aggregated into fibrous, muscular, nervous and secreting structures—all fed or nourished, it is true, from a common fountain, the blood, but the quality and quantity of that blood dependent on the natural activity of the digestion and respiratory organs and the quantity and quality of the materials with which these organs are supplied. If the digestive organs are supplied with only wholesome food material, and the respiratory with pure atmospheric air in normal quantity, the resulting blood-product will be normal so far as relates to furnishing material for the nutrition, growth and repair of every structure of the body. If, however, the food material or the air furnished is permitted to contain unwholesome or toxic materials, the blood will be very liable to become impregnated more or less, with the same, and thereby extend its disturbing influence to every structure and function of the body. But the blood is not only the fountain from which all tissues receive their material for nutrition, it is equally the primary receptacle of all the products of retrograde metabolism or waste. And to prevent it from becoming speedily toxic, special organs or structures are provided for the constant excretion or elimination of all such waste products, and such other disturbing elements as may have gained access from without.

By the foregoing elementary review, it is plain that the natural processes or functions which impart to the living human body its vital resistance, or, in other words, which constitute the *vis medicatrix nature*, are: 1, the inherent power of selection and rejection possessed by each cell or organized mass of bioplasm of which the blood and tissues are composed; 2, the oxidations by which tissue metabolism is affected; and 3, the excretory and eliminating processes by which the products of metabolism and other disturbing elements are attracted from the blood-currents and passed out of the system. The vital resistance of any living body may be said to depend directly on the activity and efficiency of these several physiologic functions and processes, be said to depend directly on the activity and efficiency of these several physiologic functions and processes. Conceding this to be true, the next inquiry is, what are the natural agents by which the efficiency of these functions and processes is maintained?

That the inherent or physiologic power of the cell organizations of both the blood and tissues to maintain

their integrity and resist unnatural impressions depends largely on hereditary transmission will be admitted by all enlightened and experienced physicians. We may see this illustrated in every neighborhood and in all grades of society. In the same localities and in families pursuing the same occupations we see more than half of the children born in one family die before they reach the age of 5 years, while in the next family no child is lost in infancy and four out of five of them born persist in living to old age. Of one it is said he has but little vital resistance, is readily affected by all disturbing influences, and speedily succumbs to disease; while another seldom yields to morbid impressions and is said to be tenacious of life. Thus the inheritance of a vigorous and active condition of cell bioplasm constitutes one of the most important elements of man's vital resistance to toxic agents of every kind. It is this same perfection of the primary cell bioplasm, both of blood and tissues, that determines the activity and perfection of the processes of assimilation, nutrition and secretion, as well as of those of oxidation and disintegration or waste. Conceding the correctness of all this, the important question still recurs: What are the natural agents by which the properties of the cell bioplasm and all metabolic processes are maintained?

The agents essential for maintaining the functions of animal life are the presence of heat, oxygen as represented in atmospheric air, and blood or some fluid containing both food material and vitalized cells. To secure the uniform presence of these agents, man and all the higher orders of animals are supplied with digestive and assimilative organs to elaborate the necessary blood; pulmonary organs through which to obtain the necessary supply of oxygen; and a vascular or circulatory apparatus for distributing both to every part of the body, while the resulting metabolism evolves the needed heat, and effects the removal of the waste products through excretion and elimination. Inheriting, thus, a vigorous bioplasmic organization, a complete development of the digestive, respiratory and circulatory organs, supplied with only wholesome food, pure air, good water and appropriate exercises both of body and mind, the individual is endowed with his highest degree of vital resistance to the impression of toxic agents of all kinds. And if toxic agents do gain access to his blood or tissues, his phagocytic activity, active oxidation processes and efficient excretory functions furnish the most efficient natural means for either destroying the toxic agents or expelling them from his system. It is the co-operation of these natural means that are personified as "Nature" in the literature of medical practice; and the more clearly they are comprehended in all their bearings by the physician, the more accurately can he follow the Hippocratic injunction to "follow nature," and the more efficiently can he aid her in overcoming her embarrassments. To maintain the full normal oxygenation and decarbonization of the blood and the natural activity of metabolism, both nutritive and disintegrative, with free elimination of waste products, should be not only a leading, but a fundamental object of the practitioner in all his efforts, either to prevent or to cure disease. The hygienic conditions necessary for accomplishing this object have already been stated, and are too familiar to you to need repetition or restatement here.

The active investigations of the last half century, aided by all the facilities afforded by organic chemistry, microscopy, biology and physics, have pretty fairly demonstrated the important etiologic fact that nearly all

the acute general diseases or febrile affections are caused by toxic agents called ptomaines, leucomains or toxalbumins, resulting either from pathogenic bacteria introduced from without, or from the retention of excrementitious products of metabolic changes within. The same investigations have developed the additional fact that these several toxic agents exert their primary disturbing or toxic influence on the organized bioplasm of the blood and tissues, directly interfering with the normal internal distribution of oxygen and with the tissue metabolisms, both nutritive and excretory, and thereby develop more or less disturbance of respiration, circulation, secretion, innervation and evolution of heat, constituting the familiar phenomena of fever. Closer analysis shows that the essential pathologic conditions are diminished oxygenation and decarbonization of the blood, and diminished or perverted tissue metabolism from the presence of some toxic agent exerting a degenerative influence on the corpuscular elements of the blood or displaying a special affinity for some particular structure or organ. Thus the toxin of the bacilli of diphtheria, in addition to its general disturbances, shows an active affinity for the membranes and glands of the air-passages; that of typhoid fever for the membranes and glandular structures connected with the digestive apparatus; and the pneumococcus toxin for the pulmonary structures. The more clearly the physician comprehends both the general bioplasmic and the special affinities of each toxic agent, the more accurately he can select and apply the appropriate remedies, provided always, that he has an equally clear knowledge of the *modus operandi* of the remedial agents he uses. All diseases arising from infectious or toxic agents have a period of incubation before active summons appear. If the physician could have charge of his patient during that period, by securing for him an abundance of pure air, good water, wholesome food and strict cleanliness, with an appropriate antitoxin or antidote, if any were known, he might so far improve his patient's processes of vital resistance as to prevent the development of disease, or, at least, render its progress mild and free from danger. The value of this mode was well illustrated by the voluntary inoculations for smallpox, extensively practiced several years before the discovery of the cow-pox vaccin by Edward Jenner, and the careful hygienic treatment of the patients during the period of incubation. Unfortunately, in the ordinary field of general practice, the physician seldom sees the patient until the period of incubation has passed and the active development of disease has taken place. It is then too late to establish complete prevention or immunity, but the application of the same means just indicated may limit the further involvement of the specific toxin in the system, and aid the natural processes of vital resistance in destroying by leucocytic activity or expelling by oxidation and excretion that already existing, and thereby lessen both the severity and duration of the disease. And this is just what is sought to be accomplished by the use of antitoxin serums now in vogue. Much additional aid can be rendered to the natural processes by free bathing or sponging of the surface with water whenever the temperature rises above 103 F., and by the internal use of such remedies as are known to be capable of promoting the natural action of the skin, kidneys, liver and other depurative organs sufficiently to prevent the retention of waste products and the formation of leucomains. And if, during the progress of disease, the functions of the vasomotor, cardiac and respiratory nervous systems become depressed, they may be efficiently sustained by the judicious use of such

nerve excitants or nerve tonics as strychnin, digitalis, strophanthus and other similar drugs. And in cases of extreme depression of the cardiac and respiration functions, further aid may be obtained by resort to direct inhalation of oxygen and injections of normal salt solution.

Guided by the facts and principles briefly stated in the preceding pages of this paper, the physician will find himself ever acting in harmony with Nature's own processes, and with the most satisfactory success. But this involves the necessity of studying, with all the facilities of modern research, the nature and effects of each toxic agent, as well as the nature and *modus operandi* of every therapeutic agent he uses. For only by studying the actual effects of toxic or disturbing agents on the blood and tissue and the natural processes of resistance, can he comprehend the true pathologic conditions involved, or the rational indications for treatment. And only by a similar knowledge of the action of each therapeutic agent can he know which to choose for fulfilling any given indication. Otherwise he must depend altogether on the dictum of authority, and give the routine list of remedies recommended for the treatment of diseases designated by the same names. In doing this he is soon found using, for the same patient on the same days, remedies widely diverse in their action, and often directly antagonistic. Thus, to relieve the pains, restlessness, and high temperature of the first stage of an attack of epidemic influenza or any other active fever, such a practitioner will often be found giving his patient liberal doses of antipyrin, phenacetin or some other libal product which promptly affords the patient temporary relief from his pains, but at the same time impairs the properties of the corpuscular elements of the blood, lessens the activity of the leucocytes and oxidation processes, and thereby favors the retention of both the primary toxin and the products of metabolism, and protracts the period of convalescence. Or, if the case be one of continued fever, he will be found applying water in the form of baths or spongings, and giving more or less wine, whisky or brandy, alternately, with strychnin and digitalis from day to day, apparently wholly unconscious of the fact that the effects of his baths, spongings and doses of strychnin and digitalis are being directly antagonized by the alcohol of the wine, whisky or brandy. Both experiments and clinic experience have shown that the external applications of water in the form of baths or spongings not only diminish the fever heat but also increase, in a marked degree, the oxygenation and decarbonization of the blood and the elimination of waste and toxic products by the kidneys and other excretory organs, and at the same time the strychnin and digitalis directly increase the sensibility and reaction of the respiratory and vasomotor nerves, thereby sustaining the important functions of respiration and circulation. And yet, every well-devised experimental investigation has demonstrated that alcohol, chloroform and ether in the system directly diminish the sensibility and action of the respiratory and vasomotor nerves in proportion to the quantity used, and also markedly retard the oxygenation and decarbonization of the blood, and lessen both the activity of leucocytes and of normal metabolism, thereby placing their effects in direct antagonism to the effects of the other remedies given in conjunction with them. A large part of the prevailing scepticism regarding the curative effects of drugs has resulted from such coincident use of antagonistic agents, and the frequent use of agents for the relief of some prominent symptoms, while their ulterior effects were injurious to the natural processes

of vital resistance instead of aiding the same. And there is no part of the whole field of medical knowledge that more needs thorough research and revision than that which relates to the action of drugs on the living body.

OBLIQUE INGUINAL HERNIA.

TYPIC OPERATION FOR ITS RADICAL CURE.

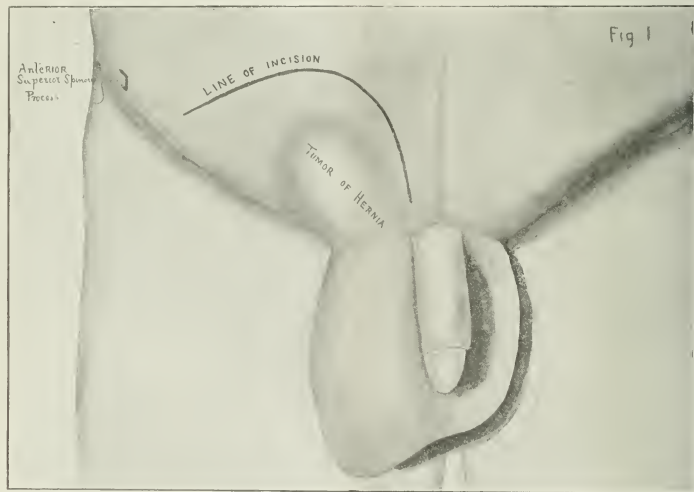

BY ALEXANDER HUGH FERGUSON, M.D.

PROFESSOR OF SURGERY, CHICAGO POST-GRADUATE MEDICAL SCHOOL,
CHICAGO.

A typical operation for the radical cure of oblique inguinal hernia is one that places all the structures involved in the same relationship to one another as they are present in a normal person. The operations that have been hitherto produced to cure inguinal hernia fall far short of being typical. A careful analysis of failures; a painstaking research for hidden truths, and a discernment of contestable premises are ever before the surgeon who hopes for more success, new discoveries and lasting operative procedures.

In the multiplicity of the new environments that have arisen and changed from time to time, herniology shows

operations then in vogue, for I was not wholly satisfied with any of the methods. It was my desire to preserve the steps in each different operation that fulfilled one indication or more and to discard those steps that did not. The result was, I recommended a "combination operation," which was well received. Since then, however, I have been my own severest critic. I freely found fault with my own work, as well as that of others. Several relapses of the rupture occurred after my method, and recurrent cases operated on by other surgeons, after other methods, came to my clinics and practice. The first important observation I made was that the return hernial protrusion began at the upper and outer portion of the seat of operation above the cord, and usually near Poupart's ligament. This I recollected had been referred to by other surgeons. While operating on these relapses I found a slit in the aponeurosis of the external abdominal muscle through which the sac and usually some fat protruded. Determining on a search for the causes of these failures, it was thought advisable to make a semilunar incision and raise a flap of skin, fascia and aponeurosis of the external oblique muscle, in order to bring into view the whole sac, and deeper structures

that there has been considerable developmental experimentation, and attendant thereto new suggestions have presented themselves; new ideas were born, and new truths discovered. In response to a firm conviction of having found an improvement on the older operation, independent thinking surgeons invented the different procedures we now possess. It is plainly observable that "do this and he doeth it," without giving the reasons why, has, in this connection, been too frequently blindly followed by the profession. It is now nearly five years since I undertook to criticize the principal

*Presented to the Section on Surgery and Anatomy, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1896.

with their relations. To my astonishment, I found an angle between the lower border of the internal abdominal oblique muscle and inner aspect of Poupart's ligament wholly unprotected by the internal oblique and transversalis muscles. In the sixth case the unprotected angle extended upward and outward to the anterior superior spine of the ilium, there being no connection whatever between Poupart's ligament and these muscles, the space being occupied by some fat and a hernial sac. This is how I made the important discovery that a deficient origin of the internal abdominal oblique and of the transversalis muscles at Poupart's ligament is a direct cause of the rupture returning in this angle

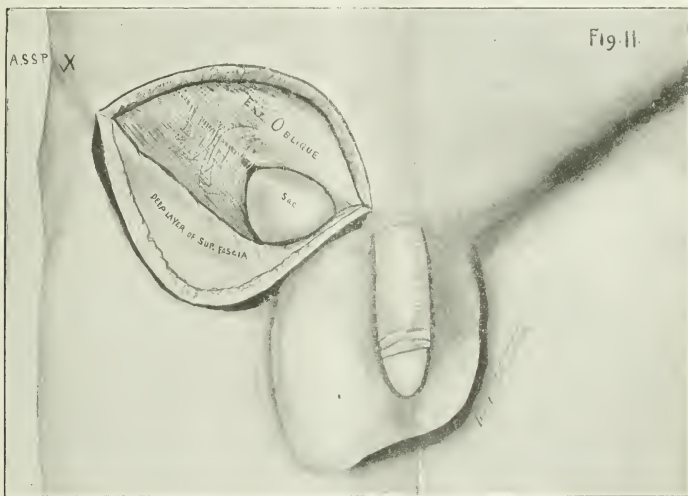

after operation for the radical cure. I then (January, 1898) began the semilunar incision in every hernial operation, and to look for the deficient origin of the internal oblique and transversalis muscles. (Dr. Nicholas Senn tells me that he "has been doing this same incision for about three years.") They were always deficient in origin. In order to clear up this question anatomically, I asked Dr. R. C. Turek, professor of anatomy in the Chicago Post-Graduate Medical School, to make fifty dissections for me of the inguinal region. This he faithfully carried out, assisted by Dr. Walter Fitzpatrick, who is an excellent artist. Dr. Turek presented his work to the Chicago Academy of Medicine as his inaugural thesis.

OPERATION.

First Step: Semilunar Skin Incision.—Begin the incision over Poupart's ligament, $1\frac{1}{2}$ inches below the anterior superior spinous process of the ilium; extend

covered by the deep layer of superficial fascia, and the superficial vessels. (Fig. 2.)

Second Step.—Cut through the external abdominal ring and intercolumnar fascia; separate the longitudinal fibers of the aponeurosis of the external oblique muscle directly over the inguinal canal, far beyond the internal ring, over the surface of the internal abdominal oblique muscle, and up under the skin, to a point nearly opposite the anterior superior spine of the ilium. Delicate transverse fibers are encountered and severed. Retract the aponeurosis of the external oblique muscle and thereby bring into sight the deep structures, viz., the contents of the inguinal canal, the whole sac, with its adhesions, the spermatic cord, ilio-inguinal nerve, internal abdominal ring usually enlarged, frequently an accumulation of subserous fat, the cremasteric muscle, conjoined tendon, internal oblique muscle, and its deficient origin at Poupart's ligament, transversalis

inward and downward in a semilunar manner, circumventing the internal abdominal ring, and terminate it over the conjoined tendon near the pubic bone. (Fig. 1.) Cut carefully backward with a very sharp knife and expose the vessels and pick them up with forceps before severing them, and thus prevent blood-staining of the tissues. Having passed through the skin, two layers of the superficial fascia, fat between them and superficial epigastric vessels down to the aponeurosis of the external oblique muscle, it will be noticed that it is not necessary to cut the superficial circumflex iliac, nor the superficial pudic vessels. Take a pledget of gauze and with it turn the flap of the skin, subjacent fat and fascia downward and outward over the thigh. This procedure brings into view the aponeurosis of the external oblique muscle, the external abdominal ring, with its pillars and intercolumnar fascia, the hernial sac, if it has descended through the external ring, external surface of Poupart's ligament, the under surface of the flap

fascia, and the internal surface of Poupart's ligament. (Fig. 3.) I consider the congenital deficient origin of the internal oblique and transversalis muscles one of the most frequent and important causes of oblique inguinal hernia. Inspect these structures carefully, and now determine whether the operation is to be typical or atypical. When the structures are well defined and not too much weakened by pressure atrophy, a typical operation can be proceeded with.

Third Step.—This step deals with the sac and its contents; the cord, cremasteric muscle, and subserous lipomata.

The sac is carefully dissected from the cord and internal ring; it is always opened (Fig. 4), contents inspected and dealt with, and ligated high up over the inserted finger (Fig. 6), cut off, and the stump dropped. In atypical operations the sac is usually preserved, as recommended by Macewen. If the sac be congenital, divide it in two, the distant half to form a tunica for the

testicle and the proximal to be treated as above mentioned.

When omentum is found within the sac it is liber-

ally withdrawn, tied en masse, cut off, the stump covered with its own peritoneum and returned within the abdomen. (Fig. 5.) This decreases the intra-abdom-

inal pressure and lessens the tendency to a return of the hernia. At this stage of the operation when the sac is opened, it is frequently found advantageous to place the

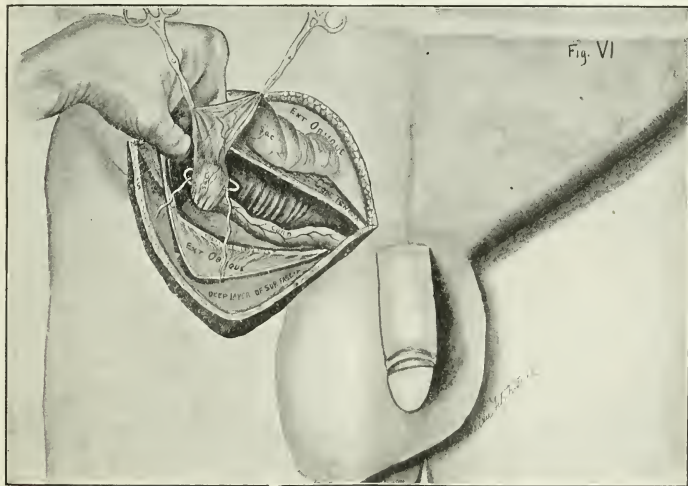

ally withdrawn, tied en masse, cut off, the stump covered with its own peritoneum and returned within the abdomen. (Fig. 5.) This decreases the intra-abdom-

inal pressure and lessens the tendency to a return of the hernia. At this stage of the operation when the sac is opened, it is frequently found advantageous to place the

patient in the Trendelenburg position to prevent protrusion of and injury to the intestines. The cord is not disturbed. I have never been satisfied

with the raising and transplantation of the cord. In more cases than have been recorded the testicle has come to grief by this unnecessary procedure. Tearing the

nor brilliant surgical results to justify its continuance. Leave the cord alone, for it is the sacred highway along which travel vital elements indispensable to the perpet-

cord out of its bed is without an anatomic reason to recommend it, a physiologic act to suggest it, an etiologic factor in hernia, congenital or acquired, to indicate it,

uity of our race. The veins in the cord are not disturbed, unless a varicocele complicates the hernia. If the cremasteric fibers are unduly thickening the cord,

they would better be removed along with adventitious tissue that is not unfrequently present.

An abnormal quantity of subserous adipose tissue is often deposited around the sac and cord and along Poupart's ligament, an etiologic factor in hernia, and if not removed tends to cause a return of the hernia. A systematic search should be made for fatty aggregations and they should be removed."

Fourth Step.—Restore the structures to their normal positions. The transversalis fascia forms the internal ring. In hernia its fibers have become more or less stretched above and around the cord. The ring in consequence is abnormally large and the fascia bulges outward. To rectify this condition take up the slack in the fascia and make an accurately-fitting ring for the cord by means of a suture, interrupted or continuous. (Fig. 7.) Do not injure the deep epigastric vessels, nor pass the needle too deeply in the direction of the large iliac vessels.

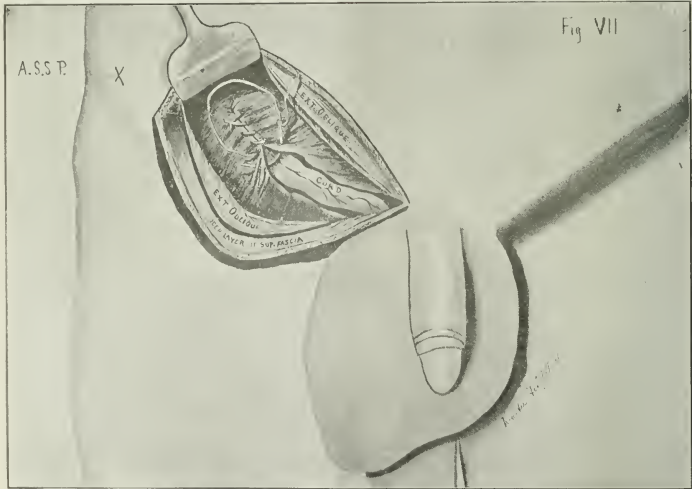

and coapt all its structures, like to like, especially the deep layer of the superficial fascia. (Fig. 10.)

COMMENDABLE FEATURES.

The different structures in the abdominal wall are placed in their normal relationship. a. The tying of the sac restores the normal rotundity of the peritoneum. b. The suturing of the transversalis fascia forming a new internal ring at the same time obliterates the hernial infundibuliform process. c. Sewing the internal oblique and transversalis muscles to Poupart's ligament secures a normal origin for them and they then find perfect protection to the internal ring cord and canal. d. The suturing of the separated fibers of the aponeurosis of the external oblique protects the underlying muscles and cord, while the skin flap covers all.

2. The four lines of suture are not opposite each other, thus securing an overlapping of the weak parts—lines of repair—by normal tissues.

3. The semilunar incision has great advantages: a.

The internal abdominal oblique and transversalis muscles suture to the internal aspect of Poupart's ligament, and restore their normal origin. I usually freshen the lower border of the muscles and scarify the surface of Poupart's ligament to insure firm union, and extend the sewing fully two-thirds down Poupart's ligament, which is the normal origin of this muscle in the female. Take care not to split Poupart's ligament by grasping with the needle the same longitudinal fibers each time. (Fig. 8) It is surprising how easily these two structures come together without the least discernible tension, and it is gratifying to observe how perfectly these powerful muscles cover and protect the internal abdominal ring and inguinal canal. (Fig. 8½.)

Bring together the separated edges of the aponeurosis of the external oblique muscle. Restore the external abdominal ring. (Fig. 9.)

In bringing the skin flap into normal position, be sure

The hernial area is uncovered as in no other way, thus affording an accurate observation of structural relationship, etiologic factors and pathologic conditions. b. There is less tendency of skin infection, extending to the deeper structures. c. Should, unhappily, a return of the rupture occur, there is no scar over it and a truss can be better borne.

4. Of all the operations I have performed, this is the simplest and easiest to execute. There is a good scientific reason furnished for every step in the operation.

5. Results so far are excellent. In the last eighteen months I have performed the above operation sixty-four times, counting each case of double hernia as two operations. There have been no relapses as yet. I do not wish to say that recurrence can not take place. The ages of my patients varied from 5 to 76 years; station in life, from poorhouse cases to the most affluent. Seven hernias in 4 men were complicated with enlarged pros-

tate, where at the same time I performed gonangiomy; 4 were strangulated; 1 (double) had chronic gonorrhoea; 2 cases had non-descending testicle; 4 had varicocele; 2 had a femoral and umbilic hernia; 1 case had an epigastric and a femoral hernia as well, all three operated on at the same time; and 1 had oblique inguinal congenital, and an acquired direct hernia on the same side.

There was one death on the fourth day after the operation—an old man, 74 years old. He had enlarged prostate, chronic cystitis, diseased kidneys, etc. The effect of the anesthetic was most likely the cause of death. Three cases suppurated, 2 had chronic gonorrhoea and the third had chronic cystitis. In 61 out of 64 cases primary union occurred. All the strangulated cases healed by first intention. Rubber gloves were used in 3 cases only—six operations. In doing the rest of these operations with bare hands, the fingers were allowed to touch the tissues as little as possible.

With a special flat, ruled probe accurate measurements were made on the operating table to ascertain: 1, the length of Poupart's ligament; 2, the length of origin of the internal oblique muscle from Poupart's ligament; 3, size of "Ferguson angle" and position of internal ring.

In the sixty-four operations the internal abdominal oblique and transversalis muscles were deficient in every case. To differentiate between the border of the internal oblique and the fibers of the cremasteric muscle a blunt dissector or protected finger is passed underneath the conjoined tendon and made to travel rapidly to Poupart's ligament, well under the border of the muscle, thus sending the cremasteric downward and hugging the main muscle to its origin, and then the measurements are taken. The origin—which is the main thing—of these two muscles was deficient in every case, the average length being $1\frac{1}{2}$ inch. It was rare to find an

The wound was occasionally cleansed with salt, and the skin with bichlorid solution (1-2000). In about half the cases chromoform catgut (Nos. 0, 1, 2 and 3) was used in skin, as well as in deeper structures. The last six months I have discarded Nos. 2 and 3. If additional strength is deemed necessary the catgut is used double. Horsehair and silkworm gut were the other materials used for the skin. Different stitching methods have been employed, viz., interrupted and containing in the deeper structures, and for skin I used external interrupted, subcutaneous interrupted, external continuous and subcutaneous continuous. Half the stitches were removed on the sixth or seventh day, the rest within ten or twelve days. The patients were kept in bed from twenty-one to twenty-eight days, enjoined not to assume any work for six weeks after operation, and advised to wear a broad support—no truss—for three or four months.

origin of 2 inches; $\frac{1}{2}$ or 1 inch was much more common.

CADAVER WORK.

As already intimated, I requested Dr. Raymond Custer Turk to execute fifty inguinal dissections in this connection. In support of my "Typic Operation for Radical Cure of Inguinal Hernia" I shall here give a few quotations from his thesis, which clearly establish my claims:

In the course of numerous operations for the relief of oblique inguinal hernia. Dr. Alexander Hugh Ferguson, of this city, has observed: 1, that with but few exceptions there was a marked deficiency in the origin of the internal oblique and the transversalis muscles from Poupart's ligament; 2, that these muscles arising only from the outer portion of Poupart's ligament, with their lower fibers deficient in number and strength, afforded but poor protection, if any, to the internal abdominal ring; 3, that a strong barrier being thus removed, the descent of the hernia through the internal ring and downward along the inguinal canal was greatly facilitated.

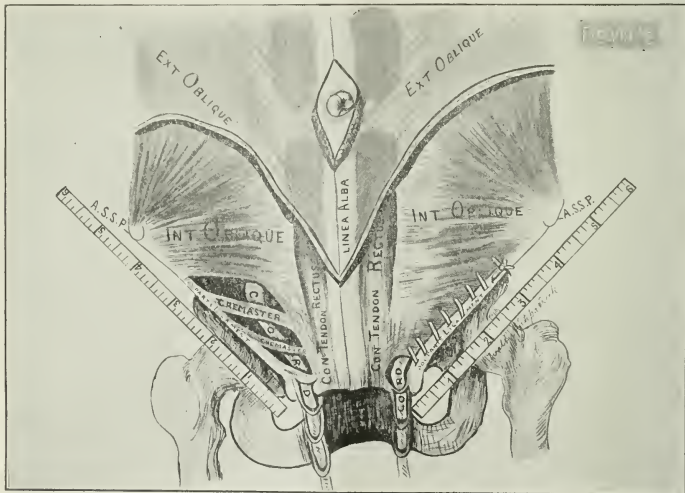

Nearly every writer on hernia makes the statement that the

hernia in its descent pushes the arched fibers of the internal oblique and the transversalis muscles out of its way, displacing them outward and upward. Dr. Ferguson, while granting that the muscles are to a greater or less degree thus displaced, asserts that this displacement would not be possible, providing always that no congenital defect in the internal ring existed, were there not an abnormally short attachment of the muscles to Poupart's ligament; that the fact that the internal oblique, by reason of this deficiency in the origin of the muscle fibers and their consequent abnormal upward arching, fails to adequately cover and protect the internal ring and assist in the support of the abdominal viscera at that point is not altogether an effect of hernia, but rather a cause. He further asserts that in a fair percentage of cases of indirect hernia, a congenital—not an acquired—deficiency in the origin of the internal oblique had been present, and had formed in the individual a predisposition to the hernia, and that the hernia had been then occasioned by the gradual "giving way" of the peritoneum and of the transversalis fascia, or by a more immediate "exciting" cause.

Arguing on this hypothesis, Dr. Ferguson concludes that in an individual of well-developed internal oblique and transversalis muscles having a firm, normal attachment well down

which 27 were of adult males and 9 of adult females, whose ages it was impossible to obtain; 1 of male and 2 of female children, with given ages, and 11 fetuses of both sexes, with ages varying from seven months to full term. In regard to the latter, they were either still-born or had died shortly after birth, for in all cases the divided funis was present.

To insure against possible mistake, the lower border of the muscle passing from Poupart's ligament to the conjoined tendon was carefully exhibited, and the cremasteric fibers differentiated. The length of origin of the internal oblique given, then, is the distance between the anterior superior spine and the lowest point on Poupart's ligament, from which well-marked internal oblique fibers pass over to the conjoined tendon. The spermatic cord, or round ligament, was then followed upward along the inguinal canal to the internal ring, the fibers of the internal oblique being thus divided in the direction of the canal. The infundibuliform process of transversalis fascia was then removed, and the margins of the internal ring defined. A needle or probe was placed as exactly as possible in the center of the ring, and from the center the following measurements were taken: the distance to the anterior superior spine of the ilium; the distance to the spine of the pubes, and to Poupart's ligament. For the length of

along Poupart's ligament, these muscles, especially the internal oblique—by closely covering and protecting the internal ring—offer strong resistance to pressure from within, and thus render the liability to hernia very small.

The lower fibers of the internal oblique, leaving Poupart's ligament and passing inward to the conjoined tendon, normally form, with the ligament, an acute angle. This we have taken the liberty to call the "Ferguson Angle." The lowest point of the muscular origin in its relation—external or internal—to the internal ring, considered together with the degree of the Ferguson angle, goes far to show the relative strength or weakness of the resistance offered by the muscle at the internal ring, and hence should not be overlooked in the study of the causation of hernia.

Acting on Dr. Ferguson's suggestion, dissections were undertaken with a view of determining in the normal cadaver: 1, the average length of the attachment of the internal oblique muscle to Poupart's ligament; 2, the position of the external and internal abdominal rings; 3, the length of the inguinal canal; 4, to estimate the amount of protection afforded the internal ring, and, 5, to note other points of interest in this connection which might come under observation in the course of the work. There were in all fifty cadavers dissected, of

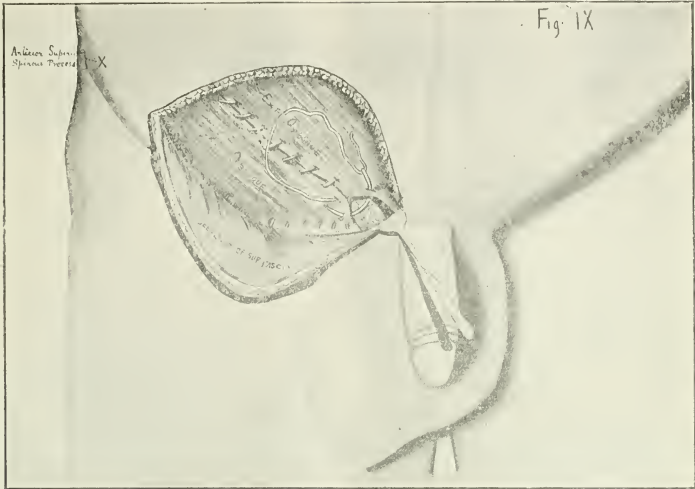

the canal the distance was taken between the center of the internal ring and the outer angle of the external aperture.

The average length of Poupart's ligament was found to be 11.2 cm. (4 $\frac{3}{8}$ inches) in the male adult—25 subjects, Dissections 40 and 43 not being counted in the averages—and 12.5 cm. (4 15-16 inches) in the female adult—9 subjects. The average distance of the apex of the external ring from the pubic spine was 2.1 cm.—13-16 inch—in the male, and in the female 1.57 cm.—5 $\frac{1}{8}$ inch. These measurements present no points of particular interest or importance other than those given by obstetricians and anatomists regarding the greater width of the female pelvis, and the smaller size of the ring in woman than in man. In a majority of the male subjects, however, I found the length of the external ring to be less than an inch (2.5 cm.), the distance usually given, in several but half an inch (1.3 cm.), in one three-eighths of an inch (1 cm.). As shown by the tables, in these dissections, the size of the female ring averaged a little less than three-fourths that of the male.

The average length of the origin of the internal oblique muscle in the male was found to be 8 cm.—3 $\frac{1}{8}$ inches. On comparing this with the average length of Poupart's ligament, it will be seen that the muscular attachment averages a little

more than two-thirds the length of the latter. Gray, Morris and others state that the internal oblique takes origin from the outer half; Quain, that it arises "from the outer half or two-thirds of the deep surface of Poupart's ligament." The

directly on Dr. Ferguson's assertion that the internal ring derives its greatest protection from the internal oblique muscle. For it is well known that the lower (innermost) fibers of the muscle are the weaker, therefore the longer the ligamentous

results obtained here do not bear out the text-book statements, the internal oblique being attached in a majority of the normal cadavers to rather more than the outer two-thirds of ligament. This fact is important, bearing as it does

origin, the farther the weak fibers pass below and internal to the internal ring, the greater is the protection afforded the ring by the strong outer muscular fibers which pass over it.

Dr. Turck was fortunate in getting a full-term male fetus that had a left congenital hernia with retained testicle, while the right side was normal. Having carefully dissected the left side, he then says: "Diagrams 1 and 2, which are life-size, drawn from the general averages, show the relative position of the rings and the length of the internal oblique origin in the male and female. The difference between the sexes is even more strikingly shown in comparison of individual cases."

COMPARISON OF THE AVERAGES OF MEASUREMENTS IN MALE AND FEMALE.

The Doctor, having assisted me at several operations, and possessing a thorough knowledge of the technic of my operation, carried out an interesting and convincing experiment on this fetus, viz.:

Measurements were taken which showed the length of Poupart's ligament to be 3.5 cm., the distance of the center of the internal ring from Poupart's ligament 9 cm., the distance from the anterior superior spine 2 cm., and from the spine of the pubes 1.8 cm. The length of the origin of the internal oblique muscle was found to be but 1.3 cm., about one-third the length of the ligament. It will be seen from these measurements, taking into consideration the 90 degrees of the Ferguson angle, that the internal ring derived but little, if any, protection from the internal oblique. The fact that the 90 degrees of the Ferguson angle persisted when no hernial protrusion was present, and that the angle was further increased when the descent occurred, would seem to indicate that the abnormal upward arching—and weak origin—of the internal oblique was not altogether due to the hernia, but

testine descended easily through the ring. The gut being returned, the cut edges of the internal oblique were united by interrupted suture, without, however, in any way reducing the size of the internal ring, and pressure once more applied to the abdomen. No amount of force, however, produced a protrusion of the abdominal contents, demonstrating clearly the valve-like action of the internal oblique.

Finally, let me draw your attention to two dissections on a male adult, who had a left oblique inguinal hernia.

SHOWING LENGTH OF ORIGIN OF INTERNAL OBLIQUE AND POSITION OF INTERNAL RINGS IN DISSECTIONS 43 AND 44—MALE

Dissections 43 and 44, respectively, of the left and right side of the cadaver of a male adult, are represented in diagrams 8 and 9. In this subject there was present on the left side an oblique inguinal hernia. The exceptionally enlarged ex-

Diagram 6—Left side—Congenital hernia.

Diagram 7.—Right side—Normal.

ternal ring, the downward and inward displacement of the internal ring, and the marked deficiency in the origin of the internal oblique, together with the largely increased degree of the Ferguson angle—in this case about 90 degrees—are, when compared with the normal relations of the parts shown on the right side, clearly exhibited. That the internal oblique muscle, because of its deficient origin and the pathologic arching of its fibers, failed to protect the left internal ring, is self-evident. That this defect in the muscle was altogether induced, or, we may say, artificially produced, by the hernia, is improbable, especially when the length of origin on the right side (3.1 cm.) is considered. It seems likely that this subject illustrates exactly one of Dr. Ferguson's points, namely, that a congenital defect in the muscle had predisposed the subject to the hernia.

Diagram 1.—General average in male—twenty-five dissections.

Diagram 2.—General average in female—nine dissections.

that there was a congenital defect and, as such, a contributing cause to the escape of the gut.

Experimentally, the gut being replaced in the abdomen, the processus funiculovaginalis was cut off flush with the internal ring, the testicle being placed between the peritoneum and transversalis fascia well to the outer side of the ring, and the ring closed by interrupted sutures through peritoneum and transversalis fascia. The internal oblique and transversalis muscles were then sutured to Poupart's ligament well down toward the pubic spine, after Dr. Ferguson's method of operation. Strong pressure was then made on the abdomen, forcing the viscera downward into the pelvis and against the lower abdominal wall, especially at the internal ring—the same procedure which had caused the hernial descent before the normal relations of the parts were restored—but no protrusion through the internal ring was obtainable.

For comparison, dissections were conducted on the right side of the same fetus, and the measurements revealed a radical difference in the position of the parts when compared with those of the left side. Diagrams 6 and 7 show the position of the parts on the right and left sides. They represent exactly the measurements given in the other, and when compared clearly demonstrate the greater amount of muscular protection which the right internal ring received. That this child, or man—providing development had gone forward normally—would have had a right oblique inguinal hernia is altogether improbable.

SHOWING RELATIVE LENGTH OF ORIGIN OF INTERNAL OBLIQUE, AND POSITIONS OF INTERNAL RINGS IN DISSECTIONS 29 AND 30.

After dividing the internal oblique fibers upward to the internal ring, the ring was enlarged to the size of the internal ring on the left side before the latter had been restored, and downward pressure again applied on the abdomen. The in-

ATYPIC OPERATIONS.

Atypic operations for the radical cure of oblique inguinal hernia are all those which do not in the completed operation leave all structures as they are present in a normal inguinal region. It is not necessary to mention these, but I wish to draw attention to plastic procedures on the sheaths of the rectus muscle, when the conjoined tendon is abnormally thinned out (Bloodgood); to the utilization of the sac (Macewen); and to the employment of the sartorius muscle to strengthen the inguinal region (Ferguson).

Some cases may present themselves—but they must be comparatively rare—where it may be advisable to do plastic work in addition to the typical operation.

PROSTATIC HYPERTROPHY.

RAMON GUITERAS, M.D.

Professor of Genito-urinary Surgery, New York Post-Graduate Medical School; Lecturer in the Medical Department of New York University.
NEW YORK.

SOME OBSERVATIONS ON THE BOTTINI OPERATION.

One of the curses of old age is hypertrophy of the prostate. Why it occurs in some unfortunates and not in others is a question that is difficult to answer, and if it could be answered it would then be possible to learn the cause, a question which now is such a puzzling one to the most learned and observing surgeons. It would seem natural to suppose that those who had in early youth suffered from venereal troubles, or had indulged too freely in the dissipation of life, would be the ones picked out for punishment in old age, but such does not seem to be the case, and in my personal experience it seems rather an unjust reward for the steady, the forbearing and the righteous.

To describe just what this condition is would be to unfold a mystery which the most distinguished pathologists have apparently not yet fathomed. For although many, in describing its pathology, make it easy to understand, others seem to be at variance with their opinion, e. g., some pathologists say that it is always a fibromatous growth and never a glandular one, while others say that it is often glandular.

The cause and pathology are, then, the two great points to be considered, and it would seem that, where there are so many eminent pathologists connected with the homes for aged men, autopsies ought to disclose the latter condition and there should be unanimity of opinion, as pathology is an exact branch. It seems to me, therefore, that the inference must be drawn that the subject has been sufficiently studied and that the pathologists neglect to examine, in a routine way, this little gland tucked down between the rectum and the pelves, in the same way that they overlooked the vermiform appendix before it began to play such an important role in the surgery of the day.

To speak superficially of the pathology as it is considered today, it would seem that enlargements of the prostate are variously classified according to their microscopic anatomy or the clinic symptoms to which they give rise. As the symptoms are chiefly due to the physical qualities of the tumor and are thus mechanic in their origin, it is manifestly more important to classify prostatic hypertrophies by their macroscopic appearance rather than by their microscopic. But at the same time it is worth mentioning that there are supposed to be three chief varieties histologically: 1, myomatous, or fibromyomatous, in which the stroma of the gland is principally involved; 2, adenomatous, in which the glandular elements predominate; and, 3, mixed forms, in which both stroma and glandular tissues are involved.

Such specialization, according to Socin, has but little surgical interest, because in clinic diagnosis it cannot be applied to good account and thus has no influence on prognosis or treatment.

Viewed clinically, prostatic hypertrophies occur in three chief forms.

1. Uniform enlargement in all directions, with the general form of the gland preserved. As the symphysis pubis and the urogenital diaphragm prevent the gland from growing downward to any great degree, the

tendency of the tumor is upward and backward into the cavity of the bladder. Thus about the orifice of the urethra is formed a ring of thickened gland tissue under the mucous membrane of the bladder. These forms of hypertrophy do not reach so great a development as others and are more mild clinically.

2. Irregular enlargement. By far the greatest number of cases belong to this variety. All parts of the gland may be enlarged, but certain portions are much larger than others, and thus many kinds of tumors are formed. The part chiefly involved is that portion of the gland just behind the beginning of the urethra. In the first form mentioned this part fades into the lateral lobes of the enlarged gland without sharp demarcation, but here it forms a tongue which overhangs the internal orifice and is termed by Mercier the "valvule prostatique." This increases to a large independent tumor which is separated from the rest of the gland by deep grooves, and thus gives rise to the well-known "middle lobe" of the prostate.

If both lateral lobes be enlarged at the same time, we have a threefold gland clearly marked, with an egg-shaped tumor on each side and a triangular pyramid behind; an arrangement which gives to the urethral orifice a "Y" shape, with the stem forward and the legs backward. The surfaces of the tumors may be smooth, or, more frequently, they are irregularly prominent, as if made up of a number of smaller tumors which project into the bladder. These nodules may separate and remain as free bodies under the mucous membrane of the bladder. The anterior commissure of the gland is seldom the seat of the hypertrophy, because there are but few if any glandular elements presented here.

3. The third form occurs when all the gland is normal except in one small area, and is termed the localized variety. It is a very rare form.

As the prostate hypertrophies, the orifice of the urethra becomes elevated, and the return flow of blood from the vesical veins is impeded by pressure on the prostatic plexus. This results in imperfect evacuation of the bladder, and consequently in residual urine. Cystitis develops, as is evidenced by a frequent desire to urinate—due to irritation of the neck of the bladder from venous congestion—and the other symptoms usually present. If the hypertrophy continues, these symptoms increase or are replaced by graver ones, and we have dilatation of the bladder, hypertrophy of the muscular and fibrous coats, and the formation of diverticula; dilation of the ureters and pelvis of the kidney, congestion and catarrhal inflammation of the entire urinary tract, with an accumulation of the urinary and inflammatory products, and perhaps septic inflammation extending from the bladder to the kidney—pyelonephritis—resulting in chronic uremia and death.

Thus we see what conditions must be relieved in order to benefit our patient. His general health should be improved; his bowels regulated, and his skin kept active by warm baths; his clothing should be warm, to prevent taking cold, and he should eat moderately and drink plenty of water. His urine should be kept in the best possible condition by the use of internal urinary antiseptics, as the benzoates, the salicylates, boric acid, etc. Oleum gaultheriae, eucalyptus, and urotropin are also of great service. Locally, his bladder should be emptied by the catheter twice a day and washed out with a boric acid solution; other antiseptic solutions, as permanganate of potassium, nitrate of silver, and borolytol, being used at intervals. When the patient has been brought into the best possible condition gen-

*Presented to the Section on Surgery and Anatomy, at the Fiftieth Annual Meeting of the American Medical Association, held in Columbus, Ohio, June 6-8, 1898.

erally and locally, an operative procedure can be considered, but an operation should never be performed until palliative means have failed.

Ligation of the internal iliacs, resection of the vas deferens, castration, prostatectomy, and the formation of a suprapubic fistula have all had their day and advocates, and the mass of practitioners seem now to be coming to the opinion that the operation by the Bottini galvanocautic incisor is in most cases the quickest, the simplest and the best.

This instrument was devised by Bottini of Pavia. When he performed his first operations—1875—he made use of the so-called “cauterizatore prostatico,” representing an instrument of the shape of a catheter of medium caliber, with a short beak, the latter carrying on a porcelain disc a platinum plate about three-fourths of an inch long. With this plate, made red-hot by the electric current, he cauterized the prostate thoroughly at different spots, if necessary repeatedly. When the eschar had been pushed off, improvement often began to set in; at times it took thirty days before the patients could notice the effect of the interference.

Two years later he was able to publish five successful cases treated in this way. With increasing experience, he discarded the cauterizer and made use only of the second instrument, the “incisore prostatico,” which removes the mechanic obstruction to the outflow of the urine at the neck of the bladder by slowly burning a groove or grooves through the same, and not by superficial destruction. This instrument has a male and female shaft, not unlike a lithotrite. The beak of the female part forms almost a right angle with its shank, and has along its concave surface a deep groove along which the male shaft glides. The shank of the male arm shows a platinum knife at its distal end, about five-eighths of an inch long, which is drawn along the groove of the female arm, toward the handle, on turning an Archimedeian screw at the outer end of the instrument. A scale (Sc.) attached to the latter admits of exactly gauging the length of the groove to be cut. The instrument further shows the so-called cooling apparatus, which was added to it in 1882. Freudenburg has made a modification of this instrument, which is the one usually used in Germany and this country. It differs principally in having a larger and better-cooled handle, and the water-pipes at a more acute angle to it. It is also a heavier instrument.

This operation has been performed about two hundred times, but I have only found about one hundred well-reported cases, exclusive of my own.

Bottini has performed this operation 80 times, but we have found only 23 cases sufficiently well reported to be of value for compounding statistics. Some of these are so lacking in important parts of their histories and the details of the operation and after-treatment that they convey little to the mind of the reader, excepting that “miracles” have been performed in a certain part of Italy by one Bottini.

In reading over Bottini's 23 wonderful reports here commented on we notice: 1, that no deaths have been reported; 2, that twenty of these patients, who had been suffering for from eight months to six years from prostatic trouble, were cured in from eleven days to three months, and all but one of them, i. e., 19, in less than one month; 3, that these cures have been accomplished by a single cut, 2 cm. or more in length, either in the posterior or one lateral lobe, or often in two lobes, sometimes, though rarely, in three; 4, that the time for the operation varied from forty-five to

ninety-five seconds. The three remaining cases were very much improved.

Any investigator devising an instrument like the Bottini incisor should naturally be proud of his achievement, but it is difficult for a reader in a distant land, accustomed to observing enlarged prostates and the sequelæ of their observation, to arouse his enthusiasm to such a point as to be able to agree with the discoverer of the galvanocautic incisor.

A reader of these reports can easily see how the heated iridioplatinum blade can glide through the prostatic bar burning a furrow through it, and reducing the height of the dam, and he can also understand how by severing and searing the vessels, the blood-supply can be sufficiently shut off to cause additional atrophy. He cannot understand, however, how a chronic cystitis which has existed for months and years can in a few days be perfectly cured, or how tone can be restored to the wall of an atonic bladder in that time.

Bottini, in some of his reports, spoke of the cases having had gonorrhœa, as if he considered it a possible causative factor of the hypertrophy. I do not think that such is the case, and, in reviewing in his mind the patients whom he has treated for this trouble, he can not remember a single one where he could establish a direct relation between the two. As the patients in whom reference to such a relation was made were about forty years of age, or under, it is possible that the symptoms mentioned may have been due to some other prostatic or seminal vesicle trouble rather than to senile hypertrophy.

In speaking of his operations, Bottini says very little about the anæsthetic used. He occasionally speaks of having given chloroform or cocaine, but often makes no allusion to it.

The frequency with which he has resorted to permanent catheterization in after-treatment, sometimes for fifteen days at a time, is a noticeable feature of these reports, and leads one to think that perhaps the bladder remains more tone than is generally supposed by being allowed to contract gradually.

It is gratifying to remark that no cases of syncope, or bladder or renal congestion followed by uræmia developed in these cases, as so frequently occurs in this country.

Another thing that strikes one as most remarkable in reading over Bottini's reports is that in only one case a marked rise of temperature, that is to 104, was mentioned. This was said to be due to malaria. The writer is, however, of the opinion that most such rises of temperature occurring after this operation in cases associated with a bad cystitis are due to septic absorption.

It was interesting to read the report of one of his cases in which a calculus was present in connection with middle lobe hypertrophy. The stone was first crushed, and then an incision made posteriorly with the incisor, it occurs to the writer that it might have been better to first perform the Bottini operation, and later the litholapaxy, as this would allow the operator to insert a larger evacuator, which is so important in litholapaxy.

Meyer has reported twelve cases, the most interesting and instructive that have been described, on account of the candor displayed in their narration, and the skillful way in which he met every obstacle.

In most of the cases he performed but one operation, although in 2 of them he was obliged to operate twice. The results were: 2 cured, 6 improved and four deaths. In most of the cases he made three incisions, and in some

four, all of good length. In the reports a marked elevation of temperature after the operation. In the first a chill was followed by temperature of 103.8, with delirium; in the second, 103.6, orchitis and abscess of testes; in a third, 101; in a fourth, 103. Two of these cases died. One of the cases was interesting on account of the number of operations performed to no avail. They were: 1, vasectomy, no benefit; 2, perineal prostatectomy, no benefit; 3, suprapubic cystostomy for inspection; 4, double castration; 5, Bottini, under ether. The patient finally died. In two of his cases Meyer found it necessary to perform a suprapubic cystostomy. Most of his operations were under local anesthesia, although two were put under a general anesthetic, in one case ether, in another Schleich's.

Freudenburg has performed this operation about thirty times, but only six of his cases are here commented upon. He has done more than any other surgeon, excepting Bottini, to perfect this operation, as he has modified the instrument in a way to make it more generally acceptable to the operating surgeon. He is a careful and conscientious man and a good observer. His results, however, while they correspond with those of the other German and American surgeons, cannot compare with Bottini's, operated on by means of his original crude instrument. This would lead us to think that if Bottini's reports can be accredited, the Freudenburg modification is a failure, but such does not seem to be the opinion of other surgeons, almost all of whom have endorsed the Freudenburg instrument as the best. His reports are intelligible, and he does not claim such perfect cures as does Bottini. He has a tendency, however, to paint the pictures of his cases before operation in a bad light, as if in an apologetic way, to explain the results that may follow. He speaks of many of them as emaciated, run down and in bad condition, with bladder and kidney complications. He usually makes three incisions of fair length, operates under eucaïn and precedes each operation by a cystoscopic examination. Most of his cases have improved. He had two deaths.

Lohnstein has operated 12 times, but only 6 of his cases have been sufficiently well reported to be of use. He usually makes two incisions, one posteriorly and the other through one of the lateral lobes, although he has made them through both lateral lobes, omitting the posterior and anterior incision. He operated twice in 2 of his cases. Of the 6 here reviewed, 5 were improved and one died. One patient collapsed before the operation could be completed. He reports another case that collapsed on being catheterized, illustrating the mistake of too rapidly emptying the bladder. The other 6 cases were only referred to, and not reported in detail, as the results were not permanent.

Simon has reported 8 cases. His reports are very interesting to read, as his methods seem different from other operators. He usually makes one incision, a posterior one, although in some he incises a lateral lobe in addition, and in others he makes three incisions. He does not seem to look at the operation so very seriously, as he performs it on patients in bad condition, suffering from cystitis, nephritis, and arteriosclerosis, having a large amount of residual urine at the time of the operation, and he allows them to return home on the following day—with at times as much as fifteen ounces of residual urine in their bladder—and then treats them in the dispensary. Some of his cases before operation had from twenty to fifty ounces of residual urine, which was very much improved by a posterior incision. He cysto-

scoped one of these cases two days after an operation, and saw a dark groove in the site of the incision; 3 cases were reported as cured, 2 as improved and 3 died.

Crespi reported 6 of Bottini's cases. There is nothing additional to be learned from this group. They were not difficult ones, and all seem to have been benefited; 1 case was operated on twice. The most interesting of his cases is a patient who was first operated on by Bottini's method, followed by two years of relief. He then had vasectomy performed, which reduced the hypertrophy one-half, and was followed by the disappearance of blood and pus from the urine. He was then again operated on by the Bottini method, and improved. Crespi reports 4 more cases, varying in age from 64 to 78 years, 1 of which was cured in a day, another in 3 weeks and 2 others improved.

Morton has reported five cases, all improved by the operation. In each there was still some residual urine present at the last report, and the patients still had frequency of urination at night. Morton made moderate-sized incisions, and operated most consistently.

Hanc reported 5 cases, ranging in age from 58 to 68 and his results were fair. In 1 case he operated twice, and in the other once.

After careful operations, frequency still existed, especially at night, though not in so marked a degree. It is interesting to notice that in the cases operated on twice the bladder still contained twelve ounces of residual urine, and he had to use the catheter.

The report of Bruce-Clarke's 4 cases as given us by Jermoli are incomplete and unsatisfactory. The operations were evidently performed under general anesthesia, and the results were all cures in a short time, notwithstanding the fact that the patients had considerable residual urine, and had suffered from prostatism for a long period.

Cecchecorelli reported 4 cases, varying in age from 41 to 60 years; all had cases of long standing, associated with catheter life; 3 of them were cured in from nine to seventeen days, and the 1 improved for a while and then died.

Lewis reported 2 cases. These were well described. Both were operated on twice, and improved. He used air to inflate the bladder. In speaking of one case after operation, he said that the patient could empty his bladder all but two or three drams, which amount is often found in a healthy viscus. This statement I take exception to, as an unobstructed, healthy bladder should be able to empty itself.

Freeman has reported 2 cases with excellent results. He speaks of 1 patient having considerable bladder irritability after the operation. I am glad to hear this mentioned, as personally I have found it to be the most persistent and obstinate post-operation symptom that we have to contend with.

Lemander has operated in 3 cases from 65 to 77 years of age. They were all of long standing, with symptoms of obstructive cystitis; 1 was relieved, 1 discharged with a permanent fistula, and 1 died three months after the operation. In the first case after one incision of 3 cm. in length, the patient did not urinate for twenty-two hours. The last 2 cases were of especial interest, the first because he was made worse rather than better by the Bottini, and was then improved by a vasectomy. The second has many points of interest: 1, both testes were very much involved by disease ascribed to catheterization; 2, their removal had no influence on the size of the prostate; 3, calculi were found in the bladder, complicating the case; 4, a suprapubic

cystotomy was performed; 5, an incision 1.75 cm. in length was made by the incisor after this, thus enabling the operator to see the action of the cautery knife through the suprapubic opening; 6, a second incision, 3 cm. long, was made by the incisor three weeks later, followed by retention, and, finally; 7, a permanent fistula had to be resorted to.

The reader can only condemn the presence of the assistant's finger in the rectum during the operation, as mentioned in one of the cases, as in order to detect the presence of the instrument he has to press up the anterior wall of the rectum in the region of the prostate, which might cause the heated blade to burn through, making a ureterorectal fistula. In criticising the poor results in these cases it would seem that the incisions were too short, and too few.

Downes, Weber, Chassaigne, Kreisel and Rydygier have also reported cases; most of which were improved. Rydygier's case died four days after the operation, of urinary extravasation, and septic peritonitis, due to catching the back of his instrument in a pocket in the bladder instead of behind the prostate, and thus burning through the serous surface of the bladder. This is an accident that is difficult to foresee, and can only be avoided by making a cystoscopic examination of the bladder some time before the operation.

Rochet has reported two cases. One died and the other was discharged seemingly improved.

The writer has performed this operation 20 times, with 2 deaths. The first 12 were all benefited and reported in the *Medical Record*—of the 8 others, 2 died, a total mortality of 10 per cent; 1 died of chronic Bright's disease and would not have been operated on had not the hospital interne reported the urine negative; death a few weeks after showed the cause to be chronic interstitial nephritis, which had been present at the time of the operation, but not to the knowledge of the operator. The other case died of sepsis. It was due to an accident, and illustrated two important features. The writer had given this operation to the house surgeon and had placed himself behind the operator with the battery. The posterior incision was being made when the writer left his post to look at the battery, which was not working well. After rectifying this, he told the operator to proceed; but during this time the patient had pulled backward, allowing the concavity of the beak to slip over the convexity of the prostate, and the cut was accordingly made through the membranous urethra into the perineum. The result of this was retention of urine, necessitating a perineal section, which was followed by sepsis and death. The two important principles illustrated by this are: 1, that the battery should always be placed on the patient's left, where it can be seen by the operator and easily grasped by him, if necessary, with his right hand; 2, that if the patient pulls away from the operator, as he is liable to do under local anesthesia, the operator must not allow his arm to remain stationary, but must follow up the patient so that the instrument will always remain in the same relative position until the incision is completed.

Of the remaining 18 cases, 15 have improved, and in two of them no residual urine is now present, while in the other 13 only about one-eighth to one-quarter of the amount present previous to the operation now exists; 3 others have been too recently operated on for comment at present. What these patients seem to complain of principally after the operation is irritability of the bladder.

GENERAL CONCLUSIONS.

Castration, vasectomy and iliac ligation are of very little benefit in prostatic hypertrophy.

The choice of operative procedure is between prostatectomy and the Bottini.

In commenting on these two, the writer thinks that the former is by far the most difficult and dangerous; in fact, he believes that in the hands of a good genito-urinary surgeon in equally picked cases, the mortality in prostatectomy would be found to be twice that of the Bottini, and that in the hands of the general practitioner it would be three times as great.

There are certain cases suitable for enucleation and others only for the Bottini.

Those for enucleation are the large, so-called glandular hypertrophies, where the prostate feels like a good-sized tumor by the rectum, and the urethra is felt to be much elongated and distorted by the hypertrophy. Here the operator can find something to enucleate and the pieces come away easily. The writer has performed the Bottini operation in a few of such cases on account of the refusal of the patient to undergo an enucleation and the benefit resulting from it has been surprising to him.

The cases calling for the Bottini are more those where the hypertrophy is not marked, but where rectal examination shows a marked induration, and urethral examination shows middle lobe impingement. In many of these cases an enucleation would be impossible, while in no case of the large tumor variety would a Bottini operation fail to be of benefit.

In comparing the mortality of prostatectomy with the Bottini in the future, statistics may show it in the latter to be as great as in the former, the same as is noticed in comparing prostatectomy with castration.

One of the reasons for this will probably be because both castration and the Bottini are considered easy operations, and ones that can be performed in almost any case, whereas the prostatectomy would be reserved for especially chosen and suitable cases.

Bottini is in a measure responsible for looking so lightly at the danger of this operation, as his reports resemble those of cases touched by a fairy's wand. Willy Meyer, in one of his articles, said: "It is almost incredible that this, as it seems, splendid operation should have been practiced for twenty-two years by virtually only one gentleman—namely, the inventor of the method, Enrico Bottini of Pavia—and that, in spite of the fact, he has repeatedly drawn the attention of the profession to his work."

It seems to the writer that the surgeons reading Bottini's report would consider them too good to be true, and for this reason have not paid sufficient attention to them. There appears to be among the other Italian observers engaged in this work a tendency "to follow the leader," and to paint the reports of their cases in the same rose hue. The German and the American observers, however, go into this subject in a more thorough and scientific way. They describe their operations more clearly and do not hesitate to mention their failures and deaths. The standard of what a cure is after an operation seems to vary; some place all under this class who do not die, while others consider the same as simply improved.

It would seem from reading over these reports that the Italians must have a better tolerance for the operations than the Germans and Americans. Such is not the case, however. The writer has a surgical service in the largest Italian hospital in this country, and 25

per cent. of the cases operated on have been Italians, notwithstanding which he has observed less improvement in them than in others.

The class of cases demanding this operation comprises those in whom there is nearly a complete retention of urine and the patient has to depend almost entirely on the catheter, also those with the tenesmus and irritability of the bladder so great that catheterization and washing out of the bladder are not able to relieve it; again, when the cystitis is very marked or troublesome, and when hematuria is a frequent symptom. An increasing amount of residual urine is another urgent cause, or when catheterization is followed by hemorrhages or bad attacks of cystitis. The cases in which it is contraindicated are where the kidneys are badly diseased, medically or surgically, or where arteriosclerosis is marked and where the heart action is weakened through valvular or fatty changes.

The question of anesthesia is an important one. The writer does not think that either cocaine or eucain relaxes spasm sufficiently, and, besides this, he is sure that most patients suffer considerably when operated on under their influence. Cocain is also said to be dangerous, and eucain in one case was found to have produced syncope. Of the general anesthetics, ether is bad for old men whose kidneys are at fault, and chloroform is bad for the heart. This has led the writer to give nitrous oxid gas in a number of his cases. The patient is put under quickly and comes out almost immediately. The danger in the hands of a man who understands its administration is nil.

In Colton's Dental Bureau, in Cooper Union, N. Y., it has been given over two thousand times without an accident. The patients have at times been kept under its influence for over two hours. It can be given on a full stomach.

In the ordinary operation three cuts are usually made. The first one is always posterior, the two others are on either side in cases of lateral lobe hypertrophy. In cases where the enlargement is irregular and situated principally in the middle lobe, the second incision should be anterior and the third through the larger of the lateral lobes. The posterior incision is usually 3 cm., the anterior 2 cm. long and the lateral 2.5 cm. The time for each cut is usually eighty or ninety seconds, and the strength of the current from forty-five to fifty amperes.

Immediately after the operation the patient may be allowed to pass water, if he desires, and he should be put to bed. Patients are generally able to walk from the table to their beds, although it is safer to carry them.

The internal treatment consists in urinary antiseptics, diluents, and antispasmodics, if necessary. As a diluent, water taken in large quantities is usually sufficient. If it is found, however, that the patient will not drink much, and that the amount of urine passed is below normal, its flow should be further stimulated by a mild diuretic, and for this purpose I am in the habit of giving a mixture of acetate of potassium, sweet spirits of nitre, three times a day in a glass of water. As a urinary antiseptic, I generally give salol in ten-grain doses three times a day, or urotropin in the same strength, the latter preferably when the urine is foul and ammoniacal. Benzoate of sodium and benzoic acid in fifteen-grain doses are also of service.

The antispasmodics are codein, morphin and belladonna. These are given for frequency, pain, tenesmus or burning. They may be prescribed singly or com-

bined, and afford the patient a great deal of relief. Codein may be given alone or in combination with belladonna, and perhaps benzoate of sodium. Morphin is rarely used, and then only for pain. It is very efficacious in combination with the extract of belladonna, a quarter of a grain of each, in suppositories at night, in cases where there is considerable frequency, pain, burning, and tenesmus. The diet should be liquid for the first few days, then semisolid soft—and full diet at the end of the week, if the patient has no rise of temperature and is feeling well.

If retention of urine occurs, as it frequently does, a catheter should be passed into the bladder and allowed to remain for twenty-four to forty-eight hours. On withdrawing the catheter, if the patient is still unable to pass much urine, he should be catheterized regularly until the sloughs have been passed, when, if he is still unable to urinate, a second operation should be performed. If the patient has complete retention and nothing can be passed into his bladder, he should either be aspirated suprapubically, or a perineal section performed.

If there is much hemorrhage, it can usually be stopped by a hot irrigation, and if not, a perineal section should be performed, after which a thick-walled perineal tube can be inserted into the bladder, around which gauze can be packed, thus making pressure between the sides of the tube and the cut posterior urethra.

The bowels should be moved by salines on the second day, after which they should be kept open for some days.

An elevation of temperature usually takes place on the night after the operation or on the following day, rising from 100 to 105 F. This rise generally goes down to normal after the bowels have been moved, but I have seen cases with a temperature of from 99 to 102 for some weeks after the operation. In such a case the fever usually disappears after the sloughs have been thrown off.

Where the bladder and the kidneys are very much involved a continuous temperature may indicate a disease of the latter organs, which should then be treated accordingly. Extravasation of urine and perineal abscess may occur, but it is improbable, as the tissues are practically seared and sealed by the burning process.

ESTIMATION OF HEMOGLOBIN.*

A COMPARISON OF THE VARIOUS METHODS.

BY B. M. LINNELL, M.D.

CHICAGO.

Most of the effort heretofore to arrive at an estimation of hemoglobin in blood has been made by means of the various color tests. These tests have multiplied until the catalogue of the various instruments resembles the list of "sure cure" remedies for the hives. This fact alone shows a dissatisfaction on the part of the clinician with the results obtained by the various color methods. The two instruments with which we are most familiar in this country are Von Fleischel's hemometer (the German), and Gower's (the English instrument.) The use of these instruments has demonstrated the sources of error as enumerated.

1. In color tests in general:

a. Two eyes rarely agree in accurate estimation of varying shades of color, thus producing individual variations.

*Presented to the Section on Practice of Medicine, at the Fifteenth Annual Meeting of the American Medical Association, held in Columbus, Ohio, June 6-9, 1899.

5. Eyes of the same individual vary at different times, due to fatigue and influence of varying intensity of light.

I have made a test of 225 cases with students examining Fleischel's hemometer. The apparatus was prepared and placed where each student made the color comparison for himself without the knowledge of the other. The variations between the various readings were about 20 per cent. Considering this error might be due to the inexperience of the observers, I made the test at a meeting of medical men, most of whom were accustomed to the use of the hemoglobinometer. The readings were as follows: A, 35; B, 39; C, 50; D, 48; E, 32; F, 30; G, 35; H, 39; I, 35; J, 42; K, 35; highest reading, 50; lowest, 30; average, 38.2; largest number of agreements of reading at 35, four. Two of the readers, F and J, are frequent users of this method, and their readings differed 12 per cent. The greatest variation was 20 per cent., the same as obtained by the students. A part of the error is accounted for by the limitations of the color test and part by the inaccuracies of the instrument used (Fleischel's).

The variations of the same eyes at different times is easily demonstrated by the observer making several readings of the same specimen, covering up the indicator while doing so each time. In my own case I have found variations of 10 per cent. with different readings of the same specimen. I have oftentimes found errors of like observation in others accustomed to use the hemoglobinometer.

2. Fleischel's instrument:

a. The errors common to color tests.

b. The normal standard of hemoglobin as represented by the instrument is too high for healthy American subjects; 80 to 85 per cent. represents nearer the normal of healthy male lives between the ages of 20 and 30, as indicated by Fleischel's instrument in this country.

c. The quantity of blood used in the test is so small that the least amount of variation in quantity used causes a great amount of variation in percentage. A difference of percentage results with a bulging or depression of the blood at the ends of the capillary tubes.

d. The area over the glass wedge under observation represents a variation of 20 per cent. The middle of the field must be picked out to obtain a correct estimate.

The above considerations have to deal entirely with the sources of error. The objections to the use of the instrument are the cost of the instrument and the necessity of using artificial light in the comparison.

3. Gower's instrument:

a. Errors common to color tests.

b. The colors of the standard tube and the hemoglobin solution are not always the same, and sometimes can not be brought to be the same. The hemoglobin often has a grayish-pink color, while the standard solution is more of an amber-pink to my eye. This makes great difficulty in comparing the shades. It makes it impossible in some cases to make an estimation of the hemoglobin.

c. In adding water to dilute the hemoglobin, one is apt to overdilute the solution, thus making it necessary to repeat the test.

d. One cannot make a number of estimates of the same specimen and strike an average.

It has the advantage of the use of a large quantity of blood, thus diminishing this source of error. The surface for comparison is larger and more uniform. The tests can be made by either natural or artificial light. It is a much cheaper instrument.

A rough method of estimation, which is a good one, is by comparing the patient's blood on a towel, hand-

kerchief or white filter or blotting paper. This has the disadvantage of the general color test, and no table of comparison, but is easily and quickly made, and will be explained more in detail later on.

There is evidently a need for a more mechanic method of determining the percentage of hemoglobin. This seems to have been found in Hammerschlag's method, which consists in placing a drop of blood in a solution of benzol and chloroform. Add one or the other of the solutions to the mixture, as the drop floats or sinks, until it remains stationary in the center of the solution; then the specific gravity of the mixture will be that of the blood. This is a modification of the method of Roy, who used a number of bottles of salt and water graded from 1025 to 1075. Lloyd Jones elaborated this method, using glycerin and water, and had a case made containing twenty bottles of solutions of different specific gravity, which he called a hemobarometer. Owing to its simplicity, Hammerschlag's method has come into more general use. This is the method used in my experiments. The normal specific gravity, as determined by Hammerschlag, is 1060.5 in healthy males of adult life. As shown by the tables in 28 observations made on 8 different persons, the average is 1060.3, the maximum observation being 1065, and the minimum 1056. The specific gravity in females is lower. In the 3 cases tabulated the maximum specific gravity is 1059.5; minimum, 1055; and average, 1057.5. The ages are all between 21 and 55, only one above 33.

In order to ascertain the amount of variation which takes place during a day under ordinary conditions, I made 17 tests on a male subject 21 years of age and in good health, during sixteen hours. The tests began at 8:30, after a breakfast, one hour previous, consisting of 1 cup of coffee, 2 slices of bread, 1 dish of rhubarb. As seen by the table, the highest sp. gr. was 1065, taken at 8:30 a. m. The next specimen, taken at 10 a. m., was 1061. I have reason to believe the first test was wrong, as it did not reach such a high mark at any other time during the day. The most of the estimates were about 1061. Dinner, with 1 glass of water, 1 cup of coffee, and 6 oz. of water one hour later as fluids, was followed by no marked fall of sp. gr. The lowest point was reached at 5:30 p. m., and was 1058. After this test the subject took a half hour's spin on a bicycle, in the open air, coming back in a mild perspiration. The hemoglobin was found to be 1063. This was the greatest change during the day, a rise of 5 points. At 9:30 p. m. observations were resumed; sp. gr. 1061. The subject drank 18 oz. of water after test, which was followed by a fall of 1 point, to 1060, but returned to 1061 in two hours. The general average of the readings for the day was 1060.8. The blood count at 3:10 p. m. was 5,600,000; hemoglobin, Gower's, 96 per cent. The variations under normal circumstances are very slight, only 2 to 4 points. These observations were made at different points about town after riding, walking, sitting quietly, eating and drinking.

I now present a table showing a comparison of the sp. gr. with tests for hemoglobin and the counts of red blood-corpuscles, both in health and disease. It will be noted that the sp. gr. varies more with the variations in percentage of hemoglobin than with the corpuscle counts. In Case No. 2 is this especially true, the reduction due to secondary anemia, a case of pulmonary tuberculosis. The examinations were made at the same sitting, but the blood was taken from different locations on the body, namely, lobe of ear, great toe and finger. The sp. gr. varied 7 points, but so did the other esti-

mated in about like proportion. The variations were probably due to the fact that the blood did not flow so freely from the toe and ear as from the finger.

In Case No. 1, a normal, healthy subject, the difference is not so marked, only 1.5 points. The hemoglobin percentages did not vary so much, while the counts vary about the same as in Case No. 2.

In Case No. 3 the sp. gr. was 1044.5, while the five hemoglobin readings varied from 37 to 47, all made by different persons and with the same specimen, except one reading by Gower's method, which was 40 per cent., the average of all being 40.7, corresponding closely to Hammerschlag's table.

In Case No. 4, one of chlorosis in which the count was not recorded, the sp. gr. was 1046, and the average hemoglobin percentage 49.7 per cent. (Fleischel's), which again corresponded closely to the table. In Case No. 2 the average of the sp. gr. tests was 1051.3, the hemoglobin, 70.8, and count 4,300,000 reds, the sp. gr. being a little lower than the corresponding hemoglobin percentage in the table.

In taking the sp. gr. I found that a great saving of time was accomplished by having the necessary apparatus collected and kept together in the following described case, and in bedside examinations some such arrangements is quite necessary to secure the best results.

The apparatus consists of an ordinary urinometer and flask, 3 bottles with cork stoppers, one each containing chloroform, benzol, and a mixture of the two, 2 simple pipettes, a stirring rod, a few sheets of round filter paper, a pipette graduated to 20 cm., with rubber tubing and mouth-piece, a glass slide and cover-glasses, one-half-dozen pen-nibs, all arranged in a case with compartments for each article.

In making the test the following points are suggested for obtaining the more rapid and accurate results:

1. All of the apparatus must be perfectly clean and dry, especially the urinometer glass. The drop of blood will cling to the particles of blood or lint left in the glass and often flatten itself against the sides.

2. Before obtaining the drop of blood from the patient the benzol and chloroform mixture should be poured into the urinometer glass and brought to a little above that of the blood as estimated. A rough estimate may be made in two ways: 1. Compare a drop of the patient's blood with that of one of a known sp. gr., namely your own. If the colors differ widely, dilute a drop of your own blood by means of the graduated pipette, using ordinary clean water as a diluent, to about 50 per cent. The mixture can be made on the glass slide which accompanies the case. Compare this with the patient's blood. The sp. gr. of blood with 50 per cent. hemoglobin was about 1045.5. If the patient's blood is lighter than the central specimen diluted to 50 per cent., then the sp. gr. of the chloroform-benzol mixture should be started below 1045.5. If darker, the mixture should be higher. This method is recommended only when the blood seems to be greatly reduced in hemoglobin, and it presupposes knowledge of the per cent. of hemoglobin of the examiner's blood. This method forms a good test for a rough color estimate. By practice one becomes expert in the estimation.

3. The finger is usually selected by us as the most reliable place to obtain sufficient blood with one puncture. The side of the finger is preferred, as the subsequent discomfort is not so great.

4. The best and cheapest instrument for producing puncture is a sharp pen-nib with one point removed. A

new one can be used with each patient, and thus the danger of infection is minimized. The same precautions in regard to not squeezing the blood out must be observed in this method as in all.

5. The mixture should be slightly above the sp. gr. of the blood, if possible, because in adding chloroform it is much easier and quicker to mix the two. As the heavier chloroform passes down through the mixture, it is partially mixed and is easily completed by slightly stirring with the glass rod. The lighter benzol, on being added, drop by drop, remains on the top, and either the urinometer glass has to be placed against the hand and carefully tipped upside-down, which is the better method when needed, or the contents must be agitated greatly with the glass rod in order to procure a uniform mixture.

6. In making estimations, I have found that the percentage of error is greatly reduced by using drops of about 10 cm. I draw about 15 cm. of blood up into the tube and then blow out 2 or 3 cm., wiping it away, then put 10 cm. into the mixture, leaving 2 or 3 cm. in the tube. The first and last portions of the blood are apt to contain either air or the water used in cleansing the pipette. Smaller drops of blood, however, do not vary the results materially if accuracy of technic is observed.

7. In mixing the benzol and chloroform it is much quicker and easier to use pipettes, pouring the solutions in drop by drop. In pouring out of a bottle it is very easy to pour too much and have to go over the process with the other solution. Then, the pipettes are more easily handled. In my laboratory I use bottles with ground-glass caps, with pipettes cut in lengths to suit and kept in the bottle.

8. The best kind of urinometer is one graded from 1025 to 1075. The spaces are wider, hence greater accuracy of reading is obtained. An ordinary urinometer, which is accurate up to 1060, will do, as pathologic conditions are such that readings with a higher sp. gr. are of no special clinic significance. The urinometers should be tested carefully to 1060. Most of them I have found erroneous in the higher numbers of the scale. The urinometer glass should stand firm and have a smooth rim to prevent the leaking of the solution when turned up against the hand.

9. In place of the graduated pipette a "white corpuscle counting" pipette from the haemocytometer may be used, or an ordinary glass tubing drawn out into a pipette. The case is so arranged that the corpuscle counter may also be carried to the bedside and a specimen taken for examination. The contents are prevented from escaping by a rubber band placed about the ends of the pipette. The case is made as small as possible, compatible with convenience and accuracy in its use. It may be obtained from Sharp & Smith, instrument makers, Chicago.

We need a system of estimating hemoglobin which will eliminate the necessary inaccuracies of color comparison.

The tests seem to show that the sp. gr. varies with the percentage of hemoglobin. Variations under normal conditions in blood are not great enough to interfere with the value of the sp. gr. test. Hammerschlag's is mechanically accurate and eliminates the necessary errors of color comparisons. The errors made in taking the blood are common to both methods.

DISCUSSION.

Dr. JEDSON DALAND, Philadelphia So far as the color

tests are concerned, I believe the reader of the paper is correct when he states that all are objectionable. A certain percentage of error in the use of von Fleischel's instrument can be reduced. I have come to the conclusion that very frequently, in making our comparison by looking through the entire field of the cylinder of distilled water and diluted blood, the attempt to cover this broad surface in one view causes a certain percentage of error. About a year ago, at a meeting of the Philadelphia Pathological Society, I suggested that a cap be placed on the cylinder, containing a slit measuring one-eighth inch in width, made of any material, which would limit the field of observation, and thus reduce some of the errors of the instrument. Another error to be overcome is the distance at which the eye is held from the instrument; a distance of eight or nine inches is the best. A number of other interesting sources of error regarding von Fleischel's instrument might be mentioned, but time will not permit. I agree with the reader of the paper that we do not usually get 100 per cent. of hemoglobin; the percentage is usually lower.

It is also well to remember that if two pipettes or more be used, the reading will be more accurate in cases where the percentage of red blood-corpuscles is less than 50. Gower's instrument is seldom employed; it is subject to a wide range of error. Occasionally the colored tube of gelatin is decolorized in the course of time.

As regards the method described, I have had no personal knowledge as to its use. The percentage of blood pigment as determined by various methods differs greatly. From a long series of observations extending over a considerable period of time, it is necessary to determine which method is the best. The translation of the hemoglobin percentage is subject to considerable variations taking place in the plasma, but this percentage is not very great; it is exceedingly limited. Although it is true that the specific gravity of the blood is chiefly due to its contained hemoglobin, the plasma also contains substances that vary in disease. It is therefore manifest that the specific gravity of the blood should not be considered as the exact equivalent of the amount of blood pigment present.

Dr. GEORGE DOCK, Ann Arbor, Mich.—I would like to corroborate everything the reader has stated regarding the advantages of the specific gravity method. It is easy to carry out. It must be borne in mind, however, that the specific gravity does not always correspond to the amount of hemoglobin present. A large amount of comparative observations with the specific gravity test and von Fleischel's hemometer have shown that hemoglobin chiefly affects the specific gravity, and there are few cases in which the readings do not correspond. Gower's method is much more faulty than von Fleischel's. In using the specific gravity method great care is necessary. If the estimation is difficult to make, a fresh drop should be used as a control, for in a trial which takes some time the density of the drop becomes altered by various causes. I have long taught that if one is limited to one method of estimating hemoglobin, Hammerschlag's specific gravity method should be chosen rather than Gower's instrument. The cap devised by Dr. Daland has for some years been a part of Meischer's modification of von Fleischel's instrument, a modification which also does away with several of the other sources of error in the old apparatus. The instrument is expensive, but we can hardly give up the estimation of the coloring matter of the blood, and for that purpose it should be preferred to the old apparatus or to that of Gower. The practitioner can, however, get along very well by the aid of Hammerschlag's method, carefully carried out.

Dr. HORACE B. ARNOLD, Boston—I made quite a number of experiments this spring on the effect of chlorosis on the heart, using the color and specific gravity methods in these cases. The results obtained are important, especially in the case of chlorosis, where the hemoglobin has a low percentage; this might have been due to the heart changes or to error in the color tests. In this case there was particular satisfaction in using the specific gravity method. The comparison made between the color test and the specific gravity method by my assistants showed that they ran close. In considering the cases of chlorosis it is important to take count of the blood-corpuscles, because in some cases we find an improvement in the condition with an increase in the amount of hemoglobin, and an increase in the number of red blood-corpuscles out of proportion to the increase in the percentage of hemoglobin. So in this case apparently there is a diminution in the percentage of hemoglobin.

ANGINA PECTORIS.*

BY JAMES DUDLEY MORGAN, M.D.

ATTENDING PHYSICIAN AT GARFIELD AND GEORGETOWN HOSPITALS, ETC. WASHINGTON, D. C.

Pain is so seldom directly associated with serious diseases of the heart that most specialists and practitioners of medicine are wont to treat lightly a patient's anxious inquiry about the heart, and to dismiss the case with no particular guidance or injunction, as one having an imaginary or neurasthenic origin.

Though it has been considerably over one hundred years—1768—since Herbenden gave the name of angina pectoris to a certain affection of the heart, which he declared must be distinguished from ordinary cardiac dyspnea, and a few years later Edward Jenner described some of the morbid conditions, which may be found in this disease, yet there is to-day no one certain and positively accepted statement of the cause of this sudden taking off of a human being, who may have previously complained but little, or not at all, of feeling badly.

Since Herbenden's time nearly all medical writers and clinicians have had something to say of the etiology of angina pectoris. Desportes located the disturbance in the vagus; Laennec in the sympathetic; Jolly in the intercostal nerves; Brouillard in the phrenic nerve; Kirsch in the spinal cord; Piorry and Cahn placed it in the brachial plexus; Romberg, Peter and Lancaux in the cardiac plexus; Leyden, Potain and Charcot express opinions not in harmony with each other; v. Basch declares it to be sclerosis of the coronary arteries; Osler says that the disease is associated more particularly with sclerosis of the root of the aorta and changes in the coronary arteries and in the myocardium. Constantin Paul, of Lariboisiere Hospital, acknowledges the frequency of atheroma in patients who have died of angina pectoris, but when he considers the large numbers of patients at Bicêtre and la Salpêtrière, who suffer from atheroma and are free from angina, he can not convince himself that the two diseases bear an undeniable casual relation to one another.

Kinnear believes the disturbance is due to hyperemia of the spinal sensory centers. Anders in his late "Practice" concerning the nature of angina, says: "We possess few if any positive data; and conclusive post-mortem evidence in support of the various theories that have been and are advocated is, as yet, wanting."

Theodor Schott of Bad Nauheim, Germany, in a very recent article on the treatment of cardiac neuroses, speaks of: 1, angina pectoris nervosa; 2, angina pectoris vasomotoria, and this complaint he attributes to spasmodic contraction of the vessels, and mentions that besides the disturbances of a nervous character, there exist also other abnormal changes in the heart; 3, a form of angina pectoris he calls vera, and states it is more frequent than the nervosa or the vasomotoria, a statement with which the writer does not believe most practitioners will agree. Musser says angina pectoris in its typical form and in association with diseases of the heart is not of common occurrence. Schott goes on to speak of the difference of the pulse in true angina pectoris, which was not appreciable to the finger and only to be found in sphygmographic tracings and which often indicated arrhythmia, tachycardia and bradycardia. He believes that the most frequent causes of this complaint are arteriosclerosis, chiefly of the coronary vessels, insufficiency and stenosis of the aortic valve, myocarditis, etc.,

*Read before the Medical and Surgical Society of Washington, D. C., April 6, 1896.

but he must confess that as yet the opinions of medical men concerning the nature of angina pectoris vera do not quite agree, but in general we are nowadays led to suppose that this disease is apt to affect the heart, when the latter has been enfeebled before.

These various affirmations and negations of conditions, which are necessarily found or are wanting in this much-discussed disease, are not brought forth to further mystify opinions, but with the desire that we may recall how little we know of angina pectoris and that a free discussion may engender more positive knowledge.

It could hardly be expected that this paper, in the time which is allotted, can take into consideration the numerous pseudo-anginas of the heart, for their causes are legion and spread over and ramify the body from migraine to podagra. It is freely admitted that cases of pseudo and true angina are sometimes associated, and that pseudo-angina may aggravate and precipitate an impending attack of true angina. The onset of this terrible disease is so sudden and startling, the suffering so great and agonizing, the termination so rapid and fearful, that consternation and fear seize both patient and friends. Balfour described the sensation of angina "as if a mailed hand grasped the chest in the cardiac region and squirted through its fingers flashes of excruciating agony."

A male, aged 42, who had previously shown no cardiac disturbance and was otherwise healthy and attending regularly to business, was seized on preparing to take his usual morning bath, with the most horrible constriction and agonizing pain in the chest. Within a half hour, after suffering untold torture with the agonies of pent-up life and suffocation, he died. At the autopsy, the left ventricle was dilated and the myocardium showed increased growth of connective tissue at the expense of the muscular tissue. The coronary arteries were in no sense occluded and the aorta was not sclerotic.

Another patient was a middle-aged married woman who had informed me that six years before, on a trip to Europe, she had been taken suddenly with the most fearful and terrifying pains over the region of the heart, associated with a sense of great suffocation, the heart feeling as if clamped within a vise; that Dr. Austin Flint, Sr., was aboard the steamer and attended her, and after some ten to fifteen minutes she was able to breathe more freely and was rid of the pain, but felt most profoundly shocked and depressed for the following twenty-four hours. He told her she had angina pectoris and must be careful in the future about her mode of living. She had no perceptible organic lesion. Being hastily summoned one day to her residence, which was some ten minutes' walk, I found she had suddenly been seized with a dagger-like pain in the heart and, exclaiming, "O, my heart," died within a few minutes. Autopsy revealed no morbid condition of the heart nor its vessels.

The writer has had what he considers a few cases of true angina pectoris, in which happily the fatal termination was at least postponed, and will present the notes of one or two, which seem most characteristic.

During the early hours of the morning, being hastily summoned to see a gentleman, aged 57, who was declared to be dying, I found the patient sitting upright in bed, with his hands over his heart, and laboring for breath. His hands and feet were cold, face blanched, pulse small and inclined to irregularity. He had a most distressing appearance, and I expected him to collapse at any moment. I gave him ether internally and nitrite of amyl

to inhale, and applied heat over his heart and to his extremities; later on dry cups were applied over the chest. This patient recovered after a severe struggle, and within less than half an hour pain had ceased and breathing was more quiet; but it was three days before he could resume his journey to Boston. I was informed that the patient had a similar, but much lighter, attack, some eighteen months before. His heart showed no organic murmurs, but the rhythm was feeble. There was no perceptible arteriosclerosis. Examination of urine was negative.

Another patient, living to-day, whom the author attended some ten years ago for frequent attacks of angina pectoris, has some interesting points connected with his case. He was a man about 40 years of age, of no bad habits nor history, inclined somewhat to corpulency, but had no digestive disturbances, nor was he in any way a neurasthenic. For a man of his size and strength, he had what you might call a feeble and somewhat compressible pulse. The heart showed no intrinsic nor extrinsic disturbance. The urine was repeatedly examined with negative results. The gentleman has had some eight or ten characteristic attacks of angina pectoris, extending over several years, and but for speedy help and remedies, which he has been taught to keep on hand, he would have, it appeared, died in one of these attacks. The treatment consisted in a complete change in his mode of living. He was made to work less, and take moderate exercise; was forbidden alcohol in any shape, and less nitrogenous food was eaten; he was to lie down after bathing; take a midday siesta, and lead a life which would in every way relieve the demands on the heart. Massage was used and the precordial region was kept slightly irritated for months, and hot foot-baths were given at night. His slight indulgence in both coffee and tobacco was stopped, and he was ordered ether, iodid of potassium and trinitrin, which he took on different occasions, extending over a period of nearly a year. On retiring at night he was ordered to give himself a hot saline enema, which had a most salutary and beneficial effect on the various enunciations, besides giving tone, without tension, to a somewhat enfeebled arterial circulation. His bedroom was changed from the first to the third floor. His trips away were to the mountains instead of to the lowlands and seashore. This patient has not had an attack for eighteen months, and his wife and self are congratulating themselves that there will be no recurrence. He may yet die suddenly of this affection, for we are too often deceived, when we relax our vigilance and persuade ourselves that recovery is in sight.

William Pepper, who suffered for some seven years from premonitions of angina pectoris, was joyous and hopeful that compensation was taking place and remarked to his physician but a few days before his death that "the battle had been won." "At seven in the evening," his physician writes, "I left him gazing upon Mount Diablo, shadowed in the gathering darkness. I was called at 8. I found him in the attitude and with the expression of *angor animi*, from which he never aroused. At the time of his death he was recovering the lost cardiac compensation and appeared on the clear road to recovery."

Any affection of the heart or systemic system, which may disturb the regular and proper supply of blood to the coronary arteries, may precipitate an attack of angina pectoris. The danger lies in the myocardium not receiving sufficient blood for its nutrition and so cause the generation and accumulation of toxins,

which poison and depress the heart, and allow of an abnormal distension of its cavities. This distension of the heart and interference with its nutrition accounts for the great pain and distress in the precordial region. Smirnow, in speaking of the dilation and distension with blood, which the heart undergoes in the paroxysm of angina, attributes the torturing precordial pain to the stretching of the net-work of afferent nerve-fibrils, which are immediately beneath the endocardium.

The quality of the blood supplied to the nutrition of the heart is the cause of many true anginas of the heart. The effects of blood changes on the heart have been investigated by several authors. Ringer found that without the presence of a lime salt in the circulating fluid, contractility of the isolated frog's ventricle cannot be supported. He also found that the production of acid, particularly that which is formed in the course of, and as the result of, muscular contraction, is also inimical to cardiac contraction. A toxin within the blood depresses the heart, increases the length of the systole and finally causes a standstill in diastole. The accumulation in the heart's substance of a toxic material seems to act on the cardiac ganglia in such a way as to destroy the heart's excitability. Any slight obstruction of the supply of blood to any part of the myocardium leads quickly to the generation of a toxin. Cohnheim says the closure of one or both coronary arteries is not necessary, any one branch of a certain size, no matter which, is sufficient to produce a limited arterial ischemia, which in such deadly manner paralyzes irrestorably the whole cardiac musculature. The effect of this deficient nutrition is the product of a heart poison, a product of metabolism, which is in a normal state carried off in the course of the blood-current, but which accumulates under defective nutrition in the substance of the heart.

What makes the action of the heart regular? It is the change of nutrition, by which, through the blood circulating in its substance, the waste of its tissue is constantly supplied, the integrity of the fibers preserved and kept consequently in a condition to contract. If the supply of blood is cut off from the substance of the heart, the organ soon loses its irritability and power of contraction. Cohnheim and Schulthess-Rechberg, in experiments on dogs, observed that ligation of any large branch of either right or left coronary "has at first no effect whatever upon the rhythm or vigor of the cardiac contraction, nor consequently upon the blood pressure, but after the lapse of ninety seconds on an average, the heart beats begin to be somewhat irregular and infrequent, yet still without affecting the blood pressure, till suddenly and at the same instant both chambers stop in diastole. From this standstill, which occurs on an average not later than two minutes, there are no means of arousing the ventricles to new life and renewed contraction. It seems as if a deadly poison had forever destroyed the heart's excitability. Accordingly it is in all probability the system of ganglia which is affected in this fashion."

It would seem from all the facts at hand, clinic, pathologic and physiologic, that whereas sclerosis of the coronary arteries or aorta, or dilation of the heart, etc., is found in a large number of cases of angina pectoris, yet attacks of true angina may occur in patients who are entirely free from organic disease of the heart, and, vice versa, we may find most extreme calcareous conditions of the coronary arteries to exist, as in a pathologic specimen I have, from the patient living to some 60 years of age, with no obtainable history of cardiac distress, and dying of a complaint entirely foreign to angina pectoris. Frey maintains that stoppage of the heart in

angina is not a necessary result of closure of a large branch of the coronary arteries, but may be brought about by numerous other interferences with the heart.

In our treatment we must ever keep in view the picture of the heart whose muscular structure is improperly nourished, whose ventricles are suddenly distended, and whose nerve and muscular fibers are stretched, and I might say stunned, by the rapid engorgement of a circulating fluid, which from the apparent embarrassment in respiration, becomes poorly oxygenated. Relieve the tension of the vascular system by inhalation of nitrite of amyl, and if pain persists, give a few whiffs of ether, which, as there is danger of heart failure, is to be preferred to chloroform on account of its stimulating effects. Morphia should not be continuously used because of its resulting depression, and if given should always be combined with atropia, which is an excellent analeptic. Camphor, also, is one of the best of the cardiac stimulants. Irritation, in the way of sinapisms, etc., to the precordia, eases the distress. The ice-bag or very hot applications have the same effect. The kidneys, skin and respiratory functions should be kept active. In the interval nitroglycerin or nitrite of sodium and iodid of potassium should be used, and the doses should be pushed to tolerance. Good results are obtained from the baths as recommended by the Oertel's method or as carried out by Dr. Schott of Nauheim. A saline bath at the temperature of 92 and reduced 5 or 6 degrees in the course of the treatment has many of the good effects of the Nauheim bath. It is well in ordering the bath to see that your patient is gently massaged, and while in the bath, which should last not longer than ten to fifteen minutes, that slight restraint be given to the flexion and extension of the limbs and body, which the patient is directed to follow. These movements draw blood to the parts and lessen the arterial tension in the system, and with the stimulating effects of the bath have a most beneficial and somewhat lasting good effect on the heart and circulation, the blood pressure being lowered, the diastolic rest of the heart lengthened, and the force of the systole increased. The result is, the ventricles are fully emptied, the peripheral resistance lessened, the whole circulation becomes freer and more active and changes in metabolism promoted, and a general well-being of the patient is noticed. With the results of the use of electricity some claim good results, but it may be said that electricity seems to be more of an adjuvant than a curative agent. To obtain any measure of success in our treatment all excesses of every kind must be corrected and the general functions of the body made to act properly.

919 McPherson Square.

TUBERCULAR PELVIC PERITONITIS.

BY CHARLES C. ALLISON, M.D.

Professor of Clinical Surgery, Omaha Medical College; Surgeon-in-Chief to the Presbyterian Hospital, etc.

OMAHA, NEB.

It seems to be generally held that the lymphatic system affords the main avenue for tubercular invasion. Thus in children, whose exposed facial integument, with repeated abrasions, invites a tubercular cervical adenolymphangitis, (1) in the adult the nasopharyngeal space, directly exposed to multiple bacterial irritations, favors this predisposition an entrance into the lymph-channels and, with suitable soil, general dissemination through the larger ducts to the bronchial and mediasti-

nal glands. Through the same system a tubercular invasion may develop from the genital lymphatics, with easy access to the histologically allied tissue—the serous peritoneum. These neighboring glands in the process of caseation may directly infect the peritoneum, or a hematogenic deposit in this region of recurrent congestions may follow as a secondary expression of a distant tuberculosis. From the intestinal canal also an ulceration may allow the tubercle bacilli to reach the peritoneum, and thus start the destructive process on this organ.

Reasons are manifest, therefore, for the exposure of the general peritoneum to this disease, while there seems to be a strong analogy between the elective area in children—the cervical and bronchial lymphatics—where the surface of the body offers least resistance, and in the invasion of the pelvic peritoneum, occurring as it usually does in females between the ages of 20 and 40 years, during which time there is most exposure to the lymphatic system in the pelvic region.

That tubal tuberculosis is elective seems well established by an analysis of 1200 autopsies by Wothen, (2) in which 20 per cent. showed tubal deposits, involving in every case the peritoneum and in the majority of cases the tubal mucosa. This relatively large proportion of tubal disease includes primary deposits only, without general peritoneal or other tubercular expressions.

Studying this disease, therefore, as a pelvic manifestation, we find its occurrence bearing a direct relation to the circulatory changes and the lymphatic engorgements which occur with greatest frequency during the functional activity of the genital system. In either case the tubercle bacilli may primarily enter the lymphatic space, or they may gain entrance through a soil previously exposed by protracted multiple bacterial infection. The types of this disease are usually well-defined, and may be said to occur in three forms.

The acute miliary form generally involves the entire peritoneum and presents a well-marked train of an acute systemic disease, with early ascitic accumulations, attended by fever, emaciation, and as a rule the general expression of a well-defined tubercular disease. The chronic caseous type of inflammation is attended by a local collection of purulent material with extensive adhesions, tissue degeneration, involving the intestinal tract. The chronic fibrous type is a more subacute form, or it may be a late stage of the types mentioned, and is attended by a dense fibroplastic exudate, a small amount of blood-stained fluid in the cavity, and as a clinic evidence, nodular masses may be felt in the pelvis, and as pointed out by Kelly, these enlargements are apt to change their relations with the pelvic organs from time to time.

The prognosis of this disease is good, although some diversity of opinion is entertained by different writers on its ultimate termination. So able and experienced a man as Munde recently said that he had not yet seen, in his own experience, one case go on to complete recovery; yet, he added, other practitioners report successful terminations, and he expects to be able to score greater success in the future.

That this disease subsides without treatment is admitted. The process of involution leaves but slight thickening in the shape of fibroplastic or pigmentary changes as traces of what was once well-defined tubercular disease.

Symptoms.—Pelvic pain is regarded as a very constant expression of this disease, although the symptomatology takes a very wide range, and a marked development of this trouble may remain for a long time unrecognized. The increased thickness of the pelvic peritoneum, due to the tubercular inflammatory process, may be looked on as the cause of frequent and painful micturition, which is a fairly constant symptom.

Should this type become chronic and assume the fibrous form, partial fixation of the uterus, with irregular pelvic indurations, will be noted. The local tenderness and the low septic range of temperature will be of value in directing attention to the nature of the trouble, while a curettage may lead to very conclusive evidence, if the bacilli are found in the debris. Local ascitic accumulations in the pelvis, in this disease, may increase in size until there is marked abdominal enlargement, yet the general peritoneum remain uninvolved. In two cases we have met this condition, and in one tubercular masses in the pelvic omentum gave the first opportunity for certain diagnosis.

Treatment.—The outcome of these cases has grown to be recognized as more successful, since 1862, when Sir Spencer Wells recorded a recovery after celiotomy. The unmistakable spontaneous recoveries that are met are also an evidence of the favorable response which may be expected under intelligent treatment, and while medicinal and hygienic treatment must be accorded a very useful place in the therapeutic measures employed in the management of this disease, yet exploration of the abdominal cavity has led to convalescence in so large a number of cases, and at the hands of so many observers, that surgical treatment must be looked on as promising.

In the employment of surgical measures, our care must be directed not only toward the removal of extensively diseased organs, but to the release of adhesions, when these adhesions threaten the welfare of the patient, and this is more particularly true in the caseous type, which may usually be regarded as the most serious form of trouble; yet it is true that in the recent miliary invasion, or in a fibroplastic involvement the simple abdominal exploration, with salient irrigation, without drainage, is the appropriate and conservative measure which promises the largest number of recoveries.

The reason for such convalescence may be accounted for by the relief of pressure, the removal of ptomaines, and gain in nutrition, with the inhibitory effect on the tubercle bacilli of the phagocytic process thus established. And although Gregg Smith records as his most unexpected recovery a case of operative infection, yet we should take all surgical precautions against the introduction of sepsis.

Representative of the fibrous type of this disease is the case of a multipara, 52 years old, who for several weeks complained of severe pain in the right lower quadrant of the abdomen, in whom a bimanual examination revealed a firm mass fixing the right tube; the temperature ranged between 99 and 101 degrees, micturition was frequent and painful, and marked tympany and constipation were present. Abdominal exploration revealed a dense mass involving the cecum, some coils of the ileum, the right tube and ovary. The peritoneum was much thickened and removal of this extensive pelvic involvement was clearly inadvisable. The abdomen was closed without drainage, and at one and a half years after the operation the patient's condition remains good.

A caseous form of tubercular inflammation with very large cystic accumulation was met in a patient 35 years old, multipara, whose trouble was fairly acute, the

symptoms having been in evidence but a few weeks. Pronounced pain, fixation of the pelvic organs, dysuria, constipation, and notable emaciation were the leading symptoms.

Exploration revealed a large tubercular cyst springing from the left tube, with nodules scattered over the pelvic peritoneum and involving the omentum. Removing this cyst and the affected part of the omentum, with irrigation and drainage, was followed by a convalescence in which, one year later, was found a postuterine tenesmus; vaginal tampons of guaiacol and oil led to a disappearance of the enlargement, and to a symptomatic recovery.

A third case was met in a nullipara, aged 31, whose disease had been present for several months, and in whom the symptom of pain was not leading, but disturbed digestion, loss of weight, partial fixation of the pelvic organs and marked rectal tenesmus were prominent symptoms. A large tubercular cyst was found on exploration, springing from the left side of the pelvis, and surrounding the base of which broken-down glands and purulent material were found. The cyst was removed, the pelvic deposits evacuated, with free irrigation and drainage, followed by convalescence, in which case an unfavorable termination was expected, and this points to similar experiences at the hands of others, which go to prove that a tubercular peritoneum loses, in a large measure, its susceptibility to other forms of bacterial inflammation.

DISEASES IN SCHOOLS*.

SPREAD AND PREVENTION.
BY LAMBERT OTT, M.D.
PHILADELPHIA.

By reason of my two years' intimate association with a school section of Philadelphia, having thirteen schools and 6031 children—5224 being in primary grades, ranging from 6 to 10 years of age, and the remainder in grammar grades—I have been able to make some valuable observations.

A trite remark of mothers, often heard by the family practitioner is: "My children were free from disease until they began attending school," and I can bear testimony to the truth of this saying, not alone from an experience in my own household, but also from the multitude of evidence gained otherwise.

One thing is evident; that there is an increase of contagious diseases during the continuance of the school period. The condemnation of Froebel's kindergarten schools is based on the necessary aggregation of little children in those tender years, when the susceptibility to contagious diseases is at its height. It is claimed that home teaching, and its consequent isolation, enhances the child's chances of attaining maturity while it lessens the possibility of other children obtaining disease. I have often watched little children in school-rooms, in and out of session, especially when seated at double desks, and have been impressed with their frequent and close personal contact, such as placing their faces together, blowing in each other's faces in a banter and, when scrutinizing a fellow pupil's work, bringing the inspiratory current in a direct cross line of the other's expiration. It often amazes me how careless physicians are in permitting children of an infected house to attend school, catering to the whims of parents,

who from stupidity or vicious indifference would rather see others contaminated than have their own children lose time by enforced absence.

The disease usually spread in schools, naming in the order of their frequency, are: diphtheria, scarlet fever, measles, whooping-cough, varicella and variola, or varioloid. There are three sources of danger: 1, being in school during the inception and development of the disease; 2, returning to school too early in the convalescence, or permitting children of an infected household to attend school; 3, in daily attendance in school during a light and overlooked attack of contagious disease.

When any of the contagious diseases occurred among children of my patrons I found in many instances that a child in the next seat had previously been absent on account of sickness, and often had the same disease as the child I was attending. In some cases I was unable to find the source of personal infection in that special classroom, but in contiguous classrooms on the same floor children had been absent with the same disease, and had but recently returned to school; from this I concluded that the mode of contamination was during recess. I have asked other physicians to investigate similarly, and they have had a like experience. One practitioner, of very large experience, stated that he believed seven-eighths of the contagious diseases in children were contracted in school.

I believe the most damage is done by children being in school during the inception and development of contagious diseases, and by a too early return during convalescence. When we consider the insidiousness of the period of incubation in children's diseases, and how often in their early stages the ambitious child will conceal its ills, knowing that absence lessens its chances of promotion, we readily understand why children are frequently found in filled classrooms with the diphtheria patch well developed in the throat, the scarlet-fever case either with a mild rash or an increasing fever prelude to its appearance, or the child who will ultimately develop whooping-cough remaining in school, with that apparently innocent preliminary cough to spread its contagion. One can scarcely believe that fully-developed contagious disease could remain among forty or fifty children any length of time without being discovered, but this I have repeatedly seen. In several instances I have noticed children with their necks tied up, and on examination found them suffering with a light form of tonsillar diphtheria, or, if not with diphtheria, always sufficiently pronounced to alarm me. I have also found in several mild cases of scarlet fever in the classroom, and have frequently found children coughing suddenly in starts, and soon after detained at home with well-developed whooping-cough.

The commoner means of contamination are: by personal contact, inspiring exhalations, kissing; by the common use of a drinking cup; by exchanging working material, such as pencils, cleansing rags, or by passing around from mouth to mouth a whistle or a mouth-organ. The habit of children kissing one another, carrying the end of a lead or slate pencil to the mouth, lending it to a neighbor who also carries it to his mouth, prior to using it, is common.

A grave question arises, viz.:—When should we permit children to return to school during the convalescence of contagious diseases? My practice has been to recommend the return after the following lapse of time.

1. Diphtheria, four weeks from its inception and one week in the open air.

*Presented to the Section on Practice of Medicine, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

2. Scarlet fever, four weeks from its inception and one week in the open air.

3. Measles, two weeks from its inception and one week in the open air.

4. Whooping-cough, not until every vestige of the cough has disappeared.

5. Smallpox, two months from its inception and one month in the open air. Some physicians have considered this time as too long, and have also undervalued the one week of out-door life. My answer to them has been, "Where is there a better ventilator of body and clothing than a romping out-door life for a convalescent child?"

We have not only the improved germ tone, but a removal of the contagious element—germ which it undoubtedly is—and a consequent lessened possibility of imparting the contagion to the healthy children with whom they at once come in contact. I hold that these restrictions should be regulated and enforced by special enactment, for when left to the too-eager mother to get her child soon into school again, or the easy-going physician, who too often caters to the whims of his patrons, they will fail of their purpose unless supported in the form of a law.

The question may be asked, "Why should all diphtheria cases be detained from school five weeks?" If we should determine the time by the bacteriologist's report, then a much longer time would be necessary. In Philadelphia physicians have sent material obtained from the throats of cases apparently recovered from diphtheria to the city bacteriologist, in the sixth week from the inception of the disease, and after being two weeks out of doors; he reported, microscopically, a number of Klebs-Loeffer bacilli present. I do not believe any one is able to positively state when the last scale of the desquamation of scarlet fever has disappeared from a child, and that there is no possibility of further contagion. Therefore, if there is ever possible an element of doubt, why not allot ample time for their convalescence, and err on the safer side? It is a bad and vicious rule to permit one child to advance by hazarding the lives of fifty others. Parents usually object to the length of time, claiming it is an unnecessary hardship, but how few mothers understand this danger, and yet you will find this same mother offering the most strenuous objections when her child is exposed to this danger to which she subjects others by returning the convalescent too soon.

The fact that contagious diseases of childhood are preeminently spread in schools is accepted by the medical and lay public, and yet how tardy have been the efforts toward instituting preventive measures. Every physician can recall some loving, earnest mother among his patrons who has learned to distinguish between the lighter and the major ills of her children, and when such a mother calls for your services, you at once, and rightly, conclude that there is something radically wrong. Why not have every teacher acquire this training, and learn to distinguish a normal from an abnormal throat, to discern the flush of fever, scarlet rash, and any suspicious cough that might lead to pertussis? A few clinic lessons added to her curriculum, and making this a part of her qualifications necessary to acquire a certificate as a teacher, is not only feasible, but practicable, and will be followed by beneficent results. I hope to see the day in which every school teacher is thus qualified to distinguish children's diseases, and with the argus eyes always on the many little ones, what better means have we to prevent the spread of contagious

diseases in schools? She should not only be taught the differential points, but the means of contamination, which she can in turn impart to other pupils. A daily medical inspection is in vogue in some of the European and American cities, but this will only be occasionally necessary if teachers receive the proper instructions. When teachers are qualified in practical clinic essentials, they can make it their morning duty to have the pupils pass in single file, and, if watchful, they will learn to discover the suffused cheek, the dull eye and the heavy countenance. Any child trivially ill is at once sent home with a note of explanation, requesting the attendance of a family physician.

The law of Pennsylvania, compelling children admitted to school to present a certificate of successful vaccination, signed by a physician, is signally defective, for there is no doubt that a number of certificates are forged, by which means parents opposed to vaccination evade the law. An amendment to the law has been passed, to admit children who after repeated trials will not "take" the vaccin virus, which must be confirmed by a qualified physician, but I have never yet found a child who did not respond to primary vaccination, when properly done with fresh and healthy vaccin lymph. The law, by which the physician's signature should be authenticated, should be more stringent, thereby barring any possibility of deception. If it is an accepted fact, and I believe it is in Philadelphia, that enforcing the vaccination law has stamped out smallpox, why not give more attention to preventing the spread of other contagious diseases in all schools, instead of the belated attention of posting a yellow label over the door of the unfortunate victim? This tabooing the infected household prevents the usual intercourse of neighbors, which in itself is advantageous, but it unfortunately leads, on the part of the doctor and family, to collusively withholding such information from the proper authorities, thereby rendering the source of infection more dangerous by inattention to details, and the proper care against intruders.

The Philadelphia Board of Health forbids principals receiving such children in school, reported with infectious diseases, until they notify them when they may be safely returned to their classrooms. In many health boards, prophylaxis does not receive the attention it should, and the major work in that line should be directed within our schools. There should be in every city, as in Philadelphia, where there are 150,000 children attending the public schools, and probably 50,000 in parochial and private schools, a school medical superintendent, with sufficient salary to enable him to devote his entire time to his work, and a complement of qualified assistants apportioned to the different districts, whose duties should be to inspect school buildings, to trace sources of infection, to respond to the call of principals or teachers for the examination of suspicious cases, and especially to guard a classroom of children where any contagion has developed and is likely to spread. Such a board, properly salaried and organized, would in the course of time develop a fund of practical details, which would reduce to a minimum the spread of contagious diseases in our schools. Their work could also be that of instructing teachers in recognizing infectious diseases in their early stages, or where there is need of watchful attention, to aid and guide them in hygienic measures. His duties should be in part to see to the proper physical training of pupils, to the proper posture to be observed in sitting and writing, to suggest remedies against the enormously grow-

ing evil, especially in our public schools, of stooping, and thus acquiring round shoulders, and to superintending the voice and lung gymnastics so essential in the developmental periods of life.

Why should it not be the morning duty of each teacher to inquire of her class whether any child present has headache, sore throat, sick stomach or pain, or is feeling ill in any way? Such children complaining should at once be examined by the visiting medical inspector, and, if sick, should be sent home, or, if malingering, returned to the classroom. Believing, as we do, that infection is for the most part spread by children sitting in school during the inception and development of contagious diseases, the danger, therefore, can be minimized by early detection through these interrogatories, supplemented by a medical examination, which renders it nearly impossible for a child to remain in school two or three days with a diphtheritic patch the throat or a developing exanthemata. Or, if this procedure be objectionable, the teacher can in the early part of the term, or once a week if necessary, instruct her pupils to report immediately when ill.

In Brussels the schools are visited weekly by trained medical inspectors, who look after all matters pertaining to the health of the pupils, in suspicious cases examining the eyes for optical defects, and in frail children suggesting such work and physical training as accords with their capabilities.

DISCUSSION.

DR. HORACE B. ARNOLD, Boston.—In November, 1894, we started a system of school inspection by physicians. The city was divided into fifty districts, and one examiner was appointed for each district. A visit was made to the schools each morning. The plan was as follows: Immediately on the assemblage of the school children, the teacher looked them over and decided whether any child was ailing. If any child was found ailing, word was sent to the mother and a notice given to the medical examiner. The medical examiner examined the child and determined the trouble, and, if contagious, or if detrimental to the health of the other children, the case was sent home. We dealt with an extensive run of contagious diseases in the city and many cases in the public schools. During the first year—fourteen months—there were 16,790 pupils examined in the schools; of this number, 6,053 were not sick, but 10,737 were found to be ill, among which number 2,041 were sick enough to be sent home; 453 had contagious diseases and would have been sources of infection through the schools. Since that time the number of contagious diseases in the schools and city has suddenly diminished. In my ward, during the past year—as school inspector—I found more cases that contracted the disease outside the schools than inside. The physicians are obliged by law to report cases of contagious diseases to the Board of Health, when the examiner visits the case to learn if proper isolation, etc., has been carried out; if not properly carried out, the case is removed to the hospital. As a result of this practice, the results have been remarkable, for there are fewer cases of contagious diseases in the tenements than in the well-to-do classes. The reason is that since the new contagious hospital can accommodate all the cases that have their origin in the tenement districts, the prompt removal of the cases to the hospital limits the spread of the diseases.

Regarding Dr. Ott's opinion as to the period at which the child should be allowed to return to school, I believe it is too short. In watching a number of cases of scarlet fever, I found desquamation occurring five and one-half weeks. Dr. Cullom places the average period of desquamation at fifty days. As regards diphtheria, the child should not be allowed to return so long as the Klebs-Löffler bacilli are demonstrable.

DR. RAYBURN, Washington, D. C.—Another important point is regarding sending children to school too early in life. No child should be sent to school before the age of seven years. In Washington we have about 50,000 children who attend school. The idea of sending children to school at the ages of 4 or 6 is wrong. At this early period they take diseases easily. Children should not be sent to the primary department before the age of 7 years and no child should be kept in one session more than four hours in length; only an exceptional child is able to bear the strain on the system for a

longer period of time. In other words, no child should come to school before the age of 7 years. The trouble is that the public school system has grown too much. One should bear in mind that the children need sound bodies as well as sound minds.

DR. BRADDOCK, Minneapolis, Minn.—Any one who studies infectious diseases knows that they increase in number during the school period. Any one who studies inspection of schools will admit that Boston has the best system. Teachers can make inspection and they can help, but not without medical inspectors; teachers working with the medical inspectors give the best results. The time limit for scarlet fever and measles may be made, but not for diphtheria; some cases of the latter may not be safe for six weeks, and some not for six or eight weeks, before they may be sent back to the school. Its contagiousness is through direct infection and not through the air. In many instances the bacilli may be in the throat, although there may be no symptoms. If we exclude children with clinic diphtheria, we should exclude children who have bacilli in their throats. The time limit of four weeks is not long enough for scarlet fever, although some cases may be safe in less than that time.

DR. E. R. AXTELL, Denver.—The statement of Dr. Ott regarding the indiscriminate use of lead pencils is a true one. Two years ago I suggested to a lead pencil manufacturer that he incorporate quinin or some bad-tasting substance with the graphite, but nothing came of it. In the private schools in Denver we had trouble with diphtheria, and I have made visits there from time to time and found patches of diphtheria in the throat.

AMERICAN.

1. *Labor in Abnormal Pelves.*—The summary of Davis' paper is as follows: 1. In 466 women examined by pelvimetry, 32 per cent. had abnormal pelves. 2. Among these, 20 per cent. required obstetric operations for safe delivery. 3. The mortality of the operations, which included the range of modern obstetric surgery, was nil from septic infection and hemorrhage. One patient died from nephritis. The fatal mortality of the operations, which included the range of one 4. The writer's experience in the Cesarean section and symphysiotomies includes fourteen Cesarean sections and eight symphysiotomies. The mortality for the mother was nil where the patient was uninfected and sound before delivery. When death occurred in the mother it was from previously existing streptococcus and pneumococcus infection or from infection with bacillus of comma before labor, or from eclampsia. In the fourteen Cesarean operations and eight symphysiotomies one child perished from inspiration pneumonia, its mother being infected before admission to the hospital. 5. In our experience celiohysterectomy with intrapelvic treatment of the stump, celiohysterectomy, symphysiotomy, forceps extraction in Walcher's position, version and embryotomy, in patients not infected before these operations were performed, have given excellent results.

2. See abstract in JOURNAL, May 27, p. 1173.

3. *Postures in Labor.*—Dickinson's paper is a study of the literature and facts as regards posture in midwifery, going back to the sixteenth and seventeenth centuries and bringing the subject down to recent times. His paper is illustrated by reproductions of ancient woodcuts and various diagrams from modern sources. His practical deductions are: 1. Posture will notably alter the shape of the pelvis in late pregnancy. 2. Increase in available room in the pelvic cavity as a whole cannot be brought about. 3. To obtain the largest conjugate at the inlet, the hanging dorsal posture is to be employed. The gain is nearly one centimeter. 4. To obtain the largest conjugate at the outlet, the full-flexed dorsal position is necessary. The increase promises to be from 1.5 to 2 cm.

4. *Prophylaxis and Treatment of Puerperal Fever.*—After a critical study of the literature, Moran concludes that the best practice is asepsis rather than antiseptic and that meddling examinations, douches, etc., are best avoided. The treatment should be based on a thorough physical and bacteriologic examination. If streptococcus infection exists, local treatment is likely to be beneficial. The surgical treatment depends on the case; of course, pus must be evacuated. In the general treatment, which embraces stimulants, strychnia, nitroglycerin to aid the heart, cold packs or sponging for fever, antipyretics are contraindicated as they depress the heart, and quinin is of little use except in malaria. Antistreptococic serum has been advised of late and Moran reports three cases in which the improvement following was, he thinks, more than a mere coincidence.

5. *Streptococcus in Gynecology.*—In reviewing the Johns Hopkins Hospital gynecologic records from October, 1894, to June, 1896, and from October, 1897, to July, 1898, Miller found complete bacteriologic records in 127 inflammatory cases, in seven of which the streptococcus pyogenes was encountered. The histories are given. Miller finds this proportion agrees with that obtained from the literature, so that this infection may be reckoned as comparatively rare. Four of his cases were puerperal parametritis and one of the others was probably of puerperal origin. In no case of pyosalpinx proper was this germ found, and he thinks it must be rare in this condition. The origin is undoubtedly from a wound and generally from a puerperal one. In only two of his seven cases was it otherwise, once from the intestines and once probably through the vagina. The route may be either through the blood-vessels or the lymphatics, preferably the latter. The characteristic symptoms are soft, elastic swelling, becoming later of a bony hardness, with frequent pus accumulations, which may burrow in any direction. The mass is generally in intimate connection with the uterus, which it immobilizes. He thinks that the streptococcus may exist and be infective

in the organism for months, or even years. Only one of the seven cases was fatal; it was one of general streptococcus infection that succumbed under operation. The others were all discharged improved after three to eight weeks' treatment; 3 have since reported, 2 feel well, and 1 is worse. In 4 of the three discharged, the peritoneal cavity was invaded at the time of operation, but in only one did symptoms of peritonitis appear and in this they were only temporary. Miller thinks that the germs may have lost their virulence to some extent or the patients have become somewhat immune or both factors co-operated. As regards the operation, the exudate usually begins in the true pelvis and should when possible be reached through the vagina, avoiding invasion of the peritoneal cavity. When diagnosis is dubious, an exploratory laparotomy may be needed, and when it cannot be reached by the vagina, incision should be made where it lies in contact with the abdominal wall. Incision or puncture with free opening of the mass with the fingers or by blunt dissection with free drainage is always indicated. Excision of tubes, ovaries or uterus is rarely required. More harm than good is done by removal of the appendages in streptococcus parametritis.

6. Gonorrhoea in Female.—Morse calls attention to the importance of this disorder and its frequency in women, which he thinks is greater than is commonly supposed. Married women are the usual innocent victims.

8. Intestinal Obstruction from Ascarides.—Taylor reports a case in which obstruction and intestinal inflammation requiring operation were caused by a mass of ascarides.

10. Progress in Medicine.—Osborne's paper is chiefly devoted to organotherapy, which he discusses in detail.

11. Insanity, Its Medicolegal Relations.—Eliot notices the features of the Connecticut law in regard to the commitment of the insane, criticizing in some points and speaking well of it in others. He is rather biased, apparently, against the plea of insanity in criminal cases. He concludes that the appointment by judges of experts in insanity does not insure the selection of the most competent men, while the appointment of experts by opposed parties results in the most diverse opinions, and that when these opinions differ, neither judge nor jury appears to be much influenced by the testimony.

12. Hypertrophics of Pharyngeal Vault.—Munger counsels the early removal of adenoids and thinks that it would be a good plan to have systematic examination of children's throats for these growths, and regulations for their removal.

13. Doctor as Medical Jurist.—Bonestell speaks of the importance of the physician giving special attention to cases in view of medicolegal exigencies, and making thorough notes as to details.

14 and 15. Bronchopneumonia in Children.—Hodghead reports a case in a child of 18 months with bronchopneumonia in which, after failure of the routine treatment, complete change was made, poultices removed, water given instead of milk, 1-10 grain of calomel given every hour until the bowels moved freely, alternating every half hour with two drops of tincture of belladonna. In twelve hours every serious symptom had abated, the bowels moved freely several times, and in twenty-four hours the temperature had fallen to 100, the child was breathing 35 times to the minute, all rattling in the larger tubes had disappeared, pulse had become stronger, cough better, and the child slept and took nourishment. The belladonna was continued in drop doses every two or three hours until the characteristic eruption was produced, after which it was gradually withdrawn. Since this case he had relied on these two drugs and with them his mortality has not been over 5 per cent. in a disease which ordinarily has a mortality of 60 to 80 per cent. Couits publishes experiences with belladonna in bronchopneumonia with children which correspond closely with those of Hodghead. He has given the extract of the old British pharmacopeia in doses of $\frac{1}{4}$ grain every three or four hours, without regard to the age of the patient. No disadvantage has been noticed except a slight delirium, easily controlled by lessening the dose, some flushing and rash.

18. The General Practitioner and the Insane.—Hall insists on the necessity of a thorough examination as to the condition and causes before sending patients to the asylum, and especially the condition as to the pelvic organs in females.

20. Cardiac Asthenia of Pneumonia.—Elsner remarks that the treatment of this condition has been very disappointing to the profession. The overwhelming toxemia has staggered our therapists and to meet it we must break away from the practices of the past. First, he protests against the indiscriminate use of those remedies which lower the vitality of the patients while they reduce the temperature, including under this head the coal-tar preparations. The indiscriminate

use of nitroglycerin is also a growing error. It may have its use in overcoming peripheral obstructions such as we meet with in senile cases with sclerotic or narrow arteries, but his experience with it has been unfortunate. In pneumonia, where we already have paralysis of the vasomotors, it is a dangerous drug. Veratrum also comes under consideration. Bleeding the patient into his own veins is a dangerous teaching and he does not venture to say how many lives have been lost by the persistent use of this cardiac depressant. The two drugs on which he relies to meet the indication in pneumonia due to paralysis of the vasomotors are strychnia and digitalis, and with these he would administer the diffusible stimulants, and he believes in giving these at short intervals. He has treated cardiac asthenia by administering, every fifteen minutes, 15 drops each of compound spirits of ether, aromatic spirits of ammonia, compound spirits of lavender and tincture of valerian—keeping this up night and day until the pulse shows improved tone and the heart action is better. Valerian is given for its quieting effect, but, with some patients who cannot take it, he has substituted whisky or brandy in corresponding doses. With this he has insisted on the internal administration every two, three or four hours, according to the case, of $\frac{1}{4}$ -gr. doses of spartein, with 4 to 6 gr. of caffeine. Finally, the alcoholic stimulant on which he depends is Tokay wine, and he thinks that it has been of great value in tablespoonful doses every half hour, given with the ethereal stimulant. Occasionally he has found it necessary to use high rectal injections of coffee and whisky and hypodermic injections of ether and oil during the periods of collapse. As regards the use of oxygen, he is uncertain and seems doubtful as to its great benefit. Naturally, the treatment here indicated requires skilled and faithful nurses. (See JOURNAL, June 24, p. 1642.)

21. Laparotomy for Typhoid Perforation.—Taylor reports two cases of operation for typhoid perforation and discusses the condition, especially the question of the early diagnosis which is so important for the welfare of the patient. He believes that careful and repeated examinations of the blood will be a very valuable aid in diagnosis and may enable us to operate earlier than would otherwise be the case, as with the onset of any acute inflammatory process, as Cabot and Thayer have shown, the number of white corpuscles is suddenly and largely increased. The danger from operation in cases of a mistaken diagnosis is not, he thinks, so great as to prevent it in suspicious cases. He sums up the indications, quoting Finney's conclusions: "First of all, the so-called diagnostic signs of perforating typhoid ulcer, most reliance is to be placed upon the development of an attack of severe, continued abdominal pain, coupled with nausea and vomiting, and at the same time a marked increase in the number of white blood-corpuscles; secondly, the surgical is the only rational treatment for perforating typhoid ulcer; thirdly, there is no contraindication to the operation, surgically speaking, save a moribund condition of the patient."

22. Evolution of Modern Therapy.—Baruch's paper is an interesting sketch of the fashions and changes of therapy in the past, leading up to our present ideas. The paper is to be continued.

23. Kalt Suture in Cataract Extraction.—Risley reports three cases in which he employed the cono-scleral suture devised by Kalt, which he claims diminished the percentage of iris prolapse. Risley's experience would seem to be rather favorable.

27. Ibid, April 15, p. 800.

29. Empyema of Gall-Bladder.—Summers reports two cases of gall-bladder empyema and discusses the condition. He sums up as follows: The chief symptoms leading to a diagnosis of empyema of the gall-bladder are: pain, and acute symptoms of inflammation in the gall-bladder region—muscular rigidity, pain on pressure, etc.—fever, chills, sweating; pressure of a tumor. Probably there will be a history of cholelithiasis. Suppurative inflammation of the right kidney and also of the vermiform appendix when displaced must be excluded. The treatment is surgical, and consists in incision and drainage of the gall-bladder. It is usually wise to aspirate the gall-bladder before incising it. It is not necessary, neither is it always practicable, to suture a gall-bladder into the abdominal cavity. Gauze packing will often suffice to protect the abdominal wound against contamination, before aspiration and incision, likewise after the establishment of drainage.

30. This address was published in the JOURNAL of June 10.

33. Burns and Scalds.—After general description of the varieties of these lesions, Leech reports a case in which a man was scalded very extensively over arms, legs and part of the

trunk and face, the injury ranging in the first and second degrees in severity. The man was put to bed and the wounds dressed with caron-oil and hypodermics given. After eight days, the hypodermics were withdrawn gradually and the local dressing changed to an ointment of iodoform, oil sassafras and vaselin. Supporting treatment continued throughout, consisting of sherry wine, whisky, brandy and egg-nog. Recovery was uneventful and he was dismissed in a little over a month after the injury. A notable incident of the case was the spontaneous combustion of the dressings during the first week.

34. *Separation of Symphysis Pubis.*—Rutherford reports a case of multipara, aged 28, who had several difficult labors, and in whom the symphysis separated spontaneously during delivery. Recovery was long and tedious and complicated with septicæmia in spite of precautions.

36. *Puerperal Sepsis.*—Garnett maintains that in spite of all that can be done it is not always possible to prevent puerperal sepsis and that its presence, even in this day of extreme modern antiseptics should not be taken as an evidence of criminal neglect, as some have advocated. In support of this view, he asks why there should be published a study of forty cases of puerperal sepsis in the John Hopkins Hospital, where every facility for its prevention must have existed.

37. *Bronchopneumonia in Children.*—Hough, after briefly describing the symptoms, mentions his treatment, which consists of stimulating expectorants, with ammonia preparations, counterirritation with mustard and camphorated oil, care to the kidneys, the use of quinin in combination with ammonia and digitalis. Aconite is an efficient remedy in the acute stage and he frequently resorts to the hot mustard bath in threatened collapse, and an emetic if mucous accumulations, which the patient cannot expectorate, exist. Good, intelligent nursing and feeding is, in his opinion, the great essential, and he places as much confidence in wise, motherly care as he does in medication.

41. *Ibid.*, April 29, p. 937.

45. *Diagnosis of Abdominal Contusions.*—The importance of an early diagnosis of the ruptured solid or hollow viscera is the subject of Taylor's paper, and he reviews the various symptoms which may aid us. Shock, he thinks, has little diagnostic value, though it may be presented in such a way as to make its manifestation diagnostic. Prolonged shock points to visceral lesions. Abdominal distension is another symptom which is not uniformly characteristic. Abolished peristalsis, however, is especially valuable, being one of the earliest manifestations, and is appreciable at the right time. Muscular rigidity is next to abolished peristalsis, and he thinks it almost infallible. Pains, vomiting and facies are not unvarying signs, nor is the pulse. Senn's method of injecting hydrogen gas has not, he thinks, received the attention by surgeons that it ought. Percussion of the abdomen is not likely to furnish any valuable information.

47. *Inversion of Uterus.*—Coe reports a case of spontaneous inversion of the uterus occurring in labor after the use of ergot, which was reduced by laparotomy by Thomas' method.

49. *Pulsating Pleurisy.*—Henry reports a case of this condition and believes, contrary to some authorities, that the most important causes are a large effusion, relaxation of the thoracic wall, and a somewhat forcible heart beat. The presence of air in the chest may co-operate, but it is not essential. In the case he reports there were three strongly pulsating tumors, which is remarkable in its way.

51. *Black Arts in Medicine.*—This article discusses some of the unethical tricks adopted by some of the more unscrupulous members of the profession.

52. See abstract in JOURNAL, xxxi, Nov. 28, 1898, p. 1173.

54. *N. Y. State Medical Society and the Code.*—Richmond's article is a plea in behalf of the position taken by the New York State Medical Society, claiming that recognition of those that the law recognizes, provided they are up to the standard of professional gentlemen, should be the rule, and that we should rid ourselves of the title "regular" as egotistic and useless.

55. *President's Address.*—Kerr's address before the California State Medical Society takes up some of the questions of modern medicine in a very satisfactory way. It suggests an order of business for the more practical working of the society, alludes to the questions of vaccination, the ethical questions that arise, the crusade against tuberculosis, and asks the society to actively interest itself in these matters.

56. *Diagnosis of Cerebrospinal Meningitis.*—Cheney's article calls attention to the great number of deaths that have occurred in San Francisco within the last year as justifying the bringing forward of the subject, and calls attention to

its diagnostic points, which are few. As regards symptoms, the best are the suddenness of the onset, the initial symptom usually being chill, severe headache, and vomiting. Headache, however, is the most constant phenomenon. The development is rapid, delirium usually comes on early, soon followed by coma and stupor. The third symptom, which is rather characteristic, is the rigidity of the muscles of the neck. These are all the points that are really characteristic of this very variable disorder. He then mentions the one diagnostic method which outweighs all that have been mentioned, namely, lumbar puncture, and describes the methods of operation and detection of the Weichselbaum meningococcus. One other procedure that is available is the blood count, one of the chief features of the disease being a high degree of leucocytosis. The absence of this symptom, therefore, would throw doubt on the diagnosis, while its presence would absolutely exclude typhoid fever, the disease most frequently confused with cerebrospinal meningitis. The last diagnostic method he mentions is the autopsy, which is of no benefit to the patient, but may be of great use to the physician in future experience. He reports three cases observed by him within the past three months. (See JOURNAL, May 13, p. 1052.)

57. *Muscle Affections.*—This is a clinical paper describing cases of rheumatic myalgia, rupture of triceps with complications, infectious neuromyositis, diffuse myositis, etc.

58. *Why So Many Young People Wear Glasses.*—Hulen, after noticing the common eye defects relieved by glasses, and stating that in many cases people are wearing glasses who do not need them, or such as they do not need, concludes: 1. That the eyes of children in the schools are more taxed than they formerly were and eye-strain brings out troubles which would have been unknown had the demands on the eyes been less. 2. Because of the defective lighting of large cities, which, with a less robust population, severely strains the optic apparatus. 3. Because physicians are beginning to notice defects and correct them. 4. Because with all of the above there are more inheriting optic weakness than was formerly the case.

59. See abstract in JOURNAL, May 6, p. 996.

60. *Ibid.*

61. *Ibid.*

62. See abstract in JOURNAL, April 22, paragraph 48, p. 894.

63. *Tent Life for Invalids.*—Gardiner calls attention to the great advantage to invalids and convalescents of open air living in a tent in the mountains of Colorado. The ranches seldom can give such accommodations as are required, but with a tent, and he describes his own, the occupant has everything in his own hands.

65. *Peritoneal Adhesions.*—In this short paper Robinson considers the condition of peritoneal adhesions, which produce one-third of all intestinal obstructions. Its results are: 1. Peritoneal bands. Peritoneal bands may cause intestinal obstructions by a segment of the bowels becoming strangulated by a band or thorough aperture. 2. By isolated peritoneal adhesions. 3. By Meckel's diverticulum and fixed appendiceal loops. 4. Peritoneal bands may fix viscera. 5. They check peristalsis. 6. They cause pain by checking visceral function. Much of the immediate and remote pain subsequent to laparotomy is due to peritonitis and resultant peritoneal adhesions.

67. *Ichthalbin in Pediatrics.*—Homburger gives his experience with the use of ichthalbin in diseases of children. The doses he gives are from 1 to 2 grains to children under 6 months of age, three times a day; to children between 6 and 12 months, 2 to 3½ grains, and those from 1 to 2 years, 3½ to 5 grains. In older children, the dose may be still further increased. He says, in concluding his paper: "In finally summing up all the statements regarding the applicability of ichthalbin in pediatrics, it must, above all, be said that it is perfectly innocuous, and that, given in the form administered by us, it is an almost tasteless preparation which may be exhibited internally without any difficulty. It is able to change weeping eczemas into the dry form within a very few days, and this, too, in cases where external remedies alone were unable to effect the purpose. In combination with the remedies usually employed externally, it hastens the cure of dry eczemas." So also does it effect the recession of the multiple furuncles which frequently accompany the debilitating diseases of childhood. In wasting diseases, such as chronic pneumonia, serofilia, chronic intestinal catarrh, etc., ichthalbin effects an increase of the body weight, by increasing the appetite. Hence the remedy may be recommended particularly during the frequently debilitating antisyphilitic cures, as well as in convalescences frequently aggravated by anorexia and debility; and also other febrile diseases in children. Of the

intestinal catarrhs, the chronic are particularly influenced benevolently by ichthialbin, while the acute and subacute are less favorably modified. It is a valuable addition to our materia medica, and is well worthy of further consideration.

41. *New Method in Inguinal Hernia*.—Lane proposes a method, which he does not claim as new, because he believes it is being used by some practitioners of reputation in the East, of obiteration of inguinal hernia without a cutting operation. The treatment is made by the application of the positive pole of a galvanic battery through the borders of the internal ring, using a current of about 20 milliamperes. With the patient in a recumbent position, with hips elevated, a sharp-pointed, grooved director is introduced above the internal ring into the canal, using the forefinger of the left hand for a guide. When the director can be freely moved along in the canal, a long needle connected with a hypodermic syringe is introduced along its course well up to the internal ring and a 4 per cent. solution of eucain is slowly injected. After the parts are anesthetized, a platinum-pointed needle, insulated at its base, is introduced along the groove up to the internal ring, the forefinger of the left hand being used as a guide to keep back any intestine or omentum that may encroach, which, however, is unlikely. The director is then withdrawn, the needle being held in place against the upper segment of the internal ring and a light current from the positive pole of the galvanic battery is turned on and gradually increased until 20 milliamperes are used, then the point and face of the needle is passed over the surface of the ring, the cord always being held in safety under the forefinger. After going over all the surface of the ring except such portion as is occupied by the cord, the needle is withdrawn and the patient puts on a truss that has been worn if possible at least a month before the operation. The length of time which the current is used is usually about seven minutes. The usual immediate results are apparently a puckering and tightening of the internal ring and surrounding tissues. The treatment may be repeated in three or four days and sometimes a third and fourth one are given. After a time, varying from fifteen days to two months, the truss is removed and if the cure seems complete, no tumor protruding or pain or feeling of weakness, etc., a recovery is pronounced. The operation is very slight, producing very little if any general disturbance. He reports a number of cases in which a cure was produced in this way.

73. *Curability of Drug Cases*.—Coe reports two cases of the opium habit and remarks on the same. He says there is no class of patients in which it is more difficult to foretell the outcome than these. A favorable case may lapse and often the most unfavorable will make a perfect and permanent recovery.

77. *Typhoid Fever*.—DeLafield, in his clinic on typhoid, makes the following points: 1. If a proper case, do not continue tubuling too long—that is, after the third week. 2. If the disease is protracted over the fourth week, although the patient has typhoid fever, begin with scraped beef. This often makes a great difference in the heart's action. 3. When beyond the fourth week, look out for convalescence. Do not look at the temperature-chart at the head of the patient's bed, but look at the patient, who is the guide which tells you if he is convalescent or not. See if the tongue is moist and clearing off, and notice the expression of his face; see if he is sleeping at night and asking for food or getting hungry. The fourth week is the right time to look for convalescence. Do not be so stupid as to have a patient convalescent and not know it; that is a very dull thing to do; in order not to do it, look at your patient and not at the temperature-chart, for the patient is often convalescent with an afternoon fever; this fact is perfectly well known. Now the rule is to disregard the afternoon temperature and to go on increasing and varying the diet and get him out of bed. Dr. DaCosta was one of the first to call attention to the importance of getting patients out of bed when convalescent with afternoon fever.

79. *Medical Inspection of School Children*.—Hinchev pleads for a revision of the school courses of study so that study at home be not necessary, and for the appointment of medical inspectors of the school, whose duties shall be extended to examining every child asking for admission, the examination including the child's eyes and all mental and bodily defects so as to adapt the studies accordingly; also to include the examination of every child returning to school after illness, taking cultures from throats after recovering from diphtheria, and carefully investigating all cases of infectious disease.

81. *Mastoid Complications in Children*.—Dench discusses the subject of middle ear inflammation following the eruptive diseases, and insists on treatment of the mastoid if it has become involved. The incision through the soft parts is not sufficient even in very young children; he holds that the mastoid antrum should be entered in every instance. The opera-

tion can be performed in a few minutes and, if thorough aseptic precautions are taken, it is devoid of danger. He calls attention to the special points in the anatomy of infants and points out that it should be borne in mind that the tympanic ring is applied to the external surface of the temporal bone and that no osseous meatus exists. "The upper wall of the canal is attached to the squamous plate of the temporal bone and the lower wall of the canal lies in immediate contact with the upper wall. In order, therefore, to obtain a perfect view of the drum membrane in an infant, it is necessary to draw the auricle downward, backward and outward; in other words, to separate the inferior from the superior wall. In the operative technic this point must also be remembered. In infants, the surgeon is seldom called on to interfere before a postauricular abscess makes its appearance. When this abscess is evacuated, the surgeon should carefully follow the membranous meatus downward as far as the tympanic ring, exposing the posterior tympanic spine. If the cortex is perforated in this region, the mastoid antrum and middle ear will be easily entered. If, however, the line of superior auricular attachment is taken as a guide, there is great danger of entering the middle cranial fossa instead of the mastoid antrum. Particular stress should be laid on this point. As I have before stated, a post-auricular abscess in an infant is always so strongly indicative of inflammation in the mastoid antrum as to necessitate operative interference. While some cases recover after simple incision of the abscess, it is never wise to depend on this procedure."

82. *Training of Blind Children*.—Drummond noticed that blind children are often defective in other respects than vision on account of their having not been able to develop self-reliance, etc., on account of their disability. The proper method of training these cases can be expressed in a few words: They should be treated, as far as possible, exactly as if they were able to see. Bad habits should be carefully looked after and eradicated at the earliest possible date.

83. *Actinomid Poisoning*.—Westcott reports a case where severe symptoms of actinomid poisoning followed the dusting of the surface for intertrigo of the groin and thighs. The surface was comparatively small and he deduces that the use of actinomid, even in insignificant exposures of the skin in young children, is distinctly dangerous to life.

85. *Malignant Disease of Sigmoid*.—Noting the small amount of literature on the matter, Ouchterlony reviews the subject of sigmoid cancer, which generally appears in the form of scirrhus, encephaloid and colloid, very rarely as sarcoma. It seldom attains large dimensions and does not as a rule tend largely to invade other parts. It is rarely recognized in its beginning, and he describes the principal symptoms, which are not always localized, tumor, hemorrhage, discharge of pus, subnormal temperature, at least at times, and in his cases excessive dryness of the tongue and intense burning in the rectum. Complications were numerous, nephritis, peritonitis, abscess, obstruction, septicemia, etc. Diagnosis is not possible in the incipient stage and often difficult later. The course is more protracted than in other varieties. Surgery affords the only means of relief, though not of absolute cure, according to his observations. A case or two, however, have been reported which seem encouraging.

86. *Treatment of Diphtheria*.—Moss treats diphtheria as follows: Calomel in proportion to the age; tincture of chlorid of iron; three or four drops every four hours, and whisky, one or two table-spoonfuls every two or three hours; a general temperature, 65 or 70, and keeping the bowels open. Keep quinin out of the patient, washing and mopping the throat with a saturated solution of chlorid of potash every hour and a half or two hours during the day and less frequently during the night. The contact of the calomel with the diseased portion of the throat is beneficial and it should be given in such a way that this will occur. If there is much purulent discharge and soughing, with bad breath, syringe the throat and nose with a 3 per cent. solution of peroxid of hydrogen every two to four hours. If laryngeal diphtheria occurs, keep the patient in a room at the temperature of 85 degrees, with moist air, and give eight to ten drops of fluid extract of jaborandi, 1 grain of muriate of ammonia, and 10 drops of glycerin every two or three hours. If signs of suffocation supervene, give an emetic, preferably ipecac. He mentions intubation as a last resort and briefly refers to antitoxin without details.

87. See abstract in JOURNAL, May 6, p. 996.

90. *Care of Delicate Children*.—In a group of cases presented by Mulford, the cause of the condition is considered to be either an autointoxication, or the existence of what are commonly termed "adenoid vegetations." Autotoxis is considered by far the most frequent cause; although these two conditions frequently co-exist they may be quite independent of each other.

When, however, the adenoid vegetations exist to the extent of obstructing respiration, autoinfection is present to a certain extent, dependent perhaps on faulty oxidation. In treating such cases all respiratory obstructions are to be removed. Drugs are very sparingly used, even laxatives are but cautiously resorted to; intestinal lavage is much to be preferred. Much may be done by instructing the parents, in guiding their children in the formation of correct habits of life. The main things to be taught are to eat properly, to play, and to rest properly, and to give proper attention to the action of the bladder and bowels.

93. *Stump in Abdominal Hysterectomy.*—Robinson, after making a median incision with catgut, beginning at the angle of the wound above the umbilicus, closes the peritoneum down to the posterior surface of the uterus, thus closing the peritoneal cavity. The ovarian arteries are ligated with catgut, close to the uterus, a large clamp is placed on the uterine side of the broad ligaments on each side of the uterus, as far down as is wished to begin to make the peritoneal cuff. The ovaries are left, and as much of the uterine ends of the oviducts as possible, to keep the nerves of ovaries, ligaments, and tubes intact, to avoid precipitate menopause. He splits the broad ligament down to the uterine arteries and ligates. The peritoneal cuff is now stripped, making it as ample as possible. The uterus is amputated just above the internal os. The upper edge of the peritoneal cuff is sutured to the parietal peritoneal edge, which is produced by the median incision, and the peritoneum is cutely closed immediately after making the cuff if desired. The uterine stump, closed to a cone by catgut, is drawn into and fixed in the abdominal wound. The abdominal wall is then closed. The two sutures of the wound over the stump are allowed to remain united for thirty-six or forty-eight hours to allow escape of wound secretion. Advantages claimed are that immediate closure of the peritoneal cavity avoids shock to a great extent. Intra-peritoneal hemorrhage is impossible, as all arterial ligatures are extraperitoneal.

94. *Diaphragmatic Hernia.*—The condition resulted from a fall in infancy and during the following years, arose from a persistent hacking cough, stooping attitude, and proxy-sus of abdominal pain, no great inconvenience was experienced until after the eighteen year, when death resulted from intestinal strangulation. Post-mortem, it was found that an opening 7.2 inches in its longest diameter existed behind the external tendinous arch of the left side of the diaphragm; the entire small intestine was found in the thorax together with appendix and caecum coli. The stomach was displaced to the right and the liver displaced until it extended one inch below the umbilicus. The spleen was located on the upper surface of the diaphragm and below the heart. The intestines were discolored and showed signs of inflammation. The left lung was entirely collapsed and carnified.

95. *Actanid Habit.*—Gilmore's case, during a period of twenty months, used from 5 to 10 grains of the drug daily, with complete satisfaction and no marked desire for an increased quantity although resisting all efforts at diminution or substitution. The case was suffering from a carcinoma of the uterus.

97. *Syphilitic Perichondritis.*—Packard reports a case of perichondritis undoubtedly syphilitic in its nature, appearing twelve years after the initial chancre. The upper portion of the auricle, the helix, and anthelix were greatly infiltrated and exceedingly tender. The diagnosis was made from the history of primary and secondary signs of syphilis, the ready response to antisyphilitic treatment and the absence of any evidence of traumatism.

98. *Paralysis and Combined Sclerosis.*—This paper is fully illustrated by figures showing the changes in the spinal cord in those cases of spinal cord disease to which he gives the name of subacute spinal paralysis. They are characterized by symptoms of numbness, ataxia and paralysis involving the legs and then the arms, progressing at first slowly, and then rapidly and running their course in one or two years. The cause is unknown but is undoubtedly some form of toxemia. It is more often associated with pernicious or profound secondary anemia than with any other conditions, and is seen after severe malarial and lead intoxication. It occurs usually in middle life or later and more often in women. It resembles light grades of multiple neuritis, such as are due to arsenic or diabetes; on the other hand it somewhat resembles locomotor ataxia in its earlier stages. It is to be recognized mainly by the presence of anemia or cachexia, the age of the patient, the progressive and rather rapid character of the symptoms, absence of much pain or tenderness over the nerves, the absence of eye symptoms and of the visceral symptoms of locomotor ataxia. The pathologic anatomy consists in a progressive degeneration involving most the posterior columns, and to less

extent the lateral columns of the spinal cord, and later the gray matter and other parts of the white matter. At the beginning the disease is systematic, affecting, however, the cervicodorsal part of the cord more severely, as a rule, but usually developing two or three specially marked foci of degeneration lower down in the cord. Pronounced changes in the blood-vessels sometimes accompany the degeneration, which is noninflammatory and often ends in softening. The treatment of the disease is always ineffective in the later stages. In the earlier stage the trouble may be helped by the use of arsenic, quinin, tonics, proper feeding, and the use of saline injections.

99. *Miliary Tuberculosis of Pleura.*—Hodenpyl describes and illustrates miliary tubercular infection without involvement of the lungs. He concludes that it is of frequent occurrence and that miliary tubercles in the pleura may apparently assume unusual significance either in causing, in susceptible individuals, or under otherwise favorable conditions, a generalized tuberculous exudative pleurisy; or by complicating through concurrent infection, an acute exudative pleurisy of independent origin. Miliary tubercles in this situation are prone to become fibrous.

100. *East-Febrile Insanity.*—Hamilton's paper is a general description of certain types of insanity following infectious fevers, especially typhoid and influenza.

101. *Fibroma of Abdominal Wall.*—Miller describes three cases of the rather rare growth of fibroma of the abdominal wall and discusses the condition.

102. *Tuberculosis.*—In this review of recent literature, Wright first notices certain commercial tendencies as shown in incidents of the manufacture of diphtheria and tuberculous antitoxin, and then alludes to the various cures of consumption which he finds are not especially supported by facts, at least as far as the serum therapy is concerned. He next remarks on the question of the infection of milk and milk products and rather throws doubt on the special dangers announced from this source. He also remarks on the possibility of the infection by tuberculosis from dust and coughing, and ridicules Frankel's appliance for filtering the expired air of consumptives. The behavior of the larynx toward tubercle infection is next reviewed, and he thinks that the statistics, especially those of Kreig, are hard to explain except on the theory that the infection has reached the larynx through the lymph channels and not through the atmosphere. In fact, he rather doubts the infection of the lungs directly through inspiration of the germ, and believes that the tubercle bacillus enters the organism in a large number if not in the majority of cases in other ways than through the lungs or stomach. It is shown by post-mortem that other localities, which are closed to clinical investigation are just as apt to be the seats of tuberculous disease as those that are open and exposed. He next notices the symptoms of pulmonary hemorrhage as an indication of tuberculosis, and refers to the comparatively recent work of Massei, which describes a type of tracheal mucous disorder, giving rise to hemorrhage without tubercular infection, and insists on the importance of the examination of the sputum, which he thinks, is not sufficiently attended to even yet. He remarks on the possibility of mistaking syphilitic laryngeal infection for tuberculosis, and notices a recently reported case of Tricifletti as illustrating this fact. In conclusion he refers to the paper of Hansemann on the secondary tubercular infection, which he thinks goes rather too far in its opposition to the higher contagion views. The paper is a conservative one but judicial in its tone.

103. *Sarcoma of Nose.*—Warthin reports an interesting case of polymorphous-cell sarcoma of the nose, and calls attention to its very excessive malignancy and its adding a new form to the sarcomata found in this region. He calls a bibliography.

104. *How to Give Anesthetics.*—Deutsch calls attention to the importance of a thorough knowledge of the patient by the anesthetist, especially the temperament, habits as to stimulants, and condition of the respiratory and circulatory organs. He thinks the Alvis inhaler the best and pleasantest apparatus. He finds the pupillary reflexes a satisfactory guide to the degree of narcosis, and believes that anesthesia should be carried simply to the point where it will allow the surgeon to do thorough work and permit a quick return to consciousness.

105. *Inoculation Theory of Malaria.*—James goes over the facts as regards the mosquito theory of inoculation and believes that, this being proven will render the chances for prevention much more hopeful than was formerly the case, as proper drainage, etc., would render a mosquito-infected region much less dangerous than was previously the case.

106. *Surgery During Hypnosis.*—McDonald reports two cases observed by him, operated by Dr. Schmitt of Nice, one of an

putation of the breast and one of ectropion of the lower left eyelid. The patient, in a state of somnambulism, followed the directions of the doctor and apparently did not experience the slightest pain.

107. *Rubber Gloves in Surgery.*—Richardson believes that rubber gloves afford the best method, while at the same time, as a precaution against accident, a thorough sterilization of the hands and arms should also be practiced. He prepares the gloves by first washing them in a soda solution, inside and out, and drying over a heater or gas flame. The inside should be dusted with a dry heat sterilized soapstone. Each pair should be wrapped in a double layer of gauze and placed in a formaldehyde sterilizer for two hours, then wrapped in a towel already at hand and sizes marked with graphite.

108. *Fever in Aseptic Surgery.*—Curtis treats of the causes and diagnosis of fever occurring in surgery with primary union of the wounds, and illustrates it with temperature curves. In a certain proportion of these cases some slight infection may be credited as the cause of the fever, but this cannot be said to be the case in all, as such fever occurs after simple fractures and subcutaneous injuries where infection is out of the question, unless it occurs through the blood. He insists on the importance of examination of the blood for leucocytosis, Widal's reaction, material germs, etc. A large proportion of cases are undoubtedly due to absorption of toxic matter in the course of healing, though there are a certain proportion that may be credited to shock. In the diagnosis of aseptic fever, however, it can be distinguished from shock by the good quality of the pulse and we can readily exclude other varieties of absorption fever (toxins, bile, thyroid juice), by the history of the case. We can distinguish it from inflammatory fever by its early appearance, by the fact that the pulse remains relatively low, and the patient has few subjective sensations other than a little thirst and flushing. The character of the pulse as well as its rate is of importance, as in aseptic cases it remains quite soft. The pulse will probably be the best guide in doubtful cases. The fall of aseptic fever is not so characteristic. It may reappear in two or three days or the temperature may continue a little above normal for weeks. He alludes, however, to the fact that there are many mixed cases as in case of toxins from sterile pus in the tubes, as in pyosalpinx or severe shock.

110. *Sanitarium Treatment of Phthisis.*—Bowditch reports the results of thirty-six cases that have been treated and discharged as arrested cases from the Sharon Sanitarium from February, 1891 to September, 1898. Excluding two cases that were there only a short time and have been discharged but a little while, there were 34 cases; 6 of these died after various periods, mostly on account of unhealthy surroundings or occupations; 1 has not been heard from recently; 24 are living, apparently well, and in active work; 3 have had slight return of their former symptoms but are still active and apparently doing well. He gives the history of the diseased cases, showing the apparent or probable cause of death. In every case efforts were made to keep the patients from returning to the same conditions as those in which the disease had developed. This is not always easy. The treatment generally was insistence on fresh air, judicious exercise and good healthy food, medicine being used rather sparingly and as an adjunct to general treatment. The reports are of interest as showing that phthisis can be arrested by treatment in a sanitarium not especially favored by climatic conditions and near a large city. This being the case, the possibilities of the cure of consumptives are greatly increased.

112.—See abstract in **FOREIGN**, May 20, p. 1116.

FOREIGN.

British Medical Journal, June 10.

Misplaced Testes and Their Surgical Treatment. H. BERTRAM ROBINSON.—The author describes the different forms of ectopia and retentio testis. Of the former the perineal type is the most common. He reports four cases, in two of which he operated by dissecting the testis free and pulling it down into the scrotum through the bottom. The crural form is rare. If he had such a case he would operate by bringing the gland into its proper place through the floor of the inguinal canal, not hesitating to cut Poupart's ligament and re-suture it afterward. The pubescence form is very rare. The testis here is alongside of the root of the penis. It is said to be due to great development of the inner attachment of the gubernaculum. In the abdominal form the testis is out of position by passing upward outside of the external oblique above the external ring into the peritoneal sac similarly placed. It has been attributed to the action of a truss on an undescended testis, but Robinson can quote cases where this factor was lacking. He reports two cases, one operated on both sides, the testicles being brought down into the

scrotum. Four forms of the retentio testis are recognized, the abdominolumbar, where it does not descend at all; the iliac, where the testicle is in close relation with the internal ring resting on the psoas; the inguinal, where it occupies any portion of the canal, including the interstitial variety, where the sac extends between the structures of the abdominal wall; and the cruroscrotal, where it stops just outside the external ring over the pubic crest, requiring careful diagnosis from the pubescence and higher perineal ectopic forms. In all but the last of these, when complicated with hernia, the operation of castration is advisable, but if the testis is outside the ring, attempts may be made to carry it down to the proper location. In this case the lower part of the gland should be attached to the perineum behind the scrotum to prevent retraction, and the cord may likewise be fixed to the pillars of the ring for the same purpose.

Ameba Dyscystariae: Relation to Tropic Abscess of Liver. D. C. MARSHALL.—This is the report of a case of recurrent liver abscess, coming on after return to the tropics, in which death was caused by a thrombus containing large numbers of the amebae, a hitherto undescribed pathologic condition. Illustrations of microscopic sections showing the conditions are given. The author emphasizes the danger of recurrence and of the too early return to the tropics—within two years—after the abscess has been cured.

Removal of Fibroid from Uterus Unicornis in Parous Subject. ALBAN DORAN.—In this case there was a myoma of a rudimentary horn connected by an imperious band with a well-developed side. The woman had twice been pregnant, once carrying the child to term. The operation left the developed side intact. The author finds the condition a very rare one, the only one reported precisely like this being one of Dr. Armand Routh's.

Lancet, June 10.

Fragments of Pathology and Therapeutics. W. HOWSHIP DICKINSON.—The Baillie lecture of Dr. Dickinson was for his subject cardiac dilatation, especially in relation to valvular lesions. He describes the mechanism of the production of this condition and sums up as follows: "Both dilatation and hypertrophy are brought about by intracardiac pressure, which is either absolutely increased or is greater than the means of resistance. Commonly these two results are associated, though the proportions vary. Hypertrophy is apt to prevail when there is undue retention of the blood during systole, dilatation when there is undue intrusion of the blood during diastole. Hypertrophy is the more apparent when the exit of the blood is impeded, dilatation when the entrance of the blood is increased. The one affects the heart in systole, the other diastole. The origin of dilatation in distension during diastole, though not the only mode of its production, may perhaps be regarded as the chief and as one to which attention needs to be emphatically called.

Effect of Baths, Massage and Exercise on Blood Pressure. WILFRED EDGECOMBE and WILLIAM BAIN.—The following is the summary of the experimental study of Edgcombe and Bain: 1. Cold baths raise the arterial pressure, maximum and mean, and lower the venous pressure; after reaction the arterial pressure falls and the venous pressure rises. 2. Percussion added to cold increases the rise in arterial pressure. 3. Warm baths of plain water lower the arterial pressures and both absolutely and relatively lower the venous pressure. 4. Turkish baths lower the arterial and venous pressures to a greater extent, though the fall in venous pressure is proportionately not so great as that in arterial pressure. 5. Saline baths at warm temperatures lower the arterial pressure to a greater extent than plain water baths at the same temperatures; the venous pressure, though absolutely lowered, is relatively raised; where the amount of saline material in solution is considerable, a further lowering of arterial pressure takes place, while the venous pressure becomes absolutely raised. 6. Dry massage lowers the arterial pressure and relatively or absolutely raises the venous pressure, provided the abdomen be not massaged too vigorously; when this is done a rise in all pressures occurs. 7. Warm temperature plus massage, as in the Aix douche, has a more powerful effect in the same direction than dry massage alone. The effect of a series of Aix douches is cumulative. 8. The effect of exercise on the blood pressure depends on the severity of the exertion. In all forms an initial rise in arterial pressure occurs; if the exercise be mild, a fall occurs during its continuance; if severe, the rise is maintained; after exercise, moderate or severe, a fall takes place. The venous pressure is raised during all forms of exercise and remains raised during the subsequent arterial fall. The return to normal after exercise takes place more or less rapidly, according to the gentleness or severity of the exercise and the temperature of the atmosphere.

Systematic Muscular Development as a Radical Cure of Hernia. A. A. WARREN.—The principal point in this paper is the value and importance of systematic muscular exercise as a substitute for operation in hernia, especially in the young. The author has followed a number of cases in which great benefit occurred by strengthening the abdominal muscles in this way, and he claims that gymnasts and athletes generally show a much more firm and smaller internal ring than do ordinary individuals. He suggests the following exercises as among the best for patients to take: 1. The patient, with his hands at his side, raises himself from the dorsal decubitus to a sitting posture twenty or thirty times, twice or oftener each day. 2. Similarly from the horizontal position, let both legs be raised from the ground almost to a perpendicular; this also twenty or thirty times till there is distinct fatigue. 3. Modify the first of these three exercises by raising the body sidewise in a rotary movement, and thus exercise the obliques. Similar modification may be introduced by extending the arms during the movements, by the use of dumb-bells or exercisers, and so on.

Revista Med. de Chile (Santiago), March.

Toxic Action of Benzene and Some of Its Derivatives. A. L. SILVA. The kidney and the liver are the organs studied in this connection, and a diffuse inflammation found to be the type of the lesions produced by benzene, phenol, nitrobenzene and anilin, which affect the kidney and liver as a protoplasmic poison, attacking the tissues directly, or disturbing by the same mechanism the centers regulating the circulation or destroying the vital elements in the blood.

Bulletin de la Societe Medicale des Hopitaux (Paris), June 1.

Linear Scarifications in Treatment of Ulcerations of Cervix Uteri. A. SREBRY.—The cervix is drawn out and scarified with fine strokes, as close together and deep as possible and crossed, similar to the dermatologic treatment of acne, etc. No pain is experienced and the blood that issues from the scarifications is never important, not requiring hemostasis. Four or five seances are usually necessary to scarify every scrap of the diseased or ectopic tissue and evacuate any cysts that may be found. The results are highly satisfactory, and the cysts do not recur.

Journal des Sciences Medicales de Lille, May 20.

Surgical Treatment of Female Incontinence of Urine. H. FALQUEE.—The aim of Fischer's operation for essential incontinence of urine in women is to sever the nerves connecting the urethra or bladder or both with the genital organs, and other methods of intervention have only succeeded when this was unconsciously accomplished. A small, long flap a centimeter in width is cut out of the tissue of the vaginal mucosa each side of the urinary meatus after two vertical incisions, leaving the urinary meatus at the lower end of the urethra untouched. The raw edges are left to cicatrize separately, with a strip of gauze between, although each of the lips is sutured with fine silk. This "lateral and inferior liberation of the meatus" includes the resection of any adhesions or bridges binding down the meatus, and will be found successful in all forms of incontinence of urine in females.

Revue Generale d'Ophthalmologie (Paris), May 30.

Prophylaxis of Expulsive Hemorrhage After Removal of a Cataract. PRIBON.—Two observations are reported of this complication, both in persons about 74 years of age, both affected with pronounced arteriosclerosis. In one the hemorrhage occurred at once and the entire contents of the eyeball were expelled, which was prevented in the other by introducing the scissors into the hernia of the vitreous body, beneath which a mass of blood could be seen, and cutting down to this mass, thus allowing the blood to escape freely. There was slow, persistent hemorrhage for six days, and later hyperemia, iritis and a pupillary exudation, but the perception of light was retained, and sight seems to be gradually improving. To avoid a similar complication when removing the cataract from the other eye in these two cases, Peschel made a wide dissection in the shape of a letter N, not allowing any aqueous humor to escape. Four to seven days later he did a small vertical linear keratotomy in the temporal half of the cornea, crossing the membrane rather obliquely, and then by slight pressure expelling the softened remnants of the lens, completing the evacuation with a David curette; scopolanin and dressing. In the second case he reopened the wound in the cornea in five days to remove the last scraps of the lens. Recovery was normal in the first, vision 10-20. There was slight hyperemia and irritation in the other case, and vision 10-40.

Centralblatt f. Chirurgie (Leipzig), June 3.

Simple Method of Trephining for Intracerebral Injections. A. KOCHER.—This communication is not a plea for these in-

jections, but merely an announcement that the technic is absolutely simple and harmless and requires no special skill on the part of the general practitioner. After a subcutaneous injection of 1 per cent. solution of cocaine, the skull is bored through with a small drill held perpendicularly, the drill withdrawn and the syringe needle inserted in its place into the brain matter. The spot best adapted is 2.5 to 3 cm. laterally from the bregma, in front of the precentral sulcus, on a level with the sulcus between the middle and superior convolutions. This spot allows the passage into the ventricle without injury to the motor centers. Four cases of tetanus observed recently at the hospital (Berne) were all treated with these intracerebral injections of tetanus antitoxin and all recovered.

Deutsche Medicinische Wochenschrift (Berlin), June 1 and 8.

New Modification of Suspension Treatment for Nervous Troubles. S. H. SCHUBERT.—The inconvenience that the weight of the limbs is unnecessarily added to the weight of the suspended spinal portion of the body, and several other inconveniences of the usual methods, are obviated by this modification, which suspends the patient seated. A large pulley wheel is mounted on top of a solid post, and a rope passes over it, from one end of which the subject is suspended by means of weights on the other end of the rope. The subject sits on a chair or seat projecting from the post, and is suspended by the head and elbows. Bearing down on the elbows relieves the pressure on the head, and the weights can be graduated to suit individual cases.

Restoration of Function of Arm in Case of Paralysis of Deltoid Muscle. M. ROTHMANN.—By means of daily passive movements of the arm, galvanization and practicing the other muscles of the shoulder, Rothmann succeeded in restoring satisfactory function in an arm paralyzed after acute articular rheumatism, notwithstanding the persisting paralysis of the deltoid.

Injections of Toxin into Brain. J. BRUNO.—Injected directly into the brain, the effect of morphia, for instance, is not at all the usual picture of intoxication with this alkaloid, but violent clonic and tonic spasms are produced, showing a local irritation of the subcortical centers known to be the spasm centers in the rabbit. A very much smaller amount will produce intoxication by this method, and experiments with sodium ferrocyanid and methylene blue demonstrate that the fluid injected makes its way through the lymph-passages into the ventricles and thus produces the direct local irritation of the subcortical centers. Intoxication follows the injection of any substance that chemically acts the protoplasm of the brain cells; ferrocyanid, for instance, harmless injected into the general circulation, produces violent intoxication by this route, but indifferent substances, such as sugar, urea, salt and Glauber's salts, produce no reaction. It is evident that it is impossible to draw any conclusions in regard to the general effect of a substance circulating in the blood from the effect of these local cerebral injections.

Muenchener Medicinische Wochenschrift, June 6.

Accidents After Manipulative Reposition. H. KAPOSI.—Pays reported last year a case of fatal fatty embolism after "brisement force" on account of ankylosis of the knee-joint, and five somewhat similar cases are on record. Czerny recently undertook to correct a flatfoot by manipulations without force, under ether, and the application of a plaster cast. The foot seemed perfectly healthy, but an acute osteomyelitis developed, with complete necrosis of the cuboid, threatening amputation, and leaving the foot in a much worse condition than before, the patient a boy of 15, not very strong, but of healthy parents. He also reports a second case of accident: a young woman, whose clubfoot he corrected by manipulations and section of Achilles' tendon and plantar fascia. The nervous plantaris must have been unduly stretched, however, as a neuritis developed, causing insomnia, general nervousness, pain and lack of appetite, lasting for six months.

Wiener Klinische Rundschau, June 4.

New Method of Determining Amount of Urea in Urine. E. FREUND and G. TOEFFEL.—Equal parts of normal concentrated urine and 95 per cent. alcohol (5 c.c.) are evaporated to dryness on the water-bath, extracted with absolute alcohol and filtered, the alcohol then evaporated to a mere trace and about 70 c.c. of a saturated ethereal solution of oxalic acid poured over and left to settle. The ethereal solution is then carefully poured off over a filter, leaving the residue in the filter, in which it can be washed in several portions with 60 to 80 c.c. of ether. When the filter is dry the contents are washed and titrated with two drops of a 1 per cent. solution of phenol phthalein until decidedly red, and then the nitrogen determined by Kjeldahl's method: 1 c.c. $\frac{1}{4}$ normal solution of sodium solution corresponds to 0.015 gram of urea. Al-

bumin or sugar in the urine does not affect the accuracy of the test.

Wiener Klinische Wochenschrift, June 1.

Dangers of Application of Murphy Button. R. FORGES.—In the course of an operation for carcinoma, involving the pylorus and transverse colon, the Murphy button was applied to the colon, at a point exactly over the spine. The patient complained of a sensation as if a stone were resting heavily where the tumor had been, and, later, symptoms of occlusion developed, terminating fatally. At the autopsy the anastomosis was found perfect, but the duodenum was compressed and its lumen closed between the Murphy button and the spine. The enforced rest in bed and compressing bandage had contributed to this effect, which could easily have been avoided if such an experience had ever been recorded before as a warning.

Gaceta Medica (Mexico), May 15.

Bacteriologic Study of Yellow Fever. A. MATIENZO.—The conclusions of this study of a number of cases of unmistakable yellow fever observed at Tampico are that none of the microbes discovered to date are the specific agent of yellow fever, posure to 15 degrees C. below zero fails to affect its virulence and development, and other characteristics proclaim its kinship with the coli bacillus and Eberth's bacillus. Sanarelli himself states that it is impossible to isolate it in more than 58 per cent. of the cases. Matienzo believes that the true agent is an infinitesimal organism, impossible to discover with our present means of research, "smaller than the infinitely small," as is probably also the case with hydrophobia, small-pox and measles.

Nord Medical (Lille), June 1.

Thyroid Treatment to Accelerate Consolidation of Fractures. LAMBRET.—The JOURNAL has called attention to the success obtained in several cases of tardy consolidation by administering thyroid extract, and this effect has been confirmed by later experiences related in the *Brazil Medico* and other exchanges. Lambret now announces that he administers thyroid extract in appropriate cases from the beginning, and finds consolidation wonderfully accelerated. He describes one case in particular, a fractured limb; the patient was walking on it the seventeenth day. Sixty centigrams of thyroïdin were administered every day.

Lyclop. Russkoi Chirurgii, No. 1.

Surgery of Lung and Diagnosis of Pleural Adhesions. K. SsAPESHKO.—The writer has been remarkably successful in his interventions on the lungs for cavities, gangrene, abscesses, etc., restricting operation to regions he knew to be surrounded by preexisting adhesions, only requiring strengthening with a few stitches. He diagnoses pleural adhesions and defines their limits by means of a blunt, hollow, eyeless needle with one opening in the side 1 to 2 mm from the tip. The other end is connected by a rubber tube with a two-branched glass tube which serves as a manometer. The blunt tip of the needle is inserted through a small incision in the skin and slowly pushed through the musculature and into the pleura costalis, when it makes a peculiar sound. Pushing it still farther, if the pleura is free from adhesions, the needle pushes up the lung, and as soon as the opening in the needle enters the pleural cavity, the fluid is aspirated into the needle by the negative pressure in the cavity, and the fluid in the manometer rises. If the fluid remains unvaried, this is evidence that there is no pleural cavity at this point, and that the walls are adherent. This test has been frequently applied and has never failed. Ssapesko has also succeeded in producing adhesions artificially—dogs—by injecting one gram of a 5 per cent. solution of formalin, or 10 to 20 per cent of potassium, or 10 per cent of nitrate of silver. He is confident that adhesions could also be produced in the human pleura in five to seven days by injecting five or six drops of a 1 to 2 per cent. solution of formalin with the needle above described, after injecting five to ten drops of a 5 per cent. solution of cocaine.

Plastic Restoration of Urethra with Continence. G. D. ROMA.—He reports a new plastic urethra made in a case in which the urethra had been completely destroyed. It was then twisted as Gersuny suggests for the rectum, in two sitings, 180 degrees each time. The patient has complete control of the emission of urine, even when the bladder is full, except when she reclines on the left side.

St. Petersburg Medicinische Wochenschrift, May 27.

Treatment of Syphilis with Specific Serum. A. VYEVODOVSKI.—Sixteen patients with fresh syphilis injected with serum from others in the late condylomatous and tertiary stages, were very much improved and all manifestations disappeared. The effect on the blood was especially marked.

the amount of hemoglobin, the number of red corpuscles and the morphologic metamorphosis of the white corpuscles all very much increased. This effect on the blood is specific, as control tests with normal serum were entirely negative. In one case, completely freed from all syphilitic manifestations by the serum treatment, January, 1896, there has been no recurrence.

Torsion of Cecum. E. CANDAU.—The writer adds another to the twenty-five cases on record in which the cecum was twisted on its axis, closing the lumen. The thirteen unoperated cases all died, and in this case there were evidences of commencing peritonitis when the laparotomy was done, fifty-four hours after the patient felt "something go wrong" when lifting a heavy weight after a hearty meal. The cecum was merely straightened and replaced.

Societies.

International Conference for Regulation of Introduction of Spirits into Africa.—This conference, which recently met at Brussels, with twelve powers represented, passed resolutions to have the import duties on spirits very much increased, according to *Sen. Med.*, June 14.

Indian Territory Medical Association.—At the annual meeting of this Association, held at South McAlester, June 20-21, the following officers were elected for the ensuing year: president, G. A. McBride, Ft. Gibson; first vice president, F. S. Clinton, Luka; second vice president, W. O. Shannon, Durant; secretary and treasurer, LeRoy Long, Caddo. The next meeting is to be held at Wagoner in December next.

Seventh Russian Medical Congress.—One of the most interesting communications presented at this successful Congress, at Kazan in May, was the report of E. Assendelft, a general practitioner in a remote corner of Russia, who has kept up with the achievements of modern surgery in his isolation, and reported 669 operations for calculi with a mortality of only 2 per cent., and no deaths in a series of 100 cases of sectio alii, out of a total of 400.

Delaware State Medical Society.—The 110th annual meeting of this Society convened in Wilmington, June 13, the address of welcome being made by Dr. Henry R. Spruance. The election of officers resulted in: president, O. D. Robinson, Georgetown; first vice president, William H. Hancker, Farnhurst; second vice president, John W. Clifton, Clayton; secretary, John Palmer, Jr., Wilmington; assistant secretary, William P. Orr, Lewes. The next meeting will be held in Rehoboth.

Tri-State Medical Association.—This Association, embracing members from Maryland, Pennsylvania and West Virginia, elected the following officers at the close of a two-days session at Markleton Sanitarium, Pa., June 22: president, J. M. Spear, Cumberland; vice presidents, Americus Enfield, Bedford, Pa., R. Gerstle, Elk Garden, West Va., and W. J. Craigie, Cumberland; recording secretary, Percival W. Lantz, Alaeka, West Va.; corresponding secretary, F. W. Fachtman, Cumberland; treasurer, H. W. Hodgson, Cumberland.

South Dakota Medical Society.—At the recent meeting of this society, held in Yankton, S. D., the following officers were elected: president, D. W. Rudgers, Yankton; first vice president, T. F. Beveredge, Bridgewater; second vice president, C. M. Keeling, Springfield; secretary and treasurer, W. J. Maytum, Alexandria; assistant secretary, L. F. Diefendorf, Aberdeen. In a discussion of a new medical law, one similar to the present Alabama law was favored and funds were appropriated for having such a law drafted, while every effort will be made to secure its passage by the next legislature, January, 1901.

American Neurological Association.—This Association, at the annual meeting, held in Atlantic City, N. J., recently, elected officers as follows: president, E. D. Fisher, New York; first vice president, Morton Prince, Boston; second vice president,

James W. Putnam, Buffalo, N. Y.; secretary and treasurer, Graeme M. Hammond, New York; councilors, James Hendrie Lloyd, Philadelphia, and Joseph Collins, New York; honorary member, Dr. Robert T. Edes, Boston. The next meeting will be held at Washington, D. C., in May, 1900.

Minnesota State Medical Society.—The new officers of this Society, the annual meeting having just closed in St. Paul, are: president, Walter Courtney, Brainerd; first vice-president, W. H. Magie, Duluth; second vice president, Helen Bissell, St. Paul; third vice-president, E. E. Bennett, Glencoe; treasurer, K. J. Hill, Minneapolis; secretary, Norman Davis, St. Paul. The question of the disposition of the \$200 donated by the Society to the New Richmond cyclone sufferers came up, and it was decided to divide the money equally among the three practicing physicians of New Richmond, all of whom lost their homes by the disaster. The Society will meet in Duluth the last Wednesday in June, 1900. A further report of the meeting will appear in the JOURNAL.

St. Louis Medical Library Association.—This Association was recently organized and a goodly number of the representative physicians of St. Louis have joined. The intent of the organization is the development of a medical library which will be in harmony with the dignity and best interests of the medical profession of St. Louis. The following officers were elected for the year 1899: president, N. B. Carson; vice-president, John H. Duncan; secretary, F. L. Henderson; treasurer, A. R. Kieffer; librarian, Frank J. Lutz. The headquarters of the library are in the Young Men's Christian Association Building. The Association requests the various medical journals of the United States to put their journals on file with the Association, and would be glad to receive books from publishers, and indeed from all interested in the organization. Due credit for all contributions will be given.

French Congress of Ophthalmology.—Among the communications presented at this Congress, held at Paris recently, was Antonelli's report of fine results obtained in lachrymal affections with very small sounds made of gelatin and 50 per cent. protargol. Rohmer warmly endorsed the practice of open treatment of the eyes after operations for cataract. He has fully established that the natural occlusion of the lids and the lachrymal secretions maintain the aseptic conditions realized, while the daylight favors the contraction of the pupil and lessens the danger of hernia of the iris. He has his patients wear a small, light, loose curtain bandage over the eye, merely as a reminder not to touch them with the fingers. Gourfein stated that the lachrymal sac in rabbits can be infected with solid cultures of Koch's bacillus. De Wecker described his successful efforts to divert the exosmotic current traversing the retina, attracted by the excess of salts in the vitreous body, which he assumes may be the primary cause of detachment of the retina. He injects for this purpose salt solutions under the conjunctiva and the capsule of Tenon, preferring sodium sulphate and gelatin. This treatment favors spontaneous cure and can do no harm.

American Proctological Society.

Meeting, held at Columbus, Ohio, June 6, 7, 1899.

SPECIALISM IN RECTAL DISEASES.

Dr. JOSEPH M. MATHEWS, Louisville, delivered this address setting forth the importance of giving rectal diseases special study, and said in part: "It is a notorious fact that there is more quackery practiced in the diseases of the rectum than in any other department of medical practice. This state of things is to be deplored. These important and most serious affections should be entitled to a separate and special consideration; and who will dare to say that those who practice them are not entitled to the privilege of forming themselves into a society? Nothing will contribute more to the advancement and to the elevation of this long neglected subject than this contemplated organization. The principal part of our knowledge must ever

come from comparing our own observations with those of others; then how apparent to all must be the utility which the Society will afford in opportunities for the mutual communication of thought and action."

PRURITUS ANI.

Dr. TUTTLE said that the term "pruritus ani" has for the scientific physician only a vague significance, but for its victims it is portentous with evil. The condition should be dealt with, constitutionally, then locally. He is not a believer in pruritus anieentially. The constitutional condition on which the theory of this disease is founded, he admits, and reckons it an important element; but he insists that there is always an exciting cause for the disturbance and on this cause will depend the physical appearance of the parts; and we know full well the diseases which cause these physical changes in the parts, and these diseases occurring in the dysesthetic patient instead of causing pain produce itching until the irritation and scratching of the parts produce pain.

Among the causes enumerated, he mentioned oxyuris vermicularis, colitis, sigmoiditis, catarrhal diseases of the rectum and uric acidemia. These pathologic conditions are the ones which he has found most often in obstinate and obscure cases. To the scientific physician all treatment must be based on his conception of the pathology of the case; remove the pathologic cause, treat the disease and not the symptom. Nitrogenous diet, alkaline diuretics, salicylic compounds and hot baths compose the general routine of treatment. Local applications of carbolic solutions, larkspur, black wash, salicylic acid, chloral hydrate, extract conii, camphor, cocaine, tar, etc., may all be used in one form or another. Having determined the variety and type of the disease producing pruritus, it is not difficult to manage, and in most cases we may confidently expect a radical cure.

MODIFICATION OF WHITEHEAD'S OPERATION FOR HEMORRHOIDS.

Dr. EARLE of Baltimore, after reviewing usual methods of operations for removal of hemorrhoids, described his own method, which consists of clamping the tumors by sections, beginning at an incision in the fourchette where primary incision is made to determine the depth at which to place the clamp. After removing the tissue above the clamp by piecemeal a continuous suture, beginning at the primary incision, is inserted around the clamp. When the first section has been cut away and sutured, the clamp is removed and the suture drawn taut, and the clamp again put in position until the whole anal circuit has been treated. He has given this method a thorough trial, and unhesitatingly considers it the safest, easiest, and by far the best method he has ever tried. The operation is practically bloodless, and healing by first intention is secured. The convalescence is complete at the end of the week.

ACT OF DEFECATION.

Dr. THOMAS CHARLES MARTIN, Cleveland, said that a knowledge of the anatomy of the rectum is necessary to form an appreciation of the physiology of defecation. The bundles of circular fibers which constitute the muscular element of the rectal valve belong to the same mechanism and have the same function as those which form the ental sphincter. It is the function of the normal rectal valve to beneficently retard the descent of the feces, and it is obviously true that it may be the especial property of the valve in certain other than normal conditions to maliciously obstruct the descent of the feces. His experience convinced him that a perfect knowledge of the rectal valve constitutes the key to an understanding of obstipation, rectal stricture and their sequelae.

CONSTIPATION FROM THE STANDPOINT OF THE PROCTOLOGIST.

Dr. A. B. COOKE, Nashville, read an exhaustive paper on this subject, and defined constipation as a diseased condition of the alimentary canal characterized by a modification of function which results in the pathologic retention of fecal matter. He stated among the causes: 1, those springing from the violation of hygienic law; 2, defective innervation, expressed either in atony of the muscular coat of the intestine or in decreased secretion; 3, sluggishness of bowel function; 4, the habitual use of purgative medicines; 5, mechanic obstruction; 6, painful affection of the anus.

The relations between constipation and disease of the rectum are intimate and noteworthy in that either may be cause, effect, or both, with reference to the other. Rectal reflexes came in for a fair share of consideration. In conclusion he stated as his conviction that in a large proportion of cases constipation either originates in or is maintained by causes located in the distal ten inches of the intestinal tract. If this be true, the notorious inadequacy of ordinary treatment is at once accounted for, and the duty of the proctologist in the premises becomes obvious.

RECTAL ADENOMATA.

Dr. WILLIAM M. BEACH, Pittsburgh, presented this subject. He defined an adenoma as a hypertrophy of gland texture, noted briefly the nature of these growths and the value of the proctoscope in their early diagnosis and treatment. There are two principal types of adenomata: 1, the gelatinous, composed of elements of mucous membrane; 2, the mixed variety, consisting of mucosa and submucous cellular tissue. The adenoma with a long pedicle is benign, while growths with a broad base tend to malignity.

After discussing symptoms and complications, he pointed out that by means of the old methods of examining the rectum it is well nigh impossible to locate these growths of the upper rectum; and that the newer proctology substitutes exact methods in diagnosis and treatment of non-malignant adenomata that are most gratifying to both the patient and surgeon.

In conclusion he said that: 1, rectal adenoma may be hard or soft and contain the constituent elements of the mucosa and submucosa; 2, these growths are benign and malignant; 3, benign in their origin, they may become malignant; 4 early recognition is of first importance, and is made possible by the new methods of inspection.

POST-OPERATIVE TREATMENT OF HEMORRHOIDS.

Dr. J. R. PENNINGTON, Chicago, presented this subject, his tampon having been described in the JOURNAL of May, 13, p. 1081.

Illinois Society for Prevention of Consumption.

Prominent physicians and laymen organized this society at a meeting held in the rooms of the Chicago Medical Society, June 20, 1899.

The meeting was called to order by Dr. ARTHUR DEAN BEVAN, president of the Chicago Medical Society, who said that the prevention of tuberculosis is an important object, not only to the physician, but to the general public. Already so much has been accomplished by modern medicine in the prevention of disease, that difficult as the problem may seem, he ventures to predict that just as surgeons have prevented wound infection and suppuration in their operative work by the application of methods based on scientific knowledge of the causes of wound infection, so in the next few years it will be possible for the medical profession, aided by a better-educated public opinion and by state and municipal authorities, to practically eliminate tuberculosis from the community. Much has been done by German authorities in preventing trichinosis by proper inspection of hog products. Ten years ago trichinosis was common in Germany, and was the cause of a great many deaths, while now it is a comparatively rare and exceptional disease. Clinical research and laboratory investigation have proven conclusively that tuberculosis, like trichinosis, is one of the diseases communicated by animals to man. In this connection, he said he had now in his laboratory a microscopic section which furnishes a good deal of food for thought in this relation. From a butcher suffering from lupus of the face, diseased tissue was removed and Thiersch grafts placed over the raw surface. In the section there were found not only typical tubercular areas and bacilli of tuberculosis, but also trichinae. Undoubtedly this butcher got the trichinae from the pork which he had eaten. It is possible that in the same way he acquired tubercle bacilli from the animal food products which he handled.

Laboratory investigation has shown that a large proportion of the milk used in our cities contains bacilli of tuberculosis. The same may be said of butter, but to a less extent. Considering these facts: 1, that tuberculosis is produced by a known germ, and, 2, that the disease may be transmitted through some product of food or by some individual suffering from the disease, it does seem within the power of man, with our present knowledge, to eliminate this common disease from the community. To do this, we must have a widespread knowledge of facts. Public opinion must be educated, and we must succeed in obtaining laws which will prevent tuberculosis by proper inspection of dairies, etc.

REPORT OF COMMITTEE ON TUBERCULOSIS.

Dr. ARTHUR R. REYNOLDS read the report of the committee appointed last December.

"The undersigned, members of the general committee on tuberculosis, of the Chicago Medical Society, appointed for the purpose of formulating plans for the organization of a society for the prevention of tuberculosis, beg to submit the following report and recommendations:

"1. The formation of such a society, chartered by the State of Illinois under the act concerning corporations, is urgently rec-

ommended, and the time is opportune by reason of the universal popular interest in the disease. The society should be framed with reference to the popular interest. Hence its membership should consist, not only of medical men, but of the laity generally, and of both men and women.

"While it requires but three individuals to incorporate, its board of trustees should be large enough to insure a full representation of all desirable interests, and since it is proposed to extend its operation throughout the State, provision should be made for trustees from localities outside of Chicago. Their number may be fixed by the laws and need be specified in the certificate of incorporation."

On motion, the report of the committee was received and the committee discharged.

Hon. CARTER H. HARRISON, mayor of Chicago, took the chair, and said the magnitude of the work to be undertaken is shown by the fact that one-tenth of all deaths are due to tuberculosis, and that being true, any effort made by the physicians of Chicago or anywhere else in the Nation to remove the cause of this dreadful disease and to discover means of exterminating it would be gladly welcomed and the subject of gratulation of citizens.

On motion, Dr. JOHN A. ROBISON was elected secretary pro tem of the meeting.

On motion of Dr. EDWARDS, a committee was appointed to report on constitution and by laws of the society.

Mr. JESSE COX was then introduced and said that tuberculosis is a disease due primarily to poverty and ignorance—ignorance which prevents people from knowing what to do to prevent the disease, and poverty preventing them from being able to carry out what they do know. As long as these two factors prevail, not all societies would be enabled to fully eradicate the disease, but much could be done toward its extermination by such a society as this. The public can be educated; the legislature can be educated and perhaps acted on in other ways. Laws can be enacted which will enable officers to meet the different regulations which can minimize the disease.

Dr. L. G. MARILLET spoke on behalf of the Chicago Veterinary Society, and presented a summary of some of the points which he was prepared to demonstrate: 1. That the tuberculin test for bovine tuberculosis is sufficiently reliable to be practical. 2. That the sale of milk from tuberculous cattle should be absolutely prohibited, and that the apparent absence of tuberculous processes in the mammae of a cow is no assurance of non-infectious milk. 3. That tuberculosis is raging among the dairies of Chicago and vicinity, and the population of Chicago is actually being infected with tuberculosis through its milk supply. This is a broad statement, calculated to scare people, but it is not made with any such intention. It is simply a fact which he is prepared to demonstrate. 4. That proper veterinary inspection of dairies will eventually result in purifying the supply, and such inspection can be conducted at very moderate cost. 5. That such inspection should be conducted under the directions of the Commissioner of Health of the City of Chicago, who, in turn, should collaborate with the state officers in their efforts to entirely exterminate the disease from domestic animals.

Dr. A. S. ALEXANDER followed and said that in order to insure absolutely wholesome, pure, innocuous milk we must have: 1. A perfectly healthy, clean cow. 2. She must be fed on perfect, sound, sweet, nutritious food. 3. She must drink uncontaminated water. 4. She must be surrounded by perfect sanitary environment and housed in a fine stable. 5. The milk so produced must be protected against secondary infection. Tuberculosis may be eradicated from any stable by the proper use of tuberculin.

Dr. WILLIAM A. EVANS, continuing the discussion, said it was not his purpose to say anything relative to the methods by which the work of the society is to be accomplished. He desired to speak to three propositions: 1. Tuberculosis is the most widespread and deadly of all diseases. 2. Its economic importance. 3. The conditions arising from tuberculosis are remediable. He said in part: Of deaths from all causes throughout the world sanitarians are agreed that approximately one in seven is due to tuberculosis. Hirsch says that each year throughout the world five million people die from this disease, the nature of which is understood. It is a disease which is preventable. According to the census of 1890, 102,188 people died of tuberculosis in the United States during that year. Recognizing the fact that statistics on the subject of tuberculosis are always below proper statistics, and recognizing the advantage, if not necessity, of concealing deaths from this fell disease, it is easy to be seen that the number of people who die from tuberculosis in the United States each year must reach 150,000. This is a safe estimate. According to the statistics of Zubiana, there die each year in

France from 150,000 to 200,000. In Germany, according to the statistics of Leyden, the number of deaths attributed to this disease each year is 170,000. According to the statistics of Tatham, endorsed by Ransome and Thorne, they die annually in England and Wales, 60,000 people or 241 for each 100,000; Vienna, 450 for each 100,000; Buda Pest, 616 for each 100,000. In Philadelphia the annual death rate from this disease reaches 2800, or 11.6 of the total death rate. In New York City the annual death rate from tuberculosis is 3500 approximately. In Chicago, from 1857 to 1896, 39,000 people died from this disease, thus constituting $\frac{1}{10}$ of the entire mortality for this city. In the last six months, according to the statistics of the Health Department, there were 1552 deaths from tuberculosis, or a death to 8.4 per cent. According to the statistics of France, Austria, Germany and Italy, approximately one-fifth of the entire death rate of those countries is due to consumption. According to the Woman's Commission of Germany, at any given moment one out of fifty are either subject to or are suffering from this disease. On the basis of one out of sixty inhabitants, this means that to day there are in these United States 1,100,000 people suffering from tuberculosis. Figured on this basis, it means that in Chicago to-night there are 30,000 people who are affected with this disease. Biggs and Prudden of the Health Department of New York City say it is within the range of probability that there are 20,000 people walking the streets of New York serving as foci of infection for the spread of this infectious, contagious disease.

Dr. Evans then compared the death-rate from tuberculosis with the death-rate from other diseases, and gave the following: Smallpox and scarlet fever, 30 to 1; typhoid, 16 to 1; cholera, 5 to 1; all combined, $4\frac{1}{2}$ to 1. Tuberculosis kills thirty times as many people in Germany as do smallpox and scarlet fever combined. It kills sixteen times as many people as does typhoid fever; it kills eight times as many as does diphtheria; it kills $4\frac{1}{2}$ times as many as smallpox, scarlet fever, typhoid and diphtheria combined. According to the statistics of Laveran, from 1832 to 1854 cholera killed 57,335, while tuberculosis kills the same number of people in one third of one year. According to the figures of Celli for Italy, from 1805 to 1863, cholera killed 214,657 people, and during the same length of time tuberculosis killed 2,000,000 people. Says Anders: "I have found from an examination of the literature and of the available official statistics, that in all great cities in which active measures have been taken to obviate the spread of tuberculosis, there has taken place a decided, though gradual decrease in the death rate from this fell disease."

All sanitary legislation is based on antecedent education, and this is the philosophy of our existence to-night. There can come no legislation capable of coping with this disease until such a public sentiment has been created, until such a public view has been established that he who makes law will read what the sky contains for him. Ignorance is responsible for the conditions that exist. To awaken public conscience we must awaken public intelligence, and the scope of this Society is to awaken public conscience by reason of an awakening of public intelligence. A disease so well understood is one which can and surely will be combated. Practically every bit of laboratory work has been gone over in connection with this disease. The laboratories must furnish us facts that we can make all potent and all powerful.

Dr. Evans then concluded by quoting the words of the Prince of Wales in opening the British Conference on this subject. "You tell me that tuberculosis is a preventable disease. If preventable, then why not prevent it."

At the conclusion of Dr. Evans' remarks, the report of the Committee on Constitution and By-Laws was read, and, after some discussion, was adopted.

Officers were elected as follows: honorary president, N. S. Davis, Sr.; president, John MacLaren; first vice-president, William A. Evans; second vice-president, Edwin Klebs; third vice-president, A. H. Baker; secretary, John A. Robison; treasurer, Elbridge G. Keith; councillor, John P. Wilson; trustees—for one year, Frank Billings, J. B. Murphy, Truman W. Miller, A. H. Baker, Joseph Hughes; for two years, Mayor C. H. Harrison, Otto Young, N. S. Davis, L. O. Goddard, A. R. Edwards; for three years, Arthur Dixon, D. B. Scully, E. B. Gurler, John B. Sherman.

The efforts of the Society with regard to legislative action will be: To urge the State Legislature to appropriate a fund adequate to the needs of the State Board of Live Stock Commissioners; this sum to be probably \$50,000 for the first year, \$30,000 for the second, and \$20,000 the third.

To insist that the Legislature augment the executive force of the Live Stock Commission sufficiently to enable the Commission properly to fulfill its duties.

To urge that the Commission be empowered to administer

the tuberculin test to all cattle in the state without the consent, or, if necessary, against the wishes of owners of cattle.

To make it necessary that the Commission begin a systematic examination of all cattle in the state, in which all cattle not proving under the tuberculin test to be free from tuberculosis shall be condemned, and the owners compensated by the state at the scale of prices fixed by the Live Stock Commissioners.

To devise and recommend an efficacious plan for the prevention of the sale of tuberculous milk in Chicago; this plan, modeled for the most part after the method adopted by Buffalo, to recommend that the Common Council enact an ordinance creating a force of experts in veterinary medicine whose duty it shall be regularly to inspect the dairies supplying milk to the Chicago market, whether or not such dairies be within the city limits; and the plan further to provide that no can of milk shall enter the milk depots of Chicago without a number corresponding with a number on the sanitary report of the dairy from which the milk was shipped.

It is said, the Board of Trustees of the Society will meet on the first Saturdays in January, April, July and October. The Society will meet annually or oftener, if deemed necessary.

Chicago Medical Society.

Regular Meeting, held June 21, 1899.

SCIENCE OF MEDICINE AND ITS RELATIONS TO THE PUBLIC.

D. ARTHUR DEAN BEVAN delivered an address as president of the society. He began by saying that there is to day, at the close of the nineteenth century, a science of medicine just as truly as there is a science of chemistry, or of astronomy or anatomy. It is customary to deny to medicine the right to be called a science, and in the past centuries, and even until the past decades of the present century it was very proper to withhold this right; but the birth and development of modern pathology and bacteriology, and the development of physiology and anatomy and chemistry have changed this. These sciences are entitled to the highest claim of science and medicine which, in a broad sense, is the study of the human body in health and disease, and resting largely on these collateral sciences, has itself become a science. It is difficult for some medical men and for the public to realize this fact. Its general recognition will be a great gain for the world. Such a recognition must abolish from the thinking mind the poor, weak, temporary dogmas which have always clung to the skirts of medicine and which have masqueraded as new schools of medicine. Because if medicine is a science, there can be but one science of medicine. There can be no room for dogmas, and these dogmas dead will exist only as dried specimens on the shelves of medical history. If new dogmas arise, they will find adherents only among the queer people who to day still consult the astrologer or clairvoyant.

To prove that medicine is to day a science, let a few cases be examined with a modern medical man. A patient presents herself to the physician with a history of cough and emaciation. The physician analyzes the body of this patient as a chemist would analyze a substance submitted to him for examination. He considers the form, color, temperature of the body and the density of the lung tissue. He examines the sputum and finds the bacilli of tuberculosis. As a result of his analysis, his finding is that the patient has tuberculosis. Just as one chemist analyzes a substance and finds arsenic in it, so a man presents himself to a surgeon with a tumor of the neck, the surgeon considers the history, examines a small piece of the tissue under the microscope and finds actinomycetes. As a result of his examination, he knows that the patient has lumpy jaw, just as the chemist might analyze a piece of ore and find gold in it.

Medicine is a science and, like all sciences, it is dependent on other sciences. Just as chemistry is dependent on physics and mathematics, so medicine is dependent on chemistry, pathology and anatomy. Medicine does not hesitate to borrow from any branch of knowledge that may aid in its development, and it follows that as these aiding sciences develop medicine will advance. Medicine must lead the world know that it began the twentieth century as a pure science, and that it has left behind it the mystery, the superstition, the dogmas of the past.

The teaching of medicine must be in the hands of scientists. Students of medicine must be taught its truths and its limitations. The public with its evergrowing ability to grasp knowledge, must be taught its truths and frankly told its limitations. Nations and communities must learn to recognize great medical truths and enforce laws based on them for the welfare of their citizens. The practice of modern medicine means the

throwing overboard of a large part of the present materia medica. It means the starting on purely scientific lines, the building of a scientific system of therapeutics. Why should not the intelligent patient know that when he has pneumonia or typhoid, or, with few exceptions, almost any form of disease, no physician in the world to day can cure the disease with medicine? If he gets well, he cures himself. All that the physician can do is to surround him with conditions most favorable for his recovery. Let the public possess this knowledge; it will in no way belittle the office of the physician.

The country consumes millions of dollars worth of drugs each year, for the most part to the detriment of the consumers. Is it not the duty of scientific physicians to instruct the public as to the uselessness and danger of such folly. This task of revolutionizing medical practice can not be accomplished in a day; it will require years of time and much labor. It is, however, time to begin; it has already begun.

Medicine as a science will continue to grow; it will crush the dogma and the false, and in the end take its place as the highest and most useful branch of human knowledge.

Dr. Bevan then discussed the great duty which the science of medicine owes to the public, under four heads:

1. By developing and teaching the science and practice of medicine along purely scientific lines.
2. By demanding a high standard of knowledge and efficiency of men desiring to practice medicine.
3. By educating the public in the great truths of medical science.
4. By obtaining national, state and municipal recognition of the great medical truths which can be incorporated into laws for the good of the community.

These four propositions were considered separately. In Chicago there are twenty medical colleges. Possibly three of these are sufficiently well conducted to warrant their recognition as scientific schools; the others have no right to such a claim. They represent either some paltry or a pathologic desire of a group of men for the title of professor and the opportunity to advance and advertise themselves. This results in the turning out of poorly equipped medical men and the lowering of physicians generally in the eyes of the people. Let such professors with their cheaply bought titles pause and think what they are doing. The members of the Chicago Medical Society should place the stamp of their disapproval on such work.

Modern medicine demands a scientific training. The modern medical school must drill its students in the sciences of anatomy, physiology, pathology, chemistry, and pharmacology in well-equipped laboratories. These laboratories must be not only teaching mediums, but workshops for the discovery of new truths. After this preliminary work the student will study medicine, surgery, obstetrics and the specialties in well-equipped hospitals and dispensaries, and these hospitals and dispensaries must be not only places where patients are treated and students study, but they must be true laboratories where the problems of the human body in health and disease will be worked out, and from these laboratories must come the discoveries of new truths.

As our government is constructed, it is probable that it would be impossible to obtain a national law controlling medical practice, although such national control in the opinion of the speaker would be most desirable. In Illinois we are in a transitional stage; spasmodic efforts have been made by the better element of the profession to obtain effective medical legislation. During the last year considerable work was done by the Illinois State Medical Society and the Chicago Medical Society in the attempt to pass a medical bill which would have raised the standard to the present excellent standards of Minnesota and New York. This attempt failed and resulted in a compromise which is unfortunate and must be corrected. Every physician who desires to practice medicine in the State of Illinois should show evidence of a fair preliminary education and of four years' study in a recognized medical school. This evidence should entitle him to come up for examination before a State examining board. He should be examined in the cardinal branches of medicine, and if he shows proper fitness, be granted a license to practice. The diploma should under no circumstances be accepted as evidence of fitness. By united efforts the physicians of Illinois can have a satisfactory medical bill passed through the next legislature.

The third and fourth propositions which Dr. Bevan discussed are so closely correlated that be treated them together, viz.: 3, by educating the public in the great truths of medical science; 4, by obtaining national, state and municipal recognition of the great medical truths which can be incorporated into laws for the good of the community. These are broad subjects and can be but briefly referred to. When we see the good accomplished by vaccination, by quarantine against yellow

fever and cholera, by antitoxin in diphtheria, the lessening of typhoid by pure water supply, the elimination of trichinosis by inspection of hog products, as done in Germany, and now the great awakening in regard to the prevention of tuberculosis, one must be impressed with the tremendous possibilities of preventive medicine. The realization of these possibilities depends on the education of the people in the dangers of disease, the cause of disease, and the practical methods of prevention. When the mass of the people are once educated in dangers and means of prevention of disease, the necessary legislation will soon follow.

Finally, he desired that his address should emphasize two great functions and duties of the Society:

1. A demand for a higher standard of medical education and laws enforcing such demand.

2. The education of the public in the great established truths of medicine; the cause of disease, the known methods of prevention, and laws which will make this knowledge operative and effective.

With high ideals, with united effort, the Chicago Medical Society can accomplish much for the science of medicine and the good of mankind.

Following Dr. Bevan's address, the annual reports of the trustees, editor, treasurer, secretary, auditing and standing committees were read and disposed of.

The election of officers resulted as announced in the JOURNAL, June 24, p. 1458.

Appropriations were then voted for salaries as follows: for secretary, \$300; for treasurer, \$200.

Orleans Parish Medical Society.

Meeting held in New Orleans, La., May 27, 1899.

SPINAL CURVATURE, DORSOCERVICAL.

Dr. H. A. GILBERT related this case, occurring in C. Q., a native of Germany, 62 years of age, the mother of six children. She enjoyed good health up to the time of the climacteric, seven years ago. She was a large well-nourished woman, weighing 245 pounds; there was no history that threw any etiologic light on her case, save that of imprudence in exposing

herself to cold and dampness. About the time of the menopause she was troubled with rheumatism, which readily yielded to treatment. Later the patient lost the use of her left arm by paralysis, subsequently recovering it completely. She was next affected with paralysis of the muscles of the back, the head becoming bent forward and a little to the right, so that the chin came to rest on the sternum, in which position it has remained during the past four years. The patient is quite well otherwise, eating and drinking with zest, while at first she could see objects only when tilted back considerably, and the button holes which she had learned to make in her acquired position were crooked. She can now, thanks to the persistent use by Dr. Gilbert of nuxvomica, iodid of potas-

sium and electricity, not only see persons at some distance from her, but also cut her button holes straight.

Dr. HAMILTON P. JONES was inclined to think that perhaps the condition was due, not to paralysis, but to the adoption of that position which gave greatest relief from rheumatic pain in the neck. In his own attack of rheumatism, some years since, he had felt ease with his head flexed, and he had had to exercise some will power to keep from acquiring a faulty position.

Dr. C. J. MILLER suggested that the case might be one of arthritis deformans. He had had a case of this disease of eleven years' standing, under observation, in which the head was drawn back and there was involvement of various joints, notably of the temporomaxillary, which was the seat of partial ankylosis. In this case no benefit whatever had resulted from rheumatic treatment.

BOWEL TROUBLES IN ADULTS.

Dr. GEO. STUMPF sounded the praises of mercurous chlorid, while Dr. R. J. Mainegra favored the use of opiates and astringents, particularly of the camphorated tincture of opium and preparation of catechu.

Dr. MILLER referred to the treatment of amebic dysentery recommended to him by Dr. W. H. Watkins, a fellow member. During the past eighteen months he has used infusion of ipecac by the rectum in this condition, never failing to obtain relief from tenesmus and bloody stools. Regarding the use of opiates in the enterocolitis of children, he mentioned the fact that in several of these cases he had found albumin in the urine; in one such case opiates had an immediate bad effect, having to be withdrawn.

GNORRHEA AND MARRIAGE.

Dr. H. B. GESSNER brought up the matter of warning patients treated for gonorrhoea not to marry until the disease is known to have been completely cured. He had under his care a young man who contracted gonorrhoea in June, 1898; various injections had been used, causing a disappearance of the discharge from the meatus. Learning recently that this man was about to marry, he caused him to have his semen examined, and gonococci were found. This patient had never been warned of the danger of communicating the disease to an innocent wife. Surely it must be the duty of the physician treating such a case to warn the sufferer of the possible dangers to others, just as he would prohibit marriage for a term of years in a case of syphilis.

Dr. PHILIP ASHER mentioned a case of pyosalpinx operated on by Prof. Ernest Lewis, in which the infection was traced to an attack of gonorrhoea in the husband six years before marriage.

Dr. MILLER knew of three men who had infected their wives through ignorance of the possibility of doing so. In one patient, who had had gonorrhoea a year and a half before, clap threa's were present in the urine. Two weeks of irrigation with permanganate solution caused all evidences of infection to disappear. Three months later his bride developed ovaritis and salpingitis; gonococci were found in the removed adnexa.

Surgeon CORDEIRA, U. S. N., assigned to the cruiser *New Orleans*, made some remarks on the sanitary conditions aboard that vessel. He said that there had been but little sickness among the 400 officers and men of that vessel during the twelve-month port, during which she formed part of the blockading squadron of Santiago, and later cruised in the vicinity of San Juan (Porto Rico). While on this duty in the heat of summer they had been compelled to sleep on deck under the open sky, on account of the great heat stored up in the metal war machine with its dark paint. There had been no colds, no rheumatism, no infectious disease at this time, save a la grippe epidemic wholly of San Juan. This good health Dr. Cordeira attributed largely to the use of distilled water, mentioning in support of his view an observation at Guantano. The marines at this point, drinking distilled water from the *Marblehead*, enjoyed excellent health, while some Cubans encamped near by were much troubled with dysentery. Again, those on board the little vessels *Scorpion* and *Wasp*, which had no distilling plants of their own but were supplied with water from the *Marblehead*, enjoyed good health until one day, forced by want, they took on board water from Daiquiri. In a short time the *Scorpion* had thirty men sick with malarial fever; the same disease also developed aboard the *Wasp*.

Dr. T. S. DANBY asked whether there had been any mosquitoes in the neighborhood, and whether any disease, e. g., nephritis, had followed the prolonged use of distilled water.

Dr. CORDEIRA answered that no mosquitoes had been seen on the vessel while they were cruising off the Antilles; he had never observed any ill effect from the use of distilled water, which he himself had been drinking for fifteen years.

Philadelphia Pathological Society.

Meeting held June 22, 1899.

LYMPHATIC DIATHESIS.

Drs. BRYAN and WALSH reported a case with sudden death, the patient, a boy three weeks of age, who, when put to bed at night, manifested no signs of illness. On the following morning he was found dead. Autopsy showed the thymus gland markedly enlarged, covering the larger blood vessels of the neck and extending downward to the heart. There were two decided enlargements of the gland, one on either side connected in the middle portion by a smaller band. The weight of the gland was 28.33 grams. The tonsils were enlarged and lungs congested, as was also the left kidney. There were no signs of syphilis. Microscopically the thymus had the appearance of being normal with the exception that more lymph follicles were present. Enlarged follicles were also present in the spleen and intestines.

Hood called attention to the fact that sudden death occurred in cases in which the thymus was found to be enlarged. Jacobi, in 1888, also spoke of the subject. In one case it was thought that death had probably been due to compression of the trachea, but this idea has been partly overruled by another writer, who stated that in order for the thymus to cause compression it would necessarily have to be ten times larger than the normal gland. Another writer attributed sudden death in these cases to compression of the pneumogastric. More recently it has been held that death results from what may be known as the lymphatic diathesis, the exact cause of which we do not know. A section of the thymus was exhibited, stained by the Van Gieson method, which showed Hassel's corpuscles.

Dr. DAVID RIESMAN referred to the Berlin case in which sudden death had occurred after the administration of a dose of anitoxin. The autopsy had shown that the thymus was enlarged. He had last year performed autopsy on a case in which sudden death had occurred during anaesthesia. In this case the follicles of the intestines were enlarged. It was possible that some cases in which sudden death occurred during recovery from diphtheria and typhoid fever might be attributed to lymphatic diathesis.

Dr. GEORGE E. WOOD spoke of those cases in which Dr. Kocher had attributed sudden death from chloroform anaesthesia to the same cause.

Dr. ALBERT WOLDERT stated that some surgeons, in operating for goiter, have recommended that previous to removal of the gland the blood vessels be ligated in order to prevent profound depression or collapse held to be due to absorption of the glandular fluid, and as Dr. H. A. Hare had reported a case in which somewhat alarming symptoms followed a blow on the thyroid, these cases of sudden death in lymphatic diathesis might possibly be due to a form of rapid auto-intoxication.

ADDISON'S DISEASE.

Dr. W. E. HUGHES presented several specimens, the first being those found in a case of this disease. In this case discoloration of the skin first began on the face. A brief history of the case was as follows: A year previous to the time he presented himself for treatment the discoloration of the face began. Three months previously there had been severe pain in the right lumbar region, afterward located in the dorsal region, and still later a sharp pain was complained of in the left lumbar region, followed by vomiting. At one time temporary improvement occurred, but death finally ensued. At the autopsy the lungs were found in a state of fibroid phthisis, abdominal glands enlarged and cheesy, left kidney small, adrenals not much enlarged but thickened and cheesy masses were found throughout. In some cases of the cheesy masses, distinct ramifications of tissue were present, extending from the periphery inward.

IMPACTION BY GALL-STONE.

Dr. HUGHES also presented a specimen of common bile-duct, in which there had been impaction produced by a gall stone in which rather sudden death occurred. The common duct was almost closed by the stone; at one point slight dilatation was present, and below this the duct was again patulous. A specimen of retroperitoneal sarcoma was also exhibited by the speaker. In this case there had been no history of syphilis. Several months before entrance into the hospital the patient stated she had noticed that a lump had suddenly developed in the abdomen on the left side near the lower border of the ribs. Subsequently slight pain was complained of, but the presence of the lump seemed to be the greatest complaint. It was thought that the tumor was not attached to the kidney, from the fact that the hand could be slipped downward between the tumor and the lower border of the ribs, further than the

tumor was slightly movable and was covered by several loops of intestines, whereas in the case of tumor of the kidney only one loop of the bowel was usually present. He had seen three cases of retroperitoneal sarcoma.

The speaker also exhibited a carcinoma of the pancreas with compression of the common bile-duct. The gall bladder had contained a large amount of pus and several gall stones. The cystic duct was obliterated.

Dr. JOSEPH SAILER, in detailing the clinical symptoms, stated that the case had been one of considerable interest because it had been a question as to where the seat of obstruction lay, whether primarily in the common duct or in the pancreas. Hydrochloric acid had been present in the gastric contents. The patient had not vomited blood.

Dr. H. A. HARE spoke of a case of a young man in which after a blow on the abdomen, there rapidly developed multiple sarcomatous growths in various parts of the body. In another case after the removal of a small abdominal tumor it appeared that there had been general dissemination subsequently, as deaths soon followed from multiple sarcomatous growths.

HYDROCEPHALUS.

Dr. DAVID RIESMAN presented a specimen of hydrocephalus in a male of 17 years. The patient had during life suffered from several severe accidents to the head, and later suffered from dementia. At the autopsy the heart and lungs were considerably larger than normal, as also were the suprarenals. The weight of the brain was fifty-eight ounces. The ventricle of the corpus callosum was obliterated. The foramen of Monroe was patulous; the pia mater stripped off readily; the specific gravity of the fluid in the cranial cavity was 1.011 and contained no sugar. Regarding the essential pathology of hydrocephalus, one writer had looked on it as due to a form of serous meningitis, but this question has not been settled. Another writer found that in hydrocephalus the medulla of the suprarenals was as a rule affected, while the cortex might seem normal.

CYSTIC TUMOR OF TESTICLE.

Dr. RIESMAN also exhibited a specimen of cystic tumor of testicle, removed from an insane patient 51 years of age. The man had during life suffered from double scrotal hernia, on the left side being composed of a loop of intestine which was adherent to the sac. A polypoid tumor of small intestine was also exhibited by the speaker, which on examination proved to be a leiomyoma. The speaker also presented specimens of gall stones removed from an insane patient. He called attention to the large number—10 per cent.—of insane persons in whom these foreign bodies were present, and also that in cases in which the stone lay in the common duct the gall-bladder was usually contracted, doubtless due to an inflammatory process extending upward.

Cleveland Medical Society.

Meeting held April 9, 1899.

TYPHOID BACILLUS AS CAUSE OF POST-TYPHOIDAL SUPPURATION.

Dr. W. T. HOWARD, in a paper on this subject, called particular attention to the considerable number of cases of typhoid in which there are complicating suppurative processes, and that in nearly all of these the typhoid bacillus is the direct cause of the suppuration. The danger of the typhoid infection to the physician or nurse caring for these cases is very definite. There are now a number of carefully recorded cases of typhoid in which the bacillus occurs in the body without the characteristic lesions of the ileum and colon. The typhoid bacillus when it gains entrance to the intestine does not necessarily produce ulcers. Post-mortem it is always necessary to make cultures before it can be positively stated that the disease was not typhoid.

Dr. L. G. TOWNSLEE asked in what percentage of cases typhoid can be diagnosed by a bacteriologic examination of the urine. Dr. R. J. WENNER asked how long after an attack of typhoid the Widal reaction holds good.

Dr. H. S. UPSON pointed out the probability from recent progress of an entire regeneration of our nomenclature of disease. Formerly we named diseases by a symptom-complex; then we began to name them by their typical pathologic lesion, but now we are approaching a much better method of classifying them according to the germ which causes them.

Dr. HOWARD, in closing, said that Richardson found the typhoid bacillus in the urine in a considerable proportion of cases, and that in some cases the bacillus appeared in the urine early and in others late in the course of the disease. The Widal test being really a reaction of immunity, the blood serum of a person who has had typhoid will give it for a very long

time after the attack. Just how long we do not yet know. The only scientific way of classifying disease is according to etiology. He is in the habit of saying to students that diphtheria is any process in any part of the body caused by the diphtheria bacillus. In answer to a further question by Dr. Wenner he said that he did not consider the diazo reaction of much importance in typhoid, because it occurs in so many other diseases with which typhoid is likely to be confused.

CEREBROSPINAL MENINGITIS.

Dr. C. J. ALDRICH made some remarks on the epidemic of cerebrospinal meningitis now occurring in Cleveland, following at a later date full report of two necropsies of cases at the City Hospital. He spoke of the great value in the diagnosis of the disease of "Kernig's sign," which has not yet been properly estimated at its full value by the profession. It is very simple, consisting in inability for a child with meningitis to sit on a bed with the legs extended flatly, for owing to a contraction of the hamstring muscles they are bent at an angle of 20 degrees or more. Lumbar puncture is undoubtedly the most valuable method of diagnosis, but requires an extensive laboratory to make the necessary careful cultures.

Dr. W. G. STERN showed cultures from the cases of cerebrospinal meningitis at the City Hospital. The diplococcus intracellularis was found in the culture from serum obtained by lumbar puncture in one case. It was found that simply inoculating the culture medium with a drop or two of the suspected fluid was unsatisfactory. It was found to be much better to overlay the medium with 5 to 10 c.c. of the serum, when growth took place readily.

Dr. WENNER noted that the cerebrospinal fluid from a case of meningitis, if examined closely will always show some clouding.

Dr. HOWARD reported a recent case at Lakeside Hospital, in which the fluid drawn by lumbar puncture seemed clear but on putting it in the centrifugal machine a considerable amount of sediment was obtained from which cultures were readily made. This case had no eye symptoms, but had slight deafness and delirium which soon passed away leaving the case with practically no symptom but weakness, and becoming an apparently chronic case. In a necropsy done for Dr. H. W. Wickes of the Marine Hospital there was a large amount of thick yellow pus at the base of the brain. The optic and olfactory nerves were covered with thick pus. Pus was also found in the pia-arachnoid under the surface of the cerebellum. Cultures could not be made from this pus, probably because the organisms were in the cells. It was noticeable, however, that the total amount of pus was less than one would expect would cause death, leading to the conclusion that the toxins produced by the organism must be very virulent.

American Medical Temperance Association.

This association, composed of members of the AMERICAN MEDICAL ASSOCIATION, and having a membership of over one hundred and sixty active practicing physicians in the United States, held its annual meeting at Columbus, Ohio, June 8. The president, Dr. N. S. Davis of Chicago, delivered the annual address: "Is There any Causative or Etiologic Relation Between the Extensive Use of Alcoholic Drinks, and the Continued Increase of Epilepsy, Inebriety, and Insanity, Both Mental and Moral, in all Countries of Europe and America?" The secretary, Dr. Crothers, reported greater activity and inquiry during the past year. Twenty-six papers on alcohol and inebriety have been read during the past year in the different medical societies in the regular profession in this country. Nearly four hundred papers and notes on these topics have been indexed in the medical journals of America alone. The election of officers resulted as follows: president, N. S. Davis, Chicago; first vice president, H. A. Didama, Syracuse, N. Y.; second vice-president, Dudley S. Reynolds, Louisville; third vice-president, W. T. Bishop, Harrisburg, Pa.; secretary, T. D. Crothers, Hartford, Conn.; corresponding secretary, J. H. Kellogg, Battle Creek, Mich.; treasurer, G. W. Webster, Chicago.

Examining Eyes of Children.—Few children would escape if the eyes were examined in the primary grades. Besides the benefit of discovering and curing ocular troubles in the incipient stage, there is the additional benefit of warning parents of incurable affections which would forbid certain trades or professions, thus preventing useless expense and disastrous consequences. H. Cohn of Breslau has recently published a tabulated report of the eyes of every school child in Breslau (50,000). He considers it very important that the examinations be made in the open air.

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$5.00
Foreign Postage	2.00
Single Copies	10 Cents

In requesting change of address, give old as well as new location.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

No. 61 Market Street, Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Those new members of the Association should send their annual subscription direct to the Treasurer, Dr. Henry P. Newman.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street, Chicago.

Original communications are accepted with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, JULY 1, 1899.

DISORDERS OF PERIPHERAL NERVES IN INFECTIOUS DISEASES.

Within the last few years a large number of cases have been reported in medical literature in which various symptoms indicating disordered activity of the peripheral nerves in the course of infectious diseases have been observed.

Some years ago Ross and Bury, in their well-known essay on "Peripheral Neuritis," pointed out that the great majority of cases of paralysis which have been recorded as following typhoid fever were not due to cerebral or spinal lesions, but to changes in the peripheral nerves, and the studies which have been made of the nerve alterations which take place in diphtheria have also shown that in a certain proportion of cases the degenerative change exists in the peripheral nerves rather than in the central nervous system.

In this connection, it is interesting to note that that most frequent infectious disease, pulmonary tuberculosis is also capable of producing results similar to those to which we have just referred, and literature in which cases of this character are recorded is not lacking. Pitres and Vaillard, two French writers, dealt with this subject as long ago as 1886 and in 1894 Carrière wrote on the subject in a Bordeaux thesis. More recently Carrière once more approaches this subject. He believes that disorders of the peripheral nerves in the course of pulmonary tuberculosis are very frequent, that they are more frequent in men than in women, that they by preference attack adults, are seen most commonly in the advanced stages of the disease and naturally occur in the chronic or subacute forms.

The manifestations produced by these lesions involve the functions of locomotion, sensibility, nutrition and vascular supply. In regard to disorders of locomotion or the secondary changes which take place in the muscles as the result of neuritis following tuberculosis, we find that the lesions may be limited or wide-spread; sometimes they involve the muscles in one limb or in part of one limb; at other times they are symmetric in both limbs and they usually develop slowly and insidiously.

In two cases which he has observed, the condition of atrophy of the muscles was like that which is seen in Aran-Duchenne paralysis. Unlike certain other forms of paralysis following neuritis with wasting and loss of power, when once developed it is usually fixed and does not have periods of temporary improvement. Certain masses of muscles seem to be particularly prone to this condition, as for example the pectoral muscles and the deltoids. On the other hand, in a certain proportion of cases the muscles of the lower extremities suffer more than those of the upper, and in certain instances, as is well known, tapping the muscles will produce a condition of undulating fibrillary contraction. In other instances, tremor is quite marked, it is usually of the small, rapid variety which disappears during the rest and may simulate that of disseminated sclerosis. For the same reasons the reflexes are usually disordered, sometimes being much enfeebled, at other times exaggerated, but it is a noteworthy fact that the pupillary reflexes are unaffected.

Neuralgia, as every physician knows who has treated this class of patients, is very frequent, occurring in not less than 75 per cent. of the cases and most frequently involves the intercostal and sciatic nerves. A more rare phenomena, which Carrière has observed in two cases, was false angina pectoris, in which the pains were severe and closely resembling those of true angina.

In regard to disorders of sensation, patients often complain of local sensations of heat and cold, particularly of the extremities, the hyperthesia over the muscles, particularly of the chest and neck, and a marked tenderness about the joints and over the surface of the tibia. In regard to trophic lesions, we find glossy skin, lesions of the nails, zona, and, as is well known, pulmonary osteoarthropathies. Of the serious local vasomotor disturbances we have localized urticaria, sweating, local asphyxia and itching of the skin. These various changes produced in the peripheral nerves by these infectious processes are undoubtedly due to the influence exercised by the toxins of the disease.

In the way of treatment, it is evident that one of the first necessities is to aid in the elimination of toxic material as much as possible, to insist that the patient should take a certain amount of rest and conserve his energies, that he shall have good, nutritious food, easily digested, and that the medicines which are employed should all of them be roborant in their character. While at first glance such drugs as antipyrin, quinin and other analgesic substances would seem to be indicated, as a

matter of fact these drugs, particularly the first, frequently seem to ultimately increase the difficulty by impairing the activity of the blood and Carriere thinks that local applications of oil of gaultheria, of menthol or guaiacol, chlorid of ethyl or of mentholated ether are much to be preferred as a means of remedying painful manifestations.

HEREDITARY TRANSFORMATION IN FICTION.

Some thirty years ago Moreau (de Tours) pointed out that an "incorrect conception of heredity looks for identical phenomena in each succeeding generation. Some have refused to admit that mental faculties were subject to heredity, because the mental character of the descendants were not precisely those of the progenitors. Each generation must copy the preceding. Father and son must present the spectacle of one being, having two births, and each time leading a different life, under the same condition. But it is not in the heredity of function or of organic or intellectual facts that the application of the law of heredity must be sought, but at the very fountain-head of the organism, in its inmost constitution. A family whose head is insane or epileptic does not of necessity consist of lunatics or epileptics, but the children may be idiotic, paralytic or scrofulous. What the father transmits to the children is not insanity, but a vicious constitution which will manifest itself under various forms in epilepsy, hysteria, scrofula, rickets, etc. This is what is to be understood by hereditary transmission."

The law thus laid down is simply an expression of the beneficent operation of atavism, whereby the type characters resist the acquired defects of the individual parent. The acquired defect taking the line of least resistance, according to the depth of degeneracy, the condition of the mother during pregnancy, and the condition of the father at the time of conception, manifests itself in a greater or lesser degree. Moreau indicated the lines along which such indications should be pursued when he divided the conditions due to degeneracy, in a family, into the following categories: 1, absence of conception; 2, retardation of conception; 3, imperfect conception; 4, incomplete products (monstrosities); 5, products whose mental, moral and physical constitution is imperfect; 6, products specially exposed to nervous disorders in the following order of frequency: epilepsy, imbecility or idiocy, deaf-mutism, insanity, cerebral paralysis and other cerebral disorders; 7, lymphatic products predisposed to tuberculosis and allied disorders; 8, products which die in infancy in a greater proportion than sound infants under the same condition; 9, products which, although they escape stress of infancy, are less adapted than others to resist disease and death.

The transformation of heredity is so often ignored even by the profession that it is hardly astonishing to find that the lay press entirely neglect it. In a recent review of "The Maternity of Harriett Wicken," by Mrs.

Dudency, the *Chicago Evening Post* remarks: "The author has neglected part of her opportunities. Harriett is the daughter of an ill-starred house, wherein, according to the dictum of Dr. Kiernan, there is degeneracy taking on many forms, all of them noxious. There is drunkenness, ne'er-do-well men and women, insanity, epilepsy, rickets and all the rest. Harriett chances to be skipped, in accordance with another law not well understood and is a fine specimen of the human animal. She marries a man with a robust longing for ratherness and her baby is witless. It has been clearly shown that genius, too, runs along these same lines of degeneration. It is no less true that such spirits as Mark Tapley's are quite as capable of transmission to descendants as the evil qualities which make up the burden of Mrs. Dudency's chapters.

"Into all lives, not only rain but sunshine falls; and it seems to be the author's misfortune here to have been unable to devise more than a moment's compensation to for all the woes of which her heroine is the unintentional conduit. Were the novel more forceful it would carry the tragedy better. It is well-planned and clearly written, but it lacks contrast which should have been given it in the failure of strength. Like all novels based on inheritance it takes a pessimistic view; and Mrs. Dudency cannot realize that there are pleasures in which she has had no share."

This criticism is in the main part just, but credits Dr. Kiernan with priority in views to which he makes no claim. It further displays the usual ignorance of the influence of the law of atavism in a normal direction. There is very little doubt but that atavism does dispose of much degenerate heredity, and would dispose of more were it not that the last is assisted by environment. The beneficent influence of atavism is shown in the ease with which the United States has assimilated the defectives poured into it for centuries. The criticism of the pessimistic tendency of heredity depicted in fiction is therefore just. Mrs. Dudency missed an excellent opportunity of teaching an optimistic lesson, by making the witless child a cretin and treating it with thyroid extract. This phase of the subject has hitherto been neglected in fiction. The beneficent effects of atavism were taught by Eugene Sue in "The Mysteries of Paris," in the case of the morally sound members of the Martial family. Of course, the classic fiction dealing with the transformation of heredity is the "Rougon-Marquart Series," of Zola. Here atavism is often beneficent in its effects.

STANDARDIZATION NEEDED.

The revision of the "United States Pharmacopeia," which is to be done next year is a matter of sufficient importance to receive the serious consideration of the profession. The physician is the one who has the greatest interest in the reliability and availability of the products of the pharmacist. They are part of the tools of his trade and on their efficiency his success to a

greater or less extent depends. It is a well-known fact that many of the crude drugs that form the basis of the pharmacopœial preparations are far from being as reliable as their proper medical usage demands. When such physiologically powerful drugs, for example, as colchicum, conium, hydrastis, hyoscyamus and others may vary in their content of active principle 200 to 300 per cent. in different samples, as has been amply demonstrated by competent authorities, it would seem that something ought to be done to eliminate these fluctuations of the crude drug from the official preparations. If the latter are not uniform in medical potency, what confidence can be placed in them or in the pharmacopœia, which certainly ought to be a reliable guide for accurate dosage and medication?

It is true, the last edition of the pharmacopœia did provide standards for cinchona, opium and nuxvomica and the recently published "British Pharmacopœia" goes a step further and "standardizes" ipecac and belladonna, but the principle has not yet been made to cover calabar, coca, colchicum, conium, gelsemium, hydrastis, podophyllum, stramonium or veratrum, to say nothing of important drugs such as aconite, cannabis indica, digitalis, ergot and strophanthus, which defy any and every chemical test thus far elaborated, and which, to be assayed at all, must be tested pharmacologically on the living animal.

It is, perhaps, demanding too much to ask the revisers of the Pharmacopœia who are soon to enter on their decennial task, to provide standards for all powerful drugs, but it seems to be well within the bounds of the reasonable and moderate to urge the expediency of extending the principle of chemical standardization to all drugs susceptible of accurate chemical assay and also of adjustment, by chemical means, to uniform standards based on a fixed percentage of active principle or principles in the finished preparation. Surely, the physician has enough to perplex and baffle him in the idiosyncrasies of individual patients, and in the irremediable difficulties of diagnosis—may he not justly demand protection from the disaster which follows in the train of a weak, inert, unreliable drug product, or of a preparation possessing an unusual and dangerous potency? The golden mean between the worthless and the toxic ought to characterize every fluid extract, solid extract or tincture administered in the treatment of disease.

The very general use of diphtheria antitoxin and the growing employment of an antitetanic serum for prophylactic purposes have acquainted the profession with the fact that the curative serums can be tested and standardized only by the physiologic method—by observing how much of the serum will preserve from sickness a test-animal into which is injected simultaneously ten times the fatal dose of the respective toxin. This is indeed a tedious, laborious, expensive and not absolutely uniform means of pronouncing on the exact strength of a given serum, but it is the only means available; there is no other, as no chemist pretends that he can test a

parcel of antitoxin with his reagents. Every word of this applies with almost equal force to the testing of a limited number of powerful and important drugs like ergot, digitalis, squill, convallaria majalis, cannabis indica and strophanthus. The chemical test for these drugs and their pharmacœutic preparations is very unreliable, and unless they are tested by the pharmacologist, on the living animal, their administration is a lottery affording no guarantee of prompt reaction or final cure. This fact is notoriously the cause of that unfortunate desuetude into which ergot and cannabis indica have largely fallen. Lacking uniformity of action and failing often to yield the expected results, the pharmacœutic preparations of the markets are discarded wholly by the disappointed practitioner. Professor Hare, in his "Therapeutics," ascribes the frequent failure of cannabis indica to the inferiority of the preparations encountered, and the worthlessness of much of the ergot on the market is beyond dispute. Witness also the report of Houghton¹, who pharmacologically tested six samples "supposed to be pure strophanthin;" one sample was *ninety* times as strong as another, and the remaining four varied between these limits of one and ninety.

If drug preparations can be made uniform in strength by the comparatively simple and inexpensive means of chemical assay, well and good, otherwise the physician has a right to ask the wealthy and prosperous manufacturer to apply the physiologic test to preparations whose activity can be gauged in no other manner.

HARMONY.

If there was one characteristic of the recent meeting of the AMERICAN MEDICAL ASSOCIATION more prominent than another, it was that of harmony and good feeling. As a consequence this occasion was one of profit to those present as well as to those absent. In this there was shown the great value of organization. All of the parts representing a great, living, active, working body were there engaged in the legitimate functions of the work to which each was individually assigned. Friction and discord were not only not observable, but were not present. All this shows that the physicians are getting together, and in doing so, constitute not only a grand, but a great army.

Scientific demonstrations either prove or disapprove theories, and are fatal to dogmas; and as dogmas melt and pass into mist, there comes a harmonious adjustment of forces. The unification and unanimous expression of a great body of scientific men has an educational as well as a psychic influence on the people, which in turn is reflected in its power on the national or state government.

A few physicians of Philadelphia got together and formulated a series of suggestions looking to improvement in the medical service of the army. Alone, they were a feeble force, but with a unanimous endorsement of their plans by the AMERICAN MEDICAL ASSOCIATION, they be

¹ Journal, Oct. 22, 1888

came great and potent and their suggestions will receive consideration.

The hypocritical members of the profession who have held aloof from the organization, ominously uttering doubts as to the highly scientific character of the work done by it, are gradually coming into the ASSOCIATION. There are still many who do not feel like associating themselves with the national body, but their reasons for this become less defined each year, and ere long, it is to be hoped by all, they will forget the antagonisms of years gone by. Every one has a profound respect for certain societies which have refrained from sending delegates to the ASSOCIATION. Those organizations, segregated as they are, exert a limited influence, but if they should become a component part of the great national organization, their influence would at once become more powerful and far-reaching.

The harmony of the Columbus meeting with its well-organized scientific demonstrations and discussions will have an influence in drawing together the factors which have so long been separated from the organization with which they have a natural identification. In the harmony of the late meeting will be found the magnet that will, it is hoped, draw together and unify the entire profession. Such a unification means a wonderful power for good; a power that will present to Congress and to the President suggestions which will not go unheeded; a power that will be recognized when it goes to the state legislatures in the interests of state medicine, and protection from mountebanks and charlatans. Harmony and united action are unseen but powerful agents for good and should be cultivated so that greater benefits may yet flow to the profession as well as to the people.

DEGENERATION.

We are afraid that the *British Medical Journal* is allowing "commercialism" to get the better of its professional rectitude. It does not seem to be satisfied with the income resulting from having two advertising pages to one reading page—68 reading to 128 advertising—but it has now begun to place advertising inserts among its reading matter. These are filled with advertisements of water as well as whisky, surgical instruments and proprietary medicines. We feel shocked at the evident decadence of the ethical and professional morals of our quondam dignified and correct contemporary. The staid organ of the British Medical Association sacrificing its dignity thus, just for a few "bob" is certainly a state of affairs not pleasant to contemplate. When this great weekly, which is supposed to represent, and be the quintessence of, journalistic purity, sets such an example, what may be expected from others?

A MATTER OF PRIORITY.

In the *Neurologische Centralblatt* of June 1, Professor Mingazzini of Rome makes a claim for a compatriot of his, the late Dr. Galassi, of the original discovery of the pulmonary phenomena described by Dr. Gifford in 1895 and rediscovered by Westphal this year. It appears

Dr. Galassi's observations were verbally reported to the Lancisi Society in Rome in 1887, and mentioned in its "Bulletin" in 1887 and 1888. It would seem from this that the "question of priority" editorially noticed in our issue of April 15, should, as far as the clinical observations and medical publication of the fact in society proceedings go, be settled in favor of the Italian observer. It happens, however, that the actual originality of the observation does not even rest here, for very soon after the appearance of Westphal's article Piltz' called attention to the fact that it had been noted by Wundt in his "Grundzuge der Physiologische Psychologie," published in 1880. Verily, as the wisest of men says, "there is nothing new under the sun."

THE TUBERCULOUS OSCULATION.

By following the rule of going away from home to get the news, we learn from one of our English contemporaries that "it has been found necessary in some parts of the United States to direct the attention of the legislatures to the desirability of prohibiting indiscriminate kissing, not, it would appear, in the interests of public morality or in deference to the susceptibility of the American Mrs. Grundy, but with a view of checking the spread of tuberculosis." The journal goes on to say that either the tubercle bacillus must possess unaccustomed virulence in the Western hemisphere or else kissing must be unduly and indeed unnecessarily prolonged. We have read somewhere a saying, apparently English in origin, that a thorough and complete kiss must last seven minutes by Shrewsbury clock, but have not heard of this being put in practice in this country. It is certain, however, as our English contemporary remarks, it will be one thing to prohibit indiscriminate kissing and another to enforce the veto, and we certainly agree with it that it is a lack of good taste to couple kissing and spitting together as nuisances, as it credits the American tuberclephobists with doing. It is to be feared, however, that it has been imposed on in this instance. If kissing has to be sacrificed for the sake of getting rid of tuberculosis, we opine that the latter will stay.

FOOD VALUE OF ALCOHOL.

The recent statements of the public press concerning the findings of Professor Atwater, the Government food expert, regarding the nutritive value of alcohol, are worthy of a passing notice. While some authorities have disputed it, the consensus of scientific opinion has always been that a certain amount of alcohol could be consumed in the body. Professor Atwater's findings are different from those of others only in that he finds a little larger quantity can be disposed of than some other hygienic authorities. He does not say that it is a healthful food or that it can be safely taken in a quantity sufficient to have any large effect in keeping the vital mechanism going. While it may be to some extent a producer of energy, its action even in small quantities, on special portions of the organism, may be deleterious. The experiments of Aschaffenburg in Kræpelin's clinic are in point as to this effect. He found that even a very moderate dose of alcohol—20 to 30 grams—had a distinctly bad effect on skilled workmen, type-setters, im-

¹ *Neurologische Cbl.*, No. 6, March 15.

pairing their capacity to work to a very considerable extent. Then we have the question of idiosyncrasy to meet. It is well known that small quantities of alcohol are very ill borne by some individuals and we cannot estimate even the food quality of alcohol in the average man by experiments on one or two. After all the question of the food value of alcohol is of infinitesimal importance. It matters very little whether two ounces of alcohol can be disposed of in the system or not when it is estimated that as a food they are not more than the equivalent to two ounces of milk or broth. The temperance reformers have overshot the mark in dwelling on this point. Alcohol is not taken as a food; it is taken for its action on the nervous system, which is altogether a different thing.

DOCTORATES IN LAW FROM A MEDICAL COLLEGE.

The *Medical Press and Circular* criticizes the action of the Jefferson Medical College for having conferred the non-medical degree of Doctor of Laws. It speaks, however, "with bated breath" in view of similar practices of English Universities which are in the habit of giving the degree of Doctor of Civil Law in a country where the civil law has never been in vogue, to individuals who cannot by any strain of the imagination be presumed to know anything about it. Its criticism is, however, well founded except perhaps in that it ignores the accepted fiction which long custom has consecrated. It would be no harm, nevertheless, if our institutions that have as their legitimate function the giving out of doctorates that mean something would cease the practice of bestowing those that mean nothing but an empty compliment. A degree in law from a medical college is not worth much and is unfair as not in accordance with true reciprocity. A degree in medicine from a law college in Philadelphia would, to use a common expression, certainly cause a "kick."

HUMAN TUBERCULOSIS AND HOUSEHOLD PETS.

The claim has frequently been made that children often become infected with certain diseases which are brought to them from other children by pet animals, such as cats and dogs, or indeed, that these animals may themselves be suffering from maladies which are capable of transmission to the human being, but while many physicians believe in the truth of these assertions, definite evidence has not yet been largely accumulated. It is also a known fact that some pet animals and birds are susceptible to tuberculosis, and while in the case of birds the bacillus is somewhat different from that which occurs in the human body, it has been supposed that this difference is simply produced by its surroundings, and that it is capable under certain circumstances of affecting human beings. Our attention has been called to this matter by an article by Tucker Wise, in which he brings forward certain evidence to prove that canary birds in particular are capable of spreading tubercular infection. He believes from his experience and literary research that tuberculosis among caged birds is an exceedingly common disease, and he points out how the fluttering of the wings of the bird distributes infected dust in the air of the room and thereby spreads tubercular infection. Altogether he has collected thirty cases of tu-

berculosis, which, in his opinion, were closely connected with infection from such pets, and he goes on to point out that in the distribution of the dust in the manner described, it may not only be inhaled from the dust of the room, but also infect various articles of food which are frequently put on tables in the neighborhood of bird cages. He also points out that it is estimated that nearly 400,000 canaries are sold every year in Great Britain, and therefore that this question of bird tuberculosis and human tuberculosis may possess a greater degree of interest than has been thought.

DIAGNOSIS OF TRICHINOSIS.

Atkinson has added another to the cases made famous by the reports of Osler, Cabot and Brown; the great increase in the proportion of eosinophilic cells in cases known to be actively infected with the trichinae. Normally these cells show a wide variation within their normal limits, from one-third of 1 per cent. to 3 per cent., yet even at the greatest they occur less frequently than any other form of white cell. In the cases of these observers the differential count has demonstrated over 50 per cent. of the leucocytes to be of the eosinophilic variety during the stage of active infection. Nor is it possible to mistake this cell for any other when the specimen, fixed by heat or in equal parts of alcohol and ether, is stained even most carelessly with the eosin and methyl blue of the Erlich triple stain, preferably the former. The intense pink with which the large spherical granules take the eosin stain, the polymorphous nucleus, the pallor of the latter even when long stained, its loose connection with the granules, all tend to make it distinctive. While this large increase may be looked on almost as pathognomonic, eosinophilia of moderate grade may occur in a vast number of other affections; in diseases of bone the writer has seen 5 per cent. of eosinophiles in sarcomatosis of the bone; in diseases of the skin, Cabot has reported a case of dermatitis herpetiformis in which the differential count of 500 leucocytes showed 19 per cent. of eosinophilia—in diseases of the spleen, of the organs of generation, of the sympathetic system, and in cases of the so-called uric acid diathesis. But there are other symptoms to be taken into consideration than this eosinophilia in making the diagnosis of trichinosis. The onset is as a rule sudden, with a chill, rigor, rapid rise of temperature, followed by profuse sweating. Intense itching pains in the limbs follow and the patients can hardly move without suffering the most intense agony. These pains are not of the aching variety common to typhoid fever, smallpox and influenza, but more of the rheumatic type. They are due to the myositis set up by the growth of the trichinae. The history of a case one might easily mistake for typhoid, but there are no rose spots, no enlargement of the spleen, no abdominal tenderness, pain, or tympanites; while, on the other hand, the Widal reaction is absent, and there is always a marked leucocytosis. One of the common symptoms to which little attention has been paid is edema of the eyelids without swelling of the feet and without albuminuria and the presence of urinary casts. A careful history will often elicit information of the patients having eaten raw meat. The case of Atkinson was remarkable in this respect; the man was a cook in a restaur-

rant, with the greatest love for raw meats of all kinds, fish, sausage, and would eat it by handfuls. This latter case pursued a rather uneventful course and was discharged in a little over a month, in good condition. During his stay in the hospital, portions of muscle were excised and the diagnosis conclusively proven by finding the trichinae among the muscular fibers. This case also illustrates the value of routine examination of blood films in hospital practice. Possibly had this not been done the diagnosis would not have been made. It may not have made any difference as far as the actual progress and recovery of the patient was concerned, still it is a part of every scientific and progressive physician to leave no stone unturned that might aid him in establishing his diagnosis.

DE MINIMIS CURAT LEX.

An unpleasant consequence of certain peculiarities of the English law regulating medical titles and the practice of medicine is seen in the celebrated Hunter case which has been the subject of much editorial writing by our British contemporaries. Dr. Hunter, for we can properly so call him, was a graduate of Jefferson Medical College, as well as a licentiate of the Society of Apothecaries and a regularly registered practitioner according to British law. A brother practitioner in his locality brought a complaint against him before the Medical Council, to the effect that he was falsely calling himself "doctor" and "physician." He was ordered prosecuted and this is reported to have given him so much mental anxiety and trouble that it affected his health and finally caused his death. Now the Medical Council is trying to escape the responsibility of its acts, claiming that it conducted the case in a friendly manner, that Dr. Hunter had expressed his willingness to defend himself and have the matter cleared up. It also claims that it was not cognizant of the exact circumstances under which the prosecution was carried on and that this also relieves it of responsibility. The facts are that Dr. Hunter's name was presented for prosecution with other cases, apparently without any distinction being made that it was any different from that of any other, notwithstanding the fact that he was regularly qualified. He had agreed to drop the title of "doctor" and asked what course he should pursue, and had been answered that no information could be given. The charge against him for the use of the term "M.D." having failed, he was prosecuted for calling himself "physician and surgeon," and was convicted in the lower court. After his death the conviction was quashed by the higher court, but in such a way as to leave the right of an L. S. A. to call himself a physician or surgeon still in question, and the Society of Apothecaries, it is said, still intends to test its legal rights. The whole matter leaves an unpleasant taste in the mouth: the "friendly" prosecution, the plea of irresponsibility, and the fuss made over names that admittedly mean nothing as indicating actual qualifications. It is not our affair though the coupling for prosecution of the use of a degree from one of our oldest and best medical colleges with really disreputable offenses against the medical law is not complimentary. It would seem better if the highest medical authority of a great country would drop hag-

gling about trifles and allowing itself to be the instrument of persecution by jealous professional rivals.

PROGNOSIS IN VALVULAR HEART DISEASE.

In some clinics of the larger hospitals it is a matter of almost daily occurrence to have patients present themselves with a history of failing health, slight exhaustion, sometimes dimness of vision, dizziness, and above all a painful spot in the region of the left nipple. In many cases, if not in the majority, there may not be leading symptoms which would lead one to believe that the patient was suffering from valvular disease of the heart. If one symptom is present in the early stage which predominates over the others, it would seem to be the pain in the region of the left nipple. In some cases this pain may be of a dull or dragging character, but as a rule it is rather sharp and more or less persistent without reference to the time of eating. In such patients the heart should at once be examined. We often meet with such cases in the dispensaries. The patient presents himself, thinking his ailment is of a trivial character, but on being requested to have an examination made, his attention is at once drawn to the heart by the physician's manipulations, and one of the first questions asked is, "Doctor, have I heart disease?" Heart disease to most patients means an incurable disease, and one in which the imagination is at its highest tension from fear of sudden and early death. It is not always easy to make reply to this direct question, and in many cases, if not the most of them, it is best not to do so. There are few patients who, when told that a valvular lesion exists, bear it well. In this condition it is really not diagnosis that the patient is thinking about, but prognosis. The words "heart disease," "early" and "sudden death," are constantly being turned over in his mind. In the clinics, where the patients are generally strangers, it is best not to tell the patient that he has heart disease. In nearly all cases it does harm. The most of them are laboring under a feeling of despondency from being out of work, family cares, or indigestion, and why should we add to their discomfort? In such cases it seems best to ask them to return again, and then again, after which time a better opportunity will have been gained of the person's characteristics. Further, the physician will be more competent to pass judgment on a case at the third examination than at the first one. He may see cause to change the original diagnosis. If he should tell the patient that the diagnosis had been changed it would cause a doubt to exist, and moreover a loss of confidence. The physician may and should be ready to acknowledge his mistake, but not always to the patient. That is another reason why a hasty diagnosis does mischief. It requires an expert of a high degree to differentiate the different varieties of heart murmurs at the first examination. If we should hear a murmur at the apex or at the base of the heart, that does not always mean that heart disease is present. A murmur situated in either region has been known to pass away. One celebrated writer states that: "With an apex-beat in the normal situation and regular in rhythm, the auscultatory phenomena may be practically disregarded." The prognosis, speaking generally, does not depend on the heart

murmur, but on the condition of the heart muscle. A heart murmur, co-existing with a regular pulse, of good quality, normal size, normal position, and normal apex-beat, is of little consequence when compared with that when those signs are absent. But how can we determine the condition of the heart muscle? This is not always an easy matter to decide. Neither the precordial pain, the size of the organ, nor the position will determine this point. We have three very important signs which are of some value: absence of apex-beat, dyspnea and weak pulse. Absence of apex-beat in valvular heart disease probably has not up to this time received the attention which its significance deserves. Muscular tone of the heart is necessarily associated with a strong contraction, and a strong contraction of the heart furnishes a pulse of good quality. Aside from the condition of the heart muscle itself certain other factors determine the prognosis in valvular heart disease, and must be taken into consideration, such as age, sex, occupation, climate, as well as the valve affected.

Medical News.

DR. HARRY FRIEDENWALL, Baltimore, has returned from a four months' tour of European hospitals.

THIS year the Metropolitan Hospital Sunday Fund, London, received a check for £10,000, about \$50,000, from Mr. George Herring.

THE PROFESSOR of chemistry, Dr. Istrate of Bukharest, has been appointed a member of the Roumania Cabinet, as Minister of Public Works.

SIR WILLIAM MACCORMAC of London has been elected an honorary president of the Thirteenth International Congress of Medicine to be held in Paris August 2-9, 1900.

THE FAITH HEALER, under whose treatment Dora Kraray, a child of Brooklyn, suffered from gangrene of the foot, making amputation necessary, has been sentenced to five year's imprisonment.

DR. J. B. ALEXANDER of Hiawatha, Kan., has been elected president of the Kansas State Board of Health and Dr. W. B. Swan of Topeka, secretary.

BY THE will of Charlotte Bostwick, Philadelphia, a contingent bequest of \$15,000 has been made the Germantown (Pa.) Dispensary and Hospital, to be added to the endowment fund of that institution.

DR. MARTIN MENDELSSOHN of Berlin was made "professor" on the occasion of the opening of the Sick Nursing Exhibition at Berlin, which he had arranged with special reference to the Tuberculosis Congress.

DR. J. ACKERMAN COLES of Scotch Plains, N. J., has presented to Brown University a life-size portrait bust of Benjamin Franklin, a replica of the one made in Paris, in 1778, while Franklin was minister at the Court of France.

A CONVALESCENTS' home for soldiers returned from the colonies has recently been opened at Sevres, near Paris, in the chateau occupied by Mme. de Pompadour, under the auspices of the association for the assistance of "militaires coloniaux."

DR. JUR. M. MORIANTA, Counsellor and Minister de l'Interieur at Tokio, Japan, has been detailed by the Mikado to study the question of sanitation in the United

States and is now in Philadelphia examining the method in vogue by that city's Board of Health relative to keeping the sanitary record and health statistics.

ABOUT three hundred and eighty candidates for license to practice medicine just appeared before the State Board of Medical Examiners in Philadelphia. Of this number about three hundred and twenty-five are regulars. About one hundred will be examined in Pittsburgh.

THE PARIS *Gazette Medicale* states that several physicians of Cologne and the Rhine countries have been arrested for selling pills to young men, which produced symptoms simulating heart disease, and thus secured their exemption from military service. The death of one who had taken too many pills led to the discovery of the trick.

THE FRENCH naval medical officer, Dr. Emily, who accompanied the Marchand scientific mission which made its way this year from the Congo to the Red Sea, has been dined and wined by the profession in France on his recent return. This is his third expedition to Darkest Africa although he is not yet quite 34 years of age. His works on natural history have attracted much attention.

AMONG THE paintings at the Paris Salon this year two medical subjects have attracted considerable attention. One, "A Consultation at the Hospital Paschal," represents Dr. Brocq examining the back of a young woman who stands picturesquely draped before him, with a number of internes in their gowns and several visiting physicians, all portraits. No lesson is perceptible. "The Accident" shows the physician summoned to the circus rider on a couch in the flies, with the clowns and musicians crowding around her and keeping back the gaping public. Still another "Accident" is a scene of a workman being carried past on a litter, the passers-by removing their hats, except one stylishly dressed man who is accosted by one of the workman, his words the title of the painting: "Flats off! Salute Labor's Wounded!" The physician is seen mounting the hospital steps in the distance.

SMALLPOX diagnosed as chickenpox at Valparaiso, Ind., has exposed that community for the past three months. The disease was conveyed from Mississippi by a student of the Northern Indiana Normal School, who was taken ill on his arrival in March. On account of the mildness of the attack and the prevalence of chickenpox the case was thought to be of the latter disease and after three days the student was allowed to attend his classes. It was observed that the subsequent cases developed in those who had not been vaccinated. Drs. Herman Spalding, chief medical inspector of the Chicago Health Department and A. W. Brayton of the Indiana State Board of Health, being ordered to make an inspection, at once pronounced the cases smallpox. There have been thirteen cases up to the present time, as nearly as can be ascertained. The vaccination of the community, the fumigation of infected houses and the prompt isolation of suspicious cases was immediately ordered. With these rules effectively enforced the authorities do not entertain fears of a general epidemic on the return of cold weather.

THE STEAMER *Nippon Maru*, from Hongkong via Yokohama and Honolulu, arrived at San Francisco June 27, having been detained at Honolulu several days in quarantine on account of two deaths which occurred on the voyage, from bubonic plague. One of these deaths occurred three days before reaching Honolulu, in the case of a Chinese steerage passenger. The ship's

doctor at first made a diagnosis of uremic poisoning, but being suspicious preserved the body for bacteriologic examination, which resulted in the discovery of the bacillus of the bubonic disease. The body was, therefore, cremated, and the vessel ordered into quarantine at Honolulu as above. The steamer arrived at San Francisco with the yellow flag flying and was at once ordered to the quarantine station, all the passengers being landed on Angel Island and neither doctors nor custom officers being allowed on board. Certain important papers were fumigated and sent on shore, but the *Maru* will be kept in quarantine for several weeks. She carried fifty-five cabin passengers, of which six are Europeans, while there are 138 Japanese and Chinese steerage passengers.

HEALTH REPORTS IN SOUTH AMERICA.—The reports of the National Institute of Hygiene in Chile, of the boards of health in Mexico, Brazil, etc., are accumulating a mine of information for future statisticians with their comprehensive, detailed, tabulated reports of hygienic, demographic and meteorologic conditions. When the countries undertook this work they had no established routine to overcome and could adopt from the start the latest and most approved methods in vogue, with the result that their stately volumes are models in every respect, and in their monthly bulletins they produce in popular form the prophylactic and other measures recommended by the highest authorities of all countries, devoting especial attention to tuberculosis, yellow fever, infant hygiene and the sanitation of cities.

Therapeutics.

SIMPLE SUMMER DIARRHÆA.

Food of all kinds should be stopped for twelve to twenty-four hours, and no milk given for several days. The intestinal canal should be cleared of all undigested food by full doses of castor-oil or syrup of rhubarb, preferably the former. Should there be excessive peristalsis attended with pain, camphorated tincture of opium may be given, in doses of 5 to 10 minims (.3-6 c.c.) to a child 1 year of age, which may be followed by some simple sedative intestinal antiseptic, such as bismuth subnitrate.

The following prescriptions are recommended:

R. Bismuthi subgallici	ʒi (3.88 gm.)
Sodii bicarbonatis	gr. v. (.3 gm.)
Crete preparate	ʒss. (1.94 gm.)
Creosoti	gtt. v. (.3 c.c.)
Syrupi cinnamoni	ʒiss. (1.84 c.c.)
Aque distillate q. s. ad	ʒiv (118.2 c.c.)

M. Sig.: Teaspoonful after each movement. *Griffin.*

R. Iodoformi	gr. iiii. (.19 gm.)
Naphtalini	gr. xv (.97 gm.)
Pulverie sacchari	ʒiiss (9.7 gm.)
Olii bergamii	gtt. ii (.12 c.c.)

M. ft. chart. No. xx.
Sig.: One in milk every hour in severe forms. *Comby.*

R. Zioci sulphocarbolicæ	gr. v (.32 gm.)
Benzoe	gr. viii (.51 gm.)
Bismuthi subnitratæ	ʒss (1.94 gm.)
Hydragryi chloridi mitis	gr. ss (.03 gm.)

M. ft. chart. x.
Sig.: One powder every one or two hours. For a child 2 or 3 years of age.

DIARRHÆA INCIDENT ON TEETHING.

R. Acidi sulphurici diluti	m. viii (.51 gm.)
Tincture opii camphorate	ʒi (3.7 c.c.)
Spiritus vini gallici	
Syrupi zingiberis	ʒi (11 c.c.)
Aque mentha piperatæ q. s. ad	ʒi (59. c.c.)

M. Sig.: Teaspoonful every three hours if necessary.

Geo. F. Butler, M.D.

FETID DIARRHÆA OF INITIAL STAGE OF SCARLATINA.

Filatov recommends the following:

R. Magnesi sulphatis	ʒi (3.88 gm.)
Acidi sulphurici	ʒi (3.7 c.c.)
Aque distillate	ʒvi (177.4 c.c.)
Syrupi	ʒi (30. c.c.)

M. Sig. A teaspoonful or tablespoonful, according to the child's age, from hour to hour.

This draught is markedly anodyne, and is well taken by little children.

ACUTE GASTRO-ENTERIC INFECTIONS.

Groech prescribes the following for patients suffering from acute infectious gastro-enteritis accompanied by vomiting, purulent dejecta, pains in the head, limbs, etc.:

R. Tincture iodi	m xv (.02 c.c.)
Syrupi simplicis	ʒv (18.5 c.c.)
Aque distillate, ad	ʒv (148.0 c.c.)

M. Sig. One tablespoonful every one or two hours, or three times daily, according to the gravity of the disease.

GASTRO INTESTINAL INTOXICATION OF INFANTS.

According to the *N. Y. Med. Jour.*, Perrier recommends in light forms unaccompanied by general phenomena such as vomiting, diarrhea, tumid abdomen, stationary or diminished weight, the suspension of milk, substituting for it boiled water, or slightly alkaline water, rice water, barley water, etc. The following prescription should be given:

R. Benzonaphthol	gr. iiii-ix (0.28-0.58 gm.)
Bismuthi salicylatæ	gr. ix-xv (0.58-0.97 gm.)
Syrupi aurantii flor.	ʒi (30 c.c.)
Mucilag. acacie	ʒxxx (84.34 c.c.)

M. Sig. One tablespoonful every two hours.

If the dejecta are fetid, infrequent, and if there is tympanitis give:

R. Hydragryi chloridi mitis	gr. ʒi-iss (.04-.09 gm.)
Sacchari lactis	gr. ss (.03 gm.)

In those forms in which to the before-mentioned symptoms are added fever, fetid breath, foul tongue, thirst and a loss of weight, milk should always be suspended, water alone being given. Gastric and intestinal lavage with boiled water, or a 0.7 per cent. saline fluid should be practiced; warm moist compresses should be applied to the abdomen, and if there is hypothermia, hot baths should be given, while tepid or cool baths should be used with hypothermia. About one fluid ounce (30 c.c.) of artificial serum should also be injected every three or four hours.

ACUTE DYSENTERY.

This disease has been treated with enemas containing sulphate of copper, under the directions of Sandwith, quite successfully. He directs that the patient should remain in bed with flannel over the abdomen, and be on a diet of boiled milk, rice water and seltzer, plus a little whisky. A dose of bismuth salicylate, 15 grains (.97 gm.), is given every four hours. The intestine is washed out daily with a quart of boric acid and starch solution, and for a few days, daily rectal injections are given with the following mixture:

R. Cupri sulphatis	gr. xv (.97 gm.)
Tincture opii	m. xv (.92 c.c.)
Amyli	ʒi (31 gm.)
Aque	ʒviii-Olii (236.5-946.3 c.c.)

Sig.: For one rectal injection. A cocain suppository may be inserted afterward if indicated.

The following prescriptions have been recommended:

R. Extracti ergotæ fluidi	ʒiiss (75 c.c.)
Tincture opii deodoratæ	ʒss (15 c.c.)

M. Sig.: Teaspoonful three times daily; or

R. Ergotinae (or aq. ex.)	gr. xx (1.29 gm.)
Extracti nucis vomicæ	gr. v (.32 gm.)
Extracti opii	gr. v (.32 gm.)

M. ft. pil. No. xx.

R. Sig.: One every four or six hours. *Bartholow.*

R. Magnesi sulphatis	gr. xl (2.50 gm.)
Tincture opii deodoratæ	gtt. v (.3 c.c.)
Syrupi limonie	ʒss (1.8 c.c.)
Aque q. s. ad	ʒii (7.39 c.c.)

M. Sig.: For one dose. Give every hour until stools change in character to feculence; then every two hours.

Bose and Bedel recommend in grave cases large intravenous injections of a 7 to 1000 saline solution. They should be administered at a comparatively early stage of the disease, and should be repeated. Each time a quantity of liquid varying from 34 (1000 c.c.) to 70 fluid ounces (1800 c.c.) is to be employed, 2 (59.14 c.c.) to 4 fluid ounces (118.29 c.c.) being injected per minute.

H. C. Wood says: "In acute dysentery involving the colon high up, I have found large enemata, containing two or three drachms of substrate of bismuth, much more efficient than the exhibition of bismuth by the mouth."

Brayton Ball advises "hot enemata of tannin and boric acid. When the stools have become diarrheal in character bismuth in large doses. Large enemata of warm or ice-cold water under low hydrostatic pressure."

Teestevin has successfully used the following:

R. Croosoti (beechwood) gr. xv (.97 gm.)
Tincture opii gtt. x. (.6 c.c.)
Lactæ (bullentia) ʒv. (18.5 cc)
Aque (bullentia) ʒiiss (192.4 c.c.)

M. Sig. Inject while hot, into the colon, after irrigating the rectum with a solution of boric acid and salicylic acid. (Thiersch's.)

"Irrigations with silver nitrate, from 20 to 30 grains (1.32 gm.) to the pint (500 c.c.) are especially useful," says W. W. Johnston," when the presence of pus in the discharges shows the persistence of unhealed ulcers. If these ulcers are in the rectum (and an examination ought always to be made to see if this is the case), they may be touched through a speculum with a strong solution of silver nitrate or with carbolic acid."

CHOLERA MORBUS.

Mistura anticholeraica—"Sun Mixture":

R Tincturæ opii.
Tincturæ capici.
Tincturæ rhei.
Spiritus camphoræ.
Spiritus menthæ piperitæ āā ʒiv (15 c.c.)

M. Sig.: Dose twenty to sixty minims (1.2 to 3.7 c.c.)

Thompson's modification of "Hope's Camphor Mixture.

R Acidi nitrici diluti ʒii (7.39 c.c.)
Spiritus camphoræ
Tincture opii āā ʒi (3.7 c.c.)
Syrupi zingiberis ʒiv (15 c.c.)
Aque menthæ piperitæ ad ʒvi (177 c.c.)

M. Sig. Teaspoonful as a dose.

F. A. Packard recommends the following prescription in cholera morbus to restore the mucous membrane to a normal condition:

R Hydragryri chloridi mitis gr. ʒi₁₂ (.005 gm.)
Pulveris aromatici gr. ii (.12 gm.)
Extracti pancreatici gr. v (.32 gm.)
Bismuthi subnitratæ gr. x (.64 gm.)

M. ft. cht. No. 1. Sig.: Take every three hours.

TO ALLAY VOMITING IN CHOLERA MORBUS.

R Creosoti
Acidi hydrocyanici dilutii āā m ii (1.2 c.c.)
Mucilag acaciæ ʒss (1.84 c.c.)
Aque q. s. ad ʒi (30 c.c.)

M. Sig.: Take at one dose.

SQUIBB'S CHOLERA MIXTURE.

R Tincturæ opii
Tincturæ capici
Spiritus camphoræ āā ʒi (3.7 c.c.)
Chloroformi ʒiiss (11 c.c.)
Alcoholia q. ad ʒi (18.5 c.c.)

M. Sig.: Twenty to forty minims (1.2 to 2.4 c.c. p. r. n.).

For children suffering from cholera infantum, F. Percy Elliott gives at the onset:

R Olei ricini ʒss to ʒi (1.8 to 3.7 c.c.)
Spiritus menthæ piperitæ . m i to m ii (.06 to .12 cc.)

M. Sig.: Give in hot milk.

For collapse:

R Beef tea ʒii (60 c.c.)
Brandy ʒii (7.39 c.c.)

By enema followed by warm bath.

"If serious, ether or aromatic spirit of ammonia, by hypodermatic injection or rectal injection of starch and warm water. Brothe (mutton, beef, veal) are better than peptonized milk; or give no food for twelve or twenty-four hours (occasional sip of hot water). Rub chest and abdomen with whiskey and water, and wrap in cotton wool or flannel."

In urgent cases Lesage advises injecting into the subcutaneous tissue, one ounce (40 c.c.) of the following solution, making from three to six injections a day.

R. Sodii sulphatis ʒiiss (9.72 gm)
Sodii chloridi ʒi (3.88 gm)
Aque distillæ ʒxxxiii (1000 c.c.)

TO ARREST VOMITING AND PURGING.

R. Bismuthi subnitratæ ʒss (5.8 gm.)
Spiritus myristicæ mxx (1.2 c.c.)
Spiritus vini gallici ʒiiss (11 c.c.)
Syrupi acaciæ ʒiiss (45 c.c.)
Aque cinnamoni q. s. ad ʒiiss (89 c.c.)

M. Sig. Teaspoonful every two hours. *Porell.*

R. Hydragryri chloridi mitis
Plumbi acetatis āā gr i (.06 gm.)

M. Ft. pulv. No. iv. Sig. One powder every three hours for a child from ten to twenty months old.

T. D. Mitchell.

In treating these cases it is often necessary to irrigate the intestines. Langford Symes says: "First wash out the rectum, then irrigate high up, with a warm normal saline or boric acid solution, the douche can be raised eighteen inches."

CHOLERA INFANTUM AND THE NURSING BOTTLE.

The perils that surround the bottle-fed baby are manifold. If a liquid reasonably resembling breast milk in composition and temperature is put into its bottle, it is still in danger of sucking in septic and possibly specific germs that have been lurking in the rubber appurtenances of the bottle. The abomination known as the Alexandra nursing-bottle, that familiar device for saving the nurse maid trouble, has commended itself to the unthinking for many years, and its use has even been upheld by some physicians who should have known better, although one would suppose that the dullest comprehension could not fail to perceive the impossibility of keeping it clean—in the ordinary sense of the word, not aseptic. Most physicians whose practice has been largely among children have, it is true, inveighed against it, but hardly any heed has been taken of their statements, perhaps because they were not clinched by indisputable demonstration. Such a demonstration seems now to have been made, and it is by no means the least of the services rendered by bacteriology. To Dr. Wendé, the health officer of Buffalo, so far as our present information goes, is due the credit of having proved the agency of the "hose" bottle in causing cholera infantum.

The flexible external tube of the Alexandra bottle, as everybody knows, is made of soft rubber, a material which speedily becomes foul when kept in contact with impure liquids or those that readily decompose. Dr. Wendé has shown that this tube, after having been in use for a little time, contains in the depths of the rubber, to say nothing of its inner surface, micro-organisms that even boiling does not destroy, as is proved by the ease with which cultures of them are grown. In consequence of Dr. Wendé's demonstration the Buffalo Board of Health some time ago passed an ordinance forbidding the sale of the "hose" nursing bottle, and during the year or more that this enactment has been in force the cholera infantum mortality of Buffalo has been fifty per cent. less than before.

But this is not all. The elimination of the "hose" does not, of course, do away with all the dangers of bottle-feeding. Not only has the baby to be guarded against bad milk, but the micro-organisms lurking in soft rubber still pursue it. Dr. Wendé finds that even the rubber nipple used when the "hose" is dispensed with soon becomes a nest for bacteria; so that in time even that must go, although it will have to be used, we presume, until a less objectionable form of nipple is devised. Dr. Wendé finds that the nipples made of white rubber are

more readily infected than the black ones; therefore, so long as rubber nipples still have to be employed, the black ones are to be preferred. What is wanted now is a nipple combining something of the elasticity of soft rubber with the germ proof quality of glass. Celluloid has been suggested as a material that might be made to fulfil these requirements, and we see no reason why it should not if properly treated. Something must be invented to supersede the soft rubber nipple.—*N. Y. Med. Jour.*, June 24.

Book Notices.

Atlas of Diseases of the Skin, including an Epitome of Pathology and Treatment. By PROF. DR. FRANZ MRACEK of VIENNA. A authorized translation from the German. Edited by HENRY W. STELWAGON, M.D., Ph.D., clinical professor of dermatology, Jefferson Medical College, Philadelphia, etc. With 63 colored plates and 39 full-page half tone illustrations. Price \$3.50 net. Cloth. Philadelphia: W. B. Saunders, 1899.

This is one of the series known as Saunders' Medical Hand-Atlases, of which the publisher claims to have contracted to sell 100,000 copies and thought it a large undertaking, but that now it will more probably amount to twice that number. If each of the series is as excellent as is this one, the statement can easily be believed. The importance of personal inspection of cases in the study of cutaneous diseases is readily appreciated, and next to the living subject are pictures which will show the appearance of the disease under consideration. To be of material advantage in skin diseases these must not be confined to black and white, but must be in colors and well executed. This is what we have in this atlas. The original cost of these plates must have been enormous, but since they are used to illustrate the book in so many different countries, and necessarily in such an enormous number, the original first cost is so divided and subdivided that it amounts to but little on each one. While pathology and treatment are well considered in the text, the great value and popularity of the book will depend on the aids to diagnosis by means of the excellent illustrations. A large number of well-selected prescriptions are given, and altogether the work will be found of very great value to the general practitioner in the treatment of skin diseases.

BOOKS AND PAMPHLETS RECEIVED.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits, or in the interests of our readers.

Transactions of American Association of Obstetricians and Gynecologists. Vol. xi. For the year 1898. Octavo. Cloth. Pp. 372. Philadelphia: Wm. J. Dornau. 1899.

Shall We Drink Wine?—A Physician's Study of the Alcohol Question. By DR. JNO. MADDEN, professor of physiology in the Wisconsin College of Physicians and Surgeons. Octavo. Cloth. Pp. 220. Milwaukee: Press of Owen and Weinbrecht Co. 1899.

Hygiene of the Mouth.—Guide to the Prevention and Control of Dental Diseases. By R. DENISON PEDLEY, F.R.C.S., Ed., L.D.S., Eng. With numerous illustrations. 8vo. Cloth. Pp. 94. Price, 2 6. London: J. P. Legg & Co. Philadelphia: S. S. White Dental Mfg. Co.

Elements of Vital Statistics. By ARTHUR NEWSHOLME, M.D., Lond., F.R.C.P., examiner in state medicine to the University of London and preventive medicine in the University of Oxford, Etc. Third edition. Octavo. Cloth. Pp. 353. Price, 83. London: Swan Sonnenschein & Co., Ltd. New York: The Macmillan Co.

Class Book of (Elementary) Practical Physiology. Including Histology, Chemical and Experimental Physiology. By DE BURCH BUCH, M.D., C.M., F.R.S.E., professor of physiology in the Yorkshire College of the Victoria University; examiner in Victoria University; additional examiner in Edinburgh University. Small octavo. Cloth. Pp. 273. Price, \$1.75. Philadelphia: P. Blakiston's Son & Co. 1899.

Hay-Fever and Its Successful Treatment. By W. C. HOLLOPETER,

A.M., M.D., clinical professor of pediatrics in the Medico-Chirurgical College of Philadelphia; physician to the Methodist Episcopal Hospital; pediatricist to the Medico-Chirurgical Hospital, to St. Joseph's Hospital; Fellow of the American Academy of Medicine, etc. Second edition. Revised and enlarged. Octavo. Cloth. Pp. 151. Price, 81. Philadelphia: P. Blakiston's Son & Co. 1899.

Atlas of Fractures and Dislocations. By Prof. Dr. H. HELFERICH of Greifswald. Translated from the third German edition by J. HUTCHINSON, JR., F.R.C.S. Sixty-eight superb chromolithographic plates with descriptions, and 150 pages of text, illustrated by 126 woodcuts. Wood's Series of Medical Hand Atlases. Muslin, 83, net. New York: Wm. Wood & Co. 1899.

Practical Diagnosis: The Use of Symptoms in the Diagnosis of Disease. By HOBART AMORY HARE, M.D., B.Sc., professor of therapeutics and materia medica in the Jefferson Medical College of Philadelphia. Fourth edition, enlarged and thoroughly revised. In one octavo volume of 622 pages, with 265 engravings and 14 full-page colored plates. Cloth, \$5.00 net. Philadelphia and New York: Lea Brothers & Co. 1899.

Manual of Surgical Treatment: By W. WATSON CHEYNE, M.B., F.R.C.S., F.R.S., professor of surgery in King's College, London, surgeon to King's College Hospital, etc., and F. F. BURCHARD, M.D. and M.S. (Lond.). F. R. C. S., teacher of a practical surgery in King's College, (Lond.), surgeon to King's College Hospital, etc. In six imperial octavo volumes, with illustrations. Vol. i, 285 pages, with 66 illustrations. Cloth \$3.00 net. Philadelphia and New York: Lea Brothers & Co. 1899.

Clinical Diagnosis: The Bacteriological, Chemical, and Microscopical Evidence of Disease. By Dr. RUDOLPH V. JAKSCH, professor of special pathology and therapeutics, and director of the medical clinic in the German University of Prague. Specially revised and enlarged by the author from the Third English Edition of the Translation by James Cagney, M.A., M.D. Fourth Edition with numerous illustrations (partly in colors. Octavo. Cloth. Pp. 535. London: Charles Griffin and Company, Limited. Phila: J. B. Lippincott Company, 1899.

Progressive Medicine: A Quarterly Digest of the Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M.D., professor of therapeutics and materia medica in the Jefferson Medical College, etc. Vol. ii, June, 1899. Surgery of the abdomen, including hernia; gynecology; diseases of the blood; dietetic and metabolic disorders; diseases of the spleen, thyroid gland, and lymphatic system; ophthalmology. Octavo. Cloth. Pp. 468. Philadelphia and New York: Lea Brothers & Co. 1899.

Deaths and Obituaries.

STEPHEN STEWART WHITE, M. D., U. S. N., died in Sitka, Alaska, May 30, of ptomain poisoning, at the age of 36 years. He was graduated from Columbia University in 1885, and, after service in the Bellevue Hospital and also the Johns Hopkins Hospital, he passed the naval examining board and was commissioned assistant-surgeon. He was assigned to the U.S. Steamship *Trenton*, which was wrecked in the harbor of Apia, Samoa, when he went to San Francisco in charge of the survivors. He later served on the Baltimore, at the Naval Academy, on the Pacific coast, and as surgeon of the *Thetis*, and in June, 1897, was ordered to the naval hospital at Sitka.

IRA DEWITTE BROWN, M.D., Albany, 1865, died at his home at Weedsport, N. Y., June 23, aged 69 years. He was for several years city editor of the *Utica Herald* and afterward editor of the *Oswego Times*, and for some time an Albany correspondent and also legislative reporter of the *Albany Journal*. In 1872 he was sent to the legislature to represent the northern district of Cayuga. At the time of his death he was editor of the *Cayuga Chief*.

WESLEY CLARK EARL, M.D., Buffalo, N. Y., died June 19, aged 64 years. During the Civil War Dr. Earl served as an army surgeon and was for a time stationed at Elmira. He had practiced in Buffalo for about twenty-five years.

NATHAN PRATT, M.D., Mildred, Del., died June 18. Dr. Pratt was 65 years of age and during the Civil War was surgeon in the United States Hospital at Philadelphia and later in the Sheridan Field Hospital at Winchester, Va.

WM. J. SCOTT, M.D., Philadelphia, a graduate of the medical department of the University of Pennsylvania, class of 1892, died June 18, aged 32 years.

E. H. FUHRMAN, M.D.—At the recent regular meeting of the Alumni Association of the Wisconsin College of Physicians and Surgeons, the following resolutions on the death of Dr. E. H. Fuhrman, in Grafton, Wis., May 26, were adopted:

Resolved, That in the death of Dr. Fuhrman, the Association has lost one of its most respected and valued members; That the sympathy of the Association be extended to his family in their sad loss;

And finally, that these resolutions be published in the *JOURNAL* and spread on the minutes of the Alumni Association.

Resolved, That a copy of these resolutions be sent to his family.

OTTO KRUEGER, M.D., }
J. H. BLEKKING, M.D., } Committee.

John Isham, M. D., Louisville, Ky., June 22, aged 40 years.
. . . S. H. Keys, M.D., Monongahela, Pa., June 24, aged 67 years.
. . . Allen G. McConkey, M.D., Modesta, Ill., June 13, aged 28 years.
. . . Henry S. McElmurray, Charleston, Mo., June 16, aged 28 years.
. . . D. C. Strong, M.D., Chetek, Wis., June 20, aged 73 years.
. . . Wm. T. Taplin, M.D., Cadillac, Mich., June 18, aged 77 years.
. . . Walter M. Wright, M.D., Dartmouth, 1874, died June 24, at Orange, Mass., at the age of 53 years.
. . . Francis J. Fella, M.D., Northwestern Ohio Medical College, 1891, died at Toledo, Ohio, June 17, as the result of a fall.

Miscellany.

Lawson Tait: Erratum.—In the obituary notice of Mr. Lawson Tait, in last week's *JOURNAL*, he was referred to as "friend and teacher" of Dr. Keith. This should read "friend and pupil."

Massage of the Stomach.—In chronic affections of the stomach, the effect of medication or local applications of nitrate of silver, etc., is much enhanced by brief massage of the organ.—*Wegeler: Semaine Méd.*, No. 19.

Gonococci in Corpus Luteum Cysts.—E. Fraenkel demonstrated that these cysts develop from excessive proliferating processes in the follicular epithelium, and he now announces the discovery of gonococci in the suppurated cysts.—*Archiv f. Gyn.*, lvii, 3.

A Virile Veteran.—Joel Parker, aged 84 years, a veteran of the Civil War, was buried in Ocean Grove, N. J., June 11. He had been twice married and was the father of twenty-four children, all of whom were present at the funeral. The oldest child is 60 years of age and the youngest six months.

Varicose Ulcers and Nerve Stretching.—As stretching the nerve induces an excessive proliferation of the tissues in the part involved, Chipault has applied the process to the treatment of varicose ulcers, first stretching the nerve—usually the musculocutaneous—and then treating the ulcer, curetting or excising, and suturing the lips of the wound, if small.—*Semaine Méd.*, No. 18.

Pyohydrophrosis Evacuated Through Bronchi.—A man 43 years of age, with chronic renal lithiasis, and a fluctuating tumor in the region of the kidney, began to cough and expectorate a thin fluid which proved to be urine, while the tumor vanished, and the patient seemed to be restored to his former condition of health.—*Med. Obsorvenje*, April.

Wet Sheet in Treatment of Hyperthermia.—According to the experience of Bevilacqua, a hydrotherapeutic measure fully as effective as cold baths, with none of their inconveniences, is to stretch a wet sheet five centimeters above the patient, who lies nude beneath it. The sheet is kept wet by spraying with water to which 10 per cent. ether may be added. He supplemets the sheet with a hot-water bottle at the feet and ice to the forehead.—*Semaine Méd.*, May 31.

New Application of Heat in Gynecology.—C. Mirtl. Based on the principle of the thermophore, a metal or hard rubber obturator is filled with sodium acetate in a liquid form and inserted into the vagina. As the fluid solidifies it generates heat, producing a constant temperature of 58 C. All the inconveniences of hot-water irrigations for the purpose are avoided and the patient can readily insert the appliance without assistance.—*Wiener Med. Presse*, 1899, No. 16.

Treatment of Lupus with Potassium Permanganate. Katschanoweki reaffirms the benefits of the dry application of finely pulverized potassium permanganate to lupus, and reports thirty-six cases thus successfully treated. The layer should be several millimeters thick and a dry bandage applied. After the scab has fallen any indifferent dressing will complete the rapid cure. Sound tissue is not affected by it and it is equally efficacious for other tuberculous ulcerations and open cavities.—*Ljetopis. russkoi chirurgii*, 1.

Professional Phosphorism.—Courtois-Suffit asserts that aside from the necrosis of the jaw produced by the fumes of phosphorus through a carious tooth, and easily prevented by excluding persons with unsound teeth from the factories, there are no specific symptoms of phosphorus intoxication beyond the peculiar odor of the breath and urine, anemia, slight but rather frequent, especially among women, and possibly albuminuria, which is, however, always isolated, never accompanied by any other symptoms of Bright's disease. Other symptoms appearing are due to other causes, auto-intoxication, etc., and must not be attributed to the phosphorus, which does not specifically affect the general health.—*Presse Méd.*, May 3.

Sanitary Report of Havana, Cuba, May, 1899.—The chief sanitary officer of the city of Havana has reported 607 deaths during the month of May, 1899. The prominent items in his report are: tuberculosis, 92; enteritis, 80; heart disease, 48; malaria, 41; pneumonia, 34; meningitis, 31; cirrhosis of the liver, 18, and measles 13. Sixteen deaths were reported as from infectious fever, 11 from typhus, 5 from typhoid, 2 from gastric fever, and none from yellow fever, puerperal fever or scarlet fever. The number of sanitary reports received from sanitary inspectors during the month was 8138; the number of sanitary advices sent to property owners, 2685, and 543 cesspools cleaned. Disinfection was effected in the following instances: yellow fever, 2; typhoid fever, 15; infectious fever, 21; pernicious fever, 6; smallpox, 1; varioloid, 7; measles, 152; diphtheria, 18; typhus, 4; tuberculosis, 81; leprosy, 2; total, 360.

Sick-rates Among Troops in Cuba.—Major S. T. Armstrong, U. S. N., chief surgeon Department of Puerto Principe, has reported for the month of May, 1899, an average of 10 per cent present and absent sick, the average strength being 1278 men. The lowest rate was 8.4 on May 5, the highest 10.8 on May 16. There are a few cases of typhoid fever in the Eighth U. S. Cavalry and the Fifteenth Infantry, but the sick-rate of the former regiment has improved greatly of late. Both regiments moved into new barrack buildings during the month. All the troops in this department are now in barracks except a command of 124 men at Nuevitas. This command is under canvas but its barrack buildings are well advanced in construction. The Department is well supplied with surgeons, trained nurses, hospital-corps men, and medical and hospital supplies. The Department of the Province of Havana has a somewhat better showing for the month. Its lowest rate of sickness, including all sick present and absent, was 5.4 per cent. on May 5, and its highest 9.6 per cent. on May 12.

William F. Jenks Memorial Prize.—The fifth triennial prize of \$500 will be awarded to the author of the best essay on "The Various Manifestations of Lethemia in Infancy and Childhood, with the Etiology and Treatment." The prize is open for competition to the whole world, but the essay must be the production of a single person, and must be written in the

English language or, if in a foreign language, accompanied by an English translation, and sent to the College of Physicians of Philadelphia, Pa., before Jan. 1, 1901, addressed to Dr. Richard C. Norris, Chairman of the William F. Jenke Prize Committee. Each essay must be typewritten, distinguished by a motto, and accompanied by a sealed envelope bearing the same motto and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay. Unsuccessful essays, may be reclaimed by their respective writers, or their agents, within one year.

A Layman's View of Lawson Tait. — The great surgeon who passed away yesterday was beyond all question one of the men who helped to make Birmingham famous. At this moment, when private animosities and professional jealousies are laid aside, it is possible to form a dispassionate estimate of the man who fought death successfully for others, and yet has yielded himself to the fell destroyer while yet in the prime of middle life. Truly may it be said, "what shadows we are and what shadows we pursue." Lawson Tait was to be judged by none of the rules and laws by which men are measured for the Temple of Fame. He had his own way of doing everything; he had a marvelous aptitude for his profession, and a masterfulness that bent even his most resentful rivals to his will. He not only earned distinction by his skill; he filled the eye as a man of distinction, and no member of his profession stood out so conspicuously in manner, speech, and general appearance. He was something more than a celebrity; he looked one. There must be something exceptional in a man who comes to Birmingham from the far north without a friend; who starts in a modest private practice in a suburban road, and yet within ten years or so finds himself at the head of an important branch of the surgical profession with an income of ten thousand a year. In every quarter of the globe the magic skill of his operating knife had become almost a proverb. For one operation, which he performed in Italy, he received a fee which would serve as a good two years' income for an ordinary professional man. The Americans sent over their young and promising surgeons to study at the feet of the Birmingham magician. During Mr. Gladstone's last Government he had the opportunity of refusing the offer of a baronetcy. A man can not leap to greatness and great fees without provoking many jealousies, and perhaps, with all his skill, there was no man in England with more enemies, and this may be held to be possibly the greatest compliment that may be paid to his memory. There is this, at any rate, to be said, that he disclosed the possibilities of the knife for cases that had hitherto been looked upon as hopeless. A man who succeeds in this way does not always get his due. There are those who say that he was fond of operating for operating's sake. Others, whose opinion is quite as valuable, look upon him as one of the benefactors of the century. Women knew it must be a desperate case if Lawson Tait's services were required. For that reason they did not know whether to pray for him, or shudder at him. He had, like all masterful men, a fine contempt for the opinions of people who did not agree with him. And, as with most geniuses, there was an erratic turn in his composition. He took to his hobbies and his houses and his friends, in fits and starts, and gave them up just as suddenly and with just the same lack of system. He achieved much, but with a more discriminating balance he might have done much greater things, and died a much happier man. But he was naturally pugnacious, and no man can fight against his predominant nature. His last public act was to take part in a furious and bitter controversy with a well-known Birmingham physician. He dearly loved a tussle of this kind, and the longer and the stronger the better. Of late years he has not taken a prominent place in the social life of the town or its public and political movements. This was in many ways to be regretted, as there was no better speaker in Birmingham, no more generous

man, and no man who took a breezier and a broader view of things. He started everything he undertook with an enthusiasm that was marvelous to watch. With him disappears a most interesting and remarkable figure, one who, beyond all dispute, has brought much distinction to the town.—*Birmingham (Eng.) Daily Mail*, June 14

Suture of Heart. Ramoni (*Arz. degli Osp.*, May 14) reports that a young man stabbed twice in the heart was brought to the hospital in a very anemic condition, and after cutting and turning back a large flap opening into the thorax, the wound in the pericardium was enlarged to 6 cm. and the two small wounds into the ventricle from which the blood was issuing "in waves" were sutured. The suture was laborious, as the passage of the first needle produced such energetic systole as to tear the stitch, and the upper wound became enlarged to 3 cm. while being tamponned with the fingers. The suture did not include the endocardium. The pericardium was sutured separately and as no blood had entered the pleural cavity and the patient was very weak, the flap was replaced without suturing either pleura or ribs. In forty-nine days the patient was dismissed entirely recovered. In the thirteen cases on record wounds of the left ventricle are more numerous and severe. In 14 per cent. of the cases in which recovery without intervention has been reported, organic lesions remain which must compromise life sooner or later.

The Index: a Suggestion.—With this number of the JOURNAL we send the index for the last volume. We believe this is as full and complete as it is possible to make it. We would call attention to the "authors' index" which, while it only covers a part of the half year, makes a list of about 1700 names. In the future we hope to make this list so complete that it shall include all authors of original papers published in the reputable medical journals of the country. This, with the cross-index of subjects will, we are sure, make a very valuable addition. In this connection we desire to make a suggestion; the half-yearly volume now makes a very large book, too large to handle easily when several volumes have to be searched. Often the indexes of several volumes have to be examined before the desired matter is found. The suggestion we make is that an extra copy of the index be kept, aside from the one bound in the volume, to be used in looking up subjects. In a few years the great value of this system will be appreciated in the economy of time and labor, the several indexes being kept together in a cover for the purpose. To accommodate those who desire to take this hint, we have had extra copies of the index printed which we will send on receipt of three two-cent stamps. This is not a money-making scheme on our part, as the cost of paper, printing, mailing and postage will be more than six cents. It is a scheme on our part, however, to assist our readers, by making available, with little labor, the large amount of information contained in the bound volumes.

Philadelphia.

MORTALITY STATISTICS.—The number of deaths for the week just closed numbered 379, a decrease of 44 over last week and of 8 over the corresponding period of last year. Of the total number of deaths, 122 occurred in children under the age of 5 years. The following were the principal causes: apoplexy, 12; nephritis, 31; cancer, 16; cholera infantum, 17; heart disease, 29; marasmus, 16; suicide, 2; sunstroke, 3; appendicitis, 4.

HOWARD HOSPITAL REPORT.—The 45th annual report of this hospital has just been issued. The number of patients admitted to the wards and private rooms was 399, as compared with 327 last year and 283 the year previous. The number of accident cases was 1618, as compared with 1525 for last year and 845 for the year 1897. The new patients were 8127, and visits to the hospital, 29,253.

Washington, D. C.

HEALTH OF THE DISTRICT.—The report of Health Officer

Woodward for the week ended June 17, shows the total number of deaths to have been 147: 84 white and 63 colored. At the close of the week there were 5 cases of smallpox, 25 of diphtheria and 68 of scarlet fever under treatment. During the week there were three fatal cases of cerebrospinal meningitis.

MEDICAL EXAMINERS APPOINTED.—The Commissioners of the District have appointed Drs. J. Taber Johnson and George N. Acker members of the Board of Medical Examiners for the term of three years. They also reappointed Dr. Henry B. Noble as a member of the Board of Dental Examiners.

TESTING POTOMAC WATER. Colonel Smart, in charge of the Laboratory of the Army Medical Museum, is making a series of scientific tests of the Potomac water in the reservoir from which Washington is supplied. So far the bacteriologic tests show the water to be dangerously contaminated with sewage and a large proportion of colon bacillus.

Baltimore.

GARRETT FREE HOSPITALS FOR CHILDREN.—The annual report of the Garrett Free Hospitals for Children is out. There are two hospitals, one in Baltimore, the Robert Garrett Hospital for children, for winter use, and a sanitarium at Mt. Airy, Md., for the summer. The buildings were opened in 1888, and 1889. A dispensary is also open during the year. Cases of contagious diseases are excluded, but provision is made for the treatment of such cases arising in the hospital in an isolation ward. During the past year 227 children were admitted; there were 52 operations and 7 deaths. At the dispensary 1167 were treated.

CATTLE SLAUGHTERING.—The State Board of Health furnishes a report giving the result of an examination by sanitary inspectors of the various towns in Maryland in which the slaughtering of cattle is conducted. The report covers nearly all the towns having a population of over 500. At the great majority of slaughter-houses the offal is fed to hogs: the fats are also rendered at most of them. The report says in effect, slaughter-houses, unless conforming to sanitary regulations, are apt to become nuisances and menaces to health. The rendering of animal fats is always offensive although the influence on public health can not be clearly traced. Open kettles are unnecessary and should be forbidden. The fats can always be sold in the rough, to large establishments where they are separated in tight tanks with a minimum of offense and cost. Feeding slaughter-house offal to hogs is filthy and wasteful. Nuisance is bound to arise on such premises. Such pork is of poor quality and may be dangerous on account of the liability to trichinosis. There ought to be a law against feeding blood or other uncooked offal to hogs. This whole matter of the regulation of slaughter-houses needs to be taken up by the sanitary authorities of the towns and villages. The smaller towns have the best regulations. The best solution would be the establishment, near each town, of one properly conducted modern abattoir equipped to handle all the refuse in a cheap and profitable manner. Local butchers could effect a considerable saving by renting the privileges of a joint abattoir.

St. Louis.

RESIGNATIONS.—Drs. A. C. Bernays and I. S. Meisenbach of the St. Louis Medical College have resigned. Dr. H. C. Dalton of the same institution retired some weeks ago.

MARRIAGES.—Mrs. Wheeler Bond of St. Louis and D. Bryson Delavan of New York City were recently married to daughters of representative St. Louis citizens.

MEDICAL SCHOOLS.—The recent consolidation of the St. Louis Medical and Missouri Medical Colleges, into the Medical Department of Washington University, makes a strong combination. The respective buildings and general equipments of the two schools are new and near to each other, as also are their clinics and hospitals, so that few cities in America now possess a more generously equipped or more liberally endowed medical college than St. Louis in the above consolidation.

DR. T. O. SUMMERS.—Members of the American Medical Editors' Association, and in fact, all physicians interested in American medical literature for the past twenty years, will probably recall Dr. Thomas Osmond Summers, whose death was noted in the JOURNAL last week. He for a number of years practiced and taught medicine in Nashville, Tenn., later lived in Florida, and for the past seven or eight years has been in St. Louis, acting as medical college teacher, practitioner and editor. He has been considered an expert on yellow fever for years, and has occasionally been called to the South in times of epidemics. He tendered his services as a yellow fever immune and expert on the breaking out of the Spanish war and was promptly given a prominent place in the medical service of the army. On retiring a few months ago he was honored with the title of surgeon-major. Dr. Summers was one of the most able and brilliant men in the medical profession of the South, possessed of a bright intellect, a congenial disposition and many engaging qualities. It has been the writer's pleasure to know him for more than twenty years. Pursued by ill-health, within a few years he has become a victim of the morphin habit, and this had dimmed the brilliancy of his mind, but never soured his gentle nature. As teacher, physician, friend, he was always true. As a head of a family he was gentle, kind, lovable and greatly beloved. At the last meeting of the Missouri State Medical Society, a paper which he had read and which bore some of the evidences of mental eccentricity, was by motion of a member rejected. Dr. Summers was present at the recent meeting of the AMERICAN MEDICAL ASSOCIATION in Columbus, and expressed to friends the sadness he felt over this action, together with the fact that he had been unable to secure appointment in the regular army as he had hoped to do.

MISSISSIPPI VALLEY MED. JOUR. ASSOCIATION.—The local medical journals of St. Louis recently organized under this name, inviting all medical journals located in the territory comprised in the Louisiana purchase to join them. The prominent objects of the organization are: the advancement of the medical profession, mutual good, and incidentally the promotion of the interests of the World's Fair to be held in St. Louis in 1903. The following officers were chosen: president, C. H. Hughes; vice-president, A. H. Ohmann-Dumezil; secretary, T. A. Hopkins. The Association will hold an annual meeting and banquet during the meeting of the Mississippi Valley Medical Association in Chicago, October next.

Queries and Minor Notes.

TREATMENT OF CANCER.

WASHINGTON, Mo., June 16, 1899.
To the Editor:—In the JOURNAL of April 29 (p. 334), mention is made of a paper by Wm. B. Coley on treatment of cancer past operation. Please send me this paper and advise me of any other literature that is worthy of recommendation bearing on the same subject. Yours truly, J. I.

Answer.—The paper referred to is the final one in the special cancer number (April, 1899) of the London Practitioner. It will be impossible for us to furnish it, but it can be obtained through the publishers, Cassell & Co. In the JOURNAL, Aug. 29 and 27, 1898, Dr. Coley published a very extensive paper on this subject, and still other articles by him appeared in 1893, 1894 and 1896 in the Am. Jour. of the Med. Sci., Medical Record, Bull. of the Johns Hopkins Hospital, etc. Other papers on the subject in this JOURNAL are those of Dr. G. Betton Massey, on the electric treatment (April 23, 1898); Dr. Etheridge on treatment by calcium carbide, July 9, 1898; Dr. Emil Ries, Nov. 26, 1897; Wyeth, on treatment with toxins, June 30, 1898, etc.

Dr. C. D. Spivak has given a very good résumé of the Russian treatment with chelodionin, in the Therapeutic Gazette, Detroit, 1897, p. 226. Mention should also be made of an article by Dr. McFadden Gaston on the treatment of cancer by electricity, in the Annals of Surgery, 1897.

HYALINE CASTS.

DANVILLE, ILL., June 20, 1899.
To the Editor:—I want some information on hyaline casts. I would like to get it on the spur of the moment. Can some few hyaline casts be present in otherwise normal urine and no kidney disease be present?—Question asked with reference to insurance companies. I should like your opinion

and reference literature named. Is not this opinion held by Dr. Haines of Rush Medical College?

ANSWER.—The tendency at the present time seems to be to regard the presence of a few hyaline casts as no more significant than is sometimes a minute quantity of albumuria. Haines and Skinner (JOURNAL, Jan. 29, 1898) state that with their very thorough method they may be found in the majority of cases, even in perfect health. It is not unreasonable to suppose that a very slight renal congestion or irritation, without any symptomatic importance whatever may exist and give rise to the formation of these casts. The writers of books are, however, timid or cautious about expressing the opinion that any form of casts is without pathologic significance, and Edes (JOURNAL, Nov. 5, 1898) cautions against underestimating their importance, while admitting the above facts.

ROBERTS' LYMPH.

GALLATIN, MO., June 14, 1899.

To the Editors:—May I take the liberty to call your attention to the enclosed "hoary fakes"—such a close neighbor—and ask what you know of Dr. Joseph R. Hawley, M.D., and the "Chicago Clinical School?"

Truly yours, W. L. B.

ANSWER.—The "Hoary Fakes," as our correspondent calls it, is a pamphlet of fourteen pages entitled, "The Roberts' Lymph Compound: Its Nature, Physiological Action and Therapeutic Value," by Dr. Joseph R. Hawley, M.D., Professor Practice of Medicine and Physical Diagnosis, Chicago Clinical School. Dr. B. F. Roberts, Discoverer of the Lymph, Green City, Mo., Milan Institute, Dr. I. M. Roberts, Medical Director and Manager, Milan, Mo. The "Dr." in front and "M.D." at the end of each of the names is worthy of notice, and the general grammatical construction in the pamphlet reflects the same indication of intelligence and intelligence on the part of the author or authors. The lymph in question is taken from young goats, and consists of extracts derived from lymphoid tissue, and lymphocytes, fat and fixed tissue-cells from the lymphatic system, incorporated in lymph-plasmas by an original process of unusual delicacy. "Another strength of lymph compound is 'permatoso,' although whether alive, embalmed or in the liquid what condition we are not informed. The action of the lymph is to "correct the effects of senility," certainly a most desirable and commendable thing to do, but not only will it do this, for "later he found that by increasing the strength of concentration of the lymph he could cure a few diseases of dissimilar pathology, as will be seen below." The names appear at the end of reports of cures, which are, to say the least and "below" are given reports of cures, which are, to say the least and remarkable. The treatment may be of some value, but the pamphlet indicates faddism, charlatanism and quackism together with strong prima facie evidence of ignorance.

I. M. Roberts is designated with a star in "Folk's Directory," and his location given as Green City, Mo., not Milan; B. F. Roberts' name does not appear at all. Dr. Joseph R. Hawley was connected with the Chicago Clinical School, but is not now according to a letter from the secretary of that school, which says: "Dr. Jos. Hawley is not connected with the Chicago Clinical School. His resignation as professor of internal medicine was accepted by the board of Directors, May 17, 1899."

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended June 24, 1899:

SMALLPOX.—UNITED STATES.

District of Columbia: Washington, June 3 to 10, 1 case.
Florida: Jacksonville, June 3 to 19, 5 cases.
Georgia: Brunswick, May 16 to June 10, 6 cases; Macon, June 3, 2 cases; Savannah, June 5, 6 cases.
Illinois: Chicago, June 10, 1 case.
Indiana: Evansville, June 3 to 17, 4 cases.
Kentucky: Louisville, June 15, 5 cases.
Louisiana: New Orleans, June 16, 1 case.
Massachusetts: Boston, June 17, 1 case; Fall River, June 13, 2 cases.
Missouri: St. Louis, June 12 to 19, 9 cases.
New Jersey: Bloomfield Township, June 5, 1 case; Ocean Township, June 13, 24 cases; Ocean City, June 14, 1 case.
Ohio: Columbus, June 17, 3 cases.
Pennsylvania: Philadelphia, June 3 to 10, 21 cases; June 10 to 17, 17 cases.
New York: New York, June 17, 5 deaths.
Virginia: Norfolk, June 19, 1 case.
Wisconsin: Milwaukee, June 17, 1 case, 1 death.

SMALLPOX.—FOREIGN.

Belgium: Antwerp, May 27 to June 3, 1 case.
Brazil: Bahia, May 29 to June 3, 1 case.
England: London, May 27 to June 3, 1 case; Liverpool, May 27 to June 3, 4 cases.
India: Bombay, May 16 to 23, 11 deaths; Calcutta, May 6 to 13, 1 death.
Greece: Athens, May 27 to June 3, 16 cases, 7 deaths.
Mexico: Chihuahua, June 3 to 10, 1 death; Nuevo Laredo, May 27 to June 3, 2 deaths.
Russia: Moscow, May 20 to 27, 15 cases, 3 deaths; Odessa, May 27 to June 3, 10 cases, 1 death; St. Petersburg, May 20 to 27, 18 cases, 2 deaths; Warsaw, May 11 to 18, 1 death.
Turkey: Constantinople, June 1 to 7, 1 death; Smyrna, May 14 to 21, 2 deaths.
Uruguay: Montevideo, May 6 to 13, 4 deaths.

YELLOW FEVER.

Brazil: Bahia, May 20 to 27, 109 cases, 31 deaths.
Colombia: Panama, June 13, 18 cases, 9 deaths.
Cuba: Puerto Principe, June 21, 2 cases, total 3 cases; Santiago, June 16 to 19, 7 cases, 2 deaths.
Mexico: Tampico, June 5, 1 case; Vera Cruz, June 8 to 15, 117 cases, 61 deaths.

CHOLERA.

India: Bombay, May 16 to 23, 1 death; Calcutta, May 6 to 13, 27 deaths; Karachi, April 24 to May 1, 1 case; Moulemein, April 15 to 30, epidemic.

PLAGUE.

India: Bombay, May 16 to 23, 174 deaths officially reported, probably 300; Calcutta, May 9 to 13, 55 deaths; Arrachee, April 9 to 16, 263 deaths; District of Murrachee and Province of Sindi, April 24 to May 1, 251 cases, 175 deaths; Mauritius, May 1, 3 cases.

The Public Service.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., to and including June 22, 1899:

Thomas W. Bath, acting asst.-surgeon, from La Harpe, Ill., to Fort Leavenworth, Kans., to accompany Troop F, 6th Cav., to San Francisco, Cal., to J. Black, acting asst.-surgeon, from the Dept. of California.

Joseph L. Bell, acting asst.-surgeon, from French Lick, Ind., to San Francisco, Cal. for duty in the Dept. of California.

Charles A. Cattermole, acting asst.-surgeon, from Lansing, Mich., to San Francisco, Cal., for assignment in the Department.

Henry C. Cline, acting asst.-surgeon, from Camp Meade, Pa., to Fort Royal, Va., for assignment of contract.

Vernon K. Eastman, acting asst.-surgeon, from Murfreesboro, Tenn., to San Francisco, Cal. for duty in the Department.

Edwin F. Gardner, major and surgeon, U. S. A., leave of absence granted.

N. N. Hereford, acting asst.-surgeon, from Baden, St. Louis, Mo., to San Francisco, Cal. for duty in the Department.

Donald P. McCord, acting asst.-surgeon, sick leave extended.

John A. Metzger, acting asst.-surgeon, from Latrobe, Pa., to San Francisco, Cal., for duty in the Department.

William Gray Miller, acting asst.-surgeon, from Newcastle, Pa., to San Francisco, Cal., for duty in the Department.

James C. Shellenberger, acting asst.-surgeon, from Piqua, Ohio, to San Francisco, Cal., for duty in the Department.

John H. Stetson, acting asst.-surgeon, from Clinton, Mo., to San Francisco, Cal., for duty in the Department.

Joseph J. Wilson, acting asst.-surgeon, from New York City to Flushing, N. Y., for assignment of contract.

Movements of Navy Medical Officers.—Changes in the medical corps of the U. S. Navy for the week ended June 24, 1899:

Surgeon L. W. Atlee, detached from the "Boston" and ordered to the "Bennington."

P. A. Surgeon R. B. Ward, detached from the "Bennington" and ordered to the "Essex."

Asst.-Surgeon F. M. Furlong, detached from the "Independence" June 30, and ordered to the "Solace" temporarily for passage to the Asiatic Station.

Surgeon C. G. Herndon, on completion of temporary duty at recruiting rendezvous at Chicago, Cleveland, Ohio, etc., ordered home to await orders.

Medical Inspector R. A. Marrison, detached from the Washington navy yard, July 1, and ordered home and to await orders.

Surgeon S. H. Dickson, ordered to the Washington navy yard, July 1.

Marine-Hospital Changes.—Official List of Changes of Station, and Promotions (Commissioned and Non-Commissioned Officers of the U. S. Marine-Hospital Service, during the week ended June 22, 1899.

Surgeon Fairfax Irwin, granted leave of absence for three months from July 8, 1899, with permission to go beyond the sea.

Surgeon H. E. Carter, detailed as quarantine officer of the port of Havana, Cuba, under executive order of Jan. 17, 1899.

Surgeon C. E. Banks, to proceed to New York City, for special temporary duty.

P. A. Surgeon C. P. Wertenbaker, to proceed to Danville, Va., for special temporary duty.

P. A. Surgeon A. C. Smith, granted leave of absence for thirty days from July 19, or when relieved.

P. A. Surgeon W. J. S. Stewart, granted leave of absence for fifty-two days from June 19, 1899.

Asst.-Surgeon L. B. Cofer, to proceed to El Paso, Texas, as inspector; to proceed to Mexico for temporary duty.

Acting Asst.-Surgeon H. C. Sirocco, granted leave of absence for ten days from June 21, 1899.

Acting Asst.-Surgeon H. C. Wakefield, granted leave of absence for thirty days from June 18, 1899, on account of sickness.

Hospital Steward and Chemist Henry Gahn, to proceed to New York City on special temporary duty.

Acting Asst.-Surgeon W. C. Mason, granted leave of absence for six days from June 28, 1899.

PROMOTION.

Junior Hospital Steward Charles Slough, to be senior hospital steward.

RESIGNATION.

P. A. Surgeon W. J. S. Stewart, resignation as P. A. Surgeon accepted as tendered, by direction of the President, to take effect Aug. 9, 1899.

CHANGE OF ADDRESS.

Bruker, C. M., from Pasadena, Cal., to Canon City, Colo.
Bass, H. W., from Richmond, Va., to Henderson, N. C.
Chase, Wm., from 247 Laclade to 4419 St. Louis Ave., St. Louis, Mo.
Dickson, W. L., from 124 Baronne, to 543 1/2 St. Charles St., New Orleans, La.

Ewing, E. W., from 226 Winchester Ave., to 604 Adams St., Chicago.
Frasier, N., from Chicago to Tusculum, Tenn.

Heger, L. A., from Brooklyn, N. Y., to 1814 G St. N. W., Washington, D. C.
Hoxie, W. E., from Chicago to Hampton, Va.

Lugham, W. H., from Philadelphia to Manor Station, Pa.
Mason, L. D., from Brooklyn, N. Y., to Greenville, Conn.

Mulick, J. W., from Chicago to Riceville, Ia.
Parker, J. O., from Ann Arbor, Mich., to La Salle, Ill.

Reed, R. W., from 47 W. 71st St., to 43 W. 91st St., New York.
Pickles, H., from Joliet to La Salle, Ill.

Rohalshauger, E. E., from Wateksa to 4308 Langley Ave., Chicago.
Rice, W. F., from Omaha, Neb., to Binghamton, N. Y.

St. Louis, B., from 3457 Bell Ave. to 219 Pine St., St. Louis, Mo.
Stoue, I. S., from 2636 to 3041 11th St., Washington, D. C.

Shivak, C. D., from Deuision to Nevada Block, Denver, Colo.
Simson, C., from Chicago to Provo, Uta.

Underwood, A. M., from Lancaster, Pa., to Grove Beach, Conn.
Whoelet, A. C., from Saratoga, Wyo., to Leoben, Pa.
Wildner, L., from Chicago to Duwling, Ill.
Whitaker, J. T., from Cincinnati, O., to Lakewood, N. Y.
Wright, J. B., from Richmond, Va., to Colasie, N. C.

The Journal of the American Medical Association

VOL. XXXIII

CHICAGO, ILLINOIS, JULY 8, 1899.

No. 2

Address.

SECTION ON STOMATOLOGY*

CHAIRMAN'S ADDRESS.

BY GEO. V. I. BROWN, M.D.

DEAN AND PROFESSOR OF ORAL SURGERY, DENTAL DEPARTMENT,
MILWAUKEE MEDICAL COLLEGE,
MILWAUKEE, WIS.

For the second time it is my privilege to give you greeting in the time-honored form of the Chairman's address. Properly you have the right to expect of me a résumé of the various evidences of progress in those directions in which our interests are particularly centered. A pursuance of this idea leads directly to the pages of the journals published during the year. It is but natural that much of the matter which they contain should prove, on a close investigation, to be merely the old coats that various subjects have long been wearing, turned the other way, fashioned over into a more modern form, perhaps edged and trimmed with something new; yet there have been new facts developed, or at least a new growth started, on old lines of development, in a few subjects, which bring them rightfully to your notice at this time, notable among these are the experiments of Dr. J. Leon Williams, whose demonstrations of his study have cast a new light on the etiology of dental caries, and are bound to have an extended influence, directly and indirectly, on the methods employed in the preservation of tooth structure; as are also his studies of the pericementum, particularly those which by the aid of the microscope have shown the collateral nerve-supply from which we positively find that nerve-filaments make their way to the pulp, not only through the apical foramen, but through the pericementum at other portions of the root surface. It is the possible clinical importance of this interesting demonstration to which I feel that I must call your attention, bearing to me as it does a more than usual import through the study of the various phenomena of neural disturbances, which have made up the larger portion of my practical work for some time past.

Last year, and also the year before, in papers before this Section, and in one before the Section on Neurology, I tried to make clear the fact that by reason of the action of the jaws through some central disturbance affecting the muscles of mastication, by mal-occlusion, habit or otherwise, the constant irritation of the membranes around the roots frequently caused reflex pain in the various points of distribution of the fifth nerve; spasmodic and other affections frequently, also any symptoms of general neurasthenia, which have hitherto usually been ascribed to eye strain, womb affection, or some of the other better known forms of nerve irritation. That such conditions might result from pulpitis or direct irri-

tation, transmitted to the nerve trunk, through the apical foramen, was well understood, but such symptoms were not commonly accepted as being likely to arise from the pericementum alone, yet from the slides which Dr. Williams has shown, the facility with which they might occur in this manner is easily comprehended. The importance of the work, and the diagnostic significance of the facts made, I am sure will become more and more apparent to others as it has to me during the investigation of the past year which by a long list of clinical evidences has added to my already strong conviction that the frequency and severity of the symptoms in nervous affections of the face, jaws, and neck are nearly always, if not induced, at least aggravated by the constant grinding of the teeth, or extreme pressure of the jaws during sleep or moments of abstraction, and with paroxysms of pain; usually, however, without consciousness of the fact by the individual at the moment. The symptomatology and diagnostic differentiation of pains of the head and face are most unreliably laid down in text-books and medical literature, therefore any step toward definite etiologic distinction is worthy of our most careful consideration.

The second subject brings to mind the fact that there has begun, and is now, in the somewhat painful and even uncertain act of being born, a new state of things with regard to the higher preliminary requirements for the admission of students to our dental colleges; also an effort to arouse interest in the unification of the laws governing the practice of dentistry throughout each of the different states, so that a license to practice granted by one board shall be everywhere accepted by other boards, and this too without lowering the standard or in any way jeopardizing the good work which even the strictest among them may be endeavoring to accomplish. This has been brought forward by Dr. E. C. Kirk in a valuable paper and editorial. It is unfortunate that at the present time there appears to be a danger of a clashing of interests between the National Board of Dental Examiners and the National Association of Dental Faculties, the two bodies whose interests should be and doubtless are centered in raising the standard of dental education, forces that ought to be in harmony instead of in opposition to each other, or vying in an endeavor to advance rather than disputing as to the manner of the progress. The dream which many of us have cherished in those moments when our Utopian fancies have held sway over the difficulties that at other times seemed insurmountable, might now be accomplished or at least set well on its way toward fulfillment by a little effort, which might perhaps in a measure help to solve the present differences. By way of a suggestion to this end, the idea is now given to you that, were the two associations named to work together, approximately at least in harmony, as do the upper and lower houses of our Congress, the legislatures and senates in our states, and agree that rules governing college management with regard to preliminary requirements, nature and length of study, require-

* Presented to the Section on Stomatology, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

ments for graduation, etc., should be acted on by each, and approved by both before becoming laws properly binding the college membership—and this much accomplished—these two bodies together should select each a certain number yearly from among themselves or outside of the membership, who should be empowered to examine both colleges and students and report jointly to both associations, also to regulate the examination methods and questions of the different boards, so that students graduating under this supervision might be everywhere accepted with merely a nominal examination or none at all, and that a license granted by one board could be accepted with perfect security by every other board, because the character of questions would be uniformly the same for all. Thus we have at once a simple and feasible plan, easily practicable and without the necessary revision of state laws or the passage of a national law, both of which are almost or nearly insurmountable obstacles. The arguments against this plan might be, on the one hand that the National Board of Examiners is a body, the members of which are largely more or less the result of political appointment and therefore objectionable on the ground of politics and perhaps of unfitness as compared with the members of the association of faculties, who are necessarily trained teachers thoroughly conversant with the needs and practical requirements of college work. Yet out of this very objection grows the particular practicability of the plan because the training and fitness of the college men by action and advice would undoubtedly influence the other body, while on the other hand, and tendency to check advance by reason of the possibility of selfish interests, expressing itself through a fear of the loss of students, would be counterbalanced by council with the examiners' association, and while it must be admitted that the personnel of state boards is often marked by ignorance and unfitness for the duties they are called on to assume, yet it must be remembered that they represent the people and voice the sentiment of the great body of practicing dentists, not enrolled on the faculty lists of colleges whose earnest desire, so far as the best of their number might dictate, would unquestionably be in the direction of an elevated standard, and while individual dishonesty may sometimes be a "bar smister" upon the escutcheon of a board, yet who can question that the majority of the delegates from each of the states would at least be fair-minded, honest and full of the zeal which every high thinking practitioner should possess? Why not then join hands, those who are fit by reason of experience and whose calling ought to lead them to favor better education with those who have been selected by reason of their inclination in the same direction. Without politics, delay or serious discord, without injury to the interest of any college, board, state, or individual, can be set in motion a systematic co-operation which could give us a higher standard of dental education, the equivalent of uniform legislation. I would suggest that this idea, if you approve it, emanate in some substantial form through cooperative committee, or direct communication to both the National Association of Dental Examiners and National Association of Dental Faculties.

Two years ago, in Philadelphia, in the chairman's address of Dr. Andrews, and again last year in my own at Denver, the idea was brought forth and stress laid on the importance of examination of the mouths of public school children by competent dentists and need of giving instruction as to the proper care and such prophylactic measures as would at least tend to check the vast amount of suffering, sickness and general infection due to the

pathogenic organisms of the oral cavity, neglected through the ignorance which prevails on this subject. I feel it my duty to again call your attention to the importance of this subject and to impress on you the need of some active step in a direction which is clearly defined, and directly in the line of the duty which rests on each one of us, much more by reason of our double interests in medicine and dentistry than it does on the dentist alone, who has perhaps less concern with regard to the public health. It is a fact that 50 per cent. of all people, certainly in the large cities, are affected with tuberculosis in some of its many forms. It is also true that the death of one of every seven by this disease is a conservative estimate. We know that affections of the stomach, and of the intestinal tract throughout its entire length, are commonly the result of infection from the mouth. We know that the bacillus of diphtheria, the pneumococci, streptococci and other pathogenic germs are frequently found in the mouth of healthy persons, that diseases of the eye, ear, nose and throat, anemia, pyemia and septicemia, together with many spasmodic and nervous diseases, are often the result of oral conditions, which, with a little care might easily have been prevented in the beginning. You are too well familiar with these facts to need a rehearsal of them, but what I feel is required this time is, some active definite organization which will begin a systematic undertaking of the promulgation of this idea and the work it contemplates in all of the cities where our influence extends. In no other way can we confer so much benefit on the two professions we represent and on our fellow-men, or reflect such undying credit on ourselves and our Section as by giving this matter the time and consideration it deserves. I would suggest, therefore, that a committee be appointed and empowered to appoint subcommittees in the various cities, to ask state local societies to assist and to correspond with the principals of schools urging that the dentists whom this committee might select be allowed, or if necessary, requested, to come to the school buildings and talk to the students on this subject; that whoever undertakes this work be urged to make examinations of the mouths and collect data as far as possible. If all this be done in the name of the Section of Stomatology and the credit resulting be laid to its door, I am sure the reward will be ample.

I have forborne thus far making mention of the value of papers of members of our Section published in current literature, or of additions from individuals among our little band of followers in book form, valuable to dental, medical and general science, choosing rather to refer to contributions from outside our membership, but I cannot, in justice, refrain from calling attention to the fact that the Section of Stomatology has reason to be proud of the scientific results of original investigations that its members have given to the world, there being no other organization of dentists, so far at least as I can learn, whose members have contributed to much scientific matter in the form of books, papers and original work, in proportion to the total membership, as have the members of this Section. This, I believe, should be not only a matter of congratulation, but one of great encouragement as well. It is a matter that makes me feel deeply the honor you have twice conferred on me, an honor that, optimistic as I am of the future of this Section, in which our hearts are bound together. I feel and know will be of ever-increasing importance in the eyes of the scientific world.

We stand to-day at a portal
Once locked with an unkind bar;

But now a ray of sunshine
Steals in, for the door's ajar.

Its wavering light reveals us
Such hidden secrets there,
That the dreams of wildest fancy
Have nothing to compare.

Pried open by force of Science,
To human minds unsealed,
The truths of Nature's text-book
Are one by one revealed.

That which the understanding
Of man but yesterday
Might wholly fail to compass,
To-morrow explains away.

Far into the boundless firmament
The eye extends its range,
While thousands of magnifications
Develop things small, strange.

Our voice's softest accent
Resounds through miles of space;
And far out-stretching metal arms
Touch every distant place.

The storm has lost its terror,
We hold its fire a slave;
To warm, to light, or fetch and carry,
Bondsman, our strength to save.

The sea gives up its treasures,
The land its fruit and gold;
The beauties of Art and Nature
Are placed in our hands to hold.

'Tis something, at least, that one should be
A soldier in this great fight,
And under the banner of Science
Do battle to set things right.

Though each be only an atom,
A tiny molecular part,
Of the Universe where truth is sought
In letters, and Science and Art.

Yet, how may a man do better
Than strive as best he can
To ease his fellow's suffering,
Or lengthen life's brief span?

URIC ACID THEORIES.

A CRITICAL REVIEW, AND SOME ORIGINAL INVESTIGATIONS.

BY ALFRED C. CROFTAN, M.D.

Late Assistant Professor of General Diagnosis, College of Physicians
and Surgeons, Chicago.
PASADENA, CAL.

MOTTO: "*Je n' enseigne pas, je raconte.*"

—*Montaigne.*

This paper constitutes a preliminary report and incorporates the results of a series of investigations made with a view of corroborating experimentally the theoretic views advanced. The details of laboratory technic, of the many quantitative analyses of blood and urine that have been made, the description of animal experiments are reserved for future publication; reports of cases are also withheld for the present until more material of this kind shall have been gathered.* I am aware of these

*The treatment advised for uric acid lesions at the end of this paper is deduced from theoretic reasons exclusively; empiric findings are scanty so far. I have, however, a record of twenty-two cases with most positive results. This paper is in the nature of an appeal to clinicians and practitioners more fortunately situated than myself as to clinical material, to try the measures advocated and to furnish me with short reports of their cases and of the therapeutic results observed. I should like at not too far distant a time to be able to publish a report on several hundred cases collected in this manner, together with the laboratory find-

limitations, still my report may be given at this early date, "or else, to-morrow a stranger will say with masterly good sense precisely what we have thought and felt all the time and we shall be forced to take with shame our own opinion from another."

As existing uric acid theories are full of inconsistencies and absurdities, it seems necessary, before erecting a new theoretic structure, to remove, by a severely critical review, the debris of exploded theory that encumbers the foundation of solidly demonstrated facts.

All investigators seem to agree that somewhere and somehow in the body uric acid enters the circulation in excess and gives rise to the protean mass of symptoms we group under the name of uric acid lesions; they begin with the mass of functional disorders, the "masked" manifestations—headaches, migraine, vertigo, certain forms of eczema and of asthma, uricaria, sciatica and a host of others—and progress in severity to lesions like nephritis uratica and gout, which are accompanied by inflammation and necrosis and lead to destructive tissue-changes.

Two facts stand:

1. Uric acid is found in the blood of gouty subjects during the attack. Garrod¹ made this discovery in 1848; it has been corroborated a thousand times since; there seems to be no doubt, therefore, that gouty blood is comparatively rich in uric acid, whether this is the case during each period of the disease has not been definitely settled. Exact quantitative methods for determining small quantities of uric acid in the blood are wanting, so that, as we shall see later on, the presence of small quantities has evaded detection. Further, Garrod² himself found uric acid in the blood of cases of chronic lead poisoning and of nephritis; Salomon³, Haig⁴, v. Jaksch⁵, in pneumonia, and v. Jaksch⁶ in anemia, dyspnea and emphysema; the quantities found in these diseases were as large as those found in gout.

2. Uric acid in the shape of its insoluble salts is found in the concretions of gout, in the joints, the kidneys, in fact in every tissue of the body with the exception of the nervous system, which seems to enjoy an immunity. This has been known since 1797 (Wollaston). So pathognomonic are these uratic deposits for gout that we may say that wherever we find urates in concretions we have gout; but we can not invert this proposition because we certainly see typical cases of gout in which concretions of uric acid do not occur. As against the primary role of uric acid is the peculiar location of these concretions. Virchow⁷, in 1884, in a lecture on nephritis uratica—gouty kidney—showed that the inflammatory and necrotic processes were found in a different part of the kidneys and joints than the concretions; in gouty kidney the characteristic kidney changes begin in the cortex, while the uratic deposits are found in the parenchyma; in the joints the inflammation starts from the synovial membranes, while the concretions are found in the cartilages. However violent the inflammation may be, and though it lead to suppuration, uric acid is never found in the exudate. He further calls attention to the great similarity as to distribution and localization that exists between these urate deposits and the manifestly secondary deposits of calcareous material found in different diseases. He arrives at the conclusion that some substance circulating in the blood with an apparently selective affinity for certain membranes prepares a suitable nidus for the deposit of urates.

logs I have on record and my own cases. I shall most gratefully receive such reports and gladly give credit, in my publication, to my colleagues who will be kind enough to assist me in this manner.

As against the theory that uric acid is the primary cause of the lesions attributed to its presence in the blood, we have the fact that it is essentially a non-toxic substance; the administration of large doses to a healthy animal or man produces none of the symptoms of acute uræmia and the exhibition of small doses for a long time is not followed by any of the disturbances commonly attributed to chronic uric acid poisoning. The excretion of uric acid and its relationship to gout and allied conditions has been exhaustively studied. The results are not uniform and no diagnostic clues are gained from the quantitative determination of the uric acid excreted; besides, a large part of the work done in this direction is essentially fictitious, because the method employed until recently, that of Hantz, is inaccurate and yields values for uric acid that are too low; but even later analysis made by Ludwig-Salkowski's method discloses very little of value (see below). Thus the evidence in favor of Garrod's old theory is scanty and insufficient.

Within the last decade a series of masterful investigations have been published on the chemical relationship between uric acid and nuclein; they seem destined to throw new light on the subject.

Based on the fact that in leucæmia a great increase in the excretion of uric acid is observed, and surmising an inter-relationship between the great katabolism of leucocytes and the large quantity of uric acid, Horbaczewski⁷ attempted the synthesis of uric acid from organic material containing large quantities of leucocytes. He made a mixture of spleen pulp and blood, heated it for several hours at body temperature (37-40 C.) in the presence of air and, in fact, obtained considerable quantities of uric acid. He surmised that the nuclein contained in the nuclei of the leucocytes furnished the material for the uric acid, and when he heated nuclein under the same conditions he succeeded in completely converting it into uric acid. This was a process of oxidation, for he found that if he excluded the air he generated no uric acid, but a peculiar group of substances instead, the so-called nuclein bodies—syn. xanthin bodies, alloxuric bases—which had previously been made from pus, internal organs and yeast nuclein by simple heating in the absence of oxygen (Kossel,⁸ Salomon⁹). They are basic substances, readily soluble in water; their chief representatives are xanthin, hypoxanthin, paraxanthin, adenin and guanin. On oxidation, then, nuclein gives uric acid; if oxidation is deficient or no oxygen is present the alloxuric bases are formed instead.**

This discovery overthrows the old doctrine that uric acid is a product of the oxidation of albumin, so to say, an intermediate product between it and urea. It is true we can oxidize uric acid into urea and we can oxidize albumin into urea, but we cannot oxidize albumin into uric acid; it was, therefore, merely an assumption without experimental foundation that uric acid is an oxidation product of albumin. Nuclein, on the other hand, can readily be oxidized into uric acid and further into

urea; the alloxuric bodies too can be oxidized into urea, but they can not be converted into uric acid by oxidation! The following diagram may illustrate this relationship:

Where in the body this oxidation process occurs is doubtful, whether in the tissues at large, in the liver or in the kidneys. Preponderance of evidence seems to point toward the kidneys, to judge from animal experiments; but conclusions in regard to the human uric acid economy drawn from observations on animals are quite unreliable, because great differences exist in this direction between man and the lower orders of animal creation (Salkowski,¹⁰ Chittenden,¹¹ Kumawaga,¹² Horbaczewski.¹³)

In order to understand the pathology of a disease it is necessary to understand the physiologic function, a perversion of which it represents. The function that is perverted is the nuclein metabolism. If oxygenation is sufficient we have the formation of uric acid; this is the normal process. Its perversion may be twofold, i. e., nuclein metabolism may be excessive or oxygenation may grow deficient; in either case we will have a decrease in the formation of uric acid and a corresponding increase in the formation of the alloxuric bases. We make this perversion responsible for so-called uric acid lesions. We maintain:

1. That uric acid is not the *materies morbi* in uric acid lesions.
2. That uric acid acts pathologically only from its tendency to form concretions.
3. That its formation, far from being a process of auto-intoxication, is a process of disintoxication.
4. That the decrease in the excretion of uric acid observed in some morbid conditions is not due to retention but to non-formation.
5. That the *materia peccans* in uric acid lesions are the alloxuric bases.
6. That in all so-called uric acid lesions we find an absolute increase over the normal of the *sum* of uric acid and alloxuric bases, and that this finding is of diagnostic value.

That uric acid is a non-toxic substance has already been emphasized, it is furthermore almost insoluble in the tissue juices; its salts are essentially insoluble. Not so the alloxuric bases; they are readily soluble and possess highly toxic properties. Rachford,¹⁴ Filehne,¹⁵ Paschikis and Pall¹⁶ are responsible for the statement that a large variety of nervous phenomena, migraine, increase in the arterial tension and arteriosclerosis, are attributable to xanthin, paraxanthin or hypoxanthin poisoning. As early as 1884 Gaucher¹⁷ discovered that the injection into the body of a healthy animal of small quantities of xanthin and hypoxanthin—both belonging to the group of alloxuric bodies—produces marked changes in the excreting cells of the kidney-parenchyma—néphrite epithéliak—Kolish and Tandler¹⁸ observed the same. My own investigations, recently completed and not yet published, made with a view of corroborating these findings,

** The term alloxuric bases is employed for the group of basic, soluble substances mentioned above; the term alloxuric bodies includes uric acid. The method employed for their determination is that of Krueger and Wulff (Zeitschrift für Phys. Chemie, vol. 20), viz.: 100 c.c. of urine that has been freed of any albumin it may contain, are heated to boiling, and 10 c.c. of a concentrated solution of sodium-bisulphite and 10 c.c. of a 13 per cent. of copper sulphate added; the mixture is then boiled for about five minutes and allowed to cool. The precipitate that forms is separated from the supernatant fluid by filtration and washed several times with distilled water of 50-60 C., then, while still moist, placed into a flask and the nitrogen it contains determined according to Kjeldahl's method. This gives the total of alloxuric bodies; in another quantity of the uric acid is determined according to Ludwig-Salkowski's method; the quantity of alloxuric bases is determined from the difference between the alloxuric bodies and the uric acid. This method seems complicated and tedious, but is exceedingly simple when the solutions are ready and the details of technic are once mastered.

positively demonstrate that both xanthin and hypoxanthin, when injected hypodermically in the strength of a 0.3 to 0.7 per cent. watery solution for a period of several months, produce granular degeneration of the epithelial cells lining the tubuli contorti and a proliferation of the endothelium of the intertubular capillaries. Albumin was invariably found after a period of three weeks. We may say, therefore, that the presence of minute quantities of alloxuric bases in the circulation is capable of producing marked anatomic kidney changes. We are indebted to Levison¹⁹ and others for the knowledge that granular atrophy of the kidney is a constant precursor of gout—the view that it is the result of a chronic form of auto-intoxication is substantiated by the fact that in lead-gout, i. e., in that form of spurious gout which is produced by the administration of small doses of lead for a long-continued time we find this same form of granular atrophy of the kidney, accompanying the systemic and arthritic manifestations (Charcot and Gombault,²⁰ Coen and Ajutolo²¹). We have compared the kidney changes of chronic lead intoxication with those formed in chronic alloxuric body intoxication; they are identical; and as the kidney changes of gout are identical with those of chronic lead intoxication, we may say that the organic kidney changes observed in uric acid subjects can be produced by alloxuric bases. We can chronicle the fact that uric acid injected into the circulation of healthy animals for a period of over three months produces no kidney changes whatever. To sum up briefly we may say, therefore, that uric acid, is incapable, as far as we know, of producing any of the symptoms of so-called uric acid poisoning when injected into the body of a healthy animal; the alloxuric bases can, on the other hand, firstly produce a series of functional disorders that are similar if not identical with those observed in the "masked" forms of uric acid intoxication, and secondly anatomic changes in the kidneys that are identical with those observed in gout, i. e., the severer forms of chronic uric acid poisoning.

The belief is prevalent that uric acid is never found in normal blood; on the other hand we know that uric acid in appreciable quantities is found in normal urine; the conclusion naturally to be drawn herefrom would be that the kidney cells convert "some substance" that is circulating in the blood into uric acid and excrete it; there are, however, quite a series of arguments against this assumption, and these we will discuss later on; a discrepancy exists somewhere. With a view of clearing up this point I undertook a series of investigations directed toward a determination of the quantity of uric acid in normal blood. In leucemia the above discrepancy seems particularly emphasized as we all know that the urine of leucemia subjects is very rich in uric acid, and that according to Salkowski,²² Landwehr and Bockendahl,²³ Stalldagen²⁴ and Salomon,²⁵ no uric acid is found in the blood. Koerner,²⁶ on the other hand, when he examined large quantities of leucemic blood, obtained by venesection, discovered considerable quantities of uric acid. This finding, coupled with the fact that the methods employed for the quantitative determination of uric acid in the blood were deficient and gave too low values (see above) and the knowledge that, owing to the great insolubility of uric acid, only very small quantities could at best be expected—the whole excretion during twenty-four hours rarely exceeds 1.2 grams in a normal subject—convinced me of the futility of looking for determinable quantities in a few cubic centimeters and led me to make analysis of larger volumes of blood. I have found uric acid in the blood of twelve normal subjects; in two the

blood was taken in bulk by venesection, in the other ten it was obtained from the operating-table. Corpuscles and serum together were examined, not the serum alone; I am at present occupied in analyzing serum and coagulum separately; whatever the result of this latter investigation may be, the fact, in my belief, is established that uric acid is found in normal blood. This makes the presence of uric acid in normal urine self-evident and relieves us of the necessity of hypothetically attributing a special uric-acid forming function to the cells of the kidney parenchyma; a leading argument against the assumption of such a role is the fact that, in no form of Bright's disease do we find a diminution of uric acid in the urine unless severely destructive changes have occurred in the kidneys; if the kidneys were concerned in the manufacture of uric acid, the severe damage they undergo functionally and organically in Bright's disease of all forms would certainly lead to a diminution of the excretion of uric acid. And here is one of the many fundamental fallacies that have been transmitted without question from medical generation to medical generation, namely, that uric acid is diminished or absent from nephritic urine; the statement is simply false, notwithstanding the publications of Bartels,²⁷ Wagner²⁸ and Fleischer.²⁹ Again their method—that of Heintz—was defective; if Ludwig-Salkowski's exact method is employed it will be found that normal values for uric acid will be registered in all but the last stages of Bright's disease. Frerichs³⁰, Van Ackeren³¹ and Stadthagen³² teach us this; my own analyses, executed in some fifty cases, corroborate their findings.

We quote and translate in a condensed form from V. Noorden, "Pathologie des Stoffwechsels," as follows:

Examinations of the urine for acid in gouty subjects date back only to the time of Garrod; his analyses of the blood and urine showed that a gouty subject as a rule excretes less uric acid than a normal subject, sometimes no uric acid at all is found in the urine. This diminution is especially apparent before the attack, and during the attack later on normal values are re-established. In the blood, on the other hand, the uric acid is increased whenever it is decreased in the urine. This is the basis of Garrod's historic theory of gout; the kidneys of a gouty subject do not excrete the uric acid as rapidly as it is formed; under a great variety of circumstances their faculty of excreting uric acid is generally diminished. Uric acid accumulates in the blood; as soon as the accumulation reaches a certain degree the attack begins; uric acid is deposited in the tissues and is later, by the aid of "inflammation" oxidized away again; the blood is thus purified of uric acid. For a time the formation and excretion of uric acid are balanced until the equilibrium is again disturbed. In chronic irregular gout the excretion of uric acid is permanently reduced. We must say that the painstaking uric acid determinations of Garrod and of his successors can hardly be considered valid to-day, as they were executed by the method of Heintz, which does not indicate an incalculably large part of the uric acid, sometimes none of it at all.

We must therefore, skip all the investigations of Lehmann, etc. (naming half a dozen others) who all corroborate Garrod's findings basing on determinations made according to Heintz and must consider only the more exact investigations of late years—too bad, that the arduous and conscientious labors of so many honest men must be considered valueless owing to their employment of a method the deficiencies of which were only recognized later.

A series of investigations made with Heintz' method even had made Garrod's findings doubtful; thus Bouchard found almost normal values in the time between the attacks and Lecombe almost always found normal values in gouty subjects. To-day (1893) the evidence in favor of abundant uric acid excretion is accumulating. The figures given by Ebstein and taken from Sprague's analyses, the figures of E. Pfeiffer and of L. Vogel—during the attack, between the attacks and in chronic atypic gout—do not differ materially from those found in healthy individuals and in a variety of non-gouty diseases.

The normal figures for a grown person on ordinary diet are given as from 0.7 to 1.2 gr. pro die; the values for uric acid in the urine of gouty subjects fluctuate within these boundaries.

From our own investigations then, and from the authoritative statements of competent writers, it appears that uric acid is a normal constituent of the blood and that the excretion of uric acid does not deviate from the normal in gouty subjects. If, however, we consider not uric acid alone, as has been done heretofore, but also the alloxuric bases—the interesting relationship of which to uric acid and to nuclein we have studied—typical excretory abnormalities of diagnostic and prognostic value will be found in “uric acid” cases, as follows: We have made a large number of quantitative determinations of the alloxuric bases—alloxuric nitrogen—in the urine of subjects suffering from gout or from other manifestations of the uratic diathesis and in every instance we have found an absolute increase in the excretion of these bodies over the normal; so that if we take the sum of uric acid and of alloxuric bases excreted we always find a typical aberration from the normal in the sense of an increase of this sum.

We are now in possession of the facts that are observed in uric acid cases; a number of old observations have been shown to be erroneous, a number of new ones have been added in their place. How, in the light of this new point of view does the normal nuclein economy of the body present itself, and how does a perversion of this function produce “uric acid” lesions? Finally, do the clinical laboratory findings correspond with the findings we should expect if our ideas are correct?

The excretion of uric acid and of alloxuric bases depends, as stated above, on the quantity of nuclein that is converted and on the activity of the oxidation processes. As the leucocytes, according to Horbaczewski and others, furnish the bulk of the nuclein, we may expect to find an increase in the uric acid and alloxuric bases, with an increase of the leucocytes. This is clinically borne out, as may be seen by the following examples: Certain drugs, as quinin, pilocarpin and atropin, that produce leucocytosis; certain infectious diseases that are accompanied by leucocytosis, leucemia in which the increase in leucocytes is excessive, also all produce a marked increase in the excretion of uric acid and of alloxuric bases. After eating we have a digestion leucocytosis and it is accompanied by an increase of the above substances in the urine, and in carcinoma of the stomach, when we have no digestion leucocytosis, this increase is not observed. Spleen extract injected into the circulation of a leucemic subject produces both a leucocytosis and an increase in the alloxuric bases. Examples of this kind might be multiplied. The second factor, the activity of the oxidation processes, clinically yields equally positive results. Wherever we have a decrease in the aerating surfaces of the lungs, as in emphysema, late stages of tuberculosis, etc., as manifested clinically by dyspnea and cyanosis, we have a decrease of the uric acid excretion and a corresponding increase of the alloxuric bases instead; the same applies to deficiencies in the hemoglobin economy and wherever we have cachectic and anemic states with deficient oxygenation we may expect to find a decrease in the excretion of uric acid and an increase in the alloxuric bases. In other words, with normal katabolism of leucocytes and normal oxygenation, we have a normal excretion of uric acid and a minimum excretion of alloxuric bases; with abnormal increase of leucocytes and normal oxygenation we have formation and excretion of uric acid to the limit of the individual oxygenation powers and alloxuric bases corresponding to the excess of nuclein katabolism beyond the oxidation powers. The maximum of excretion of alloxuric bases, finally, and a minimum of uric acid excretion is ob-

served where nuclein katabolism is excessive and oxygenation very much reduced.

Thus we see that normally all the nuclein is converted into uric acid, an innocuous non-toxic substance; a perversion of the normal function leads to the formation of alloxuric bases, the toxic properties of which we have described. Hence our statement that the formation of uric acid far from producing an auto-intoxication, on the contrary is a conservative process of disinfection. A true decrease in the excretion of uric acid is really never observed excepting where most destructive changes have occurred in the kidneys so that all the solids are mechanically retained—this occurs in the last stages of Bright's disease, in certain surgical diseases of the kidneys, probably also in those cases where serious interference with the innervation of the kidney leads to complete functional inactivity.

What, now, is the vicious circle which, by causing a perversion of the normal nuclein metabolism produces the symptoms of so-called uric acid intoxication? It would be a superfluous task to enumerate the many factors that lead to the “uric acid” habit; they have been given a thousand times in masterful monographs on the subject; we need not speak of the recognized influence of heredity, the mode of life—which without the hereditary taint probably cannot produce gout—overexertion, alcohol, lead, etc.; suffice it to say that the taint itself consists in a tendency to disintegrate a quantity of nuclein far in excess of the quantity normally disintegrated; in other words, in a uratic subject nuclein-katabolism is excessive. At first the normal oxidation processes are capable of converting almost all the katabolic products into uric acid which is duly excreted by the kidney, at the same time small quantities of the poisonous alloxuric bases are formed which, entering the circulation and passing through the kidneys, exercise the deleterious influence that they are capable of producing and that have been enumerated above. As the auto-intoxication continues vital processes fall below par and with them probably oxidation processes; anemic conditions develop functional nervous disturbances and minute anatomic changes in the kidneys, which may ultimately lead to the destructive changes detailed above. During this period uric acid is excreted in somewhat increased quantity as the oxidation processes are still up to par. As the disease progresses in severity, whether in the natural course of the affliction or aided by indiscretion in diet, alcohol, mode of life, etc., the perversion progresses too in severity, and more alloxuric bases are formed and excreted and the process of chronic poisoning goes on; it is in this period that in all probability the inflammatory changes are produced in the joints and kidneys and elsewhere, which prepare the suitable nidus for the deposit of the uric acid—in the form of urates—that during all this time continues to circulate in the blood. We have no positive knowledge that the alloxuric bases are capable of producing these inflammatory and necrotic changes in the synovial membranes, but we do know that some substance other than uric acid must produce them before urate deposits occur (Levison), and we know further that alloxuric bases do produce the kidney changes following which analogous urate deposits occur in those organs; the assumption, therefore, that they are responsible for the joint lesions too is very probable. In the last stages of gout, finally, where all organs are severely damaged, both the excretion of uric acid and the formation of urate deposits ceases, probably because no more uric acid is being formed owing to the cachexia and the lowering of oxidation processes. At this time

the alloxuric bases are excreted in large quantity.

This is, in outline, the probable pathogenesis of uric acid lesions. A careful elaboration of the detail is reserved for later publication.

Before closing I wish to call attention to two valuable diagnostic adjuvants and to some therapeutic outlines that seem of value.

In "uric acid" subjects a peculiar phenomenon is observed in the blood, which, incidentally, is a strong fact in support of the nuclein-katabolism theory. Around the nuclei of the leucocytes a series of blue-black granules is observed; the perinuclear basophile granulations of Neusser, that are vastly increased in number in uric acid cases; they are always suspicious of the uratic diathesis and probably consist of disintegration products of nuclein. (See Croftan³³.)

In the urine an increase of the sum of the uric acid and of the alloxuric bases will be found, and while quantitative determinations of the uric acid alone yield results that are diagnostically valueless, a determination of the alloxuric bases will yield valuable results, as they are always increased. Uric acid fluctuates within normal boundaries; the appearance of alloxuric bases, on the other hand, is always an indication of perversion of function in the sense of excessive nuclein-katabolism with insufficient oxygenation.

Therapeutics.—The hereditary taint exists; the general rules that empiricism has taught us as to mode of life stand with only those limitations that we must impose on all deductions we draw from empiricism. But in the fully developed condition in lithemia, gravel, the onset of gout, we have measures at our disposal that can counteract; we can exercise an intelligent prophylaxis and possibly effect a cure in many instances if we will follow the rational precepts that a recognition of the above theories dictates. Two indications obtain—a reduction in nuclein-katabolism and a raising of the processes of oxygenation.

To attain the first object everything should be avoided that will produce a leucocytosis, viz., a number of drugs should never be administered (see above) and certain articles of diet that we know produce leucocytosis—notably proteids—should be reduced. Nuclein-containing foods, such as internal organs, yolk of egg, are bad. Overeating is bad. Let it suffice to outline these points. In a true uric acid case there will be excessive nuclein-katabolism despite all we may be able to do, in the very nature of the taint, and restrictions in diet will not be of any permanent benefit; the chief point of attack will be in the direction of raising oxidation and it is here that I have had the good results that I mentioned in the footnote. A uric acid case should be treated as an anemic case in all measures employed to promote the oxygenation powers of the blood, i. e., the production of an increase in the red blood-corpuscles and of the hemoglobin and its chief oxygen carrier—iron. I administer iron in the forms and on the same rational principles that I would administer it to a chlorotic patient; arsenic is usually combined with it. I need not mention the many medical measures at our disposal to attain the above goal, nor the hygienic measures that will promote aeration of the blood; neither is this the place to critically discuss the merits or demerits of alkalies, salicylates, etc., and their efficiency as solvents and eliminators of poisonous products. The most striking results have been obtained in acute cases by inhalations of oxygen gas. On six occasions I did "cut" an attack of gout by giving the patient inhalations of oxygen repeated at short intervals; I can invariably relieve, if not cure, a uric acid headache, a

migraine, in short, lithemic attacks, by oxygen inhalations. The benefits derived from the procedure are surprising and most gratifying and the relief to the patient almost instantaneous. What oxygen will do in uremia—which in my view is due to alloxuric base poisoning, not to uric acid poisoning—I have not been able to try as yet. I have a record to-day of only twenty-two cases in which results were so positive that they merit chronicling—my clinical facilities are limited and it is for that reason and in order to know as soon as possible whether the principles I advocate, when more widely applied, will merit universal acceptance, I request my patient readers to send me short reports of cases on whom they may consider it worth while to try oxygen inhalations. It would be a boon indeed to humanity if in so simple procedures as are advised a cure could be found for one of the most wide-spread scourges of civilization.

RUBBER GLOVES OR GAUNTLETS.*

THEIR USE BY PHYSICIANS AND SURGEONS.

BY J. E. SUMMERS, JR., M.D.

SURGEON IN CHIEF CLARKSON MEMORIAL HOSPITAL, VISITING SURGEON DOUGLAS COUNTY HOSPITAL, OMAHA, NEB.

Of late an effort has been made by some of our best surgeons to lessen the dangers of infection of wounds by pointing out the great difficulties of rendering the hands of the operator and assistants absolutely free from all infection-causing germs, and for this reason urging the more general use of sterile rubber gloves by physicians and surgeons.

Numerous ways of washing the hands by surgeons, assistants and nurses have been recommended. Some of these methods, if done intelligently and conscientiously, are supposedly reliable, others are less reliable. When not safeguarded all are objectionable, because they have to include in their carrying out the personal equation of the individual. If the most experienced, worthy and reliable may forget at the critical moment, when of all others he should be the one to remember, what must be expected of the ones recognized by the courts, the one of ordinary skill and intelligence?

Greater still than the danger of infecting wounds by the surgeon, who uses ordinary diligence and skill, is the danger of infecting women after childbirth or abor-

*Read before the Nebraska State Medical Society, May 8, 1899.

tion, by the attending physician and nurse. I would venture the opinion that more women, during the child-bearing period, die or suffer invalidism from infection at the hands of the obstetric physician and nurse than from surgical operations, exclusive of those done for the relief of these conditions. The nature of the general practitioner's calling; treating all kinds of disease; coming and going at all hours; occasionally because of necessity or preference, doing "chores" about the barn, house or office; all this leads to a weaning away from the practice of ideal surgical cleanliness on his part, both as physician and surgeon. Besides it takes daily painstaking practice to successfully learn how to be surgically clean.

Let us grant for the sake of argument that a physician in attendance on the general run of cases, such as pneumonitis, pleuritis, typhoid fever, diarrhea, headache, indigestion, constipation and such like ailments is practically free from the danger of conveying these ailments to other patients. Can we say the same of all forms of ulceration, abscess, phlegmonous inflammations, erysipelas, tetanus, puerperal sepsis, diphtheria, scarlet fever, etc.?

Would you seek the services of one engaged in the treatment of such cases to confine your wives and daughters, even if you knew him to be a reasonably clean man? No and yes! No, if you knew that such a physician wore the same outer garments from house to house without donning a clean gown kept in the patient's house whenever he was brought in contact with infectious medical and surgical cases. No, if you knew that his hands were washed with a "lick and a promise" and a dash of deodorizer or antiseptic. No, if you could select a man with equal professional qualifications, and added to these a knowledge how and a practical desire to prevent infection through himself as a medium. Yes, if he were neat, painstakingly clean and used all known means to protect his patients from every source of contagion.

I know of no physician who would willingly cause unnecessary suffering and danger to those who have given him their confidence and placed their health and lives in his keeping, and it is in this spirit that I urge on you the habitual use of sterilized rubber gloves or gauntlets after cleansing the hands by some good method, in every case where your intelligence points out the advantage to your patient. *It should be the rule:* 1. In obstetric practice. 2. In operating on all forms of septic cases. 3. In the examination and treatment of all forms of septic, infectious diseases, such as erysipelas, septicemia and pyemia in which the hands come in contact with primary or secondary foci of infection—and this rule applies to the nurse also. 4. In operating on clean cases soon after operations on infected ones. 5. In abdominal sections following vaginal operations on the same individual, this may be reversed, wearing the gloves during the vaginal work, taking the gloves off or donning a fresh pair before beginning the abdominal work. 6. In examination of fresh wounds after recent examinations of or operations on dirty cases. 7. In all forms of rectal surgery.

It is a matter of choice under other circumstances whether or not gloves be worn. However, there is no question that there is less danger of infection where gloves are worn than when reliance is placed in an attempted sterilization of the naked hands. We have the testimony of two good American surgeons, Halsted of Johns Hopkins and McBurney of New York, as to the truth of the lessened dangers of infections when sterilized rubber gloves are worn by all persons taking part

in the conduct of a surgical operation. Many American and European surgeons now use rubber gloves.

An impervious cotton glove is perhaps quite as good as the rubber article—the ordinary cotton glove is not safe. During the six months I have been using the rubber gauntlets in my work my results have been more gratifying than formerly. Occasionally I have felt compelled to take off the gloves in order to carry out some technic more satisfactorily, but such acts seldom occur now. There is little difference in tactile sensibility between the naked fingers and those covered with a well-fitted, good-articled rubber glove. The advantages outweigh the possible, in rare instances, lessened tactile acuteness. One dozen pairs of the best quality can be bought for \$15. Sterilized glycerin may be used to lubricate the hands before drawing on the gloves. A glove that cannot be reasonably easily drawn over the hand after filling the glove with sterile water is too small. Vaseline or grease ruins the rubber. The gloves should be either boiled or wrapped in a towel and placed in a steam sterilizer. Lastly, rubber gloves are a protection to the physician and surgeon against infection.

SERTOTHERAPY.*

COMBINED WITH FAVORABLE CLIMATIC AND STRICT HYGIENIC SUPERVISION OF THE PATIENT—REPORT OF 106 CASES TREATED DURING 1898.

BY C. P. AMBLER, M.D.
ASHEVILLE, N. C.

The consensus of opinion among the conservative of our profession is now well established that medication in any form only plays a minor part in the treatment of pulmonary tuberculosis. It has been the experience of all that strict supervision of the patient as regards his hygienic life, including rest, exercise, diet, secretion and excretion, is first and foremost of the most vital importance and necessity. Secondary to the hygienic supervision of the patient we must admit that favorable climatic influences are without doubt our most tried and most trustworthy dependence, while medication in point of preference occupies third place.

Cases are continually being cited in which the improvement is attributed to one or the other, while our most favorable statistics are invariably presented by those at whose hands the greatest facilities for the application of all these methods are available.

In presenting this report of cases I wish to place myself on record as attributing the results obtained to these three factors in the order named.

We have insisted on the most rigid observations of all directions as to hygiene, following closely what has been found after several years' experience in institutional work to be the best for this class of patients. This has included particularly the avoidance of over-exertion; the regulation of diet; exercise and rest in bed; the observation of temperature; pulse; regulation of excretory functions; instruction as to the time for eating heaviest meals; time to elapse between meals; cold bathing; proper dress, fresh air; breathing exercise; taking of stimulants, sexual indulgence; and in fact all those little things which in themselves once occurring are nothing, but which often repeated, and carried to excess, have a marked influence on the well-being of our patient.

We can without doubt be pardoned for claiming that the climate of Asheville has been of valuable assistance.

* Presented to the Section on Practice of Medicine, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1898.

Almost without exception the patients have resided in boarding-houses and hotels, care always being taken to see that such place is conducted in a sanitary manner. It has been our policy to use as little medication by the stomach as possible, but we are free to admit that we have not hesitated to use any drug, inhalation, operation or application that a given case demanded.

I might again be pardoned while I state that I do not believe we have or ever will have a "specific" for tuberculosis. The very nature of the disease and the different circumstances concomitant with all cases render such a likelihood improbable. The past few years have developed radically new methods in the medication of this disease, the two most prominent methods, still, strictly speaking in the experimental stage, being: 1, the application of culture products direct to the patient according to Koch and his followers, and, 2, the carrying of these culture products through some lower animal, thus rendering the animal more or less "immune," and then applying the serum of this animal's blood to the patient.

After several years' experience, both in institution and private practice, with the culture product method, I am free to confess that I do not consider it without a certain element of danger, while I am equally well satisfied that better results, on the whole, followed its use than were obtained before its production.

My experience with the serum method extends over a period of two years, in a private practice devoted to tubercular diseases, and forms the basis for this paper.

It is not my intention to take up your time by citing the history and authorities of serotherapy, or to read in detail the report of the cases submitted. I shall limit my remarks to actual clinical experience, and present the tabulated report for the inspection of those so minded.

Owing to the unscrupulous mercenary methods and self-evident exaggerated reports of certain scientific and unscientific manufacturers, lauding their own products, the profession are rightfully becoming suspicious of any one advocating, using or producing sero-products. I have no ax to grind, am not before you as a manufacturer or producer, and am not here for the purpose of championing any producer's cause.

In the classification of this report I have not adhered to what many term the first, second and third stages. Under Class A we have recorded all those cases who (on commencing treatment) in our judgment had good chances for recovery. Under Class B occur those cases in which great improvement could be expected but an entire recovery was doubtful. Class C represents those cases presenting such complications or extensive involvement that but slight encouragement could be given.

Under this classification I have considered the patient's chances from all points of view: his physical condition, history, temperament, hygienic habits, surroundings, and his financial condition. This latter may seem a cold-blooded cause for classification, but nevertheless in all cases it becomes of importance. For instance, No. 46 Class A could not have been so classified (cavity being present), if she had not been financially able to refrain from work and conduct herself as one with a rapid heart must necessarily do if recovery is to be expected. Again, No. 98, Class C could have been placed in Class B in case she could have stopped work. As it was she was a charity case, compelled to work to pay her board, and did not do well.

Under each individual case the top line represents the condition upon commencement of treatment and the under line his condition on discharge or cessation of

treatment. Many cases in both B and C were compelled to stop while rapidly improving, on account of financial and domestic troubles, this undoubtedly giving a lower percentage of recoveries in these classes than was actually possible.

In summarizing the report we have kept the three classes separate and attempted to show average results in each class, believing that to average such cases without classification gives but little idea of what can be accomplished. The cases occurring under Class C were in most part poor cases, and were not treated with any idea of cure, but in an attempt to ameliorate suffering and distressing symptoms.

Class of Cases in Which Indicated.—The use of anti-tubercle serum would seem to be indicated in the incipient cases and more especially in those presenting a simple infection. As will be seen from the tabulated report, good results have also been accomplished in a majority of the cases classified under Class B, while in advanced cases we find we can often temporarily arrest progress of the disease and relieve distressing symptoms, but the remedy, even under most favorable circumstances, fails as everything must fail, to bring about recovery in such cases.

Contraindications.—Generally speaking, the use of anti-tubercle serum seems to be contraindicated in cases of miliary tuberculosis, in cases of extensive softening, high pulse, marked emaciation or decided hereditary history. This, I take it, means that these cases will, in all probability progress, no matter what form of medication is used. As a rule, the injections have not been given where the temperature reaches a maximum of over 101 degrees daily, our experience having been that such a temperature in an early case is invariably the result of some indiscretion on the part of the patient.

Advantages Over Other Forms of Medication.—The hypodermic injection of the remedy precludes the possibility of direct interference with the processes of digestion and assimilation. The absence of medication by the stomach is, with proper instruction as to diet, certainly to the advantage of the patient. We have less indigestion, less flatulency, less bowel complaint, and invariably build up a better appetite with corresponding power to better digest and assimilate a full meal of ordinary breadstuffs.

My experience corresponds exactly with that of Dr. J. Edward Stubbert of the Loomis Sanitarium for Consumption's, in that the bacilli disappear from the sputum long before the latter has entirely ceased. Relapses during treatment and after are much less frequent than under any other form of medication I have ever tried. This in itself means much when we stop to consider that in the usual course of tuberculosis the disease is one of relapses.

Allow me at this point to refer to Case 20, Class A, a patient who was under treatment for fifteen months. Two weeks after she was discharged as apparently cured she was taken down with typhoid fever and was treated by a brother practitioner in our city hospital, for six weeks, recovering fully from a severe case of fever, and without developing any untoward pulmonary symptoms. Her father now writes me, eight months later: "Nina is the picture of health, no cough, no expectoration, no fever, weighs more and is better than ever in her life"—a good test, you will admit.

Cases herein cited as "cured" have returned to their homes and in no instance, to my knowledge, has a case in Class A relapsed up to this time, notwithstanding

CLASSIFICATION.—Class A represents those patients who, after thorough physical examination, microscopic examination of sputum, consideration of family and personal history, temperament, tractability and financial ability to refrain from work, was, in our judgment, supposed to have excellent chances for recovery. Class B represents those who after the same examination, we could expect to see improve, but whose recovery was doubtful. Class C represents more advanced cases. Nothing but amelioration of symptoms and distress was promised. This class was largely composed of charity patients.

many are in unfavorable locations and others are back at work. Whether a certain degree of immunity has been established, or whether the elimination of the tubercular products has been more certain, the fact remains, *serum patients do not relapse like those treated with creosote and other allied drugs.*

Furthermore, during the entire time that these 106 cases were being treated, but 2 patients had hemorrhage serious enough to warrant calling a physician, while 55 gave a history of having bled prior to the time of beginning treatment; 1 of these 2 above referred to—No. 55, Class B—was caused by violent exertion in a young man repeatedly cautioned and later ordered out of the office for disobeying directions, and the other occurred seemingly without provocation in a young man who was so slightly affected that his parents never believed there was anything wrong with his lungs.

Night sweats have been more easily controlled. During the weeks and months necessary for the contraction and cicatrization of small cavities, *the patients have remained free from distressing symptoms and have not shown the symptoms of relapse or involvement of new tissue.*

As a rule, I have observed that the expectoration materially increased during the first two weeks of treatment, and then rapidly diminished in the favorable cases. The expectoration has rapidly changed in character as well as in amount, becoming lighter, losing its pus character, and finally appearing as a gelatinous mass. In the far advanced cases or in those with extensive cavity formation, *this influence on the expectoration was usually negative.*

Length of Time to be Administered.—The injections have been continued in those cases reported as "cured" for several weeks, and in a few cases for months, following the disappearance of tubercle bacilli, the microscopic examination being frequently made during this time. In this class of patients no unpleasant symptoms have followed the long continued use of large doses. Of the thirty-five reported as "cured" in Class A, the average length of time the injections were given was four and five-tenths months, maximum fifteen months and minimum seven weeks.

Accidents Following Administration.—In about 50 per cent. of all cases treated a local erythema occurred over and around the point of injection, during the first week. In a small percentage this erythema became more general, and in three cases was well marked from the waist to the feet. After the first week no such local or general redness of the skin followed the injection. Local swellings at the point of injection, and occasionally at nearby joints, pain in the joints and itching of the skin were frequently complained of for the first few days. When enlarged lymphatic glands have been present, especially the cervical and axillary glands, these have invariably been found to enlarge and become tender during the first two weeks, and if not easeless, they have then gradually diminished in size and finally disappeared entirely. Especially was this true of Case No. 3, Class A, a child 7 years old, with slight consolidation, and when first examined presenting distinctly enlarged cervical and axillary glands. This boy fully recovered, the glands disappeared, and he has been so well this winter that his physicians advised his parents that it was not necessary for him to go South this year. This improvement in glandular involvement has been observed in all three classes.

The symptoms mentioned above are not serious, only annoying to the patient, and when he has been posted as

to their possible occurrence he has made but little comment when arising. The only really serious symptom observed by the writer has been a sudden attack of syncope occurring in from one to five minutes following injections and lasting about two minutes. This has occurred in 5 per cent. of all cases, being accompanied by flushed face, followed by pallor, weak heart, pain in the back, nausea, and in one case violent vomiting. This, I believe, is due to the injection of the serum into a small vein, and not, as some have suggested, to the too often repeated injection at the same point. This distressing symptom passes off in a moment on placing the patient in a recumbent position and, so far as I can determine, has never been detrimental to the patient. In one case, No. 52, Class A, a man weighing 180 pounds, with good heart, this symptom was repeatedly observed.

On account of these local and systematic symptoms I have made it a rule to begin with a small injection .2 c.c., gradually increasing to .5 c.c., remaining here a few days and then gradually increasing to 1 c.c., rarely exceeding 2 c.c. at a dose, the injection being given daily in the loose skin above and back of the crest of the ilium; using a c.c. graduated syringe with the smallest size Green hypodermic needle. The use of such fine needles for serotherapy compels one to give the greatest possible attention to his instrument in order to keep the needle patent; hence the fine needle is not only more agreeable to the patient, but more liable to be rendered aseptic in order to be of service.

Serums Used.—Serums from three different manufacturers were used, the whole amount being approximately 8000 c.c. Having in the course of a very few months observed decidedly the best results from the use of Fisch's antiphthisic serum T. R., the others were discarded; altogether about 6000 c.c. of Fisch's serum were used. In justice to the manufacturers I must say that this product has invariably proven stable when properly handled, in but two bottles was cause for complaint found, due in both instances to infection from loosening of the stopper during transit.

Remarks.—The use of antistreptococic serum in conjunction with antitubercle serum, in my hands has not proven of much benefit. Streptococci have disappeared in favorable cases without it, and in advanced cases have remained, no matter whether it was given or not. It has, however, in several cases seemed to temporarily do good.

I would particularly call attention to the large gain in vital capacity of these cases, the average gain in Class A being 54 cu. in., with a maximum of 80 cu. in. This gain is in great part due to the use of the pneumatic cabinet, which instrument has been used in all cases of diminished capacity, where high fever or other contraindication was not present.

Summarizing the 106 cases reported, without regard to classification we find:

Cough and expectoration disappeared in	38, or 36 per cent.
Cough and expectoration diminished in	83, or 78 per cent.
Bacilli disappeared in	49, or 46 per cent.
Bacilli decreased in	61, or 64 per cent.
Physical signs improved in	80, or 84 per cent.
Weight gained in	92, or 87 per cent.
Vital capacity gained in	98, or 92 per cent.
Temperature and pulse became normal in	71, or 67 per cent.
Average time treated 4.9 months.	
Average amount serum used 77 c.c.	
Apparently cured (no relapse)	41, or 39 per cent.

Greatly improved	31, or 29 per cent.
Improved	14, or 13 per cent.
Stationary	7, or 6.6 per cent.
Worse	11, or 10 per cent.
Died	2, or 1.8 per cent.

In conclusion, I wish to reiterate what I have said concerning medication occupying third place in the treatment of pulmonary tuberculosis, and do not place myself on record here unequivocally as a convert to serotherapy. I have been in no hurry to report my cases treated and have only presented this paper after having had eighteen months' time for observation: the conclusion being that while serotherapy for tuberculosis in general is still in an experimental stage, the results obtained from its use in the incipient cases certainly justify one in its continued use.

With the permission of the Chairman of this Section I propose next year to follow up this report with a detailed report giving the then present condition of all cases now classified under A and B. The C cases, with few exceptions, I expect will die during the coming year.

THE SUBJECTOSCOPE.*

OR SOME SUBJECTIVE VISUAL SENSATIONS.
BY HAMILTON STILLSON, M.D.
SEATTLE, WASH.

In devising an instrument for the study of subjective visual sensations an attempt is here made to accomplish two objects: to settle some disputed questions concerning the nature of such sensations, and 2, to furnish a practical means for the autodiagnosis of disturbances or defects in the field of projection.

It is well, however, at the beginning of this paper to understand that Zehender's definition of subjective visual sensations is the accepted one. His definition is at variance with the definitions given in the Century, Standard and Foster's medical dictionaries, but it is nevertheless the most rational. For the production of subjective visual sensations—"Gesichtsempfindungen"—Zehender's definition requires the presence in the interior of the eye of real corporeal bodies.

Subjective visual sensations, therefore, differ from objective visual sensations in the fact that the latter owe their origin to corporeal things outside of the eye; they differ from hallucinations, "visions," and the like, since the latter owe their origin to disturbances of the central nervous organism and not to changes in the eye.

Phosphenes, electric stimulant flashes, etc., belong to subjective visual sensations since they owe their origin to a disturbance of the real elements of the eye, but they ought to belong to a sub-class of visual sensations, the main class being illustrated by *muscæ volitantes*. This latter is perhaps the most typical and familiar example of subjective sensations of the main class. A further refinement ought also to be made by classifying these sensations into the classes physiologic and pathologic. And while the instrument described in this paper, and which, for want of a better name, let us call the "subjectoscope," deals with both the latter named classes, it is toward physiologic subjective visual sensations that our principal experimentation will be directed.

It may be considered necessary in this introduction to apologize for the use of instrumental aids in examining visual sensations. Zehender prides himself on the fact that under favorable conditions he can experience all the known visual subjective sensations without instrumental aid, but some of the favorable conditions are "a snow bedecked landscape," "the half waking state in the

twilight," "long and intense practice," etc., some of which conditions are always absent from some of us, and the majority of them render the daily office examinations of patients' fields of vision impracticable. Besides there is usually no gain in declining instrumental aid while viewing the field of projection. It is not any more to our credit or advantage by intense practice to train our eyes to see the Purkinje figures without aid than to look at these figures in a dark room by the aid of a moving flame held near our eyes. It was surely no detraction for Helmholtz to say that the easiest way to view *muscæ volitantes* is to look at a lamp flame through a pinhole in a card. Moreover, in studying the field of projection of patients most patients require considerable aid in viewing strange images whose cause they cannot understand, the knowledge of whose shape they would impart to the oculist.

The instrument in question was suggested to the writer on viewing a blue sky through a piece of blue glass. By such means the "fliegende mücken" (Purkinje), or rapidly moving bright globular bodies in the interior of one's own eye may be readily observed by anyone. I am not aware that any previous writer has called attention to the use of blue glass in this connection, though Jullien¹ discusses the question of recognition of fading or abortive syphilitic macules by viewing the suspected skin through blue glass, a diagnostic resource first announced by A. Broca in 1893. The instrument, however, is arranged so that other colors for the background besides that of blue may be used.

The instrument consists of a three-inch lens mounted in a short tube on a suitable stand having a clamp at the proximal end into which diaphragms having pinholes of two or three sizes may be inserted, and having, eighteen inches from the distal end, a clamp for holding plates of plain and colored glass and white cardboard, and having beyond the plate a mirror mounted on a swinging arm so arranged that the mirror may reflect light through the colored glass directly through the tube and lens to the eye, or, by swinging the arm, light may be reflected on white cardboard which may then be viewed by reflected light.

Experiment 1.—Remove the pinhole diaphragm, place the mirror in position for reflecting into the eye the blue sky through a layer of homogeneous blue glass, place the eye near enough to the lens that the light coming through the lens will be uniformly blurred or diffused. A homogeneous blue field will be disclosed, and on that blue field will be observed bright moving points globular in shape, having one side shaded by a crescentic shaped shadow. These bodies on the blue field will look blue but will stand out in relief, the center of each having a bright reflex. They flit through the field like

flying gnats, but appear most distinct at a certain plane in the field of projection and resemble in that respect the corpuscles of the blood when seen in a frog's tongue under the microscope. That is to say, they come into focus where they are distinct and then pass down or up out of focus where they disappear. Occasionally a perfectly blank one will flit into view, and some are larger than others. Some will swim more rapidly and circle more swiftly than others do. The vessels through which they flow remain all the while invisible, though by fixing the attention in a certain direction one may seem to discover the course over which as a rule some of the bodies pass.

What are these flying gnats—"fliegende mucken"? Purkinje², who, though but a boy in poverty and obscurity, in 1819 made himself at once famous by describing these objects and also by describing the appearance of the shadow of the retinal vessels in one's own eye, saw them without instrumental aid by looking into a cloud covered sky. He was unable to satisfactorily account for them; and it appears to me that some confusion has arisen not only with Purkinje, but also with Zehender³ in confounding these bright moving bodies with the bright waving bodies mentioned at the end of this experiment. Zehender thinks these "fliegende mucken" are reflected light from the red blood-corpuscles in the choroidal vessels. He thinks that as the corpuscles move in the choroidal vessels light reflected from these bodies comes forward and falls on the rods and cones of the retina, thus forming their image. He offers in proof of this fact that these floating bodies are seen best and most numerous in the center of the field, where the rods are most numerous and where the retinal vessels are smallest in size, but a number of facts disprove his theory. One of my patients with rupture of the choroid and with no rupture of the retina was able to see these flying bodies very distinctly in the field corresponding with the rupture of the choroid. The blow against the eyeball had been received near the inner canthus. There was a rupture of the choroid, 2dd. in length, crescentic in shape, the center of its convexity touching the outer edge of the disc. The other rupture was 3dd. in length, the center of its curve being in the region of the macula. The white sclera could be seen through the rupture, and the broadest portion became occupied by cholesterolin. This patient, though possessed of two scotomata of crescentic shape could see these "fliegende mucken" throughout the entire center of the field of vision, the flying bodies seeming larger and more numerous at the portion of the field occupied by the scotoma than in any other portion of the field. The scotoma looked black on the blue background, and grayish white on a dark background. These rapidly moving bodies, therefore, must be produced by something in front of the retina, and if it be urged that in such a case they should produce nothing but a dark shadow like the moon in a solar eclipse, the reply may be given that the shadows of the vessels of the retina when viewed through a projectoscope are like transparent glass tubes having a shadow line along one side, giving a relief to the shadow of the vessel, so to speak. The apparent relief of the shadow of these moving bodies may be thus accounted for, and to account for the fact that one is occasionally blacker and larger than its fellows we have only to imagine one more opaque than the others. Surely Zehender's contention cannot explain the presence of the black ones. Black ones will not reflect the light. Moreover, these flying globular bodies are too large for blood-corpuscles, and they are too widely

separated from one another to be blood-corpuscles in the retinal vessels. Their rate of flow is greater than that of the blood current in the capillaries. The diameter of a blood-corpuscle is .0072 mm., which is one-fourth the diameter of the capillaries. By viewing the smallest capillaries, as in Experiment No. 2, and comparing their diameter with the apparent diameter of the moving bodies, projecting them as nearly as possible to the same distance away, it will be seen that the apparent diameter is more than one-fourth more than the apparent diameter of the capillaries.

What are they then? Helmholtz⁴, in his "Physiological Optics," thinks they are fat lymph-corpuscles. His opinion must bear great weight, but Helmholtz thinks that these lymph-corpuscles are visible only in the main trunks of the retinal vessels. The region of the macula, which alone views these moving bodies, has no large blood-vessels in the retina.

In Experiment No. 6 an attempt is made to show the lymph-spaces in the cornea, in Experiment No. 5, the lymph-spaces in the lens, and in Experiment No. 3, the lymph-spaces in the vitreous. (Sec. 5, p. 251, and 6, Vol. i, p. 210.)

Would it not be a more reasonable assumption to say that these "fliegende mucken" are the shadows of lymph-corpuscles, as they pass in the lymph-channels of the eye in such a plane as can be best viewed by the rods and cones?

We cannot close this reference to the "fliegende mucken" without referring also to Zehender's claim that they can be viewed by him with his eyes closed and in the dark. If they could be viewed in such a case, my contention that they are the shadows of the lymph-corpuscles would come to naught. Still, if they could be seen in the dark, Zehender's contention also would come to naught, for in that case they could not be reflections of the corpuscles of the choroid. What Zehender sees in the dark with his eyes closed is not the "fliegende mucken," although they resemble closely the "fliegende mucken" in some respects. Perhaps every observant person has noticed that on waking from profound slumber and gazing into a dark room numerous small points of silver-white light arranged somewhat symmetrically, grouped in the center of his field of vision, will wave and flicker before him. They do not flit and fly, but each waves and flickers. On closing the eyelids these points will continue for a time in the same location and with the same color and shape as before. But these wav-

ing points are not globular. They have no distinct outline. They do not move about the field like detached bodies, do not flit nor fly, they simply glint and glimmer and wave. What are they? I think they are localized, intensified idioretinal light. I think they are of the nature of minute localized points of "phosphORIZATION," to coin a term; they are produced in all probability by the pressure of blood in the choroidal vessels against the rods and cones somewhat in the manner of phosphores produced by the finger against the eye. They appear only when the ocular vessels are suddenly and unusually engorged with blood, and disappear when the engorgement passes away.

The above-described waving points are not flimmer scotoma, scotoma scintillans, amaurosis partialis fugax, teichopsie, though this latter scotoma may be seen in the dark with the eyes closed. In the flimmer scotoma the glimmering begins in the center of vision and spreads outward like an enlarged circle, except that the line that forms the circle is zigzag and there is amaurosis over the portion of the field that the circle has passed. Moreover, flimmer scotoma seems to be more a symptom of disturbances of nutrition of the central nervous organism than of local disturbances of the eye. It is nearly always accompanied by a sense of vertigo. (See reference No. 7, p. 61.)

Experiment No. 2.—Insert the blue glass in its position as before, place the diaphragm with the small pinhole into its place, reflect the light of the sun, or an acetylene-gas flame placed twenty feet or farther away, look through the pinhole attentively and move the diaphragm gently to and fro, or move the head to and fro, or move the mirror to and fro slightly and more or less rapidly. Fine branching lines like transparent roots of a plant will be seen converging from the periphery, many of them anastomosing, meshing themselves around the center of the field of vision. In a yellow light these branching lines are pinkish-white with a bright line along their center and dark lines along their edges. On a blue background they are clearer cut and more distinct, but blue in color. They are stationary when the eye is still, though they seem to move with the movements of the disc or of the source of light. They seem larger when the source of light is at a distance, or when they are projected into the distance or when the pinhole is large. They seem smaller, though more distinct, when the pinhole is small. W. C. Ayres* (Bd. xii, p. 29) who followed up Helmholtz' suggestion, found that these lines seem larger when the iris is under the influence of a mydriatic. What are these lines? They are undoubtedly shadow images of the blood-vessels of the retina. Purkinje was the first to describe them, in 1819 in this now famous thesis. His first described method for seeing them was to look at a cloud-bedecked sky and wave before the eyes the outstretched fingers of the hand, to and fro. To me they seem quite indistinct by this method. His second method was to wave a candle-flame near and below the eye while gazing into an otherwise darkened room. The lines look larger by this method, though they resemble mere black shadows and only the large blood-vessels can be seen in this way. Modifications of the above mentioned experiments have been made by J. Muller, Ayres⁸, Fick¹⁰, Becker¹² (Bd. xxvii pp. 1 to 20; Bd. xxvii, 1881), Dimmer¹¹ (Bd. xiii, p. 82), Meissner³, Reute¹⁴ (Bd. i, p. 558) and others. For instance, Helmholtz was, I believe, the first to render the definition of these lines distinct by searching for them through a small pinhole in a moving card, while looking at a lamp flame; and he was the first

to observe that the larger the pupil or hole in the card the larger the vessels would appear, though less distinct.

W. C. Ayres* (Bd. xiii, p. 13) used the bright reflection from a gold ring or a silver spoon flashed near the eye; but in the author's experience the vessels can be traced more nearly to the macula and can be made to appear with more vivid distinctness by the use of the blue glass in the projectoscope.

So far as I can discover, no previous writer has mentioned the fact that these blood-vessels may be seen with the eyes closed. Face the sun, close the eyelids, turn the eyes upward, and forcibly and rapidly turn the eyes repeatedly to the right and to the left. There will appear on the red background dark branching lines that resemble the lines seen in the Purkinje candle flame experiment. The main trunks of the blood-vessels are brought into the field of projection better in this way than in the other experiments mentioned.

Experiment 3.—Remove the blue glass, focus the light to the interior of the eye, insert the pinhole disc, then without oscillating the diaphragm, direct the eye and if necessary the pinhole just off the point of light. Against the background of half illumination curved and twisted channels anastomosing can be seen. These channels lie in different layers and by slightly moving the eye to and fro then holding it still a swinging motion can be imparted to some of the different layers. By means of this movement a parallax of the different layers can be made out. One of these layers seems to me to be always stationary. They are seen only in the center of the field. Their caliber is of about equal diameter throughout. Their course and the walls of the channels are quite distinct. That they are not on the surface of the cornea is readily proven by blinking the lids until a little of the oil or tears is deposited upon the cornea, then by simply moving the diaphragm the parallax of the tears and the channels can be made out. All the channels will thus be found to lie behind the cornea or at least behind its surface.

Experiment 5.—Now focus the light on the lens of the eye, use a very small pinhole, remove the eye far enough away from the pinhole to make the pinhole appear like a star; an object will be seen very much resembling the microscopic appearance of the lens of the eye; that is to say, a star-shaped body having four or five main arms with innumerable branching lines joining the main ones will appear. This star-shaped system of lines can also be seen by looking through a very small pinhole held four or five inches from the eye. That this system of branching lines is not made by the object lens or by the refrangment of light at the edge of the pinhole can be proved by rotating the object-lens or the pinhole disc on the line of vision as an axis. The striations produced by the object lens or by the disc can be made to eclipse the striations produced by the observer's eye. What is this star-shaped system of channels? It is evidently the connective tissue structures and lymph-channels of the crystalline lens. In proof of this it may be asserted that these channels or radiating lines change their relative positions slightly under the act of accommodation in somewhat the same manner as do the double images of Purkinje⁶—(Vol. i, p. 172, figs. 43 and 44).

Experiment 6.—(If in the above experiment the eye be so turned that only the front surface of the cornea be illuminated by a point of light, the very slightest opacity of the cornea will be discoverable; various dots and lines, the dots having various shapes and radiations, the lines having various radiations, can be discerned, and these dots and striations are so uniformly present

that they seem to constitute what may be termed a normal opacity of the cornea. Some of them very much resemble spots in the cornea of the frog, stained so as to show the positive picture. (See 6, Vol. 1, 146.) These opaque stellate cells can be best viewed, however, by looking at a full moon through a three-inch lens held eighteen inches from the eye and then partially intercepting the rays by means of a card, or better still, a piece of blue glass. The stellate cells will be seen to push forward on the card and accumulate at its edge. Images of other bodies in the cornea and on the cornea may also be made to show themselves by that means. The spots on the moon will leave their impression on the picture, but the opacities on the cornea can be differentiated from other opacities by observing that they move when the lids move; those in the lens in the hand will stay still when the observer's eye is rotated.

All opacities of the cornea produced by facets, leucomas, infiltrations, etc., are exhibited with great distinctness by this partial oblique illumination of the cornea.

Experiment 7.—Now, turn the eye directly toward the light, focus the lens so that complete fogging will be produced by the lens, use the disc with the small pinhole and gaze intently into the flame; in the center of the field will appear three sets of round bodies. Those of the first set are closely packed together in a layer, but they are apparently not quite hexagonal in shape though somewhat flattened. In Fig. 3, taken from Zehender, an attempt has been made to represent one set of these bodies between the blood-vessels. The large round body there depicted represents, poorly, the appearance of the entrance of the optic nerve or "blind spot."

Against a kerosene flame they seem a pale yellow. Scattered among them are disc-shaped bodies that may be globular but look like red blood-corpuscles when seen under the microscope. The outside walls are dark blue. Lining the walls is a layer of a pale yellow color, then comes a dark blue line enclosing a central portion of pale yellow. These globular bodies are scattered among the flat stippled bodies mentioned above and seem nearly but not quite in a single layer. They are all of nearly the same diameter, about as wide as a medium-shaped blood-vessel. All these disc-shaped bodies are stationary and keep relatively the same position with reference to each other, although a slight parallax can be produced by movements of the eye or card. A third kind of globular body can be seen, which, however, can be made to float about more or less freely and can be seen to cause eclipse with the disc-shaped stationary bodies. What are these globular or disc-shaped bodies? The flat stippled bodies

were thought by Zehender to be the image of the pigment cells of the choroid (sic). They cannot be such. They are too large and are not of the right shape and lie in front of the retina instead of behind it, or at least in the front layers of the retina. Zehender pictures them stippled between the blood-vessels, but a careful examination will show that the stippling extends over the blood-vessels in places. The second stationary globular body can readily be seen to be just in front of the retinal vessels, for by using an extremely small pinhole these globular bodies can be seen to be really much larger than they at first appear. A ring halo can be seen far out from their center, not only spreading over the image of their blood-vessels, but by a slight movement a parallax can be developed to show that they lie just in front of the blood-vessels. The third set that move about freely can be readily demonstrated to be in the vitreous. What are these three bodies? The last-named floating bodies are doubtless portions of food floating in the vitreous and while in small quantities may be considered normal, in large quantities become the vitreous opacities. The second-named globular bodies are doubtless in the hyaline membrane and in small numbers may be considered normal, but in large numbers constitute the opacities seen in hyalitis. The stippled bodies which Zehender called the hexagonal cells of the pigment layer and pigment dust—"pigment staub"—are doubtless in the retina, possibly in one or the other of the granular layers of the retina. It seems incredible to me that "pigment staub" lying behind the rods and cones could be thus viewed.

Experiment 8.—Remove the pinhole diaphragm, remove the colored glass, insert the white card, adjust the mirror so as to throw the light on the surface of the white card, place your eye very close to the lens, gaze intently into the center of the white card and rapidly press the finger point or a lead pencil tip against the eyeball; at first dark pulsating bodies will appear scattered around the periphery of the field, four or five bodies pulsating synchronously with the pulsations of the heart. By a little practice these may be made to appear without the pressure of the finger point on the eyeball, and by still further practice branching lines from these pulsating bodies may be seen to approach one another. These must evidently be the shadows of the large blood trunks, there being in Ranvier's¹⁵ preparation of the circulation of the blood in the retina five main blood-vessels apparent in the injected specimen of the blood-vessels of the "yellow spot" (see also 6, vol. 1, p. 172). By great patience and practice a mesh resembling a crown of these vessels can be discovered around the point of fixation.

It is to be remarked that neither by this method of viewing the system of blood-vessels in the retina, nor by that mentioned in Experiment No. 2, nor by the preparation of the retina for microscopic examination can any vessels be discovered at the region of the fovea. It should be remarked also that although the blood-vessels may be seen to pulsate in the manner just described, the blood current itself cannot be discovered, Meissner to the contrary notwithstanding.

MODERN TREATMENT OF FRACTURES.*

BY EDWARD A. TRACY, M.D.

BOSTON.

In this paper the subject of fracture treatment shall be limited to a consideration of the principles that apply to the treatment of fractures in general, and of the materials best adapted to their treatment in consonance with these principles.

The term "fracture" as used, implies a broken bone. A bone can be broken, the fragments regain an accurate reposition and unite without a callus. So that a callus is not necessarily in evidence after a fracture. Manley of New York, a surgeon of vast experience with fractures, has repeatedly observed and noted this fact, termed "primary union." The *sine qua non* for primary union in a fracture is accurate reposition of the fragments and fixation. Primary union in fracture is exceptional. It probably occurs only when there is no, or but a very temporary, displacement. Displacement in fractures is the rule. When it persists, there are the genetic factors for callus production present. The more displacement, the more these factors are called into action, and the greater the resulting callus.

From the foregoing it follows that the duty of the surgeon in attendance on a fracture case is to get the fragments into as accurate reposition as possible, and provide an efficient and safe fixation for them. Nature does the rest.

The necessity for fixation in the treatment of fractures, strange to say, is not universally admitted. The celerity with which fractured clavicles and ribs unite, and for which fixation is ordinarily impossible, is urged by some surgeons as an argument for the non-use of fixative appliances. Broken collar-bones and ribs with displacement unite, it is true, but *always with deformity*; the surgeon uses fixative apparatus to *prevent* deformity. Some surgeons have treated fractures of the tibia, and of the radius (Colles') without apparatus. In these cases, however, there was no tendency to displacement, and to coin a term, physiologic fixation was present. In these cases, therefore, the principle of fixation was not violated; but, in every case, let it be understood that mechanical is superior to physiologic fixation.

There is one fracture best treated without any fixative appliance; that is, fracture of the neck of the femur in the aged. Careful attention to the nursing of such patients is all-important. It is paradoxical, but true, that the best surgical treatment of this fracture is purely medical. Apparatus, other than a few sand-bags, is cruel and harmful. With the vast majority of fractures, comprising all others but those of the hip in the aged, mechanical fixation, where it can be obtained, prevents or limits deformity, hastens union, and it therefore always indicates.

In fractures involving the joints, there is not unanimity among surgeons as to the time for applying passive motion. Some surgeons claim it is injurious before the fourth week, and even later. No set time should be given. The indications of each individual case should be followed. Passive motion is employed to prevent adhesions in or about the joint. It is harmful to an inflamed joint, and therefore should be cautiously applied—not enough to increase the synovitis, and yet

sufficient to prevent adhesions. The timely and right application of passive motion is imperatively called for in the treatment of fractured joints to restore them to their functions.

While speaking of passive motion to prevent adhesions, a word about massage is in place. Massage is useful to aid in the nutrition of those parts which suffer from functional inactivity in consequence of the fracture. It is also of use in the absorption of exudation, tissue hemorrhage, etc., caused by the injury. It is useful, generally, to employ massage daily, commencing a few days after the injury. In this, however, as in the application of passive motion, the indications of each individual case should be followed.

The materials used for producing fixation are various. Plaster of Paris is considerably used for this purpose. The fixation produced by it is fallacious. While outside the limb appears as rigid as a stone wall, inside the broken bones can wobble about, because of the cotton batting between the limb and the "cast." Subsidence of swelling, and later on, tissue atrophy, contribute to the misfit. This is the cause of the deformities so frequently met with after the plaster-of-Paris treatment of fractures.

The scientific treatment of fractures to-day demands that the surgeon mould on the patient a splint made from a plastic material, and applicable next to the skin. By this method the best possible fixation is attained, and the surgeon has the limb under control; at any time he can inspect it by simply removing the retaining bandage—a matter of a moment or two. There are two plastic materials that can be so used. One is gummed felt, the other, wood-fiber splint material. With the felt, heat is the agent used to render it plastic. Water renders the wood-fiber material plastic. Wood-fiber material is preferable, because lighter, cleaner and cheaper, and in compound fracture cases it permits of powerful antiseptic treatment of the splinting.

In the treatment of fractures at one time, and that not so very long ago—it was deemed necessary by many leading surgeons to apply over the broken limb a roller bandage before the splints were applied. To do so to-day would be malpractice. What was once deemed by eminent surgeons a cardinal part in the treatment of fractures is in oblivion to-day. To-day surgeons teach the application of plaster of Paris in the treatment of fractures. It is not necessary to be a prophet, nor the son of a prophet, to foresee that the plaster-of-Paris roller will partake of the oblivion of its congener, the primary roller; and this because a more scientific method of treatment is demonstrable, and because the defects of plaster treatment are manifest. A prime defect, the insufficiency of the fixation produced, has been mentioned. Sequential to this are numberless deformities, readily found among hospital patients. Its danger as a primary dressing in many fractures causes it to be avoided in such cases. It prevents the surgeon from inspecting the fracture, and from employing massage and passive motion, which the scientific treatment of such cases now demands. These defects condemn its use by the practical, progressive surgeon. The lesser evils of its use are the discomfort to the patient on applying it, and on removing it; the discomfort of its weight; its dirtiness, necessitating in well-appointed hospitals a "plaster-room."

The only scientific way of applying plaster of Paris is in the form of splints: moulded on the limb and retained by a bandage. The writer discarded this method several years ago, because of the advantages

*Read before the Chelsea (Mass.) Medical Society, Feb. 16, 1899.

possessed by wood-fiber splinting as a fixative appliance in all fractures where fixation is possible.

DOUBLE SYNCHRONOUS AMPUTATION.*

THREE CASES ON LOWER EXTREMITIES.

BY THOS. W. HUNTINGTON, M.D.

SAN FRANCISCO.

This report is made for the purpose of emphasizing the value of methods recently adopted in combating surgical shock. The circumstances which usually attend a crush of such a character as to necessitate double amputation usually entail active and prolonged hemorrhage. As a rule such patient must be transported a considerable distance, often many miles, before skilled attention can be secured. Preliminary efforts at hemostasis are made hastily and in most primitive fashion, by persons untrained and often unbalanced by the exigency. Improvised tourniquets are so adjusted as to admit of their being displaced downward, whereby their efficiency becomes totally annulled; and curiously enough, a second attempt in the same direction is rarely made. Accordingly, as a rule, the surgeon is confronted by a patient who is pulseless, or nearly so, cold, and in a profound state of collapse. To defer amputation until resort may be had to reactionary measures, though altogether unsurgical, was formerly advocated by high authority; but such a policy seemed not to find justification as attested by rates of mortality. Until recently the death-rate in this class of cases, particularly where the lower extremities were involved, was enormous.

The statistics bearing on this subject are not voluminous. Agnew has reported 74 cases of synchronous amputation by various surgeons, including the upper and lower extremities. Of these, 36, about 49 per cent., died, and 38 recovered. Eliminating all except amputations of the lower extremity, there remained 55 cases, of which 33, or 60 per cent. died. Of 11 double amputations performed and reported by John Ashurst, Jr., 7, or 63 per cent. died and 4 recovered.

During the past fifteen years I have done 9 double amputations of the lower extremities, all for traumatism. The first 6 comprised 1 double thigh amputation and 5 of the legs. Of these, 4, or 66 per cent., died and 2 recovered. The last 3 cases, 1 of both thighs and 2 of the legs, all recovered. The mortality in the 11 cases is 44.4 per cent. It seems but a fair presumption, and my personal conviction is, that had the same measure been adopted in the six earlier cases as in the last three, the mortality-rate for the series would have been materially lessened.

The following is a brief history of the last three cases: R. W. B., aged 55 years, a brakeman, was injured at Galt, Cal., Feb. 22, 1897. The front wheels of a locomotive passed over both legs. He was admitted to the Southern Pacific Hospital three hours later, having been transported about thirty miles. The clothing, blankets and mattress accompanying him were saturated with blood. The patient was pale and the radial pulse could scarcely be felt. Having been advised of his coming full preparation had been made to meet every requirement. Before moving him from the stretcher twenty ounces of normal salt solution were introduced subcutaneously and efficient measures adopted for control of hemorrhage. On examination, both feet and ankles were found to be hopelessly crushed and immediate amputation was determined on. During the procedure resort

was had to infusion of salt solution several times, about two quarts being used in the aggregate. At the close of the operation the patient's condition was apparently more encouraging than when he entered the hospital. He gradually rallied and within twenty-four hours assumed something like his normal condition. In spite of our best efforts both wounds sloughed extensively and before repair was well established two sharp secondary hemorrhages occurred in one stump. Nevertheless, he went on to an excellent recovery and was well at the end of four months.

F. A. S., also a brakeman, aged 23 years, was injured at Suisun, Cal., Nov. 23, 1898, both legs being hopelessly crushed beneath the wheels of a locomotive. He arrived at the above-named hospital three hours after the injury, attended by Dr. Downing of Suisun. The hemorrhage had not been excessive but still was sufficient to entail profound shock. Similar measures to those above described were at once employed and both legs were immediately amputated, the left four inches below the knee, and the right at the knee-joint. More than two quarts of normal salt solution were introduced subcutaneously prior to and during the operation. The patient responded promptly and reaction was established within a few hours. Here also both stumps suppurated. The later history was complicated and recovery delayed. He is now, I am informed, well and waiting for the adjustment of artificial limbs.

N. M., a laborer, aged 25, was injured on Nov. 27, 1898, early in the morning, and he lay on the ground unattended for three hours before being discovered. Both legs from the knees to the ankles had been crushed into a shapeless mass by a freight train. He reached the hospital, eighty miles distant, at 7 p. m., fifteen hours after the injury. On examination it was found that not the slightest effort had been made to prevent the loss of blood. In spite of this fact he was conscious and could speak rationally. A slight impulse could be felt at the wrist. Prompt administration of salt solution was followed by general improvement, and though his condition was regarded as altogether hopeless, immediate amputation was decided on. In exactly one hour from his arrival at the hospital, both thighs were amputated near the middle point and proper dressings applied. I mention this item as more than probably an important factor in the successful termination of the case. It was estimated by my assistants that more than four quarts of salt solution were introduced during the procedure. The subsequent history was a repetition of experiences had in the former two cases. Recovery was slow, but he is now well.

It is proper to say a word with reference to the failure to secure asepsis and rapid repair in all of these cases. It must be remembered that we had to deal with wounds of a most unfortunate character. Tissues were ground to a pulp and thoroughly impregnated with filth. The apparent requirement for rapidity of action forbade anything more than formal and superficial preparation and the presence of germ infection under such circumstances would seem well-nigh inevitable. Moreover, if it be urged that all the improvement in the mortality-rates, shown during the past few years in this connection, may be attributed largely to asepsis and rapid wound healing, it will be seen that the cases above reported furnish no basis for such an argument.

DR. WARREN B. OUTTEN will soon have ready for the press a volume with the title, "Man's Inherited Martyrdom, a Fitful Study of Degeneration."

* Read at the Twenty-ninth Annual Meeting of the Medical Society of California, April, 1899.

CYST OF PANCREAS FOLLOWING TRAUMA.*

BY J. VAN DER LAAN, M.D.
MUSKOGON, MICH.

Growths, malignant or benign, pressing on or involving the excretory duct of this gland, thereby causing retention of its physiologic secretions with probably cystic distension of its capsule, are excluded from consideration in this paper; and it is proposed to limit the discussion to such cysts of this organ as are preceded by a history of mechanic violence in this region, and offer strong presumptive evidence of being due to such violence.

That this gland, lying as it does, deeply in the upper abdominal zone and apparently well protected from mechanical injury, should at times be subject to violence, which may so seriously interfere with its normal functions as to materially affect the health of the subject, seems, on superficial examination, quite improbable. On little reflection, it will be noted, however, that under favorable conditions, when the stomach is empty and the body is in a position whereby the abdominal muscles are relaxed, a severe blow, fall, or impaction at this point between two opposing forces may so affect the pancreas as to crush or bruise its structure, rupture its main or lesser ducts, dislocate it, or displace part of the gland, and, if the displaced part forms an acute angle with that normally situated, partial or complete obstruction of its duct at this point is inevitable.

Pancreatic cysts of the above etiology, Senn regards as invariably true retention cysts, whose contents, when recent, is pure pancreatic juice, which in process of time, may undergo physical and chemical changes, by reason of inflammatory processes of the diseased organ in whole or in part.

In recently formed cysts, the sac is thin and delicate, especially so when greatly distended or of rapid development. Its outer layer consists of peritoneum, its inner is soft and smooth. In old cysts, where the cyst wall has undergone various inflammatory and other changes, it is apt to be hard and thick, and may become cartilaginous or ossified.

The important and practical subjects of diagnosis and treatment require painstaking and, oftentimes, prolonged consideration, especially so when an attempt is made to differentiate this lesion of the pancreas from other conditions not infrequently acting within this region of the abdomen. Solid growths in this neighborhood, as a rule, present such differences in their physical characters that they need not be considered as offering any real difficulty in diagnosis. The diseases more apt to give trouble in point of diagnosis are: 1. Cystic disease of the gall-bladder—hydrops fellæ vesicæ. 2. Echinococcus cyst of the liver, spleen or peritoneum. 3. Localized peritonitis with effusion. 4. Ovarian cystoma. 5. Aneurysm of the abdominal aorta, or mesenteric vessels. 6. Enlargement of the lymphatics with cystic formation. 7. Hydronephrosis and pyonephrosis. 8. Cystic disease of kidneys or suprarenal capsules.

Inflammatory exudates, either with or without the formation of pus, will seldom give difficulty in diagnosis, being differentiated from the non-inflammatory formations, here, as in any other part of the body, by the usual signs of inflammation, fever, pain, etc. It is possible, however, that pus may be found without giving rise to elevation of temperature, as for instance in the case of Walsh¹, but such occurrence is so unusual that it need not be considered, and when found, treatment would be identical.

It is exceedingly important to differentiate pancreatic cyst, whether recent or of slower development, from malignant disease in this region. The most important factors in a differential diagnosis are: 1. The history of the case, in one, preceded by injury or attack of colic—when due to impaction of a calculus in the pancreatic duct—in the other absence of such injury or attack. 2. By the shape and character of the growth—being large, usually distinctly fluctuating and commonly unilocular in the one with considerable mobility, and smaller, often multilocular, rarely distinctly fluctuating and more or less fixed in the other. 3. By the rapidity of the growth—a pancreatic cyst attaining in a few weeks the size which even in malignant disease would require many months. 4. By the effect it produces on the general organism, impairing health and nutrition, in case of cyst, little as compared with malignant disease.

1. Enormous distension of the gall-bladder—hydrops fellæ vesicæ, such as are recorded in medical literature, where the cyst occupies the greater part of the abdomen—must of necessity offer great difficulty in diagnosis. With a reliable history of the case, gall-bladder distension will be found to have started in the right hypochondrium, whereas pancreatic cyst makes its appearance first in the left hypochondrium or epigastric region. In gall-bladder disease, the colon is usually anterior, in pancreatic cyst below and in front of the growth.

2. Hydatid or echinococcus cysts of the liver, spleen or peritoneum are slow in their progress, and have no history of preceding injury or attack of colic; however, in case of slowly-developing pancreatic cyst from partial obstruction of the duct of Wirsung or some of its branches, and where the cyst wall has undergone proliferative changes, it will be impossible to arrive at a definite diagnosis. This is of minor importance, however, for both diseases require practically the same surgical treatment.

3. Localized peritonitis with effusion, when met with in this region of the abdomen is to be differentiated by the history of acute peritonitis—pain, vomiting, fever, probably constipation and tympanitis, often preceded by some definite lesion of one or more viscera.

4. Ovarian cystoma, when large and not accompanied with an intelligent history, is most difficult to differentiate from pancreatic cyst, as is proven by able and painstaking surgeons, who have operated on pancreatic cyst for ovarian cystoma and only discovered their mistake during the process of the operation. Ordinarily there need be no difficulty in arriving at a satisfactory solution, especially when an intelligent history of the case is obtainable. The position of the abdomen first invaded, displacement of colon, presence or absence of growth by vaginal touch sufficiently differentiate between the two diseases.

5. From aneurysm of the abdominal aorta or mesenteric vessels pancreatic cyst is known by transmission of the aortic impulse in only one direction, which impulse will entirely disappear when the patient is made to assume the genupectoral position. Moreover, aneurysmal tumors may be made smaller by compression and usually give the "bruit" on auscultation, both of which signs are absent in pancreatic cyst.

6. Enlargement of retroperitoneal lymphatics with cystic degeneration will scarcely offer difficulty in diagnosis, as the fixed location, nodular character, comparatively smaller size, and except in extremely rapid malignant disease, slowness of growth, with probable evidences of similar changes in neighboring lymphatics or other

* Read before the Michigan State Med. Soc.
1 Medical News Dec. 30, 1893.

tissues will sufficiently differentiate between the two conditions.

7. Hydronephrosis, pyonephrosis, cysts of the suprarenal capsules, may offer difficulty in diagnosis, but all of these conditions are apt to develop from the side and extend toward the median line, are usually situated lower down, and, in case of hydronephrosis and pyonephrosis, are preceded by a more or less definite history of kidney lesion or calculi.

Of the most characteristic symptoms of pancreatic cyst, such as are of a size to be operable, the following deserve attention: History of an injury in this region or severe attack of colic; smooth globular cyst, certainly fluctuating when of recent date, and appearing in the epigastric or left hypocondriac region, crowding the stomach up, displacing the colon downward, following the respiratory movements slightly; skin of the body of a peculiar dirty sallow color; little if any pain; no very serious impairment of nutrition, except as due to digestive derangement occasioned by the pressure of the growth.

Given a case answering in the main the above description, what is a physician to do? Such a case demands a celiotomy, even if the diagnosis rests between pancreatic cyst, hydronephrosis, echinococcus of the liver spleen or peritoneum, ovarian cystoma, cysts of the kidney or suprarenal capsule—and any and all of the conditions require the same treatment, at least in so far as an exploratory laparotomy is indicated.

Here I append the history of a case of pancreatic cyst which came under my treatment in the spring of 1896, and of which the following are the more salient points:

On December 3, 1895, I was called to see J. D. J., aged 9, whose father related that the boy while coasting down a steep hill had fallen from his sled, and, when lying on the ground was run into by the sled of his playmate, which forcibly struck him in the region of the stomach, knocking the unfortunate boy "out of wind." He was removed to his home, about three blocks distant, where I found him some two hours after receipt of the injury. He was still profoundly shocked, complained of much distress in the region of the stomach and umbilicus and was vomiting. There were no signs of internal bleeding, and nothing to my mind required operative interference. There was no bloody urine, bowels moved next day, but nausea and vomiting continued; fever, if any, was slight; no evidence of peritonitis. Gradually vomiting eased up, but his general nutrition remained impaired.

I did not see him again after December 24 until March 31, 1896, when the father brought him to my office to get my opinion concerning a large tumor which had appeared about three weeks before, and was rapidly growing. The abdomen was markedly enlarged by a smooth but tense growth in the left side of the epigastrium, which gave unmistakable evidence of fluctuation. The tympanic colon was recognized below, the stomach resonance above it; breathing was short and largely costal; heart somewhat displaced upward, and the tumor appeared to be influenced by the respiratory rhythm. The boy was still pale and looked ill, no rise of temperature, appetite impaired, food causing distress from distension, which was promptly relieved by vomiting. The tumor was not painful to the touch, nor had it given evidence of pain during its rapid growth.

Remembering the accident of the preceding December, the rapidity of its growth, its position, physical characteristics, and its surroundings, a provisional diagnosis

of pancreatic cyst was made. Next day, April 1, with my friend, Dr. F. W. Garber, the boy was visited at his home, and again carefully examined. To make matters more definite, it was proposed to withdraw some of the fluid contents of the cyst, which might give valuable information as to the nature of the growth. Accordingly a hypodermic needle, properly sterilized, was introduced at the most superficial part of the cyst, and about 2 c.c. of fluid withdrawn. On arriving at my office, part of the contents of the hypodermic syringe was added to a solution of boiled starchwater, and Fehling's test applied after a few minutes. An abundant reduction of the sub-oxid of copper proved that a large part of the starch solution had been converted into grape sugar, and that whatever else the cyst contained, it was certain that the amylolytic ferment of the pancreas was actively present. There was now, therefore, no longer any reasonable doubt as to the nature of the cyst, and operation was agreed on for the next day.

About three hours after we had left the home of the patient, his father came to my office, telling me that the boy was feeling very ill, had had a chill, was vomiting, had great pain in the lower part of the abdomen, and that the tumor had disappeared. On arriving at the house, I satisfied myself that the tumor had actually disappeared, found the abdomen painful, the boy vomiting a greenish substance, temperature 102—in a word, all the symptoms of an acute peritonitis were present. It at once dawned on me that the delicate cyst wall had given way at the puncture of the needle and the cyst had thus emptied itself within the peritoneal cavity.

What to do was the important question. We had received absolute proof of the activity of the fluid now free in the peritoneum, by its ready digestion of the starch. What would the effect on the peritoneal lining be; would it disintegrate and partly digest it? The results of experiments as stated by different authors are conflicting, and besides, was not the patient even now infected, as shown by the unmistakable signs of peritonitis? Without interference, there was every reason to believe that a fatal termination could be reasonably expected; and, if the patient should be so fortunate as ultimately to escape with his life, in what condition would the contents of the abdomen come out—would not some of the organs be permanently crippled by adhesions and malpositions? Such were the important questions clamoring for a prompt answer. A hasty consultation was called, and it was decided to at once interfere; not at this time to cure the cyst, but mainly to save life from destructive peritonitis that was already fairly under way.

Preparations for immediate operation were hastily made, and in the midst of unfavorable surroundings the operation was begun, unfavorable in all respects, except that we were reasonably sure that the abdomen and immediate surroundings were fairly free from sepsis. On opening the abdomen not a trace of cyst wall could be discovered, as we had surmised, and, after carefully draining the peritoneum of its fluid and flushing the abdomen with large quantities of hot sterilized saline solution the abdominal wall was closed.

It healed by first intention. Nothing eventful occurred except the wounding of the stomach, which wound was immediately closed by suture and as a means of further protection a patch of omentum was added—and except vomiting of blood once or twice the next day recovery was uninterrupted. It was hoped that the cyst wall at the site of rupture had become sufficiently irritated to cause adhesive inflammation and thereby close the rupture. In this expectation we were not disap-

pointed, for just three weeks after the first operation the cyst made its reappearance at the original site. It was now proposed to make an attempt to cure the cyst. Accordingly the boy was again anesthetized, the incision made in the same place as before, and the abdomen opened. A great deal of thickening of the omentum was found, with adhesion to the abdominal wall at the place of first incision. No attempt was made to loosen the gastrocolic omentum, but an incision was made through it down to the cyst wall and the cyst wall was secured in the usual way—pulling it well into the wound, introducing a canula, emptying the cyst in this manner, and sewing it to the edges of the abdominal incision. A large, double, soft-rubber drainage-tube was introduced to the bottom of the cavity and the rest of the wound closed as is usual. The quantity of fluid escaping during the first few days was enormous, soaking the large thick dressings in a short time and requiring their frequent renewal.

The skin coming in contact with the moistened dressings became exceedingly red and excoriated, and it proved a difficult matter to protect it from the irritating action of the pancreatic fluid. After some trials I found that mutton tallow applied to the skin when still quite warm gave better protection than lard, vaselin and the rest of the softer ointments. One of the drainage-tubes was removed after five days; the second one was gradually shortened till at the end of the three weeks it was entirely removed. Six weeks after the last operation the fistulous tract had completely closed, and the boy was discharged. His health and nutrition had rapidly improved, and when discharged he appeared as well as ever.

The facts to which I wish to call your attention in this case are:

1. The typical history of the case, agreeing in all the important points with the classic symptoms of pancreatic cyst after injury, as described by Senn and others, with the exception that all the cases reported as far as I can learn were met with in adults, mine in a child.

2. The danger of exploratory puncture even with a small hypodermic needle—this is beautifully illustrated in the case presented, and though so careful a surgeon as Senn advises this little procedure in case of doubtful diagnosis, and strongly condemns it in case of hydatid, distension of the gall-bladder, etc., I am persuaded that in cyst of the pancreas, when of rapid development and where the cyst wall is normally thin and delicate, this little operation can not be too strongly condemned.

A few years ago so able and conservative a surgeon as Treves recommended the exploring needle in cases of doubt in appendicitis. My first case of appendicitis proved to me the absolute danger of such a method, and I have always regarded this procedure as by no means void of danger. From the experience I had in the above case of pancreatic cyst, I am more than ever convinced that the exploring needle and hypodermic syringe should be banished as a means of diagnosis in any obscure abdominal affection. The dangers are so overwhelmingly against their employment, as compared with the aid they may render, that exploratory puncture of the abdomen must henceforth be ignored.

PUBLIC BATHS along the Hudson and East River fronts of New York City have been opened for the summer, and on Rivington street a permanent public bath house, to be open the year round, and to cost \$96,000, is in course of construction.

TREATMENT OF TUBERCULOSIS.⁶

A THERAPEUTIC MEASURE BASED ON PHYSIOLOGIC CONSIDERATION.

BY J. F. PEAVY, M.D.
ASHEVILLE, N. C.

Serum therapy, claiming the designation of physiologic medicine, has a very doubtful title to that distinction. The introduction into the circulation of toxins, themselves the production of morbid action, may, under some circumstances, counteract other toxins there. Under some conditions they may excite a cellular response resulting in the generation of protective substances by the cells. The use of these agents is perhaps legitimate and promises to become scientific, but it seems a questionable use of language to distinguish as physiologic methods which depend for their results on pathologic processes.

Oxidation is the ultimate measure of vital action as well as the ultimate source of vital force or resistance of the body as a whole and of its cellular elements. Oxidation furnishes the energy with which the organism does its work, cellular and somatic, developing the potential energy of the nutritive increment into vital action. Thus, nutrition and oxidation become the ultimate factors on which depends the generation of vital force. Under normal conditions the processes balance or complement each other. This correlation may be destroyed in various ways. Overfeeding and insufficient exercise tend to prevent oxidation from keeping pace with the nutritive increment and favor the development of suboxidation products in the system. Notably, rheumatic and gouty states are produced in this way. Various special defects of nutrition may interfere with the capacity of the tissues and fluids to appropriate oxygen. Living in a poor or vitiated atmosphere lowers the physiologic oxidations, because the oxidizing capacity of the air is low.

In whatever way it may come about, lowered or defective oxidation lowers the defensive capacity of the organism. It does this by lessening the cell vitality and resistance. Thus increased vulnerability, either general or local, may arise. Special vulnerability to particular infections may be favored by inherited predisposition. When the defensive capacity falls below the point of successful resistance, the germ profits by his opportunity to occupy for his species a new nook in the economy of nature. He is able to do this because the low cell vitality and the presence of suboxidation products make for him favorable culture conditions.

Oxygen is not only the excitator of nerve sensibility and muscular contraction, thus actively supporting life, but it is also the active agent in preparing for elimination the products of waste, serving as the scavenger of the system. On account of its pre-eminent physiologic importance, the conditions of its introduction and action in the human system demand consideration. In the first place, it is of prime importance that the nutritive increment be properly maintained, supplying the materials for this organic combustion. Lower nutrition and the oxygen increment is lessened as a simple physical adjustment and the vital dynamic output proportionately diminished.

Another condition on which depends the capacity of the fluids and tissues to appropriate oxygen is their alkaline or electropositive nature. Lessening this alkalinity lowers the capacity of the red blood-cells to take up oxygen in the lungs and distribute it to the tissues, the

⁶Read at the Meeting of the Alabama State Medical Association, Mobile, April 29, 1899.

capacity of the tissues to appropriate it in effecting their own metabolism and also the solvent power of the blood for the products of oxidation.

The capacity of the red blood-cells to convey oxygen to the tissues may be impaired by defects of nutrition. Nitrogen is a necessary constituent of hemoglobin. This element is full of capacity while possessing little positive property. It appears to alter its chemic attitude and relationships to adapt itself to the intramolecular changes which hemoglobin is constantly undergoing in the discharge of its functions. A due amount of nitrogen is necessary to make vigorous blood-cells. The essential constituent of hemoglobin, however, the fundamental properties of which constitute the basis of its function, is iron. This may be deficient in quality, constituting the condition known as anemia or chlorosis, with diminished capacity to supply oxygen to the tissues.

The state of the respired air affects the amount of oxygen which the blood is able to take up in the lungs. The principal factors, aside from the constitution of the air, which make up this condition are density, humidity and electric tension. These are the variable factors. Contamination by excess of carbon dioxide and other gases may, under certain circumstances, become a factor. Other things being equal, increase of density increases the amount of oxygen which the respired air is able to give to the blood by increasing the absolute amount of oxygen in given volumes of air. Under natural conditions, the greatest atmospheric density is found at the lowest levels and, other things being equal, the oxygen increment would be greatest at the lowest levels. Other factors, however, are not and can not be equal. At low levels, there is ordinarily high atmospheric humidity and low electric tension. Moisture in the air diffuses and destroys electric tensions. At low levels, even if the air is dry, the electric tension is much lower than in higher regions, especially among mountain-peaks. The projections of the earth's surface appear to act as points concentrating the earth's electricity, these charged points charging the air flowing over them. Whether or not this is the explanation of the presence of ozone in mountain air, it appears to be accepted as a fact that the ozone is present in greater abundance than in that of low levels and that the air has increased activity, notwithstanding the fact that the absolute amount of oxygen is less.

The essential fact in the ozonic conversion of oxygen is the dissociation of the atoms of O_2 , the ordinary condition of oxygen; O_3 , the ozone of the textbooks, is an unstable triatomic grouping which returns readily to the atomic, nascent condition under the influence of disturbing affinities. This accounts for its increased chemic activity as compared with ordinary oxygen. The dissociation of the atoms of O_2 means an appropriation of energy which is represented by the nascent, polarized condition of the parted atoms. This vibrant energy is either chemic or electric energy, as circumstances may determine, as two modes of force here become identic. In the presence of oxidizable material it expends itself in chemic action. If only oxygen bonds are present the atoms fall into the unstable triatomic grouping known as ozone.

Simple altitude without compensating conditions could be only a disadvantage to persons suffering from impaired lung function on account of the diminished atmospheric pressure and consequent rarefaction of the air. Where the function of a part of the lungs is impaired or lost from tubercular infiltration, there is a tendency to compensatory dilatation of the cells of the

unaffected portions. Much diminished atmospheric pressure, either natural or produced by artificial contrivances, may carry this emphysema much beyond the point where any compensatory advantage accrues, increasing the embarrassment of respiration by interfering with the proper renewal of air in the lungs. Very high altitudes soon work the ruin of cases with hemorrhagic tendencies or weak hearts.

Moderate altitudes are, for the great majority of cases, most beneficial, and not then from diminished atmospheric pressure but from compensating conditions. These are diminished humidity, diminished miasmatic influences, diminished heat in summer season and increased electric tension in the air. This last condition pertains especially to the oxygen of the air.

Electric excitation antagonizes chemic union between atoms similarly excited, and favors it between atoms oppositely excited. Electric tension, as affecting oxygen, is defined as a condition of strained relations between the atoms of the oxygen molecule. It reaches its highest expression in a rupture of relations and the development of atomic oxygen. A partial loss of tension allows the unstable triatomic arrangement O_3 . A further diffusion of tension allows the ordinary diatomic grouping.

This electric strain increases the chemic activity of oxygen by lessening the cohesion of its atoms, causing them to part company, the more readily to enter into new combinations under the influence of disturbing affinities. This, then, is the condition which more than compensates for diminished density in mountain air, unless, indeed, the elevation be so great as to radically disturb the mechanic conditions to which the circulation is adjusted. At moderate elevations, 3000 to 4000 feet, with ordinary exercise, the oxidations are carried on more perfectly than in the denser air of low levels. The tonic effect of mountain air consists chiefly in this increased chemic activity of the oxygen, stimulating nerve and cell, increasing metabolism, and hence, the nutritive demand; promoting appetite and digestion and ridding the system promptly of the products of waste.

The process of nutrition and oxidation being fundamentally related to the development of vital force, or resistance, a method of treatment designed to stimulate the one and promote the other can certainly lay claim to a physiologic aim. If it accomplish this result, augmenting cell resistance and reparative power, it must be admitted that it acts in line with physiologic forces.

The fundamental aim in the method set forth in this paper is to increase the physiologic oxidations, at the same time utilizing the tonic effect of static electricity, stimulating metabolism, increasing the demand and the capacity for increased nutritive increment, thus building up the resisting and defensive powers of the organism.

A proximate object of the treatment is to remove the products of waste, the sewage of the system. As is well known, in conditions of suboxidations the products, especially of nitrogenous waste through lack of solubility and difficulty for incomplete oxidation, tend to be precipitated and retained in the system, acting sometimes as irritants, always as disturbers of normal cell activity and resistance.

To remove or prevent the accumulation in the system of products of suboxidation due to impaired lung function, no measures could have a stronger rational indication than the use of oxygen itself under conditions which secure its rapid appropriation.

The static machine used is an eight-plate influence

machine fitted with a Wimshurst charger or exciter, to be used when necessary, as is sometimes the case in damp weather. The patient is placed on an insulated stool connected with the positive discharge rod of the machine. The negative terminal is formed by a spray electrode having some forty-five brass points mounted on a stand, but insulated from it by a hard rubber handle. This electrode is adjusted so that the cluster of points is about two inches from the patient's mouth and nose. When the machine is operated, a strong electric wind is generated by the discharge from the points. This electric wind is rich in ozone, as is quite apparent from its odor, and is also shown by chemic tests. The ozone is due to raising the electric tension of the oxygen to the point of dissociating the atoms of some of its molecules. In this way the oxygen, already electronegative, is rendered more intensely so and its activity thereby exalted. At the same time the patient, forming as he does, the positive electrode, is positively charged, thus exalting the affinity of his fluids and tissues for the electronegative oxygen. The patient is simply required to breathe and we have the conditions for rapid and effective oxidation. The frequency and duration of the inhalations are matters to be determined by the conditions present in individual instances. The quality of ozone developed by the process varies somewhat with atmospheric conditions. Fortunately, most ozone is developed in damp, murky weather, when it is most needed. In fine weather, it is easier to get up tension in the machine and possible to get a more violent disruptive discharge, but the ozoning action is less. There is more ozone normally present in the atmosphere in fine weather, but this means simply that, like any form of electric tension, the ozonic condition of oxygen is more persistent in fine weather.

What have we a right to expect from this treatment? Oxygen, as you know, is nature's great depurative agent both in nature at large and in the animal economy as well. Under the more active form in which it is furnished by this process, we certainly have the right to claim that it facilitates the removal of the products of waste, as well as the noxious materials resulting from impaired function and diseased processes in the lungs. Ozone destroys all known germs. The claim is not here set forth that it will penetrate deeply into the tubercular masses and destroy all the germs, but it is a fair claim that it will destroy exposed bacilli and do much by direct action to inhibit their development. It will do much to destroy devitalized masses, forestalling to a degree the development and absorption of toxins. It is, however, upon the property which this high tension oxygen has of stimulating metabolism, thus promoting nutrition and cellular vigor and resistance, that our highest hopes are based. The cells in this way are made more self-protective and the process is certainly more physiologic than any protection afforded by the introduction of toxins into the circulation.

No fact is better attested than that spontaneous recovery from phthisis sometimes takes place. This can only occur through the vital resistance of the organism itself, manifested either as a local cell resistance directly exerted on the invading microbes or as a capacity to generate antitoxins, neutralizing the toxic products of germ activity and inhibiting the development of the germs themselves. At any rate, the recovery is due to the reactive vigor of the cell, and this in turn is the product of nutrition and oxidation.

Attention to dietary is necessary to insure a due amount and proportion of the different elements neces-

sary for the nutrition of the body. It is especially important that the diet should contain a sufficient amount of proteids. It is through the increased capacity to appropriate these tissue-builders that restoration of structure and function takes place. In conditions of suboxidation it is these azotized materials which cause the most mischief on account of imperfect assimilation and conversion, thus not only failing to support normal tissue change but poisoning the system by the generation of toxins. The increased oxidation secured by this method tends to clear the system of the toxic products of disturbed metabolism and promote the normal conversion of these active agents of tissue renewal.

The intention of this paper is to place the method on a rational basis and to develop, to some extent, its physiological and physical implications. The author is quite willing to let the merits of the method be determined by practical results. Cases now under treatment will be reported in due course of time.

HUMAN FACE AND JAWS.*

AS A DANGER SIGNAL OF SYSTEMIC DEFECT OR DISORDER.

BY J. G. KIERNAN, M.D.

CHICAGO.

Man is a compound organism made up of many different organs, structures and systems which have their own life, albeit subordinate to the life of the organism as a whole. These structures, organs, etc., draw on a fixed supply of the nutriment and unless this nutriment be properly distributed through the system of checks summed up in the nervous system one organ or structure will receive more than its due proportion of nutriment. The balance kept up by the checks is distributed when the organism becomes nervously exhausted either from nerve-tire, from general disease, or from other cause. If this exhaustion occurs at certain periods, called the periods of stress, or of involution and evolution, certain structures on which is thrown such stress are peculiarly apt to be affected either in the direction of arrested development or of hypertrophy. Prominent among the structures which mark these periods are the jaws and teeth, considered together.

The period of the first dentition is one of these periods of stress during evolution, the period of the second dentition is another, and the appearance of the so-called wisdom-tooth marks a third, while the disappearance of the teeth from senility is the period of involution. These conditions of nerve strain may affect the organism of the individual so that he but his descendants show the effects. To this result are often due the irregularities of the jaws and teeth resulting from the lack of balance of the proper distribution of nutriment. The defective palates are also an expression of this strain and not of conditions like mouth-breathing, due, like the defective palates, to hereditary defect evincing itself during the evolutionary periods of stress or at birth. These irregularities are danger-signals prophesying what may happen to the child of the nervously exhausted individual unless there be proper training at the periods of stress, training which will involve brain, nervous system, nutrition and exertion.

The degeneracy which results from nervous exhaustion is a prophecy of what may be rather than a destiny. As the dentist is among the earliest of the medical spe-

* Presented to the Section on Stomatology, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

cialists to whom application is made it comes within his power to outline a course of training and treatment which will prevent the child evincing irregularities from becoming a moral lunatic, an imbecile, a paranoiac, a sexual lunatic, or a victim of lesser forms of degeneracy. Here is a point at which the dentist is afforded an excellent opportunity to take part in the beneficent work of the prophylaxis of the medical profession, which has done so much for the race. The three dentitions, as they are called appropriately by Dr. Talbot, mark three periods of systemic evolution when it is possible to affect the mental and physical development favorably.

NERVOUS DISEASES.*

RELATIVE CURABILITY AND THERAPEUTIC INDICATIONS.

BY JOHN PUNTON, M.D.

PROFESSOR OF NERVOUS AND MENTAL DISEASES, UNIVERSITY MEDICAL COLLEGE; EDITOR INDEX-LANCET, ETC.
KANSAS CITY, MO.

Nervousness has been universally designated as the American disease. European and American literature abounds with alleged facts to substantiate this claim. That nervous diseases prevail to an alarming extent in this country no one assumes to deny. Moreover, their protean forms and intractable character render at times both their diagnosis and prognosis exceedingly difficult and uncertain. In view of this it is fitting that we devote some attention to their relative curability as well as devise means and methods for their relief.

According to Dana¹, there are 176 diseases of the nervous system, and while the majority of these are comparatively rare and uncommon there are at least sixty that are very common and extremely important, and it is these more especially with which the general practitioner comes more or less in contact and should be thoroughly familiar.

Owing to the extreme complexity of the nervous apparatus and its consequently laborious study, its diseases taken as a whole present more difficult problems to the physician in the manner of diagnosis, prognosis and treatment than any other class of disease. Yet I contend that few physicians, comparatively speaking, are willing to pay the necessary price—which implies close confinement for years to its special study, including practical hospital training and experience—to master the essentials, knowledge and principles that underlie the diagnosis, prognosis and treatment of even the more common nervous diseases. On this fact largely hinges the stigma of their incurability, for the relative curability of any given nervous affection is ever based on the accuracy of its early diagnosis.

In this connection it is unfortunate that even up to the present time no accurate scientific classification of diseases of the nervous system can be offered the physician to aid him in solving a doubtful diagnosis. The reason for this is obvious, but the day is rapidly approaching when all diseases of the nervous system will be recognized as due to some change of structure involving its function, and its true pathologic character strictly defined. Until this is accomplished, however, we are compelled to acknowledge our weakness by the use of terms which, if not strictly correct, have at least the redeeming feature of being practical.

By universal consent nervous diseases are roughly divided into two great classes, organic and functional. the

former including all lesions visible to the naked eye or by means of the microscope, and the latter those in which so far the lesion has not been discovered, but their effects consist in an impairment of nerve action.

In the first class the nerve elements are not as a rule primarily affected, but are so secondarily, in which event the morbid process commences outside them. In the second class this rule is completely reversed, the nerve elements being primarily affected. Moreover, as many diseases are found to affect more than one portion of the nervous apparatus, a convenient classification recognizes their special seat. According to this view, we may have diseases affecting the brain, the spinal cord or the peripheral nerves. The differential diagnosis of each, however, depends entirely on the physician's knowledge of the structure and function of the parts involved.

When we come to carefully analyze the lesions which form the basis of nervous affections we find they are not specifically numerous, and often while being essentially the same in character in different situations, they present an entirely new clinical syndrome, varying with their seat, so that a knowledge of their special effects on one part is not the equivalent of another. This accounts for a wide range of clinical phenomena which again increases the difficulties to be encountered in their diagnosis. Generally considered, the chief lesions affecting the nervous apparatus can be arranged under six groups: 1. vascular; 2. inflammatory; 3. degenerative; 4. toxic states; 5. congenital malformations, and 6. functional or unclassified lesions. The first include such conditions as anemia, hyperemia, hemorrhage, thrombosis, embolism, atheroma, aneurysms, etc.; the second all forms of meningitis, myelitis and neuritis; the third, locomotor ataxia, lateral sclerosis, progressive muscular atrophy, bulbar or nuclear palsies, infantile and other palsies. Friederich's disease, muscular dystrophies, growths and tumors; the fourth, syphilis, alcoholism, lithemia, morphinism, mercurial and all other toxic states; fifth, hydrocephalus, microcephalus, spina bifida, kyphosis, scoliosis, rickets, idiocy, etc.; sixth, neuralgias, hysteria, migraine, epilepsy, neurasthenia, catalepsy, paralysis agitata, chorea, tics, tetanus, exophthalmic goiter, occupation neurosis, etc.

The general effects of the lesions producing these pathologic states, as before remarked, present a wide and varied range of symptomatology which conforms to their special seat. When they are studied in relation to their effects on the brain, spinal cord, and peripheral nerves, the chief diseases they are responsible for in these situations are the following:

1. *Brain Diseases.*—In early life the chief nervous diseases affecting the brain are the various forms of meningitis—viz., pachymeningitis and leptomeningitis, tuberculosis and epidemic or spotted fever—and epilepsy. Meningitis and epilepsy, however, may and do occur at all ages. Next in frequency perhaps are the various forms of infantile and other palsies, viz., monoplegia, hemiplegia and paralysis of the cranial nerves. In adult life cerebral hemorrhage, thrombosis, embolism, softening and syphilis are perhaps the chief diseases, while in addition we may have cerebral abscess, tumors and the various cranial nerve palsies.

2. *Spinal Cord.*—When we consider diseases of the cord, we find the lesions producing them are even more limited than those of the brain, and are indeed comparatively few in number. While undoubtedly the great majority of its diseases are in a measure due to both quantitative and qualitative changes in the constituents of the blood, yet the vascular lesions are so uncertain in the

*Presented to the Section on Neurology and Medical Jurisprudence, at the Fifteenth Annual Meeting of the American Medical Association, held at Columbus Ohio, June 6-9, 1905.

¹Text-book on Nervous Diseases.

production of symptoms that such conditions as congestion and anemia or even hemorrhage of the cord are not easy to demonstrate. New growths, and tumors of the cord, are also on the whole extremely rare, so that the most common and consequently the more important diseases of the spinal cord are those due to inflammatory and degenerative lesions. The diseases which they produce, while presenting a wide range of variability, consist chiefly of the different forms of meningitis and myelitis together with their secondary effects resulting in the various kinds of sclerosis and atrophy. We must also remember that the cord is not only liable to suffer from lesions affecting the nerve elements primarily, but it also suffers in consequence of disease outside them, by compression, which may be due to new growths, tumors, inflammatory products, or even hemorrhage. This often results in determining degenerative and sclerotic changes giving rise to their equivalent diseases.

3. *Peripheral Nerve Diseases.*—Clinical observation and experience also teaches us that the diseases of the peripheral nerves consist chiefly of the various forms of neuralgia, neuritis, ties, spasms and paralysis of individual or groups of nerves, together with the accompanying changes common to each. Time forbids further enlargement on these; suffice it to say their unilateral character suggests their source of origin.

4. *Functional or Unclassified Diseases.*—Besides the diseases known to be due to definite lesions of the brain, spinal cord, and peripheral nerves, there are a number already referred to, which affect more or less all parts of the nervous apparatus, but so far their pathologic character has not been strictly defined. These constitute the so-called functional nervous affections such as hysteria, chorea, neurasthenia, paralysis agitans, catalepsy, epilepsy, etc., and these are by far the more prevalent and common and relatively of greater importance than the rest. By virtue of the purely subjective character of their clinical phenomena, their diagnosis is often very obscure and misleading, consequently many a curable case becomes incurable either through sheer ignorance of their nature and character, or lack of enforcing appropriate methods of treatment.

Practical knowledge and experience prove conclusively that when the two great classes of nervous diseases are duly compared irrespective of their seat, the organic are well-nigh incurable, while the so-called functional affections, are, if recognized early, for the most part curable. While there are notable exceptions to this rule, more especially when the diagnosis is made early and appropriate methods of treatment duly enforced, yet its validity cannot successfully be disputed. The time has arrived, however, when a uniform consensus of opinion is highly desirable by those most competent to judge of the relative curability of nervous diseases, on account of their great importance as well as the wide divergence of text-book opinion as to their prognosis. Take for example epilepsy. As it now stands every writer is authority unto himself, and wields his own statistics to suit his own ends. As a result scarcely any two authors agree, and the profession at large are grievously misinformed. If for instance we refer to Ranney, we are led to believe that by the relief of eye strain a large percentage of recoveries from epilepsy can confidently be looked for.

Dana states "that 5 to 10 per cent. get well." Sachs says, "I have seen but very few cases of absolute cure of genuine epilepsy." In a late paper read in my hearing, by Dr. Wharton Sinkler, on this subject, he summed up as follows: "After consideration of the cases above referred to, in which after prolonged intervals, even as

long as twenty-nine years, there has been a recurrence of the disease, we are forced to the conclusion that it is not justifiable to consider any case of epilepsy cured, no matter how great has been the interval of freedom from attacks and appearance of normal health." The discussion which followed the reading of this paper was taken part in by the leading neurologists of this country, and all concurred in the opinion that idiopathic epilepsy, if not entirely incurable, was nearly so. In spite of this, in every community we find persons claiming that they possess a remedy which is a "sure cure for fits," and yet we as a profession, while looking on with disgust, fail to put forth any special effort to prevent such fraud and deception.

Now, what has already been said of epilepsy is largely true of other diseases, such as locomotor ataxia, lateral sclerosis, paralysis agitans, and many other diseases which, after reaching a certain stage, are regarded by the best authorities as incurable. In spite of this there are men, both in and outside of our profession, who claim to possess the power to "cure these incurables," and send us reprints urging us to send our incurable cases to them. I have seen many a poor incurable nervous invalid swindled of his last dollar by such men on the promise of a cure, when all the reliable evidence is against such a prognosis. There never was a time in the history of medicine when so much fraud and deception was practiced on the helpless neurotic incurable as the present.

In view of this, and the prevailing diversity of text-book opinion in regard to the prognosis of nervous diseases, it is highly desirable, indeed an actual necessity, that a text-book authorized by this or some such competent association, be furnished the medical profession, in which is set forth reliable data based on actual facts as demonstrated by practical clinical observation and experience by those most competent to judge of the reliable curability of nervous diseases. On account of their universal prevalence and dependence on disturbances of the functions of the nervous system, which by the way dominate all parts of the human organism, nervous diseases naturally come under the observation of the family physician more frequently in their incipient and curable stage than to any other class of physicians. It is to the general practitioner, therefore, that we must of necessity look for our greatest advance in their curability, and this can only be done by their early recognition and the enforcement of appropriate methods of treatment. Failure in these essentials is largely responsible for the reproach now cast on our professional ability to successfully cope with even the more common nervous diseases.

It is not until the incipient or curable stage is passed that as a rule the nervous invalid appeals to, or is referred for aid to the neurologist, and then it is usually too late to conscientiously offer the patient more than temporary relief. Hence the common slur so often flung at the neurologist as a reward for his services, viz., "About all you can do is to make a diagnosis and offer a bad prognosis," is wholly undeserved and at best reflects the gross ignorance and lack of dignified courtesy of its author.

All authority recognizes the vast dependence of the vital organs on the normal integrity of the nervous functions, and when this neurotic influence, either through sheer ignorance or indifference, is wholly divorced from the clinical study of general disease, failure to cure often of necessity follows. Too often the nervous system is erroneously regarded as an independent organ or as an appendage to the rest of the body, when in fact it is an integral portion of every part of it, not only having spe-

cial organs of its own but also entering deeply into the formation of every bodily organ, and the manifestation of their functional activity is due almost entirely to their special nervous innervation. As the physiologic integrity of the nervous system depends entirely on its normal blood-supply, anything which tends to interfere with this, or change its relative constituents, at once impairs its specific energies. This result is either a local or constitutional lesion which, according to its nature and character, as well as seat, gives rise to clinical phenomena which indicate its pathologic characteristics. Scientific observation and experience also warrant the assertion that in their pathogenesis, functional nervous disorders owe their origin to and largely depend on qualitative and quantitative changes in the constituents of the blood, due to various causes. This results in defective innervation of the body organs, inducing malnutrition and consequent disease. As the general body organism suffers primarily, the actual neurotic basis of the malady is often obscure or held in abeyance, and this leads to mistakes in diagnosis. Consequently too often the effects are treated, rather than an effort made to remove the cause. Subsequently the real nervous affection matures, making itself manifest by actual nervous phenomena, but instead of a functional neurosis, we now have a true organic affection to deal with, which renders the case well-nigh incurable.

The transition from the curable to the incurable is often so insidious and apparently innocent in its effects on the general organism that the patient is given the benefit of the doubt by his family physician, and procrastination becomes the rule until it actually signs the death-certificate.

If it be true that functional nervous disorders in their pathogenesis are largely due to lesions of malnutrition then the therapeutic indications for their curability is self-evident. Anything that has a tendency to re-establish and maintain the normal correlation that should exist between the blood-supply on the one hand and the nervous innervation of the various bodily organs on the other becomes both a prophylactic and therapeutic agent in the prevention and cure of nervous diseases. As the means to attain this end are already well known to you, their special consideration at this time would carry us far beyond the scope of this paper; suffice it to say that too often the important rôle played in their production by hereditary influences, environment, and education are too often overlooked, and their true significance greatly misunderstood. If I have succeeded in calling attention to a subject which deserves more than a passing notice the object of this paper will have been fully met.

MALIGNANT DISEASE OF NOSE AND THROAT*

BY JONATHAN WRIGHT, M.D.

BROOKLYN, N. Y.

It is well known to all of us that statistics, those figures which *do* occasionally lie, have shown that malignant disease is apparently increasing among mankind. I have seen no statistics to prove whether this is altogether an absolute increase or whether it is to some extent a relative one. It must be remembered that the average duration of life has been prolonged into that period which is most liable to malignant disease. Emphasis has of late been given to the old observation that cancer is the disease of the rich and luxurious, of the beef eater, of the high liver and the slothful. There has been consider-

able evidence advanced to show that some forms of malignant diseases are due to the presence of a micro-organism coming in contact with the soil made suitable for its growth by the general predisposing cause of age, or by coming in contact with a local benign growth adds a malignancy to cell proliferation which we recognize in the terms carcinoma and epithelioma. It is by the light which exceptional cases throw on the questions of etiology, of differential diagnosis, and of treatment, that we may hope to advance our knowledge of this desperate and mysterious affliction of mankind. Numerous and perfectly reliable reports are appearing from time to time, which remind us that cancer, and especially sarcoma, although as a rule fatal diseases, are occasionally self-limited. The tumors which vanish of themselves in the course of time have been proved, so far as clinic and microscopic history can do it, to be occasionally true sarcoma or carcinoma. While this at times may throw a shade of doubt on the actual efficiency of the same operations it at the same time teaches us that an epithelioma or a sarcoma is not necessarily an inexorable summons of the grim avenger. Such exceptional instances are occasionally observed in the nose and throat. It may be conjectured that this is the true explanation of some of those cases in which malignant growths have failed to recur after internal operations of the pharynx and larynx. While it is within the range of possibilities that such an operation may be so complete or the disease may be so localized that every island of vicious epithelium or every nodule of perverted connective tissue is separated from its healthy environment, it is difficult for the experienced histologist to conceive that this is the usual result. The unusual course of malignant tumors ending in recovery without operation suggests that in some cases the microscope may not be so much at fault as our conception of certain forms of cell growth in the tissues. The importance of this part of the subject lies in the vista which it suggests. If there are certain influences in the animal system which under certain conditions are able to destroy the continued potentiality of malignant cell proliferation, it is not unreasonable to hope that these influences and these conditions may be revealed by the persistent endeavors of future generations of patient and honest biological workers.

I have been requested to present for your consideration that aspect which malignant disease assumes when it has its seat in the upper air-passages. In the time allotted to me it is not possible to elaborate in detail and it would not be profitable or interesting for you to hear a complete exposé of even this limited part of the general discussion. It would be superfluous to present to you the typical pictures made by a sort of composite photograph of the various cases personally observed or to be found reported in current medical literature, of epithelioma or sarcoma respectively of the nose, of the pharynx, and of the larynx. Neither would it be conformable to the plan of this discussion, as I understand it, to limit myself to the consideration of any one subdivision of the subject, and yet any complete and satisfactory study of the subject must be made by dividing and subdividing it. Malignant disease of the nose presents a clinical picture entirely different from that of the larynx. A sarcoma of the nasal septum presents problems of pathology, differential diagnosis, and treatment entirely separate from those of an epithelioma of the fauces. It seems best, therefore, that I should touch upon certain points which have interested me in connection with the subject in the hope that they will also interest you, rather than to attempt to superficially cover the whole field.

* Read at the Fifteenth Annual Meeting of the Fifth District Branch of the New York State Medical Association, held in Brooklyn, May 23, 1899.

A very few cases of pure adenoma have been reported as occurring in the nose, but a larger number have been observed in which the adenomatous elements were combined with sarcomatous or epitheliomatous characteristics. During the last three or four years I have from time to time examined adenomatous tissue removed from the nasal fossa of a case under the care of Dr. Hinkel of Buffalo. Although it repeatedly recurs in an enfeebled woman, in the upper regions of the nose, it has not as yet shown evidences of malignancy either clinically or microscopically. As this case has been reported elsewhere I take this occasion to say that it still presents every appearance of a papillary adenoma, a form of growth which was described many years ago by Billroth as "Zottenkrebs." I have also had occasion to microscopically examine four or five specimens of adenosarcoma and adenocarcinoma of the nose, and incidentally I have become acquainted with the clinical histories of these cases. One or two such I have had the opportunity of observing clinically, although in the practice of others. I have also read with care the very few reports of such cases to be found in literature. From this somewhat extended study of what is usually regarded as a very rare nasal affection it seems to me evident that while adenoma of the nose is exceedingly rare, and while, even when found to exist without evidence of malignant degeneration, it is exceedingly liable to take on later malignant characteristics. Adenocarcinoma and adenosarcoma are to be ranked among those forms of malignant disease of the nose which run a comparatively slow course, the patient frequently living many years after its inception. They would therefore often be exceedingly favorable cases for operation, but for the fact that they usually occur in very old or very much enfeebled individuals, while the operation in itself is one usually attended with much danger in that class of patients. As to the diagnosis between adenoma and adenosarcoma or carcinoma it must be remembered here as elsewhere that in the presence of clinical evidences of malignancy the value of a negative microscopic diagnosis is of small value. This is not due here, however, so much as elsewhere in the nose and throat to the fact that it is difficult or impossible to obtain a proper piece for examination, but because it is often impossible for the microscopist to give a reliable opinion as to the significance of many of the areas of round-celled infiltration in these growths, which may be either inflammatory or sarcomatous, or of those irregular areas of epithelium, which may be either simple exaggeration of the glandular epithelium or the manifestations of the suspected epitheliomatous involvement.

Besides adenosarcoma of the nose there are other forms of sarcoma when they occur on the cartilaginous nasal septum, which not only run a comparatively benign course but frequently fail to recur after extirpation, and therefore present a very favorable prognosis when seen early.

"Two Italian observers", independently of one another, have lately recorded observations which I have not hitherto seen in print, in regard to the spindle-celled, the endothelial and the angiosarcomata of the nasal septum. They assert that these forms of sarcoma in this situation in many instances present a benignity of clinical history and a failure to recur after incomplete removal, which are in striking contrast to some of the other forms of nasal sarcoma, and of the same form situated elsewhere. From my own experience with seven or eight cases of sarcoma of the nasal septum, examined microscopically,

I am inclined to corroborate these statements, but I confess I have been rather inclined to impugn my own powers of microscopic analysis rather than to suppose that any marked exception to the usual history of sarcomatous growths should be found to occur in the neoplasms of the nasal septum. As a matter of fact, however, sarcomata in other situations present many such exceptions to their usual malignity; and this is true only to a less extent of carcinoma. Nearly every one of wide experience has seen a prognosis founded on microscopic findings, and even with corroborating clinical history, refuted by the subsequent result. A large number of such instances have recently been reported from the personal experience of the observers. I refer to the papers by William Bennett² and D'Arcy Power³. So far as I know there is nothing but experience and an otherwise unsupported theory which teaches that such and such form of cellular growth is fatal in its course. Hitherto, when in any case the results have not been conformable to this experience, we have supposed that the diagnosis and not the theory has been incorrect. Too many such instances are now being constantly reported to allow us to rest easy under this assumption. If the parasitic nature of cancer is established, as the investigations of Russel, Sansfelice and Roncali foreshadow, we can have reason to suppose that an individual may not only be immune to cancer infection, but if infected, develop enough vital resistance to the germ to overcome the potentiality which it has given cell growth.

The differential diagnosis of malignant disease of the nose presents certain features which the locality brings into prominence. So far as the nasal chambers are concerned the adenomatous growths are the only ones which present much difficulty in the diagnosis between sarcoma and carcinoma. The microscope quickly decides between a small round-celled or a fibrous growth and epithelioma. So far as the clinical history, the prognosis and the treatment are concerned, it is of little consequence whether a malignant growth of the nose is an adenosarcoma or an adenocarcinoma. Epithelioma of the nasal chambers is an exceedingly rare occurrence. While it is occasionally necessary to consider the differential diagnosis between tuberculosis and syphilis of the nose, it is certainly very rare and as a matter of fact I have never heard of any case presenting any difficulties in the differential diagnosis between tubercular and malignant disease of the nose. But the cases which give rise to the most serious problems of differential diagnosis are the granulomata of syphilis and small round-celled sarcoma. In the one case we are enabled by simple modification to cause the disappearance of a vicious and alarming infiltration of important structures in a manner which is an almost unique vindication of drug therapy. In the other case we are in the presence of a rapidly growing disease which adds to the usual horrors of a malignant tumor, that of causing not only great suffering but that of mutilation and distortion of the human countenance; for in contradistinction to the benign forms of sarcoma of the nose which I have just mentioned, the small round-celled variety in this situation is the most malignant of tumors. It is therefore easily appreciated how vital is the importance of a prompt and accurate diagnosis. Of course there are a number of cases in which from the presence of various signs, it is easy to arrive at a reliable opinion. With these cases we are not at present concerned. The patient I have in mind presents himself with this history. He has suffered for several months with unilateral nasal ob-

² Lancet, Jan. 7, 1899.

³ Ibid, March 4, 1899.

¹ Martuscelli; Archivio Italiano di Otolgia, 4, 1898; Strazza; *ibid*, 2, 1899.

struction and has had occasional attacks of epistaxis. He usually at first complains of no pain. The nasal region on one side is distended and swollen and the nasofacial furrow is obliterated, the lower eyelid may be edematous and there may be lachrymation. There is a sanio-purulent discharge from the nostril. On intranasal examination a vascular tumor, with a granular surface, covered with mucus presents itself in the anterior nares, usually so far anteriorly as to be seen without the use of a speculum. It bleeds easily when touched with a probe. It is a difficult matter to make out its base of attachment. It may extend so far back as to be seen with the postnasal mirror. No odor of dead bone can be distinguished, as this in itself is usually enough to make the diagnosis of syphilis. The submental glands may be moderately enlarged.

It not infrequently happens that this is approximately the picture of these doubtful cases. Thus far it is not incompatible with the diagnosis either of syphilis or of sarcoma. Yet as has been said, it is absolutely imperative that the diagnosis should be promptly made. We remove as much of the exuberant mass as we can with the snare. If the mass is large, a hot snare may be used without danger of so charring the tissues as to spoil the piece removed for microscopic examination. Very copious and sometimes exhausting hemorrhage may follow the use of the cold snare, and when this occurs, the incident points to sarcoma, but not conclusively. The piece is given to the microscopist for examination. If he freezes the specimen for cutting sections and it is a round-celled growth, the microscopic image is blurred and indistinct, so that absolutely no opinion can be formed as to whether it is a simple inflammatory or sarcomatous granuloma. A properly hardened specimen may prevent a more definite idea of the nature of the growth, but only too frequently, and even then, differential diagnosis is still impossible. How unreliable an opinion expressed as to the nature of such structure is, I am sure many of you have had an opportunity of judging. A case has lately been reported in one of the French laryngological journals in which a hard chancre of the anterior region of the nasal fossa was mistaken for a sarcoma by a competent microscopist and a distinguished laryngologist who himself reports the case. A day was set for removing the upper jaw. There was some delay, and the roscola and other manifestations of syphilis supervening, the patient's jaw and possibly his life was saved. An exactly similar incident has once entered into my own experience with tertiary syphilitic disease. The frequency with which this sort of an incident repeats itself in an extended clinical experience, in every line of surgical practice, but especially in the observation of diseases of the nose and throat, is well known, if the error is not always frankly admitted. Here and there in medical literature will frequently be found reports of cases of mistaken diagnosis in which the mistake was discovered in time. I hope that it will not be thought too cynical to remark that in all likelihood quite as many mistakes are unrecorded because they were discovered too late. How many are never discovered we have no way of knowing, though you will remember that one distinguished confrère estimated that his would fill a graveyard. However this may be in cases of the kind I have just outlined, I am sure we are all of us ready to join with the distinguished French syphilographer in his admonition: "Dans les cas difficiles, pensez toujours à la syphilis, et pensez y encore."

We have seen that in these cases the microscope has failed to differentiate them and that brings us to the consideration of that other sheet anchor of differential diag-

nosis—the results obtained from the use of the iodid of potash.

I need not refer to the tendency of all new growths, whether malignant or not, if of recent origin, to recede to a certain extent under the use of the iodid of potash, except to draw attention to the liability of the observer of intranasal disease to be unduly impressed by this phenomenon in favor of a diagnosis of syphilis; because the recession of the growth within the narrow confines of the nasal chambers appears more marked than it does on the surface where there has been no definite and limited space to be modified by the increase or decrease of the growth. Time will soon rectify this difficulty, but two weeks is usually the shortest period of time in which under the use of the iodid of potash the diagnosis of malignant disease will become manifest.

Before we leave this subject of differential diagnosis of malignant nasal disease, one word in regard to the "clinical sense," so much relied on by many and frequently so valuable a mental possession. It is a faculty which is the articulate result of previous experience, but there is probably no faculty of the mind of the clinical observer over which it is necessary for him to keep such a close watch if he desires to escape falling into errors sometimes fatal to his patients. It is a brilliant mental equipment for the classroom, but for the difficult cases which we have been considering and which we may subsequently have the opportunity of following to the autopsy table, it is a mental equipment which should only be relied on in the absence of more demonstrable aids to diagnosis or as confirmatory of them. Malignant disease of the fauces, earlier giving rise to subjective symptoms and being more accessible to thorough examination than that of the nose, presents as a rule fewer cases in which the diagnosis for any length of time is a matter of doubt. Epithelioma, infiltrating the tissues more deeply and extending more quickly to ulceration than sarcoma, produces, more regularly than sarcoma, the lancinating pains which attend ulcerative affections of the fauces. From such a neoplasm a piece removed for microscopic diagnosis usually establishes the nature of the growth. It occasionally happens, however, that neither is the clinical picture conclusive nor is it possible to obtain a fragment for microscopic examination. I have had the opportunity of seeing many cases of malignant disease of the fauces, but the one which is most indelibly impressed on my memory was that in which the growth involved the root of the tongue without ulceration, on each side of the median line symmetrically, and also involving the hyoid bone. Although I had this case under observation in private practice for more than three months, I was unable in that time to make a diagnosis. The case is reported *in extenso* elsewhere.⁵

Sarcoma of the tonsil, while not a very common disease, is by no means a very rare one. The tonsillar tissue being a lymphoid structure and made up chiefly of small round cells, we should naturally expect the form of sarcoma to conform to that of the normal tissue. As a matter of fact that is what we observe. I have lately had occasion to study the literature of the subject and I have been able to collect the reports of thirty-two cases of sarcoma of the tonsil in which a satisfactory microscopic diagnosis was made as to the variety of sarcoma. To this number I may add one which has lately come under my own observation and another which I have examined microscopically for Dr. Hopkins of Springfield, a report of which has not yet appeared. Of these thirty-four cases all were small round-celled sarcomata excepting

five. Perhaps a further analysis of these statistics may not be uninteresting in connection with this subject. In twenty-one out of the thirty-one cases in which the age was given the patients were past 50 years of age, i. e., in over two-thirds of the cases. Dr. Bryant has reported a case of carcinoma of the tonsil occurring in a patient 17 years old, which is the youngest of which I have found a record. In my table of sarcoma cases I find five occurring between 10 and 20 years of age. The difficulty and importance of differential diagnosis in these cases lies not so much between sarcoma and carcinoma—the microscope if not the clinical aspect of the case easily settles that—but between sarcoma and simple hypertrophy or syphilitic disease. Syphilitic hypertrophy of the tonsil is very rare. I have had opportunity to see a case several times this winter through the kindness of Dr. H. M. Smith, in which the patient is at death's door, and in spite of the continued use of the iodid of potash and microscopic examinations the diagnosis is still a matter of grave doubt in my mind, as between syphilis and sarcoma.

Occasionally the history is one of simple hypertrophy. The growth is removed by tonsillectomy and the specimen is thrown away. Within a few months the growth recurs. This is a rare event for simple hypertrophy, but in a young person not so rare an event as the occurrence of sarcoma of the tonsil. In the case I examined for Dr. Hopkins, the recurrent growth did not differ sufficiently from simple hypertrophy, in microscopic appearance, to lead us to suppose that it was anything else, although subsequent recurrences revealed the undoubted nature of the growth. It may be a matter of interest for me to venture to give so much of Dr. Hopkins' forthcoming report as to say that his case has presented the most gratifying results from the use of Dr. Coley's toxins. In a recent case of my own, however, the course of the disease was in no way arrested by the toxins and he died in four months from the beginning of the history of the growth. These small round-celled sarcomata of the fauces, owing to the rapidity of their growth and their rapid infiltration of the tissues when they once spread from the tonsil, and owing to the important structures which surround them, are usually inoperable.

The larynx, which is frequently described as a cartilaginous box whose walls are said not to be traversed by lymphatics, is theoretically the site from which a cancer might be thought to be removed with the least danger of local and systemic recurrence. Owing to the obtrusive function of the larynx, a change in the voice forcing itself on the attention of both the patient and his entourage, it should be possible to detect in its earliest stages even the most insidiously growing tumor. As on this early recognition depends a cancer patient's chance for life, we see in this early impairment of function another reason why the statistics of laryngeal cancer should be of the best; but as a drawback to these obvious advantages there are other respects in which we soon recognize, after a study of the question, influences which modify our favorable assumptions.

In the first place a large proportion of laryngeal neoplasms extend so far upward as to infect the lymphatics entering over the upper border of the thyroid cartilage. In the second place, while malignant disease at a very early stage causes a notable change in function, it may be easily mistaken for conditions which are trivial and which give rise to no pressing indications for interference; or even if the case is regarded with suspicion, the difficulties in differential diagnosis are so considerable and the gravity of operative procedures are so great that

valuable time is frequently lost in arriving at a proper judgment as to treatment. In the third place the patient naturally hesitates to submit on account of what at the time appears a trifling annoyance, to the mutilation if not the annihilation of the larynx, and to the not inconsiderable danger to life itself. Even simple thyrotomy is not an operation so devoid of danger as amputation of the breast. The removal of the lining of the thyroid cartilage adds very materially to the liability of a fatal result, while laryngectomy, either unilateral or total, is one of the gravest of surgical operations and one only likely to be decided on in the face of the absolute certainty of a miserable and lingering death without such treatment. It is seen, therefore, that epithelioma of the larynx presents various special aspects of its own.

A discussion of these points as they have been alluded to may be as good a plan as any to bring the subject under your consideration. Notwithstanding the fact that anatomists have not traced lymph-channels through the cartilage, thus forming a direct channel of infection to the deep ganglia of the neck, there is a moderately thick network of lymphatics in the intralaryngeal mucosa, which communicates with the chain of cervical glands through the thyrohyoid and cricothyroid spaces. While therefore, a growth of the true cords may exist for many months without external metastasis, exemplified clinically by the late appearance of enlarged cervical lymph-nodes, we should not expect this to be the case in malignant disease of the epiglottis or of the false cords, or even of the laryngeal ventricles. Practically we find that the facts are fairly in accord with this anatomic theory, and every competent clinical observer recognizes the importance of taking into consideration the original site of the growth and the extent to which it has invaded the surrounding tissues, the latter being an exceedingly difficult, in many cases an impossible, thing to do by laryngoscopy. As to these points it may be well to quote the experience of others.

Jursz' cases are as follows: Out of 15 cases the growth involved the whole larynx in 1, right side in 2, epiglottis in 3, true cords in 4, false cords in 3, arytenoid and interarytenoid space in 2.

Of Morrell McKenzie's 53 cases, 28 sprang from the ventricular bands.

Chiari⁶ has recently given the results of his experience with laryngeal cancer. The disease began as follows: On the left vocal cord in 16 instances, on the right in 11, epiglottis in 6, arytenoid cartilage, arypiglottic folds in 13, and was undetermined in 21. It will be seen, therefore, notwithstanding the discrepancies of varying experience, that a very large proportion of these malignant growths begin on the vocal cords. It is well to remember that these cases are not only the ones which earliest give subjective symptoms which should bring them under the notice of the laryngologist, but they are the ones also which, as far as I am able to judge from my own experience and from that recorded by others, present the best prognosis when promptly operated on. On the early recognition of laryngeal cancer depends, as has been said, the patient's chance of life. We cannot here enter on a full consideration of the signs which led to such a diagnosis, but there are certain statements which will bear reiteration whenever this subject is mentioned. In a man past 30, who has never before had any nose or throat symptoms, the gradual super-vention of hoarseness lasting for more than a few weeks should always lead to a laryngoscopic examination. Any growth in the larynx of such a case should be regarded

⁶ Annales de mal de l'Oreille, March, 1896.

by the laryngoscopist with suspicion. As large a piece as possible should be removed for microscopic examination, and in case the microscopic diagnosis is one of malignancy no time should be lost in proceeding to a radical extirpation, if the case is an operable one, because the mechanical injury made by the forceps in a hitherto quiescent malignant tumor of the larynx is extremely apt to stimulate it into rapid growth and infiltration of the surrounding tissues. It probably is this fact which led to the former supposition, so completely exploded by Semon's statistics, that a benign growth might be changed into a malignant one by meddlesome intralaryngeal surgery. The question as to how far a cancer of the larynx may have invaded the tissues, except where the disease is seen on the vocal cords in its earliest stages in one of difficulty. It is the rule rather than the exception that a thyrotomy, affording a direct view of the disease, will reveal an extent of involvement of the soft parts not seen in the laryngoscopic mirror. Were it not for this fact there are doubtless some cases of epithelioma in which endolaryngeal operations by skillful hands might suffice as a radical means of extirpation. Indeed, the remarkable statistics of B. Fraenkel⁷ amply prove this but they also prove rather that he is the possessor of a diagnostic acumen and a manual dexterity to which many of us can lay no claim. As has been forcibly said, so far as endolaryngeal operation is concerned, the laryngologist should see *nolli me tangere* written boldly on a case of laryngeal cancer. A cancer of the laryngeal ventricles may have infiltrated and destroyed the underlying cartilage and be directly continuous with the perilaryngeal tissues without presenting a picture in the laryngeal mirror, or evidence to external palpation, which reveals the extent of the disease. It is not so difficult to ascertain whether a growth is high enough to have passed over the upper border of the thyroid cartilage and infiltrated the extralaryngeal tissues at that point. An enlarged cervical gland, pain, palpation will frequently reveal the condition and thus render the prognosis exceedingly grave. While any disease of the larynx quickly gives rise to subjective symptoms, and while the microscope and the iodid of potash are the sheet-anchors of differential diagnosis, it is sometimes impossible in the first instance and unwise in the latter to make use of them. Certain flat ulcerations or smooth round tumors offer no opportunity for the removal of tissue by forceps, for microscopic examination. On the other hand, in certain cases there may be so much inflammatory infiltration of the mucous membrane, and thereby so much narrowing of the laryngeal lumen, that potassium iodid can only be safely administered while the patient is in bed and under the careful supervision of a surgeon ready to do a tracheotomy at a moment's notice for the relief of a stenosis resulting from a comparatively slight increase of congestion, following the administration of the iodid of potash. While the graver forms of laryngeal edema from the use of this drug are sufficiently rare, an amount of laryngeal congestion, which under ordinary conditions would be insignificant is not infrequently sufficient to cause dangerous dyspnea in a larynx or trachea already narrowed to the danger point.

Occasionally carcinoma of the larynx will begin in such a way as to simulate localized or even non-specific diffused inflammation, and the difficulties in differential diagnosis are considerable. One or two such instances I have seen, and it may not be unprofitable to discuss this form of incipient laryngeal cancer. While a man in middle life, who has previously had no nasal pharyngeal

or laryngeal lesion, is extremely unlikely to have a simple chronic inflammatory lesion begin in the larynx without marked exciting cause for it, such as unusual voice strain, exposure, or the inordinate use of alcohol, this is not the case with those patients in whom these conditions obtain or who are exposed to the causes mentioned. Therefore, in this type of the disease the habits and the occupation and the condition of the nose and pharynx are of very great importance in arriving at a proper understanding of the case. As to chronic alcoholism, it must be remembered that individuals suffering from it are quite as frequently habitués of the club as of the saloon. A man does not by any means need to be a common drunkard to suffer from chronic alcoholism of the upper air-passages. The nose and the pharynx must always be carefully inspected in searching for the cause of laryngeal conditions which may be simply inflammatory or may be malignant. The thickening of the posterior laryngeal wall and of the interarytenoid space may mean chronic laryngitis as the result of atrophic rhinitis or of chronic alcoholism, or it may be the incipient lesion of tuberculosis, but such a condition in incipient cancer is extremely rare, though not entirely unknown. The cancers causing a swelling of the interarytenoid space are usually those which have their origin at the lower end of the pharynx and the beginning of the esophagus and secondarily invade the larynx, although they may do so early in the disease and the laryngeal symptoms may be the initial ones. A unilateral thickening at the posterior commissure and a limitation of the movement of one of the arytenoids is more apt to be due to cancer or syphilis than to a non-specific inflammation. The microscope is of little value in these cases owing to the difficulty in procuring a piece for examination, and when obtained the report is frequently of a doubtful nature. Pachydermia verrucosa of the larynx, a thickening of the surface epithelium, as pointed out by Virchow at the time of the Emperor Frederick's illness, frequently presents very puzzling histologic pictures closely resembling epithelioma. As pointed out by Fraenkel, it is impossible to know the nature of a tumor of the laryngeal ventricles until it has so infiltrated the tissues that an operation, in the event of malignancy, is out of the question. It pushes the membrane covering it into the lumen of the larynx and is itself hidden from view. Such an appearance may be also due to a gumma, a tubercle, a so-called prolapse of the ventricles, or some rare form of tumor of a benign character. I have seen several such cases which, although exceedingly puzzling, did not prove to be malignant. It is impossible to exhaust the subject of differential diagnosis of malignant disease of the larynx in its incipency, when the diagnosis is so important, for nearly every case has some peculiar combination of symptoms of its own.

There are some cases, and unfortunately they form a very large proportion still, but a proportion which is steadily diminishing, which at the first glance are seen to be hopelessly inoperable. No question arises except as to when to do a tracheotomy and how much morphin to give. These cases, when followed throughout their whole miserable course, teach only one lesson, and that is that any hope, however forlorn, of freedom from local recurrence after a radical operation, is never to be discarded in any case. Death as the immediate result of an operation offering such a hope is not to be regarded as an entire defeat, but rather as the less of two evils. When there is a chance for life the patient should be told the truth and all the pros and cons explained to him. It must then be left with him to choose, and to choose promptly,

⁷ Archiv. f. Laryngol., vi. 2.

between an operation which often entails such frightful mutilation and a more frightful lingering death. Suicide has occasionally been chosen by patients who have recovered from a laryngectomy and found life without a larynx unbearable, and it has been urged by some surgeons of great experience that total laryngectomy results in a condition worse than death, and is therefore an unjustifiable operation. Other surgeons think differently and, what is perhaps more to the point, this view is not the universal one with patients who have undergone the operation. At any rate, it does not seem to me that it is the province of the surgeon to decide for such an individual whether or not life will be worth the living.

I conceive that to be a question between the patient and his Maker. Without operation death, as the result of the disease or of his own act, leaves him with little choice. After a so-called successful operation he does have a choice between life such as it is and death. It may be said that this question does not always arise in every operable case of laryngeal cancer. It is exceptional when it should not be considered. As has been said, it is impossible to be sure from the laryngoscopic image that a malignant growth, however apparently limited, has not so far extended as to make anything less than a total laryngectomy manifestly a futile operation. Hence the patient must usually be prepared beforehand for this eventuality.

It will perhaps not be well for me to enter into further discussion of the many points involved in this subject of operation for laryngeal cancer, either as to the statistics of the results of operation, or as to the questions of operative technic and the post-operative treatment. With these I have had but little personal experience. As to an artificial larynx, so far as my observation goes, nature usually makes a better substitute even when there is no air path left from the lungs to the mouth, and the patient breathes permanently through a tube or through a trachea stitched to the episternal notch. Some of you are doubtless familiar with recent cases which have regained all intelligible voice produced by means of air forced from the pharynx, after being partly swallowed, past some fold of vibrating mucous membrane. The results in these cases are surprising.

Divided Authority in Yellow Fever.

NEW YORK, June 29, 1899.

To the Editor:—No little popular interest has been aroused in New York by the announcement promulgated by Quarantine Officer Doty of the discovery of a serum which is believed to be prophylactic against yellow fever and may be considered to have curative value. This has become known through the announcement which Dr. Doty gave to the daily press, for the medical pronouncement has yet to be made in some one of the professional papers.

The gist of the discovery set forth by Dr. Doty appears to be that his bacterial assistant, Dr. C. B. Fitzpatrick, has succeeded in isolating a germ or micro-organism from certain cases of yellow fever which were detained at the quarantine station on Swinburne Island in 1897, and that from the cultures of this germ he has produced an efficient serum.

In this announcement Dr. Doty rather detracts from the originality of the discovery by making the statement that a former assistant of Giuseppe Sanarelli has declared that this

germ and its counteracting serum are identical with those discovered two years ago by Sanarelli in his researches at Montevideo. It is said that Sanarelli has had the opportunity to supplement his laboratory experiments by conducting tests of inoculation and treatment on human subjects supplied him by the government of Uruguay from its institutions for the insane. Yet the last reports from the River Plata are to the effect that the antiamarillic serum of Sanarelli has resulted by no means as well as its discoverer expected. In view of this fact it seems that the discovery announced by Dr. Doty amounts to no more than the performance in New York of work not only already done in Montevideo but also sufficiently tested on the South American coast to give reasonable grounds for doubting its value.

Apart from this feature there are other topics which need some consideration.

In the first place, Dr. Doty, health officer of the Port of New York under the state government, says that the work has been carried out to success by Dr. Fitzpatrick. But Dr. Fitzpatrick appears as an assistant bacteriologist of the department of health of the city, he is therefore a city and not a state official. This is not the only instance in which the officials of the state and city bacteriological services have been found shifting back and forth from one appropriation to the other as need may be considered to arise.

Of more moment is the bearing of this work on the general service of the quarantine in the country. It must be remembered that Dr. Doty is a state official charged with the duty of preventing the incoming of contagious disease by sea into the State of New York. But as New York is the principal port of passenger entry on the Atlantic seaboard its quarantine is the quarantine of the whole country. This properly falls within the province of the Federal government, which has provided in its marine-hospital service an efficient system of protection, with agents in all the principal shipping ports from which disease might approach the United States. It is not considered that any study put by Dr. Doty and the New York State quarantine on the germ of yellow fever can be considered as impeding the Federal Quarantine of the Marine-Hospital service, and in the present case nothing has yet been done but the duplication of work and expense in line parallel with that already in hand in the Marine-Hospital work. No one would wish to impede the work of research, no matter by whom done, but it is proper to call attention to a chance of difficulty which is not as remote as it might seem to those who have not the opportunity to watch the practical operations of such dual systems of precaution. Suppose that Dr. Doty had not only announced an interesting scientific discovery but had declared that he would adopt it in his department of work. He has apparently a perfect right to do so. If he should choose to establish his, or Dr. Fitzpatrick's, or Sanarelli's, antiamarillic serum as a cure for yellow fever there is nothing in the law of the state to interfere. He might, if one of the transports from Cuba were to come to quarantine with yellow fever aboard, as may well be the case at any time, decide to inject his serum to cure the sick and to produce immunity in those who have been exposed and have not yet been attacked. If this were done and the serum should prove as ineffectual as it is reported from Montevideo to be, it is easy to see that a number of danger centers would be incorporated in the community of not only New York State, but of even distant states to a distance regulated only by the speed of railway travel and the period of incubation of the germ. Yet if such a mistake were in contemplation it would be seen that the Federal quarantine would take active steps and protect not only New York but every other state which might be endangered, and it would do this without much consultation with the local authorities.

This may seem an exceptional contingency and so remote

as not to need consideration. On the contrary such an event has already happened, not in New York, but at a port similarly situated on the outer edge of the continent—San Francisco. Here the situation was the same as at New York; there was a local quarantine whose officers were responsible only to the State of California. Some few years ago the State quarantine admitted to pratique a vessel from an Oriental and infected port. The Federal authority protested and in the end interfered. The strained relations were taken into the courts and finally settled in favor of the Federal system.

Now, such a state of affairs might arise in New York, for the same conditions exist. It would be all the more likely because the yellow fever serum is no new thing to the Marine Hospital surgeons. They have already had it under examination and have pronounced by no means in its favor.

Dr. Fitzpatrick says that the bacillus which was found in large numbers in connection with the cases of yellow fever under his examination at Swinburne Island is scarcely to be distinguished from bacillus coli communis. Under the microscope they look the same and they take the stain in the same way; in fact it is probable they would not have been considered specific of the yellow fever if the subjects had exhibited a sufficient supply of other bacilli not yet identified with any other disease. To this bacterium has been assigned the name of bacillus icteroides. The bacillus has been recognized as that on which Sanarelli has employed his time, the recognition having been certified to by a former assistant of the bacteriologist of Montevideo. In default of a decisive method of identification by the microscope the only means left of proving the specific nature of the bacillus icteroides as associated with the causation of yellow fever is by the result when administered to small animals. Here there is disagreement. Dr. Fitzpatrick and Dr. Sanarelli claim that small animals show the characteristics of yellow fever when under the intoxication of the bacterium which they have isolated. Other authorities deny this and produce their own experiments in proof of their contention. Of course, it is understood that if bacillus icteroides is not the specific germ of the yellow fever or is not a different organism from bacillus coli communis—which even its most ardent supporters admit that it most closely resembles—then the serum which is prepared through its employment does not carry immunizing or curative value in yellow fever.

Sanarelli's antiamarillic serum has not passed into its second year without meeting opposition. It has been under study by, among others in this country, the Army Medical Museum in Washington. The distinguished bacteriologists who have there been conducting researches have reached the conclusion that the micro-organism on which Sanarelli's, and therefore the New York investigator's, serum depends is akin to hog cholera and therefore is not specific of yellow fever. It thus appears that the most that can be claimed for the discovery which Dr. Doty communicated to the press is that it amounts to no more than the successful production here of what Sanarelli produced in 1897 in Uruguay. But that serum has been discredited by competent authorities in this country and elsewhere, particularly on the South American coast, where the opportunities for practical application of the serum have been abundant.

W.

Illinois Society for Prevention of Consumption.

CHICAGO, June, 23, 1899.

To the Editor:—One week ago there was organized in this city a society having for its object, as its name indicates, the prevention of tuberculosis. Relative to this topic and apropos of it is what the JOURNAL and the AMERICAN MEDICAL ASSOCIATION has advocated for several years, viz., that the United States Government should have a department of public health

and a competent scientific physician as medical secretary of the same. In this respect the Government is behind the times.

At the Columbus meeting of the ASSOCIATION, Dr. Joseph M. Mathews, in his presidential address, among other things stated, "That it was incumbent upon the ASSOCIATION as far scientific investigation can do so, to eliminate tuberculosis from the land, a disease so dreaded in character that it actually does remove yearly one-seventh of the population of the universe."

I have often thought that statistics are sometimes imaginary, and not as reliable as we would desire, but Dr. Mathews' statement in this respect is acknowledged by the scientific world to be approximately correct, so much so that the international conference which was held in Berlin last month to consider this topic arrived at the same conclusion, as have other analogous scientific organizations, etc.; the result of this latter congress, as we are all aware, is that much good has already been effected.

We, as scientists, veterinarians, public officials, lawyers, merchants, dairymen, and others, who were represented at the meeting organized one week ago for this cause, should unite and co-operate in stamping out this dread malady.

The old maxim, "prevention is better than cure," certainly applies with equal force and greater efficiency to tuberculosis. I quote again from Dr. Mathews' address, "That a committee be appointed from the AMERICAN MEDICAL ASSOCIATION to prepare a careful report on this subject and submit the same to the next session of Congress."

The attention of Congress has been called to this appalling fact year after year for several years, by the physicians throughout the United States, and particularly by the special committee of the ASSOCIATION, which was appointed in 1892, whose bill was endorsed by many scientific bodies of our country, advocating the idea of a department of public health for this nation, having a proper, able, and scientific medical secretary at its head to rank in dignity with other cabinet officials; had this been done years ago, the United States Government, through its department of public health, would have accomplished incalculable benefit in educating the people in preventing the disease, and thus would have been the means, possibly, of saving thousands of precious lives.

All Europe at the present time is on the alert regarding the great importance of preventing consumption. Throughout England various scientific associations have awakened to the great importance this subject deserves. We should not only devise the best methods of prevention, but our Government, state and municipal authorities should adopt measures for the care of this class of its citizens. That pulmonary tuberculosis is contagious under certain conditions is a well-known fact. Hence it is necessary to adopt measures to prevent its communicability to the healthy classes.

As to management and treatment, when tubercle bacilli are discovered in the sputum of a patient, a change of climate, all other things being equal, is perhaps the first *sine qua non* thought of. To eradicate or kill the germs is what is most desired. In pursuance of this, we must be careful not to hasten a patient's death by isolation and other methods. I am a profound believer that fully 20 per cent. of the cases of pulmonary tuberculosis are amenable to treatment that will result in recovery under suitable climatic conditions and the best hygienic environments. This is aside from any form of scientific treatment with drugs, though thorough and scientific in every detail, that might aid in increasing the percentage of recoveries.

I am a believer, also, contrary to what we are taught nowadays, that pulmonary tuberculosis is, or should be, classed as a hereditary disease—not that I desire to be understood that every case is one of heredity, and even though a hereditary taint be present in a family, that recovery should not be anticipated. Physical influence, and an optimistic view, as

much as is consistent, should enter into the cure, probably of every class of patients. My desire in the near future is to see a national department of public health where in the nation's laboratory, not only tuberculosis, but all other constitutional diseases that are preventable can be studied and investigated; indeed, where everything all along the line can be scientifically studied and statistics established irrefutably tending to "build up" the health and thereby promote the longevity of future generations and our citizens.

Very respectfully yours,

LISTON H. MONTGOMERY, M. D.

Antivivisection.

SAN FRANCISCO, July 3, 1899.

To the Editor:—It is wise to remember in the "between times," that the present seem to be years of surprising activity on the part of the many "antis." That the "antivaccinationist" and the antivivisectionist" will return from their summer vacations with renewed energy of bigotry, is in all probability certain. Being but human after all, they are subject to fatigue from overwork and senseless excitation; and also they are equally amenable to the recuperative processes of a vacation, during which lapse the people may be vaccinated or the scientific man may do some animal experimentation. But it is not well to think that the energy derived from the summer's rest will not be manifest in the fall and winter, and therefore to forget the unpleasant fact that even amongst the genus *homo sapiens* (Heaven save the mark "*sapiens*!"), are many animals which work to the evil of the race of man. When any defensive or offensive weapon, with which these "anti" gentry may be combated or attacked comes to hand, it should be carefully kept, even if encountered by the way-side during a truce in the fight. In other words, "In the time of peace, prepare for war." Some little ammunition was manufactured at the recent annual meeting of the Medical Society of the State of California, and as this sort of ammunition serves to supply more than one gun, it should not be overlooked or forgotten.

During the discussion on a paper dealing with the subject of "Ovarian Transplantation" and based entirely upon original research, Prof. Le Conte, who was present and took an active part in the discussion, was asked to express his views on the subject of vivisection. He replied as follows: "In the question of vivisection, the trouble is that the contestants do not understand one another. On one side we have men in whom sentiment overbears judgment, and who, therefore, cannot appreciate the scientific position. On the other hand, scientific men and physicians do not make sufficient allowance for the noble sentiment which underlies the agitation. When such men as Alfred Wallace and Lord Coleridge are found on the side of the antivivisectionists, there must be some noble sentiment at the bottom of the agitation. What is it? It is, of course, *universal sympathy with all nature*, and especially *with all living things*. Surely this is one of the highest sentiments that can fill the human heart. I am sure we are not a whit behind them in our estimate of the transcendent value of such sympathy. All we insist on is that, to be rational, it must be in proportion to the grade of life. I will give two examples illustrating my point of view:

"Some years ago I was discussing this subject with a distinguished lawyer in San Francisco, a man of splendid ability and exquisite taste in literature and art, but unappreciative of scientific methods. He was an ardent antivivisectionist. 'Suppose,' said I, 'In a large city like London or New York, cholera or typhoid fever had just broken out: the vital question would be: How is the disease promulgated? There are two ways in which it may be decided—the one by experiment, the other by observation. By the one method we sacrifice ten or twelve animals, under conditions which we control, and come to the

conclusion that the disease is promulgated by drinking water. By the other method we passively observe the course of the disease in relation to the several sources of water-supply, and, after the sacrifice of thousands or tens of thousands of human lives, we come to the same conclusion. Now, which way is the more merciful? Which violates our sympathetic natures the more?'

"A few weeks ago I was discussing the same subject with a very intelligent and estimable lady. She expressed great surprise that I, whom she considered as a tender-hearted man, should defend vivisection. I knew that she was very fond, perhaps too fond—some of her friends think absurdly fond—of a pet dog. 'Would you not,' said I, 'kill a thousand fleas for the comfort of your dog? For the same reason I would sacrifice a thousand dogs for the life of one man; how much more, then, for the good of humanity. I might have added—but this would have been too hard on her—'Not that we love dogs less, but man more.'

"I repeat then, let us have as much sympathy as possible with life; the more the better, but let it be in exact proportion to the grade and value of life."

This discussion of the question of vivisection by Prof. Le Conte, himself a member of the medical profession, was particularly in order, following the paper read, for the paper was based entirely upon animal experimentation and showed results that warrant in the fullest sense the continuation of the work. If postcastration atrophy can be prevented, as was demonstrated, and if transplanted ovary takes on the nature and vitality of the host, as seemed to be pretty clearly indicated, then the expenditure of a few rabbits and dogs, under conditions where the questions of pain and distress are entirely eliminated, would bring in an immense return in the shape of suffering saved to humanity.

Sympathy with life we all have and must have; but let this sympathy with life as suggested by Prof. Le Conte, be accurately gauged to the grade of life and value of the animal in the scale of life.

Paraxanthin Theory of Poisoning.

CINCINNATI, June 27, 1899.

To the Editor:—You do me great injustice in your paraxanthin editorial in the *JOURNAL* of June 24. In the heading you use the word "disprove" while Putnam and Pfaff only claim that their research "indicates," etc. Dr. Pfaff, in the original title of his paper, used the word "disprove," but after my discussion of his paper, which you have not seen, he changed the title to read "indicates." The facts are that the leucomain theory of the origin of migraine is now stronger than ever, and Dr. Pfaff, after my discussion of his paper, did not claim that he had disproved the theory. In a forthcoming paper I shall make this matter plain, and in the meantime I refer you to the discussion of Dr. Pfaff's paper for further information. The use of the word "disprove" is most unfortunate in view of the large circulation of the *JOURNAL*. I am sure, however, you meant no intentional wrong.

Very truly yours,

B. K. RACIFORD, M. D.

AN OPERATION on an insane patient at the Wisconsin State Asylum at Mendota, for the relief of perforative peritonitis, revealed in the stomach and intestines a half pound of nails of all sizes, two pocket-knife blades and several twisted pieces of wire. Some of the nails were extensively corroded, showing that they had probably been in the stomach for some time. As far as saving life was concerned, the operation, owing to the advanced disease and serious nature of the lesions, was a failure, but the findings are interesting.

AMERICAN.

1. **Celiotomy for Typhoid Fever Complications.**—Bove first remarks that until recent days typhoid fever was pronounced a contraindication to any grave surgical operation, but that more recently we have possibly gone too daringly in the other direction. He reports a case of salpingotomy and ventrosuspension of the uterus performed before the diagnosis of typhoid fever was made. The results were good and he thinks that his case, with those of Simpson and Cushing, demonstrates that relapse in typhoid fever may be produced by grave surgical operations, and that severe emergency operations may be done in this disease with a fair degree of safety, though ordinarily contraindicated.

2. **Operative Treatment of Uterine Cancer.**—Montgomery describes the condition and prospects for operation in uterine cancer, and concludes as follows: 1. Cancer of the uterus is a local disease in its origin which tends to invade the neighboring structures, but extends to the corresponding lymphatic glands much more slowly than in other parts of the body. 2. The chief dangers of relapse are from nests in the adjoining tissues, which have escaped removal, and reimplantation of fragments during the progress of the operation. 3. The data at our command forms no accurate basis on which to establish definite or positive prognosis. 4. From our present knowledge we must depend on the subsequent progress to determine the cure. If prolapse occurs it will most likely take place within the first six months. Should the patient escape two years, cure may be considered as having been established.

4. **Inflammations of Mouth and Tongue.**—Goodale considers the following phases of the subject: Suppurative inflammation of mouth and tongue, parenchymatous inflammation due to diphtheria bacilli; anomalies of circulation or angioneuroses; acute circumscribed edema of the mouth.

v. See abstract in JOURNAL, May 20, p. 1114.

7. **Picture-Taking in Three Dimensions.**—This article, of which the title gives an indirect hint as to its contents, is devoted to the subject of making casts of specimens of parts which it is desired to have reproduced for reference. The author thinks that in many cases they can supplement the rather more difficult pictures or drawings, and he describes the materials and methods which he would advise.

8. **Diagnosis in Obstetrics.**—This paper, begun in the May number, attempts to be a guide in antepartum, partum and postpartum examinations. The author considers pelvimetry, abdominal palpation, and gives a pelvimetry scale and table.

9. **Contracted Pelvis.**—Williams presents complete tables showing the frequency of this condition as noted in Johns Hopkins Hospital.

10. **Traumatic Effusion of Hip-Joint.**—This clinical lecture of Cumston describes a case of traumatic effusion of the hip-joint in a man 21 years old who was thrown from a wagon on a curb stone. He was treated with a posterior splint and moderate extension. After four weeks the bandage was removed and passive motion begun, and the patient encouraged to make some active movements. Eight days later he was allowed to leave his bed and the result has been a nearly complete recovery. The diagnosis of the condition is discussed at length.

11. **Pathology of Gall-Stones.**—McFarland describes the

pathologic conditions connected with gall-stones, the inflammatory and irritative conditions in the gall-bladder, the obstruction of the biliary ducts, cystic, hepatic, and common, the possibility of perforation and fever which often complicates diagnosis. He reviews the literature, quoting quite largely from Murphy's paper on the subject.

12. **Normal and Non-Immunized Serums.**—Parker's article considers the natural antitoxic action of the non-immunized or normal serums, and the argues at some length in favor of the view that they contain protective proteids.

16. **Quantitative Tests of Stomach Contents.**—Reed describes the simpler method of making quantitative tests of the stomach contents, the total acidity, the excess or deficiency of HCl, and the combined chlorine. He describes Toepfer's method in detail.

17. **Etiology and Treatment of Chorea.**—Collins and Abrahamson, while they mention the various forms of chorea, including Huntington's and Dubini's chorea, the tic, habit, senile and secondary choreas, confine their paper to the discussion of the ordinary type of Sydenham's chorea. They find that it is pre-eminently a disease of the young, though it may occur in mature life; that it predominates in the female sex in the ratio of three to two; that it seems to have certain racial preferences, being specially found in Jews. As to its seasonal occurrence, their figures are not exactly in accord with others and indicate nothing positive in this respect. Their statistics are also non-committal as regards the effect of school overwork, which is undoubtedly a factor. Chorea is hereditary, at least it seems to have a relation to neuropathic conditions and rheumatism in the family history. The direct action of rheumatism is of more importance, they think, than has been held to be the case by some authors. It is possible that chorea is a metarheumatic manifestation. The condition of the heart in this disorder may indicate previous rheumatic dyscrasia. Their studies oppose the views that it has any direct relation to infectious diseases except rheumatism. The exciting cause is generally some form of physical trauma such as fright, acute worry, highly wrought anticipation—very rarely gastro-intestinal irritation. It is especially liable to relapse. Brief mention is made of chorea gravidarum, which, like other choreas of adults, is a more serious condition, being, in fact, one of the gravest varieties. The mental faculties are involved to a certain extent in a certain proportion of cases. The chorea indicating a neuropathic predisposition is a form rather more serious than the mere disease ordinarily would seem. The treatment is simple. Rest is the most important measure. The patient should be put to bed and kept there if possible, but at least be made to keep longer hours in bed. Careful attention to the diet is necessary. Young children who have been accustomed to a mixed diet should be put at once on a milk diet carried to the extreme extent of tolerance. In almost every case the bulk of the diet should be milk and cereals. Any digestive complication or constipation should be met with the proper measures and a cold wet compress over the abdomen has often a very beneficial effect. Sprinkling of the spine with cold water on rising, followed by vigorous rubbing, is also very useful, and the wet pack before retiring is another measure that may be used. The medicines that can be used are few. The most important are arsenic, antipyrin, quinia, iron, exalgin and bitter tonics. Exalgin is of greatest service in the early stages of the disease in doses of from 5 to 3 grains repeated every five hours for children under 10 years. Chorea in pregnancy has much the same treatment, but is often accompanied with vomiting which will have to be specially met. It requires vigorous treatment from the start. While chorea is generally a self-limited disease, some cases are protracted and require the general treatment employed for neurasthenia. Electricity and the actual cautery have been recommended. Their value will probably rest in the mental effect produced.

18. **Oxygen With Ether for Anesthesia.**—Cole takes up this subject, on which he made a prior report in 1895, and speaks very highly of the value of oxygen combined with ether for anesthesia. Its only disadvantages are the expense, necessity for skilled administration and the possibility of not quite as effective anesthesia as with ether alone. This last is easily remedied by leaving off the oxygen. Its advantages are that the patient takes the anesthesia with much less

fear and more comfort, and more readily than ether alone. There is seldom any irritation of the air passages or the lungs, which makes it easy to keep up a continuous administration of the drug. There is practically no cyanosis. The blood may flow a little more freely, but he finds this not detrimental and thinks that if there has been any difference in the time required for anesthesia it is in favor of this combination. As regards the recovery from anesthesia, it is quicker, more comfortable and more complete than when ether alone is used. He reports twenty-four cases briefly.

19. **Medical Practice in New York.**—Van Fleet's address is in opposition to Senate Bill 644, as amended in Assembly bill 2338, concerning medical practice in New York State.

20. This paper was printed in full in the *Journal*, May 20, p. 1137.

21. See abstract in *JOURNAL*, May 13, p. 1112.

22. **Trachoma.**—Alkire considers trachoma as an infectious disease, favored by lower vitality, and he sums up the indications for treatment as follows: 1, absolute cleanliness and good hygienic surroundings; 2, improvement, if possible, of the nutrition of the body by correcting the existing abnormal conditions; 3, removal of the trachoma bodies and the use of antiseptic solutions in the eye; 4, correction of the refractive errors; 5, treatment of sequelæ according to the nature and indications.

24. See abstract in *JOURNAL*, May 13, p. 112.

26.—This paper appeared in the *JOURNAL*, February 4, p. 209.

32. **Address.**—Heacock's address was delivered before the Medical Association of the State of Alabama, at the annual meeting in April.

33.—See Abstract in the *JOURNAL*, April 15, p. 826.

34. *Ibid.*, April 1, p. 710.

35. **Three Interesting Cases.**—Downes reports a case of urethral fistula following the palliative curettement of a cancerous uterus relieved by celiotomy and by freeing of the adhesions binding down the ureter. This is the first case found on record of such fistula following the palliative curettement of a cancerous uterus and the only one where the procedure adopted was ever carried out. The second case was one of primary and secondary celiotomy for kinking of the bowels at the sigmoid flexure; the occurrence of fecal vomiting after the second operation is sufficiently rare to be placed on record. The third case is reported only for its rarity and is that of varicocele of the right lateral wall relieved by operation.

36.—See abstract in *JOURNAL*, April 15, p. 836.

37.—*Ibid.*, April 1, p. 709.

40.—*Ibid.*, April 8, p. 765.

41. **Disease in Sigmoid Flexure.**—In this article, Matthews describes four conditions of disease of the flexure: 1, simple irritation due to stagnation of intestinal contents with consequent congestion, which is best treated by giving a brisk aperient and a thorough washing out with warm water or water mixed with a slight amount of borie or carbolic acid. If this treatment does not complete the cure, a mild astringent like fluid hydrastis, $\frac{1}{2}$ oz. to 4 ozs. in water injected at bed time will probably finish the cure. Inflammation of the sigmoid is a somewhat more serious condition, an aggravation of the above described. Its treatment also consists of irrigation, mild astringents, and physiologic rest of the part. All mechanical irritations should be removed by aperient and injections. Then an astringent wash should be employed and later an oil preparation like the following: sweet almond oil, 1 pt., iodoform, 1 dram, subnitrate of bismuth, $\frac{1}{2}$ oz. This preparation should be shaken each time and 1 oz. in a teacupful of warm water deposited in the flexure every night at bed time for a week, constituting the third week of treatment, after which the cure is generally complete. Ulceration of the flexure is shown by casts of epithelium and pus in the stools, constant desire to evacuate the bowels, loss of flesh, pain over the left inguinal region in back and thighs. More active treatment is required; after usual purging, an injection of 2 ozs. of water containing 10 grains of nitrate of silver to stimulate the ulcerated surface to granulation. After that use the borie acid or carbolic solution and about the third week substitute the iodoform and oil. Matthews does not consider a

rigid diet necessary in these cases. He thinks a moderate amount of nutritious food is useful. Moderate exercise every day short of fatigue and special attention to the digestion and state of the bowels are other measures necessary. For cancer in the flexure the only curative method is resection, but colostomy or anastomosis around the flexure with a Murphy button or otherwise may be useful in some cases.

42.—See *JOURNAL*, July 1, p. 31.

43. **Experiences in Intestinal Surgery.**—This article, which is to be continued, gives a report of a rather remarkable case of a woman who underwent nine separate operations involving opening of the abdomen. The final one apparently produced a cure.

44. **Fat and Fecundity.**—Reed's paper is an elaborate discussion of the effects of the disturbances of the reproductive functions involved in obesity. The pathogenesis, course, diagnosis, prognosis and treatment of obesity are discussed. The reader is referred to the article itself as it is not easy to fully abstract it here.

45. **Nasal and Cranial Cavities and Brain Disease.**—Krauss calls attention to the dependence of disorders of the brain on those of the nasal and cranial cavities. The evil effects of deficient nasal respiration or of adenoids often have a very marked effect on the mental development, etc. He also calls attention to the bacteriologic importance of these cavities as routes of infection of the brain. He makes a plea for more careful attention to be given to the nasal mucosa than is at present the practice. The making of a nasal toilet should be a part of the daily toilet.

46. **Hygiene of the Bedroom and Bedstead.**—Tait, in his usual readable style, describes what he considers the right and wrong methods of furnishing the bedroom and of the construction of the bedstead. He describes the bedstead which he specially recommends and which he has named "the Lawson Tait bed." It is a simple iron structure.

49. **Corrections of Nasal Deformities.**—Dr. Roe's paper is a very fully illustrated surgical article giving various methods and results of operation for curing nasal deformities.

51. **Tuberculosis of Urinary Tract.**—The authors, Drs. Vander Veer and MacDonald, give here the results of study in thirty-four cases which are not themselves given in detail. Tuberculosis may appear in any part of the urinary tract as a primary infection. The two most frequent places of origin are the base of the bladder and the kidneys. From these, secondary infections occur. Primary tuberculosis, however, may be found elsewhere, for example, in the urethra. For purposes of diagnosis and treatment it should be considered from a dual standpoint: 1, as a local manifestation of a general systemic infection, and 2, as a purely local disease. This latter is the only one in which it can be considered from a surgical standpoint. The natural tendency of tuberculosis to heal is marked here as elsewhere, and many cases recover without removal of the infected parts under appropriate treatment, or spontaneously. Its early manifestations are very important. Vesical irritability with apparently normal urinary secretion is often an early symptom. Pain, before, during and after urination, particularly if referred to the perineum or middle of the urethra, is an important symptom. Hematuria occurs in more than half of the cases, and is often one of the first things to attract the notice of the patient. Pyuria, especially if intermittent and with an acid urine, calls attention to a possibility of tuberculosis and a spontaneous and intractable cystitis is also to be regarded as an indication. Retention is frequently a pronounced symptom of the early stages of tuberculosis, and as the disease advances, involving the deeper tissues, it is succeeded by incontinence. Neither of these, however, is constant. External physical examination gives very little assistance. The kidney is not often enlarged until the advanced stages of the disease. Instrumental exploration of the urethra or bladder should not be undertaken until one is satisfied that the urinary tract has been already infected. A most careful examination of the urine, apart from all local contamination, is essential, and where there is a failure to find the bacillus, inoculation of a guinea-pig is demanded. On account of the great danger of instrumental exploration, the authors seldom make but one examination, and that under the most careful aseptic precautions. Tuberculosis of the bladder

walls is most rebellious, and causes the greatest suffering. In eight cases operation by drainage was followed by cure in two and by pronounced improvement once, while the remainder were made more comfortable while they lived. The authors prefer the perineal route of operation as affording the easiest access and best drainage. In twenty-three cases of tuberculosis of the kidneys and ureter treated surgically, there were eighteen nephrectomies, with an immediate mortality of five; thirteen nephrotomies, with three deaths following operation, and three removed from exhaustion or secondary nephrectomy. Of the thirteen cases operated on by nephrotomy and partial nephrectomy, seven died, and of the remaining six two are well after prolonged treatment; one has a permanent fistula discharging pus and urine, but is in fair general health, while the others recovered after complete nephrectomy. The authors' experience coincides with that of others, that nephrotomy has little value as a curative operation, but is valuable as a preliminary and exploratory measure; twelve cases recovered after complete unilateral nephrectomy, which they consider a very satisfactory result.

59. **Carcinoma of Esophagus.**—Behrend reports a case of carcinomatous disease of the esophagus with metastasis to the retroperitoneal glands and pancreas.

62. **Tobacco and Alcohol.**—Kellogg maintains that the use of tobacco is the fundamental vice of a large proportion of cases of alcoholic habits and he has for twenty years refused to undertake the care of any case of inebriety without first stipulating for the renunciation of the use of tobacco also. The point that he especially makes is that the physiologic effects of tobacco are such as to give rise to a special craving for alcohol. His views are somewhat extreme as perhaps might be expected.

63. **Nitrogen Requirements of Human Body.**—Heald's paper is an argument for vegetarianism. He concludes from his *ex parte* study of the subject that the organism will maintain its nitrogen equilibrium with a smaller quantity of vegetable protein than of animal protein.

68. **Antral Diseases.**—In this article Arnold calls attention to the importance of diseases in the frontal sinus in cases of antral disorders, and he finds that in nearly 50 per cent. of all cases the infundibulum, which embraces the opening of the frontal sinus into the nose, is a grooved canal with a curvature in the direction of the normal opening of the antrum, and so enclosed by the projecting walls of the middle turbinated bone that it drains directly into the antrum of Highmore. He thinks that in every case of antrum suppuration, persisting after thorough drainage and thorough removal of the diseased bone, co-existing diseases of the frontal sinus will be found. He reports a case which led him to this discovery.

71. See abstract in *JOURNAL*, May 13, p. 1053.

72. *Ibid.*, April 15, p. 823.

76. **Mistakes in Gynecology.**—Cruikshank's paper is a plea for conservative practice in gynecology. He thinks that the influence of other pathologic conditions should be looked for and that this fact in the zeal for operation is overlooked and neglected. Many patients, he holds, suffer through this oversight.

85. **Hernia.**—This article, which is quite practical in its treatment of the subject, goes over the whole matter of the operative treatment of hernia. McLaren first mentions the fact that most cases of strangulated hernia are necessarily operated on by the general practitioner and are seldom reported in print. He refers to the necessity of promptness and states that the appearance of the intestines is not always a perfect guide to the prognosis. The worst appearance is when they have a dark grayish tinge, especially if there are small dark greenish spots. He thinks that in this case we should possibly not attempt to make a resection at once, but form a fecal fistula and wait for a secondary operation to restore the continuity of the bowels. The symptoms of strangulated hernia are, first of all, vomiting. This is the sign which he would most rely on. Fecal vomiting, however, is not absolutely fatal, for he has seen it occur thirty-six hours before operation which was successful. He warns against pushing the anesthesia in these cases, for fear of aspiration pneumonia which may possibly occur. The other symptoms of strangulation are: collapse, sickening pain, constipation, absence of impulse in the tumor. As regards treatment, he would certainly first use taxis, not, how-

ever, continuing the manipulation even as long as half an hour, as advised by Erichsen. In case this fails he would not wait to try other methods but proceed at once to the operation, under the most perfect antiseptic surroundings possible. The method he describes is Bassini's, which he considers the best, as it is founded on the correct anatomic principle of restoring the obliquity of the canal and closing the internal ring to its former size. In femoral hernia the obstruction is generally due to Gimbernat's ligament, and he thinks that the best exposure can be made by following Poupart's ligament. In dividing the point of constriction, the knife should be turned upward and inward, making several superficial nicks for the purpose. In a fairly recent case a radical cure may be obtained by using either the purse string or Bassini's interrupted suture in closing the canal, and drawing Poupart's ligament and the pectineal fascia together. In strangulated umbilic hernia we should first make the incision over the lower part of the sac, as the action of gravity and the weight of the clothing tend to produce ulcerations and adhesions at this point. If operation is performed sufficiently early the mortality of strangulated umbilic hernia need not be greater than that in the femoral or inguinal varieties. He has had the best results in these cases with Fowler's figure-of-eight suture, just picking up the edge of the fascia and the upper loop, taking in the adipose and skin layers. This suture keeps the fascia in accurate apposition and can be removed at any time. He leaves it for two or three weeks.

86. **Subinvolution of Uterus.**—Campbell thinks that the element of the patient's neglect enters more largely into the causation of uterine subinvolution than is usually considered, especially after miscarriage. In cases with old cervical laceration he has found that operation within ten days after a miscarriage seemed to give him better results, and especially aided the involution of the organ.

87. **Some Abdominal Operations in Country Practice.**—Moeller's paper reports some eighteen cases of operation, all but four of which were done at the patients' homes under more or less disadvantageous conditions. The majority were gynecologic or hernia operations. One was a difficult and complicated case of suprapubic cystotomy. He remarks about the difficulty under which the country practitioner labors in these cases where the patient cannot go to avail himself of hospital advantages, or immediate operation is imperatively demanded.

88. **General Melanosis.**—Beard reports a case of widespread melanotic growths throughout the abdomen, pigmentation of the urine, etc. The diagnosis of melanoid sarcoma and a very unfavorable prognosis was given. Contrary to expectations the patient did well, and now, ten years after the discovery of the condition and seven years after the attempted operation of laparotomy for its relief, she is in improved health and the original tumor has lessened in size. The case, he remarks, is worthy of report because of the number and non-malignancy of its melanomata, because of the sudden generalization of the disease and the accompanying melanemia, and because it is, so far as he knows, unique in its apparent recovery.

90. **President's Address.**—Moore's address dwells chiefly on the subject of schools, the hygiene of these, and of juvenile homes and hospitals. In the latter he thinks under-feeding is not an uncommon error. As regards inspection of schools, contagious diseases are a matter of general health precaution and do not fall under this head. But the question of school morbidity, and especially that actually due to school life is a matter of great importance. He refers to exercises, hygienic and calisthenic, the latter of which are of special value in the year or two preceding puberty. He also briefly refers to the effects of adenoid vegetations on the physical and mental development of the child.

91. **Why a Child Strains at Stool.**—Martin describes the anatomy of the lower bowel in children and especially calls attention to the disproportionate length of the colon and its mesentery, the thinness and lack of muscular development of the bowels and the existence of the rectal valves as features which produce the difficult defecation in young children. In the normally formed infant, escape from these troubles is assured in the course of development, but the trouble and suffering that they produce should be alleviated if possible. Diet, hygroscopic suppositories, and fluid enemata to liquidify the intestinal con-

tents are of service, as is also massage over the abdomen, also over the region of the colon in such a way as to directly propel the contents toward the opening and reduce the obstruction caused by any overgrowth of the rectal valves. This can be done by dilatation accomplished by gently introducing the skilled finger, which also excites the mechanism of defecation. Prolapse of the bowel, which is not uncommon in infants, is to be managed by the employment of proper measures for its reduction and correct postures at the time of the passage. A flexed position favors prolapse, therefore, extension of the limbs should be encouraged, the child assuming the erect or horizontal extended position.

95. **Maternal Impressions.**—Hestle reports four cases of deformed infant monsters brought forth by one woman, in the course of six years. The credit is given to fright on the part of the mother from seeing an opossum.

97. **Treatment of Epileptics in Colony.**—In this article, read before the American Medico-Psychological Association, the colony plan of the treatment of epileptics is eulogized and it is claimed that it has amply demonstrated its value to the epileptic and to the public.

98. **General Suppurative Peritonitis.**—McGuire advocates early operation in the case of suppurative peritonitis after the diagnosis is made. It is impossible, he thinks, to deal with the surface involved through a single incision, therefore, he advocates multiple incisions for drainage, and thorough eversion and irrigation of the bowels for cleansing purposes. In many cases the bowels will be found parietic and distended with gas, and for this condition he claims incision should be made, suturing it as soon as the gas escapes, and the bowels can be returned to the abdomen. Gauze strips should be employed and should be left in position as long as they are doing good. After-treatment is the same as in other cases of abdominal section. Rapidity of operation is most important, and while he thinks that perhaps his views will be considered as those of an extremist, only such heroic measures are likely to be generally followed by success.

100. **Tuberculous Process in Children.**—Bovaird, from an analysis of 75 cases of tuberculosis in the children's wards of the New York Foundling Hospital, found in no case any evidence of the entrance of the infection via the placenta or traumas. In no case were tuberculous lesions of the bronchial nodes absent nor in a single case was there infection of the intestinal tract alone, though in one there might have been simultaneous infection by both routes. He reports four cases illustrating his views and sums up as follows: "The primary lesion of tuberculosis in children is regularly in the bronchial lymph-nodes or lungs. Combining Northrup's series with those described in this paper, we have: Infection of the respiratory tract (lungs or bronchial tubes), 148; infection of mesenteric lymph-nodes, 3; indeterminate, 49. As to early manifestations of tuberculosis in children, these are extremely indefinite and uncertain. Tuberculous infection of the bronchial lymph-nodes, as a rule, can not be diagnosed. Latent tuberculosis is often roused and disseminated by the invasion of another disease (infection) such as measles, diphtheria, etc., the presence of tuberculosis not being suspected. The common type of tuberculosis in children is acute milary tuberculosis—it may occur in well-nourished infants. The course of tuberculosis is not often confused with chronic bronchopneumonia or enterocolitis. The early manifestations are progressive emaciation, fever, and the presence of rales over the lungs. These are insufficient for purposes of distinction. The terminal lesions include: a. Extension of the tuberculous process in the bronchial lymph-nodes and lungs, resulting in the formation of abscesses, cavities, etc. b. Diffusion of the tuberculous infection, constituting acute milary tuberculosis, the principal viscera being affected in the following order: spleen, liver, brain, kidney, heart. The involvement of the brain is most important, the meningitis being regularly fatal. c. When bone is involved and there is prolonged suppuration, waxy degeneration of the viscera may occur.

102. **Thrombosis of the Sigmoid Sinus.**—This paper consists of a report and discussion of three cases of thrombosis of the sigmoid sinus following acute otitis media. In two cases bacteriologically examined, in one the infection was due to the

pneumococcus, and in the other the streptococcus was found. The author strongly condemns the use of remedies like antipyrin and phenacetin to reduce the temperature of patients suffering with suppurating otitis media or mastoid disease, as they are liable to mask the condition and impede the diagnosis, so essential for early treatment. The principal points to which he calls attention are as follows: The impropriety of giving antipyretics in all cases of suppurative otitis media; the value of a bacteriologic examination of the secretion from the external auditory canal in all cases. The importance of operating at the earliest possible stage after a diagnosis of thrombosis has been made; the use of the normal saline solution during or immediately following the operation for sinus thrombosis.

103. **Comparative Test of Mixed-Fat Emulsion and Cod-Liver Oil.**—This paper gives the results of experiments made in the Hospital for Ruptured and Crippled in New York, as to the relative value of the mixed-fat emulsions and cod-liver oil. A certain number of strumous children were selected, the only condition being that constitutional treatment was required in addition to the surgical measures in progress and that the children should remain in the hospital until the conclusion of the test. Thirty-two cases suffering from joint disease were placed upon the emulsion and twenty-nine similar ones on cod-liver oil, given regularly in such a way as to be most easily taken. The experiments continued over 13 weeks and changes were noted weekly in regard to the following points: weight, local condition or suppuration, activity about the ward, color, and general condition. Each of these points is discussed in detail and two cases are cited. The author concludes his paper as follows: To summarize briefly, we see that 64 per cent. of the patients in the emulsion cases were suppurating and several were in a desperate condition. Of these, 65 per cent. improved. Of the oil cases, in which 20 per cent. of the patients were suppurating and none was in a serious condition, 50 per cent. improved. The weights, though continued through the whole experiment, were neither satisfactory nor conclusive, for reasons mentioned, with the exception of those for the first five weeks. These show the gains on the emulsion side to be nearly double and the losses about two-thirds those on the side of the oil. In color, 65 per cent. of the patients in the emulsion cases were improved, to be compared with 31 per cent. of those in the oil cases. Under general improvement, 68 per cent. of those in the emulsion group against 48 per cent. of those in the oil group, showed a gain, in spite of the much more serious condition of the former. In conclusion, it may be said that there seems to be a certain better appearance, impossible to classify, about the patients in the emulsion group, which is in advance of that which may be deduced from the notes, though they may show a striking gain over those in the oil group.

105. **Excision of the Right Superior Cervical Ganglion of the Sympathetic for Glaucoma.**—The authors of this paper report what they consider to be the first operation in this country to excise the superior cervical sympathetic ganglion for glaucoma. The ganglion was cut high up and all its branches severed and about one inch of the sympathetic below the ganglion was removed. The patient was immediately relieved from pain and the tension decreased to plus 1. Slight ptosis followed the operation. They think that the relief from pain alone will justify the operation and in glaucoma without complete loss of vision: they will operate upon the first favorable case. The paper concludes with a discussion of the literature on the subject and a brief bibliography.

106. **Yellow Fever in Cuba.**—Dr. Laine's paper is the result of a series of questions sent out to local practitioners of Havana in regard to the diagnosis, treatment, mortality, varieties, etc., of yellow fever. The majority appear to hold that diagnosis can be made within the first three or four days. As to the pathognomonic symptoms, there is a disagreement of opinion, but those who believe in their existence think that it is the syndrome that is pathognomonic rather than any one symptom. The treatment by Sternberg's method seems to have been pretty generally neglected in Havana and no regular system is followed. The mortality of fourteen physicians is an average of 23 per cent. and the majority of those replying to the questions consider the *fièvre de borras* and the acclimatization fever as varieties of yellow fever. The general opinion seems to be that the region of the wharves and water-front of Havana

is the most dangerous district of the city. As regards precautions, the opinions are not very definite.

107. **Crural Thrombosis.**—Coe discusses in this article the question of crural thrombosis following aseptic celiotomy and reviews the question as to infection, which he thinks is unproved, publishing also a letter from Dr. Wm. H. Welch, who is of the same opinion. He reports six cases of his own observation where the foci of infection could not be found, and reproduces brief abstracts of a number of cases reported by Wyder.

108. **Otitis of the Exanthemata.**—The special point in Truitt's article is the importance of early attention to otitis following infective eruptive disease.

109. **Expansion of Medicine.**—The annual address before the Massachusetts Medical Society by Dr. Bradford gives a historical sketch of the progress of American medicine, which is in the main gratifying. He goes over the medical history of the late war at some length and the general sanitary questions of the country are discussed. He regrets the small performances of America in bacteriologic study at the present time, as compared to some other countries, but on the whole his review is certainly encouraging.

110. **Starch Digestion.**—Austin publishes an experimental investigation of the non-retarding action of combined hydrochloric acid on starch digestion, and reaches the following conclusions: When a non-aluminous test-meal is given, free hydrochloric acid makes its appearance at the end of twenty minutes after eating, and at the end of half an hour the amount of free hydrochloric acid equals that of one or two hours after eating, where albuminous foods are taken, as shown by Experiment No. 9. Under normal conditions, the ptyalin of saliva digests most of the starchy constituents of food in the stomach within one or two hours, which takes place before free hydrochloric acid accumulates in the stomach to such an extent as to interfere temporarily with the diastatic action of saliva on starchy food. Those portions of starchy food which remain comparatively undissolved, and pass over to that part of the digestive canal where they are acted on by the pancreatic diastase constitute a very small portion of the starchy food taken. The administration of isolated diastase considerably enhances the digestion of starchy food in the stomach even under normal conditions, as shown by Experiments 7, 8, and 10. The elimination of the supply of ptyalin of saliva to the stomach will cause a marked retardation of starchy digestion in the stomach, as shown in Experiment 4. A maldigestion of starchy food, due to the deficiency of the diastatic power of saliva, can be regulated by the administration of isolated diastase, as shown in Experiment 12. The impression held by many that the diastase of saliva becomes non-active fifteen or twenty minutes after eating is totally erroneous.

112. **Chrysarobin.**—The summary of Fitz' paper is as follows: The claims of chrysarobin as a specific for warts may be summed up as follows: Success in a series of ten cases of warts on the sole of the foot in which the diagnosis was perfectly clear. Similar success in one case of warts on the hand. No failure in any case where the application was made repeatedly on the denuded surface of the wart. No subsequent recurrence of the warts.

113. **Treatment of Yellow Fever.**—Fitzpatrick reports on this article the results of experiments with serum prepared from the bacillus coli teroides at the instance of Dr. Alva H. Doty, health officer of the Port of New York. He has succeeded with this serum in saving guinea-pigs infected with a fatal dose of the culture of the yellow fever germ. Ten cubic centimeters of this serum was sufficient to prevent infection and death in a guinea-pig 300 grams in weight, while a much larger one without this protection succumbed to the same inoculation. This investigation has been referred to in the newspapers during the last week or two.

114. **Exclusion of the Intestines.**—Kammerer reports a case in which to close fistulas after an operation for appendicitis, the small intestine was united to the middle of the transverse colon with a Murphy button, the severed portion being closed with sutures, thus cutting off from the fecal circulation more than six feet of the small and large intestines. A second operation cut off the transverse colon above the transplantation. The results were good. He reports from literature five cases by Baracz, Obalinski, Friele, Wiesinger, and Parkhill,

and adds one of his own. In four of these no untoward symptoms followed complete occlusion. He describes these cases at length, and believes that unilateral exclusion may effect a cure for fecal fistula, and if successful, it is the best and simplest plan of treatment. He thinks that a diseased portion of the intestines should never be completely occluded, some escape for secretions must be allowed, and he regrets that all experimental work has taken this direction and that the secondary complete occlusion after primary exclusion should not have received some attention.

116. **Ill Effects of the Roentgen Rays.**—Orleman reports personal experience of Roentgen-ray dermatitis and ulceration which was cured by rest and skin grafting. She dwells on the therapeutic value of local rest and believes that had this been followed from the beginning, the recovery would have been more rapid. The following precautions are advised by Dr. F. H. Williams to prevent such accidents: 1. Never have the tube near the patient; it should be two or three feet away when using the fluorescent screen, and three feet or more away in taking photographs. 2. There should always be interposed a thin aluminum screen which should be ground by properly connecting it with the gas pipe. In treating these burns, it is of the first importance to realize that the local treatment is entirely secondary to a general treatment devoted to promoting the nutrition of the affected part.

122. See abstract on page 98.

123. See paragraph 109.

124. **Vermont Laboratory of Hygiene.**—Dr. Linsley, the Director of the Vermont State Laboratory gives here an account of the law organizing it and a description of its methods of work.

125. **Kidney Disease.**—Smith sums up his article on the diagnostic signs of kidney disease as follows: In conclusion it may be said that the nomenclature of kidney diseases needs to be relieved of the confusion which has so long attended it. Dropsy would seem to indicate a serious interference with the blood conditions. Uremia is complex in its nature and can be no more than an indication of functional or organic kidney disorder. Albuminous urine, as determined by the usual tests, means a faulty kidney. Tube-casts, except, possibly the hyaline, indicate serious kidney disturbances.

126. **Vaccination Sores.**—Bond, speaking of the obstinate sores which have sometimes followed vaccination, advises the use of nitrate of silver applications either in stick form or in an 80 per cent. solution, the latter being painless. Children do not resist it.

FOREIGN.

British Medical Journal, June 17.

Amputation of Lower Jaw. WILLIAM STOKES.—After remarking that nothing specially new in regard to the technic of the operation has been added of late years, Stokes reports a case of amputation of nearly one-half of the lower jaw for a multilocular cystic condition which was formerly called cystic sarcoma. The case he thinks of interest because it raises the question as to the origin and differences, clinical and pathologic, between unilocular and multilocular cystic maxillary growth, and also on account of the extension of the disease in this case to the temporomaxillary articulation. The operation was successful from a cosmetic point of view, as shown by the picture of the patient after the operation.

Treatment of Abdominal Palpitation.—WILLOUGHBY WADE.—The author remarks on the treatment of abdominal palpitation, a condition common in women and not infrequent in men. It is due to abnormally forcible pulsation of the abdominal aorta, which he considers must be due to excessive tension connected with contraction of the peripheral circulation; his treatment is the administration of nitroglycerin in doses of 1-200 of a grain given at bed time. He thinks that this drug will also be useful in cases of cold hands and feet which are not due to insufficient action of the heart, but to contraction of local arterioles.

Dissemination of Cancer of Breast. HAROLD J. STILES.—This paper is not capable of being abstracted in detail, covering, as it does, all the conditions, anatomic and pathologic, of mammary cancer. The author concludes, in agreement with Watson Cheyne, that the patient's chance of recovery lies in the first operation. If this fails, either from imperfect removal

of the disease or on account of its extent in the first instance, a later operation is seldom successful.

Probable Parental Form of Sharp-Tailed Filaria Found in Blood of Aborigines of British Guiana. C. W. DANIELS.—Daniels reports the discovery of what he considers a parental form of the sharp-tailed variety of filaria found in the natives of Guiana. He discovered it in the post-mortem examination of a native in whose blood both varieties had been found. He thinks that it will generally be difficult to discover it, as he suggests, its habitat is in the connective tissues. Several plates are given illustrating the type specimens.

Method of Operating for Umbilical Hernia, Whether for Radical Cure or When Strangulation has Occurred. HOWARD MARSH.—The author recommends certain modifications of the text-book technic of the treatment of strangulated umbilical hernia. The first is the isolation of the sac down to the opening through which it leaves the abdomen—that is to the level of the linea alba. The isolation of the sac is thus effected. A curved incision starting from the middle line above is carried over the right side of the swelling to the middle line below, and a similar incision is made on the left side, the two together forming an elliptic wound. These two incisions are so planned that they include the skin which covers all the front of the swelling, only enough being left to allow of the closure of the wound, without tension, in the middle line, when the hernia shall have been reduced and the sac removed. Next, the whole thickness of the subcutaneous fat is separated on either side from the outer surface of the sac, including its neck. This is easily carried out by a sweep of the finger and a few touches of the knife. Now, having the sac and its contents controlled, it is opened by an incision in the middle line long enough to afford free access to its interior. The omentum, any part of which when not near the neck may be cut away after ligation or clamping above and below, is unfolded and the intestines exposed, relieved of adhesions and returned. The operator then makes his way to the omentum where its neck emerges from the abdomen. This neck or stem he defines and isolates so that he can pass his finger completely around it. If it is adherent to the ring the adhesions must be separated. The stem is now tied in strands in the usual way, divided beyond the ligatures and returned into the abdomen. There will now remain the sac containing, perhaps, a large mass of more or less adherent omentum. The sac is cut away by dividing its neck at the level of the ring. Its edges are brought together with sutures, and the peritoneal cavity is thus closed. The ring itself is next obliterated by strong buried sutures and the external wound is closed. He claims that this method of first isolating the sac makes it easier to deal with its contents and the clamping and free division of such parts of the omentum as cover and obscure the intestines, saves time while dealing at once with the omentum where its sac emerges from the abdominal ring, instead of first separating, successively, the adhesions which connect it with the fundus of the sac, curtails the length of the operation one-half. This, he believes, will still further reduce the mortality of this formidable condition.

Myxedema Treated With "Colloid Material." ROBERT J. M. BUCHANAN.—A case of myxedema is reported which was treated with "colloid" material prepared from the thyroid glands, with the result of completely restoring the patient to his former condition so that he is now obliged to explain to his customers that he is the same individual formerly known to them before the treatment. The case is illustrated.

Medical Press and Circular (London) June 14.

Two Cases of Metatarsalgia. J. JACKSON CLARKE.—In this paper the author describes a couple of cases of this symptom, first described by Morton, for which he accepts the usual explanation of the misplacement of the heads of one or more of the metatarsal bones. In one of his cases he relieved the patient by having a special shoe made with a band of leather three-eighths of an inch in depth placed externally on the sole behind the heads of the metatarsals. The other case was relieved by operation.

Hey's Internal Derangement of Knee Joint. JOHN KNOTT.—The author concludes his paper, begun in a former number, and maintains that the possibility of misplacement of the fibrocartilage of a normal knee-joint, which condition is apparently commonly understood as Hey's internal derange-

ment, is a myth. He thinks the real explanation of the lesion is a slight subluxation of the head of the tibia with its adhering internal cartilages. It is caused by a slight rotation and internal flexion of the leg. An analogous misplacement of the outer condyle is the lesion causing the comparatively rare form which affects the external section of the knee-joint.

Australian Medical Gazette (Sydney, N. S. W.), May 20.

Two Cases of Stryngomyelia. G. L. O'NEILL and SINCLAIR GILLES.—The authors report two cases of stryngomyelia, one typical, the other having an involvement of the tactile sense, in which they think, however, that diagnosis was correct.

Genito-Urinary Pain. P. CLENNELL FENWICK.—The author reviews the anatomy of the nerves supplying the genito-urinary organs, and explains certain peculiar symptoms occasionally observed, among them asthma connected with urinary hyperacidity and relieved by proper treatment, tenesmus on urethral pain occurring in coition, and a rather curious symptom where pain is felt running from the umbilicus to the meatus on irritation of the former, which he finds is sometimes caused by neglect of cleanliness. In conclusion he asks whether so-called gonorrhoeal rheumatism may not be simply an advertisement of the urethral condition through the sympathetic system.

West London Medical Journal, July.

Cavendish Lecture on Etiology and Diagnosis of Cerebrospinal Fever.—WM. OSLER.—Dr. Osler alludes to the great mortality but comparative rarity of cerebrospinal meningitis, the periodic character of its outbreaks, its close resemblance to pneumonia in some respects and its difference in others, and then takes up the bacteriology of the disorder. Weichselbaum's discovery of the meningococcus after years of neglect has now become generally recognized as the casual germ, and Osler describes its peculiarities and his experience with it during the Baltimore outbreak. Excluding two mild cases in which no organisms were found, and one in which its presence was dubious and complicated with the streptococcus, he found it in thirteen cases out of sixteen in which lumbar puncture was performed. Councilman, Mallory and Wright have noted the association with other bacteria and this was especially notable in the autopsy cases of Osler. On the whole, however, his observations support those of Weichselbaum, Jaeger, Heubner, Councilman and others, that there is an organism, the diplococcus intracellularis, with special cultural peculiarities, that may reasonably be regarded as the exciting cause of the disease. The contrary view of Netter, that the pneumococcus is also the cause, and that the Weichselbaum coccus is a possible degenerate form of the pneumococcus is noticed and rejected as illogical and unwarranted. The diagnosis of cerebrospinal meningitis is not always easy and mortifying post-mortem disclosures are even more frequent than with pericarditis. Dr. Osler reviews certain features, such as the abrupt onset, the varying pyrexia, the skin rashes, the leucocytosis, not so high and persistent as in tuberculous meningitis, the more frequent arthritis or peri-arthritis, Kernig's sign, and lastly, though not by any means least, the use of lumbar puncture, than which no more valuable aid has been acquired within the past decade. Its possible therapeutic value is also mentioned with some facts rather indicating it than otherwise.

The frequency of sporadic cerebrospinal fever is still an open question and Dr. Osler gives the results of bacteriologic examinations by Dr. McCollum of 25 cases of meningitis, showing 6 of this form, 8 due to the pneumococcus, and 11 pyogenic and miscellaneous forms. Here he makes a digression on the meningitis due to the pneumococcus, its etiology, and almost universal fatality when a complication of pneumonia. The frequency of the primary type of this form is a matter for future study.

The lecture concludes with a brief section on treatment. Morphia was freely given for pain at Johns Hopkins and cool sponging was employed whenever the temperature exceeded 102.5 degrees. The mortality, 8 out of 18 cases in the hospital and 9 out of the total of 21, was not excessive, considering the severity of the cases. In two cases the spinal canal was opened, drained and irrigated, one of these being the first extensive laminectomy for acute spinal meningitis. While both cases died, as did also one by Dr. Musser, Osler considers this operation as a desperate remedy for a desperate disease, justifiable

in certain severe cases in which the spinal symptoms are very marked.

Bulletin de l'Academie de Medecine, May 20 and June 6.

Therapeutic Action of Cacodylic Acid and Cacodylate of Sodium. A. GAUTIER AND J. RENAULT.—All the advantages of arsenic treatment are obtained with these substances with absolutely none of its inconveniences. Each contains from 46 to 53 per cent. arsenic, and yet in such a combination that they are extremely soluble in water, non-toxic and non-irritating to tissues. Cacodylic acid probably combines with the cellular nuclei. Given by the mouth it does not produce diarrhea, melanoderma nor arsenic paralysis even with daily doses of 10 to 20 g. "It is a medicine surprisingly effective and applicable in the most unexpected ways, as a stimulant of nutrition, of assimilation and regeneration of the tissues and of their fundamental albuminoid principles. But its chief value lies in its power to stimulate the reproduction of the lymph-corpuses and especially of the polynuclear cells which rid the system of infection, bacteria and their products and also in its ability to cause a prodigiously rapid multiplication of the red corpuscles." It is therefore the method par excellence for sanitifying and incessantly renewing the blood and the tissues in such affections as the pretuberculosis condition, localized tuberculosis, diabetes, Basedow's disease, leucemia, etc. Gautier has been testing it for three years, and a number of reports of its use for seven months by other physicians were communicated, all extremely favorable. Renault administers the cacodylate per rectum: 5 c.c. of 25 to 40 g. sodium cacodylate in 200 grams of water. He recommends all arsenic medication by the rectum. In a case of splenic leucemia the number of red corpuscles was restored from 600,000 to over three millions in twenty days, and to normal in less than three months, with the cacodylate.

Physiologic Introduction to Section of Sympathetic. F. FRANCK.—The functions of the sympathetic as established by extensive research on new lines by Franck, include a propelling action of the eyeball by the action of the cervical cord on the muscle of Muller, showing that section must suppress or diminish exophthalmia. It is also a vasoconstrictor and dilator of the vessels of the intraocular circulation; section diminishes the intraocular tension and may prove useful in glaucoma. The cervical sympathetic does not dilate the vessels in the thyroid; it contracts them, and section therefore can only add a paralytic vasodilation to the active congestion of exophthalmic goiter. The thyroid vasodilators are contained in the laryngeals. It was impossible to discover any secretion exciting action in the thyroid on the part of the cervical sympathetic, but a cerebral vasoconstrictor action was established, although the cerebral vasodilating action is still merely hypothetical. Section can only promote the cerebral sanguine current, and, as treatment of epilepsy, etc., is problematic to say the least. The most important result of this research is the announcement that the entire sympathetic apparatus is endowed with direct sensibility and transports to the cervico-dorsal medulla centripetal nerves originating in the heart and aorta. Hence section of the sympathetic is effective by suppressing the transmission to the centers of abnormal excitations of cardio-aortic origin as well as in suppressing the centrifugal thyroid, cephalic and cardiac of abnormal excitations of cardiac irritations, the same as irritations of the sympathetic, are capable of inducing an ensemble of circulatory reactions which recall the accidents of Basedow's disease, including dilation of the thyroid vessels; consequently the effects of section of the sympathetic may be explained by its suppression of the routes of centripetal transmission in the reflex manifestations of aortic origin. This new idea of aortic sensibility transmitted by the thoraco-cervical sympathetic may suggest its resection for angina pectoris.

Presse Medicale (Paris), June 14.

Muscular Osteoma. REYNIER.—There are very few of these tumors on record, but radiography shows that they are more frequent than hitherto supposed. "They are probably caused by a fragment of periosteum being torn out at the insertion of the muscle, and favored by sanguine effusion, it proliferates in the form of a large tumor almost entirely in the body of the muscle." In the early bone-embryonic stage it casts no shadow in a radiograph, but is distinctly visible when the bone is fully formed. If it causes no disturbance, massage should be tried first and may reduce the tumor, but if the func-

tion is interfered with, the bony mass should be removed down to the actual surface of the bone beneath, not leaving a scrap of osteoma tissue, and carefully following its outlines in the muscle, so as not to encroach on the nerves and vessels in the muscle. Several cases are on record of death from septicemia or absorption of iodoform after ablation, showing that the absorption is very great in these lesions, and aseptis imperatively required. But with extra care the patient is dismissed completely cured, in entire possession of a member whose function seemed fatally compromised forever. Two cases are radiographed, 15 and 21 years of age, in which the elbow was involved, both fully developed in about six weeks after the traumatism.

Revue de Chirurgie (Paris), June 10.

Nervous Complications of Fractures of Lower End of Humerus. A. BROCA AND A. MOUCHET.—These complications appear chiefly in the young and were never noticed with other traumatic lesions of the elbow. "If electric tests indicate a serious lesion of the nerve it is best to operate at once, but if these tests are favorable, expectant treatment is preferable, as manipulations, massage and galvanic alternating current may remove the cause. If there is no improvement in four or five months, the nerve trunk must be sought, liberated, mobilized and possibly stretched. It may have to be dug out of a fibrous or osteo-fibrous sheath. If paralysis appears during the formation of a vicious callus, indicated by radiography, intervention is likewise demanded, as also with secondary paralysis caused by a badly reduced fragment, in which case it is not necessary to expose the nerve. Sensibility returns at once after intervention, but motricity may not be re-established till after weeks of massage and electricity. In case of tardy paralysis intervention is indicated at once and the nerve must have a groove cut for it to move freely and not be stretched in most of the elbow movements.

Semaine Medicale, (Paris), June 14.

Defense of the Organism by Fibrin. A. GILBERT AND L. FOURNIER.—The writers call attention to the general and local hyperfibrinosis which accompanies certain infections, most marked in pneumonia, and its importance as a salutary reaction, the excess of fibrin thus produced serving to mechanically arrest, hold and neutralize microbes and their toxins and prevent their passage into the blood. Its favorable role is not limited to infections, but is conspicuous in the repair of wounds, regeneration of tissues, cure of certain aneurysms, etc.

Centralblatt f. Chirurgie (Leipsic), June 10 and 17.

Significance of Acute Intra-abdominal Effusion. C. BAYER.—"Sudden extensive effusion into the abdomen is a positive means of differentiating internal incarceration from peritonitis."

Siphon Puncture in Abdominal Operations. C. LAUENSTEIN.—In spite of its advantages and simplicity, none of the text-books mention the siphon method of evacuating a cyst or similar cavity. A rubber tube connected with the needle or trocar is filled with water which is allowed to escape as soon as the needle is inserted in the cyst, and the contents of the cyst are thus aspirated by siphon action with no danger of their finding their way into the abdominal cavity or between the tissues.

An Absorbable Suture and Ligature Material. W. F. SNEGUIREFF.—The well-known Moscow professor asserts that he thinks he has nearly, if not quite, attained the ideal for an absorbable material for sunken sutures, in tendon fibers derived from the ligamentum nuchae of the reindeer, not twisted, but merely the straight, parallel fibers of the ligament. It is easily sterilized and is absorbed a little more slowly than catgut, which is a point in its favor. Other advantages are its relative cheapness, and the firmness and strength of the easily tied knots. He reports eighty-three laparotomies in which it was used, besides numbers of lesser operations, and the results induce him to recommend it as the long-sought, very nearly perfect suture material.

Formalin as a Remedy for Surgical Tuberculosis. J. HAHN.—The writer recommends formalin and glycerin as far superior to any substance yet used in tuberculous abscesses, and reports several cases cured to date with two or three injections of 1 to 5 per cent. formalized glycerin, the cure remarkably

prompt and permanent, and the spondylitis also cured with surprising rapidity in the plaster corset. It is especially effective in knee-joint and hip-joint abscesses. The injection is painful, sometimes requiring morphin, and there is frequently transient fever. It is repeated in two weeks. All necrotic matter must be removed.

Centralblatt f. Innere Medicin (Leipsc), No. 22.

Eosinophilia. J. PROTOWSKI.—This review of all the communications published recently on this subject, including several Polish works, rejects every theory proposed to date, except Ehrlich's, which later research has only confirmed. According to this theory the eosinophilous cells are formed in the bone marrow from the mononuclear tissue; they are contractile and respond to chemotactic attraction by emigration, which explains the accumulations of them in effusion and secretions (sputa). The chemic substances that attract the eosinophilous cells probably originate in the destruction of the epithelium and epitheloid cells of the skin, stomach, intestines and bronchi.

Dermatologisches Centralblatt (Berlin), June.

Protracted Course of Latent Period in Syphilis. T. B. V. DORT.—Observations are cited in this communication to prove that syphilis in the father induces with a more protracted and benign course of the infection when acquired by the offspring, frequently leading to erroneous diagnosis, which would have been avoided if the parental syphilis had been known.

Deutsche Medicinische Wochenschrift (Berlin), June 15.

Disinfection With Tincture of Soap. J. MIKULCZ.—The famous Breslau surgeon has been devoting much attention of late to simplifying aseptic methods in order to bring them within the reach of the general practitioner and field surgeon. He now announces that five minutes' disinfection of the hands and region to be operated on, with tincture or soap, no water beforehand, is fully as effective as the usual sublimate-alcohol method and abundance of water, while it is much cheaper and does not exhaust the patient; less exposure is required and thus post-operative pneumonia is prevented. The disinfection is much deeper; the hands remain sterile longer afterward, and the saving of time is an inestimable advantage. Tincture of soap—Seifenspiritus—is non-toxic and does not irritate even the most sensitive regions. The only disadvantage is that the hands are left slightly smooth and slippery, but this is not noticed when tricet gloves are worn and is a point in its favor in obstetric practice. He is adopting it extensively in his practice and suggests that it may be found a superior disinfectant for inanimate objects. He first wipes the hands or part with a dry piece of gauze and then scrubs with the tincture and brush for five minutes. Formula in the Pharm. Germanica: olive-oil, 6 parts; potassa (Kalilauge), 7; alcohol, 30; water 17.

Muenchener Medicinische Wochenschrift, June 13.

Prognosis of Chronic Phthisis. M. PICKERT.—The writer warns against the prevalent optimistic tendency in respect to the curability of tuberculosis in sanatoria, fearing that many disappointments will result which will reflect discredit on the profession. He urges that a six weeks' stay at a sanatorium is far from sufficient, and that Dettweiler's "stayed cured" patients averaged 142 days, Turban's 225, and Leyden's and Fraentzel's, 235 days in the sanatorium. He asserts that laryngeal tuberculosis is cured much more frequently than is generally accepted, but that a favorable prognosis in pulmonary tuberculosis is only possible with shallow infiltration of the superior lobe, restricted to one side, and extending, at the utmost, to the third rib, while tuberculous infiltrative processes in the lower lobe impose an almost absolutely unfavorable prognosis. In other respects the prognosis depends on the extent, manifestation, fever, constitution and gastric and intestinal functions, none of which should be neglected in forming the prognosis. Observation and experience are necessary, and he advocates a tuberculosis sanatorium in connection with every medical college, and the careful collection of statistics at sanatoria on three points: 1. The condition of the lungs when the patient is dismissed. 2. Comparative statistics of the condition when received and when dismissed, lungs and general health. 3. Statistics of the working capacity when dismissed.

Wiener Klinische Wochenschrift, June 15.

Gyneecologic Trifles. J. EISENBERG.—Among several suggestions to facilitate practice without an assistant, one de-

scribes a speculum, a hollow cylinder with a flat peg on top of the outer orifice, and a sloping trough fitted to the lower half, to carry off fluids without soiling or wetting the patient or bedding. Another "trifle" is rolling the strips of gauze for tampons on small round wooden sticks which project a few inches beyond each end of the roll. A wire handle, like a figure of eight cut at the bottom, fits over the two projecting ends of the roller. This handle is held by the patient or hung on some projection, and the gauze unwound directly as needed for the tampon, without coming into contact with anything but the operator's fingers.

Brazil Medico (Rio), May 22.

Symbiosis of Bacillus Icteroides and a Fungus. J. B. DE LACERDA.—The fact casually mentioned by Sanarelli, that the bacillus icteroides frequently degenerated in the ordinary culture-media, while it seemed to thrive particularly well when a certain fungus was growing on the medium with it, has been studied by Lacerda who confirms this fact, and suggests that it may explain a number of the contradictory phenomena in the life of the bacillus. The fungus seems to be a certain aspergillus, which is killed by cold weather, and the bacillus possibly only becomes pathogenic when combined with this fungus, which would explain why yellow fever disappears with the advent of cold weather, although the bacillus does not lose its virulence submitted to the very low temperatures, as Sanarelli established. It also explains why the cultures sent to Europe to be tested proved inert and non-virulent, as they had none of the fungus with them. In tubes containing some of the fungus, the bacillus icteroides gave every evidence of vitality and virulence in cultures a year old. The fact also explains why old, mouldy houses and vessels are the peculiar haunts of yellow fever.

Societies.

Fourth International Congress of Psychology. All arrangements have been completed for this Congress, which is to meet at Paris, August 20 to 25, 1900, with Ribot as president. Address of the general secretary, P. Janet, 21 rue Barbet de Jouy, Paris. There are to be seven sections.

New Jersey State Medical Society.—At the recent meeting of this Society, held in Allenhurst, the following officers were elected: president, L. M. Halsy, Williamstown; first vice-president, William Pierson, Orange; second vice-president, John D. McGill, Jersey City; third vice-president, E. L. B. Godfrey, Camden; corresponding secretary, E. W. Hedges, Plainfield; recording secretary, William J. Chandler, South Orange; treasurer, Archibald Mercer, Newark. The next annual meeting will be held in Atlantic City, beginning June 4, 1900.

Medico-Legal Society.—At the meeting of this Society, held in New York City, June 21, in the discussion on "Christian Science" and the law, the principal argument was in favor of making "Christian Scientists" amenable to the law, ex-coroner Moritz Allinger holding that the practice was iniquitous and the law should therefore be invoked to suppress it, just as in the case of other charlatany. He urged that any alleged cure which depends on the superstition of the people it seeks to aid should be condemned and the most severe penalties enforced against those who practice it. Howard Ellis also argued that those practicing "Christian Science" should be made amenable to the laws regulating practice in general. An opportunity was given for "Christian Scientists" to reply, and the extraordinary ground was taken that because they did not make use of drugs they were not in any way amenable to the laws in force in regard to medical practice.

St. Louis Medical Society.—At the meeting June 24, Dr. Thomas F. Runbold read a paper before this Society, on "Fifty Years as a Specialist in Diseases of the Nose and Throat." The paper was reminiscent and historic and Dr. Runbold being really the first physician in America to devote himself exclusively to this work, spoke with authority. He related many interesting cases, among others his first case of nasal catarrh, his experience in managing the case, and his correspondence with many of the most eminent physicians and surgeons in America, securing their views of such cases. The

opinions of Drs. L. P. Yandell of Louisville, Daniel Drake of Cincinnati, Brainerd of Chicago, Willard Parker and Valentine Mott of New York, and many other front-rank men, were crude and amusing in the light of our up-to-date knowledge of the pathology of nasal catarrh. Many, indeed all, of these great men, declared chronic, purulent, nasal catarrh incurable.

The meeting July 1 was devoted to the trial of Dr. W. H. Mayfield, for unprofessional conduct, the charges being preferred by the Missouri State Medical Society at its last session, at Sedalia. Dr. Mayfield was found guilty by a vote of 50 to 1, and expelled by vote of 46 members, the rest declining to vote. The charges against Dr. Mayfield were improper methods of advertising his sanitarium, the employing of runners or commercial representatives and the offering of commissions to physicians for sending cases to him.

Minnesota State Medical Society.

Thirty-first Annual Meeting held at Minneapolis, June 21, 1899.

DR. F. A. S. DANSMOOR, the president, in his address deplored the exclusion of medical men from public offices and the fact that recommendations of health boards were so often disregarded. He would recommend more union of effort and to this end the organization of more local societies and greater attendance and attention to business in the societies now in existence. Editors will write long articles on the "Prevention of Deaths by Tornados," and entirely ignore the almost infinitely greater number of deaths by tuberculosis and smallpox. The state will spend millions freely on practically unimportant things and refuse a few thousand dollars that are required to furnish pure water and prevent the enormous death-rate by typhoid fever and other preventable diseases.

OBSERVATIONS ON MEDICAL SERVICE OF THE LATE WAR WITH SPAIN FROM THE STANDPOINT OF A VOLUNTEER SURGEON.

DR. CLARK of Stillwater, whose post was at Chickamauga, after describing the arrangement of the camps and the difficulty of obtaining proper arrangements and supplies, said that in the typhoid cases, which were generally of low type, antiseptics, stimulants, and sustaining food were largely used with success. Temperature was not generally high except in severe cases. Orders were issued to boil all drinking water, but this was generally disregarded and in case of one regiment where it was strictly observed the percentage of sickness was the highest of any of the camps. He believed, however, that this was brought about by infection from dust and flies and not influenced materially by the boiled water. He said that the hemorrhage and diarrhea in that climate were something terrific and unknown in such climates as northern Minnesota.

ACROMEGALY.

DR. GREENE of St. Paul presented a case, in a male, 22 years old, history negative, never sick. He denies syphilis; noticed his hands and feet enlarging two years ago. The larynx is enlarged and thickened and causes so much obstruction that he has spells of difficult breathing. There is remarkable thickening of the skin and the forehead, with changes in the shape of the face approaching moon shape, fingers blunt, skin normal and strength in hands also normal; thyroid gland has enlarged notably; has improved remarkably under thyroid treatment. This has been purposely discontinued for the last ten days with marked results for the worse. Dr. Greene believes this treatment to be effectual, but insists on a good extract being used as he has had very variable results with different manufacturers' products.

INSOMNIA.

DR. J. V. SHOEMAKER of Philadelphia gave an address on this subject. He said that sleeplessness of the kind of which he should speak occurred generally in people who, in their anxiety to get ahead were neglecting their diet and the natural functions connected therewith and in short, people who were burning the candle at both ends. It does not do to drug such people as this to any extent, and he has made it a rule to give drugs to this class of cases with much caution. The physiologic remedies are of most importance and he laid great stress on physical exercises, which if necessary may be begun while the patient is in bed—massage, electricity, of which galvanic is best with the negative pole to the back of

the neck, and in children the best results had been obtained by the use of the roller electrode on various parts of the body in soothing into quiet the active and excited muscles. Good and nutritious food, entertainment, and change of scene are also often of great benefit. The beauty of all these remedies lies in the fact that they remove the cause and give the patient a natural and quiet condition.

Among drugs he mentioned opium with its products as being one of the best, most abused and probably one of the most dangerous remedies in unskilled hands. Chloral produces natural sleep but is dangerous on account of its weakening effect on the heart and is particularly so in alcoholic subjects. When necessary to use it, the best effects with least danger may be obtained by giving it by enema. Paraldehyde acts well on the whole system and produces natural soothing sleep without danger, and may be administered in doses of from 10 to 120 grains without danger. Bromides are valuable but should be used less freely, while belladonna and hyoscyamus give the best results in mental depression. He considers cannabis indica, when properly handled, one of the best and safest of all remedies, often succeeding where other things fail entirely. Sulphonal and trional should be used with caution, especially by persons with renal insolvency. He deprecated the use of mere symptomatic remedies in any case and also those in which the price is held up by proprietary means. He is in favor of using older remedies and not trying every new thing that comes up. In all cases make haste slowly.

Election of officers resulted as announced in the JOURNAL of July 1, p. 37.

Philadelphia Pediatric Society.

Meeting Held June 13, 1899.

PNEUMONIA.

DRS. J. C. GITTINGS and C. F. JUDSON presented a clinical report on certain cases of pneumonia treated at the Children's Hospital. Dr. Judson described the physical signs and symptoms present in several cases of alveolar catarrh, which could be differentiated from bronchial pneumonia. One writer states that in cases of alveolar catarrh there is first a proliferation of the cells lining the alveoli, which with the exudate finally undergoes degeneration, with collapse of the walls of these air-cells. In some instances a cheesy product may be formed, or fibrosis may occur. In the cases presented there had been moist rales, increased fremitus, and areas of consolidation. In all cases there had been great depression lasting over a considerable length of time, but followed by recovery. In connection with the study of alveolar catarrh it might be well to state that this condition was not necessarily dependent on the presence of the tubercle bacillus. In the cases reported the diplococcus had been found in the sputum most frequently, but no one organism was always present.

DR. GRAHAM had not always been able to make a differential diagnosis between bronchial pneumonia and alveolar catarrh, and wished to know the special points which had been depended on by those who had presented the paper in doubtful cases.

DR. J. C. GITTINGS stated that the most important data regarding this question was: 1. The way in which the cases originated. 2. The clinical course. In these cases at no time had there been bronchitis. 3. The area involved, in some instances the apex alone being affected. 4. The slow course pursued. 5. The gradual abatement of the disease, leaving behind no morbid change which could be detected by physical methods of diagnosis.

CASE OF RUMINATION.

DR. L. C. PETER reported and presented a case of rumination occurring in a male 7 years of age. In this case the speaker had endeavored to find out if possible why such a condition should be present in this patient. He had been told that it was partly because the patient liked to do so, and partly because he could not help it. It would appear, however, that the general system had suffered, as there had been considerable emaciation or exhaustion. The character of the material eructated had varied according to the time elapsing from its introduction of the food. Rumination had occurred without reference to the particular variety of food taken. The stomach had been frequently examined but no pouch nor any malformation had been found. The speaker referred to instances in which

this condition had been present in neurotic individuals as well as in idioey. A certain amount of neurosis doubtless existed in this case, for at the suggestion "expectorate your food," instantly it was obeyed. This act was done probably two hours after taking food—9 p.m. In regard to the treatment, trephining had been spoken of by one writer, but doubtless this was not necessary. At least there could be no valid reason for doing it. This case had been broken of the habit under the influence of suggestion, and in addition by the administration of Bland's pills.

PSEUDOMUSCULAR HYPERTROPHY.

DR. PETER also presented a boy of 7 years presenting all the typical symptoms. The boy was of neurotic parents. The father had suffered from epilepsy, and at one period lay in a trance lasting three days. The boy was mentally dull and when 3 years of age it was observed that the calves of the legs were markedly developed, as well as the muscular system generally, except in certain areas in which atrophy is present, notably in the latissimus dorsi, pectoralis major and deltoids. The bodily movement is sluggish, waddling gait. When an effort is made to assume the erect posture he first places his hands low down on the legs and virtually climbs upon himself. The reflexes are greatly diminished.

Cincinnati Academy of Medicine.

Meeting Held June 12, 1899.

CEREBROSPINAL MENINGITIS.

DR. G. A. FACKLER read the histories of three cases occurring on his own service and that of Dr. E. W. Mitchell at the Cincinnati Hospital, during the past few months. The cases all presented characteristic symptoms: sudden onset, usually with chill, rigor and high fever; headache with rapid delirium, usually of a low, muttering type but occasionally maniacal; stiffness and rigidity of the neck muscles; opisthotonos, more or less pronounced; irregular fever, Kernig's sign, carinated abdomen, tache cerebrale, absence of abdominal pain, tenderness, rose spots, and splenic enlargement; great hyperesthesia, particularly over the calves of the legs and the soles of the feet; absence of the Widal reaction after trials; a leucocytosis of from fifteen to twenty thousand; withdrawal of more than normal amount of fluid by the lumbar puncture, with temporary amelioration of the symptoms. All the cases died. Examination of this fluid by Dr. J. E. Crewe showed in all these cases a tetracoccus which did not grow on agar or blood-agar, but which flourished well on fluid bouillon. In another case of Dr. Freiwies's, a child with meningitis, acute hydrocephalus developed, and here too a tetracoccus was developed after lumbar puncture. One of the Cincinnati Hospital cases lived forty-four days.

Post-mortem examination of these cases showed well-marked macroscopic evidence of inflammation of the cerebral and spinal meninges, and in one case an area of softening involving one entire cerebellar hemisphere. A report of the microscopic changes will be made after the tissues have become sufficiently hardened. Stained specimens of the tetracoccus were exhibited under the microscope. Microphotographs were shown.

SKIN GRAFTING ACCORDING TO THIERSCH.

DR. E. P. ADAMS, after giving a graphic description of this operation, narrated a case of his own in which skin grafting had been done by this method over a large area in the region of the groin, with perfect results except over the inferior inguinal glands.

DR. J. C. OLIVER spoke of using the inner lining of an egg-shell as a substitute for grafts of skin. As far as his personal experience went, this method had never succeeded in the slightest degree. He also narrated the history of a case of severe burn of the hand in which the fingers had been flexed by the resulting cicatrix on the palm of the hand. On dissecting out the cicatrix and skin grafting he had obtained so good a result that his patient was able to make her living wrapping packages of chewing gum. He has had grafts cling to the inner surface of bone, the tibia, which had been trephined and curetted for osteomyelitis, and has had grafts take over malignant tissue. In some crushes of the foot he is in the habit of not amputating but allowing the crushed tissue

to be thrown off by natural means, and then to skin graft the stump, and is confident he had saved portions of many feet by this means.

DR. ALFRED FREIBERG advocated the method of Krause in preference to the Thiersch. In the former method the subcutaneous tissue is engrafted with the overlying skin and the whole held in place by sutures. He called attention to the excellent result obtained by a member of the Academy in a case of lupus of the face treated by this method, and exhibited before the society but a few weeks ago. He knew this could be done when only comparatively small areas were to be covered. He also thought that transference of a pedicle should be done more frequently. His reasons for these preferences were that he thought the new skin of the skin graft more liable to break down under slight mechanical insult.

Meeting held June 19, 1899.

DOUBLE TERTIAN AND ESTIVO-AUTUMNAL MALARIA.

DR. MARK A. BROWN reported a case, the patient having been sick for about six weeks with chills occurring with more or less periodicity. The examination of the blood five hours after chill showed the presence of two sets of tertian organisms, one with just beginning pigmentation, the other almost filling the red corpuscles with it had entered. Crescents were also present, but in vastly less numbers, proving the existence of the estivo-autumnal variety. As it is usual in this condition for one type to dominate the other, so in this patient the tertian fever had the upper hand, the temperature-chart showing a daily intermittent fever hardly influenced by the continued development of the estivo-autumnal parasite. Microscopic slides stained by the eosin and menthyl blue method were exhibited showing crescents and the two tertian types. The case was reported on account of its comparative rarity, the Johns Hopkins reports mentioning but thirty-one instances in a total of over 1600 cases. Dr. Brown had been able to demonstrate the condition but twice previously in several hundred cases.

WOUNDS MADE BY MODERN BULLETS.

DR. P. S. CONNOR gave an interesting lecture on this subject. He compared the wounds of the Civil War with those of the Spanish-American and gave as the result of his conclusions that the great increase in the velocity of the latter ball was in a measure beneficiary, and that the track of the bullet was clean-cut; that there was very little smashing of tissue around the track of the bullet and as a result gangrene and secondary hemorrhage were uncommon. On the other hand, the blood-vessels and nerves were not pushed to one side as they undoubtedly were by the former missiles. As a rule the late bullets perforated, though some cases of lodgment were reported. This was contrary to previous expectations as was the demonstrated fact that the bullet might also be deflected. Another point was that the bullet was liable to go "end on" and not "side on" so that large wounds were not so common. As regards chest wounds unless some essentially vital point, as a large vessel or the heart, was penetrated, the prognosis of late was very good, just as in civil practice. In abdominal wounds he said that it was rather remarkable that the two laparotomies made for gunshot wounds both resulted fatally, while the cases not operated on recovered. Of the twenty gunshot wounds involving the knee-joint, none have resulted fatally and none had to submit to amputation. Less than 5 per cent. of the wounded removed to hospitals died, a remarkable record when compared with the terrible mortalities from this cause in former wars. He thought that the antiseptic packets carried by the soldiers, when used, had not a little to do in influencing this mortality. Discussed by Drs. Dan Young, Ayres, Oliver, H. M. Brown, Boylan and Freiberg.

Orleans Parish Medical Society.

Meeting held in New Orleans, La., June 24, 1899.

TRANSPPOSITION OF VISCERA.

DRS. L. G. LEBUEUF and JULES LAZARD reported cases of transposition of the viscera.

The case of Dr. LeBeuf was W. P., white, male, 31 years old, a native of Louisiana, 4 feet 10 inches in height, weighing 75 pounds. He had been admitted from the out-patient de-

partment to a medical ward of the Charity Hospital, where he was treated for pulmonary tuberculosis, evidenced both by physical signs and by the presence of bacilli in the sputum.

Physical examination showed the apex-beat of the heart three-fourths of an inch below the level of the right nipple, one-half an inch to its left; on percussion the position of the heart was found to be the reverse of the normal, the long axis running from the base above downward and to the right. There was dullness on the left side from the sixth interspace downward over the transposed liver; spleen dullness was elicited on percussion over the tenth rib on the right. On the right side, below the heart, the position of the stomach could be made out by the tympanitic percussion note, auscultation over the site, while the patient was drinking, detected a gurgling sound as the liquid entered that viscus. Apparently all the viscera were transposed, though the positions of the cecum and sigmoid were not determined.

In the case of Dr. Lazard the diagnosis was first made on autopsy. S. Y., colored, female, 24 years of age, was admitted to the Charity Hospital, Nov. 16, 1894; her breathing was rapid, her pulse full and bounding; there was febrile temperature. Percussion having revealed an apparent dullness at the base of the left lung, a diagnosis of pneumonia was

made. On the following day she died, coma having supervened in the meantime. The autopsy, admirably illustrated by the photograph taken at the time, showed the heart on the right; there was pericarditis, with aortic degeneration; the lungs were transposed, the left having three lobes, the right two; there was nothing else abnormal here beyond a slight pleuritis. The spleen was on the right, and was congested; the liver enlarged, lay on the left. The stomach and pancreas were also transposed, while the sigmoid flexure on the one hand and the cecum and appendix on the other had changed places. The kidneys were congested, the left presenting pus. The cause of death was thought to be pyonephrosis with congestion of the kidneys.

Dr. Lazard quoted Cloquet as saying that he had found this condition three times in 10,000 autopsies; Littré and Robin as stating that it is seen only in men.

Dr. VAN SEYDEWITZ said that in Vienna he had seen a man who presented transposition of the viscera; further, he was acquainted with a man in New Orleans who is similarly peculiar in his anatomy.

AMPUTATION BY BANDS.

Dr. LEBUEF had that day attended in labor a white woman who had gone seven weeks beyond the expected time of her delivery, this having been calculated with considerable accuracy from the date of her husband's departure. He wished to call attention not so much to this point as to the deformity of the infant's left foot. It looked as though the big toe had been cut off transversely, and the second and third smaller toes—corresponding to the third and fourth metatarsals—obliquely. It looked to him like a case not of arrested development but of amputation by bands. In answer to questions, Dr. LeBuef stated that there was no distinct cicatrix, though the ends of the second and third toes looked rough; no

bands had been found in the interior of the amniotic sac; there had been quite a good deal of amniotic fluid.

DEFORMITY AT BIRTH.

Dr. C. J. MILLER had been present at the birth of a child which presented deformity of both upper extremities. The right hand, minus a thumb, was attached directly to the arm, the forearm being lacking; the left hand, which also had but the four fingers, was attached to a half-length forearm. These members were fairly well developed.

ALCOHOLIC POLYNEURITIS.

Dr. T. S. DABNEY reported a case of alcoholic polyneuritis. A young man who was a steady tippler was taken with vomiting, with jaundice; he became weak in his legs and in the course of a few days had extensor paralysis of both wrists and ankles. Cases of this kind require rest, strychnin and good food—not stimulation with the faradic current. The patient, whose onset was described, received, besides the above, 1 grain of ipecac every three hours, for its effect on the liver. In thirty days Dr. Dabney expected him to be completely well. From the suddenness of the onset and the usual rapidity of improvement it was reasoned that there could not be any actual nerve degeneration; the condition was rather one of toxæmia, such as exists in extensor paralysis complicating plumbism.

St. Louis Medical Society.

Meeting held June 17, 1899.

CEREBRAL LOCALIZATION.

Dr. ARTHUR E. MINK read a paper on this subject and stated that the researches of Flechsig have compelled us to remodel our ideas concerning the cerebral cortex. The centers of the cerebral cortex can be divided into two great groups. We have first the projection centers, which are the equivalents of sensory surfaces and are situated about the primary fissures. The tactile center is largely homologous with what was formerly termed the motor area, and is located in the paracentral lobule, part of the gyrus fornicatus, the ascending frontal and parietal convolutions and the posterior parts of the three frontal convolutions. It was formerly supposed that all parts of the cortex alike received projection fibers. This, however, is not so. Only one-third of the cortex receives projection fibers. Each projection center has centripetal and centrifugal fibers. The visual projection center is situated in and near the calcarine fissure. The auditory area is in the first temporosphenoidal convolution, the olfactory in the olfactory trigone, the anterior perforated substance, the neighboring part of the corpus callosum, part of the hippocampal gyrus and the uncinate gyrus. The olfactory sense is rudimentary in man. In some of the mammals, however, the olfactory area occupies almost two-thirds of the cerebral cortex. In man the tactile so-called motor areas largest of all, inasmuch as it duplicates for the opposite half of the body all tactile, thermal, muscular, articular, and visceral sensations. In it are represented also all sensations coming from the mouth, tongue, soft palate, pharynx, larynx, rectal and genito-urinary surfaces. In this area we find giant pyramidal cells which are the origins of the motor tract. The auditory projective area, besides receiving fibers from the organ of Corti, also sends centripetal fibers to muscles controlling movements of the ear. The association centers are the higher intellectual centers. In them are stored up the various tactile, auditory, visual, olfactory, and motor memories. In them are combined, serialized and fused, all of these various memories. They are the organs of what is termed memory, will, judgment, reason, experience, moral and esthetic sentiment. The projection area thus, in one respect, merely centers for reflexes of cortical origin.

The association centers exercise an inhibitory influence over the projection centers. When in man, through pathologic conditions, the association centers lose their control, the projection centers manifest only blind impulses and animal passions. The association centers are absent in the Rodentia, feebly developed in the Carnivora, co-equal with the projective centers in the higher apes, and occupy in man two-thirds of the entire extent of the cortex. The anterior projection area comprises the greater part of the first and second frontal convolutions and the straight convolution on the inferior surface. The middle center comprises the island of Reil. The greater posterior association center comprises the parietal convolutions, the fusiform and lingual gyri, the inferior temporal gyms and the anterior part of the external occipital lobe.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No. 61 Market Street, Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting, of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Those new members of the Association should send their annual subscription direct to the Treasurer, Dr. Henry P. Newman.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street, Chicago.

Original communications are accepted with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, JULY 8, 1899.

CHANGES IN CELLS LINING PERITONEUM, IN
INFLAMMATION.

The nature and origin of the cells lining the pleuro-peritoneal cavity have attracted much attention; the opinions on these points are as yet far from uniform. In order to solve this question it seemed only natural that the investigators should turn to embryology, in order to determine from which layer of the embryo the pleuro-peritoneal cells are developed, but great difficulties were soon met with.

In the first place, it is very hard to determine the exact moment when the law of specificity of cells goes into force; hence the different opinions among embryologists. The majority of them were of the opinion that the pleuro-peritoneal cavity constitutes a large lymph space, and that the lining cells were equivalent to the endothelial cells of vessels. Waldeyer, on the other hand, assumes that histogenetic differentiation is completed with the formation of the archiblast and the parablast. All muscles, nerves, and epithelia are derived from the archiblast; all the connective tissues and the blood from the parablast, and at the present time this view, or some modification thereof, is generally accepted. The cells covering these serous membranes have, therefore, come to be regarded quite generally as true epithelial cells.

The numerous experiments which have been made in order to determine the role played by these cells in inflammation of the peritoneum, and in the formation of peritoneal adhesions, have not led to uniform results. It is true that many points in connection with the formation of peritoneal adhesions have been cleared up, but comparatively little has been learned from these experi-

ments concerning the relations and the nature of the lining cells themselves. Generally, the question as to the role which these cells play in the formation of adhesions was lost sight of.

Kolosow investigated this question, and found that the presence of prickles upon the pleuroperitoneal epithelium or endothelium would speak against their being connective tissue cells, and he regarded them as genuine epithelium.

Ranvier, on the other hand, found that when microbes are injected into the peritoneal cavity, these cells appear to swell up, send out branches, and to act in general as young connective tissue cells. Cornil came to the same conclusions. Marchand injected a suspension of lycopodium spores into the peritoneal cavity of guinea-pigs, and examined the surface of the omentum at longer or shorter intervals. He believes that the epithelial cells under those conditions present ameboid movements and surround, together with leucocytes, foreign bodies, forming giant cells, and eventually a fine fibrillated tissue.

V. Bungner differentiates structurally between granulation cells of connective tissue and of endothelial origin, but what role the endothelial cells play in the healing of wounds, and in inflammatory processes in the peritoneal cavity, he was not able to definitely specify.

The latest research in regard to this question comes from Ziegler's laboratory in Freiburg. Buttner¹ found that in inflammations produced by the staphylococcus aureus the omentum becomes covered by a layer of fibrin, in which are a variable number of leucocytes, which also infiltrate the substance of the membrane. In the early stages of the inflammation, the covering epithelium appears very distinctly, and can be readily recognized and differentiated from other cells. He was able to find the prickles which Kolosow described. A little later in the process the epithelial cells are to a large extent desquamated, but in the cells which remain attached karyokinetic figures appear in large numbers. The desquamated epithelial cells lie in the fibrin.

The principal outcome of this series of experiments is that in no case could Buttner trace the transformation of the epithelial cells into connective tissue cells. The same results were obtained in another series of experiments, in which the omentum was carefully sutured to the abdominal wall.

The covering of the layers of the tunica vaginalis is genetically identical with the pleuroperitoneal epithelium, Buttner also experimented on this membrane, which seemed rather favorable for this kind of work, by passing a silk suture through the testicle and the skin, and then tying so that the inner layer of the tunica vaginalis was pressed against the outer quite firmly. The specimens were then removed after varying intervals, and examined after suitable preparation. The histologic examination showed that usually the epithelium undergoes disintegration, and that the epithelial cells never change into fibroblasts.

¹ Ziegler's Beiträge, 1896.

Without going into any extensive histologic details it may suffice to say that the principal result of Buttner's investigation is that the epithelium plays a negative role in the adhesion of serous membranes. The adhesions are first formed by means of a fibrinous conglutination. A direct union between the two surfaces by means of epithelial cells was not observed. There are facts which speak in favor of the true epithelial nature of these cells.

DETERMINATION OF SOUND DIRECTION.

Among the many functions that have been attributed to the semicircular canals, that of the determination whence sounds proceed, has received the support of some physiologists. Though the majority have strenuously denied this as one of their functions, some late experiments would seem to point to these canals as not wholly unconcerned in the perception of acoustic space. Their peculiar arrangement, occupying as they do three dimensions of space, is most seductive in the formation of theories bearing on our conception of space relationships. The objection was long ago pointed out that in the quadrupeds, which led a more or less topsy-turvy sort of a life, the respective relationship of these canals to the three dimensions of space must be constantly changing, and hence, in these creatures at least, they can have but little effect in the determination of space direction. Many fishes have only one or two semicircular canals. The lowest vertebrates have an ear not markedly different from the invertebrate type, as may be observed in the lamprey, which has a sacculus with auditory hairs and otoliths in communication with two semicircular canals. The bag—myxine—has only one canal. The comparative studies of Dercum¹ led him to give up all notion that these organs had anything to do with the maintenance of equilibrium or the determination of space direction. In spite of these various objections, the three prominent theories offered as explanation of the physiology of the perception of space direction point more or less to these canals.

The first theory is the crude one already mentioned and depending on the arrangement of the canals among themselves. As sounds all reach these canals through one and the same opening, it is difficult to imagine how their respective correspondence with the three dimensions of space can have any effect in the determination whence sounds proceed. This, in addition to the objections already enumerated, renders this crude though popular theory quite untenable.

Another theory in regard to the perception of space direction of sounds assumes an acoustic space analogous to the tactual and visual space, and rests on the belief that special tactual sensibilities reside in the tympanic membrane. This theory is incomplete, however, in regard to an explanation as to how a mere surface such as the tympanic membrane can determine such complex relationships as are involved in the fundamental three

dimensions of space. The association of the function of the tympanic surface with that of the canals would be rather more suggestive.

The third or motor theory assumes that certain motor impulses are awakened in particular definite relationships by the activity of the organ of hearing. The conception of the motor space is a derivative of past experience in connection with and under the influence of visual space and tactile experience. The existence of space-forms acquired through other sensations is presupposed in the conception of acoustic space. In connection with this theory it may be well to remember that, as Laborde² pointed out, the auditory nerve contains both motor and sensory fibers, the former being distributed to the semicircular canals.

In some recent experiments made by Matamoto Matsumoto³, in Professor Scripture's laboratory at Yale, many interesting phenomena were elicited. The subject was seated, blindfolded, with head in a head-rest, surrounded by a kind of spherical cage so built that its axes furnished twenty-six terminal points. A short, sharp sound was made with a sort of telephonic apparatus at each of these terminal points, and fifty experiments were performed for each point. First of all it was most emphatically demonstrated that the perception of the direction whence sound comes is not a mere matter of chance. If it had been a matter of chance, probably not 40 times in 1,000 would the judgments have been correct; as a fact, however, the judgments were correct 768 times in 1000. Of the twenty-six directions, not one was actually confused with more than eight directions. Out of some 656 possible errors, only 113 were actually noted. Sounds on the right side were never mistakenly assigned to the left side; nor were those on either side ever assigned to the median space. These observations emphasize the necessity of two ears for the correct appreciation of sound paths. The sounds of the right hemisphere were more accurately perceived than those of the left; those of the front more than those of the rear; and those from below more than those from above. These variations are probably due to the shape and direction of the pinna and to the difference in the sensitiveness of the two ears.

The four characteristics of sound waves are intensity, pitch, phase and timbre. Experimenting especially on the intensity of sound waves, Matsumoto, who inclines to the motor theory in explanation of the appreciation of sound paths, without, however, referring to the semicircular canals, concludes generally that the relative difference between the intensities of the component sounds heard by the two ears is the immediate cause of the perception of the direction of the sound. The distance of the sound depends, on the contrary, on the absolute intensity of the sound.

²Researches on Acoustic Space, Studies from Yale Lab., vol. I, 1867.

A MUTUAL help society, consisting exclusively of physicians and surgeons, is being organized in Belgium to insure its members against professional accidents.

SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS.

We no longer approach a case of tuberculosis with the fear and trepidation that have been the rule in the past, knowing that in many cases improvement or even recovery takes place as a result of intelligent management. No case should be looked on as hopeless, although treatment must sometimes be merely palliative. Surgery has thus had restricted application in the treatment of pulmonary tuberculosis and radical results are not to be expected. Of the utility of properly employed measures of this kind an instance is furnished by Turban¹, who reports a case in which extensive rib resection was followed by collapse of a tuberculous cavity in the lung, with inhibition in the activity of the morbid process. The patient was a man 21 years old, with hereditary predisposition, who had presented symptoms of pulmonary disease for two years, with fever and hemoptysis. The left lung was almost entirely destroyed, and the left side of the chest was flattened and almost immobile in respiration. The percussion-note on the left was tympanitic, the respiratory sound bronchial and in places amphoric, with tinkling and metallic rales. On the right side, at the apex, inspiration was enfeebled, and expiration prolonged. Cough was marked, with abundant purulent expectoration and tubercle bacilli in the sputum. The pulse was accelerated, the temperature elevated, cyanosis marked. In the course of two months signs of contraction of the left lung appeared, the heart being displaced toward the anterior axillary line, and pulsation becoming visible between the second and fifth intercostal spaces to the left of the sternum. Fever persisting, and signs of increased tissue destruction appearing, it was decided to remove a wedge-shaped portion of the chest wall, to permit further contraction of the lung. Accordingly, a cutaneous incision 14 cm. long was made, beginning in the third intercostal space, and passing downward and outward, and 3 cm. of the fourth, 4.5 cm. of the fifth, 7.5 cm. of the sixth, and 9 cm. of the seventh rib was removed, without opening the pleural cavity. The wound was closed by suture, and healed without complication. At first, cough and expectoration were increased and the febrile symptoms augmented, but subsequently all receded, and the chest underwent further contraction. Unpleasant symptoms recurring after a time, however, a second operation was undertaken, and 9.5 cm. of the sixth rib, 10.5 cm. of the seventh, 10.5 cm. of the eighth, and 11 cm. of the ninth rib was resected. As there had been some regeneration of the ribs resected in the primary operation, great care was now exercised in the removal of the periosteum, and this was followed by application of the thermocautery. The lung underwent further contraction, and the tympanitic note was replaced by dulness on percussion. The symptoms improved once more, although tubercle bacilli persisted in the sputum. It is pointed out that while recovery was in no sense brought about in this case by operation, a rapidly progressive process was con-

verted into a stationary one; and it is believed that the operation is justified in a relatively small number of cases, in resistant patients with extensive disease of one lung and a good condition of the other lung, in the presence of a tendency to contraction of the lung with rigidity of the thorax.

CHICAGO DIPLOMA-MILLS.

The business done by the Chicago diploma-mills is well illustrated by the fact that the county clerk's official records of physicians in one Michigan town are found to include the names of twenty-three who claim as their alma mater the notorious "Independent Medical College" of Chicago. This may be an extreme case, the diploma-mill graduate may have gravitated for some reason or other especially to that locality, but it is certainly suggestive of possibilities elsewhere. As it does not seem to be the popular thing for the diplomates of the said institution to publish the fact in Polk's Directory, it is impossible to ascertain how many such exist in any particular town or city, but the well-known business methods of such institutions make it probable that they are numerous, especially where the local laws as regard medical practice are or have been lax.

WILL THE PLAGUE REACH AMERICA?

Since the outbreak of the plague in China the disease not only has slowly gained headway in that country, but has also extended its ravages toward the south and is now prevailing to an alarming extent throughout India. At first it was thought that on the advent of hot weather the disease in India would be held in abeyance, but such does not seem to be the case. The report from the larger provinces, received last week, announces that many new cases as well as a large number of deaths have occurred. From India the plague extended westward into Egypt, in which country several cases occurred. Should it gain admission into the region surrounding the zone inhabited by those who make their annual pilgrimage to Mecca, it would not be far from Europe or from direct communication with England. It might at this time be appropriate to study how it might invade the United States by taking an eastern course. For instance at Hongkong where the disease has been prevalent for some time, it is not far to the Philippine Archipelago, between both of which intimate relationship constantly exists. In both of these countries it is safe to say that at the present time but a crude state of sanitary rules is actually demanded. Entrance into the Philippines would seriously embarrass the war now⁶ being waged in that country. From the latter country the plague might become transported to our western coast by transports, or vessels of the merchant marine.

SCHOOL NURSES' SOCIETY.

The London School Nurses' Society, which held its first annual meeting June 19, has for its object the supplying of trained nurses to the large schools in the poor districts. The nurses visit the schools and attend to the small ills with which the children may be afflicted, such

¹ Berliner Klin. Wochn., May 22, 1896.

as sore eyes, wounds, etc., special mention being made of "sore heels," evidently a common affliction. Each nurse is expected to visit four schools each day, and on an average see about 100 children. The duty of these nurses is also to send the children to a physician, hospital or home, as her judgment dictates, when necessary. The work carried on by this society is certainly a good one. If the nurses do not get a too high idea of their ability, and attempt to treat cases which belong to a physician, they ought to receive all the encouragement that it is possible to give. Such a work in the schools of some of our own large cities would undoubtedly save much prolonged suffering among children, who, through neglect, have to put up with sore eyes, septic wounds, etc., which ultimately might become serious.

"BATTLE OF THE CLUBS."

The medical profession of Great Britain is still contending with an evil that is more or less in existence with us under various disguises, namely, "club practice." The *Lancet*, *British Medical Journal*, and other medical journals have been active in this "Battle of the Clubs," and the degrading influence of such practice has been thoroughly shown up by the exposition made by these papers. The result has been that reputable medical men have refused to serve these clubs and insurance companies which have medical attendance attached and pay their doctor a beggarly pittance while they keep the profits. The profession has become so united in its action, the individual members refusing to serve without adequate remuneration, that the companies and clubs have proposed a truce. Committees appointed by these clubs have met a committee appointed by the General Medical Council, and propose a "Board of Conciliation," to arrange matters in a manner which shall be satisfactory to the medical men. After some opposition in the Council itself, that body, at its recent meeting, accepted the proposition with certain reservations. Whatever the result may be it is certain that if the medical men will stay united they can dictate their own terms. And this they will probably do, for our professional brethren there work more in unison than we do here. While occasionally a man may be found who is so lost to professional honor as to accept a position resigned by another for principle, such are very few in number and, as a rule, lack not only professional honor but medical ability as well. It is certainly to be hoped that this evil, which is insidiously creeping in in various parts of our country, may be met by a similar united action here. These schemers who, under various guises, try to get rich by trading in the services of our profession ought to be made to understand that physicians are not yet ready to be thus exploited for others' benefit.

AN AGGRESSIVE DELUSION.

The JOURNAL has so often called attention to the homidical pretenders who call themselves "Christian Scientists" and faith healers, that the subject is anything but an agreeable one, but it is one that constantly obtrudes itself in more aggravated form. One of the latest cases is that in which a child was suffered to die for lack of

proper treatment while the healers were telegraphing to the notorious Dowie for the benefit of his "absent prayers." The especially aggravating feature of the case, however, was the aggressive policy and behavior of the faith healer. After the father had called a physician, under whose treatment the child had begun to mend, the "divine healers" actively interfered and destroyed the medicines left. Another physician was called by a relative and they constantly and actively interfered with the attendant left in charge by the doctor. Finally they succeeded in preventing any proper medical care and the child died. It seems that the parents, the father especially, were inclined to have medical help, but, as one of the relatives expressed it, "they were dogged by the 'healers' until they were almost exhausted and seemed to have no will of their own." The local paper¹ took the matter up and obtained the signed statements of the physicians and relatives, but was unable to obtain those of the healer at that time. The facts thus brought out ought to arouse the proper legal authorities to action, for here we have evidence enough of wilful and, we might say, malignant, active prevention of the proper measures and a death produced in a rarely fatal disorder, whooping-cough that was twice apparently put fairly on the way to recovery by medical treatment. One rather curious fact of the case remains to be mentioned. The relative who consulted the authorities was informed that nothing could be done without the consent of the child's father, yet he was placed in a room and access refused to him by those in charge. In this case the offenders, it seems, were not the self-styled "Christian Scientists," but the followers of the kindred though rival delusion known as Dowieism. It matters not, however, which it is, as each is alike damnable in every sanitary point of view. It has been suggested, we believe, that the Chicago Zion of this sect should undergo a thorough health inspection, for who can tell what peril to individual health may be there hidden.

INTRATRACHEAL INJECTIONS.

The treatment of the cough and fever of pulmonary tuberculosis with intratracheal injections of dilute solutions of menthol, guaiacol or eucalyptol, which was first employed by Green of New York some years ago, but never generally taken up by the profession, is again attracting the attention of careful clinicians. Thompson of Cincinnati two years ago published in this journal a paper on this subject, and has since reported excellent results from its employment. In cases in which the cough is so excessive as to cause vomiting, and nutrition is in consequence rapidly failing, the placing in the trachea, an hour before eating, of 1 to 3 drams of a 2 per cent. solution of menthol, will permit of both the ingestion and assimilation of the essential nutriment. By this method the detrimental effects of the use of opium and its derivatives to control the cough are entirely avoided. These injections should not be used when there is present acute inflammation of the lungs or bronchi. In bronchiectasis, gangrene and syphilis of the lung, as well as in the case of tubercular cavities, this method excels in efficiency any other for the purpose of reducing fever, limiting the local process, and subduing the odor that

¹ Falls City (Neb.) News.

marks the breath in these cases. When there is suppuration occurring in the lungs or bronchi, guaiacol is the preferable remedy for administration in this manner, and a 1 per cent. solution is usually sufficiently strong to be effective. Under this treatment cavities in the lung have appeared to heal, and certainly the bacilli producing suppuration have been seen to disappear from the sputum. The technic is very simple to anyone at all accustomed to using the laryngoscope. Placing the mirror in the usual position and asking the patient to inspire deeply, the fluid is permitted to flow easily from the syringe into the upper portion of the larynx. If this is done gently there is very seldom any choking or other unpleasant symptom. The method, even though it be essentially symptomatic, is well worthy much wider recognition at the hands of the profession than it at present receives.

LOCATION OF THE PRIMARY LESION OF PULMONARY TUBERCULOSIS.

Birch-Hirschfeld¹ made a careful examination of thirty-four cases of latent beginning pulmonary tuberculosis with the special purpose in view of determining the exact place in the lung where the tuberculosis first begins. The bodies examined were those of apparently previously healthy individuals, who had died suddenly. He reaches the conclusion that the general belief that pulmonary tuberculosis in the adult begins as a caseous lobular pneumonia does not correspond with the facts. Interstitial tubercle formation is also exceptional as the primary form of lesion. In the majority of cases the first focus consists in a subepithelial tuberculosis infiltration in the mucous membrane of a bronchus of medium caliber of from the second to the fifth order, according to the usual designation. The peribronchial tissue is secondarily involved. On account of this infiltration the lumen of the bronchus becomes narrowed or closed completely, and the corresponding part of the lung collapses. After the obliteration of the bronchus it is possible that the tuberculous focus may heal, with encapsulation and formation of cicatricial tissue in the collapsed part of the lung. On the other hand, should disintegration of the tuberculous area in the bronchial wall occur, especially likely to take place in consequence of a mixed infection, which undoubtedly plays the principal role in disintegration, then the lumen of the bronchus may again become free and allow the transportation of tuberculous material in both directions. Rupture of vessels in the wall of the tuberculous bronchus, or bronchiectasis, would also be likely to exercise an unfavorable effect upon the progress of the disease. Based on anatomic investigations of the bronchial tree of the human lung, Birch-Hirschfeld establishes that the well-known localization of tuberculosis in the apices of the lungs takes place in a definite pulmonary area. This area corresponds to the posterior part of the lung apex and the adjacent subapical district. This tissue is supplied by a bronchial branch which is designated the ramus apicalis posterior. This is the part of the lung which during the time of puberty suffers especially on account of lack of room for growth; the bronchi and corresponding portions of the lung on that account develop poorly. This portion of the chest

takes but a very small part in the respiratory excursions. The crippling of this part of the bronchial tree is especially liable to give rise to dead spaces in the bronchi in the posterior part of the apex, in which the conditions are then very favorable for the deposition of infectious material. This local disposition should not be regarded so much as a physiologic product, but rather as the pathologic result of an unhygienic mode of life. In view of these investigations Birch-Hirschfeld would emphasize the fact that asepsis of the inspired air and gymnastics of the lungs are both factors which deserve more attention than they have heretofore received, in the prophylaxis and treatment of pulmonary tuberculosis.

PYEMIA FOLLOWING THROMBOPHLEBITIS OF SUPERIOR VENA CAVA.

In the case of a man 63 years old, the clinical diagnosis being pulmonary emphysema, bronchitis, albuminuria, and lobular pneumonia, Carl Springer¹ made the following interesting observations: Immediately below the bifurcation of the trachea, the anterior wall of the esophagus presented a diverticulum, at the summit of which was a small opening which led into a cavity situated below and to the right of the bifurcation of the trachea, and having a diameter of 2.5 cm., the contents being purulent material.

The superior vena cava presented a friable, grayish-red discolored thrombotic mass, on the intima of that part situated over the cavity mentioned. There were numerous metastatic abscesses in the lungs, the lungs containing staphylococci which stained with Gram's method, and short bacilli destained by Gram's method. Sections passing through the wall of the vena cava at the site of the thrombus showed an intense inflammation and numerous heaps of cocci. Outside of the vein were found tubercles with giant cells and caseous areas. Perforation of the wall of the vena cava had not taken place. It would seem that tuberculosis of the peribronchial lymph glands, followed by caseation and cicatrization, led to the formation of a traction diverticulum of the esophagus. The perforation of this diverticulum, due to some accident, as for instance swallowing a piece of bone, or perhaps due simply to the progressive tuberculous disintegration of tissue, opened the way for a secondary infection from the contents of the esophagus. The suppuration thus produced led to the formation of the abscess cavity described, from which the inflammation invaded the wall of the vena cava, and produced the parietal septic thrombus, from which again infected emboli were carried into the lungs and produced metastatic abscesses. The fatal consequences of perforation of esophageal diverticula usually depend on the fact that the perforation takes place into a bronchus, followed by aspiration pneumonia and gangrene of the lung; in other cases erosion of a blood-vessel may take place, but an involvement of the vena cava of the nature here described does not seem to have been observed before.

SOME FALLACIES OF VITAL STATISTICS.

In the April number of the *English Journal of the Sanitary Institute*, Dr. Edward J. Willoughby calls attention to the possible sources of fallacy in vital statis-

¹ Deutsche Arch. f. Klin. Med., 1899.

¹ Prager Med. Woch., 1890, No. 7.

tics in a rather striking way. He first refers to what should be the qualifications of the vital statistician; he should not be an actuary nor a mere mathematician, but of a naturally logical mind, trained in matters of scientific inference, inductive and deductive, and should have with this a thorough knowledge of his subject and the sources of fallacy to which it is incident. Crude recorded facts are almost always misleading, and conclusions drawn from them alone seldom correct. Thus, the apparently most rapidly increasing population may be tending to exhaustion, the healthiest show the highest death-rate, short-lived communities may have the most old people, the age at death be least in the healthiest occupations, and deaths at advanced age be no evidence of conditions favoring longevity. All conditions, and there are a host of them, should be taken into account. Thus infant mortality may be low, but if the birth-rate is also low it may indicate a serious state of affairs, and vice versa. The mortality of infants under 1 year old should be calculated on the birth-rate, and for every subsequent year, on the number actually living at that age. A shifting and a stationary population present quite different conditions when one comes to estimate from statistics such matters as the average duration of life, the mortality at different ages, etc. So also with occupation, it would be easy to show that in some of the healthiest the death-age was low, simply because they are only followed by the young, but it so happens that sanitary statisticians have occasionally overlooked even this simple fact. Also in estimating the relation of marriage to births a fallacy is likely to creep in unless the calculation is made, not on the number of marriages, but on that of women who marry. These are only individual instances of a large number of possibilities of error when all the existing conditions are not taken into account. Dr. Willoughby's paper is noteworthy, not as contributing previously unknown facts, but as calling attention in a vivid way to facts too often overlooked.

ELEPHANTIASIS A SEQUEL OF REMOVAL OF THE INGUINAL GLANDS.

A rare but very important sequel of removal of the inguinal glands has been brought to the attention of surgeons by Hamann in a paper before the Ohio State Medical Society. He reports in detail one case, occurring in a woman operated on for the radical cure of femoral hernia, in which incidentally some of the saphenous and inguinal lymph-glands were removed, and also notes having seen three cases following removal of the inguinal glands for adenitis. While this complication is rare, it is of such grave importance to the surgeon that it should always be considered when operating in this region, and it may well be that, once attention is drawn to this curious complication, it may prove not to be so rare. Clinically the cases in a few days or a few weeks after operation suffered with acute and recurrent attacks of lymphangitis with lymphatic edema, due to interference with lymph-flow produced by removal of the glands and by the cicatricial contraction. These attacks were characterized by fever and sensations of chilliness. The genitalia were the seat of a firm edema with a sensation of fullness, and at times slight redness, itching and pain. The attacks resemble erysipelas, but no connection with

it has been determined. Each succeeding attack leaves the parts more hypertrophied, the connective tissue increases in amount, and gradually a condition of elephantiasis is established. Riedel¹ reported two cases of this character following extirpation of the inguinal glands, which led him to abandon the operation entirely, substituting for it incisions and curetting. Bayer² has thrown very clear light on the pathology of the disease. He shows that the loose periglandular fat and areolar tissue contains an extensive system of lymph-spaces. From this tissue in from three to six weeks after destruction or removal of the contained gland, regeneration of the gland and the vessels quite frequently occurs. It follows, that, if during the operation, or in subsequent suppuration this periglandular fatty tissue has been destroyed, regeneration of the gland cannot occur and a condition favorable to the development of elephantiasis exists. Hence he advises that part of the fatty tissue be always allowed to remain, and that every effort be made to avoid suppuration. These conclusions are of all the more importance because when once the elephantiasis is established nothing can be done for its relief, except wide excision, which is unsatisfactory. As a very unpleasant pitfall in the way of surgeons operating in this region this complication deserves very careful consideration.

ARTHO-NEURALGIA.

This name has been given to a nervous, painful affection of one or more joints that occurs especially in women, and may simulate an organic or an inflammatory disorder. It is scarcely a distinct disease, but rather a manifestation of hysteria. A typical instance is related by Nartowski³. The patient was a woman 32 years old, who presented herself on account of pain in the knees and weakness in the feet. The family history was neurotic, and the father had been alcoholic, dying of some obscure nervous disorder. The mother, who had been a niece of the father, had suffered much from headache, and had presented hysteric symptoms. As a child, the patient had been irritable and excitable, with a good comprehension and a good memory. Menstruation had set in at the age of 16, and was regular, without noteworthy discomfort. The patient was married at 23, and bore three children, after the birth of the last artificial means being taken to prevent conception. The patient felt dissatisfied, cried a good deal, suffered from headache, and passed through periods of excitement. There was often present the feeling of a ball rising from the hypogastrium to the throat. The appetite was lost; vomiting took place soon or several hours after eating and constipation was present, with palpitation of the heart. Two years before coming under observation she was startled by the barking of a dog, when she was seized with palpitation of the heart and severe pain in both knee-joints, preventing further locomotion. The pain alternated with feelings of coldness, of heat, and of numbness. These phenomena had persisted, and were aggravated at the menstrual period. The knee-joints appeared slightly swollen, were fixed in extension, and sensitive to

¹ Arch. f. Klin. Chir., Bd. xlvii, p. 216.

² Prager Ztschr. f. Heilkunde, Bd. vi, p. 105; Arch. f. Klin. Chir., Bd. xlix, p. 637.

³ Wiener Med. Woch., May 1899, p. 1093.

slight pressure with the finger, and even to the touch of a brush. The raising of a fold of skin caused great pain, but deep pressure or approximation of the bony constituents of the joint induced none. The knee-joints and the regions thereabout were red, especially at the menstrual period, but they soon became normal. The electric reaction of the muscles was normal. Passive and active movement of the joints was attended with pain and grating. The patient was encouraged to hope for recovery, and passive movement of the joints was practiced. On the sixth day the static spark was applied to both knee-joints. Improvement rapidly ensued, and the patient was soon entirely cured.

Medical News.

DR. TRACY C. WITHERSPOON, St. Louis, has been elected to the chair of surgery in the Marion Sims College of Medicine.

A PRIZE of \$100 is to be offered at the next annual meeting of the New Jersey State Medical Society for the best essay on "Hydrophobia."

THE FIRST case of yellow fever which has appeared in quarantine, New York City, for some time was brought in by a Norwegian steamship from Cuba on June 29.

DRS. CHARLES H. HUGHES, Henry H. Mudd, A. C. Bernays, W. H. Fischel, Charles Borck, F. L. Henderson and I. N. Love, all of St. Louis, Mo., will spend August in Europe.

THE NEW buildings of the London Hospital Medical College are about completed, and will be opened by Lord Knutsford July 18. The new laboratories, wards and museums of Guy's Hospital were opened July 7.

DR. C. M. NICHOLSON, St. Louis, a few days ago married the daughter of the Hon. Norman J. Coleman, who was a member of President Cleveland's cabinet, being the first secretary of agriculture.

A FRENCH committee is raising funds to erect a monument to the memory of Pelletier and Caventou, the discoverers of quinin, for which contributions are being received from all quarters of the globe.

PROFESSOR STOKVIS of Amsterdam recently celebrated his twenty-fifth professorial anniversary. As *Janus* remarks, "without him a number of useful institutions would never have existed, *Janus* included."

DR. G. P. ROBINSON of St. Louis, for many years professor of theory and practice in the Missouri Medical College, and also dean of the college, has retired from both positions. He has been placed on the emeritus list.

DR. D. R. BROWER of Chicago has been honored by the degree of LL. D., conferred by the Georgetown University, Washington, D. C., at its recent commencement. Dr. Brower expects to leave shortly for a six weeks' trip to the Hawaiian Islands. He will be accompanied from San Francisco by Professor Senn.

THE POPE has recently presented an oil portrait of himself to Dr. Mazzoni, to whose skill the Holy Father attributes his present good health. The Pope also made Dr. Mazzoni "Surgeon in Chief to the Apostolic Person," a position of honor and trust, but with very little pay.

BENDER BOUCHER, the most important post on the eastern coast of the Persian Gulf is now invaded by the plague. As all the Anglo-Indian trade for the interior

of Persia passes through this port, the danger of further contagion is imminent.

It is gratifying to state that the charge preferred against Dr. Trumbull W. Cleveland, New York City, in the case of Violet Irene Carhart, in which death followed the administration of resorcin and salol, was dismissed from court on June 23.

DR. ALVA H. DOTY, health officer of the port of New York, claims that in two years' work in connection with Chas. E. Fitzpatrick in his laboratory on Swinburne Island, he has succeeded in confirming the alleged discovery of Sanarelli's bacillus of yellow fever.

A CABLEGRAM to the *Philadelphia Ledger* announces that Count Malherbe, the Russian Consul at Buenos Ayres, controls the manufacture of the Sanarelli serum for yellow fever. It is said that 300 bottles have been prepared quite recently, and will be sent to New York City.

THE NEXT congress of the French Association for the Advancement of Science will be held at Boulogne September 14-21. A subsection on medical electricity has recently been established by the Association, and several important papers are promised in this branch of medicine.

AMONG THE Docenten recently raised to professorships are K. Benda, P. Heymann, and G. Salomon, Berlin; B. Von Kader called from Breslau to Charkow in place of the deceased Prof. E. Grube, while Geheimrath A. Fick, for many years professor of physiology at Würzburg, has resigned.

PROFESSOR RAYMOND, who commenced his life work as a veterinary surgeon, and who succeeded Charcot as professor of nervous diseases at the Hospital de la Salpêtrière, Paris, has just been elected a member of the Academy of Medicine. The vacancy was occasioned by the death of Professor Laboulbène.

THE REVUE MEDICALE DE LA SUISSE ROMANDE has recently published a comprehensive study of "Excision of the Seminal Vesicle and Vas Deferens in Case of Castration for Primary Tuberculosis," the conclusions of research with Roux of Lausanne, signed with the author's name in full, Princess Guedroytz de Beloseroff.

A STATUE of Duchenne de Boulogne is to be unveiled with much ceremony at Boulogne, during the meeting of the French Association for the Advancement of Science, September 14 to 21. The addresses in the new section of medical electricity include endodiascopy by Bouchacourt and electrolysis of strictures by Bordier.

A HYDROPHOBIA panic is reported in Jennings, Pawnee county, Oklahoma, date of June 26. A large mortality among hogs and cattle has occurred and horses and mules are not exempt. While no deaths of human beings are yet reported, several people have been bitten. A vigilance committee is disposing of the dogs and other animals affected.

DR. C. A. L. REED of Cincinnati leaves for Europe in about two weeks, and expects to be gone about ten weeks. During his absence he will visit the British Medical Association, International Gynecological Congress at Amsterdam in August, and the Brussels Congress for the Repression of Syphilis and Venereal Diseases in September.

SINCE the return of Surgeon J. C. Boyd, from the International Tuberculosis Congress the Government has been considering the proposition of erecting in the Southwest a sanitarium for consumptives in the service of the merchant marine. It seems that the greatest

difficulty so far manifested is to select a region which may be easily reached by all lines of travel.

THE SAME plan has been adopted by the University of Pennsylvania in the appointment of the successor of Dr. Charles B. Penrose, professor of gynecology, as was done in the appointment of the successor to Dr. John B. Deaver, in that announcement is publicly made that all candidates should make a formal application to the dean of the medical department prior to September 18, 1899.

SEVERAL weeks ago a peculiar bug made its presence known in Washington, D. C., where it caused considerable anxiety from the fact that its bite gave rise to serious symptoms manifested by intense pain and rapid swelling, mostly confined to the lips. Under appropriate treatment the inflammation subsided in about forty-eight hours. Cases have since occurred in Philadelphia and New York City.

IN PORTUGAL the government informs the chief physicians in a town that a certain sum is required of the local profession for the internal revenue. The local physicians assemble and partition the assessment among themselves, according to the supposed income of each. There is a similar arrangement for each profession and a court of appeals for those dissatisfied with their assessment.—*Echo Medical*, June 11.

PROFESSOR E. A. SCHAEFER has been elected professor of physiology in the University of Edinburgh. Professor Schaefer has been actively engaged in teaching for many years as Jodrell professor of physiology in University College, London. He has made many valuable contributions on various physiologic subjects, is the author of a text-book on histology, and is the chief editor of the new edition of Quain's Anatomy.

THE CABLE announces, from Santiago de Cuba, that Surgeon Clendennin died there July 4, of yellow fever. Captain Clendennin was a native of Illinois and entered the army as an assistant surgeon in November, 1886. He reached the grade of captain in November, 1891. In June, 1898, he entered the volunteer establishment as a brigade surgeon with the rank of major, and was in charge of the army hospital at Santiago.

THE UNIVERSITY of Kiel has arranged for post-graduate medical courses this summer, and the peculiar attractions of this northern port and its neighborhood to popular resorts, will no doubt attract many students.

THE EXPENSES of the Russian Pharmaceutic Congress, to meet at Moscow in December, are to be defrayed by a rouble paid to the treasury by the pharmacists for each thousand prescriptions filled at their establishments during 1898.

A COMMITTEE made up of Drs. Philip Marvel of Woodbury, Wm. Pearson of Orange, B. A. Waddington of Salem, E. Hollingshead of Mt. Holly, and Alexander McAllister of Camden, has been appointed by the New Jersey State Medical Society to arrange for the entertainment of the AMERICAN MEDICAL ASSOCIATION at Atlantic City next year. It is thought the sum of \$2500 will be raised for the entertainment of the members of the ASSOCIATION.

FROM the outbreak of yellow fever at Santiago, Cuba, to June 25, there was reported a total of 33 cases and 5 deaths. One death occurred in the case of a member of the Fifth Infantry while the others were civilians. On June 28, 14 new cases were reported, bringing the total number of cases up to 50. So far 12 deaths have occurred. During the present year 13 cases have occurred in Havana, of which 5 proved fatal. At present there

are no cases of this disease in either Havana or Porto Rico.

THE BUREAU of Health of Philadelphia has come to the conclusion that the milk of this city is not as pure as was supposed a short time ago. It has been learned that formaldehyde has been added to keep it from turning sour. In order to do this a strength of 1-100 of 1 per cent. is all that is required. It is believed that the preservative is being sold in the form of a 40 per cent. solution. Wood alcohol has also been present in some samples.

MR. LAWSON TAIT's death was quite sudden, according to the *Lancet*. On June 13 he was seized with pain and serious symptoms connected with the kidneys, and died at 3 o'clock in the afternoon. The renal disease was of some duration, for two years ago a calculus became impacted in his urethra. This was removed by a surgical colleague, but his health had been indifferent since, and no doubt the disease which ultimately caused his death was progressing in the interval. According to his wishes his body was cremated.

SEVERAL physicians of Lille, France, have applied their scientific knowledge in perfecting industrial processes and have made large fortunes as more or less silent partners in manufacturing establishments. Professor Calmette recently presented the institute of which he is a director with a large sum given him by the proprietor of a certain industry as a share of the amount saved by certain improvements suggested by the scientist. The physicians in France take a prominent part in legislation, and the proprietor of a certain model candy factory is a practicing physician, formerly an army surgeon.

THE DREYFUS matter, according to the *British Medical Journal* has been the occasion of serious disturbances in the medical school of Lyons. Professor Agagneur had taken an active part in manifestations in favor of Captain Dreyfus and President Loubet, and the students attending his lectures had expressed their sympathy with him in this line of conduct. The next day the professor's lecture-room was invaded by a mob of persons, for the most part not belonging to the school, who made such an uproar that it was impossible for him to lecture. The Dean has posted up a notice, dated June 10, to the effect that the course of surgical pathology will be suspended till further orders.

CONSOLIDATION of the *Louisville Medical Monthly* and the *Louisville Journal of Surgery and Medicine* is announced, the two being issued after July 1, as the *Louisville Monthly Journal of Surgery and Medicine*. The *Louisville Medical Monthly* was purchased by Dr. Henry E. Tuley, early in June, he having edited one issue, that of July, and the *Louisville Journal of Surgery*, which continues the *Quarterly Journal of Rectal and Gastro-Intestinal Diseases*, was owned and edited by Drs. J. M. Mathews and H. Horace Grant. The following will be the editorial staff of the new monthly: Drs. J. M. Mathews, H. Horace Grant, A. M. Cartledge, and Henry E. Tuley. Dr. Grant will be business editor and Dr. Tuley managing editor.

A MEMBER of the Stille School of Osteopathy has opened an office for the summer in St. Joseph, Mo., and by his sign announces to practice medicine and surgery as well as osteopathy. The efforts of the AMERICAN MEDICAL ASSOCIATION, and the Association of American Medical Colleges to elevate the status of the medical profession are seriously handicapped in Missouri. Owing to the restricted power of the State Board of Health, and the indifference of the present governor and legislature the

state is overrun with osteopaths, magnetic healers, vitapaths, Christian Scientists, Divine Healers and frauds of every kind. A school of magnetic healing has recently been opened in the state, turning out healers in thirty days. The necessity of the doctor being a politician is evident in this state.

ACCORDING to the *Peoria Transcript*, Francisque Crotte, who gained such notoriety a little while ago when he alleged endorsement of the AMERICAN MEDICAL ASSOCIATION, left Peoria quite suddenly recently without leaving his address. According to the above paper, his associate and all the belongings of the pair have disappeared and the whole affair is enveloped in darkness and mystery. The paper goes on to say that Crotte's plan to start a sanitarium at Pekin, where he claims to have found mineral water with the necessary constituents for a successful treatment of consumption, has failed. The general denial of the endorsement of the ASSOCIATION of this man Crotte, made in the *JOURNAL* of June 17, and which was sent over the country by the associated press, evidently had its effect in thwarting the plans of this latest schemer.

A STATUE of Baron Larrey was recently unveiled at the military school of Val-de-Grace, near Paris, with appropriate ceremonies in honor of this surgeon and military hygienist who most worthily carried on the traditions of the great name of his father, the Baron Larrey of Napoleon's day. Of both it has been said that they were men and surgeons of "impeccable honor;" both were present in all the campaigns of their day; the father in sixty battles and four hundred engagements; the son, "Antwerp, 1832, Italy, 1859, and Army of the Rhine and Siege of Paris, 1870-71," although he never equaled his father's record of two hundred amputations in one day. In a notice of the father (*JOURNAL*, xxx, 1003) it is said that his name stands only below that of Ambrose Paré, and the name of the son has been connected with nearly every improvement in the French military health department during the century.

THE NEW City Hospital commission for St. Louis has introduced ordinances into the City Council for the immediate commencement of new buildings. By amendment to the charter, 1 per cent. of all city revenue is applicable to the above purpose; \$200,000 is now available, and within a few years buildings to the value of several millions will be erected. The old grounds, left after the destruction of the old city hospital by the cyclone a few years ago, will be utilized. The pavilion plan will be followed in the construction. Dr. Max C. Starkloff, St. Louis' excellent health officer, recently appointed to his second term, will aggressively push the work. It is gratifying to know that the clinical teaching staff of the medical colleges will, in the new hospital, have absolute control of all patients, internes, etc. The medical educational interests of St. Louis will surely be the gainers.

ON ACCOUNT of the recent death in Philadelphia of a patient under treatment by "Christian Scientists," much interest has been aroused in this subject by the daily papers. One paper especially is deserving of much credit in the manner in which it has investigated the claims of this sect. A correspondent of the *Philadelphia Press* is said to have recently gone to New York, passed the required examination and received the degree of "C. S.," which degree is said to confer upon the recipient the power to heal all manner of ailments, as well as to displace all medical attendants of whatever nature. So far Dr. Henry Beates, president of the State Board of

Medical Examiners, seems to be the one most interested in bringing the matter prominently before the district attorney. In order to determine the legal status of the case, Dr. Beates has addressed a personal communication to the district attorney, asking for a strict construction of the law governing the matter. Dr. Beates has also communicated with the attorneys-general of many states on this question, and from many has received replies indicating that urgent steps could be taken in case of death while under this method of treatment. Many defects in the laws are supposed to exist, and in order to bring them into harmony it has been suggested that the matter be referred to the Attorney-General of the United States. Regarding the case in Philadelphia, it is believed action will commence as soon as Attorney-General Elkin is heard from.

PRACTICAL TRAINING IN SANITARY SCIENCE AND PUBLIC HYGIENE.—Dr. Arthur R. Reynolds, health commissioner of Chicago, has hit upon a novel method of supplementing the inadequate force of his department. This is not meant invidiously, since, as will be seen by the following, the Doctor offers a full *quid pro quo*. He has, during the past two years or more, tentatively admitted recent graduates in medicine and senior undergraduates, intending to enter the field of preventive medicine, to the department laboratory for practical work and instruction in chemie and bacteriologic analyses and examinations of water, milk and foods, in general bacteriology and in the special bacterial diagnosis of disease. Observation of the results of this experiment has, he says in a circular letter, dated July 1, led him to believe that the opportunities and facilities thus afforded may be of great value to the future sanitary executive and health officer, and he is now desirous of systematizing the effort and making it use more widely available. He points out that "the growing popular interest in sanitary science and public hygiene is creating a demand for trained sanitarians and medical officers of health which opens up a wide field of usefulness and employment for those members of the profession who shall especially equip themselves for the work. For this equipment a practical training in the varied labors of a metropolitan health department, in which the more or less theoretic education of the college may be supplemented by the test of practical application, should be of much use." Some idea of the extent and variety of the laboratory work of the department may be formed from the following figures: During the last year 2623 bacterial examinations of suspected disease were made, chiefly of diphtheria, typhoid fever and tuberculosis; and 2635 bacterial examinations of water, ice, milk, vaccin lymph, butter and other foods. During the same period nearly 30,000 chemical analyses were made of milk and cream, water, ice, etc. During the first five months of this year, in addition to an increased proportion of examinations for diphtheria, typhoid and tuberculosis, 1030 examinations for the Canon-Pfeiffer bacillus were made and a flood of light thus thrown on the etiology of influenza. Since the identification of the scarlet fever organism by medical inspector Class, more than 500 examinations of scarlet fever have been made in the laboratory and the bacterial cause of this disease has been demonstrated biologically. The chemical work of the laboratory, the labors of the Bureau of Sanitary Inspection, of the Division of Contagious diseases, the Bureau of Vital Statistics, the antitoxin and disinfection services are equally comprehensive and furnish a practical sanitary training school.

Therapeutics.

FOR THE ESTABLISHMENT OF FREE SECRETION

of all the organs Vandoren recommends the following prescription:

- R. Tinctura aconiti gtt x. | 5
- Tinctura bryoniae aa..... ʒi | 3 90
- Tinctura digitalis ʒi | 3 90
- Potassii nitratii ʒss | 1 95
- Extracti ipecac fluidi gtt x. | 5
- Syrupi pruni Virginianæ q. s. ad. . . ʒiv | 120

Misc. Sig. For adults, teaspoonful diluted every hour until patient is better; then only as seems to be required, say every three hours while fever lasts.

Foster says, "Digitalis given in physiologic doses and along with strychnin, is administered until the pulse comes down to 90 a minute. If it can be kept there, recovery will ensue in a shorter time, as a rule, than by the use of other methods of treatment," in all of which we heartily concur. In addition to the action of digitalis upon the heart, the drug unquestionably exerts some specific action upon the disease. In order, however, to get the antitoxin effect of digitalis, the remedy should be given in the form of an infusion in doses of from 4 to 6 fluidrachms (16-24 gm.) every three or four hours, and commenced the first or second day of the disease.

HEART TONIC.

E. G. Tufts recommends as a heart tonic, especially in asthenic cases:

- R. Strychnina sulphatis gr i-iii | 02
- Pulveris camphoræ ʒi | 3 90
- Sacchari lactis gr xx. | 1 30

Misc. Fiat Capsul. No. xii. Sig. One every four or six hours. Leonard Weber, however, suggests a better method of combating heart failure; he says, "I have seen excellent results from hypodermics of one-half drachm (1.95 gm.) of a 20-per cent. solution of camphor in oil, administered every half hour as indicated, and of strychnin, gr. 1-20 (1.29 gm.) two or three times in twenty-four hours, to support the heart."

IN HEPATIZATION TO PROMOTE ABSORPTION.

- R. Ammonii carbonatis ʒii | 7 80
- Potassii iodidi ʒss | 5 85
- Syrupi aurantii corticis ʒii | 62 20
- Aque ʒii | 62 20

Sig. Teaspoonful every two hours.

L. B. Young.

TREATMENT OF TETANUS.

What appears to be one of the most distinct advances in modern therapeutics is Bacelli's method of treating tetanus, as summarized by H. C. Wood, Jr. in *Mercer's Archives* for May. This consists in thoroughly disinfecting the wound, if any exists, placing the patient on light diet in a perfectly quiet room, and administering subcutaneously a 2-per cent. solution of carbolic acid. To begin with, 3 grains of the drug may be given in twenty-four hours but this may be rapidly doubled, or even trebled, with safety, as there is a remarkable tolerance to carbolic acid manifested by men and animals suffering with tetanus. Ascoli (*Bull. d. Reale. Accad. di Roma*, Feb., 1899) has made a careful study of the results of this treatment and compared them with those obtained from the use of the antitoxic serums. Dr. Wood's table, the results of this comparison, is so graphic as to be worthy of reproduction, as follows:

Method.	Cases.	Deaths.	Treatment.	Mortality.
Bacelli	34	1	25	3.2
Tizzoni	42	7	23	17.8
Behring	28	10	33	35.7

It will be seen that the advantage which these statistics give to the Bacelli method over the serums of Tizzoni and Behring is enormous, so much so as to give rise to a considerable degree of incredulity, which, however, must give way before the repu-

tation of Ascoli. Most writers rate the mortality of tetanus at from 80 per cent. to 95 per cent. As a rational basis for this treatment it is noted that Kitasato found that a 1.5 per cent. solution of carbolic acid annulled the toxic power of the tetanus bacillus. Of course, his laboratory conditions cannot be secured in the body, but in the latter case, as Wood well points out, the blood-serum is already engaged in combating the toxins of the disease. It has long been known also that carbolic acid has specific relations with the nervous system. Certainly in view of the facts that carbolic acid has no such unpleasant sequelæ as have been noted after the use of the tetanus antitoxins, and that the remedy is always at hand, coupled with the favorable results noted, the physician caring for a case of this dreaded disease should consider this method very seriously. The ordinary symptomatic treatment should be continued along with the carbolic acid.

ICHTHYOL IN SCIATICA.

J. Crocq, in *Semaine Med.*, announces that ichthyl is the most effective substance known for sciatica, although by no means a specific. Fourteen were entirely cured and four very much improved, so that they could resume their occupations, out of twenty patients with rebellious sciatica thus treated. Six to eight capsules, each containing ten centigrams of ichthyl, are taken during the day, and the painful region is anointed with the following mixture: ichthyl, 20 grams; chloroform and balsamum tranquillans, aa 30 grams.

FUNCTIONAL ALBUMINURIA.

Diet is the most important element in treatment. Strict attention, however, should be given to hygiene while the kidneys should be well flushed with plain or alkaline waters and hot water before meals. Aitken recommends the following prescription:

- R. Acidi gallici ʒi-ʒii | 3.9-7 80
- Acidi sulphurici diluti ʒss | 1 95
- Tinctura lupulini ʒi | 3 90
- Infusi lupulini, q. s. ad. . . ʒvi | 186 60

Misc. Sig. Tablespoonful three times daily.

Butler has successfully employed the following method of treatment. Correct gastric and intestinal indigestion, by regulating the diet and, if necessary, to temporarily aid digestion, pepsin, taka diastase or diluted hydrochloric acid being administered according to indications. The bowels should be kept freely open, and occasionally a blue pill given. In addition, as a routine treatment, the patient should take from 5 to 10 minims (.24-.6 gm.) of Fowler's solution, and 5 to 8 grains (.3-.5 gm.) of benzolol after each meal.

ACUTE NEPHRITIS.

For a child of six or eight years.

- R. Tinctura digitalis ʒss | 1 95
- Liquoris ammon. acetatis ʒss | 46 60
- Spiritus atheris nitrosi ʒii | 7 80
- Syrupi toluantii ʒss | 17 30
- Aque cari q. s. ad. . . ʒiii | 93 30

Misc. Sig. Teaspoonful every two hours.

Goodhart and Starr.

Brouovski says strontium lactate 60-90 grains (3.8-5.7 gm.) daily, is a pure diuretic, and is more valuable than any other remedy in the treatment of acute inflammatory conditions of the kidney.

ACUTE LOBAR PNEUMONIA.

During the first few days of the disease, C. J. MacGuire advises perfect rest in bed so far as possible, and calomel, gr. 1-15-1-5, according to effect, every three to six hours, and

- R. Liq. ammonii acetatis ʒi | 31 10
- Tinct. opii camphorata ʒvi | 23 40
- Spiritus atheris nitrosi ʒiv | 15 60
- Aque laurocerasi ʒss | 15 50
- Syrupi toluantii ʒss | 15 50
- Aque camphoræ q. s. ad. . . ʒiv | 124 40

Misc. Sig. Dessertspoonful every two hours in water.

During the early stage accompanied by much inflammatory pain, Foxwell recommends the following:

R. Tincture aconiti m. i (.06 gm.) every half hour for twelve doses, then every hour, or antimonii et potassii tartras gr. ¼ (.008 gm.) every hour for twelve doses, then less frequently. We think it much wiser to administer m. ½ (.03 gm.) every half hour, in a teaspoonful rather than a larger dose.]

In exhaustion, strychnin, hypodermically, in full doses, from 1-20—1-12 grain (.003-.005 gm.) every two or three hours, while in collapse, or when it is threatened, or at a time of crisis, Wood and Fitz recommend atropin. Its checking excessive sweating often gives it further advantage; caffeine in small dose as an adjuvant or, in special cases, to overcome stupor. We quote further, from Wood and Fitz, "When, in the first twenty-four hours of a pneumonia, there is violent constitutional reaction, with flushed face, rapid and noisy breathing, bloody sputa, intense headache and drowsiness, a hard, bounding, or a tense, corded pulse, venesection may markedly lessen all symptoms, and, if combined with dry cupping over the whole chest, may, we believe, lessen the amount of engorgement of the lung and the final area of consolidation."

CHRONIC NEPHRITIS.

An invaluable diuretic in this disease is Trousseau's diuretic wine.

R. Junip. contus5x	39 00
Pulveris digitalis3ii	7 80
Pulveris scillæ3i	3 90
Vini XericiOj	497 60

After macerating for four days, add

Potassi acetatis3iii	1170
------------------	-----------	------

Express and filter. Sig. For an adult, a tablespoonful three times daily.

W. H. Thompson recommends the following as a simple diuretic mixture:

R. Spiritus atheris nitrosi3iss	5 85
Tinct. ferri chloridi	
Tinct. nucis vomice aa3i	3 90
Syrupi3iii	93 30

Misce. Sig. Two teaspoonfuls, three times daily.

Diuretin in 15-grain (.92 gm.) doses every three or four hours will stimulate the kidneys in certain cases better than almost any other remedy. It should be administered in solution in some aromatic water, but should never be dispensed in powders. The drug being incompatible with acids, the remedy should not be given immediately after eating, lest unpleasant symptoms arise from the action of the gastric juice upon the drug.

For the purpose of stimulating the kidneys, Dr. J. M. Patton advises the following:

R. Hydrargyri chloridi mitis gr. xviii	1 17
Sacchari lactisq. s.	

Misce. Fiat cht. No. vi. Sig. One powder three times daily while the bowels are kept closed by opium.

Eberle recommends for ascites:

R. Potassii bitartratis3i	31 10
Potassii sulphatis3ss	15 50
Pulveris scillæ3ii	7 80
Antimonii et potassii tartratis gr. i	06

Misce. Sig. One teaspoonful in a glass of water every four hours until active purgation and diuresis follow.

Miscellany.

Pollution of Rivers.—A large committee has been studying the river water in various parts of Germany, and has come to the conclusion that the refuse from factories, etc., is a much more important source of pollution than human dejecta, which, when previously duly filtered, need cause no concern. This report has been sent to each town interested in the question.

Medical Tribunals of Honor.—Those recently established in Prussia (see JOURNAL, XXXII, p. 507) are not exclusively medical, as the court is composed of four physicians and one

judge, and they are flagrantly unjust in one particular at least: they only include in their jurisdiction diplomaed members of the profession. Individuals practicing medicine irregularly are exempt from molestation by them as long as they abstain from assuming the title of physician or doctor, and physicians serving the state, and thus already under official discipline, are also exempt. Virchow, Langerhans and many others fought the measure in the Landtag, and thousands of protests were received, but as the *Semaine Medicale* observes, the Confederated States of Germany display a marked tendency to make the professions all feel the weight of authority.

Government Restrictions on Exportation of Plague Microbes.—The Indian Government has done very wisely in placing certain restrictions on persons wishing to carry or send cultures of the plague bacillus out of the country. To our mind the only remarkable thing is that steps were not taken in this direction before; for it is well known that many medical men who came to India for plague duty took with them specimens of the plague bacillus when they left the country. . . . The present action of the Indian Government is based on a representation from the health officer of the Port of Bombay, to the effect that a certain doctor took cultures of the plague bacillus on board the P. and O. ship *Carthage*, and continued to make experiments with them during the voyage. No cases of plague occurred on board; but it was noticed that two dead rats were found on the return trip to Bombay. Considering the close association between dead rats and plague, this fact, if known, must have caused general alarm, and we have no doubt that very considerable expense was incurred in the thorough disinfection of the vessel.

Professor Hafkine, the sanitary commissioner with the Government of Bombay, and the surgeon-general with the Government are agreed that the practice is most dangerous and should be stopped, and on their recommendation the Government of India, in exercise of the powers conferred by Section 2 of the Epidemic Disease Act of 1897, has issued the following regulations:

1. No person without the written or printed permission in this behalf of the Local Government in whose territories the port is situated, under the signature of a secretary to Government first obtained, shall take, either on his own person or in any baggage or parcel, or as cargo or otherwise howsoever, or shall send or permit to be taken or sent, on his account, either on the person of another or in any baggage or parcel, or as cargo or otherwise howsoever, any plague microbes or cultures on board any vessel in any port in British India.

2. No person, whether he has or has not obtained permission as herein required, shall take, send, or permit to be taken or sent as aforesaid, any such microbes or cultures, on any such vessel at any such port unless and until he has

a. Given fourteen clear days' notice in writing of his intention so to do to the health officer of such port, and

b. By a certificate signed by such person, and in such other manner as may be required by such officer, satisfied such officer that all such microbes or cultures are addressed to and intended for scientific purposes at some recognized constituted laboratory or laboratories specified by such person in his own handwriting, and are secured in a tin or tins, of adequate strength, hermetically sealed, and labeled with such distinguishing inscription as will suffice to make immediately manifest the nature of the contents thereof.—*Indian Medical Record*, May 31.

Provision for Physical Examinations Valid.—The New Jersey act of May 12, 1896, entitled "A supplement to an act entitled 'An act concerning evidence,'" and providing that on or before the trial of any personal injury case the court may, on application of any party therein, order and direct an examination of the person injured as to the injury complained of by a competent physician or physicians, surgeon or surgeons, in order to qualify the latter to testify as to the nature, extent and probable duration of the injury complained of, the supreme court of New Jersey holds, is constitutional. It considers that the proceeding authorized by the statute is a proceeding to obtain evidence analogous to proceedings that authorize an in-

spection of property and the taking of depositions, and that a statutory enactment such as this properly comes under the title of an act concerning evidence. Nor does it think that this act can be regarded as an infringement of the constitutional right of a party in a civil suit to be confronted by the witnesses. And it declares that neither will the consideration of any unfairness in resort to these proceedings be of any avail. The subject being deemed within the cognizance of the legislature, the legislative policy must prevail. In many of its sister states, the supreme court of New Jersey continues, case of *McGovern vs. Hope*, orders of this sort have been made; in others refused. In the main, the orders have been made under a power inherent in the court, and in some of the courts denied solely on the ground of lack of competent legislative authority. In the trial of causes, it goes on to say, orders have been made requiring a party alleged to have sustained an injury which is the subject matter of the suit to exhibit the injured limb to the jury, where such exhibition would not be accompanied by indecent exposure; and orders have been made in the courts of New Jersey without objection for the examination of the injured party in an adjoining room by reputable physicians, and such examinations have been had. In proceedings for divorce and nullity of marriage, orders for inspection of the body which are indelicate and distressing to the parties are made whenever necessary, and it is settled that the courts are not at liberty to decline to order such an inspection on the ground of indecency alone. This leads the court to go on to declare that where a suit is brought in which there is involved the consideration of injuries of a delicate nature, and which are, nevertheless, made the basis of damages to be awarded by a jury, there is no reason why such orders should not be made as would be appropriate to the administration of justice. The plaintiff, having brought suit and made claim for damages on account of personal injuries of that nature, cannot complain that the defendant resorts to legal methods to ascertain the existence and extent of such injuries. In executing the powers conferred upon the court under this statute in question, the supreme court says, the proceedings will be so controlled in the designation of physicians and surgeons, and with respect to the mode in which the examination shall be conducted, as to give both parties an equal opportunity of having witnesses present at the examination; and will also require, as far as practicable, the examination to be conducted in such a matter as not to subject the plaintiff to any unnecessary annoyance or exposure of her person.

Louisville.

VACATIONS.—Drs. J. M. Mathews and H. Horace Grant will leave on the 12th for Europe, where they will attend the meeting of the British Medical Association. Dr. I. N. Bloom, appointed chairman of the delegation to the dermatological section of the International Congress, will leave early in July for that meeting. Dr. J. B. Marvin will spend the summer in California. Dr. Henry E. Tuley will spend the month of August at Star Island, Mich. Dr. J. W. Guest, one of the city physicians, will be resident physician at Rockcastle Springs, Ky., for the summer.

COMMENCEMENTS.—The annual commencements of the spring and summer medical colleges were held last week. The Kentucky School of Medicine awarded twenty-four diplomas. The medical department of Kentucky University graduated nine, and the Hospital College of Medicine seventeen.

Philadelphia.

MORTALITY STATISTICS.—The total number of deaths which have occurred in this city during the week just passed was 420, an increase of 41 over last week, and a decrease of 135 over the corresponding period of last year. The principal causes of death were as follows: Apoplexy, 16; nephritis, 28; cancer, 14; cholera infantum, 36; tuberculosis, 45; diabetes, 2; heart disease, 36; pneumonia, 15; appendicitis, 2; suicide, 5.

RESIDENT PHYSICIANS TO GERMAN HOSPITAL.—As a result of the competitive examination for positions on the resident staff of this Philadelphia hospital, the following named have been appointed: Drs. Frank H. Dye and A. E. Wilcox of the University of Pennsylvania, and Dr. Ferguson of Jefferson Medical College.

STATE HEALTH OFFICER AND MAYOR CROSS SWORDS.—Differences between these officials have arisen over the prevention of pollution of the Schuylkill River and the necessary remedy for its betterment. The mayor is reported as saying that he has no jurisdiction in the matter, and that the State Board of Health should therefore apply the remedy. Twice he has called the attention of the state health officer to his duty, while the latter says he is doing his duty, and refuses to answer the letter of the mayor, while to others in the health department he replies cordially.

REQUEST TO CHARITY.—By the will of the late William Gallagher the sum of \$200 has been devised to St. Joseph's and an equal sum to St. Agnes Hospital. The residuary estate of the deceased will be divided equally between the above-named institutions and several other charitable organizations.

CHANGE IN HOSPITAL STAFF.—Owing to the resignation of Dr. J. G. O'Hara, Dr. H. F. Harbridge has been appointed one of the physicians to St. Mary's Hospital.

WILL SAIL FOR AMSTERDAM.—Dr. J. Montgomery Baldy and Dr. G. Hudson Makuen, delegates from this country to the medical congress which convenes in Amsterdam at an early date will sail on July 28 for the above-named city.

ENTERTAINMENT.—June 24 the Philadelphia Medical Club tendered a reception in honor of Dr. G. W. Guthrie of Wilkesbarre, president of the Medical Society of Pennsylvania.

WARNING TO MEDICAL STUDENTS.—A case which will doubtless elicit considerable interest on the part of the different medical colleges of this city occurred a few days ago. It seems that A. W., a colored woman 37 years of age, suffered from septicemia following a premature birth of a child. The patient had been visited by a senior medical student in one of the medical colleges and he had made an examination although no regular graduate in medicine was present at the time. After seeing the case the student advised that the district physician be called in attendance. The patient, however, was taken to the Philadelphia Hospital where she subsequently died. At the inquest Coroner Dugan took pains to warn the medical student against attending such cases, stating that if it had been in evidence that the woman had died of neglect the attendant would have found himself involved in serious trouble.

Queries and Minor Notes.

MEDICAL PRACTICE.

To the Editor:—Will you please to inform me as to whether a physician is required to pass an examination to practice his profession in California, Oregon or Washington? How would the west coast of Oregon be for one who for the last year or two has had slight pulmonary hemorrhage? Practice laws of the several states were published some time ago, but I am unable to find the JOURNAL in which published. Respectfully, C. E. B.

ANSWER.—1. In California the presentation and verification of a satisfactory diploma is required for license. In Oregon and Washington an examination is required in all cases, the laws being nearly identical in the two states.

2. The principal advantage of western Oregon or Washington to one who has pulmonary trouble would probably be in a milder climate than in the northern Atlantic states. The rainy season makes it not so favorable for out-door life as Southern California, which is the resort of consumptives who require a mild seaside climate. Eastern Washington and Oregon have less rain and sunshine and therefore may be naturally considered more favorable in these respects.

3. The medical practice requirements of the different states, as published by the Illinois State Board of Health in its last report, will be found in the JOURNAL for Nov. 12, 1898.

WORKS ON TUMORS.

To the Editor:—Will you kindly write me what you believe to be the best book available on tumors; one with the best cuts and descriptive text? I want it for microscopic work. Very truly, J. L. C.

ANSWER.—For a general work on tumors, that of Bland Sutton, though

small, is one of the best. It makes no speciality of the microscopic character, in fact the text is rather brief, but it is scientific and modern and what it states is reliable. The cuts also are good. The work of Senn is fuller in the histologic descriptions and might be preferred. Both of these works are, we are informed, now out of print and not easily obtained. Probably the needs would be pretty fully met by some of the recent works on pathology, general and special, that of Zeigler, published in 1888 by William Wood & Co., being as good as any, if not the best.

ROBERTS' LYMPH.

To the Editor:—In your last edition of the JOURNAL you state that Dr. Joseph R. Hawley made mistakes in his article on Dr. B. F. Roberts' lymph. The facts are I had Dr. Hawley's article copied by our local printer and the errors were made by him; as I refer to Dr. Hawley's article I find the mistakes you spoke of absent, but I did not find the errors in my copy until I had sent out over fifty. I write this statement in justification of Dr. Hawley, who ought not to be censured for some other person's mistakes. Dr. B. F. Roberts is my cousin. Very truly,
I. M. ROBERTS.

WHO KNOWS?

To the Editor:—A physician of my acquaintance told me recently that he had noticed in some of the medical journals an account of a wonderful spring in Wisconsin, for the cure of diabetes, but he was unable to remember where he had seen the article. Can you give me any information on the subject? Yours very truly,
C. W. W.

ANSWER:—We know of no such spring. Possibly some of our readers can furnish the information.

The Public Service.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., to and including June 29, 1899:

Daniel M. Appel, major and surgeon, U. S. A., leave of absence granted, to take effect on the closing of the general hospital at Savannah, Ga.
Henry A. Barnhardt, acting asst.-surgeon, from Camp Meade, Middletown, Pa., to accompany 10th U. S. Infantry to Manila, P. I.

Allen J. Black, acting asst.-surgeon, revocation of orders directing him to accompany Co. B, Batt. of Engineers, to San Francisco, Cal.

Charles C. Byrne, colonel and asst. surgeon-general, U. S. A., member of a retiring board to meet at Governor's Island, N. Y.

Hymen M. Cohen, acting asst.-surgeon, now at Willet's Point, N. Y., to accompany Co. B, Batt. of Engineers, to San Francisco, Cal., and there to report for duty in the Dept. of California.

W. H. Forwood, colonel and asst. surgeon-general, U. S. A., member of a retiring board convened in San Francisco, Cal.

Robert J. Gibson, major and surgeon, U. S. A., member of a retiring board convened in San Francisco, Cal.

James M. Kennedy, captain and asst.-surgeon, U. S. A., former orders amended so as to require him to report to the commanding general, Department of California, for duty.

James P. Kimball, major and surgeon, U. S. A., member of a retiring board to meet at Governor's Island, N. Y.

Timothy Leary, acting asst.-surgeon, from the Department of Porto Rico to the Department of Santiago.

George W. Pattison, acting asst.-surgeon, from Camp Meade, Middletown, Pa., to Buffalo, N. Y., for annulment of contract.

Paul Shillock, captain and asst.-surgeon, U. S. A., relieved from duty at Fort Grant, Ariz., at once to report for temporary duty in the Department of California.

Dwight B. Taylor, acting asst.-surgeon, sick leave granted from the Division of Cuba is extended.

Roy A. Wilson, acting asst.-surgeon, from Camp Meade, Middletown, Pa., to post duty at Willet's Point, N. Y.

Movements of Navy Medical Officers.—Changes in the medical corps of the U. S. Navy for the week ending July 1, 1899:

Asst.-Surgeon W. L. Bell, detached from the naval hospital, Mare Island, Cal., and ordered to the "Philadelphia."

Asst.-Surgeon H. E. Odell, detached from the "Philadelphia" and ordered to the naval hospital, Mare Island, Cal.

Asst.-Surgeon F. M. Bogan, ordered to additional duty at the Boston navy yard.

P. A. Surgeon R. G. Brodick, ordered to Washington, D. C., July 6, for examination for retirement, and then home and to wait orders.

P. A. Surgeon J. C. Rosenbluth, detached from the "Buffalo," when put out of commission, and ordered to the "Vermont" immediately.

Marine-Hospital Changes.—Official List of Changes of Station, and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine-Hospital Service, for the seven days ended June 29, 1899.

Surgeon A. W. Swetelle, detailed as inspector of relief stations of the third and fourth class.

P. A. Surgeon R. M. Woodward, upon being relieved by P. A. Surgeon A. R. Thomas, to proceed to Washington, D. C., for assignment to duty.

P. A. Surgeon A. R. Thomas, upon being relieved by P. A. Surgeon G. T. Vaughan, to proceed to Reedy Island Quarantine Station and assume command of the service.

Acting Asst.-Surgeon E. B. Hallet, granted leave of absence for two days from July 4, 1899.

Acting Asst.-Surgeon W. S. Walkley, granted leave of absence for three days from June 28, 1899.

Sanitary Inspector W. F. Brunner, granted leave of absence for three days from June 28, 1899.

Sanitary Inspector J. C. Rodman, granted leave of absence for seven days from June 27, 1899.

Hospital Steward E. J. Thurston, to proceed to New York City for special temporary duty.

PROMOTION.

P. A. Surgeon W. J. Pettus, commissioned as surgeon.

APPOINTMENT.

Frederick Townsend, of Michigan, to be acting asst.-surgeon, U. S. Marine-Hospital Service, for duty at Sault Ste. Marie, Mich.

Health Reports.—The following cases of smallpox, yellow fever, cholera, plague and leprosy, have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended July 1, 1899:

SMALLPOX.

Indiana: Evansville, June 10 to 17, 1 case.

Kansas: Kansas City, June 16 to 23, 2 cases.

Louisiana: New Orleans, June 10 to 17, 1 case.

Massachusetts: Boston, June 24, 2 cases; Fall River, June 21, total to date, 34 cases.

Minnesota: Appleton, June 16, to date 12 cases; Worthington, June 16, 5 cases.

Missouri: Farmington, June 19, reported; St. Joseph, Oct. 26 to Apr. 19, 56 cases, 1 death; St. Louis, June 19, 9 cases.

Nebraska: Omaha, June 10 to 17, 2 cases.

New York: New York, June 17 to 24, 2 cases.

Pennsylvania: Philadelphia, June 24, 2 cases; Pittsburg, June 10 to 17, 1 case.

Porto Rico: Ponce, June 10, 1 case.

Ohio: Cleveland, June 3 to 17, 13 cases, 1 death; Columbus, June 16 to 23, 1 case; Massillon, June 17, 1 case.

South Carolina: Greenville, June 10 to 17, 1 case.

Virginia: Newport News, to June 24, 583 cases, 14 deaths; Norfolk, to June 22, 822 cases, 14 deaths; Portsmouth, to June 22, 344 cases, 5 deaths.

Washington: Spokane, June 17, 4 cases, 3 deaths.

SMALLPOX—FOREIGN.

Belgium: Antwerp, June 3 to 10, 3 cases, 1 death.

Brazil: Rio de Janeiro, May 5 to 19, 60 cases, 20 deaths.

Cuba: Nuevitas, June 16, 1 case.

Egypt: Cairo, May 22 to June 3, 4 deaths.

England: London, June 3 to 10, 1 case, 1 death.

Greece: Athens, June 3 to 10, 18 cases, 7 deaths.

India: Bombay, May 23 to 30, 9 deaths; Madras, May 13 to 26, 3 deaths.

Russia: Moscow, May 27 to June 3, 34 cases, 7 deaths; Odessa, June 3 to 10, 6 cases, 3 deaths; St. Petersburg, May 27 to June 3, 25 cases, 5 deaths.

Warsaw, May 27 to June 3, 1 death.

Scotland: Glasgow, June 3 to 10, 1 case.

Turkey: Smyrna, June 3 to 10, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, May 6 to 19, 34 cases, 17 deaths.

Cuba: Havana, June 8 to 15, 1 death.

Matanzas: Matanzas, June 2, 1 case; Santiago, from outbreak to June 30, 35 cases, 11 deaths. All but 4 were among troops.

Mexico: Tampico, June 3 to 9, 2 cases; Vera Cruz, June 8 to 22, 79 deaths.

CHOLERA.

India: Bombay, May 23 to 30, 2 deaths; Madras, May 20 to 27, 5 deaths.

PLAGUE.

India: Bombay, May 23 to 30, 124 deaths; Madras, May 20 to 26, 1 death.

Persia: Bushir, June 3, 1 case.

LEPROSY.

Texas: Eagle Pass, June 30, 1 case.

CHANGE OF ADDRESS.

Case, G. B., from 114 Euclid Ave. to Colonial Arcade, Cleveland, Ohio.

Clark, C. G., from Ann Arbor, Mich., to Pittsfield, Mass.

Carlson, E. P., from Chicago to 1019 University Av., Madison, Wis.

Case, C. L., from Louisville, Ky., to Middleburg, Ind.

Campbell, P. F., from Bensalem to Elwood, Neb.

Foerster, O. H., from Milwaukee, Wis., to 3604 Walnut, Philadelphia, Pa.

Fanning, G. J., from New Orleans to Phillipsburg, Mont.

Hadley, E., from 236 N. Penn. to Willoughby Bldg., Indianapolis, Ind.

Horton, R. W., from Greenview to Waxhatch, Texas.

Harris, J. G., from 911 Washington, Chicago, to 918 S. 12th St., Philadelphia.

Hartley, R. A., from Chicago to Redlands, Cal.

Hartshorn, W. E., from Minneapolis, Minn., to Box 1087, New Haven, Conn.

Kurtz, T. J., from Chicago, to 313 West Court, Flint, Mich.

Kuhn, B. F., from Chicago to North Webster, Ind.

Layne, E. R., from Hualdsburg to Danville, Ga.

Lawrence, A., from Millville to Malden, Mass.

Mogk, W. A., from Ann Arbor to 546 Second Av., Detroit, Mich.

McSwain, D. L., from De Funiat Springs to Nocatee, Fla.

Notage, H. P., Providence, R. I., to Goshen, Mass.

Nauman, B. J., from Mendota to Peru, Ill.

Purdue, F., from Swinton, Mo., to Alto Pass, Ill.

Piper, E. D., from Chicago to Waukegan, Ill.

Fittner, J. H., from Nashville, Tenn., to High Springs, Fla.

Richmond, C. B., from 711 17th St. to 1737 Melton St., Denver, Colo.

Roop, J. W., from Montrose to Snyder, Ark.

Sherman, C. F., from 1936 to 1556 N. Halsted St., Chicago.

Smith, J. P., from 280 State to 69 Washington, Chicago.

Samuel, J. R., from 2501 Oxford to 1617 N. Broad, Philadelphia, Pa.

Strout, A. B., from 319 W. Indiana to 533 W. Monroe, Chicago.

Soule, C. E., from Morris to Sheridan, Ill.

Tenney, L. P., from Crockett to Archer City, Texas.

Woods, J. G., from Louisville, Ky., to Meersburg, La.

Weld, W. H., from Deadwood, S. D., to Fort Atkinson, Wis.

BEST METHODS IN THE TREATMENT OF APPENDICITIS.*

THEIR SOCIOLOGIC BEARING.
BY ROBERT T. MORRIS, M.D.
NEW YORK CITY.

It seems strange when accurate knowledge is so easily accessible on the subject of appendicitis, that bad methods in the management of the disease still persist. I will briefly review some of these, and approximately in the order of their importance.

The worst method is that which treats the patients by various medical means. Many of these recover without further attacks, many die and a larger number have recurrent attacks and suffer more or less invalidism for months or for years. It is impossible to determine in advance which course will be followed by any one case. That is always determined afterward. Consequently the cases that are going to recover without further attacks, recover; the ones that are going to get into dangerous complications, get into dangerous complications; the ones that are going to have recurrent attacks, have recurrent attacks, under medical treatment. There is no way for determining in advance what the eventual outcome of any case will be. The death-rate under proper surgical treatment in the first stages of an attack is a fraction of 1 per cent. The death-rate under medical treatment of any sort has not been shown to be less than 25 per cent., consequently the rational deduction is that the conservative treatment of these cases is the one which avoids speculation and arrives at a definite and satisfactory conclusion early in the history of the case.

Next after medical treatment comes various bad methods of surgical treatment which have a special death-rate of their own. Methods of surgical treatment which have a death-rate of their own are here briefly enumerated:

Iodoform Gauze Packing.—This is harmful in two ways. The peritoneum absorbs iodoform with such rapidity that toxic effects are produced in some patients from a very small quantity of the drug. If we examine the urine of patients who are thought to be dying from septicemia or exhaustion, and who have iodoform gauze in the peritoneal cavity, the result will surprise those of us who have not made such examinations. A little urine stirred up with a pinch of calomel in a saucer will show the brownish reaction, as iodid of mercury is formed in cases in which the urine contains iodine. A marked peculiarity of these cases of death from iodoform poisoning is the good appearance of the wound itself.

Gauze Packing.—Gauze packing without iodoform stands close to iodoform gauze packing in the order of injurious resources which have a special death-rate of their own. Strong and well men cannot bear in the abdominal cavity the presence of a half yard of gauze, and I do not know why a weak and exhausted patient should

be asked to bear what cannot be borne by a strong man. Aside from the shock caused by gauze packing, the gauze causes excessive lymph exudation. This causes a rich culture-medium for bacteria, and further, it forms strong and troublesome adhesions of viscera. When gauze packing is removed, it causes so much distress that surgeons sometimes anesthetize the patient when the dressing is changed. Gauze packing often causes post-operative obstruction and ileus by its direct mechanical effect, as does also the drain in the form of strips of gauze which are carried to various points among viscera for drainage, when peristalsis of the bowel causes the drainage strips to encircle bowel loops. It is impossible to guard well against post-operative ventral hernia in any case in which gauze packing or multiple gauze strips have been employed. Gauze packing or gauze strips are not only harmful but they are unnecessary and may be entirely replaced by a narrow drainage wick covered with gutta-percha tissue, which avoids adhesion formation to the mesh of the wick. The narrow wick allows the wound to be closed and accurately sutured. It must be managed with a knowledge of the mechanical principles involved in dealing with capillarity.

Extensive and Multiple Incisions.—The necessity for making an incision four inches in length should rarely ever occur in any case of appendicitis. Multiple incisions are unnecessary. The short incision of $\frac{1}{2}$ inches in length for interval cases or primary infection cases before abscess has developed, is all-sufficient for surgeons who have given themselves opportunities for training in adhesion work, in most of the cases. In cases with abscess and wide-spread infection, an incision three inches in length is usually sufficient. The idea that all parts of the peritoneal cavity should be reached by the surgeon in cases of wide-spread infection, is erroneous and based on ordinary ideas of cleanliness, and not on a knowledge of what the peritoneum is able to accomplish. In chief toxin-bearing collections of fluid are quickly evacuated, and the appendix removed; if the patient is not kept under an anesthetic for a long time; if the bowels are properly managed afterward, we need give little attention to the remainder of the septic fluid which is distributed about in the peritoneal cavity. There is a hyperleucocytosis already well established in almost every case with wide-spread infection, and the polynuclear leucocytes make easy work of removing the infected material left in the peritoneal cavity.

Protracted Operation.—Almost any operation for appendicitis, no matter how extensive the complications, should be completed in less than thirty minutes from the time of beginning operation. Operations which drag along to an hour or more, perhaps with much unnecessary handling of viscera, long exposure of the open wound and long-continued anesthesia, leave the patient in an unfavorable condition for rallying quickly from the operation.

Leaving Adherent Appendices.—A method which must have a special death-rate of its own consists in leaving infected appendices among adhesions. Such appendices are frequently gangrenous in part and they often

*Presented to the Section on Surgery and Anatomy at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

contain concretions and mucous inclusions. It is rarely ever necessary to leave such adherent appendices after one has become trained in adhesion work.

Protecting the Peritoneum.—"Guarding the peritoneum" is a method which may not have a large death-rate of its own, but which certainly causes delay in operative work. It consists in carefully walling off an abscess with gauze, especially arranged to protect the peritoneum. This requires a larger incision than is necessary and also the expenditure of time. It is based on conventional ideas of cleanliness rather than on present knowledge. It is much better to work rapidly through a small incision, let pus flow as fast and as freely as it will anywhere over the peritoneum and blow it out with hydrogen dioxide from time to time as the work proceeds. In the *N. Y. Medical Journal*, for April 29, 1899, I published a list of seventy-six consecutive cases of the most dangerous class of appendicitis, that had gone on to the stage of general suppurative peritonitis, septic peritonitis with liquefied lymph instead of abscess formation, multiple acute, single acute, and old abscesses, and managed by the principles briefly outlined above, with only eight deaths. I have operated on a very much larger number of cases in the interval, with various adhesion complications, and primary infection cases before abscess formation, and have not as yet had a death in this class of cases. Most of them were operated on through the inch and a half incision.

Bad methods in the treatment of the subject of appendicitis are quite as important as bad methods in the treatment of appendicitis. It is difficult for one to cut a clear path through the tangle of ignorance on the subject, and those of us who are doing it for the rest of the profession get little credit and have to content ourselves with the *mens conscia recti*. I believe that personally this work costs me thousands of dollars annually, and it makes enemies of men whom I would wish to call my friends. I would gladly drop the subject out of my field of discussion in surgical society meetings, but there is yet a moral demand for all of the voices that can be raised for the right, while thousands of patients are unnecessarily dying every year from appendicitis, and still more thousands are suffering the wreck of health and ambition and are disabled in the race of life for which they have equipped themselves. The greatest wrong is done to society by writers and speakers on the subject who have not taken the opportunities that are easily available for becoming properly informed, and who have little hesitation about expressing crude and dangerous opinions. I shall take this occasion for quoting some examples of such harmful and injurious influence. It seems necessary in order to do this to make direct criticism of the men who furnish such examples of bad influence. It is my custom, based on principle, to avoid criticism of my colleagues excepting at medical society meetings where there is fair opportunity for defense. All of the men who have been selected for this group of criticism and who are living in this country have been notified by letter of my intentions, and all have been asked to be present or to have some representative at this meeting, to make such answer as may seem proper.

Example A.—In the December, 1898, number of *Health Culture*, Dr. S. R. Beckwith has an article opposing the operative treatment of appendicitis. On reference to "Polk's Medical Directory," I find that Dr. Beckwith was formerly surgeon to all the railroads entering Cleveland, Ohio; that he is a member of the Ohio State Homeopathic Medical Society, American Institute of

Homeopathy and New Jersey State Homeopathic Society. In this article in question Dr. Beckwith says the reader may ask why he exposes the error of operation for appendicitis in a lay journal instead of choosing a medical journal for the purpose, and his answer is, that in medicine and in surgery improvements have come mostly from the people. Blood-letting he quotes as an instance of a method that was wiped out of existence by the people, and he proposes to direct his writings against operation in appendicitis to health journals.

Here are some quotations from the article in *Health Culture*: "The appendix is a hollow tube from four to six inches in length. The lower end of the tube is attached to the small intestine, passes through the internal and middle coats of the small intestine, and is attached to the inner fibers of a valve that guards the entrance between the small and large intestines." The function of the appendix he says is to work this valve, so that unprepared matters shall not escape too soon into the large intestine. Here appears a cut furnished by Dr. Beckwith in illustration of his anatomic position of the appendix.

FIGURE 2.

Just below this valve the small intestine enters into the large one as shown at No. 5 in Figure 2. The valvular movement so accommodates itself that foreign substances, as where a child swallows a penny, readily pass into the large intestine. Number 4 in Figure 2 represents the vermiform appendix. It is a hollow tube from four to six inches in length; the lower end of the tube is attached to the small intestine, passes through the internal and middle coat of this, and is attached to the inner fibers of the valve.

Dr. Beckwith says that the appendix occurs in all mammalia, and is remarkably well developed in the hog. Any one who questions his anatomy can easily verify it by dissecting a hog, and he will make humble apology to any one who finds on such dissection that he is wrong, provided that a photograph of the dissection be sent him for examination. Dr. Beckwith says that appendicitis is extremely rare. "In more than fifty years of surgical practice" (graduated in 1853, according to "Polk's Directory") he has seen but two cases of the disease. Surgeons of larger experience have never seen a case. This author says that in the operation the entire appendix cannot be removed without producing death, the valve motion would cease at once if this were done, and death would as certainly follow as in an unrelieved case of strangulated hernia. All that modern surgeons do, and here is where they practice deception, is to snip off a portion of the tail of the appendix; the portion which remains becomes modified, so that it can still operate the valve. Dr. Beckwith's article is made up of columns of this sort of statement and his conclusions from time to time are against the modern idea of operation.

Articles of this sort, when read by medical men are harmless, because it is apparent that the author is not mentally responsible for what he says. But we must con-

sider that this article was published in a lay journal where it was presumably read by thousands of the laity, and its conclusions might have readily been the means of bringing misery into more than one household, because of the average lay reader's trust in an article which gives anatomic details, and which is signed by a physician. The editors of *Health Culture* are culpable in the matter of publishing such an article, but there is no means provided whereby they can be punished for this imposition on the people. They do the harm and innocent people are made to suffer.

Example B.—In the *JOURNAL* for April 8, 1899, Dr. Wilbur F. Sterman has an article on the "Medical and Surgical Treatment of Appendicitis." The author refers to a previous communication of his that was published in the *JOURNAL* for Dec. 18, 1897, advocating medical treatment, and he states that it was very favorably commented on by Dr. Haughton and others. Dr. Haughton's article, which many of us remember, consisted of conclusions based on cases treated medically, in which typically bad results were obtained, and no better warning against medical treatment could well have been published than this prop which Dr. Sterman quotes for supporting his side of the case. To show Dr. Sterman's honesty of intention, however, I quote from his article: "The constant aim of every member of the medical profession should be the welfare of humanity at large, and the greatest good to the greatest number." That certainly shows a sufficiently broad type of mind and it is too bad that Dr. Sterman has not learned that medical treatment is not the sort which carries out his intention toward the public. He is probably situated in an environment in which it is difficult to make a proper selection of authorities and to know the real difference between proper surgical treatment and medical treatment of any sort in appendicitis. Like many others in his position he fails to take into account the known pathology of appendicitis, and instead of being guided by the principles based on pathology, he depends chiefly on limited personal experience, and bad authority. He quotes from Ewald: "It is also shown by statistics that from 90 per cent. to 91 per cent. of all diseases of the appendix taken in their broadest sense recover without operation." Men like Ewald are responsible for leading physicians like Dr. Sterman astray. I have forgotten which Dr. Ewald it was who made this statement, as there are several surgeons of that name in Germany, but he has no such statistics as Dr. Sterman quotes. The reason why he has no such statistics is because patients with concretions in the appendix, with mucus inclusions, with tuberculosis of the appendix, with chronic abscess, and with adhesion complications, are not cured after the subsidence of acute attacks, and when these patients drop out at intervals in various subsequent attacks and complications they are not recorded for percentage statistics. The statement that such statistics are available is false and this Ewald disgraces German medicine. I would respectfully request German authorities to look after such careless unscientific writers, if they wish to preserve the fair name of Germany in the interests of pure science.

Dr. Sterman quotes again from an article by Treves, as he says, but I suspect that he is quoting from memory and consequently will not hold Treves responsible for the following quotation: "Concerning appendicitis obliterans and chronic recurrent appendicitis, even these cases do not invariably require operation. In some examples of the relapsing form much can be done by medical treatment. In the recurrent type, if operation is to be con-

sidered at all, it might be well to take the risk of waiting for another attack which may never come. In the chronic relapsing cases, however, if the surgeon deciding upon operation limits himself to the following indications he had better take advantage of the interval. (The words in italics interpolated in the text are mine.) Operation is indicated when: 1. The attacks have been very numerous. *Patients die in the first or second or any attack without furnishing symptoms for prognosis.* 2. The attacks are increasing in severity and frequency. *What they are doing is decided after death or recovery and not before death or recovery.* 3. The last attack has been so severe as to place the patient's life in considerable danger. *We know how to avoid such unnecessary risk and suffering on the part of the patient.* 4. The constant relapses have reduced the patient to a condition of chronic invalidism, and rendered him unfit to follow any occupation." *Horrible!* Would Dr. Sterman have us believe that English surgeons allow their bankers and their barristers, their sons and daughters and mothers and brothers to get into such predicament as is here depicted? If it were true, I would say shame on any member of our profession to-day, no matter who he is or where he lives, who allows an appendicitis patient to become a chronic invalid provided he is in a position to enjoy enlightened resources. Concerning the matter of waiting for the interval in order to have a safe operation, I would like to ask if that represents courage on the surgeon's part, or does not the word "safe" refer chiefly to the surgeon's reputation? If all patients would get to the safe interval, we would never need to operate to save life in appendicitis.

Dr. Sterman further says: "Thus from all other true and eminent sources of authority such as these, comes the warning note of conservatism in behalf of judgment and good sense." He apparently has not learned that appendicitis is not the disease to give opportunities for exercise of judgment and common sense. He evidently is not familiar with the statistics of the operation, or he would not speak of conservative treatment as that which has the largest death-rate.

Dr. Sterman then reports on two patients of his own who were subjected to medical treatment, both of whom recovered from acute attacks, but with much more suffering and delay than would have occurred under proper surgical treatment, and further than that, both of his patients must be expected to go through the same ordeal again at no distant day, we hope safely. This prognosis of their having to go through the same ordeal again is based on our common knowledge of the nature of the disease, and its familiar pathology. Dr. Sterman thinks that the patients will not have further trouble. Why does he think so? It is only a physician's hope. All of us who are sympathetic know what that is. We are prone to deceive ourselves in hoping good things for our patients, and patients die because we hope instead of applying principles.

Example C.—The *Medical Record*, Dec. 17, 1898, contains an article by Dr. T. J. Hutton of Chicago, entitled "A Cheap Cure for Appendicitis." Under the title are published statements of the doctor's standing: "Formerly Resident Physician Long Island College Hospital, Brooklyn, Brigham Hall Private Hospital, Canandaigua, N. Y., Burn Brac Private Hospital, Philadelphia, Professor of Diseases of the Mind and Nervous System in the College of Physicians and Surgeons in Chicago." Dr. Hutton's treatment consisted chiefly in the free use of calomel and soda purgation, supplemented by hot applications, these to be followed by salines if the

action of the calomel was too slow. He stated that enormous quantities of calomel could be given with impunity in cases of appendicitis with obstruction of the bowels. He stated that he could recall 100 cases with the symptoms of typhlitis, and perityphlitis, that he had treated, but never yet had he seen one that did not recover under that treatment. I immediately wrote the Doctor at his Chicago address, asking him for detailed history of any ten consecutive cases of the list, if he could furnish them. The letter was returned to me in New York, postmarked on the envelope "moved, left no address." The following number of the *Medical Record* contained a statement from the secretary of the College of Physicians and Surgeons of Chicago, stating that Dr. T. J. Hutton was not a professor in that college nor was he in any way connected with it. It was apparently a case of fraud throughout. And yet from the fact that the article was published in a medical journal of the standing of the *Medical Record*, and because the author subscribed himself as a professor in the College of Physicians and Surgeons of Chicago, the article must have done great harm, because it was in line with the ideas of a very large number of men who have not yet acquired principles that are to be applied in the management of appendicitis.

Example D.—Early last year, Dr. M. O. Terry of Utica published a statement to the effect that he had cured forty-nine out of fifty-one cases of appendicitis, by medical means with a so-called oil treatment, that he had previously advocated with much confidence. If these cases were in reality appendicitis cases, there must have been among them the usual proportion of concretions, of mucus inclusions, of tuberculosis, of chronic abscess and adhesion complications. The proportion of cases in which these things occur has been carefully worked out and published in a series of tables in the third edition of my book on the subject, and the data taken from actual observation of specimens must be taken into account whenever a physician speaks of medical cure of appendicitis. Knowing that Dr. Terry's number of patients could not be cured after the subsidence of acute symptoms when they still carried concretions, mucus inclusions, tuberculosis, chronic abscess, and peritoneal adhesions, I asked for a more detailed report on the cases, but it has been impossible to obtain such a report. Dr. Terry's excuse was that it was difficult to find out what became of the cases, and my argument is that he should not have published a report on cases that he could not find out about. I offered to pay all expenses of men employed by Dr. Terry or by myself, as he wished, in order to trace the history of his forty-nine cases, but I have not been enabled to obtain information about that. Our correspondence on the subject will be found in the files of the *N. Y. Medical Times* for 1898. It is of considerable interest and worthy of perusal by all who are at work on the subject of appendicitis. Finding that I could not get a report on the forty-nine cases said to have been cured, I asked Dr. Terry to report on ten consecutive cases. He finally gave, in the *Medical Times*, a report on ten cases, but these appeared not to be consecutive cases, and there was nothing to show that the methods for making a correct diagnosis had been employed, and no statement of interval palpation finding and nothing excepting a statement that most of the patients considered themselves cured. Consequently we are left without any foothold for guidance in placing a calculation on the data that Dr. Terry furnished. I have had occasion to operate on several patients who had undergone Dr. Terry's oil

treatment. By hearsay I have learned of the expected proportion of deaths and exacerbations in patients who had undergone this form of treatment at the hands of Dr. Terry, and of others who stated that they had followed his methods, and it is much to be regretted that Dr. Terry cannot be persuaded to apply scientific methods in making a report for us. I do not wish to infer that it is his intention to be dishonest in the matter; his reports simply indicate a lack of scientific training and an unwillingness to learn the real facts about his cases because of his confidence in a method of treatment that he is advocating. Much suffering results in consequence of his writings because others who are too busy to acquire a knowledge of the real pathology and the real statistics of appendicitis, depend on such reports for guidance.

Example E.—Apropos of the publication of one series of 100 consecutive unselected appendicitis operations of my own with a death-rate of 2 per cent., Dr. E. C. Savidge of New York wrote, in the *Medical Record* of Dec. 12, 1896, commenting on this paper, in connection with the statistics of certain European operators who had furnished creditable statistics in other fields of work. I quote from Dr. Savidge's letter in the *Record*, as follows: "The statistics of Morris when compared with surgeons who have a 10 per cent. or 20 per cent. mortality prove logically that he is five or ten times more skillful than they. The figures of Pean and Jacobs logically prove that they have five or ten times more individual art than the principal surgeons at the New York hospitals. But does anybody who knows the whole ground believe these logical deductions? Suppose that surgeons with fancy statistics meet a dozen desperate cases in their respective lines, each with one bare operative chance in a hundred, would these gentlemen have regard for their statistics and refuse the patient the one poor chance by operation, or would they rule out from their statistics these practically moribund cases? In such event, where the operators may be soberness and truth itself, their figures are vainglorious cheats as tests of comparative skill." This is an example of one of the most harmful types of writers who would bar progress, because it represents the communistic spirit carried into a liberal profession. Intolerance of merit is common enough, but this usually works itself out in petty revenge in private, and there are few who are bold enough to publicly write as Dr. Savidge did, and divert the attention of the profession from the real point at stake, the data of progress. Dr. Savidge turns my utilitarian intention into a crime, for I consider that publication of misleading surgical statistics is a crime if the surgeon's position is such that others depend on him for guidance in choosing methods of procedure. My statistics were not published for the purpose of showing any superior skill on my part, in fact I had not anticipated any such strange reading of the report. They were published for the benefit of surgeons, to show what could be accomplished by following certain surgical principles that had been elaborated in the texts accompanying these statistics. I had not "refused help to any moribund patient," but had operated in every acute appendicitis case that I had seen, with the exception of two patients who were dead when I arrived, and 20 per cent. death-rate in these 100 cases would have been quite legitimate. There were thirty-eight cases with abscess or worse complications, and most of the 100 had adhesion complications. The object of the report was to show why the death-rate was 2 per cent. instead of 20 per cent. and to show it in such a way that the report would be of

value to surgeons. Dr. Savidge diverted my effort and placed me in a contemptible position on the basis of the report, because to a high-minded, conscientious physician nothing seems more contemptible than refusing help to a suffering patient in order to advance any selfish interests of one's own.

Example F.—At the Denver meeting of the AMERICAN MEDICAL ASSOCIATION, Dr. W. W. Keen of Philadelphia was reported to have said in one of the discussions, "I protest against the statement that we can obtain a surgical death-rate of only 2 per cent. in appendicitis. I challenge any operator in this room to take 100 well persons and operate upon them without losing more than 2 per cent." On reading the report, my natural impression was that Dr. Keen had been misquoted, but on inquiry it was learned that the report was correct. This is an example of the most harmful type of obstruction to progress, because of the importance of its author. Concerning a death-rate of 2 per cent. in operations on well people, Drs. Bull and Coley have published in the *Annals of Surgery* a report on over 8000 hernia operations at the hands of several operators with a death-rate of a fraction of 1 per cent. Dr. Coley informs me that he has operated on over six hundred hernia cases with the loss of only one patient. Concerning the death-rate of 2 per cent. in appendicitis operations, Dr. M. M. Johnson and I have each recently published a list of 100 consecutive unselected appendicitis operations with a death-rate of only 2 per cent., and if we wished to make a report on selected cases, omitting abscess and septic peritonitis cases, we could show a death-rate of nil up to date.

Dr. Keen then was wrong, but let us consider for a moment how much more important a matter it is for Dr. Keen to be wrong than for Dr. S. R. Beckwith, for example, to be wrong. Most patriotic members of the profession like to believe that there are as truly great men in our profession as in any other profession to-day. We like to believe that there are no greater surgeons than American surgeons. According to human experience, greatness implies the possession of constructive motives, nobility of purpose, catholicity of view, erudition. It means caution in assertion that is not based on knowledge. When a man has arrived at Dr. Keen's position in the profession, it is our natural tendency to group him among our great men, and so much weight is given to his expressions of opinion that he quickly adds a strong bar to progress in any direction when he discredits advance work without having given attention to the subject. If the argument is made that he was not discrediting advance work, but was simply dissuading members of the audience from expecting such statistics at their own hands, then he was in the position of a teacher of law who argues that legal principles are not to be taught the class because so many members will fail to carry them out in practice. The reports on 2 per cent. death-rate statistics in appendicitis surgery had been made for the purpose of sustaining the principles of treatment that gave such statistics.

In closing, it is no more than right to express a feeling of pride in the results that have been accomplished in appendicitis work by many American surgeons. Let us take for comparison, a showing from France, a report on appendicitis in the French army, by Chauvel, in the *Bulletin de l'Académie de Médecine* for January, 1899. A study of cases of appendicitis in the French army during the last three years, 171 in number, shows that 83 were treated medically and 88 operated on. Medical treatment had a mortality of 4 per cent among those treated before the fourth day, 37.8 per cent. among those

treated from the fourth to the eleventh day and over 50 per cent. of those whose affection was not diagnosed and treated until after the eleventh day. Surgical treatment had a mortality rate of 42 per cent. among those operated on in the first five days, 30 per cent. among those operated on from the fifth to the tenth day. There were two deaths among those who were operated on in the interval. Another point that will amaze American surgeons in these statistics is the fact that the mortality among cases in which the surgeon removed the appendix amounts to 7 out of 18 cases, while in 56 cases in which the operation was restricted to opening abscesses and draining, there were 16 deaths. I make no comments in this grewsome and horrible display, except to say that the way is known for making the death-rate in appendicitis in the French army less than 2 per cent. as soon as the French surgeons choose to adopt methods which give a trifling death-rate. From English reports I am unable to obtain statistics that would not reflect on individual surgeons and this I do not choose to do. Suffice it to say that England is to-day very far in the rear of enlightened management of appendicitis. Germany, which has led the world in medicine and in surgery for many years, shows that in the peculiar field of appendicitis work, methods commonly employed are not representative of German science.

The discussion following this and other papers on appendicitis, read at the same time, will be published at the completion of the series, which will be in about two weeks.

EMPYEMA OF ANTRUM.*

BY HENRY G. OHLS, M.D.

CHICAGO.

From a time at least as early as the meeting of Eneas and Dido, caverns—antra—have been the abiding places of mystery and romance. From a perusal of the literature one might even suspect that the same terms would apply to much that has been written about the antrum. The increased attention given diseases of the nares and the accessory cavities has greatly increased the number of cases recognized within the last two decades. Lennox Browne¹ states that no cases were diagnosed during his association with Sir Morrell Mackenzie, 1866-73. Post-mortem investigation² now brings to light numerous cases not recognized during life.

Anatomy.—Let us refer briefly to the anatomy of the antrum, merely noting its vulnerable points and those peculiarities that give to inflammation of this cavity its peculiar characteristics. It is a closed cavity, except for the ostium maxillare, which is located about 2 to 2.5 cm. above the floor, and opens into the lower part of the hiatus semilunaris, which is often a continuation of the infundibulum in the form of a half tube, according to Fillebrown³. The relations between the frontal sinus, the infundibulum, hiatus and ostium maxillare are well shown in the excellent plates by Howard A. Lathrop⁴ in the Warren Triennial Prize Essay for 1898. The outer border of the floor is often marked by prominences corresponding to the projecting palatal roots of the first and second molars, and less often of the second bicuspid and third molar. The bone covering the roots is often very thin, as is also the inner wall just posterior to and a little below the hiatus. Indeed, the bone is often lacking in the latter location. The infraorbital nerve and the anterior and posterior dental nerves run through canals in the walls of the antrum; 16 per cent. of antra are divided more or less completely by bone septa in

* Read before the Chicago Laryngological and Climatological Society, May 20, 1899.

various directions, according to Eugene S. Talbot⁵. M. Boulay⁶ points out, in addition to these divisions, the diverticula that often extend toward the canines, inward, or into the zygoma. The mucous membrane is somewhat thicker than in the other sinuses, and is provided with more glands. The early development of the antrum, about the fourth fetal month, is also a matter of interest. The size, shape and relations between the antra and the nasal cavities and the palatal arch vary exceedingly. (Zuckerland⁷).

Age and Sex of Subjects.—Gottlieb Kicer⁸, from a study of 200 post-mortems made without regard to the cause of death, including 89 males and 106 females, found a total of 88 empyemas, of which 39 affected the antrum. Of the latter, 1 occurred between the ages of 10 and 20 years; 13 between 20 and 40; 16 between 40 and 60; 9 between 60 and 80. D'Arcy Power⁹ reports an empyema in a child, and Alex Douglas¹⁰ saw a case in a 3-weeks-old infant. M. Rudaux¹¹ reports a case in a 3-months-old child, due to the eruption of a tooth into the floor of the antrum. St. Clair Thompson¹² attributes these cases to acute osteomyelitis of the maxilla, while George Avellis¹³ attributes them to tubercular disease. Lennox Browne¹⁴ thinks the possibility of empyema occurring at a very early age is evident on account of the early development of this sinus as compared with the other sinuses.

Etiology.—Diseases of Teeth: It is a matter of historic interest at least that the only clearly discerned cause of empyema was until a comparatively recent period, caries of the teeth, and the teeth will certainly always demand attention in diagnosis and treatment. But that this is even the principal cause of empyema is more than questionable, though it will require more statistics to gain an exact idea of the relative importance of different pathologic processes. Kicer⁸, in a study of 68 cases found the empyema was dental disease in 65 per cent. F. Berger¹⁵, Ingals¹⁶, Wm. Carr¹⁷, and Geo. W. Major¹⁸ attribute a majority of these cases to a dental origin.

R. C. Myles¹⁹ and C. W. Richardson²⁰ found the teeth and the nose equally responsible. Lennox Browne²¹ found dental caries seldom the cause of acute sinusitis and less often the cause of chronic empyema than was formerly believed. Bosworth²² inclines to a similar view, while at the same time taking exception to Zuckerland's²³ theory that most empyemas were due to an extension of the inflammatory process from the nares. As learning on the relation between diseased teeth and empyemas, the observations of E. S. Talbot⁵ are interesting but not conclusive as to the proportion of empyemas caused by dental disease. In 6,000 antra he found 1,274 abscessed molars, of which 76, or 6 per cent., extended into and discharged into the antrum. Of 384 pulpless teeth, 4 were accompanied by empyema.

The Ostium Maxillare.—The antrum is no less vulnerable from the direction of the ostium maxillare. From the relation between the ostium and the infundibulum above described it is evident that in many cases the antrum receives the drainage from the frontal sinus and the anterior ethmoidal cells. When that secretion happens to be purulent or loaded with pathogenic bacteria, autoinfection ensues. The antrum is subject in short to all the pathologic processes affecting the nasal mucous membrane, though Bosworth²⁰ is undoubtedly correct in the statement that there is rarely direct extension of diseased conditions from the nares into the antrum. Possibly atrophic rhinitis might be considered an exception.

Necrosis in the middle meatus may cause empyema either by direct infection or by obstruction to the ostium.

The principal nasal factor in empyema is doubtless obstruction of the ostium whether that be due to acute rhinitis, hypertrophic rhinitis, influenza, septal or turbinal deformity, polypi or other tumors, foreign bodies, including tampons or traumatism, including cauterization and other operations. Of constitutional causes may be mentioned the exanthems, erysipelas, mineral poisons, syphilis and tuberculosis. Major¹⁸, Watson²⁴, Ingals²⁵ recognized that polypi often caused empyema, but did not consider them the principal cause, as did Bosworth²⁶. H. I. Jones²⁷ found that epidemic influenza was followed by a large increase in the number of empyemas. Saint Hilaire²⁸ saw two cases of empyema induced by plugging the nares to control epistaxis. H. V. Würdemann described an empyema of the maxillary, ethmoid and sphenoidal sinuses with general septicemia following an attempted removal of the inferior turbinate. Henry L. Wagner²⁹ treated a case of seropurulent sinusitis of three years' duration due to lead poisoning.

Pathology.—Without attempting to consider all the pathologic conditions that may be encountered in the antrum it will be sufficient for the present to divide the subject as follows: 1. Acute catarrhal sinusitis, *a*, with patent ostium, *b*, with closed ostium. 2. Subacute sinusitis (*do*). 3. Chronic sinusitis (*do*). The chronic form has been further classified by Lennox Browne³⁰ as 1, catarrhal or mucous; 2, serous or dropsical; 3, purulent; 4, cystic.

Dundas Grant³¹ and Lennox Browne³² adopted, from Lermoyez, the following classification of the signs of latent empyema that certainly leaves little to be desired:

Presumptive: Unilateral discharge, intermittent discharge, infraorbital pain, subjective fetor, upper molar caries, pus in middle meatus, mucous polypi, lateral swelling of cheek.

Probable: Return of discharge on bending forward or to opposite side, opacity on transillumination.

Certain: Puncture and transfusion, puncture and irrigation, puncture and aspiration—1, inferior meatus; 2, alveolus; 3, canine fossa; 4, middle meatus—catheterization, inflation, irrigation.

ACUTE CATARRHAL SINUSITIS WITH PATENT OSTIUM.

Symptoms.—This condition usually develops during the course of an acute rhinitis or more especially in connection with an acute exacerbation of a chronic or hypertrophic rhinitis. The subjective symptoms are discharge, mucous at first, which changes rapidly into a thin canary-colored purulent fluid, often excessive in amount, that runs freely from the nostril or passes into the nasopharynx. The patient often experiences an unpleasant odor that is not apparent to others. The discharge in many cases continues free for a week or more, then diminishes and ceases in from two to three weeks. Pain is not marked but there is usually a sensation of slight pressure over the region of the antrum and some tenderness on pressure over the cheek and brow. There is malaise, slight fever and loss of appetite, sometimes constipation and insomnia—from the annoyance due to the excessive discharge. On inspection the discharge can be seen in the middle meatus or dripping from the middle of the outer border of the middle turbinate. There is usually some hypertrophy or more often an intumescent condition of the turbinates. The diagnosis is easily made and the prognosis favorable as indicated above. It is rarely continued as a chronic disease.

Treatment.—The patency of the ostium should be carefully maintained by applications of cocaine made by the physician, or a small amount of powdered sugar of milk containing 4 per cent. of cocaine may be intrusted to

the patient with directions to insufflate a few grains of the powder three times a day if the nose is stopped. Ingals³⁵ formula, as follows, is an excellent preparation for this purpose:

Sodii bicarb.	gr. i	065
Sodii biborate.	gr. i	065
Mag. carb. levis.	gr. iii	20
Sacch. lact. q. s. ad.	gr. c	50
Cocain mur.	gr. iv	26
M. ft. pulv.		

Mild antiseptic douches followed by oily sprays will add much to the patient's comfort. In some cases the swelling of the tissues is reduced for several hours by the application of a solution of adrenals. In other cases I have used it without effect. To reduce the engorgement of the membranes I would recommend a trial of the injection of hot air into the nares, as used by E. L. Vansant³⁴ for the relief of frontal headache, as he had previously³⁵ applied it to the ear in the dry treatment of otorrhea. Internally tonic doses of nux and quinin are indicated, and usually the discharge is favorably affected by the administration of belladonna and camphor.

Plate 37.—Reproduced from "Annals of Surgery," by courtesy of Dr. H. A. Lothrop, Boston.

Left nasal fossa, external wall, turbinate bone removed. Probe from turbinate fossa to frontal sinus. Arrow is lost in infundibulum under septum between bulla ethmoidalis and uncinate process. Lower portion of hiatus semilunaris obstructed by a small polyp (p) which hangs from the ethmoid bulla (B).
f.a. Fissura ethmoidalis inferior. P, Frontal sinus. f.b. Frontal bulla.

ACUTE CATARRHAL SINUSITIS WITH OSTIUM CLOSED.

When the catarrhal inflammation of the antral mucous membrane is excessive and swelling of the soft tissues about the orifice impedes the free exit of secretions, there is an immediate change in the symptoms. With closure of the orifice there is absorption of air and usually rapid increase and decomposition of the secretions. Halasz³⁰ describes a mild serous form with occasional closure of the ostium. Frohann³⁷ also described a similar condition characterized by pain on pressure over the antrum and toothache occurring in sound teeth early in the morning without constitutional disturbance. The typical case presents a rapid aggravation of symptoms. Pressure on the walls of the antrum increases. Pain becomes the prominent symptom. Usually there is supraorbital pain, and intense neuralgia of any or all the branches of the trigeminus may follow. The tenderness on pressure over the antrum becomes more pronounced, and the sharp neuralgic pain may be varied by the sensation of a red-hot wire along the course of the nerve. The pain varies

in intensity, but there is an almost constant throbbing with frightful paroxysms. There is tenderness of the molars on percussion, even when sound. Redness and swelling of the cheek are rarely if ever present when the inflammation is confined to the interior of the antrum. On inspection the nares may be free from excessive discharge, but the soft tissues will be found swollen and there may usually be found some further cause of obstruction, as deflection or enchondroma of the septum or polypi. Howard A. Lothrop's³⁸ plate number 37 shows a very small polyp blocking the lower part of the hiatus.

Diagnosis.—As pain is such a prominent symptom and often involving the dental nerves, with no discharge to draw attention to the sinus, the condition of the teeth at once demands our attention. Tapping the upper teeth with a steel instrument will determine the probability of the antrum being filled by the lack of resonance³⁹. If pulpless molars or bicuspidis are present, the root canals should be opened. If a palatal root abscess is found, the canal should be enlarged for drainage and treated antiseptically. If drainage is insufficient, or the symptoms too urgent to permit an attempt to save the tooth, it should be extracted and a free opening made into the antrum, the thin plate of bone being probably carious but not allowing sufficient drainage. If, on the other hand, the teeth are sound, we may resort to transillumination of the antrum, for, whatever may be said as to the fallibility of this measure, it is a diagnostic resource of the highest value in this condition. It must be remembered, however, that abnormal thickness of the bone walls of the antrum will make a shadow and that the inflammatory thickening of the lining membrane will maintain opacity for some time after the fluid products of inflammation are removed.

Scheppegrell⁴⁰ has epitomized the indications obtained by different authors as follow: 1. Opacity of cheek, Voltolini—Heryng. 2. Opacity of pupil, Davidson. 3. Absence of luminous sensation, Garel. 4. Lamp under maxillary sinus, not nasal fossa, Ruault. 5. Opacity of nasal wall observed by rhinoscopy, Robertson.

In a case of acute sinusitis, at least in which the disease of the teeth has been eliminated and transillumination gives positive evidence of opacity as shown in Myles' excellent plate⁴¹, I should feel that the diagnosis was quite certain. To confirm the diagnosis and at the same time to relieve the condition an effort should now be made by application of cocain solution to so contract and anesthetize the membrane about the hiatus that probing the ostium may be practiced. To facilitate this procedure it may be necessary to remove polypi about the hiatus. Continental operators⁴² often resect the anterior part of the middle turbinate to gain additional space for passing the probe. Our patients do not often consent to such an operation for our convenience. If probing is practicable, the antrum may be irrigated through the opening or hydrogen peroxid may be injected, a method attributed by Lennox Browne⁴² to his namesake, our distinguished confrere. Keeping the ostium open and irrigating with mild antiseptic solutions ought within a few weeks to produce a cure in the case of simple catarrhal inflammation described. I do not describe the subacute form as being merely a transitional stage. If the symptoms continue over six weeks, we may consider the case has assumed the characteristics of chronic empyema. Probably a large majority of cases never pass through the acute stage above described, but are so mild from the beginning that they are never di-

agnosed unless an acute exacerbation intervenes, especially when occurring with polypi or other conditions that maintain discharge. As we found acute catarrhal sinusitis due usually to acute infection or the result of acute rhinitis, the chronic form is usually associated with some of the more chronic nasal diseases mentioned under etiology. The symptoms of chronic empyema are marked by variability rather than by intensity, being often quiescent for long periods. The periods of increased discharge have often been diagnosed as recurring influenza—Lennox Browne.⁴³ An offensive odor may be the only symptom, as in Bronner's case. Long-continued suppuration with pus passing into the stomach is frequently the cause of serious impairment of the health either through dyspepsia and anemia or through sepsis from absorption; if, then, a few weeks' treatment by irrigating the antrum through the ostium fails to bring about a cessation of discharge, the question of surgical interference must be decided. There are many who puncture the antrum as a routine means of diagnosis. Charles Lucius⁴⁵ says puncture only is pathognomonic. C. H. Knight⁴⁶ warns against exploratory puncture and relates a case in which puncture on three days in succession only revealed pus on the third day, the inference being that if pus was present at first the puncture was inefficient, while if it was not present the puncture probably infected the antrum. Puncture may be performed either in the middle or lower meatus. The middle meatus below and posterior to the hiatus offers the least resistance as the bony wall is very thin or often lacking at that point, but it is much less accessible in the average case. Geo. E. Shambaugh⁴⁷ describes the method of puncturing with a curved needle directed downward and outward to avoid wounding the orbit. For drainage and after-treatment by irrigation the lower meatus offers obvious advantages. Lichtwitz⁴⁸ or Krause's trocar or drills of various kinds may be used, a moderate opening being sufficient for the diagnosis of the presence of fluid. Cohen's drill with canula is one of the best devices. Zeim⁴⁹ prefers Cooper's opening through the palatal border of the alveolus followed by irrigation by a powerful force-pump.

When at last the diagnosis of empyema is definitely established, either by opening the sinus wall or through the alveolus as above described, the route chosen should be enlarged to an average diameter of about one-quarter inch. In the alveolus an Ingals'⁵⁰ double-flanged soft-rubber tube of suitable length may be introduced; or a tube of hard rubber or gold may be fitted and retained if necessary, by attachment to the adjacent teeth. Various devices have been resorted to to prevent food entering the antrum, an occurrence that I have found occurs very infrequently with a tube of moderate size. Mulhall⁵¹ and Meyes⁵² devised tubes with lids or hinges. The danger of improperly constructed tubes slipping completely into the antrum is by no means theoretic, as Cheate, Dundas Grant and Wm. Hill⁵³ have recently reported cases. Wat-on Williams (*ibid*) reported a peg lost in a similar manner but was fortunate enough to recover it via the ostium maxillare without operation. When opening is made in the inferior meatus, a soft-rubber tube may be introduced to prevent too rapid contraction and to facilitate irrigation. Certain cases will recover under irrigation with antiseptics and stimulating applications. Dr. Chas. J. Whalen personally reports peculiarly good results from injections of a solution of 1 to 4 per cent. formaldehyde in water. Few patients like irrigation well enough to continue its use after all discharge ceases, but Law⁵⁴ reports a case in which unnecessary irrigation was practiced daily for three years.

There remains for our consideration a class of cases still large, that experience only temporary relief from the measures advocated; and they will try our patience to the utmost unless we clearly recognize the fact that such degenerative changes in the lining membrane of the antrum or such new growths have developed that a radical operation is necessary. I dismiss without consideration the use of the curette through the small opening hitherto described. Myles⁵⁵ prefers opening the lower anterior border of the malar ridge, sacrificing a tooth. DeRoaldes and King⁵⁴ advocate the Luc operation, cutting away the anterior bone wall of the antrum, perforating the nasal wall and introducing a funnel-shaped soft-rubber tube from the antrum into the lower meatus, curetting all diseased tissues and closing the soft tissues over the defect in the anterior wall. N. Senn⁵⁵ makes a temporary osteoplastic resection of the anterior wall, removes the cause of the suppuration, passes a fenestrated drainage-tube into the naris either through the ostium or an opening made into the middle inferior meatus and projecting into the mouth through a defect cut in the bone flap. Howard A. Lothrop⁵⁶, in a case of combined suppuration of all the accessory cavities of one side, for which all the teeth had been removed and the canine and alveolar operation had been performed, cut away all the naso-antral wall beneath the lower turbinate.

I will describe only two cases of antrum disease, one a personal experience of mild acute catarrhal sinusitis, the other a typical severe inflammation due to a root abscess and followed by recurring frontal headaches. The personal experience occurred in the spring of 1891. As to the etiology, I had been the subject of hypertrophic rhinitis for several years and rarely passed through a winter without one or more severe coryzas with much swelling of the turbinates. On this occasion, at the beginning of the attack I had no reason to anticipate more than the usual coryza. After a few days, however, the discharge became much freer from the left nostril and was accompanied by a heavy feeling in the left antrum, with some tenderness on pressure. For about a week the discharge was thin, canary-colored and excessive in amount; so excessive in fact that the only way I could sleep was lying on the right side with my head on the edge of the bed with a receptacle beneath to catch the constant drip from the nostril. I noticed a peculiar musty or mousy odor which my companions said they could not detect. From the beginning of the coryza to the cessation of discharge was a period of nearly three weeks. Treatment was limited to mild antiseptic douches and, I think, a mild oily spray. Later I had linear cauterization performed on the hypertrophied turbinate on four occasions, and have been almost entirely free from acute rhinitis, though in wet, cold weather I experience an increase of secretion and dropping into the throat.

The other patient was a young married woman who began having severe pain in the upper teeth April 14, 1895. Her general health was poor, due principally to being five months pregnant. Her teeth, never good, showed a tendency to rapid decay. The dentist removed an old filling from the right upper first molar and made the usual applications to kill the root nerve, without mitigating the pain, which grew more intense. She finally consulted another dentist, who advised extraction, which was performed by Dr. Slonaker under gas anesthesia on April 25. The ache in the side of the face continued, with severe neuralgic pains shooting through the branches of the trigeminal and the facial. May 5, Dr. C. L. Wright removed a filling from the second molar and

found pus in the pulp cavity. May 7 I examined the antrum, at Hinsdale. Finding that my chemical battery would not heat Dr. Ingals' electric lamp, I substituted an ordinary electrode of coiled No. 20 platinum wire protected by a two-dram vial. The right antrum was opaque. The turbinates were moderately swollen but no unusual discharge was detected in the nose. Dr. Slonaker thereupon extracted the second molar under gas, and enlarged the opening into the antrum. Three or four drams of thick pus escaped. The antrum was irrigated through the maxillary opening, the irrigating fluid passing into the naris without the slightest difficulty. Diluted peroxid of hydrogen and a saturated solution of boric acid were used through a bent Eustachian catheter twice a day for two weeks. The opening then becoming contracted, I advised enlarging the opening and introducing a tube. As further operative interference was absolutely refused I devised a tube from an ordinary hard-rubber connector to fit the opening in the bone. It was 3 mm. in diameter and 25 mm. long, with a round collar at the lower end. This allowed free drainage without permitting food to pass into the antrum except on rare occasions. For a few weeks longer the antrum was irrigated daily until the discharge ceased. At no time was there any redness or swelling of the cheek.

The patient has worn the tube to the present time, fearing a repetition of her experience with a closed antrum. She has been subject to occasional severe frontal headaches lasting from one to three days usually following an exposure to cold air. Sleeping in a cold room is sure to be followed by a frontal headache. The lower and middle turbinates of both sides, and submucous swellings on the septum, have been repeatedly cauterized without materially modifying the character or frequency of the headaches. And in spite of the cauterization the turbinates remained puffy. On looking about for an apparatus to apply hot air, as recommended by Vansant²⁴ I saw a machinist's oil-can with a long nozzle which can be heated without injury over a Bunsen burner or spirit lamp. The hard-rubber tube and nasal tip enables the patient to inhale air as hot as can be borne. The entry of cold air is regulated by inserting a perforated cork in the inlet. The heat can be retained longer by placing pieces of electric light carbon in the can. The patient has only recently used this apparatus but found the hot air very grateful. The pain was relieved in a short time instead of persisting two or three days as formerly.

DISCUSSION.

DR. W. L. BALLENGER.—There are two points in Dr. Ohls' paper to which I wish to refer: the use of a cautery electrode protected by a two-dram vial as a transillumination lamp; and the liability of improperly selected or applied drainage-tubes to enter the antral cavity. For about four years it has been my custom to use an electrode in the manner described by the essayist for transillumination purposes. I read somewhere of the method and adopted it, with very satisfactory results. I have also used the Heryng lamp and find it adapted to a much greater variety of uses than the electrode lamp.

About two years ago Mrs. B., wife of Dr. B., of a suburban city, consulted me concerning a chronic empyema of the antrum of Highmore. She had been previously treated by her husband and a local rhinologist, who opened the antrum between the first molar and bicuspid. Not having a suitable antral tube a piece of black soft-rubber tubing was used instead. A few weeks later the tube disappeared and it became a question of some importance as to whether the tube had entered the antrum or had been discharged externally. At this stage I was consulted. I attempted to explore the antrum by means of probes and solutions, but did not arrive at a definite result. A few weeks later she consulted me again, and as the discharge had abated considerably, we decided not to enlarge the antral opening as planned, but to continue the treatment by frequent irrigations. Three months later I received a letter from her stating that during a violent attack of sneezing the long lost drainage-tube was expelled through her nose. It had been carried in the antrum for nearly a year. I subsequently did a radical operation, removing the anterior wall of the antrum, and found the cavity filled with edematous granulation tissue. This was removed with a curette and the cavity packed with gauze moistened with the compound tincture of benzoin. I may say, briefly, that the case went on to complete recovery. As I expect to report the case more fully at another time I will not give further details now.

DR. GEO. E. SHAMBAUGH.—I wish to say a word about the use of the term "infundibulum," which we find used in a variety of senses. Sometimes it is applied to the anterior extremity of the hiatus semilunaris, sometimes to the nasal extremity of the nasofrontal duct, which may or may not open into the hiatus semilunaris. Zuckerkandl, who is a good authority on the anatomy of the nose, uses the term "hiatus semilunaris" as applying to the mouth of a depression several millimeters deep which runs its entire length and which he calls the infundibulum. It is in the depth of the infundibulum, therefore, near its posterior end, that the ostium maxillare is found, while the anterior extremity of the infundibulum as a rule opens into the ostium frontalis, which leads into the frontal sinus. The Anatomical Nomenclature Commission, in 1895, gave the term "infundibulum ethmoidalis" to the entire space between the uniform process of the ethmoid and the bulla ethmoidalis.

DR. J. HOLINGER.—Empyema of Highmore's antrum was

considered of rather infrequent occurrence about ten or fifteen years ago. The oftener we look for it, the oftener we find it. At first only the typical forms with large accumulations of pus were diagnosed; catarrhal forms have been recognized only lately. I am thankful to Dr. Ohls, because I learned things that were new to me. I would like to ask whether the etiologic factor, caries of the teeth, is not pushed too much in the foreground? This is the reason why I put this question: Last summer I treated a boy of 15 years whose empyema recurred several times. At each recurrence one or several teeth were extracted, so that he had not one tooth in his upper jaw. Even at the side where he had no empyema not a tooth was left. He was cured after Dr. Oswald and I chiseled away bone plates at the lower and anterior angle. I saw him repeatedly last winter and spring; no recurrence can be found.

Dr. O. T. FREER.—In cases where the antrum is divided by septa, into separate compartments, the drill or trocar entering the antrum through the alveolar process or beneath the inferior turbinate body, may penetrate a compartment containing air, while the one filled with pus may not be entered at all. The great pain felt by patients when the alveolar process is being drilled through amounts to acute agony. Dr. Ohls states that Continental operators remove the anterior half of the middle turbinate body in order to gain access to the natural opening of the antrum for the purpose of exploration. From my memory of the literature on the subject of empyema of the accessory sinuses, the middle turbinate is resected chiefly in order to gain access to the frontal sinus, as when the hiatus semilunaris is thus exposed we get an easier approach to the natural opening of the frontal sinus where it enters the infundibulum.

A. M. CORWIN.—My personal experience with empyema of the antrum includes eight or ten cases. In only one of these were polypi present, and I could not decide whether these were the result or the cause of purulent process. Whatever the relation between these conditions, in some cases nasal polypi do not seem to be a frequent cause. In the large number of cases of polypi that occur, how seldom do we find antral disease. One of my cases of some months' duration, in a medical student, was of interest because I succeeded in curing it entirely by making an opening with a small trephine, above the alveolar process in the canine fossa, through which the cavity was washed by mild antiseptics, an ordinary Eustachian catheter being passed. In another case, a dentist had removed a tooth and put in a gold tube and treated the patient for months without recognizing the specific process which was evidently present, as manifested by a gumma of the hard palate and nasal ulceration on the corresponding side. There was profuse purulent discharge from the antrum through the normal opening. The removal of the tube and the granulation which partially filled it and surrounded its upper end, and the simple washing out of the cavity and the exhibition of iodid brought about prompt recovery.

Dr. JOHN A. ROMSON.—I did not notice that Dr. Ohls, gave as one of the causes of empyema of the antrum, malignant disease. I think it should be included, as empyema is often one of the forerunners of carcinoma of the antrum, as was well illustrated in a subject who came under my observation in February. Mr. S., aged 70, consulted me for the purpose of having a diagnosis. He said he had noticed, two months previously, pain in his eyes, more severe in the right eye, which increased in severity day by day. He had been subject to nasal catarrh for some time before, the amount of secretion being great, and the nasal passages closing toward night, the right being worse than the left. For five weeks previous to consulting me the right eye had been congested, the right maxillary bone tender, and the soft tissue of the right cheek swollen. He had been under the constant treatment of a homeopathic physician for ophthalmia, but obtaining no relief, had decided to make a change. An examination revealed the presence of empyema of the antrum, and the signs also pointed quite conclusively to malignant disease being the primary cause. Dr. Senn operated by opening and draining the antrum on February 28. There was great relief from the painful symptoms, but notwithstanding a thorough euretteage of the cavity, a second operation was necessary on March 11, when a portion of the maxillary bone and the carcinomatous mass were removed. The patient was discharged from the hospital on April 10. Some years ago I saw a case of empyema the result of carcinoma of the antrum, in which the cancer extended to the eye, and there was secondary carcinoma of the liver with ascites. The eye was enucleated and the antrum drained, but the patient later succumbed to systemic infection.

INTESTINAL ANASTOMOSIS.*

BY J. HENRY BARBAT, M.D.

SAN FRANCISCO, CAL.

The question as to which method of intestinal anastomosis is the best is still unsettled; each deviser of a new method claiming his method or device to be superior to all others. Not having any method or device of my own I have endeavored to find out which was the most feasible for the use of the average surgeon; and also to determine which gave the best results. A method which requires extraordinary skill and a large amount of practice to perfect is not a feasible one for the average operator. With regard to results the case is different; we can demonstrate the difference between the results attained by the various methods by removing the specimens and subjecting them to microscopic examination. The ideal result would be the accurate apposition of the respective layers of the intestine without the interposition of any scar tissue; therefore the nearer we approach this ideal the better will be our result.

I have conducted a series of experiments on dogs; confining myself to circular enterorrhaphy of the small intestine; I adopted this variety of anastomosis because the results better demonstrate the value of the method used, and it is conceded that it is the most difficult to do properly, besides it is the only method which restores the bowel to its natural condition; and is the operation which should always be selected when no contraindications exist.

Before detailing my work allow me to recall to your mind the minute anatomy of the intestine. The intestinal wall consists of four coats, starting on the outside we first have the peritoneum; next to the peritoneum is the layer of longitudinal muscular fiber; on top of this and closely adherent to it we find the circular muscular layer, which is in the small intestine about three times as thick as the previous one. The next coat is the submucosa or fibrous layer and on top of this the mucosa.

These various layers each have a special significance in surgery; the peritoneum is simply a protecting coat and does not stand much strain, especially when inflamed, but is of especial value after injuries by pouring out lymph which prevents leakage and covers over the exposed surfaces. The muscular coats are of no consequence from a surgical standpoint as their function is simply to move the intestinal contents along, and a failure to get union would only cause a break in the peristaltic wave, which would not impair the integrity of the bowel. Muscle tissue after being cut will never repair in such a manner that the muscle cells will cross over the point of division; there will always be a layer of scar tissue between the muscle cells at the point of union. The submucosa is the tough membrane which gives the bowel its strength; it is impervious to gas or liquid and it has been clearly demonstrated by Halsted that it is the only coat which possesses the strength necessary to support the strain of sutures in an enterorrhaphy. The mucosa is a purely functional layer and is of no importance as far as the strength of the gut is concerned.

It will thus be seen that in order to have a secure anastomosis the peritoneum and submucosa are the only coats which are essential, therefore the method which approximates these coats the earliest must of necessity be the best. Now let us see the result of the various methods immediately after the question and see which one gives the best approximation.

* Based on Experimental Research done in the Medical Department of the University of California.

A careful examination of *all* specimens obtained from suture operations showed the peritoneal coats in apposition—except at the mesenteric attachment—and the other layers in their natural relation, except at the points where the sutures had been passed. At these places the muscularis and mucosa were cut through, allowing the submucosa to come together with the intervention of the peritoneum only.

tion of the parts varies but little in any of the suture operations; we have at the point of union a double layer of intestine, with the two peritoneal surfaces in contact and the cut ends of gut projecting into the lumen of the bowel; naturally at the point of mesenteric attachment there are no peritoneal surfaces, and we find here the most accurate apposition of layers that is obtained in suture methods.

Suture—42 days.

Murphy button—65 days.

In the Murphy button specimens the muscularis and mucosa were pressed out of the way completely so that the peritoneum and submucosa were the only coats left between the jaws of the button around the whole circumference of the gut; even at the point of attachment of the mesentery the peritoneum was infolded so that there was no uncovered surface at any point. With the

This is due to the fact that the intestine is not invaginated at this point to the same extent that it is where the bowel is covered by peritoneum, and therefore there is a better chance to bring the corresponding layers in apposition at this point. After a period varying from four to six weeks we find that the mucosa begins to grow over the cut ends and thereby becomes continuous, but the

Suture—36 days.

Frank coupler—20 days.

Frank coupler the mucosa was pressed out but the muscularis was still intact. These results prove that the Murphy button places the parts in the best relative position for proper union, at the start.

By examining the specimens removed at given intervals we can watch the process of repair and determine the value of the result obtained. We find that the rela-

other layers maintain their normal relation except where the sutures have cut through the mucosa and muscularis; at these points we find the peritoneum continuous on the outer surface of the bowel and the submucous layers in contact. But this approximation is only found at the circumference of the intestine where the sutures have

been placed, and there therefore remains a double layer of gut projecting into the bowel with only the peritoneal surfaces in contact. If we follow these cases we will find that the connective tissue which is formed between the approximated surfaces begins to contract and, as the amount of contraction depends on the amount of scar tissue it necessarily follows that with the two comparatively wide surfaces which we get in

nothing but the peritoneum and submucosa; the mucosa is lacking over the line of approximation for a variable distance, usually not more than one-twentieth of an inch, and as I stated, a regeneration begins from four to six weeks after. We find the connective tissue gradually absorbing, except at the submucous layer, allowing the closer approximation of the muscular layers, but never

Murphy button—36 days.

Suture—90 days. Showing result usually obtained by suture.

all suture anastomoses we will have considerable contraction. Moreover, the diaphragm, which is formed by the double layer of intestine, contains circular muscular fibers and we will have a continuous contraction of these fibers within the ring of the bowel. In the Murphy button cases we have a different condition of affairs; immediately after the comple-

disappearing completely or allowing the muscle cells to cross the line of union.

We therefore have in a specimen which has ceased to change, the following arrangement: the peritoneum is continuous and the blood-vessels and lymphatics are seen to cross over from one side to the other; the two muscular layers are in line and in close contact, a layer of con-

Murphy button—57 days.

Murphy button—36 days.

tion of the operation we have the peritoneum and submucosa only at the point of union, i. e., in the bite of the button.

The ends of the intestine, which are within the interior of the button, are held by these layers until the pressure necrosis which takes place liberates the button. After the button has passed, we still have at the point of union

nective tissue preventing the cells from passing across; the submucosa forms a continuous layer, the direction of the fibers being parallel with those on each side; there is usually a slight thickening at the point of union. The mucosa is completely regenerated, except its muscularis which, like the other, comes in close contact without being continuous. The results obtained with the Frank

coupler are similar to those with the Murphy button. I was unable to obtain any of Chaput's buttons and can not therefore judge of its comparative value. The perfection of the result depends to a considerable extent on the accuracy of the technic, and the character of the intestine that is being operated on, a thin gut giving a very different result from one that is thick or slightly inflamed; this holds good no matter which method of anastomosis is used.

of the gut till it met the end of the first stitch. The ends are tied, being careful that all knots are within the lumen of the bowel; this accurately approximates the cut edges layer to layer. A superficial stitch is then placed, keeping as close to the line of union as feasible, so as to produce as little invagination as possible; it is essential that the sutures be very accurately placed or we will have leaking.

Murphy button—65 days.

Murphy button—36 days.

With regard to technic, I have been able by suture approximation to obtain results which equalled those obtained by any other method; but this requires considerable practice and there are few men who have the time or opportunity to perfect themselves in this line of work. The method which yielded the best result was as follows: a very fine catgut suture was inserted, beginning at the

This method is not as safe as those which turn in a wider portion of bowel, but anatomically it gives the best result of any of the suture methods and equals in some instances that obtained by the use of the Murphy button. The various methods which necessitate the use of cylinders of various substances from potato to rubber, or forceps to hold the cut ends in position during the opera-

Murphy button—47 days.

point of attachment of the mesentery, and passing through all the coats of the bowel, keeping as close to the cut edge as possible. The suture was passed across from one cut edge to the other until it reached a point opposite the beginning; a second suture was begun at the same point as the first and continued around on the other side

tion, do not yield any better results, in fact the results are not as good as may be obtained without mechanical assistance. All these devices entail the invagination of too much intestine and therefore there will be more contraction than if we use some other method which does away with this feature.

The technic to be observed in introducing the Murphy button is as follows: a puckering over-stitch is introduced, beginning at a point opposite the attachment of the mesentery and continued around the cut end of the bowel and the beginning, taking a special stitch through the mesentery. This special stitch is of great importance as it draws the mesentery into the bite of the button and insures against having the uncovered space at this point. The two halves of the button, held in forceps, are introduced and the sutures tied. It is well to place the half which has the spring in last as it is more difficult to hold it in position after its introduction than the other portion. All that now remains to do is to push the two halves together, being careful that the mesentery is in line. Care must be observed in placing the suture to have it close to the cut edge of the intestine, especially if the mucosa is thickened, or it will be found impossible to pull the whole thickness of the bowel into the bite of the button.

With regard to the dangers which have been claimed by the opponents of the Murphy button, I have analyzed them all and find that there are very few real ones. The

I was explaining to the gentlemen who were assisting me the necessity of always providing sufficient arterial supply to the cut ends, even if it should be necessary to remove an inch or two more of the bowel, and at the same time committed the error I was warning them against, showing how watchful we should be in this respect.

One thing which has caused many accidents is a defective button, and unfortunately we find the market flooded with poorly constructed buttons. Not all operators are capable of judging whether the button they are about to use is mechanically perfect or not. There are very few buttons in the market which conform in every particular to the requirements we expect to find in a perfectly constructed article. The closed button should be perfectly smooth all over and the drainage holes should not have sharp edges; the largest diameter should be where the two halves came together; the spring must be sufficiently strong to completely cut off the circulation of the ends of the bowel, which are within the button, or else necrosis can not occur and the button will not be passed; this has occurred in many cases. The pressure

Suture—57 days.

Murphy button—3 days. Showing mucosa and muscularis pressed away at point of union.

majority are due to faulty technic, or faulty buttons. In some cases the two halves are not pushed together sufficiently tight to cut off the circulation or to cut through the mucous and muscular coats; in these cases the button may remain as a permanent fixture, with more or less serious effect according to its locality. In two cases which I saw, the silk ligature that was used to draw the bowel over the button was cut so long that it projected out beyond the jaws and prevented its escape; in both cases the buttons were removed and the reason of the failure clearly demonstrated; this disaster may be averted by using catgut instead of silk.

With regard to sloughing and necrosis, I have yet to see a case that was directly due to the presence of the button: in the majority of cases in which this accident has happened we will find that the operator has neglected to provide for the nutrition to the cut end of the gut by cutting on the wrong side of one of the mesenteric vessels, or by including the vessel—which is oftentimes found on the very edge—in the suture which approximates the divided mesentery. This accident happened to me in one of my cases of circular enterorrhaphy.

edges must not be too wide or necrosis will not take place as soon as it should, and a wider ring of scar tissue will be left than if the edges are narrow.

The only real danger which I can conceive is the possibility of a button getting caught at the ileocecal valve, and I believe that this is more theoretical than real, because in my experiments on dogs I was obliged, in some cases where the intestines were smaller than the button, to stretch the gut with forceps before it could be introduced. Notwithstanding this all the buttons were passed without any trouble. In a few cases it has happened that the button has fallen into the stomach after gastro-enterostomy has been performed; this can easily be obviated by having the half of the button which goes in the stomach of a little smaller diameter than the other, when it will be impossible to have the button go the wrong way. I have utilized this method by taking two buttons of different sizes and using the male half of one and the female half of the other; and in two cases of gastro-enterostomy in which I used these altered buttons, I found them to work perfectly.

The Frank coupler gives a result which approaches

closely to that of the Murphy button, and the idea of having absorbable ends is a good one; but we have to place our entire dependence on a piece of rubber tubing, the strength and elasticity of which we are not capable of judging, and which varies with age. The decalcified bone ends are sometimes found warped out of shape and cannot then approximate as accurately as they should. In one of my cases in which I used the coupler there was slight leakage at the point of mesenteric junction, which caused a localized abscess to form; fortunately, however, it did not cause death.

The cause of the leakage was insufficient pressure on the folded-in mesentery, just after the completion of the operation; the exudation of lymph, which occurred shortly after, evidently closed the interstices between the mesenteric layers, because the line of union was found to be perfect except at that point, and the infectious material was found completely encapsulated. It will be remembered that the special stitch which is taken through the mesentery draws in an extra fold of peritoneum, increasing the thickness of the gut at that point, and in the case of the coupler making it a source of danger at that spot, as the rubber may not be sufficiently strong to press the layers tight enough to prevent leakage.

With regard to the apposition of the coats of the bowel, the Frank coupler gives as good results as any other method, but the device as made at present is not as safe as the Murphy button.

One point that was noted in my work was that fewer adhesions were found at the line of union in the button, than in the suture cases; this is due to the fact that in

all suture operations the stitches pass through the outer coats of the intestine and there is always some slight oozing of blood at the stitch holes, which increases the tendency to adhesion. On the contrary, in the button cases there is never any bleeding at the line of union and no exposure of sutures to tend toward the production of adhesions.

One thing to be observed in using mechanical devices is to use the largest size which can be easily introduced into the bowel, as it must necessarily follow that the diameter of the opening left by the button will be slightly smaller than the button itself, and if we use any device whose diameter is considerably less than that of the intestine we are sure to have contraction follow.

The conclusions which I have deduced from my experiments are as follows:

1. It is possible to make a safe and satisfactory end-to-end anastomosis.
2. With practice, a surgeon can, with nothing but a needle and thread, sew a divided bowel together and obtain a result which will almost equal that obtained by the use of the Murphy button.
3. The result obtained by the Murphy button is superior to that of any suture method yet devised.
4. The Murphy button and Frank coupler give the same anatomic result.
5. Contraction following end-to-end anastomosis is usually due to faulty technic.
6. The Murphy button is much safer and more reliable than the Frank coupler.

7. A perfect Murphy button, properly introduced, is the quickest, safest, and most reliable means of obtaining an anastomosis between any two viscera.

8. All devices which are used to support the gut in suture operations are unnecessary, and as good, if not better results, may be obtained without them.

My thanks are due to Drs. F. B. Carpenter, George H. Evans and Wm. Barbat for their able assistance in the work on which the paper is based.

MONSTROSITY OR DOUBLE FETUS.

BY J. E. BENTON, M.D.

CENTRAL CITY, MEB.

Myself and father, Dr. E. A. Benton, were called in consultation by Dr. W. N. Hunt of this city at 1 p.m., June 15, 1899, in the case of Mrs. D., a multipara in her fourth confinement. She had been in labor for about twelve hours with a vertex presentation in the first position, and strong labor pains for several hours after complete dilation of the os had failed to advance the head beyond the lower third of the pelvis. From

external examination and the history of the case, twin pregnancy was diagnosed, and under chloroform, forceps were applied and the head brought down with considerable difficulty through the external parts; but no more progress could be made toward delivery. We then concluded we had to deal with some kind of monstrosity. We amputated the head and tried to turn or bring it in position to deliver, but failed. We then brought down arms and shoulder and amputated all, but failed to deliver. We commenced hasty preparations for a

Cesarean section, but patient began sinking rapidly and died in less than an hour, although every effort was made to sustain the heart action. There was no hemorrhage or assignable cause for death other than shock. Post-mortem was made two hours after death and the monstrosity removed; amputated parts were stitched on. The accompanying photographs show the peculiar formation as much as possible, and it explains nearly all. The sex could not be determined. The caudal appendage so plainly seen in back view is undoubtedly a rudimentary development of a leg, it contained a bone and joint, evidently a knee-joint. The weight of the monstrosity was twelve pounds.

ANASTOMOSIS OF BLADDER TO RECTUM.

EXPERIMENTAL RESEARCH THEREON: A PRELIMINARY REPORT.

BY JACOB FRANK, M. D.

Surgeon to the St. Elizabeth and German Hospitals; Consulting Surgeon to the Jewish Orphan Home and Home for Aged Jews, Chicago; Corresponding Member of the Sociedad Médica "Pedro Escobedo"; Member of the Pan-American Congress, International Medical Congress, American Medical Association, etc. CHICAGO.

In the spring of 1898 a series of experiments on the unilateral and bilateral implantation of the severed ureters into the rectum was conducted after a special method of my own, with the object of relieving many of the grave pathologic conditions arising in the bladder, that are aggravated by the presence of urine, or in congenital malformations, as exstrophy, as well as the avoidance of a nephrectomy for neoplasms involving the ureters, or injuries to the ureters in laparotomies. The ultimate results of these were discouraging, although the operative technic was all that could have been wished for. From the knowledge and experience gained, and keeping in mind the numerous pathologic conditions to which the bladder is heir, the plan of anastomosing the bladder to the rectum seemed feasible and was carried out on fifteen dogs, with good results. After looking over all the available literature upon the subject of exstrophy of the bladder, etc., I find no one attempting this method, and therefore I think I may claim originality for the same.

The operation consists of anastomosing the bladder to the rectum with my decalcified bone coupler, a description of which can be found in the *Medical Record*, Oct. 3, 1896, the *JOURNAL*, June 19, 1897, and in *Medicine*, January, 1897. The technic is as follows: in a male dog the incision is made in the groin, and in a bitch in the median line. Generally the bladder is found distended, and is emptied by squeezing it gently with the hand, when the urine escapes through the natural channel. The rectum is next picked up and freed of its contents, as in any intestinal operation. The bladder and the rectum are then brought forward and placed in position for anastomosis. Two or three interrupted Lembert sutures are now taken about half an inch below the lower ends of the incisions determined upon in the bladder and rectum, care being exercised in selecting them that the coupler, when it is inserted, will not encroach upon the ureteral openings in the bladder. A longitudinal incision is then made in the bladder large enough for the coupler selected, and a puckering string applied over and over the cut margin. The rectum is next opened in its long axis and a puckering string similarly applied. The suture should be taken so that the free ends lie uppermost, thus facilitating easy tying. The operator now slips the coupler into the bladder opening, at the same time gently spreading the collars apart, while an assistant makes one knot and draws down on the puckering string until the rubber tubing is felt; another knot is made and the ligature cut off short. The other half of the coupler is then slipped into the rectal opening and likewise tied and cut off. Several interrupted Lembert sutures are taken around the borders to make the work more secure. The operation is very simple and can be accomplished in ten or fifteen minutes.

Of the fifteen dogs operated upon, ten recovered and five died. Post-mortems showed no septic conditions of ureters or kidneys. In the first two experiments the technic was not thoroughly understood, and a large amount of unnecessary work was done. Several of the

dogs that recovered were killed for pathologic and bacteriologic examination. Three are still living—the longest three months—and it is my intention to keep these somewhat longer and then kill them for the further study of the effects of the operation upon the ureters, kidneys and site of anastomosis. The dogs pass three or four watery stools a day through the rectum, and the male dogs hoist their legs in the act of micturition but without accomplishing it through the penis. The animals are playful and lively after recovery, and one not knowing an operation has been performed would have no suspicion aroused.

In the first six experiments a $\frac{3}{8}$ inch coupler was used, but later in large dogs a $\frac{7}{8}$ inch, and in smaller dogs a $\frac{3}{4}$ inch coupler was inserted. The small piece of rubber tubing has never failed to pass away. Silk was used in all experiments. The following pathologic and bacteriologic reports of experiments 4 and 13 were made for me by Dr. Maximilian Herzog:

EXPERIMENT 4.—Male dog, weight 22 pounds; operated on May 6, 1899, killed May 21, 1899. At the post-mortem examination the following technic and inoculations were made: The ureters of both kidneys were ligated a short distance below their origin from the pelvis, and the kidney removed. A platinum loop previously heated was introduced through an opening—made under the usual aseptic conditions—into the pelvis of each kidney, and a blood-serum and glycerin-agar tube inoculated from each side. Of these four culture-media three remained permanently sterile. One blood-serum tube on the third day showed a moist, shiny, whitish growth which liquefied the culture soil. The growth consisted of very small bacilli, the character of which was not studied any further. They were not colon bacilli, and their appearance was probably due to contamination. At the site where the anastomosis was made the tissue appeared perfectly smooth and normal. No redness or swelling was noticeable to the naked eye. Microscopic sections made from this part, including both the bladder and rectum, were stained by various methods.

In the rectum the following conditions were noted: The intestinal and bladder walls have completely united, and blend in such a manner that the two tissues form an acute angle of about 80 degrees, which projects into the bladder. The intestinal surface is lined by mucous membrane, the bladder surface by stratified epithelium. Both these tissues present a normal appearance. They do not come completely together. On one side the intestinal mucous membrane becomes thinned out, on the other layers of epithelial cells lining the bladder become gradually reduced to a single layer. It appears as if from here the epithelial cells were in the act of growing over to reach the mucous membrane, although a small strip of tissue has not yet been covered by epithelial cells. Here connective tissue lies free to the surface. This connective tissue consists of cells of an embryonal type and of fibroblasts. The union between the bladder and rectal walls is complete throughout their whole thickness. One generally cannot distinguish—at the line of the union—what was originally bladder and what was intestinal tissue. The mucous membrane of the rectum, and the epithelial lining of the bladder have entirely disappeared at the line of union. Still one can see the lymphoid tissue of the rectum at the site of the union, although the lymph follicles vary from the normal in that they show a diffuse infiltration of polymorphonuclear leucocytes. So numerous are the latter that they predominate over the cells of a lymphoid character.

Gram's stain shows, in the tissues of the anastomosis around the line of union, short bacilli with rounded ends, which have poorly kept the stain. These micro-organisms are probably colon bacilli. The examination of the kidney tissues—cortex, medulla and pelvis—show normal conditions, with no evidence of inflammation or degeneration.

EXPERIMENT 13.—Bitch; weight 40 pounds; operated on June 1, 1899, killed June 28, 1899. The animal is well nourished, in perfect health, very playful and lively; killed by chloroform narcosis. Externally the abdomen presents in the median line, beginning about an inch above the symphysis pubis and extending upward for a distance of about $2\frac{1}{2}$ inches, a healed, smooth, linear cicatrix. Upon opening the abdomen by a long median incision, the large omentum is found very slightly adherent to the internal surface of the abdominal parietes at the site of the cicatrix. The extent of these adhesions is very small. The omentum shows no signs of inflammation.

The abdominal and pelvic cavities do not contain any fluid. The peritoneum is smooth and shining, and shows no redness or evidence of inflammation. The bladder is well contracted, firmly united to the rectum, and the place of union is everywhere covered by an uninterrupted coat of smooth peritoneum. An inspection of the intestines shows them to be normal.

The kidneys are now freed from the surrounding connective tissue, and a heated platinum loop introduced into the pelvis, and cultures made under the usual aseptic precautions. The ureters are then dissected free and the kidneys, ureters, bladder and part of the rectum removed.

The kidneys are of normal size and appearance, but, like all the internal organs, are congested in consequence of the death by chloroform. Cortex and medulla show normal relation and appearance. The pelvis do not contain any appreciable amount of fluid. The mucous membrane of the pelvis is smooth and pale, and presents no signs of inflammation. The ureters are not enlarged. The internal surface of the bladder, which contained some fecal matter, is thrown into rugae. In color it is pale pink, and microscopically shows no inflammatory changes. The anastomosis is firm, and admits the tip of the index finger. The anterior aspect of the ring is lined by bladder tissue, the posterior by rectal mucous membrane, which appears perfectly normal. Where the tissues from the bladder and the rectum meet, there is a slight depression which runs along the whole opening. The rectal mucous membrane in the neighborhood of the anastomosis appears normal. All internal organs, such as spleen, liver, lungs, heart, etc., are in a normal condition.

MICROSCOPIC EXAMINATION.—Pieces of tissue were fixed in Zenker's fluid, imbedded in paraffin, and stained by various methods.

ANASTOMOSIS.—The union between the wall of the rectum and that of the bladder is perfect. There is no doubling up of either intestinal or vesical tissue, and the line of union contains very little newly-formed connective (ciatricial) tissue. No evidence of inflammation is found in the line of union. The rectum presents a normal histologic appearance. The internal surface of the bladder, however, shows some marked changes. The lining epithelium at and near the point of union is missing, and the tissue forming the surface has the character of granulation tissue. It consists of a vascular tissue formed of round cells imbedded in a matrix of fusiform cells and connective-tissue fibers. It appears, therefore, that the presence of the fecal matter with its numerous bacteria has set up an inflammatory reaction on the internal surface of the bladder. Bacteria, however, were not found in the granulation tissue, nor in the tissue forming the line of union between the bladder and rectum. The following very interesting observation was made at the line of union: In some places the columnar epithelium of the rectal mucous membrane has grown from the rectal tissue over to the bladder surface. This covering of the bladder surface by intestinal epithelium is not yet very extensive, but there undoubtedly exists a marked tendency of the intestinal epithelium to grow by extension over the bladder surface and cover it, which, in consequence of irritation, has lost its own epithelium. In both kidneys the pelvis, medulla and cortex present no appreciable histologic changes, and no signs of inflammation or degeneration. There are found, however, a few micro-organisms in both organs as follows:

Right kidney, in tissue near the surface of the pelvis, bacilli, a few diplococci and some deeply staining round bodies which look like either torula saccharomyces or protozoic bodies; in the cortex a few bacilli in the convoluted tubules and in Bowman's capsules.

Left kidney, in tissue near surface of the pelvis, a few bacilli; in the cortex likewise a few bacilli.

These micro-organisms are nowhere found in large numbers but only seen sparingly here and there.

BACTERIOLOGIC EXAMINATION.—Two glycerin-agar tubes were inoculated from the pelvis of each kidney. Of each of the two groups one developed a growth, consisting in each instance of a mixture of bacilli—colon as it appears—and diplococci.

Epiërisis: It must be conceded that both kidneys in this case had become infected. But it appears moreover that the infection must have only recently occurred. The number of micro-organisms found in the kidney was not large, and there were not yet present any appreciable histologic changes. The mucous membrane of the bladder, it appears, in consequence of the irritation from the fecal matter, had lost, in part at least, its epithelium and had developed signs of a reactionary inflammation. It is not unreasonable to suppose that the infection which had occurred might have been prevented

by regularly washing out the bladder, which, in the case of a dog, cannot be well done, but which could be done with a human patient.

The above is only preliminary to a complete paper which will be published in a short time, containing a detailed account of all the experimental work, together with microphotographs, photographs of the gross specimens and drawings illustrating the technic.

SEEING CAPILLARY CIRCULATION IN ONE'S OWN RETINA.*

BY C. E. NORTON, M.D.
LEWISTON, ME.

This paper is presented to the ASSOCIATION for three reasons: 1, the subject has a scientific interest; 2, it has a practical bearing; and 3, I have presented it for a personal reason. I have written a short note on this subject before. On reading this note some oculists and other scientific men have expressed the opinion that the phenomena seen are not due to the capillary circulation, but are due to *muscæ volitantes*. Believing, as I do, that it is possible to see the corpuscles of the blood moving in the capillaries of the retina and that these corpuscles are not the same as *muscæ volitantes*, nor should they receive the same name if we wish to preserve scientific accuracy in our nomenclature, I have written this paper, in which I endeavor to demonstrate the accuracy of my belief.

Over twenty years ago I discovered that while looking at a clear sky through a piece of dark blue glass I was able to see small, bright objects moving in all directions with a peculiar jerky motion. Later experiments showed me that these bright objects could be seen more plainly if several thicknesses of glass were used. I have never failed in endeavoring to demonstrate this phenomena to others. I have found that the same thing can be seen by the use of glass of other colors, but it is plainer with the blue than with any other glass that I have used. I can explain the action of colored glass only on the theory that the high color obscures the vision of external objects and allows the attention to be concentrated on entoptic phenomena and the bright color furnishes a homogeneous background which affords a proper contrast when the entoptic vision is projected on it.

I will endeavor to answer the question: "Why is this phenomenon not due to *muscæ volitantes*?" In the first place it will be well to define the terms used. *Muscæ volitantes* are due to particles, strands, or masses floating more or less freely in the vitreous humor, or in a chamber between the vitreous and the crystalline lens. Any motion of *muscæ* is due either to gravity or to movements of the eyes, and this movement may be in any direction. If we suddenly turn the eyes upward and immediately down again the *muscæ* will float upward and then gradually settle down into the lower field of vision and sometimes below the field of vision. They may follow the same path in falling down that they had in going up. Again, by a sudden turn of the eye downward and then holding it still we may be able to cause these muscæntic particles to rebound and rise higher in the field of vision. Again, it is possible while lying on the back to get one of the particles to float directly in the center of the field of vision, and we may be able by care to balance and hold the particle in this central position.

The particles that can be seen with the blue glass have

*Presented to the Section on Ophthalmology, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio June 6-9, 1899.

1 *Annales D' Oculistique* (English edition), May, 1896.

none of these properties of *muscæ*. The particles are not floating freely, but move only in definite lines. Gravity has no effect on them. Movement of the eyes in any direction carries all of the particles seen in the same direction, with the same angular velocity that the eye has. Suddenly stopping the motion of the eye does not allow the particles to fall in any way. It is an impossibility to make these particles rebound. They never move backward and forward in the same path. It is absolutely impossible to bring one of them to the center of the field of vision. The particles that produce *muscæ volitantes* are frequently globular in appearance, or sometimes ring-like, and these rings sometimes have a darker center. These rings or globes may be of sufficient size to subtend one or more minutes of the arc. In all of these respects *muscæ* differ from the spots seen with the blue glass. The latter are so small that it is impossible to perceive any structure whatever. Sometimes a number of globular or ring-like *muscæ* may be seen to be connected together by a band, forming an appearance resembling a string of beads. These strings may sometimes be straight and of some length. The particles seen with blue glass are never connected together by any visible band, neither are they ever arranged in a straight line of an appreciable length.

Having pointed out the dissimilarity between *muscæ* and the particles seen with the blue glass, we will consider these particles more particularly. They are very small and without visible structure. Their motion is a peculiar jerky one, each particle moving forward rapidly for a moment and then for a moment having a slower motion. During the rapid part of the motion the particles seem to be slightly elongated; without doubt this apparent elongation is due to the "persistence of vision." The motion of these particles exactly corresponds to that seen in the capillaries in the web of a frog's foot when it is examined under the microscope. The motion is never forward and back along a single path, but always in one direction. The jerks of this motion are synchronous with the pulse-beat. The number of jerks may be increased by anything that will increase the number of heart-beats, for example, physical exercise.

None of these particles can be seen in the field at the point of fixation corresponding on the retina to the macula lutea, but they are seen all around this point and their paths bear the same relation to the point of fixation that the retinal capillaries do to the macula lutea. Any movement of the eye gives the particles together in their paths the same movement both in speed and in distance as the angular movement of the eye. This fact would prove that the particles must be very near the percipient layer of the retina, as if they were situated any appreciable distance in front of the retina, their angular motion would be different from that of the eye.

The foregoing evidence seems to show that there is no similarity between these particles and *muscæ volitantes*, with the slightest exception that they are both entoptic appearances. There is everything to prove and nothing to disprove that the appearance is due to the image or shadow of the blood-corpuscles in the capillaries of the retina falling on its percipient layer. That these corpuscles have been seen and described by others there is no doubt. The only claim to originality that I make is that I have discovered an easy method of seeing them when the eyes are in health.

This subject has a practical bearing. This appearance is sometimes seen without the aid of blue glass. When this occurs frequently or constantly in the case of persons who are not trying to see it, it is valuable

evidence of ocular overwork. And when the appearance is continuous I have seen some evidence tending to show that it is a premonitory symptom of neurasthenia, but I have been unable to give this subject the attention which it doubtless deserves, as this class of patients seldom come to an oculist.

DISCUSSION.

DR. GEORGE M. GOULD.—I do not know that I can add anything of value to this discussion until I can make the experiments with the blue glass, and I can have no opinion on the matter at present further than that derived from a general consideration of the subject. I cannot see how there can be sufficient magnifying power added to the eye to make it possible to see the red blood-corpuscles. It takes a very high magnification to enable us to see them by the microscope. I have considered the phenomena spoken of as a matter of accommodation. Last year I spent some time in the mountains, and while there I noticed a great prevalence of *muscæ volitantes*, which were present all the time I remained there. I found that if I examined them without accommodation they were say a quarter of an inch in diameter, when looking at distant clouds, but with the use of the accommodation, and especially with the aid of ground glass, they narrowed down to the size of pin points. I have been supposing that these were the phenomena that the Doctor alluded to. I shall be very much interested in going through the experiments spoken of, and yet I cannot readily see theoretically how the retina can see its own red blood-corpuscles. This subject is indirectly related to a little instrument I meant to have shown at the meeting last year in Denver, but which was unfortunately broken in transit. It consisted in revolving a pinhole-perforated disc, 1/16 of an inch around the center of the pupil, so that it would throw shadows on either side of the capillaries.

DR. A. B. HALE.—If Dr. Norton will refer to Zeng's article in the *Monatsblätter* of April, 1897, he will find corroboration of his studies in perhaps more detail. It was enough to convince me that one could see his own blood-corpuscles and Zeng even thinks he can detect the red from the white corpuscles. The work was very thoroughly done and with enough detail to make one abandon the idea of *muscæ volitantes*.

DR. EDWARD JACKSON.—There can be no doubt as to what it is, for any one who has seen it will at once be struck by the resemblance to the capillary structure of the frog's foot. We must remember that the corpuscle is there in close relation to the retinal percipient elements so that the image is as large as the object. If you will take some object at a known distance and compare it with the size of these moving bodies, you can satisfy yourself that they are approximately the size of the blood-corpuscles; I think they are a little larger than the blood-corpuscles, probably from diffusion. I can see them even against this gray sky without any blue glass, and I can always see them against a blue sky. I think the blue brings them out because it approaches nearly to the complementary color of the corpuscle. There can be no question but that they correspond in size to the projected image of a blood-corpuscle situated in the retina and their motion is very characteristic.

DR. C. E. NORTON.—In my experiments with the colored glass I have found that the glasses having the colors that came near the violet end of the spectrum showed the corpuscles much more distinctly than those approaching the red, and I have not been able to see them very distinctly with any other glass, but I do not know that this has any special significance.

CHRONIC INTERSTITIAL NEPHRITIS.

TREATMENT OF THE HEART THEREIN.

BY ARTHUR R. ELLIOTT, M.D.

CHICAGO.

The sequence of events occurring in the cardiovascular apparatus during the progress of chronic interstitial nephritis is recognized as constituting an integral part of the pathologic incidence of this form of Bright's disease. The changes taking place may be briefly summed up as sclerosis of the arterial system and hypertrophy of the heart, conditions which in the fullness of their development invariably result in heart failure. The constancy of these circulatory accompaniments has been recognized since the days of Bright, who placed the per-

*Presented to the Section on Practice of Medicine, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-8, 1898.

centage of occurrence at 65. More recent estimates make a much higher showing, Goodhart's post-mortem average being 89.6 per cent., Ewald's 84 per cent., Kanthack and Holmes' 90 per cent., while Dickinson, Tiard, Balfour and others regard it as certain that thickening of the arteries and hypertrophy of the left ventricle are invariably associated with cirrhotic kidneys. It is not too much to say that hypertrophy of the heart and arterial fibrosis accompany, in some degree, every interstitial nephritis of any standing, and are dominant factors in the clinical history. In brief detail the cardiovascular sequence is as follows: As a result of the renal lesion and the consequent imperfect depuration of the blood or because of conditions which coexist, although not necessarily the outcome of the renal changes, an abnormally high vascular tension becomes established and may persist for years and progressively increase. This sooner or later brings about certain alterations in the walls of the arterioles, resulting in thickening, loss of elasticity and increasing resistance to the onward passage of the blood. This imposes an increased burden upon the left ventricle, which undergoes hypertrophy to cope successfully with the high peripheral resistance. Thus compensation is established. Up to a certain point this hypertrophy of the heart may be said to be a "compensatory" or at least an "accommodation" enlargement, and it is to that extent fortuitous and desirable, and so long as it compensates the renal lesion, its purposes are good. The evils of excessive hypertrophy may as a rule be successfully combated, but deficient or faulty compensation is fraught with serious consequences to the patient.

Samuel West¹, in the last Lettsomian lectures, remarks, "A persistently high tension under ordinary conditions is of itself mischievous, but not so with granular kidney, paradoxical as it may seem. The patient is best without granular kidney, but if the kidneys be granular, it is better that the tension be high than low; in other words, the patient is worse with low tension."

The changes in the arteries are progressive, and the increased blood-pressure permanent. The hypertrophied muscular tissue is prone to degenerative changes, and shows a greater tendency to subsequent exhaustion and weakness than the normal heart tissues, so that it is but a question of time until increasing impairment of the nutrition of the myocardium with constantly growing peripheral resistance results in failure of compensation and dilation of the hypertrophied ventricles. This nice adjustment to conditions that Nature brings about in the circulatory organs suffices by its compensation of the renal lesion to obviate the main danger of the nephritis, the retention of the uremic toxins. The debt which the kidneys owe the heart in this way is amply demonstrated when the cardiac compensation fails. Then the greatly diminished urine, increasing albuminuria, and rapidly developing uremia leave us in no doubt as to what organ has conserved the life of the patient. Moreover, because of the friendly offices of the heart we can obtain but little true idea of what the organic capacity of the kidneys really is, for what they are able to accomplish with the co-operation of a sustained blood-pressure and what they are capable of when deprived of such assistance are two widely different things. Kidneys which can well maintain their function under increased blood-pressure prove miserably inadequate when such support is removed. In a general way it may in consequence be stated that the condition of the heart is the best gauge of the disease. The clinical history of the vast majority of cases at their termination is that the excretion of urine was sufficiently good for the maintenance of life

and that the direct cause of death came elsewhere than from the kidneys—usually the heart.

Furbringer² is at some pains to point out that the heart does not simply compensate but overcompensates the kidney lesion. This may be a necessity imposed by the peculiar character of the renal changes but, however that may be, the cardiac condition is one of tense adjustment which becomes progressively more susceptible to influence, more sensitive, more resentful to any increase in the circulatory load. During the early stages of the disease the cardiac hypertrophy is not extreme enough to give rise to symptoms sufficiently pronounced to awaken even the notice of the patient. With the progress of the malady, evidences of embarrassment on the part of the heart become manifest, and giddiness, dyspnea on exertion, cardiac discomfort, headache and palpitation give to the clinical picture the "cardiac" aspect it seldom loses during subsequent progress. These symptoms are at first transitory, occurring at night time or following unusual exertion. With the onward march of the disease, these signs of impaired circulation become more permanent and distinct, and during the last few weeks the dyspnea is constant and dropsy and uremic symptoms supervene. At the same time the pulse loses somewhat in tension and the heart sounds become less distinct and accentuated. The pulse, save in rare instances, may be said never to lose the element of tension, although this may become modified through failure of the muscular power of the heart.

In the treatment of chronic interstitial nephritis, if we are to draw any inference from the clinical history, we have decidedly to deal with more than one set of organs—the kidneys. The damage wrought by degenerative process in the kidneys is irremediable, and in our endeavors to favorably influence the progress of the disease, we may with profit teach our art to follow Nature's lead and assist her in her heroic efforts at a conservative systemic compensation. Unaided the preservative adjustment in the circulatory organs—which is Nature's compromise with the erring kidneys—is sufficient of itself to extend the course of the disease over many years, and with such perfect accommodation that it may be only through some untoward circumstance that the real condition of affairs is discovered. By contrast, the futility of our own endeavors when the compensation has failed is apparent. The problem before us in the management of the disease will always include our utmost to conserve the damaged kidneys, and, if possible, stay the progress of the degenerative changes there, but it is no less incumbent upon us and important to maintain the *status quo* in the circulatory system. No greater mistake could be made than to approach the question of treatment solely from the standpoint of the kidneys and leave the overburdened heart and arteries to shift for themselves under the exigencies of an impaired organic life. With the greatest care we must avoid all conditions which threaten the hypertrophied and sensitive heart fibers. We must employ all means to support the tone of the cardiac muscle and promote the equanimity of its nervous mechanism, and when compensation fails, we must strive to restore, if possible, the damaged heart wall and re-establish previously existing conditions.

In my remarks upon treatment, I shall make no direct reference to the measures one should address toward the control of the renal condition, but will confine myself to the treatment of the heart and arteries. The conditions which confront us here are, as we have seen, thickened and inelastic arteries which are constantly

subjected to the strain of a heightened tension, and a hypertrophied and sensitive heart muscle. Thus the patient is exposed to the risk of rupture of the degenerated vessels on one hand, and to failure of the hypertrophied heart on the other. As has been pointed out, both the increased tension and cardiac enlargement are compensatory and preservative, and on this account any effort to qualify either, unless taken with full understanding of conditions, may prove meddlesome and mischievous. The question is: At what point is one's intervention warranted? It is impossible to lay down any rule, but it would seem best to abstain from any active intervention as long as there are no definite subjective symptoms present. As soon as compensation passes in either direction the point of exact adjustment there is not lack of evidence to publish it. An increase of tension in the arterial system beyond the bounds of safety becomes manifest in dizziness, ringing in the ears, headache, disturbed cardiac action, unusual fullness of vessels, occasionally epistaxis, or it may be temporary amblyopia. The first sign of a flagging heart is seen in the pulse, which loses some of its hardness and becomes irregular and frequent. Additional signs are dyspnea, post-sternal weight and discomfort, cough on exertion or recumbency, and some diminution in the volume of urine.

In the early stages of the nephritis, if it be our good fortune to assume charge of the case at that amenable period, we should begin while compensation is still well maintained to take measures to ensure permanence to the existing conditions. If the full co-operation of the patient can be secured, much may be done for his future health. With this end in view it may be well to set the matter plainly before him and definitely state the necessities of his case, for it is often difficult to secure the faithful and permanent co-operation of the patient in so chronic a disease. As an assurance that no important detail of the patient's life escape, it is well to have him set forth minutely and in full a sample day of his life, his hours of work and sleep, his manner of occupation, his diet and habits. In this way a more thorough regulation of the small details of life, which are often important, may be secured. It is well to bear in mind that the directions to the patient are for his permanent adoption. We should, therefore, not risk misunderstanding, by lack of explicitness of direction or by trusting important details to the faulty memory of the patient. It is far more satisfactory to furnish him with full written particulars of the course to be pursued.

The details of life which will need especial care in regulating are the diet, clothing, exercise and baths. Exercise is of more importance to the nephritic than perhaps to any other, because of the great need that exists to secure as good a nutritive condition as may be. Regular exercise in the open air should be recommended. This may consist of walks upon the level, perhaps golf upon a level course, or easy bicycle riding upon a smooth and level road. Strenuous forms of exercise, such as tennis and horseback riding, should be interdicted, and the patient must be counseled never to hurry, run, or climb long flights of stairs, walk in the face of a strong wind, or attempt to mount steep acclivities, lift heavy weights, or strain at stool, and to be careful not to exert upon a full stomach. He should be warned to carefully guard against exhaustion and desist from all activity at the earliest approach of a continuous fatigue.

The clothing is a matter of much importance. These patients very easily take cold, in which case the kidneys and heart bear the brunt of the disturbance, and often to their permanent detriment. Moreover, the con-

tact of a chill air upon the surface causes contraction of the cutaneous capillaries, thus raising arterial tension and increasing the work of the heart. The patient must be cased in woolen garments from head to foot, and sleep with flannel next to the skin. In this manner, as Dickinson facetiously remarks, he may carry the temperature of summer under his waistcoat while breathing the air of winter, and so provide himself without leaving home with one of the advantages of travel.

The diet best suited to the control of the renal lesion is also best adapted for the heart. The cardiovascular changes are Nature's responsive efforts to combat imperfect blood depuration. Consequently, the careful regulation of the diet, according to the principles in vogue must form, especially in the earlier stages of the disease, the corner-stone of our treatment of the heart. The flatulence and autointoxication of indigestion are of all things the most disturbing to both the heart and kidneys. This is a development to which these patients are especially prone. The most scrupulous regularity of habit in regard to meals must be imposed, and the preparation of the food should of preference be by simple method. The patient must be cautioned against heavy meals, and eating to satiety, and be instructed against fast eating and insufficient mastication of the food. The regularity of the bowels should be scrupulously maintained, and an occasional mild mercurial purge administered. Warning must be made against the immoderate use of tobacco, the use of alcoholics, sexual excess, and emotional disturbances, because of their disturbing effect upon the cardiac system.

At the earliest signs of cardiac embarrassment some restriction in activity should be insisted upon and when compensation seems threatened, or has already given way, absolute rest in bed must be enforced. It should be remembered, however, that, beneficial as rest may be to tide over a period of wavering compensation, prolonged bodily inaction is undesirable and may work positive harm by impairing the nutrition, and thus hastening the degenerative changes at work in the cardiac walls. During the period of rest, massage and passive movements may do much to obviate these undesirable results. The greatest importance attaches to sustaining the mental tone of the patient, and regular sleep, which is one of the best of heart tonics, should be secured. To this end paraldehyde, trional and sulphonal may all serve excellent purposes and when a simple reflex irritability seems to be the underlying cause, the bromids may suffice. Chloral is frequently a dangerous cardiac depressant and opium is bad for the kidneys.

The medicinal measures which we can bring to bear upon the heart during the existence of its compensation are limited to the vasodilators. The effect of these remedies is largely mechanical. They act by dilating the capillaries, lowering peripheral resistance and thus diminishing the work of the heart. Moreover, by allowing a freer passage of blood through the vessels, the nutrition of the various tissues is improved. They are useful to overcome excess of tension in the arterial system, and are valuable aids in securing relief to an overburdened heart. To meet alarming symptoms and produce at once a decided effect upon blood-pressure, no measure is so useful as a free catharsis. In selecting a cathartic for this purpose, it is not a matter of indifference which one is chosen. Some preparation of mercury should be employed, for from it more decided benefit can be derived than from larger doses of other purgatives. The beneficial effect upon the tension of such a measure is well demonstrated in sphygmographic pulse-tracings

taken before and after the action of an aperient. This effect may be continued and supplemented by repeated depletion from the bowels or better by means of vasodilators. The vasodilators most useful in controlling arterial tension are the nitrites and the iodids. To meet emergencies amyl nitrite may be employed by inhalation, but its action is too ephemeral to admit of its continued use. For this purpose nitroglycerin is usually the drug of choice. It is well to bear in mind when prescribing the nitrites that those who have supernormal tension manifest a peculiar tolerance toward their action. Given in conventional doses they may prove disappointing. Nitroglycerin is very diffusible and within a few (five) minutes its effects become apparent, while at the end of three hours the arterial tension resumes its usual degree. A longer period than three hours should, therefore, not be allowed to elapse between doses, if a continuous effect is to be secured. The action of the iodids upon the vascular tension has been a subject of much dispute; some observers denying to them all effect and even condemning their use, while others enthusiastically praise them. Vierordt² expresses himself unqualifiedly in their favor, and reports undoubted good effects in the control of tension. He regards the "modus operandi" of the iodids as entirely hypothetical, and, taking exception to Huchard and others who attribute to them direct action upon the heart and vasomotor nerves, he thinks it probable that the morbid process in the blood-vessels, which otherwise always shows a progressive character, is brought to a standstill, and that consequently the heightened blood-pressure is gradually lowered, which would provide for a decided amelioration of the circulatory function, although no retrogression of the vascular changes may be looked for. Judged from the effects upon the tension when administered for a considerable period, they may certainly be accounted a valuable means of relief to the overloaded circulation, and they may as well tend to restrain the hyperplasia in the kidneys. The most appropriate forms for administration are sodium and potassium iodids, in from five to ten grain doses given well diluted one hour after meals. Mercury protoiodid seems occasionally to render very happy service in cases marked by a bilious habit with coated tongue and sluggish liver. It is undesirable to give a prolonged course of mercury in nephritis, so that the protoiodid is best employed as an alternating substitute with one of the other iodids, and not continued for longer than two weeks at a time. One-sixth of a grain thrice daily is an appropriate quantity.

It is unnecessary to state that heart tonics of the digitalis group should never be used during the stage of cardiac hypertrophy. Digitalis and its congeners are only admissible when there is indication of failing compensation. In employing digitalis, its vasoconstrictor action must be borne in mind and provided against or the peripheral resistance may be dangerously augmented. This is best accomplished by the simultaneous administration of a vasodilator. A good practice is to give the vasodilator about one hour after the digitalis. The latter is slowly absorbed, while the vasodilators are without exception quickly diffusible, and by this arrangement of administration, the maximum effect of each falls together and control of tension is secured. It is a safe rule to follow, to always combine a nitrite or iodid with digitalis in interstitial nephritis, for some element of tension is never lacking. Strophanthus may be advantageously substituted for digitalis when the pulse tension is high. Its efficacy as a heart tonic is established and it lacks the arterial action of digitalis. It must, however, be used

with caution in advanced degeneration of the myocardium. If digitalis and strophanthus fail to elicit response from the failing heart, the outlook is grave indeed, and recourse to other measures holds out small prospect. Caffein and theobromin may prove of value on occasion, and nuxvomica and strychnin will always be of the utmost value as adjuvants to any plan of treatment.

In the employment of the measures referred to it may be stated that digitalis and the heart tonics should in all cases be reserved for a failing heart while the vasodilators may be employed throughout, first as conservators of the heart by modifying peripheral resistance, and afterward as guards to the action of the heart tonics.

Time will not permit of more than a cursory reference to the applicability of the Schott gymnastic methods to the failing heart of Bright's disease, nor is my own experience in their use sufficient to enable me to dogmatize. Schott gymnastic exercises comprise certain volitional muscular movements made against graduated resistance applied by the hand of the operator, and having for their object the stimulation of the circulation in the muscles brought into action whereby the heart is reflexly induced to stronger and more abundant contractions with a simultaneous relieving of the venous and acceleration of the arterial and lymphatic circulations. These movements are applied according to a definite plan and with such attention to detail as to secure in an increased degree all the good effects of passive movements with little or no fatigue. To quote the words of R. Douglas Powell³: "The effect of the Schott exercises may be said to be a stimulation of the heart's action with some steadying effect and increased completion of systole, an improved circulation through the coronary arteries, and an increased mobility of the blood by its readier passage in greater bulk through the muscles, especially on their venous side. Their effect on the general blood-pressure is that during the exercise itself the pressure first rises above the normal, but begins to fall even during the continuance of the exercise, so that at the end of the treatment it has usually reached the normal. After cessation the pressure continues to fall and may become subnormal for half an hour or longer, when it slowly rises again to its initial height."

These exercises have been found of most excellent service in the failing heart of valvular compensation. By analogy it would seem not unlikely that they might prove to be a valuable contribution toward our means of sustaining the degenerated heart of granular kidney. At the outset, however, we are confronted by the fact that these movements are absolutely contradicted in advanced arteriosclerosis characterized by hypertension and degenerated vessels, and that they offer but slight prospect of success in cases with even moderate arterial change. In arteriosclerosis, the increased energy of the heart's action caused by the muscular contractions is but inadequately offset by the coincident dilation of the arteries and hence a dangerous raising of the blood-pressure and strain upon the heart results. In place of an improvement of the cardiac insufficiency in such cases, the opposite effect is brought about. It is apparent at once that very few of the cases we are considering are eligible for this plan of treatment. Still just as there are certain cases of arteriosclerosis of moderate grade in which the Schott exercises may with certain modifications be employed to advantage, so there may be an occasional nephritic heart capable of deriving benefit from mechanico-gymnastics. In considering the question of the proper selection for mechanical treatment,

no general rule can be laid down. Each must be judged upon its own merits and with the utmost care, for great damage may be inflicted in unsuitable cases. When the sclerosis of the arteries is not general and advanced and the superficial vessels not rigid, an attempt with resistance exercises may be made, beginning in an insinuating way with the gentlest movements and desisting upon the first sign of fatigue. No progression should be made to the more trying movements until a beneficial reaction is apparent from the easier exercises. If these fail to elicit results, it is needless to persist. In cases where the heart is so feeble that the primary rise of blood-pressure caused by even gentle exercises interferes with its action, continuance of the treatment can but result harmfully. It may be laid down as an absolute rule to be followed in these cases, that when there is so advanced a degree of degeneration of the myocardium that digitalis and other heart stimulants are without effect, no attempt with resistance exercises should be made. In patients whose muscular powers are greatly enfeebled the treatment is also forbidden. Dropsy may be taken as a contraindication, as may also persistent dyspnea and engorgement of the rigid heart.

It is unnecessary to state that in using a measure which in these cases is so largely tentative, every precaution should be employed to secure safety and success. Not only should all the rules laid down by Schott and Besly Thorn be scrupulously obeyed, but the patient's condition must in all cases be looked to to furnish the individual indications so necessary to the success of any measure.

Although gymnastic exercises are but rarely permissible in the weak heart of interstitial nephritis, massage and passive movements are much more widely applicable. The experiments of Bruton and Tunncliffe⁵ go to show that the effect of massage and passive movements is to improve the circulation of lymph within the tissues and to determine to the muscles a larger supply of blood, thus at once stimulating nutrition and affording mechanical relief to an overloaded heart. The employment of these measures is accompanied primarily by a slight and transient rise in blood-pressure, which is soon followed by a fall in tension less extreme and not so long sustained as that following resistance exercises. The effect, therefore, of these measures is the same in quality as the Schott movements, differing only in degree and duration, while the dangerous increase of blood-pressure is eliminated. They furnish valuable means of obviating the circulatory stagnation and malnutrition of prolonged and enforced rest. In fact, it is this last conservative function that is the principal office of all these mechanical measures in the cases under consideration. Too much must not be expected of them. The very nature of the factors which bring about dilation of the hypertrophied heart of Bright's disease precludes the possibility of great or permanent results from any or every means we can bring to bear. Once dilation has taken place the outlook is indeed a dark one.

In concluding my remarks, I cannot do better than to repeat the words of Leonard G. Guthrie,⁶ who gives as a guarding principle in the treatment of chronic nephritis the motto: "Watch the heart and pulse." Herein I am convinced is the surest way to the successful management of this widespread disease. Sooner or later the morbid process must end in death. But this termination can be longest postponed, the patient's interests can best be served, and his condition most securely palliated by placing the heart upon a therapeutic parity with the kidneys.

DISCUSSION.

DR. C. H. MILLS of Illinois.—I have had a great deal of experience in diseases of the heart, largely during my service of fourteen months in charge of the hospital. Under me came a great many cases of organic diseases of the heart. Aconite is a great remedy in Bright's disease of the kidneys and in the irritable heart. Besides there were given tonics—iron, gentian, cinchona, and when a sedative was needed, aconite.

DR. R. H. HENRY of Illinois.—I wish to say a word in regard to the use of mercury and iodid of potassium, for I was much impressed by the remarks made by Dr. Elliott. I believe the use of mercury and iodid of potassium will prolong the life in these cases; also, the use of the other tonics and vasomotor dilators. The long-continued use of iodid of potassium without disturbances of the stomach will prolong life in the most hopeless instances. The mercury has a specific effect in unloading the canal and in increasing the activity of the cells lining the canal, and so unloading a sluggish condition. I usually combine the nitrates with it, and I have had satisfactory results.

DR. NORMAN BRADEN of Los Angeles, Cal.—I am really satisfied that there is nothing left to be said regarding the management of these cases; the speaker has covered the ground in such a thoughtful, judicious and able manner. Patients, in the light of existing knowledge, who can be managed as Dr. Elliott has suggested, will have the best treatment extant. From what he has stated, however, one would almost come to think that we ought to expect a curative effect from the iodids—a curative effect upon the disease itself. I fear that this is not justified by the experience of the profession. And so the thought that occurs to my mind as the paramount one is the need of further study to discover some means that shall less the progress of the disease; i. e., to stop the interstitial nephritis and lessen thereby the coincident thickening of the heart muscle and vessel-walls. It is probably true that the heart must undergo hypertrophy in all cases of interstitial nephritis. It is probably true that hypertrophy is exactly in proportion to the amount of disease in the kidneys, although I doubt if that is always the case. I think these pathologic processes which are conservative do not always go on exactly to this conservatism. Sometimes the hypertrophy is greater or less than necessary; we see that in the fibrosis of pulmonary tuberculosis. There it is a conservative condition; it helps to cure the patient. We know that when there is no hypertrophy the disease runs on rapidly to destruction. This shows the conservative power of Nature. It is, therefore, not true that we always have hypertrophy of the heart coming on with the interstitial nephritis in due proportion. I do not know that we know that patients die of heart failure. So long as the heart remains hypertrophied, and not dilated, we believe that the patients are going to live. We observe a number of cases where there is no giving away of the heart or blood-vessels, but where injury to the nervous centers and brain particularly seems to be the predominating cause of death. The amount of urea did not justify the expectation of fatal issue. The great desideratum in the treatment of this disease is to get the means of lessening the interstitial nephritis.

DR. ALFRED STENDEL of Philadelphia.—The paper of Dr. Elliott's is of unusual interest, which lies in the fact that he has pointed out the general relations of interstitial nephritis, and particularly that the vascular system is the point of attack for medical men. In the early stages, with treatment we can do good. Reduce the blood-pressure, and if possible control the fibrific changes, particularly with the Schott or mechanical method, with which I have had experience. Physiologists have shown that the effect of exercise is to reduce the blood-pressure in the muscles. I believe that the reduction in the blood-pressure is greater than Dr. Elliott is inclined to state in his paper. There is an increase in the blood-pressure in the beginning of the Schott treatment, but this is only temporary; it is soon followed by a fall in the pressure. In treating a case of chronic interstitial nephritis from the beginning, the institution of the systematic mechanical treatment may prevent fibrific changes in the blood-vessels and in the organs. For this disease is a general disease which affects the kidneys, liver, heart muscle, brain and other organs, sometimes one more than another—and it is to be controlled by measures which control the blood in general. We do not know how the nature of the poison developed, but we do have the means by

which we can obviate its effects. The continued use of mercury in small doses, I believe, may influence the elimination of this poison. As for the iodids, I am convinced that those of sodium and potassium are the preferable salts; they are better borne and have a less disturbing influence upon the heart. The mechanical treatment, I am convinced, is the treatment of the future for this disease. It should be given when the disease is forming.

DR. EDWARD F. WELLS of Chicago.—I wish to speak briefly upon a single point, that is, the reduction of blood-pressure. In interstitial nephritis there is an increase in the blood-pressure and a hypertrophy of the heart. This increase in blood-pressure causes a thickening of the arteries, the cardiac hypertrophy increases more and more, and if the patient takes some amount of active labor it is necessary that his nutrition should be kept up. The first thing to do is to stop any excessive amount of exercise he may be taking, and limit the amount of nitrogenous food, and I believe that a careful regime, such as the avoidance of draughts, regulation of his diet, the giving of large amounts of fluids to reduce the amount of poison in his system, will do vastly more good toward reducing the blood-pressure and relieving the patient and prolonging his life than any drugs. I do not wish to be understood as deprecating the use of drugs; I believe that the iodids are the drugs to be used. We should not lose sight of the careful regulation of the diet.

DR. JENKINS of Iowa.—I am very much pleased with Dr. Elliott's paper, and I wish to emphasize one portion of it regarding the use of nitroglycerin in cases of chronic interstitial nephritis. I have frequently had patients come to me with this disease for treatment, coming from other physicians, who had failed to try this remedy. Placing them on the use of strychnin, regulating their diet, and giving nitroglycerin relieved their symptoms and gave them many months of comfortable living. For this reason I am glad Dr. Elliott emphasized that portion of his paper. The disease has not been well treated until recently. Now it is, with careful bathing and dressing, dieting, regulation of bowels, with the administration of such vasomotor dilators as glonoin, one drop every two, three or four hours, and up to five drops, that benefit is to be derived.

DR. ARTHUR R. ELLIOTT, closing the discussion.—I wish to express my pleasure at the amount of discussion my paper called forth. I think cases of interstitial nephritis cannot be classified as all belonging to the cardiac type, any more than they can be said to belong to the purely nephritic type. The fibrosis is a general one affecting different portions of the body in different degrees. I would like to state that in the preparation of my paper I was influenced in setting forth measures of direct treatment against the disease in the later stages, i. e., when cardiac hypertrophy was present or failure threatened. I did not enter into any discussion of the early stages of the disease. If we could get hold of the disease in the earliest stages I think that hygienic, dietetic and other measures would give better results than could be obtained through the use of drugs. The cardiovascular changes of nephritis are Nature's protest against the results of imperfect metabolism in the blood-stream.

SYSTOLIC MITRAL MURMURS.*

THEIR TRANSMISSION, WITH SPECIAL REFERENCE TO THE NATURE OF THE SO-CALLED ANEMIC MURMURS.

BY HORACE D. ARNOLD, M.D.

Physician to Out-patients, Boston City Hospital; Assistant Professor of Clinical Medicine, Tufts Medical College.
BOSTON.

What is familiar to us is not necessarily well understood and yet in medicine as much as in any branch of learning we are to accept this feeling of familiarity for knowledge. This thought must be my excuse, if one is necessary, for bringing to your attention a subject so familiar as the heart murmurs.

The question whether a systolic murmur is organic or functional is being constantly brought up for our decision, yet although it has been discussed many times there is still lacking that unanimity of opinion among the best authorities which would assure us that it has been definitely settled. The question is one of practical importance, and any addition to our knowledge, however small,

should be welcome in our efforts to find a solution.

A review of the literature shows that the discussion has turned chiefly on the points of maximum intensity of these murmurs. The second left intercostal space has been the battle-field of the champions. Whether the point of maximum intensity was just over the pulmonary artery or a little outside of it has been the burning question. So many theories have been advanced to explain the murmurs in this region that Balfour¹ has well called it the "region of romance" for cardiac murmurs. In all this discussion the area of transmission of these murmurs has received little attention, although it seems to the writer to be of considerable importance. In fact, the method of conduction of the sounds and murmurs of the heart to the surface of the chest, and the area over which they may be heard have only of late received much attention, and we have still much to learn of these important and fundamental matters.

Gibson² in his recent book says: "We are by no means thoroughly acquainted with the physical facts which regulate the extent to which the sounds are conducted." And again: "The direction of propagation and the extent of conduction constitute a subject of much difficulty in the study of murmurs."

When a murmur is heard at a given point on the chest, one fact at least is true, namely, that there exist at this point vibrations of the chest wall capable of transmission to the ear and of such a character and intensity that they produce the sensation of sound. How these vibrations originate, where they start, and how they reach the points at which they are heard, are questions less definitely determined—questions of probability rather than fact, which still come to some extent within the realm of opinion and theory. It is important to thus recognize when we cross the boundary separating fact from theory.

Clinically, we find that these vibrations reach the chest wall at certain areas; experimentally, we find that such vibrations may be caused by certain physical conditions; pathologically, we find these conditions existing at certain points in the heart and blood-vessels. In this way we can demonstrate the cause of certain murmurs. For example, we know that mitral regurgitation may cause vibrations which are heard as a systolic murmur near the apex of the heart. These vibrations are also heard in other areas, as will be considered later. It is worth while noting at this point, however, that the so-called anemic or functional murmurs frequently occur in trivial disturbances of health, are often transitory, and are rarely so associated with fatal disease as to give us the opportunity to definitely determine their cause by pathologic investigation. Our explanation of many of them is, therefore, based on inference, and carries a greater or less degree of probability rather than certainty.

It is generally accepted that mitral murmurs are heard best near the apex of the heart, and we commonly speak of this place as the "mitral area." The term is a good one, provided we do not assume that all murmurs heard in this area are generated at the mitral valve. It is not very uncommon to find a systolic murmur from the aortic valve transmitted to this point, and occasionally a presystolic murmur in this area finds its only explanation in aortic insufficiency. The vital point in all these cases is that the vibrations are carried here through the medium of the wall of the left ventricle and the blood within its cavity. This fact should be kept in mind when we speak of the "mitral area." In the same way it requires very little study of the distribution of murmurs to show that it is not safe to argue that because a murmur is heard at the aortic pulmonic, or tricuspid

* Presented to the Section on Practice of Medicine at the Fifth Annual Meeting of the American Medical Association, held at Columbus Ohio, June 6-9, 1899.

area, it necessarily originates at the valve with a corresponding name.

It is useful, in the ordinary examination of the heart, to keep these four valve "areas" in mind, but in a careful study of murmurs it is better to picture the anatomical relations of the normal heart and blood-vessels to the chest wall. If we will modify this picture to suit the given case, as shown by the evidence of inspection, palpation and percussion; if we further bear in mind the area and consistency of the lungs, the thickness of the chest wall, and the bony or muscular nature of the chest wall at a given place, then, and not fill them, we are prepared to interpret intelligently the conditions which determine the distribution of cardiac murmurs. In this way we shall find an explanation of many things which at first seem confusing and obscure.

Continuing our study of the mitral regurgitant murmur, it is generally stated that it is transmitted to the left from the "mitral area" into the axilla and may be heard at the angle of the scapula. Gibson's description is, in my opinion, more accurate. He says: "It is propagated from this region in every direction, but to a different extent it is conducted to a greater distance in the direction of the axilla and scapula." Again: "Very frequently the murmur is found to have a position of intensity almost as great as that over the apex-beat at a point between the left shoulder-blade and the vertebral column, and there can not be the shadow of a doubt that the conduction of the murmur to this point is due to the proximity of the left auricle."

This area in the back just described, which we may call the mitral area in the back, has received little consideration in most text-books. They seldom attempt to explain how the murmur reaches this point and apparently leave one to infer that it is transmitted around the chest-wall from the apex. This view is wrong, for it would not account for those cases referred to by Gibson in which the intensity at the mitral area in the back is "almost as great as at the apex," and greater than in the intervening space in the axilla. Still less will it account for those cases in which the murmur is transmitted as far as the axilla and is then lost, and yet reappears at the mitral area in the back. And, further, we sometimes have cases in which the murmur is actually louder in the back than at the apex. The explanation is undoubtedly found, as Gibson says, in the "proximity of the left auricle."

From our association of the mitral murmurs with the apex of the heart, which lies superficially, we are apt to forget how deep in the chest the murmur originates. The mitral valve is deeply situated, the left auricle more so. It is the blood passing through the mitral valve into the auricle which causes the murmur, and, except so far as the vibration of the valve curtains partake in the production of the murmur, it originates in the blood within the auricular cavity. It is a safe assumption then, that at the posterior surface of the auricle vibrations of considerable intensity exist. How do they reach the back?

Between the left auricle and the vertebral column lie the aorta, esophagus, vena azygos, and surrounding tissues of the posterior mediastinum. Although the distance to the spine is short, the vibrations do not traverse this path ordinarily, and we must conclude that these structures are not good conductors. Were the vibrations thus carried to the spine they would be heard with greatest intensity where the bony structures of the spine come nearest to the surface. This is not the case. The mitral area of the back, where the murmur is most constantly heard and with the greatest intensity, lies a short distance inside the inner border of the left scapula and a

short distance above its lower angle. This is the point where there is the thinnest layer of muscle in this part of the back. It lies just outside the deep longitudinal muscles along the spine, while it occupies a triangular interspace left by the trapezius, the latissimus dorsi, and the rhomboideus major muscles. Having ruled out the spine, the only medium of conduction from the left auricle to this thin part of the chest wall is the pulmonary tissue.

It is generally held that the pulmonary tissue offers an impediment to the transmission of vibrations from the heart, rather than a favorable avenue of conduction. This is certainly true in a relative sense, as compared with such avenues of conduction as the muscular walls of the heart or the column of blood within the heart or aorta, but it is true only in this relative sense. Furthermore, the extent to which it is true depends on the condition of the pulmonary tissue. If that is condensed or consolidated, it is recognized as a very good conductor of vibrations. On the other hand, if emphysema, the opposite condition to condensation—is present, we have a very poor conductor of vibrations, and it may be noted in passing that with an emphysematous condition of the lung a mitral murmur is inaudible or only very faintly heard in the back. Between these two extremes lies the condition of the normal pulmonary tissue, which, I think, from all the evidence, we must accept as a fairly good conductor of vibrations from the heart. This, at least, is an opinion into which I have been forced in trying to account for many of the peculiarities of the distribution of heart murmurs, and it seems the only rational way to account for the transmission of the mitral regurgitant murmur to the mitral area in the back.

Turning now to the front of the chest, let us consider how the conduction of vibrations by the normal lung tissue may affect the distribution of the murmur there. Does it not give us a more rational explanation of the characteristic distribution of the murmur in front? As Gibson says: "It is propagated in every direction, but to a greater extent in the direction of the axilla." Were it transmitted from the apex alone, and solely by the chest wall, we should expect it to be transmitted best and farthest in the direction in which there is the best chance for bone conduction, and this is to the right and not to the left of the apex. If, however, we accept the view that the vibrations may be carried a moderate distance by the lung tissue, we have an easy explanation of the transmission to the left of the apex, for the distance from the vibrating left border of the auricle and ventricle to the chest wall as it rounds back into the axilla is only a short one. It is not claimed that there is no lateral transmission of murmurs by the chest wall itself, for that certainly exists, but it is felt that too much stress has been laid on this factor, and that, taken alone, it does not fully explain the phenomena.

A consideration of the thickness of the chest wall in front will perhaps give us an explanation of the common view that the murmur is transmitted to the left from the *apex* instead of, as is the fact, from the whole left border of the heart. The pectoral muscles form a thick layer and offer more or less of an impediment to the transmission of vibrations to the surface over them. Outside the boundaries of the pectoral muscles the murmur is heard more distinctly because the chest wall is thinner, and this gives us an area which extends along the border of the pectoral muscle from the apex to the left and up into the axilla.

The removal of the obstruction of the pectoral muscles throws interesting light on the subject. It is easily accomplished. If the left arm is raised upward and is then laid across the face so that the forearm and elbow

lie across the eyes, the pectoral muscles are relaxed and may then be pushed inward toward the median line far enough to allow the bell of the stethoscope to be applied to the chest wall at or just outside the mammary line. We are now listening just outside the left border of the heart, with a chest wall as thin as it is farther down at the apex. This maneuver is best accomplished with the patient lying on the back, as better relaxation of the muscles is thus obtained. In females the breast may usually be carried out of the way in the same manner.

In this way we find not only that the murmur is audible all along the left border of the heart but that its intensity is greater at a given distance up from the apex than it is at the same distance to the left of the apex. Not infrequently the murmur is louder farther up the left border of the heart than at the apex itself. A very common place to hear the murmur loudest is in the third interspace. This is easily understood if we remember that we are now listening just opposite the mitral valve, the center of the left auricle, and the thickest part of the left ventricle—in other words, near the place where the vibrations should exist with greatest intensity. If we admit that the lung tissue is a fair conductor of vibrations, we readily explain why the murmur is heard so loud in the third interspace near the left border of the heart. Whether the murmur is heard loudest here or at the apex depends largely on the relative conducting power of the pulmonary tissue and the wall of the left ventricle in a given case.

We have followed the area of transmission of the mitral regurgitant murmur up the left border of the heart to the third interspace. In many cases it does not stop here, but we find the area extends still farther into the second interspace. Here we reach Naunyn's area and then the pulmonary area. I believe the medium of conduction here is the same as a little farther down, namely, from the upper part of the left auricle and the base of the left ventricle through the pulmonary tissue to the chest wall. It is quite possible that the left auricular appendix plays a part in the conduction of the murmur to this point, for it is the part of the left auricle which comes nearest to the surface of the chest. But by our explanation it is no longer necessary to assume that this appendix must touch the chest wall, or even that it must reach the anterior surface of the heart in order to have the murmur conducted to the second left interspace. The objection of Russell and his followers thus falls to the ground, while the conclusion of Naunyn and Balfour that this murmur may be of mitral origin stands, although their explanation that the left auricular appendix alone is the medium of conduction is, as Russell shows, "not proven."

Turning now from the conduction of the mitral systolic murmur beyond the area of the heart, we have still one area to consider over the heart itself. This may be called the "valvular area." It is about the junction of the third left costal cartilage and interspace with the sternum. Here we are directly over the anatomical position of the valves as they lie close together. It would seem almost superfluous to recall the fact that it is at or close to the valves beneath this area that all valvular murmurs originate, were it not that many very excellent text-books are careless about this matter, and say, for example, that the aortic systolic murmur originates at the aortic area. The chief medium of conduction from the valves to the front of the chest is the thick muscular walls at the base of the ventricles, in which the valves are imbedded. The path for conduction is direct, the distance is not great, and, as a result, any valvular murmur can as a rule be heard at this area and fre-

quently is louder and more distinct than at the more distant area corresponding to the valve at which it is generated.

We are not accustomed to pay so much attention to this "valvular area" because the fact that a murmur is heard here gives us little help in determining which valve is affected. Nevertheless, in studying the distribution of a given murmur this area should receive attention, for the murmur is sometimes heard here with marked intensity. This is true of mitral murmurs as well as others. Between this "valvular area" and the apex we find the mitral murmur transmitted with greater or less intensity according to the condition of the left ventricular wall beneath and the character of the lung and chest wall overlying the heart at a given point.

We are now prepared to consider the transmission of the mitral systolic murmur farther upward at the base of the heart and to the "aortic area" so-called. We have just seen that the vibrations are strong in the thick muscular base of the left ventricle. At this point the aortic begins and, remembering also the close connection of the aortic and mitral valves as well as the fact that during systole there is a continuous column of blood from the ventricle into the aorta, with the current flowing into the aorta, we should not be surprised to find the mitral systolic murmur carried into the aorta and audible at the aortic area. That it is thus carried to the aortic area may be frequently demonstrated, though I am not prepared to say how far it may be transmitted through the arteries beyond. The fact that mitral murmurs may be thus heard at the base and the mechanism by which this is brought about should be kept in mind when studying functional murmurs.

Mitral murmurs are frequently conducted over the chest far beyond the areas which we have considered, and the total area may include the whole chest. It is enough to say that the whole area of distribution depends on the intensity of the vibrations and the character of the conducting media. A further consideration of this topic is not necessary for the purposes of this paper.

We now come to the consideration of the so-called "anemic" murmurs. To say these murmurs are due to anemia to state a fact but to give no explanation of that fact. They are ordinarily included under the head of functional murmurs, indicating that they are not due to a pathologic condition of the valves or wall of the heart. This is not strictly true, for it is generally recognized that in some conditions of anemia the heart becomes dilated and the character of the murmur indicates valvular insufficiency as clearly as in organic disease. We shall consider only those murmurs which are heard in the second left intercostal space.

They are ordinarily ascribed to the pulmonary artery because they are heard in the "pulmonary" area. Since no lesions of the pulmonary artery are found, they are attributed to the condition of the blood itself. Is this interpretation correct? It certainly has not passed without challenge.

It is not my purpose to thoroughly review the discussion of this subject, but merely to mention a few explanations by well-known authorities to show that we need not feel bound to the view that the murmur originates in the pulmonary artery. Naunyn and Balfour contend that the murmur comes from the mitral valve. Russell asserts that it reaches the surface from the pulmonary artery. He does not, however, fall back on the state of the blood for an explanation, but thinks it might be caused by a dilated left auricle pressing upon and narrowing the lumen of the pulmonary artery, or that it might be a tricuspid regurgitant murmur transmitted

up the conus arteriosus. Gibson also attributes the murmur to tricuspid incompetence. Sansom thinks the murmur is due to fibrillary tremor of the muscle of the conus arteriosus below the pulmonary valves.

Let us turn to the testimony of the murmurs themselves. I hold with those writers who state that the most common site for anemic murmur is at the base of the heart, especially in the second left interspace. But although the point of maximum intensity is often here, a study of the area of distribution shows it to be comparatively rare to find the murmur limited to this area. By moving the pectoral muscle out of the way, as previously described, the murmur will very commonly be found to be transmitted around the left border of the heart from the second into the third and sometimes into the fourth interspace. In quite a large number of cases the murmur has as great or even a greater intensity in the third than in the second interspace. This at once recalls the conditions we found while studying the mitral murmur and it immediately raises a difficulty in accounting for our murmur, on the supposition that it originates in the pulmonary artery or at the tricuspid valve.

The similarity to a mitral murmur is increased when we find the murmur transmitted still farther to the apex of the heart. And when we find it also transmitted to the mitral area in the back, the conclusion becomes inevitable that we have to deal with a murmur of mitral insufficiency. That mitral regurgitation may occur in some conditions of anemia is recognized by all writers. The only new thing in this study is the demonstration of a continuous series of transition stages among the anemic murmurs from a location limited to the pulmonary area to that of a characteristic murmur of mitral regurgitation. May we not be dealing with the same murmur in all these stages? If not where shall we draw the line between the anemic murmur due to mitral regurgitation and one due to some other cause?

Of all locations in which the murmur is heard, that at the mitral area in the back is the one showing most conclusively that it is a mitral murmur, and this is also the area which throws the greatest difficulties in the way of accounting for the murmurs at any other orifice. Using this area in the back as a test, I was surprised to find that the murmur was audible here in many cases in which it did not reach the apex. In fact, I have repeatedly heard the murmur in the back when in front it was only to be heard in the second left interspace and faintly in the third interspace. In some of these cases it was fully as loud in the back as in the front, in others it was only faint and distant, but still distinct. These observations I have frequently had verified by others so as to eliminate the possible element of enthusiasm and expectancy which leads one to hear what he wishes to hear, whether it is present or not. The results of the observations on a large number of cases carried on for several months may be summarized by saying that careful observation will show a systolic murmur at the mitral area in the back in a surprisingly large proportion of the anemic murmurs, even when they are not heard at the apex. This is not a constant accompaniment of the anemic murmur, neither is it of the organic mitral murmur, for reasons before stated. It should be added that in many of the cases, including practically all cases in which the murmur failed to reach the apex, there was no demonstrable dilatation of the heart. If we accept these data as correct, we are inevitably forced to the conclusion that many of the so-called "anemic" murmurs are of mitral origin, whether they reach the mitral area at the apex or not.

It may be urged that I have simply reported a series of cases which apparently grade into one another, and that it is a mere assumption on my part that they have a common origin. What proof is there that we are dealing with the same underlying cause through these various gradations?

This proof is to be found by watching the same case pass through the gradations from one stage to another. In a number of cases which have started with an "anemic" murmur heard in the second left intercostal space, extending around the left border of the heart to the apex, and heard also in the back, the area of distribution has diminished as progress has been made toward recovery. There has been left only a typical "anemic" murmur in the second left interspace, and in favorable cases this also has disappeared. The order of disappearance has not always been the same. Sometimes it has disappeared first in the back, less often first at the apex. In front we sometimes find a gradual recession of the murmur from the apex toward the base, more often we find the area splitting into an area at the base and one at the apex and generally the area at the apex disappears before the one at the base.

It may still be urged that our murmur may be a composite one, that we have, to be sure, in some cases a mitral murmur but combined with it an anemic murmur at the pulmonary orifice, and that the two verge into one another. I should meet this objection first by citing those cases in which an apparently typical "anemic" murmur at the base is accompanied by a murmur in the back, but by no other evidence of mitral regurgitation. And then, as confirmatory evidence that murmurs in the second left interspace only may have the same origin as typical mitral murmurs, I will record some observations made upon long-distance runners.

On April 19 last I had the pleasure of assisting Dr. Harold Williams of Boston in an investigation of the effects of long-distance running carried out on the contestants in a Marathon race. This is a 25-mile road race, modeled after the course run by the ancient Greek who carried the news of victory from Marathon to Athens. The results of the observations were embodied in a paper read by Dr. Williams before the last meeting of the American Climatological Association.⁴ We need consider here only the effect upon the heart in causing murmurs.

The course of 25 miles was run by the winner in 2 hours, 54 minutes, 38 seconds—a little better than a mile in seven minutes. During the next hour twelve other contestants finished. These men were all healthy young adults. They were examined both before and after the race. The hearts of all were normal before the race, with the exception of a varying degree of physiologic hypertrophy due to exercise. No murmurs were heard before the race. The general effect upon the men may be described as one of extreme muscular exhaustion.

Here we had a number of human beings voluntarily submitting themselves to an experiment in which we could learn the result of pure muscular exhaustion of the cardiac muscle in healthy hearts. The exhaustion of the cardiac muscle was shown by a change from strong to weak action by lowered blood-pressure, as shown by sphygmographic tracings, by rapidity of action, and by a perceptible dilatation or distension of the heart.

Of the 13 men examined after the race, 11 had developed a cardiac murmur. The murmur was in all instances systolic. In every instance it was heard in the second left intercostal space. In two cases it was confined to this space. In three others it reached along the left border of the heart to the third or fourth interspace.

In the other six it was continued beyond this area to the apex, was transmitted a short distance to the left of the apex, and was audible at the mitral area in the back. In all cases the murmur was temporary and disappeared as soon as the heart had a little time to rest. It is also interesting to note that the two men who did not have murmurs were the winners, whose hearts were unusually strong, and better adapted to withstand the strain.

I think we are justified in assuming that the underlying cause of the murmur was the same in all these cases and was the weakness of the cardiac muscle from exhaustion. We may also assume that the mechanism of the production of the murmur was the same in all instances. Since, then, in the more characteristically marked cases it was a mitral regurgitant murmur we must assume that it was due to mitral regurgitation in all cases. Hence we have demonstrated by this experiment, first, that weakness of the cardiac muscle may cause mitral regurgitation, and second that a murmur thus due to cardiac weakness may exhibit all the gradations from what would ordinarily be accepted as a hemic murmur at the base to an undoubted mitral murmur at the apex.

It only remains now to show that weakness of the cardiac muscle exists in anemia, then our proof is complete that the anemic murmur is not due directly to the condition of the blood itself, but to a resultant mitral insufficiency. In the fatal cases of anemia the cardiac muscle is frequently found in a state of fatty degeneration, due to insufficient nourishment by the impoverished blood. Dilatation may or may not exist. It is inconceivable that the myocardium should remain perfectly normal through all the earlier stages of anemia and at a given point suddenly develop fatty degeneration. Various stages of impaired nutrition undoubtedly precede this. Impaired nutrition implies weakened muscular action. The mechanical results of a weakened myocardium will be the same whether the weakness is caused by poor nutrition or by tire from overexertion, as in the runners. In the runners we got mitral regurgitation, in the weak heart of anemia we should have the same condition.

It has been too often assumed that we cannot have mitral regurgitation unless we have actual dilatation of the cavity of the ventricle. Were this true, it would constitute a serious objection to our explanation of anemic murmurs, for such dilatation does not always exist. The studies of Ludwig and Hesse, however, together with the experiments of Roy and Adams, show that the complete closure of the mitral valve involves a much more complex mechanism than does the closure of the semilunar valves at the arterial orifices. The exact apposition of the mitral flaps is secured not alone by the force of the blood-pressure bringing the flaps toward each other, but by muscular contraction of the ventricular wall in narrowing the orifice and by the co-ordinated action of the papillary muscles in properly staying the flaps and preventing them from being forced too far. It is unnecessary to discuss here just what proportion of the proper adjustment is due to the muscle of the wall of the ventricle or to the papillary muscles. Probably a sufficient weakening of either force might allow regurgitation. In anemia both are probably affected, and the weakening of the muscle in anemia gives an adequate cause for mitral regurgitation, whether dilatation exists or not.

We may summarize our studies in this paper as follows:

Mitral systolic murmurs may not only be heard at the mitral area at the apex and extending toward the axilla,

but also at the mitral area in the back, along the left border of the heart, in the second left interspace, at the base, and at the "valvular" area.

Anemic murmurs are not confined alone to the pulmonary area and second left interspace. They extend by varying gradations around the left border of the heart, to the apex, and to the mitral area in the back, thus gradually assuming the characteristics of a true mitral regurgitant murmur. The transmission to the mitral area in the back may exist, whether the murmur is heard at the apex or not, and even in what appear in front to be typical anemic murmurs.

We find a dividing line between the so-called anemic murmurs and the mitral murmurs.

The presumption that these different gradations in the distribution of the murmur all have a common origin is strengthened by finding these different gradations successively in the different stages of the same case. It is practically proved by finding all these gradations in healthy hearts which have been subjected to the same severe exhausting strain, as in the runners mentioned.

Weakened muscular action of the heart exists in anemia as a result of poor nutrition. Weakened muscular action is an adequate cause for mitral insufficiency, whether dilatation exists or not.

The points which are new in this demonstration are the study of the area of distribution of these murmurs rather than the point of maximum intensity, the demonstration of the transition stages between the anemic murmurs and the mitral regurgitant murmurs, the demonstration of the frequency with which anemic murmurs are heard in the back, and the importance placed upon the transmission of murmurs by pulmonary tissue.

Other observers have noted that an anemic murmur is sometimes transmitted to the mitral area in the back, although they apparently have not appreciated the full significance of the fact. Barr reports that in 115 cases of simple chlorosis he found the murmur in the back as well as at the base and apex in 22 cases. He does not specify whether dilatation existed or not, and he mentions no cases where the murmur was heard in the back and at the base, but was absent at the apex.

Sansom says: "I have frequently noted a systolic murmur audible at the angle of the left scapula in uncomplicated anemia. In fact the murmur in anemia can answer to all the criteria of one due to regurgitation from organic causes. Such murmurs can be experimentally induced in animals by copious bleedings." He also quotes Macalister: "When an animal is bled till it is feeble, a murmur indicating regurgitation from the ventricle is heard with the heart sounds. You may inject proper saline solution to make up the normal quantity of circulating fluid, but still the regurgitation occurs. As the animal makes blood again, so that its muscles are again properly nourished, the murmur disappears."

Prince⁸ and McCollom⁹ have made interesting observations on the hearts of healthy men, examined for positions as firemen or policemen, where the murmurs were apparently due to excitement and were temporary. The murmurs were ascribed to mitral regurgitation due to imperfect action of the cardiac muscle. The murmur is similar to that found in the long-distance runners, already cited. The point in common in these cases of excited action, in the exhausted hearts of the runners, and in the anemic hearts is the failure of the muscle to do its part toward the closure of the mitral orifice. Prince found a systolic mitral murmur in 25 of 77 healthy men, and McCollom in 27 of 200 men. In 8 of the 25 cases noted by Prince, the murmur was heard also in the sec-

on the left intercostal space and sometimes can be traced upward to this point from the apex." In a number of cases in his table he notes that this area was not examined. "Sometimes the murmurs are heard in the back beneath the scapula—this was not always looked for." "They are sometimes heard equally loud at the junction of the fourth rib and sternum on the left side, i. e., over the mitral valve."

In reviewing the literature on this subject, it is not my purpose to give a complete bibliography—such a bibliography might well include all works which have been published on the heart. The following works have been of assistance in studying the subject:

DISCUSSION.

DR. NORMAN BRIDGE of Los Angeles.—I do not know but Dr. Arnold, in that part of his paper which time did not permit him to read, may have referred to the point I have in mind. But as I recall it he took no account of the possibility of the air in the bronchi being capable of transmitting the heart murmurs to the back. I do not recall any one having referred to that. It may not be a matter of consequence, but it seems to me that, in auscultation of lung troubles and diseases and disorders of the pleura, we should and do take into account this element largely, and find it extremely useful from the standpoint of diagnosis, proving that sound, voice and air are transmitted through the air in the bronchi to the walls of the

chest; variations of these sounds so transmitted are matters of great moment in the diagnosis; and it seems to me that heart murmurs must be transmitted too in this way as truly as by means of lung tissues. That may account to some degree for the otherwise unaccountable loudness of the mitral murmurs at the back.

DR. HORACE B. ARNOLD of Boston.—Replying to Dr. Bridge I would state that I used the term "pulmonary tissue" in the general sense. I usually include transmission of vibrations through the air in the bronchi, i. e., its divisions after entering the lung, and include it as pulmonary tissue. I consider conduction in the lung as possible by conduction through the chest wall or spine.

MYOPIA.*

OPERATIVE TREATMENT IN HIGH DEGREES THEREOF.

BY ALLEN T. HAIGHT, M.D.

Professor of Ophthalmology, Chicago Clinical School; Attending Eye and Ear Surgeon, Cook County Hospital and German American Hospital; Oculist and Aurist to the Illinois Industrial School for Girls; Member of the American Medical Association, etc.
 CHICAGO.

The advance of civilization has brought many advantages and blessings to the human race but has also furnished extra care, extra requirements on mentality, and necessarily a decided increase in the use of the eyes, especially for near work. This constant and continued use of the eyes for near work is one of the most potent factors in the production of axial myopia. By axial myopia we mean a receding of the posterior portion of the eye, making the distance from the cornea to the macular greater than normal. This is brought about by the combined action of accommodation and convergence.

The condition is most frequently acquired by children compelled to do a great deal of studying, at close range, perhaps in very poor illumination, and also by persons engaged entirely in fine work, which they hold close to the eyes in order to get a perfect image on the retina. The accommodation is used to a greater degree than normal, and the action of the internal recti muscles is increased so far as to fix both eyes upon the near work, thereby bringing a strain directly on the sclera at the temporal side of the head of the optic nerve. Under this continued tension or stretching the sclera at this point soon assumes a condition of inflammation, and gradually we have a chronic sclerochoroiditis which is followed by an atrophy and thinning of the sclera and afterward by a gradual separation from the optic disc. In this way that portion of the eye between the optic disc and the macula glauca is weakened and is forced back by the normal tension of the eye, and we have established a change in refraction known as myopia. It is not necessary to state here that this is not the only cause of myopia. It is, however, the most frequent cause of myopia of high degrees.

Heredity plays a very important part in progressive myopia. It is true that the children of myopic parents are rarely, if ever, born near-sighted. On the other hand they have an undoubted predisposition to myopia, since they are prone to inherit the anatomical peculiarities of their parents, and if forced to continue studies or to enter occupations requiring near work they usually develop myopia.

Experiments have been made with children of normal eyes not predisposed to myopia and children with normal eyes predisposed to myopia, that is, whose parents one or both have been myopic, with the result that the greater percentage of the latter under close work in school have developed myopia.

* Read before the Illinois State Medical Society, May, 1899.

Dr. B. Behim Schwarzback has reported in the *British Medical Journal*, examinations of the eyes of 1853 black people, mostly children, natives of towns in the middle province of South Africa, with the astonishing result that only 87 out of this number had weaker sight than the normal sighted Caucasian, the others possessing acuteness of vision equal to or greater than the normal sight of the European. The subnormal sight mentioned was due to myopia acquired at school, thus proving that the detrimental causes which produced short sight in children of the white race have the same effect on the optic organ of the dark race.

If it were possible to have made an examination of the eyes of the aborigines of this country, no doubt the percentage of acuteness of vision would have been similar to this result, as in our day the great acuteness of vision of the American Indian is well established.

Since in this paper we shall discuss operative treatment of high degrees of myopia, we will not refer to myopia of less than 12 diopters, further than to suggest a régime for myopia of less degree. How often the oculist hears the parents or guardians of children who come under his care remark that the child is a regular book-worm and reads continually at every opportunity, and prefers reading to playing out of doors with other children. Now, the reason for this will, with very few exceptions, be found in the fact that the child is myopic or near-sighted and not overstudious, and derives enjoyment out of reading because he can see to read and cannot see in the distance well enough to enter in the outdoor pleasures of other children of his age. The parents of these children, laboring under the impression that they are very studious and exceptionally bright—and they are brighter than most children of their age—will strain a point to give them superior educational advantages and fit them for some occupation that will require life-long use of the eyes for close work, and think they are doing their duty. The fact is they are putting that child in the best possible position for him or her to develop a progressive myopia of high degree and possibly entire loss of useful vision, if not complete blindness. These children should be carefully refracted, deprived of as much reading as possible and placed in some occupation best calculated to avoid close application with the eyes or much work in a stooping position.

Operative treatment of myopia consists of the removal of the lens from the eye, and by so doing we must consider the following: 1. We reduce the myopia from 10 to 16 diopters, according to the eyes of the patient. 2. We improve distant vision and impair near vision. 3. We destroy the power of accommodation. 4. We stop the progress of myopia. 5. We materially lessen the probability of complete blindness resulting from choroiditis or detachment of the retina.

For people who are compelled to do near work the operation offers few advantages, but there are many who will derive great benefit and advantages from the operation. The operation of removal of the lens for myopia has been performed with gratifying results many times in Germany and Austria, frequently in France and England, and a comparatively few times in the United States. It is true we do not find as large a percentage of myopia in this country as in Europe, but there are very many people in America who would derive great benefit from the operation. The first suggestion of operative treatment for myopia is found in the writings of Abbe Desmonceaux in 1776, quoted by Otto. Adolph Weber, in 1858, at the Ophthalmological Society of Heidelberg, suggested the removal of the lens

for myopia and stated that he had frequently performed the operation with success. In the discussion which followed Von Graefe spoke against it. Six years later, Donders ridiculed it in his writings. Nothing more was heard of the operation until Fukala published his paper in 1889. Vacher, before the French Society of Ophthalmology, on "The Treatment of Progressive Myopia and the Prevention of Separation of the Retina by the Extraction of the Transparent Lens," claims to have made the operation before those of Fukala; however, Vacher brought forward the removal of the transparent lens as a means of suppressing the myopia. He gave the results of seven operations in patients, all of whom were over 50 years of age, with myopia of 15 diopters and upward, and marked or advancing staphyloma.

Pflüger, before the congress at Rome in 1894, stated that he had performed dissections of the lens in one eye on thirty patients affected with high myopia. The degree of myopia varied from 10 to 20 diopters, the age of the patients from 10 to 40 years. In all the cases sharpness of vision was increased. In many cases it was doubled and even tripled. No evil results occurred in any of his cases.

Von Hippel, in a paper read before the Ophthalmological Society of Heidelberg, reports his results of 60 operations, the degree of myopia varying from 10 to 20 diopters, and the ages of the patients from infancy to 50 years. He found that choroidal lesions, even when extensive, are not aggravated by operation. In all cases dissection was practiced after an installation of atropin. At the expiration of about a week a softened mass of lens was evacuated without iridectomy.

In some instances vision acuteness rose to $\frac{1}{6}$, and in most cases it was from 4 to 6 times better than before the operation.

Wrag reports 123 cases of myopia, 246 eyes, with especial reference to points upon which the advisability of operation of removal of the lens was based. Of the above number 38 cases including other cases of detached retina had vision less than $\frac{1}{36}$ in one eye and 10 had less than $\frac{1}{36}$ in both eyes. He considered that his figures admitted of three deductions: that the vision was invariably less in the fourth decade than in the third; that retinal detachment is less to be feared than the changes in the retina and choroid; and that it is not necessary to regard every myopia of 12 diopters and upward as hopelessly drifting to a detached retina and blindness.

Julius Archer has collected reports from various quarters, of about 400 cases which have been operated on up to 1895. In most of the cases the myopia existing at the time of the operation was arrested in the eye operated on, during which time it continued to advance in the other eye on which no operation had been performed.

Goldzieher said that the operation was a wondrous advance in ophthalmology and in most of his cases perfect vision without glasses was obtained.

Professor Eucls of Vienna, discussing operative treatment of myopia, says: "In all people where a high degree of myopia exists an application of lenses, even when the retina and choroid are sound, is proved a practical failure." He suggests the removal of the lens as a "radical cure." Since that time he has shown many excellent results that have convinced oculists of its utility.

F. Otto reports the result of 85 cases of high myopia operated on by dissection, with subsequent removal of the lens by linear operation.

Professor Noyes remarks of myopia, reviewing over

1700 cases operated on in private practice, that it is found that 7.6 per cent. exceed 10 diopters. In these it was rare to find vision above .4; in many instances it was much less.

In operating on such cases two serious considerations arise: 1, an intraocular hemorrhage; 2, detachment of the retina. A third possibility cannot be entirely ignored, viz., a low grade of iridocyclitis, produced by traumatism causing turbidity of the vitreous and defeating the purpose of the operation. While hemorrhage may be spontaneous it is not induced so readily by needle operation as by section, for extraction and published reports do not specify this accident. On the other hand detachment of the retina is the misfortune chiefly dreaded.

Darier, before the International Congress of Moscow, gave an account of 142 cases operated in his practice, in 85 per cent. of which a distinct improvement in vision could be shown. In 10 per cent. vision was stationary and in 5 per cent. the eye was lost. This occurred in three cases from an infectious process and in four cases from the detachment of the retina.

According to Distler the operative treatment of high myopia is almost without danger. The acuteness of vision is improved and binocular vision is restored. Loss of accommodation is not a serious disadvantage. The danger of hemorrhage or detachment of the retina is not lessened by the operation, nor is it increased.

Gelpke and Bihler operated on every myope whose vision could not be improved sufficiently with glasses. They have operated on 74 eyes, with bad results in 3.4 per cent. The average increase in acuteness of vision was fivefold.

Meighan, Sweigger, Alt of St. Louis, Sattler, Panas, Liudsay, Johnston, Prof. Szili, Drussart, Morren, Edward Jackson, Frost, and others have reported cases of operation with a great percentage of improvement in vision and decrease in development of change in the fundus.

Grosz thought the operation should still be held in reserve and that we are not justified in operating in every case with confident hope of uninterrupted success. Most operators advocate operating first by discission and subsequently by extraction of the opaque lens mass by linear incision without iridectomy. Some, however, operate by a simple repeated needling.

Dr. H. E. Stafford reports three cases of extraction of the clear lens for myopia. He made an ordinary extraction without any iridectomy, lacerating the capsule of the lens with the point of the knife as it passed across the anterior chamber. The lens was delivered by the lid. The results of these cases fully convinced Dr. Stafford that the operation should be done without attempting artificial ripening.

In my own experience I have operated upon several eyes, two by dissolution of the lens by needling and five by discission and subsequent extraction of the soft lens without iridectomy and am decidedly in favor of the latter operative procedure for several reasons: 1. The length of time required is in some cases less than one-third of that required by the first procedure, which is a very important point in your consideration of the patient. 2. There is less danger of adhesions forming between the iris and the zonula. 3. There is less danger of setting up a low grade of iridocyclitis from continued pressure of the lens substance on the ciliary body.

The results I have obtained in my operations have been highly satisfactory to me and to my patients, and I do not hesitate to advise operation in cases where myopia

exceeds 12 diopters in either eye, in patients between 10 and 30 years of age, confidently expecting that I shall materially improve the vision of by far the greater percentage operated on.

CASE 1.—Miss O., aged 12 years, a school-girl, with obscure family history, was seen in March, 1897. Vision in right eye was 10/200, left eye 2/200. Ophthalmoscope showed marked staphyloma posticum in both eyes with chorochoritis more marked in the left, refraction—14 diopters in right and—16 diopters in left. Glasses did not materially improve the left eye and the best vision obtainable in the right was 20/100. The patient was unable to perform near work, with or without correction, with left eye on account of condition of fundus. Atropin was instilled in the left eye and discission was performed under cocaine anesthesia, followed by cold applications made to the eye to prevent inflammation from too rapid expansion of the lens matter. Four needlings were necessary to complete absorption, and a period of five months intervened before the pupillary space was clear and the eye pronounced well. Examination of the eye in July, 1897, showed the vision to be 20/80 or 1/4, a very satisfactory increase from 1/100 before operation. The inflammation of the fundus had almost disappeared and patient was able to read fine print with a +5 sphere. Examination of the eyes in March, 1899, shows no change in the left but vision of the right eye is only 5/200, due to increased fundus changes.

CASE 2.—Mr. F., aged 18 years, a schoolboy, with normal heredity, was seen in April, 1897. He had myopia of 18 diopters in the left eye, 23 diopters in the right, and posterior staphyloma in both eyes. No further fundus changes were present. Vision O.D. 5/200, O.S. 4/200. Best vision obtainable with glasses was 20.80 in right with—15 diopters and 20/100 in left with—18 diopters. Left eye operated with discission April 20, followed by linear incision and extraction of softened lens mass ten days later. Some lens matter remained in eye and needling was done five weeks later. Three months after operation vision was 20/30 for distance and patient was able to read with—3D. Right eye was operated on in similar manner on September 10 by discission and later by extraction of lens with no final needling required. Vision in this eye was 20/40+ and patient could read 20/30+ with—1.50, axis 120° and fine print with +2D. Patient had binocular vision after operations.

CASE 3.—M. G. F., a bookkeeper aged 22 years, was seen in June, 1898. His father was myopic. The patient had myopia of 8 diopters each eye. Ophthalmoscope showed—15 diopters in each eye with posterior staphyloma and hyperemia of retina. Vision in each eye was 5/200. Vision in right eye improved to 20/100 with—15D. Vision of left eye improved to 20/100 with—12 C.,—3 cyl., axis 180°. Patient's right eye operated first, followed two months later by operation on the left—both by discission and extraction of lens mass without iridectomy. Recovery was uneventful except for formation of secondary cataract in each eye which required needling. Patient had 20/40 vision in each eye after operation and was able to do all ordinary work with glasses, but required a +3 in right and +4 in left for reading. A peculiar feature of this case was the disappearance of 3 diopters of astigmatism from left eye after operation.

CASE 4.—Miss M. J., aged 11 years, a schoolgirl, with obscure family history, was seen in December, 1898. Ophthalmoscope showed myopia of 10 diopters with right eye, and 16 diopters in the left. There was beginning posterior staphyloma in the right eye, marked in the left. Vision O.D. 10/200, vision O.S. 4/200. Vision O.D. 20/30 with—8D. Vision O.S. 20/200 with—14D. The left eye was operated on by discission and lens mass followed to absorb. Five needlings were necessary for complete absorption and nearly six months' time elapsed. The best vision obtainable in this eye was 20/60—and patient has a slightly irregular pupil. She is able to read with a +5D. The right eye will be operated on if the myopia increases.

DISORDERS OF NERVOUS SYSTEM*

ACCOMPANYING GYNECIC DISEASES.

BY R. S. HILL, M.D.

Councillor of Alabama State Medical Association.
 MONTGOMERY, ALA.

The progress in the science of medicine precludes the possibility of the entire field being properly surveyed by one mind, therefore specialists are necessary for the satisfactory cultivation of its soil, much of which remains yet to be upturned by the ploughshare of research. No one, however, is fitted for a specialist who is not well grounded in the general subjects of anatomy, physiology and pathology, for a clear appreciation of the relationship and interdependence of the various tissues of the body is necessary in order to judge of the effect produced on the function of structure of one tissue by disease of another. This being manifestly important in reaching a correct diagnosis, Battey's and Tait's opinion that the removal of normal ovaries would cure nervousness, not only had no physiologic justification, but showed a total disregard for the general principles of physiology. I feel safe in saying that our present knowledge will not tolerate a suggestion that the normal function of any organ can disorganize that of another, notwithstanding the seeming exception of vomiting in pregnancy.

Viewing the human system as a most delicate and complicated piece of machinery, its cells differentiated into many groups called organs and glands, it is readily understood how the impairment of one or more of the organs may derange the entire system. I recognize, however, the fact that the female genital tissues are not necessary to individual life and, therefore, an exception may be taken in their case; nevertheless, I believe the connection between these parts and the rest of the system is so intimate and intricate as to justify the opinion that gynecic diseases and injuries are primarily responsible for many nervous disorders. I am free to admit that abnormal nervous manifestations may present themselves in a patient with disease of some portion of her genital tissues, without there existing the relationship of effect and cause; and I confess that I know of no way of reaching a positive conclusion as to when the gynecic disease is producing the nervousness.

Turning our attention to the nervous system, we find a marvelous anatomic structure, surpassed only by its wonderful physiologic action. Its cells possess a most delicate sensitiveness for the perception of impressions or impulses, an inconceivable capacity of association for their analysis, and an incomparable retentive force for their preservation. There exists between the cells a per-

fect state of equilibrium for uniformity in action. While these faculties are, practically, the possession of inheritance, the degree of perfection or accuracy with which the normal cell functionates is in proportion to its vitality, which is largely dependent on the quantity and quality of nourishment assimilated. As for the quantity, I hardly think the withdrawal of nutriment from the nerve-cells can directly and alone cause a disorganization of the functions of the cerebral cells, to the degree called insanity, but a large number of the cases of so-called nervousness are produced in this way. In regard to the quality of nutriment certain toxic principles entering the circulation and carried in sufficient quantity to the psychic cells will overthrow their power of correct analyses or reasoning, and cause what I understand to be functional insanity. There is another factor in the production of nervousness, by gynecic abnormalities, which I regard as too potent to be lost sight of, viz., the moral shock or effect produced on a patient by the recognition of the existence of an abnormal condition of her genital parts. I have seen this most severe in old complete lacerations of the perineum, where the total loss of the restraining function of the anal spincters acted as almost a constant reminder to the patient of her unfortunate condition.

A few words at this point may not be amiss on how impressions and conclusions are retained by the nerve-cells. If we admit, as we must, that these cells receive impressions, convert them into ideas and retain not only the primary impulse but also the idea, we must be prepared to accept the theory, as the most reasonable one so far presented, that there is produced a material change in the organized matter of each cell, every time it responds to an impulse, be it normal or abnormal impulse, and in accordance with the laws of direct cellular heredity, this material change passes, with decreasing distinctness, unless there is a repetition of the primary stimulus, through generation after generation of cells, until it is finally lost. While it is difficult for us to conceive of a material change in the nerve-cells to represent every experience, conscious, or unconscious, had by man, yet this is no harder task, nor is it more incredible than the crediting in the ovum of the mother and the spermatozoa of the father, some material representative of every class, if not of every cell, in the organisms of these respective individuals, and to deny this would be to destroy the theory of physiologic heredity and leave us in the confusion of ignorance. If we are correct in regard to the manner in which nerve-cells retain impressions and ideas, we have a physiologic explanation for the prognoses in nervous derangements, being largely determined by the length of time the disorder has existed.

However much we would like to prosecute our studies in this inviting field, we must forego our inclination, and approach nearer the heart of our subject by considering the nervous connection between the genital parts and other tissues. Byron Robinson says the uterus has twenty or more nerve cords running to the solar plexus, and that it, of all organs, "has the most intimate and profound connection with the cerebrospinal axis and abdominal brain." "That the connection of the genital and urinary system with all the great nerve-centers, is intimate and very large." I think anatomist and physiologist have proven beyond all question. If this is true, we have only to call to mind the laws of reflex action to understand how an irritation can pass from the genital system, through the hypogastric to the solar plexus, and by it be sent, with more or less force, over the numerous nerve-tracks to the viscera. As every impulse passing over a

* Read before the Alabama State Medical Association, April, 1899.

centrifugal nerve causes the cells which the nerve supplies to perform their characteristic function and as no cell, or set of cells, can properly discharge its duty without a period of rest, therefore, a more or less constant irritation from diseased genital tissue, traveling, as indicated above, to the viscera, will sooner or later overtax the cells concerned in the preparation of food, and thus cause an improper supply of nourishment to be furnished for assimilation. Being acquainted with the intimate connection between the sympathetic and the cerebrospinal nervous systems, and knowing the readiness with which an irritation may be transmitted by reflex action from one to the other, should we not be inclined at least to speculate on the possibility, if not the probability, of an irritation from the genital tissue traveling through the hypogastric or solar plexus to some of the higher cells of the cerebrospinal system, disorganizing their function to the extent of causing objective abnormal nerve manifestations?

With this mere summary of what appear to me to be plausible theories, I will report a few cases which have been under my care.

CASE 1.—Mrs. B., white, multipara, 40 years of age, nervous and eccentric, family history good, presented endometritis, incomplete laceration of the perineum of several years' standing, and relaxation of the posterior vaginal wall. Curettage, posterior colporrhaphy and perineorrhaphy were performed. The bowels were moved on the second day. On the third day nervousness began to increase, and continued to do so for a week, at the end of which time she was quite insane; suspicious of her family and attendants; speech irrational and disconnected; unable to recognize her surroundings; sleep little and disturbed. Bromid of soda, chloral and sulphonal were given at different times to promote rest, but had little or no effect. Her suspicions of evil designs on the part of her attendants caused a great deal of difficulty in giving nourishment, to say nothing of medicine. Efforts were chiefly directed toward keeping the skin, kidneys and bowels active. Digestion was very much impaired from the beginning. At the expiration of four weeks she began to improve and made a rapid and complete recovery; result of operation good.

CASE 2.—Mrs. P., white, widow, multipara, 38 years of age, anemic and nervous, family history negative as to nervous disease, had complete laceration of the perineum ten years previous to coming under my care. A fibroid tumor the size of an orange was present in the soft tissue between the uterus and bladder. Menorrhagia and metrorrhagia were severe. Curettage and removal of tumor through the vagina was done. Ten days afterward the perineum was repaired. The bowels were moved by purgative and enema, on the third day. Nervousness began to increase before the bowels acted and continued to do so until she became entirely irrational. The bowels were kept active, and nourishment and tonics freely administered. In the third week some mental improvement was noticeable, and by the sixth week she had entirely recovered. The result of the operation was good. The patient has gained in weight and at this time is in perfect health.

CASE 3.—Mrs. G., white, multipara, 27 years old, anemic and nervous but with no family history of nervousness, was reported to have had "several fits." The perineum was completely lacerated at the first confinement, six years ago, but she had been in good health up to that time. Four unsuccessful efforts to repair laceration were made before she came under my care. I repaired the tear and the third day afterward moved her bowels. Her nervous condition showed a decided increase on the

fifth day, and on the tenth day she was thoroughly irresponsible; constantly complained that some member of her family was dead; would get out of bed immediately on being left alone. Bromid of soda and sulphonal were used to cause sleep, but had no effect. The bowels were kept open and stimulants and nourishment freely administered. Digestion was very much impaired before and after operation. Mental improvement began at the end of the third week and continued to a complete and hasty recovery. The result of the operation was all that could have been desired. When last heard from her physical and mental health were good and there have been no more fits.

CASE 4.—Mrs. S. J., white, widow, multipara, 31 years old, with no family history obtainable, anemic and nervous, presented endometritis, growths in the vagina and bladder, hemorrhoids and complete laceration of the perineum. I curetted, removed the growths from the vagina and bladder and tied the hemorrhoids, and the patient progressed nicely. At the end of the second week, I repaired the lacerated perineum. The bowels were moved, as is my custom in these cases, on the third day. Nervousness was decidedly worse on the fifth day and on the ninth she had hysterical coma. The abnormal nervous manifestations continued, with more or less violence, two weeks, when change for the better was recognized. The same general plan of treatment was adopted in this as in the preceding cases and recovery was complete in seven weeks. The perineum united perfectly and she has experienced good health since she was discharged.

CASE 5.—Mrs. S., white, married, 30 years old, multipara, gave history of her father, a drunkard; mother weak-minded, and one brother, about 20 years of age, very peculiar. The patient was anemic and nervous; her digestion was very poor; she had complete laceration of the perineum, bilateral lacerated and hypertrophied cervix uteri, and endometritis. I curetted, repaired the lacerated perineum, and amputated the cervix. This patient went through the same experience as those above reported. Her general health continued to improve after her return home, but her nervousness remained practically the same as it was before she was operated on. I lost sight of her for twelve months or more, but during the latter part of last year she was brought back to me in a very much impaired mental and physical condition, when I prescribed a tonic for her and advised that she be kept under close observation or sent to an insane asylum.

Here we have five patients, to all appearances similarly affected, and four recovered and are now enjoying good health, while the fifth improved in physical health, but experienced no decided or lasting effect on her nervousness, and is now, after a little more than a year, presenting alarming signs of complete mental derangement. What were the factors in these patients acting as causes in the production of the nervousness before and the acute insanity after operation?

1. The knowledge of the existence of abnormal pelvic condition caused a more or less continued mental worry, which depressed the general vitality, and the function of digestion shared in the loss of force.

2. By reflex action abnormal nerve impulses were sent from the seat of the primary trouble to the abdominal viscera, disturbing their function more or less.

3. The slight mental and physical shock produced by the operation further lowered the vitality and impaired the power of digestion.

These all combined rendered the intestinal tract incapable of doing its work, as a result of which fermentation took place in the intestines, producing toxic princi-

ples. These toxic principles, being conveyed in sufficient force to the already anemic psychic cells, rendered them incapable of correct reasoning. Another factor in the fifth patient was the inherited nerve weakness from both parents, which I believe is responsible for her present condition.

CASE 6.—Mrs. J., white, married, 35 years of age, multipara, with good family history, had endometritis, bilateral lacerated and hypertrophied cervix uteri, and was anemic and nervous. She also suffered with dyspepsia and frequent attacks of intestinal colic, and experienced no appreciable improvement from several years of medicinal treatment. I advised curettage and amputation of the cervix, telling her, however, that I could not promise that the operation would prevent the intestinal colic; I could only say that it would relieve the local condition, which was probably partially responsible for her ill health. She submitted to the operation and remained at the infirmary about four weeks. Since her return home, several months ago, she has improved in general health and has only had one attack of colic, whereas, before the operation she had them almost daily.

This is a case in which I think we are perfectly justified in saying that impulses were sent from the diseased uterus through the hypogastric to the solar plexus, and from the latter to Meisner's and also to Auerbach's plexus, the former regulating the secretions and the latter the peristalsis of the intestines. Thus both these functions were disturbed, causing spasmodic intestinal pain and imperfect digestion of food. An improper supply of nourishment being furnished the system, anemia and nervous irritability developed.

CASE 7.—Mrs. P., white, married, multipara, 32 years old, but very much reduced in health, was extremely nervous and irritable. She had one sister insane. Two years previous to her coming to me she had been confined in an insane asylum for three months. Vaginal examination revealed purulent ovaries and tubes, which were subsequently removed, without liberating the pus. The second day after the operation she became violently insane, fought the nurses and made every effort to get out of bed, which was prevented only by force. An attendant had to be constantly by her to prevent her doing herself harm. No suppuration followed the operation and no elevation of temperature, except immediately following her struggles to get out of bed. Her mental condition showed signs of improvement in the fourth week, and at the end of the seventh week was practically as it was before the operation. Her general health improved very much. When last heard from, eight months after her discharge, she had again lost her mental faculties and her husband was preparing to send her to an insane asylum.

CASE 8.—Miss W., white, 22 years of age, father dead, and mother an epileptic mentally incapable of caring for herself, was "led astray" and contracted gonorrhoea. She had been confined to her bed several months previous to my being called to see her, was very much emaciated and complained of pain in her pelvic cavity. On examination I found her pelvis filled with an immovable mass. As the only chance of saving her life, I proposed abdominal section, which readily received the sanction of her physician and herself. I opened the abdomen and found, as I had apprehended, numerous and dense intestinal and omental adhesions, which, on being separated, revealed a number of pus-pockets. The ovaries and tubes were suppurating foci, and I removed them, washed the pelvis out and inserted a gauze drainage. The patient made an uninterrupted recovery and was sent home. Two or three

weeks later I was summoned to see her and she informed me that after eating she experienced "a lumping and gripping in the lower part of her abdomen." This gradually increased, until there was almost a complete intestinal obstruction. I advised that the abdomen be opened for the purpose of relieving the intestinal obstruction by destroying the adhesions, which I was confident were responsible for the trouble. I knew that more adhesions would form, but hoped they would not constrict the bowels. After entering the abdomen and separating the constricting bands, I examined the ligatures placed on the pedicles at the previous operation and found no trouble from them. The patient made a good recovery and went home very much improved in health, and I am reliably informed that she continued in very good condition for a year or more, when she became acutely insane and died within a few weeks.

Individuals who, by reason of inheriting nerve-cells of limited capacity, require, when in comparatively good health, a discharge of the full force of their psychic cells to perform their duties, are liable to have their mental functions disorganized by any conditions which tend to lower their vitality. Every major operation is attended with more or less shock, and the cessation—natural or artificial—of the function of the ovaries produces a decided impression on the nervous system. Therefore the operation, in the last two cases, may have added to the already present tendency to mental incapacity; nevertheless, they were operations of necessity, and ordinarily, by removing the condition which was causing the ill health, should have ultimately strengthened the capacity of the psychic cells to discharge their duty.

Correspondence.

Blackmailing.

ST. LOUIS, July 6, 1899.

To the Editor:—There is a crying evil prevailing in the United States against which no remedy has yet been found. It is sporadic in character and unsparing of the individual singled out for its victim. This evil or curse is known as "blackmailing," and it is an evil by the side of which assassination or highway robbery is a mere bagatelle. The watchword of the brave is, "thy purse or thy life," the watchword of the blackmailer is, "thy money or thy character," which to many is more precious than life.

The chosen victims of the blackmailer are chiefly medical men, who are singled out under a flimsy plea of damages for malpractice. The nominal plaintiff can not possibly attain his nefarious object without an affiliation with an attorney, whose only consideration usually is a contingent fee. Such attorneys are happily rare, but moral perverts can be found in every calling, and are well known to every searcher for such material. These psychomoral freaks are shrewd enough to circumvent unwary, unsophisticated persons to pose as plaintiffs and to load them with the odium of such criminal proceedings, making them responsible for all expenses, but keeping for themselves the pelf arising therefrom.

Numerous victims are met with in all parts of this country. The chosen unfortunate physician would sometimes rather buy off or make a compromise of the matter than endure the annoyance, expenses and blackguardism incident to such law suits. Occasionally these worthies strike a rock and are stranded, but they do not remain inactive long, and soon are in chase of another victim.

But why do they remain unpunished? Did they not try to obtain money under false pretenses? Did they not cause great expense, inflict untold mental sufferings? Did they not defame

and outrage with their spurious charges? It would be interesting to sociologists and pathologists if a posthumous examination could be made of the contents of the blackmailer's cranium. Many of the cerebral central areas, as those of affection, honor and benevolence, would, no doubt, be found poorly developed, while those of greed and rapacity would be abnormally prominent. With such physical degeneracy they would be incapable of doing the right thing, except by chance. An asylum for the demented should be their habitat. But if the structures of the brain are found normal, their malefactions are due to psychic and moral perversion, and the precincts of a prison should be their dwelling place. They should be under guardianship, either in a penal or an eleemosynary institution, and should never be suffered to go about without surveillance.

S. POLLAK, M.D.

Hemophilia.

CLEVELAND, OHIO, July 7, 1899.

To the Editor:—In the JOURNAL of June 24 (p. 1449), relating to an article read by Dr. G. W. Wagner, before the Detroit Medical and Library Association, on "Hemophilia," I notice he regards "exposure of bleeding wounds to the air" by him as probably original treatment. Perhaps it is original, but this means of controlling capillary oozing in these cases was suggested to me about twenty-five years ago by the late Dr. Isaac N. Harris, professor of physiology and histology in the Western Reserve Medical College. I do not know that it was original with him. This procedure proved efficacious in more than one instance to my knowledge. Respectfully,

A. J. COOK, M.D.

1. **Eruptions in Typhoid Fever.**—DaCosta describes and illustrates, by cases, the occasional varieties of eruptions aside from the characteristic rose spots of typhoid fever. The scarlatiniform rash may come on early or late, and he has known it to occur even in convalescence. It is a uniform red rash seen all over the body, though not universally so, more distinct in some places than in others, easily influenced by pressure, having periods of greater and less intensity, of partial disappearance and vivid return. It generally lasts a week or a little longer and passes away without desquamation. Two cases are described. The mealy eruption is rarer and more misleading and has much resemblance to the condition in typhus. Measles may complicate typhoid fever and this may lead to confusion. Two cases of this complication are described. The differences are the coarser, more papular and crescentic eruption of true measles; the itching and desquamation also are not seen in typhoid fever rash; the temperature range is also quite different and distinct. Still another type of rash is the mottling of the skin occasionally observed, which he considers due to a hyperemia. All these eruptions are probably due to nervous vasomotor disturbances, but how this is produced he does not say. There is nothing in these rashes which seems to add any special gravity to the disease when they occur.

2. **Typhoid Fever in the Late War.**—This article is the result of an inspection made under the order of the surgeon general in the late summer of 1898. It is published by permission of the war department. The first point noticed was the lack of scientific diagnosis of typhoid fever, many cases being

called malaria, though malaria was a very rare disease among the soldiers. The origin could be easily traced in most cases. Its spread was not so generally due to the water-supply as to carelessness in camp police. The statements made in this regard are very striking. There is no evidence that milk was a frequent vehicle. Note is made of the apparent intermittent character of the disease among the soldiers. He concludes as a result of the studies that a regiment thoroughly infected does not better matters by change of camp; there should be thorough disinfection of everything, clothing, blankets, tentage, etc. If the regiment is infected before the infection has become marked, the typhoid may disappear or at least decrease. A sea voyage of some days or weeks may rid a command not too much infected, of the disease, but a short voyage would have no such effect if the regiment was thoroughly infected.

3. **Carcinoma and Tuberculosis.**—Warthin reports two cases of the coexistence of carcinoma and tuberculosis of the mammary glands, which he thinks are unique. He is inclined to follow Ribbert's view that the tuberculous process may act as a primary factor in exciting the carcinomatous condition, but thinks this relation is a very rare one. In his second case he considers the tuberculous process as a secondary infection to the carcinoma.

4. **Kernig's Sign in Meningitis.**—Herrick gives a thorough discussion of this phenomenon, considered by Kernig as characteristic of pial inflammation and always present in such conditions. It is described as follows: If a patient with meningitis is made to sit up, as on the edge of the bed, the thigh being, therefore, at right angles with the back, it is extremely difficult to extend the leg because of the presence of a marked flexor contraction. In 19 cases observed by Herrick, this sign was present in 17, and in the two where it was absent, both children, the single examination was made shortly before death when there was a general marked laxity of all muscles. It may have been present earlier. In 100 cases of disease other than meningitis, it was present only in 2. No satisfactory explanation of this phenomenon has been offered and Herrick does not attempt to explain it other than by saying that there is probably such increase in tone as to exaggerate the natural difficulty of extension to actual flexor contraction. (See *JOURNAL*, xxxii, p 1013.)

6. **Cystonephrosis.**—Fenger advocates the eversion, or turning inside out, of the sac of cystonephrosis, through an opening large enough to permit this, combined with methodic consecutive division of the partition walls one after another so as to lay bare and turn out for inspection the whole inner wall. This is the surest way of finding the ureteral opening. He reports a case at length, illustrating the value of this operation.

7. **Triple Infection.**—Eshner reports a case of tuberculosis with intercurrent typhoid fever complicated by pneumonia.

11. **Alkalinity of Blood.**—After an elaborate review of the literature of the subject, Salisbury ends his paper with the following conclusions, which he thinks are justified in the present state of our knowledge: The reaction of human blood is constantly alkaline. The alkaline reaction is due partly to inorganic alkalies and partly to substances of organic nature which are probably derived from the proteid food. The regulation of the reaction of the blood is due to the action of the kidneys and probably the liver. The alkaline reaction of the blood is reduced in various diseases—uremia, diabetes. In infections it is lowered in proportion to the virulence of the infection, but increases with the recovery of the organism, and in immune animals is above the normal. In the treatment of disease causes of acid reaction should be avoided, particularly in infections. Thus the action of the skin and kidneys should be favored and the production of acids by fermentation in the intestinal canal should be prevented. The administration of

alkalies in moderation is useful, but cannot be expected to raise the alkalinity of the blood to a high degree. This is due to the fact that inorganic alkalies are either temporarily stored in the liver or rapidly excreted by the kidneys. The increase of alkalinity in cases of recovery from infections is probably not the cause of recovery, but is due to the production in the blood of a curative substance which is alkaline in reaction. The substance is a nitrogenous organic compound, and is derived from the proteids. A meat diet, therefore, would seem especially suited for patients suffering from infection. It may be the case that the nitrogenous constituents of beef tea, although not proteids, are capable of furnishing the material from which such an alkaline protective agent can be produced.

12. **Cystitis Faveolata.**—Kreissl describes a condition which he has not found specially mentioned in the literature, occurring in cystitis, consisting in the gradual production of minute holes in the muscular coat of the bladder and after long continuance extending even to the interstitial connective tissues and even penetrating the bladder wall, producing pericystitis. It is distinguishable from the real diverticula of the bladder in which the opening is smaller than the cavity behind it and the holes thus appear like dark spots through the cystoscope while in this condition they are visible through their whole depth. They aggravate the condition by offering pockets for morbid secretions and rendering it difficult to cleanse the bladder by irrigation. He thinks chinolol, 1/10 grain to the ounce of distilled water, is the best remedy for this condition. Under it the condition of the urine improves rapidly, irritation subsides, and the intervals become longer. Later, Guyon's instillations of nitrite of silver may be employed.

14. **Protargol in Gonorrhoea.**—Baum's paper gives a tabulated statement of fifty cases treated by him according to Neisser's method, with protargol, using injections three daily. The last one a prolonged one, thirty minutes, beginning with .25 per cent. solution, gradually increased to .5 and 1 per cent. After a few days the last or prolonged injection is alone used. The other two injections are replaced by a 2.5 per cent. suspension of bismuth or iodoform, a 3 per cent. solution of boric acid or a .25 per cent. solution of sulphate of zinc. The fact that the solution is not precipitated by albumin probably accounts for some of the good results obtained and the penetration into the follicles and periurethral tissue must be greater. This method is a decided advance in the treatment of gonorrhoea.

15. **Floating Kidney with Hydronephrosis.**—Kohlscher calls attention to the fact that intermittent hydronephrosis is not a rare complication of floating kidney, and he advises the following course in such accidents: Replace the kidney and keep the patient in bed; wait twenty-four hours for the spontaneous emptying of the tumor. If this occurs, a simple anchoring of the kidney in its normal position is sufficient to effect a cure, and in the light of our present knowledge seems to be superior to McArthur's or Senn's operation. If after twenty-four hours no decrease in the tumor has taken place, ureteral catheterization is to be employed, accompanied by deep massage. If nephropexy is performed, it should be preceded by a nephrotomy, which should include such repair of the pelvis of the kidney as is indicated in the case; the ureteral catheter should be left in position to act as a guide during the operation.

16. **Hot Air Cauterization in Lupus.**—The object of this paper is to bring before the profession of this country the method of Dr. Hollaender of Berlin for lupus vulgaris—hot-air cauterization. He describes and illustrates the apparatus and also several cases treated by Hollaender according to this method, which seems to be a success.

17. **Caput Obstipum Musculare.**—The summary of Harris' paper is as follows: 1. Caput obstipum musculare is a post-natal chronic inflammatory condition due to infection

principally affecting the sternocleidomastoid muscle, and accompanied by contraction; 2, the affection is principally for a variable though considerable time progressive; 3, the best treatment is complete extirpation of the contracted muscle and the involved surrounding tissues.

19.—**Modern Sanitation and Quarantine.**—Souchon describes the requisites of modern scientific quarantine, especially with reference to yellow fever, as derived from experience in New Orleans and Louisiana.

20.—**Splenomedullary Leucemia.**—The patient was a white man, 37 years of age, a native of Louisiana and a farmer by occupation. In June, 1898, while shearing sheep, he was taken with a pain in the splenic region. Three days later the spleen was noticed to be growing large; there was no fever, but diarrhea or several days' duration. The spleen continued to swell, the increase in size ceasing from time to time only to recur, until it filled the whole of the left side of the abdomen and encroached noticeably on the right side. Of some bearing on the etiology of the case, in conjunction with the history of traumatism suffered while shearing sheep, is the fact that the patient suffered a severe blow on the right tibia some months after the beginning of the splenic enlargement, the skin over the site of injury being still discolored and tender at the time of his admission to the hospital. The blood was perfectly natural in color, a surprising fact, considering the enormous number of white blood-corpuscles. It flowed freely from the finger and was easily spread between cover-glasses, contrary to the observation of Cabot, who says it flows sluggishly and is difficult to spread on account of the masses of white cells contained in it. Coagulation was slow. Nucleated red blood-corpuscles were noticed. Of leucocytes there were found—polymorphonuclear cells, lymphocytes, eosinophiles—largely increased in number—and a very large number of myelocytes, characteristic of the splenomedullary form of leucemia.

21.—**Mental Suggestion and Charlatanism.**—Scott's article notices the importance and utility of suggestion in the cure of disease, and then reviews "Christian Science," showing up its absurdity.

22.—**Diagnosis of Hip-Joint Disease.**—Napier describes the method of diagnosis in hip-joint disease quite thoroughly, but we cannot follow him fully in detail. The conditions which may resemble it are, simple contusion or sprain, which may simulate its symptoms very closely, though observation and rest in bed will clear up the diagnosis. Traumatic or rheumatic synovitis sometimes resembles the sudden acute attacks of hip disease, but there is usually more swelling and redness and more swelling over the joint. The pain is in the hip and the muscular twitchings during sleep are rare. In rheumatism there is often history of previous attacks and the duration of either form of synovitis helps to clear the diagnosis. Chronic synovitis may also give us the symptoms of bone disease, and dislocation of the hip has often been readily mistaken. Coxa vara is a rare condition, first described by Muller in 1859. It is a bending of the neck of the femur which usually occurs in males at the age of 14 or 16, but may occur earlier. The trochanter becomes elevated, there is usually pain, some atrophy, and later muscular spasms. The principal characteristics are limited abduction, elevation of the trochanter and pain after exercise. Pott's disease with lumbar abscess may also simulate this trouble.

25.—**Unification Needed.**—Lusk's paper is a plea for more concentration and unified effort on the part of the profession. He thinks that medicine has not received the consideration it should, and is convinced that the position we occupy is largely due to our own neglect of opportunity and will be unimproved unless we adopt principles or measures in keeping with good sound common sense and in accordance with the standards governing the closing years of the century instead of those prevail-

ing 100 years ago. We ignore the truth that in union there is strength, and subdivide our efforts and waste our energies. There are in the United States nearly one hundred thousand members of the regular profession. Imagine our power socially and practically if we paid allegiance to one national association, for instance, the one that has always taken the lead in power and numbers, viz., the AMERICAN MEDICAL ASSOCIATION. This should be strengthened by an enormously increased membership to which every physician should feel the same loyalty as to the country in which he lives. After enumerating some of the numerous national organizations, he asks, "Now why could not a majority of those numerous societies accomplish fully as important results in their special lines organized in sections, thus representing branches of the one great body? Why is this marked isolation necessary? I will leave the answer with you."

Another point noticed by him is the multiplication of medical colleges, and he specially notes the fact that the craze for adding "Professor" to one's name seems to especially affect the profession in the middle West. Thus, in Missouri, there have been organized since 1840 thirty-three medical colleges, sixteen of which survived in 1895. The following quotation from the annual address of Dr. Richmond of St. Joseph, Mo., president of the state society, is to the point: "A few, shrewd and ambitious for self-promotion, seeing how they would reap advantages from a professorship, organized a college. Those who were left out, not willing to be overtopped by the big professors, organized a second. Still there were a few who were not supplied, and disaffection springing up in one, it swarmed, and a third was the result. Of the forty-four doctors then in town I was one of the four who was not a professor, a distinction of which I am not ashamed. In selecting their faculties it was not necessary to go beyond the city limits, only to the suburbs." Still another question is the part we take in politics. Thus far in our profession we have done little, but the time has arrived when it is absolutely essential that we should make our power known, not necessarily in seeking position, but in selection of those who will recognize our position and our reasonable demands.

26.—**Prophylaxis in Obstetrics.**—The principal points in this paper are the necessity of attention to: 1, family and personal history; 2, general physical examination; 3, general hygiene, as food, clothing, etc.; 4, special attention to urine; 5, care of nipples and breast; 6, asepsis and douching before and after labor; 7, prevention of postpartum hemorrhage; 8, repair of lacerations.

29.—**Vaccin Virus in Eye.**—Eagleton reports a case of a doctor who accidentally had a vaccin tube pushed against the eyeball with some force. It was followed by a bleb beneath the conjunctiva. The patient had been protected by previous vaccination, otherwise there would probably have been loss of an eye.

31.—**Percentage of Color Blindness.**—Mullen has collected statistics as to the occurrence of color blindness from various sources in different countries, which show quite a wide variation from different sources of report. The total number of cases examined was 308,919, the larger number, 181,169, being from the United States. The average percentage of color blindness of the total was 1.82, the largest 3.80 in Denmark, the lowest .01 per cent. in France. In the United States the percentage was 1.53 for men and .0073 for women. [These figures do not give one full confidence in the reliability of the reports].—Ed.

34.—**Operation on Injured Eye in Sympathetic Ophthalmia.**—First remarking that common experience justifies enucleation of the injured eye before the occurrence of sympathetic ophthalmia, while after this has begun it is generally useless, Sattler states that he has been led to restrict the operation to those cases in which the injured eye is a source of uncontrollable suffering, or because it harbors a concealed foreign body, or

it could be assumed that the measure would be necessitated sooner or later. In other cases, however, where sympathetic ophthalmia has occurred, but is not attended by unbearable pain, operation should not be recklessly attempted. So long as this is not done there remains a small chance that it may furnish further along, the opportunity for a partial restoration of sight even in the injured eye. Three cases especially impressed him to adopt conservative measures in his later practice. He says: "To summarize briefly: Enucleation of an injured eye—particularly in rupture of the sclera, punctured wounds of globe with extension to the uveal tract—when active sympathetic ophthalmia of the fellow eye has been excited, is not justifiable, for the reason that after a complete subsidence of inflammatory reaction in both eyes, the injured eye may alone offer a chance for a partial restoration of sight. Enucleation of an injured eye which has excited sympathetic ophthalmia is justifiable and often a means of necessity, in case of traumatism produced by the lodgment in the eye of a foreign body which cannot be localized. If such are a source of continued suffering, the enucleation should be speedily done, but without a hope or prospect that this will influence the course of the inflammatory disturbance. Enucleation of the injured eye with the hope that it will favorably influence the progress of sympathetic ophthalmia has little or no foundation in accurate clinical observation or surgical experience. There certainly is no reliable proof that it has ever arrested or even retarded the fatal course once begun. It must, therefore, be considered an uncertain measure of interference, which expediency even can only counsel in a small number of cases. It must furthermore be added that there are no reliable data that it is harmful in the sense that it excites a more rapid or more disastrous course in the sympathetically affected eye. This is more likely due to the inherent degenerative activity, which varies in each case, so far as its destructive fatality is concerned."

35.—**Euphthalmin Mydriasis.**—This synthetic product, closely related to eucain B, was brought to the notice of ophthalmologists a couple of years ago, and its value reported by various European authorities. Jackson reports from his own observations, as follows: Euphthalmin acts on the eye as a true mydriatic. Its influence is more feeble and brief than that of homatropin. Its influence on accommodation is relatively slight, so that it has no practical value as a cycloplegic; and its cycloplegic influence causes but trifling annoyance when it is used as a mydriatic. It is the best agent we have to produce brief dilatation of the pupil under strong light, and stands next to cocaine in value for dilating the pupil for ophthalmoscopic examination. Combined with cocaine, it produces a satisfactory mydriasis for the examination of the eye, with the least annoyance to the patient and the most rapid recovery.

37.—**Vomiting of Pregnancy.**—Buford, after reviewing the physiology of vomiting, comes to the conclusion that the anabolism of the fetus and mother gives us an increased generation of the irritant which causes emesis, and a deficient elimination by the kidney produces its accumulation in the system. Summarizing these, he reaches the following conclusions: 1. The cases of vomitus gravidarum is not a reflex but the by-products of anabolic cell metabolism, which acts centrally, as apomorphia does. 2. The nephritis, which is usual concomitant of vomitus gravidarum, and is itself the result of hyperhydrochloria, is the cause of deficient elimination. The postulate that defective nutrition is a result of the above conditions is an accepted fact. The therapeutic endeavor should be directed to relieve the cause. This is best done: a, by lavage of the stomach thoroughly three times a day with alkaline antiseptic solutions; b, baths and massage to enable the skin to assist the kidney; c, by exercising freely in open air; d, the diet of proper quantity and quality. The induction of abortion to relieve vomiting of pregnancy he has never seen justified, and it is only mentioned here to be condemned.

38.—**Strabismus.**—Bear describes a special method of advancement of the tendons in strabismus, which is rather too detailed to abstract here. He also describes one or two other operations suited to special cases. He claims for his method that it is the safest and the simplest of processes.

40.—See abstract in JOURNAL, May 27, p. 1172.

41.—**Mastoiditis.**—Davidson's paper describes the condition of mastoid inflammation, its diagnosis and treatment. He thinks the most valuable diagnostic points are tenderness on deep pressure, and the sagging of the posterior superior wall of the canal, which are sufficient evidences of its existence; that we should never wait for redness and edema behind the ear to occur before making a positive diagnosis. In case of complicating acute suppurative of the middle ear, the first indication is thorough drainage through the canal, and the use of constant ice applications in contact with the mastoid process. He would continue this for four or five days in acute cases before resorting to operation, if possible. Hot applications, leeches and Wild's incision are condemned. In chronic cases he would not use ice applications at all, and in his judgment they should be immediately operated on. The operation is described in detail. Injury to the lateral sinus is bound to occur sometimes, but hemorrhage from it is easily controlled. The danger is from infection.

43.—**Alveolar Hemorrhage.**—Excessive bleeding after tooth extraction is noticed by Hartman, and is due to traumatism, laceration and fracture of the bone, or to hemorrhagic diathesis. Simple and direct pressure on the part is the best treatment, but tannin is the best agent for local application and may be used in conjunction with pressure. Monsel's solution is dangerous and not to be relied on. In cases known to be bleeders, it is well to give 10 grains of gallic acid every hour, commencing just before the operation, and continuing until bleeding stops.

45.—**Eclampsia.**—This is defined by Snyder as "an auto-intoxication caused by an agent producing coagulation, and characterized by convulsions, loss of sensation and consciousness, accompanied by frontal headaches and epigastric pains." In summarizing the treatment he concludes that the only rational procedure is to have all the emunctories active, as the bowels with compound colocyath, the bladder by mechanical means, a diet of milk and digestible foods. The patient is then placed in a hot bath or hot pack, when perspiration is soon established and prodromes vanish. After labor has begun, in addition use chloroform for spasm, and deliver the child by artificial means. Give cardiac stimulants; after labor use only the hot packs. From this treatment he considers the mortality due to eclampsia can be greatly reduced.

46.—**Auto-intoxication.**—Chittenden discusses the facts and theories relating to auto-intoxication, from the standpoint of general metabolism, considering auto-intoxication a possibility within the reach of every individual organ, tissue, and cell of the body. This conception of auto-intoxication does not exclude the possibility of another form of toxemia resulting from the absorption of products formed by the action of micro-organisms in the intestinal tract. Considering the possibility of auto-intoxication resulting from the action of normal products of tissue katabolism (xanthin, hypoxanthin, guanin, and adenin), either because of excessive production or tardy elimination, the recent evidence indicates that adenin is intensely toxic, is resistant to change within the body, is not excreted as allantoin or uric acid, and produces marked pathologic changes. Hypoxanthin is non-toxic, probably because of its early conversion into uric acid and allantin. Xanthin is likewise easily changed, and is more resistant; only when a methyl group is introduced into the xanthin molecule does it resist changes. The toxicity of the methyl compound increases with the number of methyl groups introduced. Acetone and its production is considered in

this connection as a toxic substance, although in a healthy individual large doses are required to produce much effect; still, in inanition, the weakened conditions attendant on the severe forms of diabetes, and in some other diseases, acetone may be present and its possible physiologic effect is to be considered. The writer considers the chief factor in auto-intoxication "a phase of perverted metabolism which as yet cannot be localized, and doubtless does not admit of distinct localization. The production of so-called toxins is, without doubt, in many cases at least, the initial cause of the disturbances, but no one of the bodies can be held directly responsible for the physiologic results which ultimately appear. This, that, or the other substance, produced in undue amount, may simply set in motion a chain of events from which eventually is developed a series of symptoms only remotely connected with the primary action of the so-called toxin. The extreme sensitiveness of the nervous system to toxic substances renders it probable that autopoisons exert their primary influence here, and that many phases of auto-intoxication are due to primary disturbances of the metabolism of the nervous system."

47.—**Indigo Group in Internal Medicine.**—Discussing the relation of indol to free HCl in the gastric secretion, Vaux concludes that in:

1. Gastric conditions such as achylia, characterized by a total persistent absence of free HCl, and lactic acid, will ultimately be the source of indicanuria.

2. This condition will be materially advanced or delayed, according to the presence or absence of motility.

3. The indicanuria of gastric cancer must in a large measure be attributed to proteid degeneration.

4. Conditions of the stomach marked by excessive or continuous secretion of HCl, act in a similar manner to those with anachlorhydria, though for a different reason.

5. Primary enteric affections are usually the source of an increased formation of indol, and this is in direct proportion to their severity.

6. Constipation, unless in a person of unusual absorptive powers, or extending to the small gut, does not produce a marked indicanuria. While it is pointed out that intestinal stasis either in a moderate or pronounced degree always results in a relative increase in the elimination of indol, it is also well to remember that a condition of stasis may be present without any apparent torpidity of the bowels.

48. **Sarcoma of Thyroid.**—Cnumston had under his observation for some months a case presenting moderate enlargement of the left lobe of the thyroid. Afterward, showing a tendency to rapid growth, and having attained the size of an apple, excision was effected. Examination of the neoplasm showed the capsule of the gland intact, the gland uniformly firm in consistency. Microscopic examination defined a typical follicular goiter at the upper part of the gland, which had become invaded by spindle-celled sarcoma in the septa dividing the vesicles of the gland. A focus of sarcomatous tissue, the size of a cherry, was found in the lower part of the gland. The writer discusses the subject of malignant neoplasms of this gland very fully, as well as the technic for their removal.

53. **Multiple Arthropathy.**—Simpson's case differs from arthritis deformans in some respects. While the progressive joint involvement was uniform, the first joints involved were the larger ones, the smaller articulations being last affected. The patient, a male, aged 43, presenting a fairly clear hereditary history of joint troubles, observed the arthropathy in the ankle-joints first, later the knees, the spinal column, in the dorsal, then in the cervical regions; and eventually the shoulders and elbows. Five or six years after the onset of the earliest symptoms the metacarpophalangeal joints became afflicted, were swollen, painful and with a marked tendency to fixation with noticeable ulnar deviation of the hands. It was observed that in damp weather, as a rule, the tenderness and discomfort

in and about the joints was decreased and an improvement was marked in the patient's general condition. The articular swelling was in this case apparently due, to a large extent at least, to the effusion into the joint; practically no deposit occurred about the joints. The case presenting an "unjointing" of almost the entire body, suffering from principally from the soreness experienced on attempted motion, and from the loss of muscular power.

55. **Ectopic Pregnancy.**—McLaren briefly reports fourteen cases of ectopic pregnancy, occurring under his observation, the last one a case of interstitial pregnancy with missed labor and death of the child, delivered by abdominal section thirteen months after conception. He thinks that there has been a larger mortality (3 in 14) in his experience so far than there would be were it repeated.

56. **Catgut.**—Boeckmann reviews the subject of catgut and its preparation for surgical use. He has tried to learn the trade secret of its preparation, but without success. He describes in detail the methods of cleansing, antiseptic impregnation, reduction, drying and stretching, hardening, putting in receptacles and sterilizing, which last he prefers to secure by dry heat. He believes that the ideal catgut is in our reach and will render all other kinds of suturing and ligating material superfluous. It must be aseptic, antiseptic, strong, pliable and durable. It is ideal, however, only in the hands of an ideal surgeon. Catgut of the best make as to strength, cleanliness and sterility, and surgically prepared by washing, silverizing, drying, stretching, exposure to sunlight, hardening in alcohol, with or without the addition of formalin, and sterilization by dry heat, put up in hermetically sealed envelopes is an almost ideal suturing and ligating material, subject, however, to improvement. If trouble arises, the surgeon is responsible.

57. **Pediatric Cases.**—Putnam presents, in this clinical lecture, cases of double and single harelip, cervical and tubercular adenitis, tuber-culosis of phalanx and congenital dislocation of hip.

58. **Uric Acid Diathesis.**—The special point in Schultz' paper is that Rigg's disease is a uric acid manifestation and should be treated by constitutional methods, as well as local means.

59. **Varicose Ulcers of Leg.**—Brown's reports indicate that this paper is written largely to praise antinosis and nosophen in these conditions. Galvanism was also used.

63. **Propagation of Typhoid Fever.**—Ramsur finds, from his observations, that typhoid fever in small towns is fly-borne. In cities with good sewerage systems, it is necessarily water-borne. In cities typhoid prevails at any season, provided the germs remain active at all temperatures. In villages, on the other hand, it is largely autumnal and most extensive during the hotter, dry months when propagation by flies is possible.

64. **Laboratory of Ontario Board of Health.**—Mackenzie, bacteriologist of the Ontario Provincial Board of Health, describes the methods of work in the laboratory of the board. The diseases investigated were tuberculosis, cerebrospinal meningitis, etc. During the past few months he has been studying the hay bacillus noticed by Moeller, and closely resembling the tubercle bacillus. He finds, as differences, that its pathogenic virulence on animals is slight, and that the Sudan III. stain for tubercle bacillus will not affect this. Its practical importance, he thinks, arises from the danger of confusing it with the tubercle bacillus in butter and milk.

69. **Does Tobacco Cause Amblyopia?**—The term tobacco amblyopia commonly used is objected to by the author as not consistent with the physiologic action of tobacco. The most that can be said is that it may produce a sympathetic amblyopic condition through disorder of the stomach. Tobacco amblyopia, therefore, is a disorder of those not accustomed to tobacco, rather than that of tobacco habitués.

81. **Fracture of Radius.**—Richardson recommends the fol-

lowing method of reducing fracture of the lower end of the radius, which is practiced in the Pennsylvania Hospital. The surgeon stands in front of the patient, interlaces his fingers beneath the supinated wrist and palm of the injured member, so that his two index fingers parallel crosswise beneath the lower end of the upper fragment of the radius. The palms of the surgeon's hands are then closed in upon the thenar and the hypothenar portions of the patient's hand, respectively, while the surgeon's thumbs rest parallel lengthwise on the upwardly displaced fragment of the radius. The parts are thus firmly grasped by the surgeon while the following movements are made: The patient's wrist is excessively extended by carrying his hand upward. When hyperextension has thus been secured the surgeon makes powerful traction on the wrist in the line of hyperextension. While this traction is maintained the hand is suddenly carried into full flexion, and at the same time powerful downward pressure on the upwardly displaced lower fragment of the radius is made by the surgeon's thumbs, opposed by the interlaced index fingers beneath the lower end of the upper fragment. The excessive extension of the first portion of the movement has always loosened or disintegrated the displaced lower fragment while the subsequent traction flexion and direct thumb pressure has not yet failed to accurately force the lower fragment into its proper position. Separated epiphysis of the lower end of the radius is likewise easily reducible by this manipulation. For comminuted or complicated or very oblique fractures extension and moulding alone are called for in most instances. The patient does not anticipate what is coming; the two movements are made with lightning-like rapidity in a small fraction of a second, and, in nearly every case, perfect reduction has been accomplished before the patient realizes that he has been hurt; so anesthesia is unnecessary for making a single effort at reduction by the proposed method. Should the manipulation fail to secure perfect reduction at the first attempt, it is better not to repeat the maneuver until anesthesia has been induced, for the pain of repeating it would be intolerable.

86. **Interesting Cases.**—Manley reports three cases of rather peculiar interest. The first was one of mammoth dermoid cyst of the scrotum complicated with inguinal hernia in a man 60 years old, which was successfully extirpated and reduced. The second was of embryonic umbilical hernia, containing the stomach, small intestines, cecum and colon with the liver, spleen and pancreas, in a new-born female infant. There was practically no abdominal cavity, therefore its reduction was out of the question and the child succumbed. The third was a large irreducible umbilico-ventral hernia in an aged woman, relieved by supporting bandages.

93. **Etiology of Rheumatic Fever.**—Wertz reports the causes, so far as known, of acute rheumatism—season, cold and dampness, drought, which seems to have a relation as shown by English statistics, and locality, the infection seeming to cling to certain houses, like that of diphtheria, erysipelas, etc. As regards the bacteriology, he is brief and does not refer to some of the later researches and reports on this subject.

95. **Treatment of Diphtheria.**—Brubaker remarks on some of the difficulties and annoyances in the treatment of diphtheria, the difficulty of sometimes obtaining a satisfactory bacteriologic examination and the uncertainty as to when danger of infection ceases. As to the treatment, prophylaxis is of the utmost importance, but the area of contagion is a limited one and much can be done by isolation and disinfection. For local treatment he limits himself to the use of chlorid of iron given in medium doses. Preparations of mercury should also be given. He would advise a laxative followed by catharsis and afterward small doses continued. Antitoxin should be used in all cases and should be from a reliable laboratory. It should be used early, not waiting even for the bacteriologic report. The surgery of the disease is another matter briefly mentioned,

and in some cases it should be also done early. He thinks it a good practice, when intubation has been decided on, to prepare at the same time for immediate tracheotomy in case of failure in inserting the tube. Further, this measure is not certain to afford great relief as the membranes may extend deeply into the trachea and bronchial tubes, and it is well to state these facts to parents and friends.

97. **Indicanuria and Phenoluria in Children.**—Thomas' article reports five cases of children in whom he found conditions of apparent intoxication by these substances, the pathologic action of which he discusses in the light of the present literature. What is actually known of the subject is summed up by him as follows: 1. The presence of these substances in the urine is the result of a process of putrefaction of the albuminoid contents of the intestines whether intermingled in normal quantities or otherwise—usually the former. 2. Indol and phenol are converted by a well-understood process into sulphoconjugate acids, which are said to be not very toxic. He is not certain as regards this point and is continuing investigation on the subject. It appears that the liver plays a prominent part in the production of phenols, while indol is apparently formed in the intestines. On the other hand, the liver is said to impede the passage of these substances through the portal circulation, and when there is much indican in the urine we usually find alimentary glycosuria. His five cases were children, four girls and one boy, between the ages of 4 and 9 years. The symptomatology in these cases is, on the whole, rather indefinite, affecting the general condition and the state of the digestive organs. There was anemia, slight emaciation, muscular insufficiency, digestive disorders, some nervous exhaustion, and in one case respiratory trouble (dyspeptic asthma). The treatment is directed to the general condition, moderate exercise, out-of-door life, salt and sulphur baths. With an arthritic heredity, too much rich food should not be given, and he advises dispensing with meat or allowing it only in small quantities. The bowels should be looked after and kept disinfected.

98. **Tetanus.**—Ward reports a case of tetanus occurring a week after injury in which death occurred on the second day from asphyxia.

99. **Address.**—Barrow's address is that delivered before the Kentucky State Medical Society in May.

100. **Indications of Enucleation.**—Evans, after quoting the indications for enucleation as given by Knapp and Swanzy, states that there are many cases where it is impossible for him to say that this operation is required. He believes that altogether too many primary enucleations are done, and that they should be limited to those cases known to contain a foreign body that cannot be extracted, and to those of excessive laceration of the globe. Sympathetic ophthalmia does not develop for at least three weeks after injury, thus giving ample time to wait and see what rest and attention will do and still enucleate in time if required. He thinks, moreover, that the exciting eye, if closely watched, gives sufficient and timely warning of the approaching danger to the other eye.

101. **Bullet Wounds of Intestines.**—Three cases are reported by Woolsey, of multiple pistol-shot wounds of the intestines, treated by operation. One case has been previously reported in the *Annals of Surgery*. In one, death occurred from intestinal sepsis, the other two recovered. In discussing these cases the author condemns Senn's hydrogen insufflation as a diagnostic method, holding that it increases the danger of escape of intestinal contents and consequent risk of peritonitis. As regards prognosis, the number of wounds is an important element, as is also the condition of the stomach and bowels as to fulness or emptiness. Wounds of the large intestine, with its more solid contents, are less likely to be followed by their escape, and if the bowels are empty the chances of their perforation are diminished. The curious fact noted at Santiago,

that all cases of abdominal injury operated on died and the only recoveries were those uninterfered with, is here noted, and the author concludes that the modern small caliber bullets afford more chance for conservative surgery than was formerly the case with large missiles. He also refers to the influence of the different reaction of individuals to intestinal wounds. The proportion of mortality of perforating wounds of the intestines has decreased from 90 to about 43 per cent. of cases operated on early, since the introduction of antiseptics. As regards treatment, the earlier the operation the better. It is useless to make a small incision; it should be at least five or six inches long. After checking hemorrhage, if it exists, the wounds should be searched out and closed with Lembert sutures. Two rows of continuous sutures are safer and more quickly applied than a single row of interrupted sutures. The other important points are the liberal use of hot normal salt solution, to cleanse the surfaces, to keep the exposed surfaces warm and moist and combat shock. The ideal method would be to avoid drainage, but if there is any question as to complete closure or of the retention of infectious matter in the abdomen, drainage would be advisable.

102. **Paralysis Agitans.**—This article is an analytic study of twenty-four cases of this disorder with special reference to its etiology and treatment. The special points noted are the preponderance of Irish—about one-half of the whole—among those affected, the advanced age, it being most frequent from the fifth decade on, and the influence of heredity in a certain proportion of cases, on which point the author's studies are not in entire accord with those of other observers. As regards occupation, nothing special was determined. As to causes, these cases, like others, show that the most important factors are age, sex, nationality, morality, violent emotions, especially depressing ones, direct and indirect heredity, and infectious diseases. The symptoms of the disorder are analyzed and studied at considerable length. Their onset is usually insidious, though sometimes abrupt; muscular rigidity, tremor, some pain. In most of these cases the disease was preponderantly diplegic, which is not in accordance with the statements of many other writers. The disorder is uniformly progressive. The mind is not affected unless it be at the very last. As regards treatment, diet and mode of living are principally to be considered. Some methods recommended are mentioned only to be condemned, such as vibration, Swedish gymnastics, and electricity. As for drugs, the two which seem to give some benefit are hyoscyamin and duboisin, but these should be given with great care. They are only palliative at best. Other drugs mentioned are hypnotics. The salicylates are condemned by the authors.

103. **Etiology of Texas Cattle Fever.**—Smith's paper reviews the facts as to the etiology of the Texas cattle fever, and concludes with some considerations in regard to the causation of malaria based on the analogy with Texas fever. He believes that malaria can be eradicated by proper care, at least outside of the tropics. In our climate vigorous efforts should be made to prevent it.

105. **Doctor as Carrier of Infection.**—In this article Howell calls attention to the fact that without proper precautions the doctor himself may become a disseminator of the disease which he treats, and that he has himself followed certain precautions, such as using a gossamer overcoat in infectious cases, keeping a couple of these in use and disinfecting them after each utilization. Other methods of precaution are also mentioned.

106. **Smallpox.**—Lyle reviews the history of the late smallpox epidemic in Cincinnati, giving tabulated statistics and notes of special features. The general character of the epidemic was very mild, the death percentage being only 1.75.

107. **Tuberculosis Diagnosis.**—Spiers' article is a protest against microscopic and chemical diagnostic tests in tuberculosis. He thinks that the presence of tubercle bacilli is not

reliable, that the tuberculin test has no general value, and that we should abandon the germ theory of the disease altogether. The above gives a sufficient idea of the trend of the paper.

108. **Alcoholic Neuritis.**—This paper contains a very elaborate report of a case of multiple alcoholic neuritis with autopsy and microscopic examination of the cord and brain. The authors found degenerative lesions irregularly distributed in the cortex of the brain, and in the stichochrome cells of the motor cortex, and arehystichochrome cells in which the nucleus varied in position and the staining was irregular. The chief lesions, however, were found in the cord and medullary nuclei, and the following are the general conclusions: 1. In fatal alcoholic multiple neuritis grave variations from the normal structure (equivalent picture of Nissl) of the ganglion cells of the anterior and posterior horns, the columns of Clarke, the nucleus of Stilling, and the nuclei of the medulla are always to be found when studied by appropriate methods. 2. These cystologic variations are characterized by their extreme polymorphism. They may consist of simple swelling of the ganglion cell or its chromatin particles; fine granular disintegration of the chromatin; destruction of the chromatin; central peripheral, perinuclear, and general chromatolysis; wandering of the nucleus to an eccentric position, the destruction of the achromatic structures to complete disintegration of the cell. 3. To what extent these lesions are due to the direct action of the alcoholic poison on the molecular structure of the ganglion cell (primary), or the degeneration of the peripheral extensions of both sensory and motor neurons (secondary), cannot, we believe, be accurately determined. The conclusion drawn is, that the peripheral degeneration is the much more important one of the two. 4. The best hypothesis yet offered to account for the degeneration of the cells of the column of Clarke is that of VanGehuchten, by the assumption that the ganglion cells of a nervous chain exercise the one upon the other a trophic action, the suspension of which produces a chromatolysis and disappearance of the corresponding cells.

109. **Premature Labor.**—Coe calls attention to the tolerance of rough handling exhibited by the uterus in certain cases, showing the incorrectness of the statement commonly taught, that it is easily excited by artificial means, and showing that dilatation of the cervix is by no means a certain method of inducing abortion. He gives five cases showing that gauze tamponade and water-bags, while invaluable for the purpose of softening and dilating the cervix and lower uterine segment, cannot be depended on to excite labor pains provided the membranes remain intact.

110. **Variation in Human Gait.**—Bradford's paper gives illustrations of the gaits in different styles of walking and calls attention to their importance in the construction of proper footwear and in training for marching, etc.

111. **Bicycling and Heart Disease.**—Getchell finds that acute dilatation of the heart is an accident that may be expected from overexertion in an unathletic rider, and that if the conditions are repeated, permanent dilatation, especially of the right heart, may result, with a consequent dilatation of the aorticulventricular valves. In the athletic, hypertrophy may be produced with a possible consequence of disease of the aortic valves. He thinks that children under the age of 12 or 13 years should be restricted in this exercise as they are liable to overdo it. With healthy young adults, precaution should be exercised against hill climbing and excessively rapid riding. After the age of 40 the bicycle may be beneficial or a positive danger. Proper regard for hills, excessive exercise against high winds, rough roads and the gear of the wheel will make it beneficial, while one indiscreet overexertion may cause irreparable injury.

112. **Prognosis of Pneumonia.**—King reviews the different varieties of pneumonia, based on their etiology, and concludes as follows: A pneumococcus pneumonia in a previously healthy individual under 65 tends to recovery by crisis, runs a

distinct and definite course, is not complicated by pleural effusions and does not leave, after recovery, permanent injury to the lungs, or cause abscess or gangrene. On the other hand, it gives the largest mortality, and death in fatal cases is due to acute toxemia. Tubercular pneumonia either at the beginning of phthisis or in its course runs an acute and often alarming course, is more irregular in its development, may terminate in crisis as in the former type or by gradual subsidence, is not attended by suppuration of lung or pleura, may, however, produce pleuritis, dry or with effusion, is seldom, if ever, immediately fatal, and it is doubtful whether it has any harmful results on the tuberculous process. Streptococcus pneumonia—including all pneumonias depending on infection by pyogenic organisms—forms a large portion of all pneumonias, is always the class in which empyema, abscess and gangrene or septic complications of other origin are to be feared and in case of recovery is liable to more or less seriously impair the integrity of the lung or pleura. Influenza pneumonia, if uncomplicated, runs a shorter course in which less marked disturbance of the body temperature is associated with much greater vasomotor nerve disturbances and with profound prostration. It does not tend to terminate by crisis, does not involve the pleura, nor itself permanently affect the integrity of the lungs. It is rarely fatal. On the other hand, it, more than any other, predisposes the lung to infection by pathogenic germs, especially the streptococcus and tubercle bacilli, and is consequently more than any other, subject to after complications and sequelae. He reports four cases illustrating each of these types.

113. **Intensity of Heart Tones.**—The following are the conclusions of this paper:

1. The loudness of the heart tones may be measured by testing the distance to which they are transmitted from their clinical point of auscultation.

2. This may be determined by two methods. The first method consists of measuring the distance to which the heart tones are propagated along definite routes on the chest. The second method consists of introducing between the stethoscope and chest wall a soft rubber rod of varying length, the tones gradually becoming less distinct as successive rods of increasing length are employed.

3. Of the two methods the latter is by far the more accurate, although this by no means represents an ideal attainment.

4. The employment of either method does away with memory in observing the progress of the strength of the heart in individual cases, and enables us to more easily distinguish any accentuation of the tones.

5. The order in which the tones can no longer be heard is as follows, beginning with the weakest tones: First aortic, first pulmonary, second tricuspid, second mitral, second aortic, second pulmonary, first tricuspid, and first mitral tone.

6. Until a universal stethoscope is employed we cannot hope to make the method of measuring the heart tones of general application, but must content ourselves with the application of the method to individual cases.

7. The first point beyond the hepatic region where the cardiac tones are no longer audible marks the lower border of the liver.

115.—See abstract in JOURNAL, July 8, par. 122, p. 93.

116.—See abstract in JOURNAL, May 6, p. 1000.

118. **Nerve-Cell Changes in Cerebrospinal Meningitis.**—Schwab ends his paper as follows:

1. In epidemic cerebrospinal meningitis we have to do with a process which affects the sensory cells.

2. The Clark system of cells shows a greater tendency to react to the disease than any other system of cells.

3. This tendency cannot be explained by means of the effect of the mechanical pressure of the exudate.

4. The degeneration of these cells is caused by a toxin which originates from the specific agent of the disease, the

micrococcus intracellularis meningitidis of Weichselbaum, which has a special affinity, first, for all sensory cells; secondly, particularly for the cells of Clark's column, therein showing a possible specific action toward these cells.

5. If the exudate does exert any pressure it is to be regarded as affecting the cells indirectly, i. e., it diminishes the normal resistance of the cells which come within the line of its force, and the cells so acted upon react easier to the toxic material than the others.

119. **Vaginitis.**—The method of treatment advised in this paper by Creel is the use of suppositories made of alum and glycerin, with carbolic acid and ichthyol. These are easily applied high up, and are not irritative, but at once begin to exert a soothing effect on the inflamed tissues. He briefly reports a number of cases in which this method was employed.

British Medical Journal, June 24.

Croonian Lecture on Some Points Connected With Sleep, Sleeplessness and Hypnotics. JOHN BUCKLEY BRADBURY.—This first lecture reviews the theories of sleep, the histologic, the various hypotheses as enunciated by Remon y Cajal, Duval Lagaro and others; the vasomotor, revived in a modified form by Howells; the chemical theories, of which only the recent one of Errera is considered worthy of mention, and the psychological theory which he feels obliged to discard. The fundamental change, Bradbury holds, must be in the neurons, and this, he is inclined to think, must be of a chemical nature. In support of this, he refers to the investigations of various observers on the action of poisons on the nerve-cell, those of W. Ludwig, Binz, Goldscheider and Flatau, and Demoor. He follows the latter author, however, in admitting that we must confess ignorance of the intimate nature of the cause of sleep. The lecture is valuable as a comprehensive review of the principal facts and theories of the physiology of the condition so far as known.

Lancet, June 17 and 24.

Physical Diagnosis in Insane. JAMES F. GEMMEL.—The author calls attention to the difficulty of obtaining subjective symptoms in the examination of the insane, on account of their mental condition and their insensitiveness. Retention of urine is often discovered only by posture and gait. Strangulated hernia may be observed only when the patient is stripped for a bath, enteric fever only shown after the eruption has appeared, and numerous other instances might be cited common in the alienist's experience. Hence the necessity of the closest observation of every minute symptom and the necessary greater dependence on physical signs than in the sane. He details cases of purulent meningitis, phlegmonous gastritis and volvulus, illustrating the above points, and discusses the diagnosis.

"Chronic Venereal Sores," or "Ulcerating Granuloma," WITH ILLUSTRATIVE CASE. J. MAITLAND.—In 1898 Maitland described under the name "chronic venereal sores" an affection apparently the same as that observed in British Guiana, by Drs. Conyers and Daniels, and called by them "groin ulceration." He here reports another typical case of the disease which is fairly common in Southern India. It consists essentially in a chronic non-indurated more or less extensive ulceration originating usually from a bubo, not affecting the general health, and is contagious, auto-inoculable, and of venereal origin in the majority of cases. In its early stage the sore strongly resembles yaws, and as in that disorder, when healing action begins, the skin structure not being completely destroyed, inlets of new epithelium spring up at various points over the sore. In yaws, however, the sores never attain the size here seen, and are scattered over the body instead of being localized. This disease appears to affect young and middle-aged adults, and to be confined to the colored races. The disease is never affected by constitutional treatment or by local applications. Complete excision or amputation through healthy tissues is most effective, though sometimes thorough re-

moval of soft tissues with a sharp spoon followed by the use of Vienna paste may produce an apparent cure.

Danger of High Altitudes for Patients Affected With Arteriosclerosis. TH. FINDLATER ZANGGER.—The author calls attention to the strain on the heart and arteries at elevations of three and four thousand feet and above, and especially of rapid ascents. Mountain railways are in this way dangerous to an unsuspecting public. The bad results in these cases, heart collapse, angina pectoris, cardiac asthma and apoplexy, often only appear after the return to the lowlands, and patients with cirrhotic kidneys are in greatest danger. In case of apoplexy, it is generally the combined influence of a few things slight in themselves, that, added to the altitude, produce the worst results. Over-feeding, over-exertion, exposure to hot sun, bowel neglect all have their part. Zangger advises an almost vegetarian diet in arteriosclerosis, with use of mineral waters, caution as to stimulants and avoidance of exercise in the heat of the day, especially in shut up valleys where the sun's rays are intensified in the rarified atmosphere.

Evolution of Lines of Sight. CHALMERS PRENTICE.—The author of this article finds from his studies of animals and men that the tendency to parallelism and convergence of the lines of sight is a late acquisition in evolution, and that it is incomplete, even in civilized man. In examination of over 3000 cases post-mortem he has not seen a single case that appeared perfectly straight. After death the tendency is divergent. From these and other facts, he concludes that the evolution of the optic axis is not yet complete, and that we are in a chronic state of eye strain, exhausting energy and probably seriously embarrassing us in the struggle of life. How serious is this handicap it is impossible to say, but it must be great, judging from the extent of the visual centers, which are many times as great as those that govern the movements of the arm or the leg.

Preventive Inoculation. W. M. HAFFKINE.—This address gives the results of the work of antiplague inoculation in India under Haffkine's direction. After demonstration of the effect of the serum on animals, its harmlessness in man was demonstrated by voluntary experiments by the officers of the laboratory and other Europeans and native residents of Bombay, and this was followed by more severe tests in several local prisons where a certain proportion of the inmates consented to the inoculation. In still other tests only a proportion of the population were inoculated, a course that after the previous demonstration of the value of the treatment and their willingness to receive the serum, is open to criticism. The results were generally and uniformly good, the difference in the mortality between the protected and the unprotected being estimated as high as 80 per cent, or more, in favor of the former. The duration of protection appears to be at least six months, and the Indian Government recognizes the certificates as exempting the holder from plague regulations for at least that period. The plague research laboratory is at work endeavoring to extend and perfect the discoveries already made for the better control of the pestilence. Typhoid inoculation is also mentioned and faith expressed that it will have a high practical value. As regards the relative value of inoculation and segregation disinfectant methods, Haffkine points out the distinction between purely parasitic germs and those that are both saprophytic and parasitic. In the former case the patient is the sole source of infection, and isolation is effective; in the latter he is only one source out of many, and other measures must be resorted to.

Tribuna Medica (Rio), v. 6.

Gases Produced by Bacillus Coli. C. LEPIERRE.—The complete absence of carbonic anhydride in the gases produced in cultures of the bacillus coli, excludes all idea of a fermentation similar to that of the sugars. Oxygen is also absent, and the gases seem to resemble certain intestinal gases in their composition. Another point brought out in this study is that while

the production of gas is almost invariably in the first few days, with the bacillus coli, it is extremely irregular with the "para-coli bacilli," and usually absent altogether.

Greece Medicine (Syra), June.

Pernicious Convulsive Malarial Fever. J. KARDANATIS.—This extremely rare and generally fatal disease is frequently simulated by ordinary malarial infection in persons predisposed to convulsions, but the latter is essentially a benign affection. "Gastro-intestinal affections in general prepare a favorable soil for the installation of malarial infection, even the spasmodic form."

Lithiasis of Prepuce. A. LOUIS.—When the patient applied for relief from the pains which had tormented him for seven years, the penis was shaped like the tongue of a bell, the prepuce gorged with calculi, requiring an incision to release them. Over a hundred were evacuated, from the size of a grape seed to that of a pea.

Progres Medicale (Paris) June 17.

Falling of Hair From Emotion. F. BOISSIER.—Several carefully observed cases have been recorded of late in this journal, and a still more striking case is now added: a normal, healthy farmer, 35 years of age, saw his child thrown and trampled by a mule. He supposed it killed, and experienced in his fright and anguish a sensation of chilliness and tension in his face and head. The child escaped with bruises, but the father's hair, beard and eyebrows commenced to drop out the next day, and by the end of a week he was entirely bald. A new growth of hair appeared in time, but finer, and exactly the color of the hair of an Albino.

Revue Hebdomadaire de Laryngologie, d'Otologie, etc. (Bordeaux), xx, 16, 17.

Lesions of Inner Table of Skull With Suppurations of Middle Ear. BRINDEL.—Necrosis of the inner table was found in 36 out of 142 operations on the mastoid apophysis. The cases were: simple mastoiditis in 15; Bezold's mastoiditis, 5; mastoiditis with thrombosis of the lateral sinus (latter not disturbed), 1; suppurative phlebitis of the lateral sinus, 1; cerebral complications, 5; otorrhea with occasional vertigo, 2, and otorrhea without vertigo, 7. Lesions of the inner table are rather more frequent with chronic than with acute otorrhea. They frequently give no clinical evidence of their presence, and produce no special phenomena. In a third there were no other lesions of the apophysis; in the rest there was also necrosis of the outer table or Bezold's mastoiditis. Four had facial paralysis, all cured by the intervention; 5 died; a large subdural abscess was evacuated in 2; 18 were treated by opening and curetting the antrum, tympanum and tympanomastoid passage. Complete evidences of the apophysis was done in 1 case and Garnault's method in another (reaching the antrum by detaching the meatus and raising the upper half of the bony passage without disturbing the tympanum). Moure's method of closing the retro-auricular wound at once, while it renders dressing the wound more difficult for the operator, secures cicatrization by first intention with scarcely a trace of the intervention, and is highly to be commended.

Cocainized Mentho-Phenol. A. RONAIN.—Two years' experience has convinced the writer that the combined anesthetic, gently caustic and powerfully antiseptic action of equal parts of phenic acid, menthol and cocain hydrochlorate produce a combination extremely valuable in oto-rhino-laryngology. To increase the caustic action he varies the formula to phenic acid, 1 part; menthol and cocain, $\frac{1}{2}$ part.

Revue Medicale (Nontreat), June 21.

Thymus in Therapeutics. C. E. BOISVERT.—A distressing case of Graves' disease, rebellious to all medication for three years and threatening melancholic mania, was improved in a week and practically cured in three months, with fifteen to twenty-five grains of extract of lamb thymus a day. The only symptom left was a slight tumefaction of the thyroid. This case, as reported in detail, is a most convincing argument in favor of thymus medication, abundant at first and decreasing to suspension according to the manifestations of the disease.

Semaine Medicale (Paris), June 21.

Induced or Simulated Affections. EDITORIAL.—This article completes a study of affections induced or simulated by beggars, soldiers or convicts, and is a record of perverted human ingenuity. Severe bronchitic rales are simulated by a piece of cork tied to a string which is fastened to a tooth and the cork swallowed; hematemesis by vomiting blood which has been drunk for the purpose. Voluntary tympanism and retention of urine can be carried to a remarkable extent by some persons and only yield to the administration of an anesthetic. The local lesions and general disturbances that can be induced by plants, burns, etc., are legion, and each is described in detail. A deceptive icterus can be induced by steeping tobacco in oil, drying and smoking it all night. Then follow vomiting, fever and icterus that persist for weeks.

Centralblatt f. Chirurgie (Leipzig), June 24.

Sphincter Ani Destroyed by a Phlegmon: Plastic Operation. K. G. LENNANDER.—Almost normal continence was attained by this operation in which the levatores ani and glutei maximi were applied to a defect involving the sphincter and part of the posterior wall of the rectum, caused by a gangrenous phlegmon. Lennander recommends the method for a secondary operation after extirpation of a cancer of these regions.

Deutsche Medicinische Wochenschrift (Berlin), June 15 and 22.

Surgical Treatment of Benign Gastric Affections. W. PETERSEN.—This study of sixty cases, operated on at Czerny's clinic, emphasizes the fact that there is no field in which the harmonious working together of the physician and the surgeon is more imperatively required than in this. The ultimate results have proved extremely favorable; before 1895, 50 per cent. cured and 10 per cent. improved out of 281; since 1895, 80 per cent. cured and 10 per cent. improved, with 1 death, out of 32. Of 7 patients operated on for gastralgias, 4 were completely cured by gastroenterostomy; 1 by detaching pericholecystic adhesions; 1 by "pyloro-plastics" and a secondary gastroenterostomy; 1 is still under observation. Only 3 cases of fresh hemorrhage from the stomach were encountered, although there was a record of hemorrhages in 4 of the cases of stenosis, all cured by the intervention. One of the three fresh cases was evidently a vicarious bleeding from the parenchyma in place of the menses, and neither gastroenterostomy nor division of the pylorus nor enlargement of the gastro-intestinal fistula proved effective. The other two cases were characteristic ulcus hemorrhages, cured by partial excision of the ulcus and gastroenterostomy in one case, and by the latter alone in the other, which establishes a new basis for operative treatment of ulcus hemorrhages, as it obviates the very important objection that the search for and ablation of the ulcus is too difficult and dangerous under the circumstances. It will be great progress if other observations confirm the result in this case; that gastroenterostomy alone, enables the stomach to empty itself and its walls to contract, and thus arrest further hemorrhage. A dilated stomach subsides rapidly at first and then more slowly, after surgical intervention, but seldom returns to normal size. The motor function is in most cases fully restored to normal; in a few cases it was permanently diminished. The amount of HCl decreases, and bile is frequently found in the stomach, but neither the bile nor the lack of HCl cause any appreciable clinical disturbances. The absolute indications for intervention are: Stenosis of the pylorus with a high degree of mechanical insufficiency—permanent decrease of the amount of urine and of the weight. The relative indications, after failure of internal therapeutics, are a high degree of atonic mechanical insufficiency, threatening hemorrhage, severe gastralgia and uncontrollable vomiting—from fresh ulcus, ulcus cicatrix, perigastritis and adhesions.

Muenchener Medicinische Wochenschrift, June 20.

Value of Bremer Test in Diabetes. H. SCHNEIDER.—The behavior of the blood with anilin dyes varies in certain

circumstances, and Premer (*JOURNAL*, xxx, p. 438) considers it a test for diabetes, but Schneider finds that the peculiar reaction known as Bremer's test depends on the acidity of the fluid mixed with the blood or of the blood itself, and is by no means confined to diabetes, but occurs whenever the blood, urine or other fluid is abnormally acid. It has no value as a differentiating test for diabetes, but may possibly be utilized some day as a test of the alkalinity of the blood.

Williamson's Test of Diabetic Blood. RUMPF.—Contrary to the above experience with Bremer's test, Rumpf considers Williamson's test a very useful means of differentiating diabetes, as the blood and urine of a diabetic subject evidently contains some substance that takes the color out of an alkaline solution of methylene blue, heated in the water-bath for 1½ to 5 minutes. It proved especially beneficial in a recent case of a patient brought to the hospital with the diagnosis "apoplexy." No urine could be obtained, but the Williamson test on a few drops of blood confirmed the assumption of diabetic coma.

Spindle-shaped Enlargement of Esophagus. T. RUMPEL.—A healthy man under observation for several years presented unmistakable evidences of this condition, which caused no disturbance except the occasional accumulation of part of the food in the esophagus, requiring auto-sounding. Experiments with a hard sound resulted in death from perforation peritonitis. The esophagus was found absolutely normal except for the enlargement, which was evidently due to a nervous spasm constricting the lower end. "All efforts to overcome such a constriction mechanically are worse than useless as they increase the functional spasm."

Wiener Kiinische Wochenschrift, June 22.

Setio Cesareo on account of Retrovaginal Cervix Myoma. E. WERTHEIM.—Called to a primipara after three days of ineffectual labor, a myoma was found obstructing the passage, requiring Cesarean section although the fetus was known to be dead. As the unusually large fetus was extracted the decidua was found decidedly degenerated, and instead of replacing the uterus and postponing the removal of the myoma to a more favorable season, as proposed, the danger of sepsis required the immediate extirpation of the myoma and uterus, which was accomplished through the vagina, with prompt recovery. The walls of the uterus were found thoroughly infected. Wertheim asserts that the results of Cesarean section in case of a myoma preventing delivery would be much more favorable than at present, if at the slightest suspicion of infection in the uterus, the radical operation was practiced as in this case, instead of conservative section or supravaginal amputation.

St. Petersburger Medicinische Wochenschrift, June 17.

Methylene Blue in Therapeutics. MICHAÏLOW.—This experimental study of the effects of methylene blue on the tissues and organs, demonstrates its utter unfitness for use in therapeutics at the doses hitherto prescribed.

Gazzetta degli Ospedale (Bilan), June 11 and 16.

Aqueous Extract of Tubercle Bacillus. E. MARAGLIANO.—Flourishing cultures are strained and the contents of the filter mixed with distilled water, equal in amount to the fluid strained out, kept on the water-bath at 90 to 95 C. for forty-eight hours, then evaporated to one-tenth and filtered. The result is a brownish fluid which Maragliano calls aqueous tuberculin or aqueous extract of the tubercle bacillus (see *JOURNAL*, xxx, p. 747). About five times as much of the essential toxic principle (which should be the standard for the strength of tuberculin), is obtained with water than with glycerin, while the degree of heat is just adapted to extract the maximum without attenuating the toxins, as occurs with Behring's tuberculin with a maceration at 150 C., while Koch's T. R. is obtained with water without any heat. From this aqueous extract a powder is obtained by desiccation. An alcoholic precipitate and an alcoholic extract are also derived from it, and

by the addition of 1 per cent. sulphuric acid, needle crystals are deposited which dissolve readily in water and possess a toxic power of 1 to 3333. All these derivatives of the aqueous tuberculin produce the same toxic action and in the same way as the aqueous and the glycerin tuberculin, and the action of each is neutralized by the serum. He considers the alcohol extract of the sediment the purest form of the aqueous tuberculin; its toxic energy is 1 to 20,000. He has obtained an aqueous tuberculin that kills a guinea-pig at 1 to 100, but the product he distributes is standardized to kill at 1 to 20,000 or 25,000.

Acetonuria and Fatty Acids. DE AMBROSI.—The research of the writer has established a direct connection between the amount of fatty acids in the stomach and of acetone in the urine.

Entorrhagia in Abdominal Typhus. L. MAZZOTTI.—The usual cause is the corrosion of a vessel connecting with one of Peyer's patches, as the scab drops off that has formed over it, which usually occurs at the end of the third or fourth week. Another cause is the hyperemia of the mucosa of the colon, which usually accompanies the height of the disease process, and appears at the end of the second or the beginning of the third week. Entorrhagia from this cause is easily cured by injections of hemostatic and astringent substances per rectum. The entorrhagia that appears during the first week does not depend on a local process but rather on the general condition, and represents a dyscrasia of the entire organism, such as Trousseau's hemorrhagic putrid fever.

Trauma of the Spleen. E. CURTI.—A young farmer was tossed by a bull, the horn entering the left hypochondrium and lacerating the spleen and diaphragm. Brought to the hospital in severe collapse, the spleen was removed and the diaphragm sutured, the operation completed in twenty minutes, but the patient did not recover from the traumatic shock and died in four hours. At the autopsy the success of the operation was fully demonstrated and if the patient could have revived from the traumatic shock, there was no lesion or hemorrhage in either the abdominal or pleural cavity to have prevented recovery.

Cronica Medica (Lima), May 31.

Aneurysm in Both Popliteal Regions. M. ALCEDAN.—As much as a pound of clots were taken from the inflamed and extremely painful aneurysm of the left knee, which required ligating. After disinfecting the cavity the patient was transferred to the aseptic operating-room and the other aneurysm, larger than a goose egg, but not painful, was enucleated. The results of this dual operation were complete recovery of the enucleated limb and dry gangrene, necessitating amputation of the other.

Societies.

COMING MEETINGS.

Rocky Mountain Inter-State Medical Association, Salt Lake City, Utah, July 25 and 26.

Eighth Norwegian Medical Congress.—The addresses already announced for this Congress, which is to meet at Christiania, August 24 to 26, are: "Diabetes," by J. Bugge; "Traumatic Lumbago," by R. Natvig; "Prostatitis," by J. Roll, and "Modern Surgical Treatment of Tuberculosis," by O. Borchgrevink.

Cass County Medical Association.—At the annual meeting of this Association, at Logansport, Ind., held June 30, the following officers were elected: President, A. Coleman; secretary, J. Z. Powell; censors, W. H. Bell, J. A. Little and A. J. Herrmann.

International Conference for Prophylaxis of Syphilis and Venereal Diseases.—Besides the delegates of governments and large municipalities, all physicians, jurists and officials especially conversant with the hygienic and admin-

istrative questions in regard to prostitution and venereal diseases, are invited to take part in this Conference, which is to be held, as previously announced in the *Journal*, at Brussels, Sept. 4 to 8, 1899. The subjects appointed for discussion, to be presented by two or three speakers, are: 1. "Have the systems of regulation of prostitution at present enforced any influence on the frequency and the dissemination of syphilis and venereal diseases?" 2. Is the present system of medical surveillance of prostitution susceptible of improvement? 3. From an exclusively medical point of view, is it advantageous to maintain houses of prostitution or to suppress them? 4. Is the administrative organization of police surveillance of prostitution susceptible of improvement? 5. What legal measures would diminish the number of women who seek in prostitution a means of existence? 6. Aside from the question of prostitution, what general measures are advisable to effectively prevent the spread of syphilis and venereal diseases. No subjects except the above will be admitted to discussion. Communications relating to statistics or questions not on the programme will be translated, printed and distributed to the members before the Conference opens, if received in time. Secretary General: Professor Dubois-Havenith, No. 19 rue du Gouvernement provisoire, Brussels. Dr. Havenith is collecting the bibliography of the works published on the above questions and appeals to persons who have published works on these subjects to send him a copy at their earliest convenience. Dr. Dyer of New Orleans has been officially appointed to study the question of prostitution in the United States.

French Congress of Otolaryngology.—P. Bonnier, in his address on "Tests for the Hearing," at this congress at Paris, asserted that all the present tests are defective and lack precision for comparing the results between individuals. He suggests as a great improvement tests with a tuning-fork with 100 double vibrations to the second. The striation in its image produced by the angular displacement disappears at a certain moment. He designates this moment zero, and from this point the hearing capacities, solid and aerial, can be measured in positive and negative values expressed in seconds. The length of the time required for the extinction of the work renders the difference of a few seconds immaterial. Courtaud recommended a couple of tuning-forks and rubber tubes for the detection of simulated deafness on the same principle as described in *THE JOURNAL* (p. 1253). Lermoyez reported a case of Bezold's mastoiditis in a nursing, the first on record. Lacroix presented an inhaler in which the medicinal substances are rendered much more volatile and effective by being heated as an outer receptacle is filled with water at 50 to 100 degrees C. Malherbe presented a small U-shaped celluloid tube which he inserts in the ear after petromastoidean evidences, one end in the antrum, the other in the external meatus, the concavity fitting over the apophysis. It is valuable in cases of sclerotic processes filling the passage, is worn without inconvenience, and is invisible from without. Lermoyez advocated treatment of nasal hemorrhage by acting directly on the secretory terminals of the nerves with atropin (0.25 milligram), and on the vasoconstrictor centers of the spinal cord with strychnin (2 milligrams). These amounts are taken daily for one week; doubled the following week, and tripled the week after in extremely severe cases. Treatment is recommended after suspension for ten days. Local treatment is the last resort if this fails.

California Academy of Medicine.

June Meeting.

CASE OF SYPHILIS.

DES. DUBLEY TAIT AND GUIDO CAGLIERI exhibited a patient with the following history: The patient, a man of 49 years of age, a farmer by occupation, living in the San Joaquin valley, about one year ago noticed a swelling in the right subclavicular

region, just above the breast; this attained to the size of a nut, later suppurated, and after three months closed. Five months ago a swelling appeared in the right groin, which reached the size of an English walnut; it broke down, was incised and drained, but failing to heal, the gland was partially excised. Soon after there appeared enlargements in the left submaxillary and right preauricular regions. These suppurated, broke down and exhibited necrotic tissue. One month later there was suppuration of the glands in the right supraclavicular region. Ten days before entering the hospital swelling appeared in the left tonsillar region. Careful physical examination revealed nothing abnormal in the chest or abdomen; the urine was normal and the special senses were not in any way affected.

The diagnosis was obscure. At Fresno an "analysis" of some pus from one of the suppurating lesions had been made with the statement that tubercle bacilli had been found. This is, however, quite improbable, not only for the reason that it is very seldom and with extreme difficulty that tubercle bacilli can be found in pus from ulcerating areas and suppurating glands, but also because the case does not seem to be one of tubercular lesion. For a time glanders was considered, the patient presenting many characteristic points of resemblance to a case of chronic farcy reported by me a short time ago. This diagnosis was very soon abandoned, however. An injection of mallein, instead of producing an increase of temperature, caused marked decrease. Though no syphilitic history could be obtained, I concluded the case to be one of syphilitic lesion, of an unusual sort, and concluded to make use of intravenous injections. Potassium iodid was tried for two days, but resulted in such a severe eruption that it had to be abandoned. A 1 in 200 solution of cyanid of mercury was employed, the quantity injected at each time ranging from 1.25 to 6.05 gms. After two injections had been made the lesions were about 50 per cent. improved; the necrotic tissue had been entirely discharged and healing was well advanced. At the present time the patient has had four injections in the right median basilic vein, and improvement is continuous and rapid; the glands in the groin have almost disappeared. Have since noted that mallein is of no diagnostic value in man.

DR. GUIDO CAGLIERI.—There can be no doubt that the statement coming from Fresno, to the effect that tubercle bacilli had been found in the glandular pus, was incorrect. It is almost impossible to find the bacilli in glandular pus, for one thing, and for another the case was not at all like the picture, clinically, of tubercular trouble. It is quite possible that some other organism may have been noticed and mistaken for the tubercle bacilli. Quite a number of organisms have been recognized lately, and described as closely resembling the tubercle bacillus. It is at least possible that one of these was noted, though even this is problematic.

DR. HAROLD BRUNN.—I should like to call attention to the value of the hemoglobin test for syphilis in these cases where the diagnosis is somewhat obscure or impossible to get at from the history. I recently made use of it in two cases with very gratifying results. The last case occurred in a patient, a man of family, from whom no history of infection could be obtained. The wife was perfectly well and so were the children. An ulcerating area appeared on the upper lip which might, from the appearance and course of development, have been an epithelioma, though it was not characteristic of the lesion. I tested the blood and found about 80 to 85 per cent. hemoglobin. I then had the man rub in about a dram of mercury at night, and the next morning the blood examination showed a drop in the hemoglobin to 50 to 55 per cent. Three weeks later, under continued syphilitic treatment, the ulcer had entirely healed up. The test is of no value if the patient is under treatment by mercury in any form, and it is also negative unless in the presence of an active lesion, but under proper circumstances it bids

fair to give excellent results. In a case of active lesion, the patient not being under any treatment, a good-sized dose of mercury should show a drop in the amount of hemoglobin, within twelve to twenty-four hours, of from 15 to 35 per cent.

DR. D. W. MONTGOMERY.—I have found great difficulty in using the Fleischl apparatus. I tried for some time to obtain a normal standard for comparison, but without avail. In no case could I get a reading of more than 85 per cent. hemoglobin, even in a perfectly healthy man. It may be that I lack the technical skill in handling the instrument, but all my efforts were negative.

DR. DUDLEY TAIT.—I have not personally made use of the apparatus, but I had one of the internes at the French hospital make a test in a very clear and beautiful case of syphilis, recent, with an active lesion and absolutely no history of mercurial treatment. The test was erroneously made, for before the injection of mercury the blood showed about 80 per cent. hemoglobin, while after an intravenous injection of cyanid of mercury, the Gower apparatus showed an increase of over 20 per cent.

DR. HAROLD BRUNN.—The Von Fleischl instrument is not accurate for blood, the index being decidedly too high. Rarely ever can one get a hemoglobin percentage of 100, and never in my experience in a normal case. The normal runs from 80 to 90 per cent., and the test should be made with that understanding. I do not consider the reading accurate within 5, and always give my readings as between two points on the scale, as for instance, 80 to 85 per cent. One source of error is in the diaphragm opening. This may be somewhat reduced by making use of a paper cone, but even then there is a goodly chance for error. At the lower end of the scale the error is much larger, and the results are very unreliable when this portion of the scale is in use.

DR. D. W. MONTGOMERY.—In considering such a case as the one presented, it would be wise to remember the condition of coxidoïdal disease, reported by Dr. Rixford some few years ago to the state society. He found two cases, both occurring in the San Joaquin valley, and both strongly resembling the case just reported by Dr. Tait. When Dr. Tait described the various lesions which had presented themselves in the patient exhibited, I was quite of the opinion that he was about to present another case of this rare affection. Evidently, the present case is not one of that disease, for it cleared up too well and too soon under the antisiphilitic treatment. But in all such cases, coming especially from the San Joaquin valley, the possibility of coxidoïdal disease should not be forgotten, and the specific germ, the coxidia, should be carefully looked for. The disease seems to be endemic in that valley. Dr. Rixford reported two cases from there, and I have since seen a third, coming from the same locality, and exhibiting the same general symptoms and clinical picture. The one I saw came from there some time ago. He broke out with an eruption, strongly resembling buds, quite similar to potassium iodid poisoning or mycosis fungoides. There was considerable glandular involvement and the coxidia could be found in the glandular pus. Clinically, the picture was much like the case of syphilis reported to-night by Dr. Tait. The coxidia was found in great numbers.

Two points of interest in these cases present themselves: The disease seems to first attack the lungs, or at least this was true in the two cases reported by Rixford and in the case seen by myself. The affection subsequently involved the skin and later the glands. The germ is found in all localities which are involved in the disease process. The abscesses may occur anywhere—in the lungs, the skin, the glands or any of the organs, and, wherever the abscesses appear, there the coxidia may be found in the pus. The disease may be mistaken for syphilis, mycosis fungoides or tuberculosis.

2. Both of the cases reported by Rixford occurred in Portuguese who came from the same town in Portugal. For this

reason there was some question that the disease occurred in this country; it might have been contracted in Portugal and brought to the San Joaquin valley by the patients. The case I have mentioned, however, tends to disprove this assumption, and indicates that the disease is endemic in the valley. My patient was a German who had been working on the Valley Road, and the locality where he contracted the disease is unknown, as he was traveling about a good deal.

The coxidia has been thought by some observers to be a yeast germ, and not an animal parasite. This, I think, is not the case, for it seems to be subject to endogenous reproduction. I have tried to grow the germ, but unsuccessfully on any culture-medium at hand. It would not grow on agar. I had no malt at the time, so could not make the attempt to grow it on that culture-medium. Other observers have also found great difficulty in making cultures. I injected a rabbit with some of the pus, but as I only returned to the city last night, I have had no time to ascertain whether the rabbit has become affected; I am doubtful whether it has developed the disease. So far as the particular case presented by Dr. Tait is concerned, I am sure the diagnosis of syphilis was correct and the treatment certainly a most brilliant success. I spoke of these other cases, however, for the reason that they so strongly resembled the case of Dr. Tait's that I should have looked for the coxidia in the glandular pus of this patient. The coxidia would not have been found in this instance, but in all similar cases, especially when the patient comes from the San Joaquin valley, the possibility should be recognized.

CASE OF LUPUS.

DR. PHILIP MILLS JONES presented a patient whom he desired to have all carefully examine, for the reason that her condition was rapidly improving, and he did not wish to continue the treatment until the case had been inspected and further progress noted by others. The patient was sent to him by Dr. Regensburger, with the diagnosis of lupus. The woman is about 48 years of age, a native of Bordeaux, and has had an affection of the face for thirty-six years. It commenced when she was a child of 12, and has persistently increased in extent until the present, in spite of all effort. Very many specialists have had the patient under their charge with no benefit to the condition. Dr. Jones commenced treatment by exposure to X-rays some two months ago. The face, save the right side, which is involved from the hair line to below the lower margin of the jaw, including the entire ear, was protected by means of a heavy lead plate, perforated with a hole to correspond with the area involved. The woman was then exposed within three or four inches of a low vacuum X-ray tube for from two to eight minutes, three times a week. The length of the exposure and the frequency of the treatments was decided largely by the effect on the skin; when too much reddened by the rays, the exposures were made shorter and less frequent. A slight dermatitis developed just below the eye, and a slight conjunctivitis was also produced by the rays, a few of which managed to strike the conjunctiva at one or two sittings. These troubles have now entirely passed, and indeed were but trifling in the first instance. The maximum intensity of the rays was directed toward the lower portion of the area involved, and this part of the affection is very materially better than is the ear and the upper portion. It is so rapidly improving that but little idea of the condition when the treatment was commenced can now be formed. At that time the whole area was as badly involved as the worst portion now present. The lower area is almost well, the nodules have disappeared, and the skin is regaining its soft and pliable nature.

This is the second case of lupus the doctor has treated by means of X-ray exposure. The first was entirely cured of a lesion on the forehead which had lasted, in spite of all treatment, for seven years. The patient has been away for four months, but reports no change in appearance of former lesion.

DR. D. W. MONTGOMERY.—This seems to be a clear case of lupus. The history, the nodules and the general clinical picture all go to confirm the diagnosis of lupus. There is, however, a great difference between lupus and skin tuberculosis; clinically, if not etiologically, and whether both diseases are caused by the tubercle bacillus is still an open question. The tubercle bacillus is, however, found in both lesions, and if they will both yield to X-ray exposure it leads one to question whether the exposure to these rays would not be of benefit in tubercular lesions of other sorts. Lupus is found to commence before the 16th year, but tuberculosis of the skin may commence at any age. The question of the two diseases being the same affection is disputed by many good observers, but claimed by others. I am strongly inclined to believe that they are not the same affection, clinically, even if they prove to be etiologically. Lupus, true lupus, is a very rare disease in this country, and particularly so in California. I do not remember to have ever seen a case of true lupus occurring in a native; but tuberculosis of the skin is fairly common.

DR. P. M. JONES.—According to the differentiation made by Dr. Montgomery, the first case I treated in this way was not true lupus, but was rather tubercular lesion of the skin, for it occurred in a man of about 50 years. It was, however, entirely healed by the X-ray exposure, and to date has remained healed. In regard to what Dr. Montgomery has said of tuberculosis in other regions. I have exposed three cases of clear tubercular lesion of the lungs, in all of which patients the bacilli could be found in goodly numbers in the sputum. The patients all improved, the bacilli disappeared from the sputum, the night temperatures ceased, and now the patients say that they "feel perfectly well." I do not say that the patients were cured by the X-ray exposure, for it may have been spontaneous cure in all of them, but they certainly are now well, and also just as certainly had tuberculosis of the lungs at the time treatment was commenced.

(To be continued.)

New York County Medical Association.

Stated Meeting June 19, 1899.

ACUTE BRONCHITIS—A SYMPTOM; ITS TREATMENT FROM AN ETIOLOGIC STANDPOINT.

DR. THOMAS F. REILLY read a paper with this title, and showed that the inflammation of the mucous membrane of the respiratory tract is only a small part of the disease process, and that, as a rule, the bronchitis which so many physicians strive to treat, is only a symptom of a vitiated state of the constitution. A preliminary throat irritation almost invariably precedes, by several hours, an attack of acute rheumatism. Such a conception of acute bronchitis is of the greatest value in connection with the treatment. The therapeutics of acute bronchitis should consist in something more than the administration of nauseating cough mixtures. Probably the most common cause of bronchial catarrh in children is the elimination of toxic products from the gastro-intestinal tract. In most juvenile institutions attacks of bronchial catarrh are especially frequent after visiting days, and can be traced to the sweets and dainties given the little ones by their visitors. A judicious evacative treatment will usually banish the unpleasant symptoms very speedily, far more so than if our efforts are directed toward the bronchial catarrh *per se*.

The most common etiologic factor in the cases of bronchial catarrh seen in private practice is that toxic condition described under the general name of lithemia. The speaker referred to the very common experience of being able to stand a wetting or exposure to inclement weather in the country without developing bronchitis, while the same person would "catch cold" in the city under far less provocation. The experience of Nansen and his associates in the Arctic region was very signifi-

cant in this connection. Although these men had been exposed to the most bitter cold and trying climatic conditions they hardly knew what it was to suffer from ordinary colds, but no sooner had they returned to civilization than almost all of them developed colds. This would seem to bear out the theory of the infectious nature of bronchitis; the germ-free air of the Arctic region prevented these men, in spite of the exposure, from developing these affections of the respiratory organs which would certainly have followed a much less exposure in a more impure air.

With reference to the treatment, he said that from time immemorial expectorants have been used in cases of bronchitis, and they doubtless relieve the present distress, but it is very problematic whether they really exert any curative action. Ammonia preparations probably owe much of their action to their stimulating properties. The most rational treatment consists in efforts to eliminate the toxic products which are the primary cause of the bronchial inflammation.

NON-MALIGNANT STRICTURES OF ESOPHAGUS AND THEIR TREATMENT.

DR. HENRY MANN SILVER read a paper on this subject. He gave a careful review of the literature, and also reported the case of a child 4 years old, who had come under his observation last October with a stricture of the esophagus, the result of drinking a corrosive liquid. A No. 11 bougie was obstructed at a distance of 9 $\frac{3}{4}$ inches from the teeth, and, as the child was failing steadily, gastrostomy was performed. A month later retrograde dilatation was begun, and this part of the treatment was greatly facilitated by the use of an electric headlight and a series of endoscopes made after the general pattern of the Kelly cystoscope. In January dilatation with bougies passed in through the mouth had been commenced, and on April 18 the gastric fistula was closed. During the whole treatment there was no leakage and no irritation of the surrounding skin. A peculiar feature was a persistently subnormal temperature in the morning. It is worthy of note that the passage of the metallic bougie could be satisfactorily watched with the aid of the fluoroscope.

Turning to a consideration of the treatment in detail, the author said that when a powerful corrosive had been swallowed, giving rise to much inflammation and to the rapid development of a stricture of the esophagus, or when the regurgitation of a considerable quantity of food indicated that a distinct pouch had been formed, he would favor gastrostomy; if, however, there had been but little inflammation, and there was not much regurgitation, gastrostomy would seem to be the better operation. By the insertion of several silk sutures into the stomach, this viscus could be examined with ease, and this should always be done before deciding whether the operation should be completed as a gastrostomy or a gastrostomy. Dr. Abbe devised the ingenious method of dilating the stricture by bougies introduced from below, and then dividing the stricture with a string—the so-called "string-saw" method. During this dilating process of treatment the patient should be encouraged to eat solid food. The very brilliant results from gastrostomy and retrograde dilatation should point out the value of timely surgical intervention; if long delayed, the prognosis becomes much more grave.

DR. GEORGE WOOLSEY, speaking of retrograde dilatation and its advantages, said that much difficulty was often experienced in finding the cardiac end of the esophagus, largely because of the defective anatomic descriptions. A little practical "wrinkle" in this connection is to pull down on the lesser curvature of the stomach, and then cause the bougie to follow this curvature. Having once succeeded in passing the bougie, one or more strings should be attached to the bougie and brought out at the mouth. He condemned internal esophagotomy.

DR. WILLY MEYER advised, for strictures of the lower third of the esophagus, the employment of Abbe's string-saw method, although admitting that while the immediate results were often

good in dense strictures, they were often disappointing later on. He exhibited two adult patients on whom he had done gastrostomy by one of the modern methods. The fistulae were watertight.

DR. JOSEPH D. BRYANT spoke of external esophagotomy, and also described a modification of the string-saw method which he had devised with the object of eliminating certain objectionable features of that otherwise very useful procedure. He said that in doing an external esophagotomy, the low operation is preferable because the distance to the cardia is thereby lessened. In opening the esophagus, care should be taken to make the incision sufficiently posterior to avoid injuring the recurrent laryngeal nerve.

DR. ROBERT ABBE said that he had accidentally hit upon the string-saw method while endeavoring to pass the bougies, with strings attached, on a case under his care about seven years ago. One of the bougies being hugged tightly, he had moved the silk to and fro, and found that the bougie had not only been freed, but that he could then pass, in rapid succession, several bougies of larger size! The patient on whom he had first tried the plan was still alive and well, and free from any return of the stricture. He recently applied this same string-saw method very satisfactorily to the treatment of a case of chronic laryngeal stenosis.

DR. JOHN A. WYETH pointed out that a very great deal could be gained in cases of esophageal stricture, whether malignant or benign, by prolonged rest of the part. For this reason he advised gastrostomy early, and asserted that if this treatment were adopted it would often be unnecessary, after a few months of such rest of the esophagus, to use bougies at all.

DR. MAX EINHORN urged the claims of the esophagoscope, an instrument which he considered superior to the endoscope. He also alluded to those rare cases known as spasmodic strictures of the esophagus.

DR. B. FARQUHAR CURTIS reminded those present that while the surgical procedure advocated by the previous speakers had accomplished excellent results, and were the safest and best at present known for this unfortunate class of cases, still the treatment was often full of disappointment. Such strictures were very prone to recur. They should be treated on the same principles as strictures of the urethra. The beauty of the string-saw method is that the strings can be kept in place and the treatment extended over a period of many weeks, during which time the patient's general nutrition can be improved.

Cleveland Medical Society.

Meeting Held June 23, 1899.

INTESTINAL OBSTRUCTION FOLLOWING ABDOMINAL SECTION EITHER IMMEDIATELY OR REMOTELY.

DR. J. B. DEAYER of Philadelphia presented this topic. He prefaced his remarks by detailing the histories of eight selected cases. Intestinal obstruction following operation is due either to paresis, the result of sepsis or traumatism, or to mechanical causes. The latter form causes 2 per cent. of deaths after abdominal section, and wherever suspected to exist invariably indicates immediate reopening of the abdominal cavity to free the adhesions. Most commonly the intestine is adherent to a fixed surface that has been denuded of its peritoneum. Peristalsis then causes kinking and obstruction. Two coils of bowel may adhere, in which case obstruction is often due to bending over the pelvic brim or the edge of an adherent omentum. Rarely, bands of adhesions may be found running in various directions, and occasionally a portion of bowel has been included in a ligature. Postoperative paresis or septic peritonitis are the only conditions with which mechanical obstruction can be confused. The latter may be distinguished by its more sudden onset, by the absolute constipation with inability to pass flatus, the late occurrence of vomiting, the lack of correspondence of temperature and pulse with the evident

gravity of the case and the absence of all septic symptoms. Cases of acute abdominal pain, with absolute constipation and nausea, following an abdominal operation, even if at some interval, demand immediate incision. As to preventing the formation of adhesions, an early operation in a case in which it is indicated has decided advantages over a late one. Operation should be expeditious, the viscera should be handled as little as possible, and air should be kept out of the abdominal cavity as much as possible. After symptoms of mechanical obstruction have continued for twenty-four hours, the results of secondary operation are not favorable. In these cases appendicitis must always be thought of, as, perhaps owing to the frequent ill-advised use of opium, it is more often called intestinal obstruction than any other intra-abdominal ailment. All stumps should have peritoneum drawn over the raw surface, and the peritoneum should not be injured with irritating solutions.

DR. C. A. HAMANN noted the occurrence of obstruction from the ring of constriction left after an operation for strangulated hernia. This ring frequently sloughs, adhesions form and obstruction results. Such cases have rise of temperature for some time following operation.

DR. A. F. HOUSE asked whether the dry or the wet aseptic method of abdominal operation was most likely to be followed by formation of adhesions.

DR. HUNTER ROBB remarked that septic infection was the most common cause of obstruction following operation. He thoroughly cauterizes all pedicles and stumps before returning them to the abdomen, and thinks that has some influence in preventing the formation of adhesions. In every case he places 300 to 500 c.c. of salt solution in the abdominal cavity before closing up, and thinks that also has a beneficial effect in this respect.

DR. F. E. BUNTS expressed surprise at the fact of obstruction occurring so late—even several years—after operation. He commended the speaker for maintaining that the surgeon should refuse to operate in any case which has passed into the hopeless stage, and thought all surgeons should pay more attention to this point. He could not see how the placing of a small amount of saline solution in the abdomen could have any effect in preventing the formation of adhesions, as it is all absorbed in a very few hours.

DR. W. H. HUMISTON said he either covered all stumps and denuded spots with peritoneum, or if time for this was lacking, he cauterized with a 95 per cent. solution of carbolic acid. In his experience, packing with iodoform gauze had had unfavorable results.

DR. DUDLEY P. ALLEN said his experience with obstruction due to mechanical causes was very limited, the septic form being much more common. He did not favor immediate interference unless the obstruction was certainly absolute, as he had seen cases of partial obstruction recover under small doses of opium with rectal feeding. Cathartics aggravate the condition. Ordinarily he used nothing in the abdominal cavity when operating, and did not think this favored adhesions. If he used anything it had been sterile water. He agreed with the speaker that it was important to handle the intestines as little as possible, and to be expeditious.

DR. M. ROSENWASSER had had little experience in these cases. Where the mechanical obstruction was not complete tentative measures sufficed as a rule, but when it was complete early operation was imperative.

DR. DEAYER, in closing, said he had had no experience with the cautery in abdominal work. He thought dry gauze in contact with peritoneum more likely to disturb the endothelium than wet gauze. Undoubtedly where only partial obstruction existed the surgeon might delay incision, give very small doses of opium and feed by the rectum. It is often difficult to at once distinguish the complete from the incomplete obstruction, and in such a case he would advise immediate incision.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance	\$ 5.00
Foreign Postage	2.00
Single Copies	10 Cents

In requesting change of address, give old as well as new location.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No. 61 Market Street, Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription to the weekly JOURNAL of the Association will be forwarded regularly.

These new members of the Association should send their annual subscription direct to the Treasurer, Dr. Henry P. Newman.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street, Chicago.

Original communications are accepted with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, JULY 15, 1899.

TREATMENT OF PERFORATING ULCERS OF STOMACH AND DUODENUM.

The prognosis of perforating ulcers of the stomach and intestine would seem to improve in the same degree as the practitioner learns to make early diagnosis of these cases and to immediately secure surgical treatment. According to Lennander, who presents a study of his cases of peritonitis following ulcers of the stomach and duodenum on which operations were made during the years between 1889 and 1897¹, the statistics so far published show that one-fourth to one-third of the cases of perforating ulcers of the stomach or duodenum which are operated on are saved. The first condition in order that a large number of cases of this kind may be saved is, that physicians abandon the idea that their first duty in such cases is to alleviate pain. The pain should, on the other hand, guide to a diagnosis, the principal element of which is: here must be operated at once, or, an operation is not indicated, at least not an immediate operation. If the treatment is begun with a large dose of morphin and warm applications, then the patient as well as the physician are led into false expectations, which are succeeded by cruel disappointment when the abdominal distension indicates the existence of a diffuse peritonitis. Even when it is determined that an immediate operation should be made, little or no morphin should be given, because of the danger of intestinal paresis after the operation.

According to Lennander, the diagnosis of perforating ulcers of the stomach and duodenum rests on the history of previous symptoms of ulcers, on the appearance of violent pain in the epigastrium, with or without symptoms

of shock, with or without vomiting, on the rigidity of the abdominal muscles, and on local tenderness.

The abdominal incision should at once be made of sufficient extent to exactly determine the situation of the perforation and the extent of infection of the peritoneum. The perforations, which may be situated on the anterior or posterior surfaces of the stomach, or on any of the different parts of the duodenum, should be closed by bringing the serous surfaces together over a large extent and without tension, preferably by two rows of Lembert sutures. In case such closure is not possible, then the perforation should be covered by omentum, and the region separated from the rest of the abdominal cavity by means of tampons.

In the vicinity of the orifices of the stomach attention must be paid to the prevention of narrowing or bending during closure of the ulcer. This narrowing is best avoided by uniting the surfaces in a vertical direction with respect to the long diameter of the stomach or the superior horizontal part of the duodenum. When the perforation has been closed, all parts of the abdominal cavity which appear to have been infected are cleansed in the most painstaking manner, especial attention being given to the left subphrenic space. Inasmuch as a high degree of meteorism prevents careful cleansing of the abdominal cavity, an early operation is specially indicated. All those places in which exudate and pus are likely to become collected should be drained by means of gauze or tubes.

The prognosis depends principally on the length of time at which the operation is made after the perforation has taken place, also on the quantity and quality of the contents of the stomach which have become extravasated into the peritoneal cavity. The majority of the deaths have been caused by diffuse peritonitis; next in order come the subphrenic abscesses, and in a few cases pelvic abscesses.

While pelvic abscesses are readily diagnosed and operated on, the accumulation of pus in the subphrenic spaces is more difficult of treatment, because they are likely to early infect the pleural cavity, the lungs and the pericardium, and to become the starting-points of pyemia and septicemia. Subphrenic abscesses should not be emptied by means of transpleural operations in other cases than those in which an empyema exists or in which the pleural cavity is obliterated. In all other cases the incision should run along the costal arch, together with, in some cases, resection of the ribs below the lower limit of the pleura, according to the method originally proposed by Lannelongue in 1887.

When a perforating gastric or duodenal ulcer has been diagnosed, but operation for some reason or other not determined on, then there should be given no food whatsoever by mouth for at least one week, even if the patient's general condition improves so greatly that the original diagnosis becomes questioned.

Lennander's cases may be summarized as follows: No operation: One case of subphrenic abscess following

¹Aisberättelser från Akademiska Sjukhuset, Upsala, 1897-8, p. 93.

perforation of the stomach, in a woman 36 years old; recovery. Eleven cases were operated upon. In six there was a diffuse peritonitis, which in two cases followed perforation of duodenal ulcers, three cases perforation of gastric ulcers on the anterior surface of the stomach, and in one case on the posterior surface. In four of these cases the ulcers were found, and in three they were completely closed by means of sutures, in one incompletely sutured and tamponed. One of the cases operated on fifteen hours after the perforation died from diffuse peritonitis, in the other three the peritonitis subsided. Nevertheless, one died on the seventeenth day after the operation, from sepsis following an incompletely drained subphrenic abscess; another died two months and twenty-two days after the operation, from purulent pericarditis, due to a small subphrenic abscess; the third case died three and one-half months after the operation, having left the hospital in apparently good condition, on account of hemorrhage from the bowels. The other two cases of diffuse peritonitis, in which the ulcers were not sutured because not found, died three to four days after the operation. In five cases there was found a circumscribed suppurative peritonitis, which, in two cases followed a ruptured duodenal ulcer, in two cases ruptured gastric ulcer, and in one followed the taking of phosphorus for the purpose of producing abortion. Of these cases three recovered after operation, while two died.

VALUE OF MEAT EXTRACTS.

The flesh food which is taken into the human system consists of proteids with about .3 per cent. of creatin. The nitrogenous waste which is thrown out of the system by the kidneys consists of urea with about .3 per cent. of creatinin, the latter being an anhydrid of creatin. We would therefore be inclined to the belief that the proteids, when they have served their purpose in the human economy are eliminated as urea and the creatin as creatinin. The proteids are essential in a dietary because they repair muscular waste, and this waste is excreted as urea; but the excreted urea is not a measure of the muscular waste for when an excess of proteids is ingested that which is not required for metabolic processes is oxidized to urea with the production of heat and energy, and immediately eliminated. The ingestion of an excess is followed so promptly by the excretion of an increased quantity of urea that no time is given for the building up and breaking down of muscular tissue. Creatin is generally considered to be a transition product in the retrogression of albuminoids to urea, but the relation between it and the more complex molecule on the one side and the simple molecule on the other is not clearly defined. Urea is formed in the liver; but if the creatin of the metabolic processes be converted by this organ into urea, why should the creatin of the excess of albuminoids taken as food be excreted as its anhydrid instead of undergoing a reduction to urea in its passage through

the liver? Professor J. W. Mallet¹, of the University of Virginia, has shown by some recent experiments that creatin introduced into the alimentary canal is not concerned in metabolism, but is eliminated as creatinin. First he elaborated a practical method for the separation of urea, creatin and creatinin from the urine. This method was tested by adding known quantities of these substances to normal urine. Of the urea 96.4 per cent. was recovered; of the creatin 86.9 and of the creatinin 95.0 per cent. He then administered the flesh basis in various doses to the human subject in a series of experiments and collected the urine of the succeeding twenty-four hours for analysis when creatin was ingested in 5, 10 and 15 grain doses from 96.18 to 98.24 per cent. was recovered. When creatin was ingested in doses of from 3 to 15 grams, it was evident that nearly all of that swallowed was converted into creatinin and eliminated in this latter form, very small amounts, however, escaping and undergoing elimination unchanged. The creatin recovered, as such, or represented by creatinin, constituted 95.73 to 98.92 per cent. of that taken into the system. The quantity of urea in these instances was practically unaltered. The main conclusion to be drawn from the experiments is manifestly that by far the larger part of the flesh bases ingested, if not absolutely the whole, does not undergo metabolism with the production of urea, or anything else, but is eliminated by way of the kidneys. It may also be fairly concluded that these bases occurring in food may be entirely disregarded as sources of energy. Hence it is important for analysis, in determining the nutritive value of meats and of articles of food prepared from meat, to distinguish between the nitrogen of the flesh bases and that of the albuminoid substances. The proteids build up the nitrogenous tissues and furnish muscular energy and heat, while the flesh bases are not available for any of these purposes. If the nitrogen of the food be made the basis for the calculation of the proteids without excluding the nitrogen of the creatin present, the food value will be greatly overestimated. Physicians generally recognize the absence of nutritive value in these extractives, but their use is frequently prescribed on account of their reputed value as nerve stimulants. Professor Mallet's observations on the physiologic effects of the doses administered tend to deprive them even of this credit. The most decided effect observed was a retardation of the action of the heart; and if this was accompanied by any change in the force of impulse in the radial artery it was probably a diminution of force. In the meat extracts the presence of salts of potassium has to be considered, but aside from this such extracts are reduced by these observations from the rank of foods or medicines to that of mere condiments or flavoring matters.

BY THE will of the late Joseph Murray, \$200 has been devised to the Germantown (Pa.) Hospital, and a like sum to the Presbyterian Hospital of Philadelphia.

¹The Physiological Effect of Creatin and Creatinin and Their Value as Nutrients. Bulletin No. 66, U. S. Dept. of Agriculture, 1898.

TUBERCULOSIS IN ANIMALS.

It is evident that the stock and dairy interests are becoming alarmed at the prospect of wholesale slaughter of their stock by reason of the convictions of the public on the subject of the contagiousness of tuberculosis. It is not wise to disregard this alarm. The community has no better right to inflict unnecessary harm by slaughter of stock than it has to inflict such harm by unwise tolerance of an evil. As a further consideration, the execution of law and, in fact, the law itself can never rise much above the level of public sentiment. Further, the defense of a private interest gains enough by intensity and directness to offset the larger clientele of a public interest. On the other hand, the farmer will eventually suffer enormous loss unless something is done to eradicate this disease. All statistics on the subject show its rapid spread; for example, the slaughter-house record of Leipzig are as follows: 1888, 11.1 per cent. tubercular; 1889, 14.9 per cent.; 1890, 22.3 per cent.; 1891, 26.7 per cent.; 1895, 33.3 per cent.; for Berlin, 1883, 2.86 per cent. tubercular, and 1895, 15.45 per cent. It is probable that the increase among dairy animals has been still greater. These figures are convincing even after allowing the largest possible margin for error.

As to its prevalence, there has been wide variance in the experience of writers. At Kiel the slaughter-house statistics show that 66 per cent. of the Danish cattle have the disease. In Illinois the Board of Live Stock Commissioners report tuberculosis in 20 per cent. of 2200 cows examined. This is among dairy herds. The Wisconsin station has found tuberculosis in 10 per cent. of the cows it has examined. The Vermont station has examined one-fifth of the cows of that state, and from 2 to 3 per cent. have been found tubercular. In Germany, in 1895, meat condemnations by reason of tuberculosis entailed a loss of one and a half million dollars. The disease being so common and increasing so rapidly the farmer cannot afford to ignore the question, view it as narrowly as he will.

The question whether human and bovine tuberculosis is the same disease was answered affirmatively by Villemin, Chauveau, Klebs and Schuppel in the years 1868 to 1878. Volumes would be required to record the confirmatory work that has since been published. Theobald Smith of Boston demonstrated a difference in virulence between tubercle bacilli obtained from cows and tubercle bacilli from the human subject, but this in no wise disturbs the original conclusion that the diseases are identical. What shall be done with tuberculous animals is a very important question, and, as a subsidiary proposition, how are we to know that a given animal is tubercular? There is no question as to the advisability of using tuberculin. Eber, as a result of 563 inoculations, found 74 mistakes or 13.14 per cent. Bang, as the result of 515 inoculations, found 50 mistakes, 9.7 per cent. This allows for errors of every kind. 1. There may have been a slight tuberculosis in an unusual locality, the lesion having been overlooked. 2. One reaction protects

against another for six months in many instances. 3. The great percentage of failures is in advanced tuberculosis, where the general debility and the physical signs leave no possibility of escape for the sick animal. Bearing these things in mind, the accuracy of the test is very great. Says Conn: "In detecting the presence of tuberculosis in our animal, then, tuberculin is very accurate; too accurate, indeed, to be a guide for the indiscriminate slaughter of reacting animals."

Shall the state slaughter all animals which respond to tuberculin is a question of importance. Bang, of Copenhagen, objects to this and suggests the following plan:

1. The farmer consents to accurately follow out directions given him by the veterinarian. Without this the whole plan is useless.
2. The herd is tested with tuberculin and on the results an infected herd is separated into three groups.
3. Group No. 1 is composed of healthy animals, and these are so handled as to keep them healthy.
4. Group No. 2 is composed of animals which, by tuberculin and by physical signs and symptoms, show advanced tuberculosis. These are killed at once. The meat is sold subject to inspection.
5. Group No. 3 is composed of those animals showing incipient tuberculosis. These animals are separated as to stables, pastures, troughs, attendance, etc., from Group No. 1.
6. Animals in Group No. 3 are kept under good hygienic condition; their milk is sterilized before using.
7. The calves from No. 3 are separated from their mothers and raised on sterilized milk. They are inoculated with tuberculin and on the results depends whether they are placed with Herd No. 1 or No. 3.
8. Every six months the healthy herd is inoculated with tuberculin, and reacting animals are placed in Herd No. 3.
9. Animals in Herd No. 3 that no longer react are not placed in Herd No. 1.

The statistics of an experiment along this line, lasting five years, is as follows: 1892, number of animals in Herd No. 3, 131, number in Herd No. 1, 77; 1897, number in Herd No. 3, 48, number in Herd No. 1, 155. This and other observations on this method demonstrate great remedial value in this, which is the most economic of all suggested plans. It demands the co-operation of the farmer. In this it does not differ from any other plan. Any will be inefficacious until the stockman enters fully into the spirit of it. To this end accurate reliable information must be carried into the home of everyone. In the meanwhile, many milkmen will see that it is to their financial interest to guarantee freedom from tuberculosis. To all asking it, the state boards will go to investigate, advise and act as action is demanded. The state herds will be kept clean. The market for tubercular animals for breeding purposes will narrow year by year, and so step by step education will spread. But at the present time the animal and his owner must be handled with the same moderation with which we handle the man who has tuberculosis.

THE MEDICAL CRISIS IN FRANCE.

The *British Medical Journal* recently gave a summary of a dissertation presented to the University of Lyons by M. Ernest Perthuisot, who discusses the "Medical Crisis" in France. The causes assigned are: 1. There are too many doctors. 2. The profession in France has in one way or another suffered discredit in recent years. 3. Quacks are allowed to take the bread out of the mouths of legally qualified practitioners. As regards plethora, M. Perthuisot shows that the condition is becoming acute. The number of doctors is increasing out of all proportion to the increase of population. He estimates that while the vacancies left in the ranks of the profession by death or retirement amount to six or seven hundred a year, the annual output of graduates by universities is at present more than eleven hundred, and the increase is so steadily progressive that in his opinion the number of doctors in France will within a limited time, perhaps ten years, have doubled itself.

CONGENITAL TUBERCULOSIS.

While congenital tuberculosis in both men and the lower animals is rare, there is no doubt that it does occasionally occur. More often than which is transmitted from parent to offspring is a predisposition to the disease, the activity of which is augmented by exposure to infective conditions. An instance of congenital tuberculosis in the calf was recently reported by Ravenel, to the Pathologic Society of Philadelphia, and specimens from a further example of the same kind were exhibited by MacFadyen at a late meeting of the Pathological Society of London. As a rule the calves of tuberculous cows are born free from tuberculosis, and fetid infection is usually, if not always, associated with tuberculosis of the placenta or of the uterus. Dissemination takes place under these circumstances through the blood-stream, as indicated by the wide-spread and discrete distribution of the lesions.

TRANSPLANTATION OF OVARY.

The *Medical Press and Circular* does not approve of the operation of ovarian transplantation. It says: "To leave a little bit of healthy ovarian tissue, when this is possible, is doubtless a good instance of conservative surgery, but to insinuate a whole ovary, belonging to another woman, into the peritoneal cavity, is hardly a procedure that commends itself to one's surgical instincts, and is likely to set up serious mischief." Whether serious mischief here likely to be set up is medical or surgical mischief is uncertain; the fact that aseptic transplantation is possible has been proven, and if so, what is the damage thus produced? One can conceive that such operations might lead to curious speculations as to heredity, but that these might extend to the point of producing "serious mischief" seems hardly probable to say the least. Should it be so, the questions would not then be medical, but legal or social ones, and our surgical instincts are not directly affected by matters so far ahead as that, provided they do not legally involve the operator. Ovarian transplantation may or may not have a brilliant future before it—that is a question on which we venture no opinion—but it has not thus far been proven dangerous nor mischievous.

INFECTION BY TELEPHONE.

Infection by telephone is again to the front. A Chicago doctor has found germs and calls attention of the public to the same. The Board of Health is called on to act and the newspapers have a fresh topic for scare-heads and sensational articles. The *JOURNAL* has already expressed an opinion on this subject, but under the circumstances it may be justifiable to notice a few facts that were not stated before. The whole subject of infection by telephone was gone over by the Health Department of Chicago four or five years ago and with the result that in all the public telephones examined no evidence of special danger of infection was discovered. The use of the transmitter requires no direct contact or inhalation if the user keeps at the proper distance, and therefore the peril is not excessive even if germs exist. As they have not been found to any extent, the risk may be said to be insignificant. The explanation of these periodic revivals of the telephone scare may possibly be found in some commercial speculation, the intended introduction of an "aseptic transmitter," or some similar enterprise for which the newspapers are being "worked." Commercial enterprise without principle seems to be one of the orders of the day and, we regret to say, appears to seek a special field in the prevalent imperfect and erroneous vulgarization of medical facts.

EXTERMINATION OF MALARIA.

The Liverpool School of Tropical Medicine will send an expedition to Sierra Leone, Africa, next month, the object being to ascertain whether it is possible to exterminate from a small area the malaria-bearing mosquitoes which infect some parts of that region. The expedition will consist of men connected directly or indirectly with the school, and selected by their fitness for the special work. One of these will be Major Ronald Ross, lecturer in tropical medicine in the University College, Liverpool, who published a paper on "The Possibility of Exterminating Malaria from Certain Localities by a New Method," in the *British Medical Journal* for July 1. The success of his method of ridding the locality of the mosquito depends on the fact that in their predeveloped stage they are little wriggling larvæ, inhabiting stagnant puddles, especially in marshy regions. The ridding the locality of the pest will be made by filling up or draining the land. Whether the idea is new is doubtful, for it has been generally recognized in this country that mosquitoes are to be found in greatest numbers in low wet grounds and the corollary of this would be to drain, or eliminate the moisture. But we do not wish to belittle the importance of the possible scientific value of the proposed expedition; on the contrary we hope that it may result in such an increase of knowledge in reference to the disease and its cause that a method of eliminating it may finally result. We, in this country, have reasons now, if never before, for being deeply interested in this, as well as all tropical diseases.

HYSTERIC MISALLIANCES.

One of the unpleasant facts to patriotic Americans is the success of fortune-hunting dukes, etc., in captivating American heiresses, and the tendency of certain native snobs to take satisfaction in such events. Why any self-respecting citizen of this country should see any-

thing desirable in exchanging sovereignty in a republic for subjection, or the privilege of becoming even a highly titled subject, in a monarchy, is not self-evident in the nature of things; it is really a degradation politically and should also be socially. It becomes somewhat more mortifying, however, when these events and tendencies are regarded abroad as characteristically American, and made the subject of elaborate medico-sociologic discussion. A French medical expert has utilized and made prominent some of these American women as examples of sexual and hysteric morbidity, their prominence probably leading him to their selection, though equally numerous instances could without question have been found among his own countrywomen. One instance that he quotes is well known in this country as a most pronounced example of neurotic and insane heredity. Another is hardly American but more properly Italian, as the name indicates. Notwithstanding these facts, there are still enough prominent examples of European misalliances by American women to keep us still unpleasantly before the world and serve as texts for foreigners to dilate on American degeneracies. The medical side of the subject being thus prominently brought forth, while not pleasant, has perhaps the advantage that it may aid in calling the attention of a certain class to the unfortunate aspect in which they appear abroad.

THE KISSING BOGEY.

During the past week or two the eastern section of our country has, according to the newspapers, been suffering from the invasion of a new enemy to human comfort, the "kissing bug." It is said to attack sleepers and produce an acute swelling, usually on the lips—its favorite point of attack—hence the popular appellation. So far we have seen little mention of it in medical literature except in the Philadelphia correspondence of the *Medical News*, which gives a delightfully indefinite description of the creature that is supposed to be the offender, calling it a parasite of the hedging "about an inch in length, of dark brownish red color, and having six legs and long antennae." The name given it is, however, a better identification—"opiscaetus" (opiscetus?) personatus, a European species that is quite capable of performing the accredited "kissing bug" role. Other newspaper identifications have been published and it is possible that every kind of nocturnally received puncture, from a flea bite up, is being credited to this new and fashionable cause. Reports of its performances are coming in from all parts of the East and Middle West, and even deaths are reported from its bite. It is hardly probable that we have any general exaggeration of the frequency of any one species, though there may be a local increase. We must therefore assume, as most likely, that a large proportion of the cases reported have in them a mental element due to the newspaper reports. Cases of painful stings or bites during sleep are not uncommon. We have nearly all of us experienced them or observed their effects, but any ordinary or extraordinary event of the kind just now is credited to the "kissing bug." The probability that it is the species referred to by the Philadelphia correspondent, or some allied one of the

family, is the greater, as that insect is a well-known infester of dwellings and its bite is sufficiently painful and serious to meet the descriptions. Other species, however, may be implicated, several of the water-bugs, *Notonecta* and *Belostoma*, are said to be poisonous, and there is a possibility that the electric light so general in our towns and villages may attract them in unaccustomed numbers so as to render more frequent the accidents of their bites. For the most part, however, we think the present epidemic of "kissing bug," except, perhaps, locally on our eastern border, is largely a matter of the imagination.

SHOULD THE PHYSICIAN PRESCRIBE PATENTED DRUGS?

An editorial in the *Medical News* (July 8), after defining a patent medicine in the technical and restrictive sense, answers the above questions affirmatively: 1, because the writer thinks these substances are of a very decided value and, therefore, it is to the interest of the profession to use them; and 2, because the physician has no right to deprive his patients of chemical products which he knows are especially indicated, simply because he does not approve of the methods by which they are manufactured or protected. If the strict definition of the *News* is accepted, then little objection could be made to the views expressed. We heartily endorse the sentiments contained in the concluding paragraph of the editorial: "There is a class of preparations which we believe physicians should carefully avoid using, namely, medical substances advertised to the laity. These should be avoided not from the business standpoint that they deprive the profession of practice, for this they do not do, because patients who take these preparations usually do so with such disastrous effects that the profession is pecuniarily benefited in the end by acute cases being transferred into chronic ones, but because the advertisement of these preparations to the laity causes non-medical readers to dose themselves with compounds which in many cases are not only useless but distinctly harmful. The products of those manufacturers who sell a preparation to the medical profession with the right hand and the same preparation to the laity with the left should also be carefully avoided in writing prescriptions."

LANDRY'S PARALYSIS.

While the precise nature of the disorder first described by Landry, and hence known by his name, remains unknown, there seems good reason for believing that the symptomatic manifestations of the affection are dependent on deranged functional activity of the peripheral motor neuron. Going a step further, it may readily be conceived that the disturbance of function is due to the activity of toxic substances introduced from without or generated within the body as a result of the vital activity of micro-organisms or of derangement in the bodily metabolism. However this may be, in some cases the symptoms have been indicative of peripheral neuritis, in others of anterior poliomyelitis. Of the infectious nature of the disease the presence of constitutional symptoms of greater or less gravity may be accepted as evidence. Symptoms of the affection consist in gradually

progressive and extending motor paralysis of flaccid type, with loss of reflexes, preservation of electric reactions, escape of sphincters, slight if any disturbance of sensibility, rapidity of course, and usually a fatal termination. It will thus be seen that the diagnosis may often be attended with considerable difficulty. Some of the points of differentiation from diseases that it may simulate or may be simulated by it are laid down in a brief communication presented by Haynes¹ at one of the recent meetings of the Brooklyn Pathological Society. In cases of multiple neuritis there is usually a history of ingestion or of exposure to the action of some poison, or of a preceding acute infectious disease; though the onset is sudden, the course is slow, sensibility is involved, electric reactions are lost, muscular atrophy takes place, and the disease usually terminates in recovery, sometimes after a tedious convalescence. Transverse myelitis is usually preceded by a history of injury or pressure, or of syphilis, or other infectious disease, and the symptoms are localized, sensibility and the sphincters are involved, and muscular atrophy takes place, with alteration in the electric reactions. Diffuse myelitis is attended with more pronounced constitutional and spinal symptoms, while in disseminated myelitis the spinal symptoms are scattered in accordance with the number and situation of the foci of disease. Meningomyelitis is attended early with muscular spasms, pain, fever, and other marked constitutional symptoms, the symptoms of meningitis preceding the development of palsy, while cerebral symptoms are present in the cerebrospinal form. In the ordinary form of anterior poliomyelitis, as seen in children and adults, there is limitation of the paralysis to certain groups of muscles, and in polioencephalitis, the cortex and cranial centers are implicated; while in Landry's paralysis, only the efferent spinal motor nerves and the anterior horns of the gray matter of the cord and the medulla are involved. The morbid process consists in an exudative inflammation, with cellular infiltration of the circumvascular sheath, degeneration of the ganglion-cells and loss of structural elements, with or without degeneration of the anterior roots. Haynes recommends, besides the usual remedies, antistreptococcal serum, as it has been found that animals infected experimentally with streptococci and their toxins exhibit changes in the nervous system that bear a striking resemblance to those that have been found in some cases of Landry's paralysis.

SPONTANEOUS GANGRENE IN CHILD, DUE TO DISEASE OF VESSEL WALL.

There have been a few instances described in which spontaneous gangrene has developed in rather young children; Reynaud has observed such cases. Leyden and others have described gangrene following typhoid fever and other infectious diseases. In a case described by Lehmann, symmetric gangrene, resembling senile gangrene, developed in a child 9 months old, apparently on account of changes in the vessel walls. Gœbel² describes the following case: For six weeks an eighteen months old child complained of pain in the left leg, which became blue, somewhat swollen,

and cold to the touch. The clinical diagnosis was gangrene due to obstruction in the anterior tibial artery. At the autopsy there was found pneumonia, necrosis of the tonsils, and thrombosis of the abdominal aorta and the left popliteal and anterior tibial arteries; the thrombi were oldest in the popliteal artery. Where the popliteal artery branches, and in the first portion of the anterior tibial artery, there were found the following pathologic changes: At many points the endothelium was absent, the intima and inner elastic coat somewhat swollen and split up into a thin network of fibers—a local endarteritis, due perhaps to primary injury of the elastic coat. The resulting roughness of the vessel probably induced the thrombus formation. The nature of the changes in the vessel remains obscure.

RELATIONS BETWEEN MENSTRUATION AND TUBERCULOSIS.

Both ovulation and menstruation, though distinct processes, have each a profound influence on the female organism. That they are affected by disease is well and generally known, but that they have other relations therewith has not been made the subject of extensive inquiry. It has been observed that the thyroid gland is sometimes enlarged at the menstrual period, and that in cases of pulmonary tuberculosis the menstrual discharge may be replaced by hemorrhage from the lungs. Some interesting observations in this connection have been made by Neumann³, who relates that some tuberculous patients present regularly during menstruation increased febrile reaction; and that even otherwise afebrile patients exhibit, either before or with the onset of the period, elevation of temperature, with or without changed or aggravated conditions in the lung, continuing for some days after the cessation of the period. This phenomenon should arouse suspicion, even when the general condition is satisfactory in the intervals. Sometimes the catarrhal state in an obviously diseased portion of the lung is aggravated, without fever, during the menstruation period. Instead of rough intensified breathing, crackling and crepitation, or even phenomena of consonance, are audible. If these phenomena recur repeatedly, with or without fever, in conjunction with menstruation, the prognosis must be guarded. Not rarely indications of increased destruction appear, during and following the period. In patients, in whom improvement appears to be taking place, the recurrence of crackling and rales during the menstrual period must give rise to caution. In suspicious cases or in patients apparently anemic only, it is not uncommon to detect during the menstrual period, in lungs believed to be sound, auscultatory signs of latent disease. In some tuberculous patients in whom the general condition exhibits no change at the beginning of menstruation, a recession of the respiratory symptoms is observed with the cessation of the period. This may be repeated at successive periods, and the prognosis is thus rendered the more favorable. From the foregoing consideration tuberculous patients should avoid before, during and directly after the menstrual period, all things that increase the existing irritative state and that contribute to the extension of existing and latent foci. They are thus

¹ N. Y. Med. Jour., May 27, 1899, p. 743.

² Deutsche Arch. f. Klin. Med., 1896, 63, p. 184.

³ Berlin. Klin. Woch., May 22, 1896, p. 455.

advised to rest in bed while being supplied with abundance of air and bland, nutritious food. Traveling during the menstrual period, by tuberculous patients, is to be interdicted.

Medical News.

THE U. S. transport *McClellan* recently arrived at quarantine, New York City, from Santiago, with two well-developed cases of yellow fever on board.

ARRANGEMENTS are being made in Hamburg, Germany, for an institute for the study of tropical diseases.

SCURVY is prevalent in the famine-stricken Volga region in Russia. Over fifty-five thousand cases have been reported.

AT THE recent commencement of Harvard University the honorary degree of A.M. was conferred on Dr. W. T. Councilman, formerly connected with the Medical School of the Johns Hopkins University.

DR. A. C. CROFTAN, Pasadena, Cal., leaves in a few days for Europe. He proposes to go direct to Vienna, to do special work on diseases of the chest, under Nothnagel. He will be gone about four months.

DR. WEBSTER FOX, Philadelphia, is in Europe. While away he will attend the meeting of the British Medical Association, and also the International Ophthalmological Society at Utrecht, Holland, in September.

DEATH from the use of chloroform as an anesthetic occurred in New York City on June 28, in the case of a boy of 9 years, to whom the chloroform was administered for an operation on the throat. The operation had not begun, however, when the death occurred.

DR. FAYETTE C. EWING of St. Louis will sail July 27, for London, to attend the International Otological Congress, as a delegate from the Western Oto-Laryngologic Association. Dr. Ewing has recently accepted the associate editorship of the *Laryngoscope*.

THE LONDON Cancer Society has commissioned Dr. A. E. Duffy to proceed to the United States for the purpose of collecting data regarding cancer, and to especially study the investigations being made at Buffalo, N. Y. A prize of \$50 has also been offered by the Society for the best essay on cancer.

ACCORDING to a recent decree a physician wishing to practice in Hungary must be a graduate of a Hungarian medical college, or have his foreign diploma accepted by one. This excludes Hungarians who have graduated at Vienna, and is also hard on Croats and others who reside in Hungary but do not understand Hungarian. The decree is for the double purpose of restricting the number of physicians practicing in the country and increasing the attendance at the universities.

DR. WOODS HUTCHINSON, at the last meeting of the Zoological Society of London, read a paper on tuberculosis. This mortality fell most heavily on the ruminant animals in the Society's gardens. Of 215 necropsies made during the last six months, 49, or 25.3 per cent. of the animals and birds presented lesions of tuberculosis. This mortality fell most heavily on the rudiments and gallina, and least so on the carnivores and raptores. Race seemed to have little influence on susceptibility, mode of housing but little more, but food habits much more. A close correspondence seemed to exist between immunity and the relative size of the heart in both birds and animals.

ADVISES through the United States Legation at Monrovia, June 7, confirm the report that a plague is raging at Grand Bassam in the French Ivory Coast country. This colony is adjacent to Liberia on the east coast, and to the British gold coast on the west. The disease is very similar to the bubonic plague, and is quite fatal. It is reported that at least two or three hundred people have already succumbed to the disease. Three European physicians are thought to have been victims. All homeward bound German steamers are quarantined against taking any African passengers to Germany.

THE AUTOMOBILE is of especial interest to physicians, but its high price places it beyond the reach of those whom it would most benefit. The *Gazette Medicale de Paris* suggests adopting the plan that is proving such a boon to the fishermen along the French coast; a company was formed for the purchase of small steam vessels for their use, in place of their untrustworthy sail boats. These are rented to the fishermen, who never could have accumulated sufficient capital to buy them. The writer urges capital to found a "medical automobile society" on the same plan, which might prove mutually profitable.

RELATIVE to the somewhat indiscriminate appropriations which New York City has been accustomed to make for the support of private charities, a committee of the Charity Organization Society has been making inquiry as to the methods of distribution of such appropriations in other cities and recommends that the New York City appropriations be limited to such agencies as children's institutions and hospitals, and be discontinued in the case of medical dispensaries; also that they be continued only to industrial schools until such are assimilated with the public school system, discontinued for fresh air work carried on by private societies and that appropriations to founding asylums and children's institutions be on a *pe capita* and *per diem* basis.

THE MEDICAL college founded in 1883 by French Jesuits at Beyrout, Turkey, has recently been recognized officially as the peer of the French colleges, its diplomas entitling the holders to practice anywhere in Turkey, France or its colonies. The *Journal de Médecine* protests most energetically against this order of things.

A LITERAL translation of the "Thousand and One Nights," into French, has just been completed by a young physician, Dr. Mardrus of Marseilles, a Mohammedan of Cairo. He is familiar with Arabian lore and life, but also thoroughly at home in Paris, where he completed his education. The combination of Parisian, Arabian and medical knowledge is said to have produced a rare work, as the author has traveled and observed much and had access to many unpublished manuscripts.

IN 1896, Dr. Levi Cooper Lane, founder of the Cooper Medical College of San Francisco, Cal., founded and endowed a course of lectures to be delivered annually and known as the Lane Medical Lectures. The course consists of ten lectures by one of renown or ability of note, selected at present by Dr. Lane, and after him by certain trustees, and the lectures are subsequently to be the property of Cooper College. William Macewen was the first to be invited to deliver this course, in 1896, and he was followed by Christopher Heath and Thomas C. Allbutt, in 1897 and 1898. The course for the present year, delivered June 28 to July 3 by Dr. Nicholas Senn, of Chicago, as previously noted in the JOURNAL, has been very well attended and awakened much interest. The

lectures were as follows: "Introductory;" "Traumatic Shock;" "Prophylactic Hemostasis;" "Treatment of Hemorrhage" (two lectures); "Gunshot Wounds;" "Wound Infection;" "Treatment of Wounds;" "Compound Fractures;" "Technic of Modern Amputations."

PRINCESS LOUISE of Coburg, daughter of the King of Belgium, has been definitely incarcerated in the Lindenhof sanitarium at Coswig, near Dresden, as two medicolegal experts at Vienna, with the concurrence of the Faculty of Medicine, have officially decided that she is mentally and morally irresponsible. They ascribe her condition to the commotio cerebri caused some years ago by a fall of nearly a hundred feet, in the mountains, and a subsequent typhoid fever.

EXCURSIONS for medical study are organized every summer in France to acquaint physicians with the watering places, springs, etc., of the country. This year Professor Landouzy is in charge, and will personally conduct the party to the Auvergne and other resorts, September 2 to 13. Half-fare railroad rates are given to the profession and the expense of the trip is 200 francs per capita, or about \$40 for the eleven days, hotels, etc., included.

FROM the *Lancet* of July 1 we learn that the 32 cases of plague in Egypt, previously referred to in the *JOURNAL*, have been spread over the two months of May and June and limited only to one town, but chiefly to one dirty corner of that town, a native bazaar. The victims have all been from the lowest class of natives and the lowest Europeans. The correspondent says that the present localization is confirmatory of the theory of place infection, capable of eradication by giving attention to cleanliness. The sanitary department is isolating cases, watching friends of the infected, cleansing the habitations and possessions of the patients, etc. Two policemen, not on police duty, and one hospital orderly had contracted the disease at the date of the correspondence, June 24, and the municipality of Alexandria had passed suitable sanitary measures. The writer says that the plague has done one good thing in emboldening the Egyptian Government to pass a measure which the sanitary officials proposed some time ago but which did not meet the approval of the General Government.

THE CHICAGO Health Department has inaugurated a new movement in sanitation—house-to-house instruction as to hygiene and sanitary matters. Some forty physicians, largely recent graduates, have volunteered to disseminate the information, making a regular canvass of their districts, pointing out defects and advising householders and parents as to the proper care of children, the abatement of nuisances, the methods of sterilizing milk and water, the needs of cleanliness, etc. The object is the prevention, rather than the cure, of disease, and the inspectors are not expected to prescribe for or treat cases unless in emergencies. The department will have the advantage of receiving fuller and more detailed information than could have been obtained through its paid forces alone, the voluntary inspectors will have the benefit of their practical experience in sanitary work, and the public, or that portion that most needs it, will get the instruction it should have in matters on which it most requires enlightenment. The work will be largely if not entirely in the thickly settled and poorer portions of the city, and the result of the experiment will be watched for with interest.

PHYSICIANS in charge of the laboratories of Jefferson Medical College, Philadelphia, have for some time been studying the condition of the urine after prolonged

exercise on the bicycle. In most instances the urine was selected from those individuals known as "record breakers," forty or fifty cases being studied, examinations made before and after the ride, and again a few days afterward. In quite a number, after a ride of twenty minutes temporary albuminuria occurred.

THE INDIA correspondent of the *Lancet* (July 1) reports the number of deaths from the plague rapidly diminishing. The total for the whole of India for the week ending June 4 was 511, while in Bombay the weekly total mortality had fallen almost to its normal level, and the reported plague mortality was only 64. At the date of writing, June 7, there were still about 4,000 persons living in camps, while in Karachi the outbreak had almost subsided and in Poona the deaths were very few. Calcutta reported but twenty or thirty a week. Still the infection lingers and fails to be stamped out entirely anywhere. He considers the organization for the treatment of plague-cases at the Medical College Hospital in Calcutta unsatisfactory, "the accommodation provided being a small, dark, cellar-like ward on the ground floor, which is also used for cholera and other infectious cases. In fact, cholera cases of plague in Egypt, previously referred to in cases and plague cases frequently occupy adjoining beds."

TABETIC CLUBFOOT.—One of the rarest complications of tabes dorsalis is a deformity of the foot in which sometimes the arch yields and the patient walks on the inner border, while the outer border is everted, and sometimes the arch is increased, constituting the so-called Chinese foot. Both of these conditions must be looked on as trophic disturbances, allied to the arthropathies. After the joints are obliterated, sometimes the altered bones undergo fracture and it has been thought in some instances that the muscles also were affected. An interesting example of the deformity has recently been reported by Schulz¹ in which radiographs disclosed the existence of spontaneous fractures in the affected parts. The patient was a man, 33 years old, with a history of syphilis twelve years previously. He presented induration of the cervical and inguinal glands, and prominence of the left tibia in its lower third. The condition of clubfoot had been present for six years, while the remaining symptoms had made their appearance two or three years later. There was slight ataxia in the lower extremities and slight swaying when the eyes were closed. The pupils were unequal and responded to light but sluggishly. The knee-jerks were wanting, although an occasional response could be obtained on the right. Lancing pains in the extremities occurred from time to time. The most marked sensory disturbance consisted in a double sensation when the left foot was pricked, the sense of contact being followed after several seconds by one of pain. There was a perforated ulcer of the left foot that had been present for six years intermittently. An existing sinus was 0.75 cm. deep, but did not lead to roughened bone. The foot was markedly clubbed, with strong plantar arching, and about two cm. shorter than the right. In its middle it was broader from side to side, and the toes were deflected outward. On palpation the heads of the first and third metatarsal bones were found to be considerably thickened. A skiagraph showed that the joint between the astragalus and the os calcis, as well as that between the scaphoid and the cuboid, was almost completely obliterated, while that between the cuboid and the external cuneiform and the heads of the last two

¹ *Berliner Klin. Woch.*, May 28, 1909, p. 477.

metatarsal bones was represented by a compressed mass without indication of articular line. The cuboid bone appeared fractured, and the fissure appeared to extend between the scaphoid and the internal cuneiform bones. Enlargement of the heads of the first and third metatarsal bones was evident. The scaphoid bone also was enlarged, and its tuberosity appeared to be separated from the body of the bone. The nature of the tabetic clubfoot has hitherto not been clearly understood, and this demonstration shows its mode of origin in at least some cases. It is possible that as a result of disturbances in the nutrition of the bones of the foot these were rendered more fragile, and are more readily fractured through the agency of the superincumbent weight.

Therapeutics.

CORRECTION.

An error in dosage occurred in this department in last issue, under the caption "Heart Tonic (p. 113). In the first item of prescription, "Strychnine Sulph., gr. 1/3" should appear instead of "gr. i-iii." The metric dosage, however, is correct.

UREMIA.

For urenic attacks, Delafeld advises chloral 10 grains (.6 gm.) per os, or 20 grains (1.29 gm.) per rectum, every three or four hours, or nitroglycerin gr. 1/100 (.0001 gm.) to 1/50 gr. (.001 gm.) repeated as indicated by pulse tension. Hot packs, except in cases with cerebral symptoms and feeble pulse.

COLIC.

Acute gastric and intestinal colic is one of the diseases frequently met with, especially in summer, that is often refractory to treatment so far as immediate relief is concerned. While by appropriate means the physician may readily, in a week or so, relieve the condition that causes the colic, it is the pain that the patient wishes to be rid of, and the physician is likely to be judged by his success in relieving that promptly.

In such a case morphin is even more objectionable than usual, yet it is the surest means at hand. The physician early in his career finds that most of the ordinary remedies recommended for colic as a rule are failures. The following formula devised by H. C. Wood is simple and nearly always effective.

R. Chloroform	ʒiiss	6

Syrup rhamnus cathartica q. s.
Make an electuary.

Sig. A teaspoonful night and morning. This formula has an ancient appearance, but it has recently been published in some of the medical journals, and is credited to the *Journal de Médecine de Paris*. After all, not everything that is good is new.

Klemperer directs the injection of eight ounces of tepid water on retiring, allowing it to be retained until absorbed. Increase the quantity progressively each night while lowering the temperature of the water. If necessary, give an ordinary injection in the morning. Four to six weeks suffices to establish unaided defecation.

Deaths and Obituaries.

W. A. DIXON, M.D., Ripley, Ohio, died at the Good Samaritan Hospital in Cincinnati, June 24. The doctor was born near Ripley in 1835, and in 1856 entered the University at Delaware, Ohio, after which he engaged in educational work, and during his teaching read medicine to later enter Jefferson Medical College, Philadelphia. In 1862 he became a contract surgeon in the army, under General W. T. Sherman, his service continuing through the campaign, which ended with the fall of Atlanta, when he was assigned to the general hospital, and there remained until the close of the war. After the war he took his degree in medicine from the Ohio Medical College, later locating in Ripley. Besides being a member of the Ohio State Medical Association, he was a member and regular attendant of the AMERICAN MEDICAL ASSOCIATION, where he has also presented a number of papers.

ROBERT LAUGHLIN REA, M.D., a retired practitioner, died at his home in Chicago, July 11. Dr Rea was born in Virginia in 1827, and received his degree of M.D. from the Medical College of Ohio in 1855. Soon after he was elected demonstrator of anatomy in that institution, continuing in that relationship until the spring of 1857, when he resumed practice in Oxford, Ohio, and there delivered courses of lectures on anatomy and physiology in the Western Female Seminary. He came to Chicago in 1859 and was appointed professor of anatomy in Rush Medical College. He was later connected with the Chicago Medical College and in 1882 accepted the chair of surgery in the College of Physicians and Surgeons, Chicago, from which he retired four years later.

WILLIAM HOWARD NELSON, M.D., Bellevue, N. Y., 1891, died at his home in New Rochelle, N. Y., July 6, aged 41 years. He was born in New Brunswick, N. J., and at time of his death was an alderman of the town.

GEORGE THOMAS DUTCHER, M.D., College of P. and S., N. Y.,

1894, died June 23, aged 30 years, in Pasadena, Cal. His residence began there soon after his graduation.

JAMES O'REILLY, M.D., Burlington, Vt., 1875, of New York, died from paralysis June 26. He was born in County Meath, Ireland, 71 years ago, was in part educated for the priesthood at Kilmore College, then studied medicine in Dublin, and finally came to this country, but retired from active practice about fifteen years ago.

W. A. GEORGE, M.D., Keasauqua, Ia., died on the train while en route from San Diego, Cal., June 3, of Bright's disease. Dr. George was born in 1853, and received his degree of M.D. at Bellevue in 1876.

E. S. GARNER, M.D., St. Joseph, Mo., a member of the Missouri State Board of Health and a graduate of the College of Physicians and Surgeons, New York City, died at his home, July 7.

Percy E. Cleveland, M.D., Nashville, died June 25, aged 37 years. . . . Geo. V. Converse, M.D., Hillsboro, Ia., July 1, aged 41 years. . . . Frederick W. Fabricus, Acting Assistant Surgeon, U. S. A., of yellow fever, at Santiago, Cuba, June 25. . . . Nathaniel Green, M.D., Middletown, Conn., grandson of the Major General of the Revolutionary fame, at his home, July 8, aged 90 years. . . . E. L. Hamilton, M.D., Richmond, Ark., July 5, aged 63 years. . . . Frank E. Noble, M.D., Jersey City, N. J., June 29, aged 75 years. . . . Henry G. P. Spencer, M.D., Jefferson, 1846, of Watertown, N. Y., Minneapolis, Minn., June 27, aged 78 years.

DEATHS ABROAD.

SIR WILLIAM HENRY FLOWER of London, Eng., born in Stratford-on-the-Avon, 1831, elected Fellow of the Royal College of Surgeons in 1857, and President of the Zoological Society, died July 2.

J. E. GRAHAM, M.D., died at Gravenhurst, Ont., July 7, from tuberculosis. In 1870 he was a resident physician in the Brooklyn City Hospital, N. Y., and in 1889 the President of the American Dermatological Association.

Book Notices.

Text-Book of Mental Diseases, with special reference to the Pathological Aspects of Insanity. By W. BEVAN LEWIS, L. R. C. P. (London), M. R. C. S. (Eng.). Second Edition, Thoroughly Revised, enlarged, and in Part Re-Written. With Illustrations in the Text, Charts, and Twenty-Six Lithographed Plates. Philadelphia: P. Blakiston's Son & Co. 1899.

This second edition of Dr. Bevan Lewis' well-known work has been largely re-written, especially in the first or anatomic section, to bring it up to the advances made in this department since the appearance of the earlier edition. The work has always been unique in the fullness of its anatomic descriptions, and its reputation will evidently be maintained. In its clinical section it has never been so thorough and satisfying as is demanded of a text-book, and this edition is in some respects an improvement over its predecessor, but it still has its deficiencies. The changes are a chapter on progressive systematic insanity, which was needed, and some minor additions and alterations. The work is still unequal in this department, some subjects being treated fully and satisfactorily, others altogether too meagerly. The treatment of the paranoias and other degenerative conditions of mental disorder, such as circular insanity, is unsatisfactory, and primary confusional insanity, the importance of which is nowadays coming to be recognized, is not mentioned at all. On the other hand, paresis, alcoholic and epileptic insanity are quite fully treated. As a whole the work is an excellent one for reference in the library of the specialist or the practitioner who is interested in its subject, but as a text-book for students, it cannot very well supplant others already in the market.

Les projectiles des armes de guerre, leur action vulnérante, par les Drs. H. NIMIER, médecin principal de l'armée, professeur au Val-de-Grâce, et Ed. LAVAL, médecin aide-major de 1re classe. 1 vol. in-12 avec gravures, 3 fr.—Félix Alcan éditeur. (Military Projectiles, their wounding action. By Drs. H. Nimier and Ed. Laval.)

This volume is the reproduction of lectures delivered at the Val-de-Grâce. It discusses the effects on the organism of both small arm and military projectiles, their action on the tissues, their effective zones, their moral effects, etc. It does not include the results of recent experience during the past year, but this does not make the work much less valuable as a theoretic and practical study of its subject.

Miscellany.

No Certificate, No Pay.—The court of civil appeals of Texas holds that there was no error in a refusal, in the case of Wilson vs. Vick, to allow a bill for medical services, because the facts did not show that the party claiming the compensation had received a certificate authorizing him to practice medicine, and that the same had been recorded as provided by the statute.

Not Evidence of Improper Treatment.—Evidence that the plaintiff in a personal injury case spoke bitterly against the physician who treated him, and that he discharged the physician, the supreme court of South Carolina holds, in Disher vs. Railroad Company, does not at all tend to prove that his injury was made permanent by improper treatment of his physician.

One X-Ray Examination Enough.—The supreme court of Wisconsin holds that there was no abuse of discretion in refusing to compel the plaintiff, in the personal injury case of Bolter vs. the Ross Lumber Company, to submit to a second examination by the X-ray process. It recites that he had submitted to one such examination, lasting two hours or more, during which he was, by accident, burned, and had also permitted two of the defendant's medical witnesses to examine him, but refused to submit to another examination by such process. But just what importance it attaches to these points, respectively, it does not state.

Prohibited Disclosure.—An applicant for life insurance, in answering questions put to him, stated that he was in good health, had only had la grippe slightly, several times, and nothing more than la grippe or cold, in five years, but had consulted his physician four weeks previously for la grippe, or cold. He also denied ever having had certain named diseases; and the policy of insurance provided that if any of these answers were untrue, the policy should become null and void. When sued on this policy, the insurance company called as a witness the physician who was mentioned in the application, and, after the latter had testified that he had been consulted for la grippe, asked him whether he was consulted during this period for any other disease than la grippe. This was objected to as incompetent under the Michigan statute, which prohibits a physician or surgeon from disclosing any information which he may have acquired in attending any patient, in his professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon. Under these circumstances, and the physician having further testified that all the information he had pertaining to any alleged complaints of the insured was acquired during the relation of physician and patient, and that he had no information pertaining to his condition aside from what he obtained by observation, and from his statements while acting as his physician, the supreme court of Michigan holds, Jones vs. Preferred Bankers' Life Assurance Company, that the question asked and objected to was incompetent and properly excluded.

Asbestos and Nasal Synechia.—A small piece of sheet asbestos has been found an ideal substance for the post-operative treatment of nasal synechia, soft, yielding, sterilized in the flame, and perfectly tolerated.—*Presse Med.*, June 21.

Reflected Light from Walls.—The percentage of light reflected from the walls of a room is largest with mirrors and white walls, respectively 92 and 70 per cent. Next comes light orange, 54.8; light green, 46.5; light yellow, 40; light blue, 30, and bright red, 16.2 per cent.—*Munch. Med. Woch.*, May 30.

Urticaria and Odors.—Joal reports three cases in which certain odors produced urticaria. In one the odors from aromatic essences used in the manufacture of liquors; in another, of iodoform, and a third the odor from roses, lilacs and hyacinths, accompanied in the two last cases with symptoms of hay-fever.—*Revue Heb. de Laryng.*, June 10.

Staining Test of Red Corpuscles.—Iovane states that the red corpuscles stain blue with methylene blue in the newly-born as a physiologic phenomenon, but that when this occurs a few months later and after, it is pathognomonic of anemia, the degree proportional to the severity of the anemia and the disappearance of the stain a certain sign of return to normal.—*Pediatria*, 2.

Intoxication from Saline Injection.—Severe tenesmus, epithelial desquamation, cholera nostras and syncopal condition followed a rectal injection of a nearly saturated solution of coarse salt. Vermerseh, who reports the case, advises the mention of table salt in ordering saline rectal injections and the indications of the precise amount, as a "pinch," "handful," etc., are terms too vague for the general public, always inclined to exaggerate doses.

Yeast and Levurin in Furunculosis.—The remarkably favorable results obtained in furunculosis, with yeast fresh from the brewery, has led to the production of an extract containing the active principles of the yeast, called Levurin by Couturieux, its inventor. One or two teaspoonfuls a day is the efficient daily dose and it is proving wonderfully effective, with no inconveniences of any kind from its use.—*Presse Medicale*, No. 46.

Function of Spleen.—The spleen was removed from a couple of dogs suffering with biliary fistulae and the results demonstrated that the spleen is a reservoir for the pigment of the red corpuscles as they are normally or abnormally destroyed. The pigment is conveyed from the spleen to the liver where it is eliminated as bile pigment. If the spleen is removed the pigment is distributed throughout the entire circulation with the chief localization in the bone marrow and the bile abnormally poor in pigment.—*Policlinico*, March 1.

Health in Michigan.—Reports to the Michigan State Board of Health show that the diseases most prevalent in that state, during June, were rheumatism, neuralgia, bronchitis, diarrhoea and tonsillitis. Compared with the preceding month, cholera morbus, typhoid fever, diarrhoea, inflammation of bowels and consumption increased, and pneumonia, influenza, scarlet fever, measles, pleuritis and cerebrospinal meningitis decreased in area of prevalence. Compared with the average for June in the thirteen years, 1886-98, cerebrospinal meningitis was more prevalent, and whooping-cough, diphtheria, pneumonia, erysipelas, scarlet fever, remittent fever, intermittent fever, influenza, measles, consumption and pleuritis less prevalent. Reports from all sources show consumption reported at 22 places more; measles at 38; scarlet fever at 14 places less; typhoid fever at 14 and diphtheria at 5 places more; whooping-cough at 7, and cerebrospinal meningitis at 26 places less and smallpox at 2 places more, in June, 1899, than in the preceding month.

Regulation of Privy Vaults.—The third appellate division of the supreme court of New York says, in the recently decided case of Cartwright vs. the Board of Health of the City of Cohoes, that the legislature may lawfully confer on the board

of health the power to enact sanitary ordinances having the force of law within the localities for which they act. That privy vaults in a city may be detrimental to the public health, when located near to inhabited dwellings or places of business, it also thinks, needs very little argument to prove; and, within established principles, they are eminently proper subjects for regulation by boards of health. More specifically does the court hold that an ordinance or regulation of a board of health is reasonable which provides that "No owner, lessee, occupant or agent of any building or premises shall maintain within the city any privy, privy vault or cesspool made or built in the earth within twenty-five feet of any door or window of any residence upon such premises, or any residence upon the adjoining premises, and such maintenance of any privy, privy vault or cesspool is hereby declared to be a nuisance and condition detrimental to life and health. And any or all privies, privy vaults and cesspools existing within the city shall be removed or filled up by the owner, lessee, occupant, agent or other person having charge or control of the premises on which they exist, whenever the same becomes a nuisance and condition detrimental to life and health, by rendering the soil, air or water impure, injurious, unwholesome, or they constitute a condition of any kind detrimental to life and health." The ordinance being a reasonable one,—one that the board had a right to pass,—the court further holds that the board had a right to enforce it in the manner provided by the statute, even though that involved, to some extent, the destruction of the plaintiff's property. Moreover, under the New York statute, the court holds that the board of health could have acted on its own inspection and knowledge of the premises, and was not obliged to hear anybody.

Physical Examination as a New Question.—In the recent personal injury case of Mary Elizabeth Lane vs. the Spokane Falls & Northern Railway Co., the supreme court of the state of Washington takes up the important question, here presented to it for the first time, of whether the courts of that state have the power to compel one who sues to recover damages for injuries to his person to submit to an examination by medical experts appointed by the court, for the purpose of ascertaining the nature, character, and extent of his injuries. It explains that actions of this character have, in recent years, become so numerous that the question is of far greater importance than it could possibly have been twenty-five years ago, and that it is not surprising that most of the cases in which the question has arisen or is discussed at all are of recent origin. In Iowa, Nebraska, Kansas, Wisconsin, Alabama, Arkansas, Ohio, Michigan, Georgia, Minnesota and Missouri, it continues, it has been held that the court possesses the inherent power to make such an order; while in Illinois, New York, Indiana, and the United States supreme court the power is denied. For itself, the court indorses and adopts the view expressed in a dissenting opinion in the supreme court of the United States, "that a party who voluntarily comes into court alleging personal injuries, and demanding damages therefor, should permit disinterested witnesses to see the nature and extent of those injuries, in order that the jury may be informed thereof by other than the plaintiff and his friends, and that compliance with such an order may be enforced by staying the trial or dismissing the case." It is to be presumed, further says the supreme court of Washington, that, in exercising this power, the trial court will always see that only proper physicians or surgeons, and where possible, wholly disinterested ones, are appointed to conduct the examination, and that the expense of such examination should be borne by the party requesting it. Care, it adds, should be exercised to avoid all unnecessary inconvenience and annoyance to the plaintiff, and, when desired, it should be made in the presence of the counsel and friends of the party to be examined, and the trial court should be free to exercise that sound discretion which the nature of the case and the ends of justice may require.

Does Life Insurance Lead to Suicide?—In a recent statement to the *Philadelphia Ledger*, L. G. Fouse, president of the Fidelity Mutual Life Insurance Company of Philadelphia, said: "Every manager of a life insurance company who wants to be frank must recognize that a large proportion of the suicides occurring within the first policy year are deliberate and intentional suicides, and planned at the time the policy was taken out. These people usually take large amounts. That there is a great amount of fraud of this kind is not a matter of conjecture." It was even stated that several years ago an insurance company gave out that they would pay suicide claims without question, with the result that an unduly large proportion of suicides occurred in members of that company. A table recently published by one of the insurance companies gives figures showing that the suicide rate for forty-five cities of the United States during 1889 was 12.7 per 100,000, and in 1898 the rate had increased to 17 per 100,000. The suicide clause, as now generally inserted by insurance companies, stipulates that payments will not be made in those cases where suicides occur within two or three years of the time the policy was written. After that time has elapsed it is considered that the insured person did not contemplate suicide at the time of taking the insurance. It was further stated that one reason the companies do not contest these cases is because it is feared that public sentiment would be raised against them. On the other hand, Henry C. Lippincott, manager of agencies of the Pennsylvania Mutual Life Insurance Company, stated that he knew of at least one company which did not contain a clause with reference to suicide, and that an increase of suicides had not occurred. In reply to the question of statistics on this question he replied that statistics could be made to prove almost anything. According to a recent decision made in the state of Missouri, under the statute governing certain classes of insurance companies, it is no defense against the payment of the policy that the insured committed suicide, unless it be shown that he contemplated suicide at the time the policy was written.

Medical Practice in Illinois.—At the present time the subjects on which examination is required by the Illinois State Board of Health, for medical practice in Illinois are the following: anatomy, chemistry, gynecology, hygiene, materia medica and therapeutics, medical jurisprudence, obstetrics, pathology and bacteriology, practice of medicine, physiology, and surgery. At the quarterly meeting of the Board, July 11, the first held under the new medical practice act, the following rules among others were adopted:

State certificates authorizing the practice of medicine and surgery in the State of Illinois are issued by the State Board of Health on complying with the following requirements, based on the Act to Regulate the Practice of Medicine in the State of Illinois, in force July 1, 1899.

1. The applicant must present to the State Board of Health for verification at the office of the secretary, in Springfield, or in Chicago, at the time of the examination, the diploma or license of a legally chartered medical institution in good standing. The diploma or license should be forwarded, prepaid, by express or registered mail. If by mail, letter postage must be affixed to the package.

2. Said diploma or license must be accompanied by the affidavit of the holder and applicant that he or she is the lawful possessor of the same, and is the person named therein. The affidavit must show, also, the number of years the applicant has studied medicine, including the time spent in attendance at medical colleges.

3. The affidavit must be accompanied by letters of recommendation with regard to the moral and professional character of the applicant from at least two reputable men who live in Illinois, or, if from non-residents of the state, such letters must be endorsed by reputable medical men of Illinois.

4. The applicant must pass an examination in those general subjects and topics a knowledge of which is commonly and generally required of candidates for the degree of Doctor of Medicine by reputable medical colleges in the United States.

5. The fee of \$10 for an examination must be paid in advance. If not paid in person, the fee should be transmitted by postal money order, draft or check made payable to the secre-

tary of the State Board of Health. No responsibility will be assumed for fees transmitted in any other manner.

The fee of \$5 for a certificate can be paid in advance, or when the applicant is notified that a certificate will be issued.

6. Persons desiring to take an examination, should file their applications with the secretary as soon as possible, so as to enable the board to determine as far as practicable the number to arrange for. It is preferred that the affidavit and letters of recommendation be submitted in due form to the secretary at Springfield before the examination.

Examinations will be held quarterly in Chicago, at the Great Northern Hotel, or, in exceptional instances, in the office of the board at Springfield.

At the same meeting the board adopted the following resolution:

WHEREAS: Section 2, of an Act to Regulate the Practice of Medicine in the State of Illinois, and to repeal an act named therein, approved April 24, 1899, in force July 1, 1899, gives the State Board of Health discretionary power as to granting certificates to graduates of legally chartered medical colleges in Illinois in good standing as may be determined by the board, and,

WHEREAS: It is evident, notwithstanding the discretionary power given the board, that the true intent and purpose of this Act is to require all persons to prove their qualifications to the State Board of Health by passing an examination; therefore, be it

Resolved: That all applicants for a state certificate to practice medicine and surgery in the state of Illinois, who are graduates of medical colleges in good standing, as may be determined by this board, shall, before receiving a certificate, be obliged to pass an examination such as contemplated in Section 2, of an Act to Regulate the Practice of Medicine in the State of Illinois, in force July 1, 1899.

Resolved: That the phrase "medical college or institution in good standing," in the first paragraph of Section 2, of the Act to Regulate the Practice of Medicine in the State of Illinois, in force July 1, 1899, is hereby defined to include only legally organized, properly conducted medical institutions, having a sufficient and competent corps of instructors and ample facilities for teaching, dissections, ambulatory and hospital clinics, which conform to the requirements relative to the preliminary education of matriculants, the course and period of study, the number, character and length of lecture terms, the duration of attendance on hospital and clinical instruction, which obtain in the majority of medical colleges in the United States.

The Illinois State Board of Health, however, will not consider in good standing, after Jan. 1, 1900, any medical institution which does not require of all students (excepting graduates of reputable colleges of arts and sciences, or reputable colleges of dentistry, pharmacy or veterinary medicine, to whom one year's advanced standing may be granted) as a condition of graduation, an attendance of four full courses of lectures of at least six months each, in four separate years, no two courses commencing or ending in the same calendar year of time.

Resolved: That no medical college issue a catalogue of announcement in which are contained misrepresentations respecting its teaching, clinical or hospital facilities, its faculty or its courses of study, or false representation as to the number of students matriculated or in attendance, will be regarded as in good standing.

Proper Subject of Autopsy.—Article 1024A of the Texas Code of Criminal Procedure authorizes the justice of peace, whenever an inquest is held to ascertain the cause of death, to call in some regular practicing physician, if he deems it necessary, and it is impracticable to secure the services of the county physician to make an autopsy in order to determine whether the death was occasioned by violence; and if so, "the nature and character of the violence used." Now what meaning is to be given to the words in quotation marks? Are they to be restricted to the ascertainment of the physical nature of the violence, or is their meaning to be so extended as to include the circumstances attending the act, which may disclose its moral quality? The broader sense is decided on by the supreme court of Texas: in the case of Polk County vs. Phillips. More specifically, it holds that the calling in of a physician for the purpose of determining whether the deceased was, at the time of the assault on him, lying down, as testified to by one witness, or whether he was on his feet, resisting his arrest with deadly weapons, as testified to by other witnesses, was a purpose contemplated by the statute. The sole object of

the statute which provides for an inquest on a dead body, the supreme court says, is to aid the enforcement of the law by the detection of crime, in case an offense has been committed. In accomplishing the purpose of the inquest, it is as important to determine the characteristics of an act of violence which has led to a death as it is to determine the fact that there was violence, and that death was its result. Hence, the liberal construction of the statutory provision in question.

Warranty Against Using Insurance and Intoxicants.—An applicant for life insurance agreed and warranted that he would not use intoxicating liquors to excess. When subsequently sued for the insurance, the company pleaded this as a defense, averring, as a breach of the warranty, that, after the to excess, until he became a physical wreck, and that such dissipation contributed to his death. The parties seeking to recover the insurance replied that, before the date of the application for the insurance, and before the issuing of the policy, the insured had used intoxicants to excess to such an extent as to render him diseased from such dissipation, which disease affected him at the time of said application, of which the company had knowledge at the time of application, and thereafter, before the issuing and delivering of the policy; that the diseased condition continued until his death, and his return to such dissipation was merely a recurrence of the disease, over which he had no control. Their counsel quoted from eminent writers on medical jurisprudence, showing that drunkenness is a disease, and that it is liable to occur periodically, and argued from these facts that the company, knowing that the insured was diseased, and the cause of it, having issued the policy, could not then honestly refuse payment. But the decision on this point, of the appellate court of Indiana, is with the insurance company. It pronounces the agreement a promissory warranty; holds that it contravened no rule of law, and that it should be enforced. The court says, Northwestern Life Assurance Company vs. Bodurtha, that it thinks it would be a dangerous precedent to hold that the deplorable conditions, physical and mental, which are likely to follow the immoderate use of intoxicants, should preclude business transactions with one who in the past may have been the victim of the habit, but who promises to be temperate in the future, and to release such party from the obligations of a valid contract because of his failure to keep his promise.

Varieties of, and Post-Mortem Findings in, Deaths from the Plague.—Since the plague has gained such prominence in the thoughts of the medical world it seems fitting to review somewhat the literature of the disease. From the reports, it might at first be thought that in all cases in which death occurs from the plague, there had been suppurating buboes present during life; but this does not necessarily occur. So far all the data regarding the disease has not found its way into the text-books on this side of the Atlantic, and any reliable information bearing on the subject becomes of considerable importance at this time. Probably one of the best and most satisfactory reports yet made is that of the Arthur Road Hospital of Bombay, 1897. The report is made by Khan Bahadur N. H. Chosky, Extra Assistant Health Officer of the Bombay municipality, and is based on a series of 939 cases of bubonic plague. The work is mainly the work of the hospital staff in conjunction with members of the Austrian Commission, consisting of Dr. Heinrich Albrecht, Dr. A. Ghon, Dr. Franz Muller (Privat-Dozent at the Klinik Nothnagel, Vienna), and Dr. R. Poch. The post-mortem appearances described were from a series of 54 autopsies, mostly conducted by Dr. Heinrich Albrecht and his assistant, Dr. Ghon.

The following types of the disease have been described: 1. Pestsis minor, or extremely mild plague. 2. Pestsis ambulans. 3. Pestsis simplex bubonica, or simple bubonic plague. 4. Pestsis septica or septic plague. 5. Pestsis pulmonalis, or pneu-

monic plague. 6. Non-typical forms of plague. Of the first variety, there were but few treated in the Arthur Road Hospital. It is ordinarily attended by a slight febrile reaction, and pain over the deep-seated glands—generally femoral or inguinal—which may be still enlarged, but without any exudation around them. Of the treatment, all that had been recommended was a general aperient and some fomentation, the patient usually being able to return to work within three or four days. The report further says: "It is needless to add that such glandular swellings subside and totally disappear within three to four days, and it is probable that this was the character of the majority of the 'early' cases so-called that gave such favorable results with Yersin's serum." Of the second variety, only a few cases were treated. The history is that of one suffering from sudden fever of short range, with glandular enlargement, pain and tenderness of the glands, the patient being confined to the bed for three or four days without much systematic disturbance. "He does not feel himself sufficiently ill to consult a medical man; perhaps takes rest and shakes off the fever, and then goes about with an indolent swelling for a few days." It is the simple bubonic and septic forms of plague that are so characteristic of the disease.

Of the 939 cases of plague admitted, 8.33 per cent. had no buboes. Most of the latter (8 per cent.) belonged to the pneumonia type. The regions affected by buboes were: femoral, 32.12 per cent; femora-inguinal, 23.36 per cent.; axillary, 16.35 per cent.; inguinal, 12.38 per cent.; cervical, 5.25 per cent.; multiple, 4.67 per cent. It is stated that the buboes present a characteristic appearance. In the early stages, if incised, free hemorrhage occurs, and on section the gland appears as a swollen mass of an intensely brownish-red, brick-red or purplish color, and occasionally a thick black streak has been observed running through it. Once the buboes form, they either resolve, or else end in suppuration and sloughing. On the first day of sloughing the bacilli were always found in the pus, gradually diminishing until finally the discharge becomes sterile. In pestis pulmonalis, or pneumonic plague, the lungs seem to be primarily infected, thus causing a primary pneumonia. At the autopsies, deep-seated axillary buboes were nearly always found. In this form the sputum is usually laden with bacilli.

The non-typical forms of plague generally occurred during the subsidence of the epidemic. This type was generally manifested by a slight rise of fever, diffuse swelling mostly confined to the region of parotid and cervical glands, absence of glandular enlargements or pain, and gradual subsidence under the administration of cold applications, and of calcium chlorid internally. The post-mortem findings were very complete. This report begins as follows:

If it were possible to convey in one word the principal post-mortem changes that are found in the system, that word would be *hemorrhage*—hemorrhages in every conceivable and inconceivable part of the body, hemorrhages in the dura mater, larynx, mediastinum, pleura, pericardium, lungs, stomach, intestines, kidneys, liver, spleen, bladder, intima of the vena cava and jugular vein, hemorrhages around the buboes, subcutaneous tissue of the neck, arm, forearm, thigh, and retroperitoneal connective tissue. These hemorrhages were observed in all the fifty-four autopsies that were made. The brain meninges, spinal cord and esophagus showed few changes other than congestion. The pharynx in many cases was covered over with a false membrane, as was also the larynx, the latter often being edematous. The thyroid was generally normal, the lungs were generally "blood full," and in most cases when there was not much extensive pneumonia, greatly edematous. On section a large amount of serosanguineous fluid flowed out of them—in fact they seemed to be thoroughly soaked in like a sponge. The mucus in the bronchioles was blood-tinged. If pneumonia existed it was the characteristic lobular type, in isolated patches, having a mottled gray appearance. The heart muscle showed evidences of acute degeneration, generally fatty. The cavities were generally dilated. Hemorrhages were found on the pericardium, epicardium, and endocardium. The stomach was hardly ever normal, the mucous membrane being bile-stained and showing hemorrhages which were extremely characteristic in that they were always punctate, as those along the entire intestinal tract. The liver generally appeared slightly swollen.

"blood full," and in a state of acute infective degeneration, occasionally fatty. Its substance was soft, and the capsule at times adherent. In one case emboli of plague bacilli were found. The spleen was generally enlarged, but not usually to such a degree as to be detected during life. It was usually in a state of acute degeneration. Hemorrhagic infarcts were noticeable on its surface beneath the capsule, and occasionally small abscesses and cysts were present. On section the color was of a deep chocolate brown. The Malpighian bodies were swollen and could occasionally be distinctly seen, and so also the trabeculae and fibrous structure. In cases that had suffered from malaria, the peculiar dark pigmentation due to it was also noticed. The kidneys were in a state of acute parenchymatous degeneration, the capsule adherent and stellate. In the substance hemorrhages and hemorrhagic infarcts were found. Small cysts and abscesses were also observed. The suprarenals were normal. In the mesentery hemorrhages were found, also in the retroperitoneal connective tissue and in the loose connective tissue in the abdomen, surrounding the various organs. The mesenteric glands were not often very much enlarged or infected. Hemorrhages were also noticed on the ovaries, and in the intestines, small and large punctate ones. The mucous membrane was usually inflamed. The marrow of the long bones, as the femur, was often noticed in a state of acute red degeneration, and the synovial fringes of the knee-joint distinctly infected. The buboes were quite characteristic, and such as are not met with in any other affection. They were swollen, enlarged and surrounded by serosanguineous or hemorrhagic exudation. On section they appeared of a dark purplish color and "blood full."

In no case was the plague attributed to ratbites, either immediately or some time previous to infection. And as regards flies and fleas, ants, bugs and even mosquitoes, however enticing the theory appeared as tending to solve the difficult problem, it was more fanciful than real, appealing as it did more to the imagination than to common sense.

Apert from the above mentioned modes (1, through the skin; 2, from the contents of buboes; 3, sputum), it is but reasonable to assume that the plague epidemic which progresses like a regular wave from one end of the country to the other, either slowly or rapidly, generally the former, infects those susceptible to infection through the atmosphere, as in influenza and other similar infections, and in acute infection of this kind, pervading so insidiously and so widely, atmospheric agency must be a potent factor."

Philadelphia.

SAFE-GUARDS AGAINST DISEASE.—J. Lewis Good, chief of the Bureau of Health of Philadelphia, has been quite active of late in making provision for the prevention of yellow fever or any other infectious disease. After a thorough inspection of the Federal Quarantine station and its equipments, at the Breakwater and Reedy Island, it is believed that any sporadic case which comes to those places will be speedily detected and placed in quarantine.

MORTALITY STATISTICS.—The number of deaths during the past week was 435, an increase of 15 over last week, and a decrease of 285 over the corresponding period of last year. Of the total number, 189 occurred in children under the age of 5 years. The principal causes were: Apoplexy, 13; nephritis, 30; cancer, 7; cholera infantum, 52; tuberculosis, 46; heart disease, 27; pneumonia, 21; appendicitis, 1; marasmus, 18; rheumatism, 4; paralysis, 2; suicide, 4.

WATER FILTERS FOR PUBLIC SCHOOLS.—The Committee on Hygiene, of the Board of Education, have for some time been investigating the different varieties of filters to be placed in the public schools of Philadelphia. Since it is known that many children drink the water as it comes from the hydrants, even in a spirit of defiance to the restrictions, it becomes evident that such a safe-guard is very essential in preventing the spread of typhoid fever. A filter has been selected which is supposed to be 95 per cent. germ-proof. The sum of \$37,000 will be expended in placing the filters in the schools.

ROOF GARDEN FOR CHILDREN'S HOSPITAL.—In memory of his sister, Dr. T. W. Wilson has recently presented the Children's

Hospital with a roof garden, provided with all the necessary arrangements for obtaining fresh air and sunshine for the invalids of that institution. It is believed that this provision will be instrumental in lowering the infant mortality, especially during the summer months. The new addition costs about \$5000.

"GLORIOUS FOURTH" IN PHILADELPHIA.—From a medical standpoint the nature of the injuries and the weapons by which wounds were inflicted in July 4 celebrations, in Philadelphia, are of interest. The small toy pistol and the toy cannon, while innocent looking, are almost as dangerous as the fire cracker. The three injuries most frequently met with were burns of hands and fingers (53); burns of the eyes (43); burns of the face (35); and gunshot wounds of the hand (30). Of these injuries it is supposed that at least four people will partly, if not totally, lose their eyesight, while in many instances amputations have already been made.

Queries and Minor Notes.

MEDICAL PRACTICE.

MORESONVILLE, ILL., July 29, 1899.
To the Editor:—Some time ago I saw in the JOURNAL an article giving the medical practice acts or legal requirements of the States. I wish to know the law or legal requirements in Colorado or California and can not find that article. Respectfully,
R. W. R.

ANSWER:—The article referred to is the notice of the report of the Illinois State Board of Health published in the JOURNAL of Nov. 12, 1898. There have been, so far as we are aware, no changes in the laws of California or Colorado since that date, a law which passed the legislature in the latter State having been vetoed by the Governor. In each the presentation of a diploma from a recognized medical college suffices to obtain a certificate from the Board of Examiners; in Colorado, adding a diploma, a successful examination will also admit to practice.

"APPENDICEAL" OR "APPENDICULAR"?

CHICAGO, ILL., July 14, 1899.
To the Editor:—Of late I have several times noticed the use of the word "appendical" as an adjective relating to conditions of the appendix. Having "consulted the authorities," and vainly, for its origin or sanction, I seek the columns of the JOURNAL in the hope of being enlightened. Is "appendiceal" a proper term, or is "appendicular" the correct thing? W. B. H.

The Public Service.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., to and including July 6, 1899:

Charles Norton Barney, acting asst.-surgeon, from San Francisco, Cal., to Manila, P. I., by the *Para*, July 12, 1899.

Frank W. Dudley, acting asst.-surgeon, to Manila, P. I., by the *Para* July 12, 1899.

Basil H. Dutcher, lieutenant and asst.-surgeon, U. S. Army, relieved from present duty to proceed to San Francisco, Cal., for service in the Department of California.

Julius A. Escobow, acting asst.-surgeon, from Washington, D. C., to Havana for duty in the Division of Cuba.

Charles E. B. Flagg, captain and asst.-surgeon U. S. Army, to San Francisco, for duty in the Department of California.

Frank W. Foxworthy, acting asst.-surgeon, to Manila, P. I., by the *Para*, July 12, 1899.

S. J. Fraser, acting asst.-surgeon, to Manila, P. I., by the *Para*, July 12, 1899.

Louis L. Gilman, acting asst.-surgeon, from Rochester, New Hampshire, to Fort Ethan Allen, Vermont.

Henry S. Greenleaf, lieutenant and asst.-surgeon U. S. Army, to San Francisco for duty in the Department of California.

Stevens T. Harris, acting asst.-surgeon, from Carrollton, Georgia, to San Francisco, Cal.

Edward P. Hayward, acting asst.-surgeon, to Manila, P. I., by the *Para*, July 12, 1899.

Denise C. Howard, captain and asst.-surgeon U. S. Army, detailed temporarily as a member of a retiring board convened in New York City.

S. Chase de Kraft, acting asst.-surgeon, from Cambridge, Md., to San Francisco for duty in the Department of California.

Julius C. LeHardy, acting asst.-surgeon from Savannah, Ga., to San Francisco for duty in the Department of California.

Henry Lippincott, lieutenant-colonel, deputy surgeon-general U. S. Army, president of a board convened at Denver, Colo., to examine persons designated for appointment as second lieutenants in the army.

Willard S. H. Matthews, major and surgeon Vols., from the general hospital at San Francisco, Cal., to Manila, P. I., for assignment.

John R. McMill, acting asst.-surgeon from Milwaukee, Wis., to San Francisco for temporary duty in the Department of California.

Clarence B. Millhoff, lieutenant and asst. surgeon U. S. Army, from Camp Meade, Middletown, Pa., to Manila, P. I., accompanying the 19th U. S. Infantry.

Curtis E. Munn, major and surgeon U. S. Army, member of a board in Denver, Colo., to examine persons designated for appointment as second lieutenants in the Army.

George Nawlove, acting asst.-surgeon, from Somertown, Philadelphia, Pa., to Fort Leavenworth, Kans., for duty.

Oway W. Rash, lieutenant and asst.-surgeon, U. S. Army, to San Francisco for duty in the Department of California.

Robert F. Robins, acting asst.-surgeon, from Philadelphia, Pa., to duty in the Department of California.

Ernest C. Schultze, acting asst.-surgeon, from New York City, N. Y., to the Department of California.

Gilbert E. Seaman, acting asst.-surgeon, from Milwaukee, Wis., to the Department of California.

Engene L. Swift, captain and asst.-surgeon, U. S. Army, from Fort Sherman, N. Y., to San Francisco for temporary duty in the Department of California.

James W. Van Dusen, acting asst.-surgeon, from Norwalk, Ohio, to duty in the Department of California.

Richard Wilson, acting asst.-surgeon, from the Department of Porto Rico to duty in the Department of California.

Ezra Woodruff, major and surgeon U. S. Army, from Fort Trumbull, Conn., to Camp Meade, Middletown, Pa.

Appointment of Surgeons and Assistant-Surgeons of Volunteers.—On July 7, 1899, announcement was made by the War Department of the names of the medical men selected by the President as the surgeons and assistant-surgeons of the Volunteer regiments that are to be raised for service in the Philippines. Only two of these appointments are promotions of medical officers of the regular medical corps. The following are the names in order of rank:

Surgeons with the rank of major:—Ogden Rafferty, captain and asst.-surgeon, U. S. Army, late brigade surgeon, Ohio. Charles F. Mason, captain and asst.-surgeon, U. S. Army, late brigade surgeon, Vols. John R. McMill, late brigade surgeon Vols. Frank C. Armstrong, late surgeon 21st Kansas. Thomas W. Chalmers, late surgeon 12th New York. Charles L. Z. Anderson, late asst.-surgeon U. S. Army and at present an acting asst.-surgeon. B. Albert Lieberman, late surgeon 6th Missouri. Joseph N. Henry, late surgeon 4th U. S. Vol. Infantry.

Assistant-surgeons with the rank of captain:—John B. Hereford, late surgeon 1st Missouri. James C. Minor, late surgeon 1st Arkansas. Frank W. Foxworthy, late asst.-surgeon 160th Indiana. Abram L. Haines, late surgeon 204th New York. James J. Erwin, late asst.-surgeon 10th Ohio. W. E. Parker, late acting asst.-surgeon. James E. Shellenburger, late surgeon 3d Ohio.

Assistant-surgeons with the rank of first lieutenant:—William H. Coon, acting asst.-surgeon. Lomax S. Anderson, late asst.-surgeon 3th U. S. Vol. Infantry. Leonard K. Graves, late asst.-surgeon 201st New York. Ralph S. Porter, late asst.-surgeon 2nd Illinois. John A. Metzger, acting asst.-surgeon. Patrick J. McKenna, late asst.-surgeon 2nd U. S. Vol. Engineers. Albert H. Eber, late asst.-surgeon 35th Michigan. John E. Boyd, late captain 2nd South Carolina.

Movements of Navy Medical Officers.—Changes in the medical corps of the U. S. Navy for the week ending July 8, 1899:

June 30.—Asst.-Surgeon Ralph W. Plummer, appointed asst.-surgeon from July 1, 1899.

July 3.—Medical Inspector J. C. Wise, granted sick leave for three months.

Marine-Hospital Changes.—Official List of Changes of Station, and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine-Hospital Service, for the seven days ended July 6, 1899.

Surgeon R. D. Murray, to defer departure to Key West, Fla., as directed by Bureau letter of May 15, 1899) until further orders, and to proceed to New Orleans, La., for special temporary duty.

Surgeon Eugene Wasden, to proceed to Norfolk, Va., and assume temporary charge of the Service at that port not later than July 17, 1899.

Asst.-Surgeon W. K. McAdam, Bureau letter of May 15, 1899, relieving Asst.-Surgeon McAdam from duty at Key West, Fla., revoked and directed to resume command of the Service at Key West.

Asst.-Surgeon D. E. Robinson, relieved from duty at Chicago, Ill., and directed to proceed to Mobile, Ala., and report to the commanding officer for duty and assignment to quarters.

Acting Asst.-Surgeon G. H. Altrea, granted leave of absence for four days.

Acting Asst.-Surgeon L. C. Bean granted leave of absence for two days.

Fred C. McLean appointed acting asst.-surgeon, U. S. Marine-Hospital Service, for duty at Evansville, Ind.

RESIGNATION.

Sanitary Inspector W. F. Brunner, resignation accepted as tendered, to take effect June 30, 1899.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended July 1, 1899:

SMALLPOX—UNITED STATES.

Georgia: Savannah, June 18, 5 cases.

Illinois: Chicago, June 24 to 30, 2 cases.

Indiana: Evansville, June 24 to July 1, 6 cases.

Kentucky: Louisville, June 24 to 30, 4 cases.

Louisiana: New Orleans, June 24 to July 1, 2 cases, 1 death; Shreveport, June 24 to July 1, 1 case.

Massachusetts: Boston, June 30 to July 2, 2 cases, 1 death; Fall River, June 27, 1 case.

New York: New York, June 24 to July 1, 7 cases.

North Carolina: Charlotte, June 24 to July 1, 2 cases.

Ohio: Cincinnati, June 23 to 30, 1 case; Cleveland, June 24 to July 1, 2 cases.

Oregon: Portland, June 29 to date, 4 cases.

Pennsylvania: Allegheny Co., June 3 to 26, 11 cases; Belle Vernon, June 3 to 26, 1 case; Browville Township, June 3 to 26, 34 cases; Cambria Co., June 3 to 26, 22 cases; Clearfield Co., June 3 to 26, 1 case; Fayette Co., June 3 to 26, 10 cases; Jefferson Co., June 3 to 26, 5 cases; Philadelphia, June 3 to 26, 40 cases; Somerset Co., June 3 to 26, 9 cases; Washington Co., June 3 to 26, 11 cases; Westmoreland Co., June 3 to 26, 1 case; at Penn Station, several.

Virginia: Norfolk, July 2, 1 case; to date, 255.

Washington: Wallawalla, June 29, 8 cases.

West Virginia: Beewood, July 1, 1 case.

SMALLPOX—FOREIGN.

Belgium: Antwerp, June 10 to 17, 3 cases, 1 death.

Brazil: Bahia, June 10 to 17, 1 case; Rio de Janeiro, May 19 to 26, 16 deaths.

China: Hongkong, May 4 to 27, 5 cases, 2 deaths.

Cuba: Havana, June 29, 4 deaths.

England: Liverpool, June 10 to 17, 1 death; London, June 10 to 17, 1 case; Gibraltar, June 5 to 11, 1 case.

Greece: Athens, June 10 to 17, 82 cases, 7 deaths.

India: Bombay, May 27 to June 4, 4 deaths; Calcutta, May 13 to 20, 1 death.

Mexico: Mexico, June 3 to 25, 25 cases, 16 deaths.

Russia: Moscow, June 10 to 11 cases, 11 deaths; Odessa, June 10 to 17, 7 cases, 1 death; St. Petersburg, June 3 to 17, 36 cases, 12 deaths; Warsaw, June 3 to 10, 1 death.

Scotland: Glasgow, June 10 to 17, 1 death.

Strait Settlements: Singapore, April 1 to 30, 13 deaths.

Turkey: Smyrna, June 11 to 18, 8 deaths.

YELLOW FEVER.

Africa: Grand Bassa, Ivory Coast, reported present.

Brazil: Bahia, June 3 to 17, 70 cases, 36 deaths; Rio de Janeiro, May 19 to 26, 10 deaths.

Columbia: Panama, June 16 to 23, 3 cases, 3 deaths.

Cuba: Havana, June 15, 6 cases, 12 deaths; Matanzas, June 17 to 24, 1 case death; Santiago, June 3 to 10, 11 cases, 20 deaths, principally among troops.

Mexico: Cardoba, June 21, 23 cases, 14 deaths; Merida, July 1, 1 case; Mexico, June 3 to 25, 2 deaths; Vera Cruz, June 22 to 29, 35 deaths.

San Salvador: San Salvador, June 20, reported present.

CHOLERA.

India: Calcutta, May 13 to 27, 46 cases; Kurrachea, May 10 to 17, 29 cases.

PLAQUE.

China: Hongkong, May 6 to 27, 319 cases, 93 deaths.

Alexandria, June 16 to date, 35 cases, 10 deaths.

India: Bombay, May 30 to June 8, 66 deaths; Calcutta, May 13 to 27, 10 cases; Kurrachea, May 14 to 16, 10 cases; Mauritius, May 4 to 22, 5 deaths.

On Japanese steamship *Nippon Maru*, from Hongkong, and Japanese ports, for San Francisco, May 20, 1 death.

CHANGE OF ADDRESS.

Brown, P. W., from Atlar to Fish Hook Hill.

Clark, R. C., from 8227 to 6204 Peoria Ave., Pittsburg, Pa.

Bacop, J. E., from Waukesha, Wis., to Enid, Oklahoma Territory.

Bradley, H. M., from Riverside Hospital to 400 W. 57th New York City.

Chase, O. E., from Ann Arbor to Travers City, Mich.

Conrader, H. D., from Ann Arbor, Mich., to 154 Washington St., Elmira, N. Y.

Cross, E. D., from 3141 Indiana to 3142 Prairie Ave., Chicago.

Clark, from 305 7th Mo. to Elms, Ill.

Conrad, George, from 347 S. Main St. to Univ. Hosp., Ann Arbor, Mich.

Cunningham, from 1285 to 1271 Van Buren St., Chicago.

Clarke, J. T., from 411 Michigan to 503 S. 14th St., Toledo, Ohio.

Parsons, A. R., from 414 Indiana to 100 State St., Chicago.

Dittmore, J. H., from Troy to Axtell, Kans.

Flynn, J. C., from Philadelphia to Box 36, Salem, N. J.

Griffin, O. A., from 1929 Deming Court to 901 S. Chicago.

Griffin, O. A., from Ann Arbor, Mich., to Fayette, Ohio.

Hawley, E. R., from 3614 Lake Ave. to The Lorraine, 36th and Ellis Ave., Chicago.

Hawley, E. R., from Ann Arbor, Mich., to Fairmount, Ind.

Hardy, J. J., from Wittville to Cayana, Indian Territory.

Hitt, A. W., from 95 E. 51st to 147 E. Lake St., Chicago.

Hunt, E. F., from Lexington Hotel to 100 State St., Chicago.

Holladay, F. S., from Detroit to Club House, Les Cheneaux Islands, Mich.

Hering, E. R., from Cross Plains to Manawa, Wis.

Leahy, E. R., from 230 Commerce Building, Kansas City, Mo.

Litvin, A., from 291 W. 14th St., to 350 E. North Ave., Chicago.

Mitchell, J. M., from Pontiac to 687 Jackson Boulevard, Chicago.

Murray, H. D., from Thomson to 100 State St., Chicago.

Nichols, C. M., from Philadelphia to Delaware Water Gap, Pa.

Norris, R. W., from Philadelphia to Eleanor, Pa.

Owen, D. W. C., from 3864 Park to 1509 S. Vandeventer, St. Louis, Mo.

Randolph, A. G., from Monroe St. Hosp. to 323 W. Van Buren St., Chicago.

Richmond, W. B., from Ann Arbor, Mich., to Mt. Pleasant, Iowa.

Ross, E. R., from Chicago to 111 Milwaukee, Wis.

Sepp, C. E., from Mt. Vernon to South Omaha, Neb.

Shannon, L. W., from 713 Harrison to 228 Maxwell St., Chicago.

Stephen, J. T., from Kosciusko to Zilpha, Miss.

Stearns, E. E., from 186 Winchester Ave. to 716 Congress St., Chicago.

Spencer, N. W., from Walnut, Iowa, to Montrose, S. D.

Thornton, J. W., from Earlring, to Lansing, Iowa.

Wilson, A. L., from 1327 N. Illinois St. to 1520 N. Capitol Av., Indianapolis, Ind.

Wiley, H. H., from Detroit to Utica, Mich.

Wright, J. H., from Richmond, Va., to Coharie, N. C.

THE UTERUS*

WHY VAGINOFIXATION, VENTROFIXATION AND VENTRO-SUSPENSION THEREOF SHOULD BE AVOIDED IN CASES THAT RETAIN ANY CAPACITY FOR CONCEPTION.

BY ALBERT GOLDSPOHN, M.D.

Professor of Gynecology Post-Graduate Medical School; Senior Gynecologist to the German Hospital; Attending Gynecologist to the Post-Graduate and Charity Hospitals.
CHICAGO.

1. They are "unnatural, unsurgical and unscientific." The aggregate normal effect of the healthy and properly developed supports, attachments and guy-ropes of the uterus is to hold it in a state of stable equilibrium, in a sufficient degree of anteversion to secure the supporting aggregate impact of intra-abdominal pressure upon its posterior surface. This, the greatest of all forces in the abdomen and pelvis, then maintains that forward obliquity of the body and fundus of the uterus which experience has abundantly demonstrated to be not merely essential, as a rule, to maintain a normal balance in its circulation and in that of the adnexa, but also to be the most benign safeguard against descensus of the uterus or ovaries, or both. While the entire organ has a considerable but very variable degree of mobility in all directions, its principal portion—the body—has a very large range of normal mobility, like an inverted pendulum in an anteroposterior direction. This wide range of motion of its body, which is so necessary in view of the bladder, and its general freedom to expand and contract, and to rise untrammelled in pregnancy from the pelvis into the abdomen, are secured chiefly by the total absence of all connections or attachments to its vertex and its anterior or posterior surfaces. Therefore, the thought of opening the abdomen from any direction and inflicting fixations upon any one of these surfaces which are destined to be free, and thereby limiting the normal mobility or expansibility of the body of the uterus in some degree, is repugnant to every rational instinct; especially as it is done or proposed for conditions that are never serious, that may cause an *indicatio quod valetudinem* but never *quod vitam*. These operations effect at best a substitution of one abnormal condition for another. They are a loan from the domain of pathology, that we need to make exceptionally when the proper supports of the uterus are very seriously deranged or defective, as in those cases of marked descensus uteri in which hysterectomy seems still more objectionable or less effective. Pronounced cases of the so-called prolapse of the uterus, especially those of the genuine type in which there is not merely an elongation of the supravaginal cervix, but an actual descent of the entire uterus, are not radically curable by any kind or degree of plastic proced-

ures upon cervix, vagina and perineum, singly or combined; but they require either a shortening of the broad and sacrouterine ligaments or some ventral fixation of the uterus as a supplementary act to the plastiques upon the pelvic floor. But, fortunately, these cases are mostly beyond the period of their life in which pregnancy is possible or probable, and if they are not, they should be sterilized, at the time of the operation, by removal of the Fallopian tubes alone, which should be excised from the uterus and the resulting wounds sewed up. Otherwise a cure of such marked cases of descensus should not be attempted by the help of an auxiliary ventrofixation, if attempted at all.

2. The essential features in the technic of these operations that give them any stability in good results that they may or are intended to do are in every detail directly antagonistic to the interests of the uterus in gestation and labor. There is no parallelism of functions here. Any choice of technic that is intended to avoid serious complications in labor correspondingly sacrifices the certainty or durability of the principal purposes of the operation; and vice versa. So, in ventrofixation, in order to avoid obstetric complications, the point of fixation on the uterus dare not be taken upon its posterior surface nor upon its vertex, but as low down upon its anterior surface as is likely to do any holding. The point of attachment to the abdominal wall should not be taken low down, so as to enable the uterus to rise into the abdomen in gestation; and to permit the deeper muscular strata in the uterine wall to slide by—the fixed point caught in the ligatures² in gestation, these should be passed as superficially in the uterine wall as is likely to do any good, while, on the other hand, if a complete and lasting result in holding the displaced organs in an improved position—not to speak of a perfect one—is the aim of the operator, he must of necessity do very differently and in an opposite direction in each of these features. He cannot serve both masters in the same act.

Thus, vesicofixation alone, or intraperitoneal vaginofixation—making seroserosus junctions—do not interfere with labor; but, pregnancy and labor also uniformly destroy the fixations. On the other hand, extraperitoneal vaginofixation—creating a serosofibrous or fibrofibrous junction—holds the uterus as a rule, but it also, quite as certainly, presents obstacles to gestation and labor which are so serious that this operation has already been practically discarded. What is true of this operation is also true, to a milder degree, of the direct and firm fixation of the fundus uteri to the abdominal wall by a serosofibrous or by a fibrofibrous junction, without any intervening band—the ventrofixation of Leopold³ and Czerny⁴. This operation is of real service for some cases of extreme descensus uteri, as before mentioned, and in other rare and extreme conditions with which the round ligaments can not be made to cope successfully, and it is permissible then, because sterility either exists or it is readily accepted and secured at the same time.

*Presented to the Section on Obstetrics and Diseases of Women, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1898.

But as examples of the obstetric complications that it has otherwise induced, the following should be kept in memory: Out of Milander's² collection of 54 cases of pregnancy and labor after this operation, 11 cases, or 20 per cent., required severe operative delivery; † in Noble's American collection of 43 cases, or 16.25 per cent. and 18 in Noble's⁴ foreign collection of 133 cases, 13.5 per cent. W. A. N. Dorland⁷ collected 179 cases of pregnancy following this operation, in which 111—62.01 per cent., or nearly two-thirds of the whole number—experience some uncommon abnormality in gestation or in labor, or in both; and in 37.99 per cent. of the cases these disturbances occurred as complications of labor, which are more serious. Disorders during gestation that are recorded are, among others, excessive vomiting, abortions, interference with the bladder and many traction pains so severe as to make the recumbent posture necessary, or to require the induction of premature labor. Leaving aside the disasters following extraperitoneal vaginofixation as an obsolete operation, the following are some of the serious or fatal complications of parturition after ventrofixation alone: Gubaroff,⁸ Veldi¹⁹, Mackenrodt¹¹, Norris¹², C. P. Noble¹³, Michaelis¹⁴, Krim¹⁵ and Guerdard¹⁶, Strassman¹⁷, Gottschalk¹⁸, Ols-hausen¹⁹ and Edebohl's²⁰, each report one case, while Bidone²¹ publishes four instances in three patients out of six total cases of pregnancy following ventrofixation. This operator advises an abdominal section for the removal of the fixation two months before term, in every case of this kind. In all these cases together four Cesarean sections were made and were followed by recovery; and two Porro operations ended fatally, and in the remaining cases other severe and uncommon operative aid was required.

It is true that these obstetric disasters are usually avoided by a mediate fixation—the so-called ventrosuspension, in which the uterus becomes hitched to the abdominal wall by one or more bands that allow it a variable degree of mobility. But what is gained in this direction is largely lost in another regard, from the imminent liability to intestinal obstruction and to the suffering of more frequent and unavoidable abdominal pains due to smaller interferences with the intestines that cling to all such unnatural and intruding bands, bridges or clefts, spanning from one viscus to another, or from any viscus to the abdominal parietes. Notwithstanding some nice names that are calculated to obscure their heinous nature, they are always pathologic, whether arising spontaneously from disease or from misdirected efforts of a surgeon. And the latter would usually regard an operation for their removal at some convenient time as proper, when such menacing bands have originated otherwise than by his voluntary act.

The reports of cases of ileus following at variable periods after ventrosuspension, have only begun to appear. But I have chanced to notice the following without any exhaustive search: Ruchl²², Jacobs²³, Ols-hausen²⁴, and A. L. Smith²⁵ each publish a case; while Rufus B. Hall says he has dealt with three cases and thinks the operation of ventrosuspension has had its day. In a second abdominal section for severe disabling pain in the abdomen, on account of which the patient could not walk nor stand erect, Professor Fitsch²⁶ found the omentum so engaged between the uterus and bladder, after a former ventrofixation by Ols-hausen's method—attaching the uterus at its cornua or the origins of the round ligaments—that he had to reset a large portion of it.

Furthermore, Fihling's statistics show a mortality-

rate of 5 per cent. after all these operations²⁷ (Stein-thal²⁷) and ventral hernia has followed these, as other abdominal sections, in the hands of many men, more frequently than that. And finally, the rate of recurrence of retroversion, etc., after this operation, is so high, when the operation has been carefully done so that it will not create serious obstetric complications, that no intelligent patient will accept it if the truth in regard to it is honestly stated by the doctor.

Again, everything about these so-called artificial ligaments is very uncertain and ungovernable, whether they be constructed by the use of the urachus, or a strip of parietal peritoneum sewed to the uterus or drawn through a slit on its surface, whether they be developed by the pulling out of an exclusively peritoneal parietal fixation of the fundus or of the cornua, or whether they be formed by sewing the round ligaments of the uterus into a median ventral incision or against or into the abdominal wall at points laterally from the median line, so that clefts or pockets for the omentum or intestines result. No operator knows with any reasonable certainty what will be the strength of his newly-made attachments for desirable service or for occult mischief; he does not know how soon nor how long they will pull out, nor how long these enemies to nature and its efforts will last. This entire matter is made ungovernable by the uncertain and incalculable degree of peritoneal reaction upon the sutures of any kind of material—as foreign bodies—and by the frequency of slight infections that nature overcomes readily enough, but does so by throwing out an amount of exudate and by forming a volume or depth of adhesions that were not bargained for by the operator. This fact has been repeatedly impressed upon me in doing second abdominal sections upon various cases. A striking one was a few weeks ago: In doing a vaginal hysterectomy only for a large metritic uterus and septic tubo-ovarian conglomerate and ovarian cyst of one side, I was surprised to find two short and very dense fibrous bands close together and nearly a centimeter in thickness, attached to the fundus and holding it high up against the upper vesical boundary. Nothing but actual cutting would sever them; and in case of pregnancy they would have done mischief certainly. These resulted, as my records show, from a mere auxiliary vesicofixation with finest silk and a round milliner's needle, that I had made two years previously to supplement an intra-abdominal shortening of both round ligaments for a retroverted metritic uterus, after curettage and removal of adnexæ of one side, while at that time I could not expect that more than a slight seroserosous union would result, that would not embarrass any uterine function.

3. But another most commanding reason why these *denier* operative resorts to things pathologic in gynecologic surgery are not only not necessary but out of order in all possibly fruitful females is, that there are other surgical expedients quite generally available, that are entirely within the domain of normal anatomy and physiology, that help nature and are assisted by nature because they exercise a parallelism and no antagonism of forces. The only normal structures that exist and can be consistently made use of upon this declaration of principles, for the purpose here intended, are the round ligaments of the uterus. They are the only things that, as a part of the uterus, keep pace with it in its physiologic changes and migrations. They grow with it approximately in thickness and length during gestation. They participate with it in involution after parturition. They may be dealt with: 1, by median ventral celio-

omy; 2, by anterior median, vaginal celiotomy, and 3, by way of the inguinal canals. By the first route they can be shortened or can be made to hold the uterus, anteverted only by intra-abdominal methods which consist exclusively of looping them upon themselves or upon each other, or upon the anterior or posterior surface of the uterus; and this is only possible by means of sutures that are in danger of cutting off the circulation partly on the one hand and of cutting out on the other; so that the extent and permanency of the desired adhesions that are necessary to maintain the loops or other transformations in the ligaments is uncertain; and they do not stand the test of pregnancy and labor, although they do not present any obstacles to these functions. Substantially the same intra-abdominal shortening of the round ligaments can be made by the vaginal route with a good result, in the absence of pregnancy, especially when supplemented with a seroserosus vesicofixation. Furthermore, vaginal fixation of the round ligaments is ideally a creditable procedure and is recommended by several good gynecologists—Bode, Wertheim and others. I have no experience with it. But all these operations either do positively not stand the test of normal child-birth or they have a great burden of proof yet to bring that they can stand it. Far better are the results from shortening the round ligaments by way of their natural channels—the inguinal canals. Here no dependence is placed upon light suturing or slight adhesions. The ligaments are not distorted, and no sutures or plastic junctions of any kind are needed within the peritoneal cavity, as in shortening these ligaments by every other possible route. On the other hand, the strong central half of the ligaments alone is made use of, additionally reinforced by a strip of firmly attached peritoneum, and untrammelled by any kinks or sutures. Thus alone can they be expected—and in this manner alone have they been proven—to fulfill their ideal function, i. e., to grow, *pari passu*, with the uterus in gestation, to become involuted with it in the puerperal period and to guide and guard it in anteversion thereafter.

The original Alexander operation greatly modified and improved is the only operation practiced or proposed that not only does not borrow from things pathologic and antagonistic to nature—as do all ventral attachments—and does not create obstacles to gestation or labor, but also guarantees against a return of the retroversion afterward, provided that the operation is properly performed. And this means a very much greater conception as to its technic and requirements than was entertained by Alexander himself, or is entertained now by those who speak of one-inch incision, of not laying open the inguinal canal, of not opening the peritoneal cavity and similar perile vagaries. This, the modern procedure, which resembles that of Bassini for hernia far more than it does the operation introduced by Alexander, is the only operation that has been proven, or is likely to be proven, to stand the crucial test of pregnancy and labor. All others, according to all evidence so far available, either create obstacles to these functions, or the good that they offer or were intended to do is ended by their supervision.

And when this modern Alexander is combined with inguinal celiotomy* by way of the temporarily dilated internal inguinal ring, for the severing of adhesions, for the resection or removal of diseased appendages and for

the permanent restoration of descended ovaries to their normal locations, it most nearly fulfills the highest ideals now entertained.

This combination originated with the writer accidentally and was executed by him completely for the first time, Sept. 18, 1893, when he removed a diseased tube and ovary via the left internal inguinal ring, in the course of an Alexander operation. From Jan. 1, 1897, to May 29, 1899, inclusive, I performed these combined operations, called by me the "Improved and Extended Alexander Operation," sixty-five times; twelve times with simple digital exploration, or examination or freeing of the adnexa of both sides, which I never omit; 19 times with resection of one ovary; 13 times with removal of one ovary and tube; once with removal of both ovaries and tubes that were unexpectedly found to be tubercular, very adherent and moderately distended, with cheesy pus; 11 times with removal of tube and ovary of one side and resection of the other ovary. Seventeen times a descended ovary was suspended by shortening its proper lateral suspensory ligament, and in five or six cases salpingostomy was done. One of the simple cases was pregnant two and one-half months, and the uterus remains now in normal position, some four months after a normal labor.

In one instance a tubal pregnancy, which was just beginning to rupture, was removed with the tube entire, and the ovary—the only one—left in. Although I have always done one or more other operations—such as curettement, Schroeder cervix operation, colporrhaphy or perineorrhaphy—in conjunction with this extended Alexander, in every case except the pregnant one I can join a number of other operators in declaring that even this extended Alexander operation, in careful and competent hands, has practically no mortality; for after a total number of over 170 cases of all Alexander operations—old and new—I have yet to experience the first death. And the results in the last 100 cases, in most of which not merely the retroversion but also the other half of the indications, i. e., that pertaining to the appendages, was attended to, are so satisfactory that they distinctly emphasize the importance of the extension feature of the operation. And by cutting nothing but skin and fat and severing all the other structures—all the supporting ones—bluntly by splitting, in making the wound; and by following the principles and technic of the Bassini hernia operation always in closing it, we not only avoid the supervention of hernia, but incidentally cure a number of inguinal hernia that are impending or are fully developed.

UTERINE RETRODISPLACEMENTS.*

A NEW OPERATION FOR THEIR CURE.

BY C. E. RUTH, M.D.

Professor of Surgical and Descriptive Anatomy, Keokuk Medical College;
Professor of Clinical Surgery, St. Joseph's Hospital,
KEOKUK, IOWA.

Had the older plans always been satisfactory, I should not present this one, hence no apology is required for obtruding yet another method upon you. It may probably be more properly called a new application of an old principle, and has for its object the replacing of the round ligaments or their temporary substitution by efficient means until they are again able to hold the uterus forward enough to entirely prevent retrodisplacement.

It is equally applicable to retroflexion and version. It can be used almost equally well in the lean and obese. It requires little time, usually not more than five or ten minutes of intra-abdominal work. An incision is made at or near the median line above the pubes, the length of which depends upon the thickness of the abdominal walls, skill of the operator and the intra-abdominal and pelvic pathology and will usually not need to be more than two or three inches in length.

The uterus is brought forward and a large ordinary full curved needle, or, if the operator prefers, a needle may be used with the eye at the point, armed with a full-sized kangaroo tendon, which is passed under the peritoneum, directly across the anterior surface of the uterus, then along the interior of the round ligaments, or, when they are absent or practically so, the needle simply passes along the interior of the peritoneal fold which represents the course of the round ligament. When the abdominal ring is reached, the needle no longer follows the round ligament, but pierces the abdominal wall directly opposite the ring and emerges through the skin in contact with Poupart's ligament, near its middle on one or the other side.

The needle is now unthreaded, the end of the tendon split, say two inches, one half is again threaded into the needle and passes under Poupart's ligament to the opposite side of the same and the ends are next tied together over the ligament. This fastening of the end of the tendon to Poupart's ligament may be done through a small incision down to the ligament or subcutaneously, as the operator may desire. The other end is dealt with in like manner, enough tension being made to bring the uterus as far forward as may be desired and retain it in position. A little care is required to have the tension the same on each side, or the uterus will be drawn to one or the other side, as the large kangaroo tendon does not run readily for so great a distance. It will be noticed that the long round ligaments will thus be thrown into numerous folds and convolutions as it is taken up on the running thread.

The life of this material is at least two months and if it were necessary it might probably be made longer. At the end of two months the tendon has practically disappeared and its place has been taken by exudation material which has become for the most part a strong fibro-intestinal cord which has little tendency to relax under any ordinary tension.

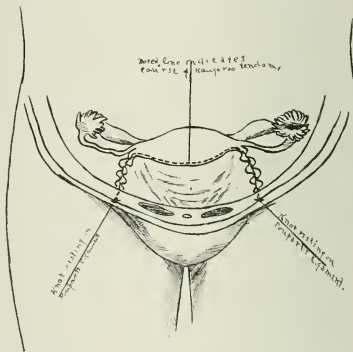

In January, 1899, I operated on Jennie M., aged 17 years, for retroflexio uteri. I first made the usual incision on the right side for an "Alexander's operation" and found no round ligament in the inguinal canal. As it was necessary to open the abdomen I concluded to open in the median line that I might the more readily

deal with any ovarian or tubal pathology, should it exist. I found the abdominal portion of the round ligaments almost entirely absent, being represented by little more than folds of peritoneum, extending from the point of normal uterine attachment of the round ligaments to the abdominal rings.

As my patient was but 17 years old, with healthy ovaries and tubes, I did not feel justified in doing a ventrofixation or suspension, nor had I any confidence in the ordinary intra-abdominal methods of shortening the round ligaments, being long successful in ligaments so attenuated or rudimentary as these.

I was of opinion that I would obtain a better immediate and remote result in far less time by using the kangaroo tendon in the manner already referred to than by doing any of the ordinary intra-abdominal operations for shortening the round ligaments. Dr. T. J. Maxwell, professor of surgery in the Keokuk Medical College, was present at the time and noted the case with which the uterus was brought and held forward to any desired position by means of the tendon, whose ends were fastened around the middle of Poupart's ligament.

The uterus was not absolutely or rigidly fixed, as one

might suppose, but yielded to the pressure upward and tension downward by virtue of the fact that the tendon did not pass in a straight line from one side to the other, but in a slightly irregular segment of a circle. Again a slight give was to be obtained from the attachment of the tendon ends to the middle of Poupart's ligament. A Hodge pessary was introduced and worn two months. On its removal the uterus remained in perfect position, or rather in the antevruted position in which it was placed at the time of operation.

Three and one-half months after the operation, the uterus is still in position, with no discomfort from it whatever, and no apparent tendency to relaxation of the round ligament supports. I am aware that one case is not enough to prove an operative procedure thoroughly, especially in three and one-half or four months' time, but it may teach us some things.

The following points may be said to be worthy of consideration:

1. It exposes no denuded traumatized surface to contract troublesome adhesions.
2. It does not permanently introduce any foreign material.

*Presented to the Section on Obstetrics and Diseases of Women, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

3. It enables the natural supports to take up the work successfully.

4. It gives the desired position of the uterus.

5. It leaves the uterus with ample mobility.

6. It does not interfere with the development of any part of the uterus in performing its normal physiologic functions.

7. It is as quickly done as any operation having for its object the accomplishment of the same ends, and can be done in much less time than some of them.

8. It gives every opportunity for dealing with any ovarian, Fallopian or uterine pathology, with but a single wound, for the abdominal wall is in no sense weakened, except at the central incision, as nothing is cut over Poupard's ligament except the skin and superficial fascia. The skin cuts may be entirely obviated by substituting the cutaneous incisions with needle punctures only.

DISCUSSION ON PAPERS OF DRs. GOLDSPOHN AND RUTH.

DR. THOMAS J. MAXWELL, Keokuk, Iowa.—I saw Dr. Ruth perform the operation he has described. He did it easily, and he has very well represented it. Of course, it was an experiment. I did not know how it would terminate at the time, but it seems to have ended successfully. The operation is not a difficult one to do. It is a little more complicated than a simple suspension of the uterus, but if it should prove successful by further operations, it will be a great advancement in the fixation or correction of this common condition of retroversion of the uterus.

DR. ALBERT GOLDSPOHN, Chicago.—I wish to say in a few words that the value of all operations for rectifying retroversion of the uterus should be determined by one crucial test, that is, they do not create complications in gestations or obstructions to labor; and, on the other hand, that their results will also not be wiped out when those physiologic phenomena supervene, and on that test I do not have much faith in the procedure described by Dr. Ruth. Furthermore, anything calculated to assist the contraction or growing strong of the round ligaments that is done outside of the post parturient period is not likely to be successful. The only time when we can expect such a contraction of the round ligaments to take place is when involution is in progress in the uterus and the round ligaments. That time is limited to a couple of months after labor. And outside of that period, all surgical or mechanical measures that serve temporarily only, with the expectation that the round ligaments will contract because of the rest that is given them, are not successful; they will not be found to be successful in the end, when a large number of cases are observed for years; because the round ligaments will not usually become short and strong, permanently, at any other time, even if they are believed of duty for a number of months.

DR. B. SHERWOOD-DUNN, Boston.—I recently operated on a case in which the uterus was fixed forward by the vaginal route, for disease of the ovaries, and I found a ligamentous band six inches in length. My personal experience has led me to adopt one of two courses in fastening the uterus forward, that is, intra-abdominal shortening of the round ligaments by the Gill-Wylie method, or the Alexander operation to maintain the physiologic relations. It does not interfere with the physiologic performance of the duty of the round ligaments, and it does not give rise to the subsequent complications which the essayist has brought forward. I have followed Dr. Goldspohn's writings for years with great interest; he has devoted much time and attention to this subject, and I have gathered the impression in my own mind that there is no man in our profession in this country who has written more, or who has paid as much attention to this particular subject as the essayist, and I am glad to have heard his paper to-day.

DR. CHARLES E. PADDOCK, Chicago.—I wish to thank Dr. Goldspohn for his excellent paper. It is a great help to those who are giving obstetrics considerable attention. In my own practice I have encountered ease after ease of ventrofixation, and these operations must be looked upon as being only of temporary benefit. As a rule, many women abort after these operations, and they are left in a deplorable condition. These women go through pregnancy nervous wrecks; they suffer during their entire pregnancy. I have seen very few cases that went on to term after operations for ventrofixation of the uterus; many of the women have aborted. Intestinal obstruction is also a factor to be considered.

Intestinal obstruction is also a factor to be considered.

DR. WILLIAM H. HUMISTON, Cleveland, Ohio.—I was very much interested in the Alexander operation when it was first brought to the attention of the profession. I visited Alexander, saw him operated by his method, and I did many operations by his method after I returned home, and I find that in order to make a success of shortening the round ligaments you must have normal adnexa. If you have not normal adnexa and you have a retroversion of the uterus to deal with, the operation is not indicated. You can cure these cases, where you have a simple endometritis, by a curettement, placing the uterus well forward, with the woman in the knee-chest position, and supporting it with a pessary. It has been my experience that where we have diseased appendages, shortening of the round ligaments will do no good. I do not do ventrofixation unless there is a diseased condition of the appendages which will require their total removal on both sides, then I make it. But in the simple cases of retroversion of the uterus without diseased appendages, I have not failed to obtain a good result by an ordinary curettement, with replacement of the uterus and keeping it in position from six to twelve weeks.

DR. C. C. FRIEDERICK, Buffalo.—After having had considerable experience with ventrofixation, I have discarded it because I feared the results, from the experiences of other men; but in reply to Dr. Paddock, with reference to women aborting as the result of ventrofixation, I will say that I have had six cases of pregnancy out of seventy-five ventrofixations that I performed about five or six years ago, and none of them aborted; some were pregnant twice, and they went through labor without any pain or distress. Because some women have distress following ventrofixations it does not follow that all of them do. Some have difficult labors, others comparatively easy ones. I never do ventrofixation unless it be to suspend the uterus in a case of prolapse, or in a case where I have removed the tubes entirely and there is no chance of the woman becoming pregnant again, or in a case in which I remove both tubes and ovaries, or in a woman who has passed the menopause; I either do internal shortening of the round ligaments, or Gill-Wylie's, or Dudley's, or the Alexander operation as modified by Edebohls. I never did but two Alexander operations, and was not pleased with them. I have done seventy-five after the method spoken of by Dr. Goldspohn, all being successful with the exception of one, which recurred after a severe labor and a very hard pull.

DR. JAMES F. W. ROSS, Toronto, Ont.—I have some pronounced views on this subject, and I feel somewhat diffident in speaking on account of being a guest. However, I am pleased to have been called upon. I never do ventrofixation; it is an operation for which I have no use. It is anatomically and physiologically unsound, as Dr. Mann of Buffalo said years ago. The experience of Dr. Frederick may be well and good; but the statistics of Dr. Goldspohn convince me positively that my own views on the subject have been correct. A large number of cases have been brought forward in which a difficulty in labor has been found as a consequence of this abnormal condition in which the uterus has been placed. The miscarriages that have been produced, and the intestinal obstruction which has followed in some cases show conclusively that if the Creator intended the uterus should have a ligament in that place he would have put it there. The Alexander operation has been too highly overrated, in my estimation, by Dr. Goldspohn. There are other well-known operators in the country who have given us decidedly adverse opinions regarding its benefits. A considerable number of cases have been reported in which the uterus has gone back again to its original condition; cases in which hernia has followed as a consequence of the operation, and cases in which it was impossible to find the ligaments. The only method that meets with any approval is the intra-abdominal shortening of the round ligaments. Within the past year I have had one melancholy experience with it. I shortened the round ligaments intra-abdominally, and the patient during the act of vomiting tore a large rent in the left broad ligament. I was called out of town that afternoon, and did not return home until the next morning. I opened the abdomen and found it full of blood. A colleague operated on a woman in Pittsburg last year, I assisted him, and she bled to death the next day in consequence of a similar accident. I have fastened the uterus by ventrofixation in one or two cases for prolapse, but the next day the uterus was down between the legs. So the operation is of no service in those cases.

The gentleman who read the first paper gave us an admirable drawing, and I only hope his method may be of more service than those operations that have been fully described. I cannot understand why kangaroo tendon should not allow the uterus to come back after absorption has taken place; we have nothing left but a certain amount of cicatricial tissue, and we all know from our experience with abdominal hernia that after

the use of a drainage-tube, cicatricial tissue will stretch to a very great extent. Dr. Pancoast a few years ago showed a specimen before the Philadelphia County Medical Society, of a uterus with a ligament about two and a half inches long after ventrofixation. If this adhesion is produced and the uterus allowed to have a ligament two and a half inches long it is bound to go back and rest in its original place over the sacrum and sacrum nerves, and again produce pain. Many women can be treated by the old-time methods, and their condition can be improved, and I consider many of the young girls operated on need no operation at all. Their symptoms are not due to flexion of the uterus, because there are many women going around with retroflexion of the uterus, unmarried women, who suffer nothing whatever, and show no symptoms of the condition. If they become nervous and hysterical and neurasthenic, and we examine the uterus and find it is turned backward, we are apt to jump to the conclusion that it is the flexion of the uterus which is producing the trouble. A number of cases require no operation, and the ideal operation has not yet, in my opinion, been reached.

DR. JOSEPH EASTMAN, Indianapolis.—For the past five or six years I have been pleased in operating upon cases of prolapse of the uterus, retroverted uteri, etc., by the Mackenrodt operation, opening up through the anterior cul-de-sac into the peritoneal cavity, bringing the uterus forward, stitching it firmly, going well up toward the urethra, using the uterus as a splint at the anterior vaginal wall, thus overcoming the chronic spasms and distress which are an annoyance to women who have passed the menopause, adding to this a complete Emmet's operation upon the perineum, and I have succeeded in relieving a larger number of women than I have in those cases where I have made complete extirpation of the uterus by the vagina. While this operation is objectionable in case pregnancy should take place by changing the axis of the uterus, the operation of Mackenrodt has given satisfaction in cases where there is a possibility of pregnancy occurring.

DR. RUFUS B. HALL, Cincinnati.—I was not here in time to hear all the paper of the essayist, but with reference to ventrofixation, I can recall a number of cases operated upon by myself, where the operation was not made for retroversion, but for disease of the adnexa on one side, a tumor, or what not, with, at the same time, possibly a retroverted uterus. For a number of years I practiced fixing the uterus forward in cases where I could leave a healthy ovary, or an ovary that I could leave at all. I can recall half a dozen or more women who have borne children since those operations, and, with one exception, not a single one has aborted. I have reason to believe that abortion was induced in that one case. This woman has since borne two living children. I mention these cases as a matter of justice. I have no doubt that many of these women suffer greatly, and that they not infrequently abort; many women abort much easier than others. But this is not the most serious objection to this operation. In my experience the uterine ligament is a greater reason why we should not do the operation than any other. I claim we have no right to do an operation which places a patient in this additional risk to jeopardize life hereafter. I have had three cases of intestinal obstruction containing a coil of ileum around this little ligament left afterward. Two of the cases I have operated on, the other having declined operative measures. In these two cases the obstruction was not great, but enough to require great care to tide them over several attacks. The case in which operation was refused died. Autopsy revealed a simple case of intestinal obstruction which could have been relieved by operation, and life undoubtedly saved.

DR. C. R. REED, Middleport, Ohio.—In 1870 I treated cases of retroversion and retroflexion of the uterus by certain methods, and I have continued to treat them since that time, and I believe that the operations that have been described to-day are unnecessary in healthy conditions of the uterus and adnexa. I have treated hundreds of cases of retroversion of the uterus, as well as cases of retroflexion of this organ, have seen the women fifteen years later and they have declared themselves to be in perfect health. They have borne children since. I fear that we do not make a distinction between a healthy uterus with slight displacement and a simple retroversion or retroflexion, which does not necessarily cause a morbid condition aside from displacement. I have found trouble in managing those cases in which there was a roomy pelvis. Now, there may be cases in which fixation or suspension of the uterus, after the manner suggested in the papers, may prove successful, and it may be a proper operation to perform; but I rise to protest against resorting to suspension or fixation of the uterus in cases where simple means will accomplish the same or a better purpose.

DR. RUTH, closing the discussion on his part.—No member

respects the opinions of Dr. Goldspon more than I. It is not worth while to take up all the objections of the different forms of operations that have been devised and practiced for the relief and cure of uterine displacements. We must recognize the fact that only about 15 or 20 per cent. of the cases of retroflexion are cured by any method of either medical or mechanical treatment. This, I believe, we are all willing to grant. A mere displacement of the uterus, a retroversion or reflexion, does not necessarily mean that the patient needs any sort of treatment. I have had a little experience with the different forms of ventrofixation and suspension, and with me they have been so unsatisfactory in the main that I have practically abandoned them. I do not believe in the case of a woman who may possibly become pregnant, that we should substitute one pathologic condition for another. The normal uterus must be a mobile uterus, and the principal point in connection with my paper was the fact, as I have found in my experience, that we cannot expect. Dr. Goldspon may say that he never finds a case in which we can find sufficient strength, when he has folded the parts together in the abdominal portion far enough, that they will give sufficient strength to hold the uterus forward and be able to carry the individual through the period of pregnancy, and yet maintain the uterus in its anterior position. That may be his experience. I do find attenuated ligaments which give me much trouble in a few cases, so that I have devised this simple plan which you have heard me describe. I hope further experience will demonstrate its usefulness and success.

DR. GOLDSPOHN, closing the discussion.—Answering my friend from Cleveland (Dr. Humiston), and Dr. Reed, I will say that I saw things as they see them, and used their weapons just as they do, up to five years ago. At that time I sacrificed the appendage in toto of a much greater number of women in proportion than I do now. I will say further, that I have good cause to believe that they would sacrifice the appendages entirely in one-half the cases in which I do this combination of operations and save the patient's fertility in every case, and also get them well. You cannot handle with pessaries the cases in which I do this operation. It must be understood that I am not speaking of simple cases. The old Alexander operation is not competent to deal with these cases. But, when I stretch the small openings in the peritoneal cavity, that are necessarily made if the round ligaments are shortened properly, by introducing a pedicle forceps and separating its blades, I can introduce my index finger into the cul-de-sac and sweep it over the entire posterior surface of the uterus and liberate the appendages, draw them out of the opening on either side, and trim or remove them. I care very little about the extent of adhesions. But I must have insured myself by repeated bimanual palpation, when the bladder and intestines are empty, that there is no pus, etc., there that could be squeezed into the abdominal cavity. I have my finger in there just as well as I do in a vaginal section, and as a skillful surgeon can deal with the adhesions through a small median ventral incision. The old Alexander operation, without this extension or combination with inguinal celiotomy by way of the dilated internal inguinal ring, is utterly out of question.

I agree with what has been said with reference to slender ligaments. But the part of the round ligament that lies within the broad ligament, is, alone, made to serve. And in drawing out this portion of the round ligament (illustrating) that lies within the broad ligament, you will find the peritoneum intimately adherent to it on one side. We should guard against stripping this off; I always preserve it and a wider strip of the layer of peritoneum, if possible, to reinforce the ligament. After separating the adhesions of the uterus and ovaries, I bring the ligament out far enough by loosening it from the lateral end of the broad ligament, so that when we pull upon it we pull from the fundus uteri, and not from the attachment in the broad ligament, and then bring the uterus far enough forward. When the round ligaments are developed by the operator in this manner, I have not yet found that they would not hold. I attach the ligaments, not to movable and elastic muscles, but to the under surface of Poupart's ligament, which is unyielding.

In regard to the technic of doing this, and how it can be done so as not to cut off the circulation in the round ligament, let me say that by grasping some muscle tissue in each suture before passing the needle through or around the round ligament, the ligament becomes cushioned in vascular muscle, which guards against cutting off its circulation; and the bunch of muscle which we draw down against the under surface of Poupart's ligament at the same time also secures the guarantee against hernia. (Dr. Goldspon went into further details connected with the method described by him, by drawings on the blackboard.)

CEREBROSPINAL MENINGITIS.*

SOME UNUSUAL FEATURES IN THE EPIDEMIC FORM.

BY GEORGE LOUGHEAD EYSTER, M.D.

ROCK ISLAND, ILL.

The writer makes report of the following two cases of epidemic cerebrospinal meningitis with regret that they do not carry with them any original research or new matter in the etiology or pathology of this disease, but with the idea that they emphasize one of the theories as to the access to the meninges of the pathogenic micro-organism now generally recognized as its exciting cause, viz., through the nasal chambers, and secondly, that they rather uniquely illustrate the markedly intermittent type of the disease, with the accompanying lesson that unless great caution is used by the observer, he may readily confound apparent therapeutic results with coincidents in the course of the disease.

It is thought by a large number of authorities that the infection atrium of this disease is the nasal chambers. Indeed Strumpell early pointed out that the disease is frequently preceded by an intense coryza, and Weichselbaum and other bacteriologists following him find the diplococcus intracellularis meningitidis in the nasal discharges of a large proportion of those affected by epidemic cerebrospinal meningitis.

In both the following cases there was history of preceding coryza, the presence of mucopurulent discharges from the nose, cultures from which developed a coccus with all the characteristics of Weichselbaum's diplococcus. In both, the disease was markedly intermittent, assuming in one the tertian type, and in the other the quotidian.

CASE I.—T. B., a saloonkeeper, aged 46 years, gave a negative family history; had always been a healthy, robust man; had never been seriously sick; drank moderately, but never to excess. He was attacked by violent chill and rigor at 4 p. m., February 26, 1899. When first seen by the writer, five hours later, he was very restless, continuously tossing from one side of the bed to the other. The face was livid, with extreme anxiety depicted upon it. There was diffuse and uniform redness of the conjunctiva. The pupils were unequal, the right much dilated, the left contracted; the tongue was heavily coated. The head was retracted; there was convulsive contraction of the muscles of the arms and legs. The temperature was 105.3; pulse 130, respiration 28. There was a mucopurulent nasal discharge, which it was learned had existed for several days previously. He complained of the most intense pain throughout the whole head, and of shooting, stabbing pains radiating from the upper portion of the spine. These pains were much aggravated by pressure upon the spinous processes of the cervical and upper dorsal vertebrae.

There was marked hyperesthesia of the skin, rendering it extremely painful to the slightest touch. Any attempt to flex the head evoked outcries of agonizing pain. There was marked delirium, which rapidly increased until it became maniacal and he had to be restrained to be kept in bed.

Twelve hours after the chill there was a herpetic eruption about the lips, and petechiae appeared upon the abdomen and chest. At this time the symptoms began to decline, and at 8 p. m. of the second day the temperature was normal; pulse 72, respiration 18; delirium had disappeared; pain in the head and about the spine had much subsided, so that the patient complained only of slight

headache. The tongue cleared, and during the following twenty-four hours there was some appetite for food. There were some hours of refreshing sleep. Forty-eight hours after initial chill, there was a return of pain, with some vomiting. Temperature was 101, pulse 120, respiration 32. Delirium, head retraction, convulsive muscular contraction appeared which rapidly developed into marked opisthotonos. This condition lasted for several hours, gradually subsiding until in about twelve hours the patient appeared in comparatively normal condition. Temperature 98.3, pulse 80, respiration 20.

On the fourth day the patient felt quite well, was rational, and complained but little of any discomfort. This condition continued until the evening of the fifth day, when he became comatose, with stertorous breathing, and clonic spasm of the muscles of most of the body. Temperature 102, pulse 112, respiration 28. There was involuntary urination and a duration of this condition for twelve hours.

On the morning of the sixth day temperature was 97.8, pulse 62, respiration 20. Patient's condition was good during the sixth day, and until evening of the seventh day, when there was a recurrence of the symptoms of the third day; with return on the morning of the eighth to an apparently normal state.

The evening of the ninth day there was another recurrence of opisthotonos and delirium, but the temperature was 97.2, pulse 48, respiration 26. The delirium and convulsions were of shorter duration, subsiding in about four hours, and it was observed that there was paralysis of both lower extremities, and the patient appeared somewhat dull, was slightly deaf, but would respond rationally when spoken to.

At 8 p. m. of the eleventh day, he went into a comatose state, with stertorous breathing. Temperature was 100.2, pulse 42, respiration 24. He remained in this condition for fifteen hours, when he again became conscious, and partially rational; there were involuntary dejections from the bowels and bladder; temperature 97, pulse 34, respiration 26. This continued until 6 p. m. on the seventeenth day, when he again became comatose—temperature 96.5, pulse 32, respiration 24—and continued in this state until death, which occurred at 7 a. m. on the eighteenth day. Urinalysis was made several times after the third day, and albumin in considerable quantity with numerous casts was found upon each examination.

A specimen of the mucopurulent nasal discharge from the nose was taken at the first visit made, and again, about forty-eight hours later. Lumbar puncture was made on the fifth day, and about half an ounce of fluid withdrawn. Cultures from all three of these specimens were made on blood-serum agar and colonies of micrococci developed which appeared in diplococcus form of two hemispheres, separated by an unstained interval, and were readily decolorized by the Gram method of staining, and were undoubtedly the diplococcus intracellularis meningitidis of Weichselbaum.

Autopsy was made six hours after death. The dependent portions of the body exhibited extensive livid areas. On opening the calvarium the dura was found congested, and thickened, and at a number of points adherent to the arachnoid. The entire pia was infiltrated with a thick purulent fluid, especially marked about the posterior regions of the cerebellum, with numerous deposits of fibrinous lymph throughout the meninges, and especially along the course of the larger vessels. There were several foci of softened semipurulent tissue in the brain substance. The membranes of the cord were in much the same condition as those of the brain.

*Presented to the Section on Practice of Medicine, at the Fifteenth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

The dura was separated from the vertebrae at several points by extravasated blood. The cord was almost imbedded in a thick fibrinopurulent exudate. The roots of the spinal nerves were bathed in pus. Numerous points of myelitic softening were found in the cord. The lungs were hyperemic and edematous. The heart was soft and flabby, containing some soft coagula. The liver was congested, and its tissue soft and friable. The kidneys were flabby and congested, and the renal tubules were filled with fat granules and fibrinous casts.

Cultures made from the cerebral and spinal fluids developed the diplococcus intracellularis meningitidis.

CASE 2.—J. M., a female aged 9 years, came home from school at 3 p. m., February 20, complaining of severe headache, some chilling and vomiting. When seen, one hour later, there was general clonic spasm, retraction of the head; pupils were extremely dilated; temperature was 106, pulse 150, respiration 42. There was intense coryza, with mucopurulent discharge, which was said to have been in existence for three days; there was delirium, which was succeeded after about six hours by a semicomatose condition from which the patient could be aroused only to complain of intense pain in head.

Temperature gradually declined until 8 a. m. February 21; the temperature was 99, pulse 90, respiration 22. The pain in the head was greatly relieved, though there was still some retraction which, on attempt at flexion, gave rise to pain in neck.

At 5 p. m. there were again clonic convulsions. Temperature was 103, pulse 130, respiration 34. There were also delirium, head retraction, and later semicoma.

Third day. Morning temperature was 99, pulse 92, respiration 24. She was rational, had slight headache, feeling fairly well. At 6 p. m. there was recurrence of convulsions, severe headache, and delirium—temperature 102, pulse 120, respiration 32—followed by slight coma and gradual decline of symptoms, until morning, when the child was found quite deaf, and displayed difficulty in swallowing.

This condition continued for fifteen days, with morning remission or intermission, and evening accession; the accession growing of milder nature each evening, until on the sixteenth day no seizure occurred, and the evening temperature was normal. On the fifth day lumbar puncture was made, and two drams of fluid withdrawn. Cultures from this and from the nasal discharge were made, and developed the diplococcus intracellularis meningitidis.

The child went through a protracted convalescence, suffering for a time complete loss of voice, distortion of vision, difficulty in swallowing, and albuminuria, but at the present writing has regained her normal condition, with the exception of partial deafness.

CEREBROSPINAL MENINGITIS.*

BY T. N. MILLER, M.D.

ROCKFORD, ILL.

Cerebrospinal meningitis is probably a microbial disease. Recent researches prove that the diplococcus intracellularis meningitidis of Weichselbaum is the active causative agent in producing the disease. Cerebrospinal meningitis has appeared at different times and in widely separated regions in an epidemic form, remaining in the same regions as an endemic disease, and manifesting itself in sporadic cases. There was such an epidemic in Northern Illinois in 1878 and 1879, and to

the sporadic cases following that scourge and coming under my own personal care this paper will be devoted.

It is not my purpose to enter exhaustively into the history of cerebrospinal meningitis, which must be familiar to you all. It will suffice for our purpose to say that preceding the beginning of the nineteenth century we have no clearly defined and sharply outlined picture of this disease. Visseux of Geneva gave, in 1805, the first clear clinical record of the disease. Then, American writers at Medfield, Mass., in 1806, took up the history. From this time we have a series of epidemics occurring in groups from 1805 till 1816; from 1837 till 1860, and then 1856 till 1864. Since that time we have had scattered epidemics of the disease, which, indeed, may be said to have become endemic in most of our large cities, so that the yearly mortality statistics of most of them show some victims of this disease. Its history shows clearly that cerebrospinal meningitis appears simultaneously in widely separated communities having no common means of communication and under entirely different hygienic surroundings. It attacks both sexes alike, and may appear in homes of luxury as well as in the abodes of poverty. It is usually said to be more severe when overcrowding and filth abound, still Scotland has never been visited by it, although "crowd-poisoning" is as great there as in any country. Its history also shows us that cerebrospinal meningitis occurs most frequently in the winter months.

In 1887 Weichselbaum described the diplococcus intracellularis meningitidis, which he found in six cases of cerebrospinal meningitis, though he did not consider it is the cause of the disease, but only as associated with the pneumococcus, the causative microbe. In 1895 Jager found the same diplococcus in twelve cases, and Huebner found it in nine. In the remarkable monograph by Councilman, Mallory and Wright of Boston on the 111 cases of an epidemic occurring there, the diplococcus was demonstrated in 31 cases of the 35 examined post-mortem, hence, as Prof. Sydney Thayer says, "There is now no doubt that it"—the diplococcus intracellularis—"is the cause of this disease."

This microbe, hidden in the cellular bodies of the polymuclear leucocytes, is demonstrated with difficulty. It is best grown on Loeffler's blood serum and is stained by Gram's method. The cocci are coffee-bean shaped and appear in pairs or tetrads. The usual point of entrance into the system is given as the nasal mucous membrane, though this is not clearly proven. In some cases its presence in the nasal cavities of well people, as well as those suffering from the disease, has been demonstrated. It is quite probable that in cases complicated with dysentery, it may gain entrance to the blood by the lesion in the bowels. In experimental research, pure cultures injected subcutaneously will not produce the disease, but when thrown into the serous cavities of the susceptible animal they will always produce it. The difficulty of cultivation and the low vitality of the microbes have rendered the disease one of the most difficult of experimental investigation and the hardest to decide as to the mode of entrance into the system as well as to the means of propagation outside the human body.

That cerebrospinal meningitis is contagious is held by but few writers at the present day, though doubtless many of you may have read in the JOURNAL of this year a series of articles by Dr. W. J. Class of the Chicago Health Department and recall his conclusions "that epidemic cerebrospinal meningitis is to be classed among contagious diseases, belonging in this respect to the same category as phthisis pulmonalis"; and, again,

*Presented to the Section on Practice of Medicine, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus Ohio, June 6-9, 1896.

"persons affected with this disease should, whenever possible, be isolated and all evacuations rendered sterile by the use of antiseptics." I think these conclusions are hardly justified by the cases cited in the article and certainly not in the history of epidemic cerebrospinal meningitis. All contagious diseases spread by contact of the well with the sick or along the usual avenues of travel. This disease does neither. J. Lewis Smith says of the epidemic in New York in 1871: "Cerebrospinal fever, previously unknown in New York, began, as stated above, in 1871 among the horses in the large stables of the city car and stage lines, disabling many and proving very fatal, while among the people the epidemic did not properly commence till January, 1873. Although a few isolated cases occurred in December, 1871, no evidence existed as far as I am aware that the disease was in any instance communicated by these animals to man. Those who had charge of the infected horses, as the veterinary surgeons and stablemen, did not contract the malady, certainly not more frequently than others who were not exposed."

Professor Osler says: "The disease is not directly contagious; it is probably not transmitted by clothing or the secretions." Wood and Fitz, in the "Practice," say: "It is not contagious; the attendants of the sick are rarely affected, and there is no evidence that the disease passes directly or indirectly from man to man. It is not known to be caused by fomites." Loomis' "Practice" says: "Cerebrospinal meningitis is in no sense a contagious disease." Professor Whitaker remarks: "The fact that the disease occurs at the same time in places so remote from each other speaks decidedly against the theory of contagion." L. Emmet Holt says: "It is not contagious in the ordinary acceptance of the term."

So we might continue to cite from other well-recognized authorities, but sufficient has already been given to show that in the opinions of the best writers cerebrospinal meningitis is not contagious. To appeal to our own personal experience, we all have treated cases without enjoining isolation and we have no cause to regret our action in this respect. I have never known a nurse or attendant to contract the disease by caring for the sick. Can we say this of any contagious disease?

It is extremely difficult to give a clear pen picture that will cover the multiform symptoms of cerebrospinal meningitis. It will help us in our task to describe it as it appears under the different forms of the fulminant or malignant, the ordinary type, and anomalous forms.

The malignant type presents the awful picture of rapid descent from apparent robust health to death in a few short hours or days at the longest. Almost like a stroke of lightning from a clear sky, its victim is hurried into eternity. There is evidence of great shock; chill or chilling sensation; acute agonizing pain in the head and back of neck; pupils usually contracted and irresponsive to light; pulse small, thready and often irregular; cutaneous circulation sluggish, and surface often mottled or spotted; delirium that is soon followed by swift oncoming coma, preceded by convulsions or convulsive movements and death soon closes the scene. The poison, as is shown by the profound alteration in the blood, the comatose condition, the convulsive movements, and the swift coming of the end, has rapidly and surely done its deadly work.

In the ordinary form the onset is more gradual. The patient often complains of not feeling well for a day or two, with chilly sensations, rarely a regular chill, with more or less pain in the head and neck and sensitive

places along the spine; there is always more or less hyperesthesia of the cutaneous surface; the pulse is almost always accelerated and the cutaneous circulation sluggish. The temperature is very irregular, seldom above 103, and has no regular daily curve, as in typhoid fever. The characteristic stiffness of the muscles of the back of the neck develop in a day or two and may go on to complete opisthotonos in the second week, at which time tonic convulsions are very frequently produced. Dysphagia may also develop to such an extent as to hinder the patient's taking medicine or sufficient nourishment. Delirium is very common in the severe cases, requiring constant watchfulness to prevent the patient from injuring himself. The ability to apparently converse rationally, and yet to have no distinct knowledge of passing events, so that when convalescence is established, the patient will take up the work engaged in on the day taken sick, is a characteristic in many cases of this disease. In those recovering, the rigidity of the muscles of the neck gradually grows less, pain is less constant, the mind becomes more rational, the rest more quiet and refreshing, the temperature approaches the natural, and thus convalescence is fully established; while in fatal cases the patient is either racked with pain by frequently recurring convulsions which exhaust the strength, or the pulse becomes more rapid and weak, until he sinks into coma, the forerunner of death. The duration of cerebrospinal meningitis is from two weeks to two months.

Of the anomalous forms I wish to speak of but a few of the many types. The abortive may begin like the ordinary attack, only with less fierceness and with all the characteristic symptoms, as chill, hyperesthesia, headache, stiffness of muscles of neck, sensitive spots along the spine, and yet all these subside in a few days and soon complete restoration to health takes place.

The intermittent type has much in common with intermittent fever, though it may develop many of the characteristic symptoms of the true disease and yet have an intermission of a week or more, with a complete return. This is the form which leads to the use of large doses of quinin for its cure.

Pathology.—In the fulminant type, where death occurs in 24 to 48 hours in the majority of cases, an intense hyperemia of brain and cord and an effusion of bloody serum in the ventricles of the brain may be the only manifestations visible to the naked eye, though the microscope will reveal the beginning of fibrinous deposit over the basilar surface of the brain and crinated red blood-corpuscles. There is also visible a profound alteration of the blood, characteristic of intense systemic poisoning, as shown by its dark color and soft clots.

In the cases where death occurs later in the disease we have the clear evidence of the profound alteration of the blood with added evidence of local inflammation, with patches of purulent matter in the ventricles over the base and in the sulci of the brain. The brain tissue is much softened, especially in the cerebellum and the posterior surface of the cerebrum. There is not usually a large amount of effusion in the ventricles or the spinal canal. The microbes found—by cultivation—are the diplococcus intracellularis meningitidis of Weichselbaum, the pneumococcus, and various pus-producing bacilli. There are no characteristic lesions found in other parts of the body. There is often hypostatic congestion of the lungs, bronchitis, pleuritis, and pericardial effusions, as well as effusion of blood beneath the skin, which gave rise to the name of "spotted fever," sometimes applied to the disease. In a word, there is evi-

dence of systemic poison and consequent congestion in other organs than the brain and spinal cord.

Diagnosis.—When cerebrospinal meningitis occurs as an epidemic with the clear-cut characteristic symptoms of chill, intense pain in head and back, stiffness of muscles in back of neck, irregular fever and pulse, and hyperesthesia of skin, there is usually little difficulty in diagnosis, taking the whole history into consideration. It has not the slow on-coming, the gradual rise and regular curve of temperature of typhoid fever, nor the intense persistent fever and the intense mottling of the whole surface peculiar to typhus. In malignant scarlet fever we may have the intense headache, vomiting, chill, and the convulsions which characterize fulminant cerebrospinal meningitis, but there the parallel ends, as in one the high temperature continues unabated and the scarlet rash may appear, while in the other the temperature varies and only spots, not a rash, are shown. In all doubtful cases that live long enough the diagnosis may be cleared up by Quinke's lumbar puncture and cultivation of the fluid obtained from the spinal canal. The presence of the diplococcus intracellularis of Weichselbaum puts at rest our diagnosis and stamps the disease as epidemic cerebrospinal meningitis.

Prognosis.—Cerebrospinal meningitis is justly regarded as a most fatal disease, both from its intense nature and the vital parts it involves in inflammation. It is usually fatal in the very young as well as those beyond 50 years of age. The death-rate varies in different epidemics from 20 to 79 per cent. The fatality of sporadic cases varies at different times. Of my own cases, nine in number, only one resulted fatally, and that was in a woman over 60 years of age. Of those who survived, not one was left with any infirmity or impairment of any organ. Several were of more than the average degree of severity and take in the range of age from the infant of one month and four days to the grandmother of over 60 years. I can hardly believe that this result was due merely to chance nor to the fact that the disease was lighter, but rather to the systematic and faithful use of remedies to avert disaster.

Treatment.—To treat this disease symptomatically, as we are sometimes advised, when the symptoms change so radically and in such a short time, seems to me the height of medical folly, and there is just as much foolishness in trying every remedy that has been advocated for it, even when sanctioned by high authority. The discovery of the microbe that causes the disease leads us to the hope that the day is not far distant when an antitoxin or serum will be found which will give us complete control of this dread disease. In the meantime we must use the remedies that have stood the test of time and experience. In the earlier stages we clearly need to lessen the congestion of the brain and spinal cord, and at the present time we know of no better remedies than ergot and calabar bean pushed to full physiologic results. In the bromids we have a less efficient agent, but more valuable in children than for adults. In this stage of a disease that is so depressing on the system and so debilitating, to say that we should avoid bleeding or even the local application of leeches seems almost axiomatic. With the strong bounding pulse, the pulsating carotids, the flushed face, the active delirium, and the stertorous breathing, the temptation to bleed may be very strong, but beware of the delusion: the reaction is sure to come—and that swiftly—when we will need all the vital forces intact to overcome the tendency to fatal collapse.

While I cannot call the opiates "the sheet anchor of hope" in this disease, yet I can see how they are of great aid in all stages of the disease—in the earlier to relieve shock, and in the latter stages to procure the rest and quiet which is so essential to overcome its depressing effects.

The early, and by that I mean within the first three days of the beginning of the disease, and continued use of the iodids I consider of paramount importance, from their well-known power to prevent supuration and effusion into the ventricles of the brain and also softening of the brain tissue. For it seems to me that the paralysis which is so often fatal is due to softened and disintegrated brain tissue rather than to effusion pressing upon the nerve centers.

To assist these remedies I have used counterirritants in the form of mustard plasters or mustard-oil liniment to the spine. In more than one case and instance I have witnessed the strong mustard liniment applied and seen the little patient cease its moaning and tossing and fall into a quiet refreshing sleep. I have never used cold applications or the ice coil, for fear of the distressing effect upon the general circulation and the stagnation of blood when applied.

That cerebrospinal meningitis demands the best care and nursing, and most judicious feeding during the whole course of the disease is clearly self-evident. But I will not weary your patience further than to say that we must secure the best ventilated room possible, free from extra noises, and a nurse who will see that the patient is properly cared for without undue disturbance, and who will watch the many changing phases of the disease and meet the many emergencies that arise, with promptness and tact.

DISCUSSION ON PAPERS OF DRs. EYSTER AND MILLER.

Dr. J. C. WILSON called attention briefly to three points. The first is the importance of Kernig's sign in diagnosis. This sign consists in a condition of spastic contraction of the flexor muscles of the thigh which prevents the extension of the leg when the thigh is flexed at right angles to the long axis of the trunk. This sign has been found to be present in almost all cases of cerebrospinal fever, and has been especially studied in this country by Herrick of Chicago. It is of diagnostic importance at a time like this when cerebrospinal fever, and enteric fever are prevalent.

The second point relates to the contagiousness of cerebrospinal fever. While the direct transmissibility of the disease has not yet been established, there are many points in its clinical history and in its epidemic prevalence that indicate some form of transmissibility, and until the matter is finally settled it is better to assume the possibility of direct transmission and carry into effect such measures as isolation and the disinfection of localities.

The third point relates to the treatment. Recent observations are in entire harmony with the experience of the older practitioners as regards the use of opium in full doses in the management of this disease.

Dr. DIBAMA of Syracuse.—A few years ago at Syracuse there was an epidemic of cerebrospinal meningitis. The attacks were like those mentioned here, very severe. I saw patients perfectly well, and the next day they were dead. The treatment given consisted in large doses of bromids, without any effect whatever. Word came to us that Dr. Wilson of Pennsylvania had decided that this was cerebrospinal fever, and that the successful treatment was by the use of opium alone. We resorted to the opium treatment immediately. The cases so treated got well, while the cases under other treatment died.

Dr. J. H. MUSSER of Philadelphia.—I wish to speak of the value of the lumbar puncture as a diagnostic procedure and as a therapeutic measure. It has been my fortune to see a number of cases of this disease recently, and I cannot reinforce too strongly what has been said upon the necessity of lumbar puncture in making a diagnosis. This should be resorted to in order to confirm those who are suspicious of the nature of the case. The procedure is not dangerous. I have performed it in a number of cases, and never have I seen any ill results following. However, as a therapeutic measure, there is no doubt that in some cases there is great relief. It is a

relief to the headache and to the irritative symptoms that occur in the early period of this disease. Often when we have the stupor coming on relief follows the withdrawal of the fluid.

I wish to call attention to the operation of laminectomy that was first performed by Dr. Rollinson of London, which was successful; my cases were not so relieved. I am satisfied that laminectomy is a rational procedure. Where perfect asepsis can be obtained, and where there is great pressure, then laminectomy is indicated. In a case treated by Dr. Martin he removed the lamina of the lumbar portion of the cord. In many cases where the pressure is small it will be impossible to get any fluid unless you aspirate. In other cases where there is much lymph you plunge your needle into a mass of the consistency of butter, and so you get no fluid. Three such cases occurred under my care. I do not wish to take away the importance of opium; outside of the mechanical procedure opium is the only drug in the treatment of cerebrospinal meningitis.

DR. T. B. FUTCHER of Baltimore.—I was in charge of an epidemic of cerebrospinal meningitis during the past year in Maryland. In 1892 there was an epidemic in the northern part of the state, but since then there has been no epidemic in the state until during the last twelve or thirteen months. During the past year 17 cases were admitted to Dr. Osler's wards in the Johns Hopkins Hospital. Of these 17 cases, 8, or 47 per cent., terminated fatally. I wish to confirm Dr. Musser's statement regarding lumbar puncture, from a therapeutic and diagnostic standpoint. If all the cases were obtained early enough one would be enabled to make a positive diagnosis in a large percentage of these cases. Well-known organisms die out in the spinal fluid readily. At the end of two weeks the examination of the cover-slides may prove negative, but if lumbar puncture be done before this, in a great percentage of cases the diplococcus will be found. In many cases this procedure is done from a therapeutic standpoint with temporary results only. I regret to say that no cases recovered in which lumbar puncture was done as a therapeutic remedy. In one case it was performed, and twelve hours after the puncture there was a marked relief in the symptoms, the stupor and the rigidity diminished, and in several instances there was a rise of three to four degrees in the temperature. I have not the slightest doubt that the patients' lives were markedly prolonged in two or three cases.

In regard to Kernig's sign, it was present in all cases in which it was looked for. In regard to the symptomatology of the disease, in a small percentage of the cases one of the earliest symptoms was development of a severe arthritis. In one case the arthritic symptoms appeared on the third day of the disease. There was a marked swelling of the joints, pain, and a purpuric appearance of the joints. In one case, on the second day after admission there was a distinct fluctuation in the knee-joint. This was aspirated, cultures taken, and germs were found in the cultures. This is the first case in which the organism has been found in the joint in arthritis associated with cerebrospinal meningitis, and the first case in which it was found in the general circulation of the blood. This case in which the organism was found in the joint cavity throws some light upon the character of the arthritis in infectious diseases and lesions of the spinal cord. It is distinctly due to organisms in the particular case, and here it is fair to assume that the arthritis may be considered as secondary to the spinal lesions of a trophic nature.

DR. SCOTT of Iowa.—I wish to speak of the contagiousness of the disorder. I also believe that it is often impossible in many cases to trace every infectious disease to some previous case. I believe that there must be some source at large outside of the body. For that reason I believe that the origin of infectious diseases is decomposing animal and vegetable matter. I believe that if cerebrospinal meningitis occurred in the throat and as the germs occur there it would be contagious. I believe that if it occurred in the alimentary tract it would be contagious. If it did not occur in closed sacs it would be scattered and eliminated from the body, and the contagion scattered by the atmosphere or some mechanical means.

DR. E. WATSON, Ft. Madison, Iowa.—In a disease, the pathology of which is obscure, the therapeutic indications must of necessity be of an empiric character. And as far as its contagious or noncontagious character is concerned, whether we find Weiselsbaum's bacillus or the pneumococcus intracellulularis present or not, or whether we have the disease on account of or independent of these germs does not matter so much in our management of its contagious or noncontagious character. Better consider this dangerous and terribly mortal disease dangerous to all concerned and isolate your patient if for no other reason than that of rest. In a severe and unusually prolonged case of mine, following la grippe, I kept the patient isolated, and observed what Dr. Wilson of Pennsylvania tried to emphatically bring before you, namely, to give this contagious

character the benefit of a doubt. I gave her gelsemium, opium, belladonna, bromids, chloral and ergot, as well as several other things that the symptoms called for; made hot applications for prolonged periods, which relieved her of pain, and when sufficiently recovered sent her to Albuquerque, N. M., whence she returned splendidly recovered.

Some gentlemen emphasize the use of opium alone, but it does not matter which of the remedies you use, or even the surgical procedures mentioned by Dr. Musser—spinal puncture and laparotomy—they are all, every one, sedative measures. I think that where we fear organized processes we may with benefit give our patients iodids in the late stage to carry off morbid accumulations through the absorbents. I doubt if opium, so emphatically insisted on by some of my confrères, can be used at all in the younger children.

DR. BRADWELL of St. Louis.—During the past winter there were 34 cases of epidemic cerebrospinal meningitis in the wards of St. Luke's Hospital, where an opportunity for studying the disease was had, especially from the bacteriologic and pathologic standpoint. In 33 cases was the diplococcus demonstrated. In the other case the clinical signs were the same as the rest, and it was practically a sporadic case. The previous reports of the disease show the diplococcus lanceolatus to be the specific microorganism. It is mentioned that Gram's method of stain is the differential test between the diplococcus lanceolatus and the diplococcus intracellulularis meningitidis; in experience it is a poor means of diagnosis. In one decolorize, in the other not. In the coverslip preparations some color deeply and others very feebly.

I also wish to reiterate the value of the lumbar puncture as a means of diagnosis. It is interesting to find this microorganism. In one particular class where there occurred a bad exudation great improvement followed this procedure. As for the clinical aspects of the case, the sign of Kernig was invariably present. It was present in 34 cases. One case was of especial interest, as it was one of intrauterine cerebrospinal meningitis. The case occurred in a woman who was in the hospital, and was at the seventh month of pregnancy. She was sick two days; the disease was of the fulminant order. The fetus was dead. The woman lived one day. The autopsy showed a meningitis of both mother and child, which was confirmed by bacteriologic methods. The diplococcus was found in both mother and child.

DR. RABOLD of St. Louis.—I am interested in the last case reported, which is the only one on record of the microorganism passing from the mother to the child. In the midst of the St. Louis epidemic there was one death a week from it. Statistics show that during 1896 there were 18 cases and 17 deaths; during 1897 13 cases, with 10 deaths; this year there have been 141 cases, with 81 deaths. At the time of an epidemic in the city we sent out two physicians who asked a series of questions from the physicians, and there were 43 answers received. Among the questions asked was that of Kernig. Many of them did not know what Kernig's sign was. We described it thus: The patient is laid over on the bed; then the leg is extend and relaxed. If the patient then be raised to a sitting posture the legs are drawn up on the abdomen and the legs are crossed over each other. It is a remarkable sign. In the histories received it appeared in 95 per cent. of the cases, and appeared early, always within forty-eight hours.

Regarding the contagiousness of it, there were only two cases that gave evidences that the microorganism was conveyed from one patient to another. One was a woman who contracted the disease and left her husband and went home. The physician begged her husband not to go near her, but he disobeyed; the result was that he contracted the disease and died within five days. In the other instance there were three children in one house, and one after the other contracted the disease.

DR. J. M. ANDERS of Philadelphia.—During the past winter I was called to see a case of this disease. The patient was in a house that might be described as a small tenement, with about six families in it, and the children numbered about thirty. As I entered I found the door of the bedroom wide open and the children in the hall. No precautions had been taken, and the children had free access to the sick-room. The patient had reached the sixth week of illness. No other case of this nature happened in this home. In leaving Philadelphia I was told that none had developed, which shows it to be a noncontagious disease. I concur fully with the views expressed regarding the diplococcus intracellulularis; that it can be shown to have the specific requirements of the disease and fulfill the requirements of Koch's law.

I was also going to mention a case illustrating the value of the lumbar puncture as a diagnostic measure. In another case where the symptoms were obscure the patient reached the fourth day of illness, and the only symptom that pointed to this disease was the severe headache. As there were other

cases in the vicinity, I suggested lumbar puncture, which was at once resorted to, and there was found the diplococcus intracellularis, and diagnosis was so made on that fact alone; on the day following rigidity of the neck muscles appeared. In obscure cases lumbar puncture should be resorted to to make a diagnosis.

In regard to the treatment, I was struck with the fact that many physicians regard ergot as the remedy of choice. I have seen six cases in consultation, and in four of them was ergot resorted to, to the total exclusion of opium.

DR. T. N. MILLER, closing the discussion.—There seems to be a wide diversity of opinion regarding the treatment of this disease. The line of treatment has proved successful in my experience, and also in the experience of many other physicians in that section of the country from which I come. Ergot is valuable. Opium should be used at all stages of the disease. I have never seen the necessity of using the heroic doses advocated by physicians.

APPENDICITIS.*

AS A CAUSE OF INFLAMMATORY DISEASE OF THE RIGHT OVARY AND TUBE,

BY A. J. OCHSNER, M.D.

CHICAGO.

During the past five years surgeons have frequently observed the fact that appendicitis may occur in patients suffering from an inflammatory condition of the ovaries and tubes. In reviewing the appendicitis literature, I found a number of articles treating directly of this feature, while it is referred to occasionally in articles discussing the etiology and diagnosis of salpingitis.

Most of these observers speak of the difficulty encountered in making a differential diagnosis. George R. Fowler¹ points out the fact that the proximity of the appendix to the adnexa may confuse both objective and subjective symptoms, making differential diagnosis especially difficult.

Sonnenburg² points out the frequency with which the two conditions are confounded, as well as the fact that they may occur together, but does not place appendicitis in a casual relation to inflammation of the adnexa with sufficient emphasis. Dr. Krueger³, Sonnenburg's assistant, describes twenty-one cases in which his chief found the appendix and the ovary and tube simultaneously involved, giving an abundance of valuable experience especially in the direction of diagnosis. Deaver⁴ says that if the appendix is very long and overhangs the brim of the pelvis, it may lead to disease of the pelvic contents. He cites a case in which "the right ovary was the seat of an abscess which had evidently been infected by the perforated appendix"⁵. Delagénière⁶ considers the disease of the appendix secondary to the inflammation of the uterine appendages, in case they occur in the same patient. M. Borchardt⁷ shows that there is a relation between the two conditions. C. Bernaribeig⁸ reports an interesting case in which an appendicitis due to a foreign body in the organ coexisted with double salpingitis. Charles Polle⁹ has written fully on this condition. H. Barnsby¹⁰ shows that appendicitis may be caused by inflammation of the adnexa. J. M. Brooks¹¹ as early as 1895, in the discussion of a paper by Robert Morris, stated that he had found both conditions in the same patient. A year ago an interesting paper by T. J. Rhoads¹² brought out the same fact. Richelot¹³ reports six cases in which the differential diagnosis was impossible. Dr. Coe of New York¹⁴ states that appendicitis occurs as a complication of disease of the adnexa, and that the latter condition is sometimes secondary to the former. Howard Crutcher¹⁵ points out the likelihood that the appendix has much to do with inflammation of the adnexa. Lennander¹⁶ says that whenever appendicitis re-

sults in peritonitis in the iliac fossa and in the pelvis, it is plain that disease of the adnexa may result. Vautrin¹⁷ points out the similarity between appendicitis and pyosalpinx and their intercurent effect, but does not state clearly the effect of one upon the other.

It is impossible to review everything that has been written upon the subject of appendicitis, because the past few years have averaged over three hundred articles each upon this subject, but, so far as my investigation of the literature has extended, no author seems to lay sufficient stress upon this source of inflammation of the right ovary and tube.

A number of years ago, during an abdominal section which I performed for the removal of an inflamed ovary, my attention was drawn to the fact that inflammatory disease, especially of the right ovary and tube, is caused by affection originating in an appendicitis, and as my experience has increased, I have become more and more convinced of the fact that this condition occurs very frequently, and it is the object of this paper to point out this fact and its importance, and to substantiate these ideas by a number of histories.

At first it seemed difficult to explain how the right ovary and tube could become implicated except in case of perforation or gangrene of the appendix, or the formation of an appendiceal abscess but since the description of the appendiceal-ovarian ligament by Clado it can readily be understood how an affection can progress from the appendix to the right ovary, because the lymphatic and vascular supply of the two organs is in a measure common. Nothing can be more simple than the infection of the right Fallopian tube in case of the formation of an appendiceal abscess, because the fimbriated extremity is most perfectly constructed for this end. There are other facts which indicate that inflammation of the right ovary and tube is frequently due to appendicitis.

Ribbert¹⁸ in examining the appendix in 400 cases, found fecal concretions in 38, and they were found as often in women as in men, which would indicate that appendicitis is as common in one sex as in the other, notwithstanding the fact that operators in general seem to agree that it is much more frequent in men. This, as well as my own observations, has convinced me that the difference is due to the fact that in women the right ovary and tube is so frequently infected secondarily that these cases are supposed to suffer from the latter condition alone, and that in the treatment of these cases the real cause of the inflammation is entirely overlooked.

It is a generally recognized fact that at least 15 per cent. of all cases of appendicitis occur in children under 15 years of age, and that in these the number of girls equals the number of boys. This is also confirmed by my observations. Later in life, if there is a recurrence it is at once diagnosed in the male as an appendicitis, while in the female a certain number of those cases are diagnosed as ovaritis or salpingitis.

In many of these patients in whom there is but a catarrhal appendicitis, possibly complicated with the presence in the appendix of a fecal concretion, the patient is not disturbed except during the period of menstruation, when the temporary congestion is sufficient to increase the irritation in the appendix, as well as in the Fallopian tube, giving rise to a pain of greater or less severity, which is usually looked upon as dysmenorrhea due to the presence of salpingitis.

A number of my patients showed this symptom when the operation demonstrated the presence of catarrhal appendicitis, with or without a foreign body in the lumen of the appendix, or there were severe adhesions

*Presented to the Section on Surgery and Anatomy, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

showing that at some previous time a portion of the appendix had become gangrenous, or there was partial or complete obliteration of the lumen of the appendix—appendicitis obliterans of Senn. Whenever the pain in dysmenorrhea is entirely or mostly on the right side, especially if it is quite high, it is well to suspect the presence of an appendicitis in connection with the disturbance of the ovary and tube.

In giving the histories of my cases, I will give the one which drew my attention to this fact in full, and then all the cases which I treated the past year—1898—consecutively, and in abstracts only, as a review of all my cases of this class would make the paper unnecessarily long and correspondingly uninteresting.

CASE 1.—Miss Lillie H., aged 19 years, the daughter of healthy parents, had enjoyed good health until four years previous to the operation, when she was attacked with a very sudden, severe pain in the right hypochondriac region, accompanied with nausea and vomiting. At first a diagnosis of intestinal obstruction was made, but later this was changed to circumscribed perityphlitic peritonitis.

The treatment consisted of hot fomentations and hypodermic injections of morphia. She was confined to her bed for three weeks. During the next year she had a similar attack which was now supposed to be due to inflammation of the ovary and tube. Later in the same year she had another attack, and was treated by means of tonics, rest in bed and electricity. One year previous to the operation she had another attack, which again yielded to treatment by means of sedatives and hot fomentations. At this time the attending physician, a man of excellent ability, found a prolapsed uterus, an ante-flexed cervix, and an extremely tender prolapsed right ovary. She was now treated with counterirritation over the abdomen, local treatment of the cervix and the vaginal vault with tincture of iodine and warm douches. Cotton tampons were tried, but the right ovary was so tender that the patient could not endure the pain.

Her menstruation had always been painful and scanty. She had constantly suffered from constipation. Her appetite had been insufficient, and she had not slept well. During all this time the hygienic surroundings of the patient were excellent. Still she had constantly lost in strength. For several months she had been a confirmed neurasthenic, confined to her bed the greater part of the time.

Physical examination revealed a fairly well nourished girl of medium size, with masculine features, dark hair and eyes, skin rough, upper lip and chin covered with hair, and facial expression indicative of severe suffering. Lungs, kidneys and heart were normal; there was a slight anemic murmur. The uterus was prolapsed, the right ovary prolapsed and so extremely tender that it was impossible to determine the extent of adhesions. A diagnosis of chronic ovaritis was made, and an abdominal section recommended.

On Oct. 18, 1888, a median incision was made, extending from the symphysis pubis to within an inch of the umbilicus. This disclosed the following condition: The omentum was adherent about the cecum, the lower end of the ilium and the appendix and also to the parietal peritoneum, indicating that what I supposed to be a perityphlitic abscess had existed during the first attack mentioned in the history, and that the other conditions were secondary. The right ovary and tube were adherent to the uterus and to a mass consisting of the cecum, appendix and omentum, being held by strong cicatricial adhesions, which accounted for the extreme tenderness of the right ovary. I removed the right ovary

and tube, loosened the adhesions which bound down the uterus, but did not dare to disturb the adhesions about the cecum. The wound was closed without drainage.

The patient made a normal recovery. Her neurotic condition vanished, her skin became clear, and she developed into a very beautiful young woman. For two years she had not been able to attend school at all, and for the two years previously only a small portion of the time. Two months after the operation she entered school again and attended regularly for the remainder of this and the next year, when she married. She has since borne five healthy children, and has constantly been in excellent health.

I saw her again in September, 1898, ten years after her operation, and fourteen years after her original attack of appendicitis, and found her in a most excellent condition.

In this case it is plain that an abscess had formed about the appendix, making the latter organ harmless, but that a portion of the infectious material had been carried down to the right ovary and tube, causing an infection of these organs, which caused the severe suffering. Being a virgin, the infection must have come from the appendix.

ABSTRACTS OF HISTORIES OF SIMILAR CASES OPERATED AT AUGUSTANA HOSPITAL DURING 1898.

CASE 1.—No. 4677, Miss E. H., aged 16 years, entered the hospital March 1, 1898. The patient has always enjoyed good health, having grown up in the country. She menstruated at 13 years of age, without pain until one year ago, when she suffered from a typical attack of appendicitis. Since then she has suffered severely during each menstrual period. She has had four typical attacks of appendicitis during the past year: the last one began one month ago, and she is just now recovering. Her present condition is that of a very well nourished girl, evidently unusually strong and vigorous when in good health; she is somewhat anemic, tongue clear, appetite good previous to recent attack, now absent; heart, lungs and kidneys normal. A slight swelling is perceptible over the region of the appendix, also slight dulness on percussion, vaginal examination cannot be made, as patient is a virgin. She has been nauseated, but has abstained from food almost completely during attack.

Diagnosis.—Acute appendicitis; fourth attack.

Laparotomy showed the appendix perforated, imbedded in the midst of adhesions, being surrounded with about half an ounce of pus containing a fecal concretion. The right ovary and fimbriated extremity of the tube were strongly adherent to the surrounding tissues, and helped to form the abscess wall.

CASE 2.—No. 4679, Miss H. M. B., aged 20 years, was admitted March 1, 1898. Aside from the ordinary children's diseases patient has had no severe sickness. Menstruation began at 15 years of age, being regular and only very slightly uncomfortable, and not painful until two years ago, when she began to feel a sharp pain in the right inguinal region during the greater portion of the period. She was able to control this by taking acetanilid, viburnum and whisky. During the last three periods the pain has been excruciating, necessitating the use of morphia hypodermically. The pain is always located precisely in the region of McBurney's point. During the interval this portion of the abdomen is somewhat tender under pressure. The patient has lost several pounds in weight during the past year.

Her present condition is that of a slightly built girl; her facial expression indicates that she has suffered severely of late; tongue coated; appetite bad; bowels regular; heart, lungs and kidneys normal; tenderness over region of appendix.

Diagnosis.—Acute catarrhal appendicitis.

Laparotomy showed the appendix to be severely congested, club-shaped and containing fecal concretion five-eighths of an inch in length and a quarter of an inch in diameter—too large to escape into the cecum on account of the constricted condition of the proximal end of the lumen. The right ovary is also severely congested and more than twice the size of the left one.

CASE 3.—No. 4716. This patient, a married woman 20 years of age, came under my care March 14, 1898, giving the following history:

She was always healthy until two years ago, when she experienced a very severe instrumental labor, lasting sixty hours, during which she suffered a severe laceration of the cervix and perineum. She has not been well since; her menstruation

has been irregular, the discharge being profuse and somewhat prolonged. During the past year she has had several attacks of severe pain in the right inguinal region, usually lasting from four to five days, and recurring every four to ten weeks. Two weeks ago her present attack commenced with severe pain in the region of the appendix. She has suffered from nausea but has not vomited. The lower part of the abdomen has been exquisitely tender. She has had no chills. The temperature has not been observed.

Her present condition is that of a fairly well nourished woman, tongue coated, appetite poor, constipated; heart, lungs and kidneys normal. There is considerable yellowish vaginal discharge; the lower portion of the abdomen is tender and tense; perineum and cervix are lacerated; there is a fluctuating very tender mass to right of uterus.

Diagnosis.—Right-sided pyosalpinx, involving vermiform appendix.

A laparotomy demonstrated the presence of an abscess involving the right ovary, tube and appendix, probably, though not positively, of tubal origin.

CASE 4.—No. 4766, Mrs. E. H., 26 years of age, married about two years, was admitted March 25, 1898. She gave the following history:

She had scarlet fever, diphtheria, pleurisy and typhoid fever as a child. Menstruation began at 18; always regular and painless until three years ago. She has one living child, 5 months old; had rather hard instrumental labor; and has suffered considerable pain in lower portion of abdomen ever since. She has had a few chills, some rise of temperature, and had a fetid vaginal discharge for several weeks after child was born. She was compelled to cease nursing the child when it was two months old, on account of weakness; has menstruated normally twice since, six and two weeks ago. Three months ago, while sitting perfectly still, she had a severe sudden pain in the region of the appendix, lasting two hours, then pain became more profuse and lasted for two days. She had a chill, followed by a fever; vomited once; was constipated. Six weeks and two weeks ago she had slight but similar attacks. One week ago she had a very severe attack; vomited several times; had chills, fever, headache; pain extended in the direction of the umbilicus.

Her present condition is that of a fairly well nourished woman; tongue coated; soft and flabby; appetite fair; bowels constipated; pulse 110; strong, compressible; heart, lungs and kidneys normal; tenderness over region of appendix and right ovary.

Diagnosis.—Acute attack of recurrent catarrhal appendicitis, implicating right ovary and tube.

This was confirmed by the laparotomy, the primary trouble being in the appendix.

CASE 5.—No. 4794, Mrs. J. B. H., aged 26 years, married one year, was admitted April 5, 1898. As a child she was well. She began menstruation at 14 years of age; was never regular, and usually painful; the period varying from four weeks to three months. She has had two typical attacks of appendicitis; one four months ago, lasting two weeks, the other six weeks ago, lasting three weeks, and has been out of bed a little over a week since the last attack.

Her present condition is that of a well nourished but slightly anemic woman, showing the effects of her recent illness. There is considerable tenderness in the region of the appendix. Both ovaries are tender upon vaginal examination.

Diagnosis.—Recurrent appendicitis complicated with ovaritis.

A laparotomy demonstrated a universally adherent appendix, the distal three-quarters of an inch being almost completely destroyed, probably by an attack not recorded in the history, as the patient's parent could not be consulted, and she was unable to give a history of her childhood, although she thought that her health had been generally good. The lumen of the appendix was almost completely obliterated near its attachment to the cecum, preventing the escape of a quantity of pus and mucus and fecal concretions in its lumen. Both ovaries showed old adhesions, probably resulting from infection at time of destruction of the distal end of the appendix. Both ovaries, but especially the right one, and the right tube were acutely congested.

CASE 6.—No. 4823, Mrs. M. D., aged 38 years, married seventeen years, the mother of five children, was admitted April 8, 1898. She does not remember her childhood's diseases. She began to menstruate at 15; had an attack similar to the present one at the age of 26; a second one at 35, and several slighter attacks which she cannot locate accurately as to time. Two weeks ago she suddenly felt a severe pain in the right inguinal region, which was especially severe upon trying to extend the thigh. She has felt slightly chilly several times, but has had

no real chill, and has been nauseated but has not vomited. Her complexion is slightly yellowish, but no distinct icterus.

Her present condition is that of a fairly nourished woman, with heart, lungs and kidneys normal. She has pain and tenderness in the region of the appendix, and the right ovary is tender.

Diagnosis.—Recurrent appendicitis, implicating right ovary and tube.

The laparotomy demonstrated an appendix bent upon itself at an acute angle about its middle on account of strong adhesions, due to an inflammation long past. The enlarged distal end contained a quantity of septic material. A marked congestion and recent adhesions demonstrated the presence of a recent inflammation. The right ovary contained a cyst as large as a hen's egg. The right tube was severely congested, showing a recent irritation; it was very tortuous and the fimbriated extremities were agglutinated to a considerable extent. The gall-bladder contained two very sharp gall-stones, as large as a bean.

CASE 7.—No. 4950, Miss E. B., entered hospital May 10, 1898.

She was very healthy until about one year ago when she acquired a right femoral hernia, which was relieved by an operation seven months ago. This, however, had no effect upon the pain in the right inguinal region, from which she still suffers. The patient is a virgin and consequently the examination is made entirely by external manipulation. There is severe tenderness upon pressure in the region of the appendix and the right ovary; other organs are normal. Menstruation is painful.

Diagnosis.—Chronic appendicitis.

Laparotomy shows appendix 10 inches in length containing a number of fecal concretions, the largest one the size of a pea; proximal end constricted but not obliterated. The distal end of the appendix was strongly adherent to the ovary and tube, the fimbriated extremity of the latter being also obliterated.

CASE 8.—No. 4989, Miss J. F., a saleslady, aged 33 years, was admitted to hospital May 28, 1898.

She has always been well until two months ago; began to menstruate at 17 years of age, suffering very slight pain at times. Eight weeks ago she began to suffer from severe pain distributed over the entire abdomen; this became more and more circumscribed during the first three weeks, when it became permanently located in the right inguinal region. She suffered from nausea and vomiting, but had no chills. During the first week the pain was severe; during the second week the patient was up a little; during the third week she menstruated and immediately after had a relapse. From this time on she had chills repeatedly. A week ago she menstruated and suffered more pain than usually. The pain and tenderness in the right inguinal region have persisted. Her present condition is that of a slightly emaciated woman; complexion not clear; tongue coated, appetite fair, bowels regular, pulse 100, fairly strong, has temperature of 100 in the afternoon. Lungs and kidneys are normal; heart sound over mitral valve is not perfectly clear, otherwise heart is normal. A large, rather firm, mass is found in the lower portion of the abdomen, on the right side, extending to the median line and nearly up to the umbilicus. The mass can be felt through the vagina.

Diagnosis.—Pelvic abscess probably of tubal origin.

The laparotomy demonstrated the presence of a universally adherent ovarian cyst, to the upper portion of which was attached a long inflamed perforated appendix. The cyst had evidently caused neither pain nor inconvenience until it became infected from the appendix.

CASE 9.—No. 5137, Mrs. Wm. D., 32 years of age, married at the age of 29, was admitted July 9, 1898.

As a child she was delicate. She had pneumonia several times; menstruated at 11; suffered from an attack of peritonitis as a child. From 23 to 28 years she suffered from dyspepsia, since then from constipation. At the ages of 24 and 25 she suffered from cholera morbus during the summer for a week at a time, and about three years ago from intestinal obstruction. She was confined to bed for two months, then she slowly improved, until one year ago, when she seemed quite well. Shortly after this she suffered from pain in the region of the appendix and from nausea and vomiting. Nine months ago she had a similar attack, confining her to bed for six weeks. Since then she has improved slowly, having several slight attacks of a similar character but less severe, and lasting only a few days at a time.

Her present condition shows her to be about twenty pounds below average weight; her tongue is coated; her appetite fair; starches and carbohydrates cause eructations. She suffers from nausea occasionally; is constipated; lungs, heart and kidneys are normal. There is tenderness over the appendix and right ovary, and a swelling the size of a small hen's egg

is perceptible upon digital examination, in region of right ovary and tube.

Diagnosis.—Recurrent appendicitis with secondary infection of right ovary and tube.

Laparotomy showed the proximal end of the appendix obliterated, the latter being the size of a thumb, thoroughly distended with mucus. The Fallopian tube was in precisely the same condition, being about twice the size of the appendix, perfectly closed at both ends and filled with the same material. The appendix, ovary and tube were surrounded by a mass of adhesions.

Case 10.—No. 5145, Mrs. F. P., 25 years of age, was admitted to hospital July 11, 1898.

The patient enjoyed good health until shortly after her marriage, three years ago, when she began to suffer from severe pain in the region of both ovaries and tubes. Two and a half years ago she had a severe attack of peritonitis, resulting in a large pelvic abscess, from which over a quart of extremely fetid pus was evacuated by a vaginal incision. Drainage was established, and the patient became apparently well until ten months ago, when the abscess refilled and was again evacuated in the same manner, again apparently resulting in recovery.

Her present condition shows her to be badly nourished; tongue thickly coated; appetite poor; constipated; pulse normal; menstruation regular but painful and too profuse; heart and lungs normal; urine contains blood, pus and albumin, is strongly acid, is loaded with urates, and has a specific gravity of 1030. Pain and tenderness exist in the right inguinal region. Bimanual examination shows presence of an inflammatory mass in the right inguinal region.

Diagnosis.—Pyosalpinx probably implicating appendix.

Laparotomy demonstrated the right tube to be distended to the size of three fingers and closed at both ends; the appendix constricted but not completely obstructed at proximal end, and contains large fecal stone also mucus and detritus. The appendix, ovary and tube are adherent to each other as well as to omentum and cecum.

Case 11.—No. 5235, Mrs. M. L., aged 31 years, entered the hospital August 8, 1898.

The patient had the usual children's diseases, but does not remember having been severely ill. She had suffered from indigestion and constipation for a long time—cannot tell how long. For several years she has had a heavy feeling in the region of the appendix, which became quite painful at times. Six months ago, immediately after her confinement, she suffered from acute pain in the right inguinal region. At this time she had a slight chill followed by a little fever. This became more diffuse, but later again circumscribed. There is now a constant dragging pain in the right inguinal region. The right thigh cannot be fully extended without pain. This condition has not changed during the past month.

Her present condition is that of a poorly nourished woman, anemic, with tongue coated, appetite insufficient, bowels constipated, pulse weak. There is tenderness upon pressure in the right inguinal region. Bimanual examination determines a small mass in the region of the right Fallopian tube, but extending too high to be confined to that organ.

Diagnosis.—Doubtful, probably recurrent catarrhal appendicitis with secondary infection of tube and ovary.

Laparotomy disclosed a small mass in the right inguinal region bound together by strong adhesions, containing a club-shaped appendix which had at one time been perforated, an ovary covered with connective tissue and containing several small cysts, the largest the size of a hen's egg, and the right tube $\frac{3}{4}$ of an inch in diameter closed at both ends and containing a clear fluid.

Case 12.—No. 5453, Miss E. W., 21 years of age, was admitted October 4, 1898.

She had the usual diseases of childhood, but has otherwise been well. Menstruation began at 16, being regular but very painful, especially on the right side. About a year ago patient experienced pain and tenderness in the right inguinal region, which has persisted ever since. Four months ago a sudden exacerbation compelled her to remain in bed for three weeks. At this time she suffered from severe pain, chills and fever. Nine weeks ago she suddenly experienced the same symptoms, together with vomiting. For three weeks she has been better.

Her present condition shows her to be well nourished; tongue clean; appetite good; bowels regular; heart, lungs and kidneys normal; moderate bilateral enlargement of thyroid gland; abdominal walls thick; pain and tenderness over McBurney's point; no abnormal dullness. Vaginal examination is negative except for tenderness in region of right ovary and tube; no accumulation; no perceptible enlargement.

Diagnosis.—Recurrent appendicitis, possibly involving right ovary and tube.

Laparotomy demonstrated the following conditions: The dis-

tal half of the appendix was completely destroyed by an inflammation, evidently many years past, and not determined in the history; the proximal half the size of a thumb, in an inflamed condition, the walls being greatly thickened. An adhesion extended from the end of the obliterated appendix in the direction of the right ovary, which was covered with cicatricial tissue. The right Fallopian tube was very tortuous and severely congested, both ovary and tube having evidently suffered as a result of secondary infection from the inflamed appendix.

Case 13.—No. 5458, Miss D. F., aged 28 years, entered the hospital October 5, 1898.

The patient was healthy until 13 years of age, when she suffered from what was supposed to be typhoid fever. She is said to have had a very sudden attack of the fever, with severe pain over the entire abdomen, later confined to the right inguinal region. She vomited, had intestinal obstruction and in fact all the symptoms of a gangrenous appendicitis wrongly diagnosed as typhoid fever. Since this time the patient has never been well, has constantly suffered from indigestion, constipation, severe dysmenorrhoea and general abdominal pains. She is now a confirmed invalid.

Her present condition shows her to be badly nourished; her facial expression is that of a patient who has suffered severely for years; her heart is normal but rather weak, respiration is shallow, kidneys normal; pain and tenderness over entire abdomen but especially over appendix and right ovary.

Diagnosis.—Adhesions following extensive peritonitis due to appendicitis.

Laparotomy demonstrated only the proximal portion of the appendix as present, held down by strong, old adhesions, the distal portion being recognizable as a band of connective tissue. The right tube is club-shaped and adherent to the ovary and remnant of the appendix by means of strong, old adhesions.

Case 14.—No. 5534, Miss R. P., aged 24 years, was admitted Oct. 30, 1898.

She was always unusually vigorous and well, and able to work until six months ago, when she suddenly experienced an excruciating pain in the region of the appendix, followed by severe tenderness in the entire abdomen, which later became confined to the right inguinal region. She was nauseated, and the pain was so severe that morphia had to be used hypodermically to secure relief. Since this time each menstrual period has been very painful, and she has suffered from two acute attacks since the first one. The last attack, which occurred a week ago, was especially severe.

Her present condition is that of a fairly nourished young woman, normal in every respect except that she suffers from pain in the right inguinal region, which is increased upon pressure. The abdominal walls are tense, and the right hip cannot be fully extended without giving rise to pain.

Diagnosis.—Recurrent appendicitis, probably involving the right ovary and tube, on account of the increased pain present during menstruation.

Laparotomy demonstrated the appendix to be constricted near its middle and bound down at this point by a strong adhesion, which evidently existed for a considerable time. The distal end contained mucus and detritus and was considerably distended. The right ovary and tube were severely congested, and the right tube quite tortuous.

Case 15.—No. 5535, Miss J. A., 24 years of age, was admitted to the hospital Oct. 30, 1898.

She had children's diseases, but was otherwise strong and healthy, having spent her youth on a farm. Menstruation began at 15, being regular and normal. Three years ago she first experienced dull pain in the right inguinal region; about the same time she began to suffer frequently from nausea. From this time on she has felt some pain in this region during each menstrual period. This has increased very greatly during the past year, so that she scarcely recovers now from the effects of one period before the next one begins. Her former vigorous appearance has disappeared, and she has now the look of an invalid.

Her present condition is that of a fairly well nourished, strongly built young woman; tongue coated; appetite not satisfactory; bowels constipated, heart, lungs and kidneys normal; complaints of pain in right inguinal region, which is considerably increased upon pressure. She has received local treatment of uterus. The right ovary is tender, but not perceptibly enlarged.

Diagnosis.—Chronic catarrhal appendicitis.

Laparotomy disclosed that the appendix contained several concretions, varying in size from a grape seed to an orange seed. The mucous membrane showed a catarrhal inflammation. The right ovary was found in a condition indicating chronic inflammation.

TABLE OF APPENDICITIS CASES OPERATED AT AUGUSTA HOSPITAL DURING THE YEAR 1908.
I. Children 15 years of age and younger; five boys, six girls.

No.	Record No.	Date of Admission.	Age.	Diagnosis.	Condition found during operation.
3	4612	Feb. 8.	14	External fistula, appendiceal abscess.	Perforated appendix communicating with fistula.
3	4613	Apr. 28.	15	Recurrent appendicitis, four attacks.	Grossly thickened suppurating appendix, old adhesions.
3	4912	May 1.	15	Recurrent appendicitis, acute attack.	Strongly adherent appendix, abscess at extremity.
3	5374	Sept. 13.	8	Recurrent appendicitis, second attack.	Perforated appendix containing concretions, abscess.
3	5555	Nov. 6.	4	Acute perforative appendicitis.	Gangrenous appendix about to perforate.
3	5675	Apr. 25.	11	Recurrent appendicitis, four attacks.	Gangrenous perforated appendix.
3	5254	Aug. 1.	11	Perforative appendicitis, diffuse peritonitis.	Gangrenous perforated appendix, general peritonitis.
3	5305	Aug. 29.	8	Perforative appendicitis, large abscess.	Gangrenous perforated appendix, large circumscribed abscess.
3	5369	Sept. 18.	11	Perforative appendicitis.	Gangrenous perforated appendix, many concretions.
3	5389	Oct. 25.	13	Recurrent appendicitis, mild attack.	Adherent club-shaped appendix, constrictions; abscess in end.
6	5523	Oct. 26.	10	Perforative appendicitis, abscess.	Perforated gangrenous appendix, circumscribed abscess.
II. Adults suffering from appendicitis uncomplicated; thirty-four males, thirty females.					
2	4495	Jan. 4.	28	Recurrent appendicitis, five years.	Strong adhesions to omentum and cecum partly obliterated.
2	4385	Jan. 16.	31	Recurrent appendicitis, acute attack.	Catarrhal appendix, adhesions, appendix contains concretions.
2	4628	Feb. 22.	24	Recurrent appendicitis, in interval.	Perforated appendix, adhesions.
4	4684	March 3.	35	Recurrent appendicitis, violent acute attack.	Gangrenous perforated appendix, diffuse peritonitis.
4	4724	March 14.	35	Chronic appendicitis.	Tubercular appendicitis.
4	4875	Apr. 11.	36	Recurrent appendicitis, acute attack.	Appendicitis oolitarsis, abscess in end.
6	4885	Apr. 28.	19	Acute perforative appendicitis.	Perforated gangrenous appendicitis, abscess in pelvis.
8	4902	May 1.	29	Acute perforative appendicitis.	Perforated gangrenous appendix, abscess retrocaecal.
9	4952	May 10.	35	Acute recurrent appendicitis.	Catarrhal appendicitis, fecal concretions.
11	4952	May 15.	30	Acute perforative appendicitis.	Gangrenous perforated appendix, general peritonitis.
11	4991	May 29.	21	Recurrent appendicitis, in interval.	Adherent club-shaped appendix, had been perforated.
12	5002	June 29.	28	Recurrent appendicitis.	Adherent appendix, obliterans lumen proximal end.
13	5071	June 29.	17	Recurrent appendicitis.	Appendix curled up snail-shaped, strongly adherent.
10	4952	May 15.	28	Hernia following incision for appendicitis operation.	Adherent appendix, scar in place of gangrenous portion.
15	5112	July 3.	20	Recurrent appendicitis, gangrenous appendix.	Gangrenous appendix, about to perforate.
16	5141	July 10.	28	Chronic appendicitis, ten weeks.	Gangrenous appendix, leaving scar tissue and abscess.
17	5141	July 10.	28	Recurrent appendicitis, acute attack.	Partly obstructed appendix with large stone.
18	5179	July 19.	27	Acute appendicitis, fulminating.	Acute suppurative appendix, not circumscribed.
19	5182	July 21.	23	Recurrent appendicitis, in interval.	Partly obliterated, club-shaped appendix, enteroliths.
20	5192	July 26.	24	Recurrent appendicitis, in interval.	Partly obliterated, club-shaped appendix, enteroliths.
22	5201	July 27.	22	Acute suppurative appendicitis.	Severely congested adherent appendix, quantity free fluid in abdomen.
22	5201	July 27.	27	Acute perforative appendicitis, intest. and obstruct.	Perforated gangrenous appendix, general peritonitis.
23	5227	Aug. 1.	33	Acute perforative appendicitis.	Perforated gangrenous appendix, circumscribed abscess.
23	5227	Aug. 1.	33	Acute perforative appendicitis.	Perforated gangrenous appendix, circumscribed abscess.
23	5418	Sept. 25.	18	Recurrent acute attack, catarrhal.	Perforated gangrenous appendix, circumscribed abscess.
26	5424	Sept. 27.	32	Recurrent appendicitis, third attack in one month.	Severely congested appendix distended with mucus.
27	5466	Oct. 6.	47	Recurrent appendicitis, obliterans.	Cicatricial constriction, foreign body.
29	5539	Nov. 1.	20	Perforative appendicitis, gangrenous peritonitis.	Adherent appendix, abscess in distal end.
29	5539	Nov. 1.	20	Traumatic chronic appendicitis.	Strongly adherent partly obliterated appendix.
30	5542	Nov. 2.	44	Acute peritonitis, strangulated hernia.	Perforated appendix, cecum and omentum in inguinal hernia.
31	5652	Dec. 5.	21	Recurrent appendicitis, acute attack.	Adherent appendix, abscess in distal end.
31	5648	Dec. 11.	28	Chronic appendicitis.	Adherent appendix, cicatricial thickening, abscess in end.
33	5687	Dec. 27.	21	Recurrent appendicitis, in interval.	Adherent club-shaped appendix, had been perforated.
34	4861	Apr. 28.	25	Recurrent appendicitis, in interval.	Adherent club-shaped appendix, obliterans, abscess in end.
34	4861	Apr. 28.	25	Recurrent appendicitis, in interval.	Adherent club-shaped appendix, obliterans, abscess in end.
35	4624	Feb. 13.	19	Recurrent appendicitis, acute attack.	Adherent club-shaped appendix, cicatricial contractions.
35	4645	Feb. 17.	28	Recurrent appendicitis, chronic, in interval.	Adherent small shaped appendix, cicatricial constrictions.
4	4678	March 1.	17	Acute perforative appendicitis.	Gangrenous perforated appendix, partial strangulation of appendix.
4	4678	March 1.	24	Recurrent appendicitis, acute attack.	Adhesions causing partial strangulation of appendix.
6	4775	March 25.	36	Acute appendicitis.	Perforated appendix surrounded with fibrous exudate.
7	4840	Apr. 12.	39	Acute appendicitis, perforative.	Perforated appendix, abscess containing concretions.
9	4911	May 3.	21	Recurrent appendicitis, acute exacerbation.	Strongly adherent appendix with acute abscess.
9	4911	May 3.	21	Recurrent appendicitis, convalescent.	Adherent appendix obliterans.
10	4956	May 18.	30	Acute perforative appendicitis.	Perforated gangrenous appendix.
11	4966	May 22.	40	Chronic appendicitis.	Adherent appendix, mucosa ulcerated and cicatricial.
12	5002	June 29.	28	Recurrent appendicitis, during interval.	Strongly adherent, partly obliterated appendix.
13	5037	June 10.	23	Recurrent appendicitis, during interval.	Adherent appendix partly obliterated, contains concretions.
14	5068	June 29.	20	Recurrent appendicitis, during interval.	Adherent appendix partly obliterated, contains concretions.
15	5099	June 28.	41	Chronic appendicitis, in interval.	Gangrenous perforated appendix, surrounded with omentum.
15	5099	June 28.	41	Chronic appendicitis, in interval.	Strongly adherent appendix, had extensive peritonitis.
17	5082	June 26.	38	Chronic appendicitis, in interval.	Strongly adherent appendix, obliterans abscess in end.
18	5154	July 12.	40	Chronic appendicitis, in interval.	Strongly adherent appendix, cicatricial contractions.
19	5182	July 21.	23	Recurrent appendicitis, in interval.	Club-shaped adherent appendix, cicatricial contractions.
20	5169	July 29.	18	Acute perforative appendicitis.	Club-shaped adherent appendix with abscess.
21	5176	July 29.	49	Adhesions following appendicitis.	Strongly adherent appendix, fixing cecum.
22	5206	July 28.	32	Chronic appendicitis, in interval.	Adherent appendix, cicatricial constrictions.
23	5212	July 31.	34	Chronic appendicitis, recurrent.	Adherent club-shaped appendix, concretions.
24	5248	Aug. 14.	55	Tubercular peritonitis.	Tubercular appendix.
25	5258	Aug. 16.	20	Recurrent appendicitis, acute attack.	Severely congested appendix, containing mucus.
26	5267	Aug. 16.	15	Recurrent appendicitis, in interval.	Strongly adherent club-shaped appendix.
27	5296	Aug. 26.	17	Intestinal obstruction following app. operation.	Adhesions causing volvulus of ilium.
28	5411	Sept. 25.	39	Chronic recurrent appendicitis, in interval.	Partly obstructed lumen, large incarcerated enterolith.
29	5619	Nov. 29.	24	Acute septic appendicitis.	Severely congested acutely inflamed appendix.
30	5683	Dec. 18.	21	Recurrent appendicitis, acute perforative.	Perforated gangrenous appendix, abscess.
III. Appendicitis with secondary infection of adnexa; fifteen cases.					
1	4677	March 1.	16	Recurrent appendicitis, acute attack.	Perforated appendix, adherent to right ovary and tube.
3	4679	March 1.	20	Recurrent catarrhal appendix.	Severely congested right ovary and appendix containing stone.
3	4716	March 12.	21	Pyosalpinx, recurrent appendicitis.	Abscess involving appendix, right ovary and tube.
4	4766	March 24.	36	Recurrent appendicitis.	Appendix strongly adherent, evidence of perforation, adhesions involving right ovary.
5	4794	Apr. 3.	26	Recurrent appendicitis.	Appendix strongly adherent, club-shaped, distal extremity cicatricial, infected right ovary.
6	4823	Apr. 7.	38	Recurrent app. implicating r. ovary and tube.	Constricted distorted appendix, inflamed adherent cystic ovary and tube.
7	4950	May 15.	23	Chronic catarrhal appendicitis.	Long appendix containing concretions, adherent to ovary and tube.
8	4969	May 29.	33	Pelvic abscess, probably tubal.	Acute appendicitis with infected ovarian cyst.
10	5145	July 13.	25	Pyosalpinx, implicating appendix.	Appendicitis obliterans, secondary byrosalpinx.
10	5145	July 13.	25	Pyosalpinx, implicating appendix.	Constricted appendix, containing detritus and secondary pyosalpinx.
11	5225	Aug. 8.	31	Chronic catarrhal appendicitis.	Appendicitis obliterans, secondary infection of right ovary and tube.
12	5473	Oct. 4.	28	Recurrent appendicitis, in interval.	Chronic recurrent appendicitis, secondary ovaritis and salpingitis.
13	5488	Oct. 10.	28	Adhesions following appendicitis.	Chronic recurrent appendicitis, secondary ovaritis and salpingitis.
14	5235	Oct. 20.	24	Recurrent appendicitis, secondary ovaritis, salpingitis.	Constricted adherent appendix containing detritus, secondary ovaritis and salpingitis.
15	5535	Oct. 30.	34	Catarrhal appendicitis.	Catarrhal appendicitis, concretions, chronic ovaritis.
Patients suffering primarily from inflammation of adnexa and secondarily from appendicitis.					
1	4531	Jan. 12.	32	Pyosalpinx.	Hydrosalpinx, cystic ovary, adherent appendix.
2	4762	March 22.	27	Pyosalpinx.	Suppurating ovarian cyst involving appendix.
3	4811	Apr. 5.	45	Chronic appendicitis.	Salpingitis, adhesions of ovary, tube and appendix.
3	4811	Apr. 10.	45	Chronic adhesions after abortion.	Salpingitis, adhesions of ovary, tube and appendix.
5	4916	May 5.	23	Pyosalpinx.	Pyosalpinx with adhesions of appendix.
6	4940	May 12.	26	Ovaritis.	Gonorrhoeal infection both ovaries, tubes and appendix.
7	4943	May 14.	27	Pyosalpinx.	Double pyosalpinx involving appendix.
7	4943	May 15.	27	Pyosalpinx.	Double pyosalpinx involving appendix.
9	5067	June 21.	34	Pyosalpinx.	Suppurating ovarian cyst involving appendix.
10	5225	Sept. 4.	40	Pyosalpinx, chronic appendicitis.	Double pyosalpinx involving fecal concretions.
12	5454	Sept. 27.	26	Salpingitis.	Double pyosalpinx involving fecal concretions.
12	5454	Sept. 27.	26	Salpingitis.	Salpingitis right side, catarrhal appendicitis.
13	5500	Nov. 22.	85	Pyosalpinx.	Adherent right ovary, tubes and appendix.
13	5500	Nov. 22.	85	Pyosalpinx.	Double pyosalpinx involving appendix.

A review of the histories from which I have constructed the accompanying table which represents 103 cases at the Augustana Hospital, in which I removed the appendix, for inflammatory disease, during the year 1898, will demonstrate the following significant facts: There were 90 patients suffering primarily from appendicitis and 13 in which the primary disease was either in the adnexæ, or both appendix and tubes were so extensively implicated that it was impossible to determine the primary seat of the inflammation. Of the patients suffering primarily from appendicitis, 39 were male and 51 female. Of the latter 36 suffered from appendicitis alone, and 15 suffered from appendicitis with a secondary involvement of the right ovary and tube. Eleven patients were under 15 years of age, and of these 5 were boys and 6 were girls. All the children suffered from acute attacks, with either gangrenous appendices or perforations.

Judging from this year's experience, as well as from my very much larger former observations, I am certain that the matter of secondary infection, especially of the right ovary and tube, has been very much underestimated. The following conclusions seem to be borne out by this experience:

1. Appendicitis frequently causes inflammatory diseases of the right ovary and tube, and occasionally the left side is also involved.
2. This condition is especially likely to give rise to chronic invalidism, because of the periodic exacerbation resulting from the congestion due to menstruation.
3. In operating for the relief of pyosalpinx, the condition of the appendix should always be determined.
4. In operating for chronic or recurrent appendicitis in patients suffering also from dysmenorrhea, the right ovary and tube should be examined.
5. If the pain is limited to the right side in severe dysmenorrhea, the appendix is frequently primarily involved.
6. In catarrhal appendicitis in which there is a fecal concretions in the appendix, or in appendicitis obliterans, the pain is frequently most severe during menstruation.
7. In patients who have recovered from gangrenous appendicitis there is frequently no further disturbance from the condition of the appendix, except the digestive disturbance due to adhesions, while the secondary disturbance in the ovary and Fallopian tube may continue to be very great.
8. In young girls suffering from dysmenorrhea the history should be followed very carefully, in order to determine the presence of a previous attack of appendicitis.
9. The fact that many of these cases are mistaken for salpingitis accounts for the theory that appendicitis is more common in men than in women.

[The foregoing is one of a series of six papers on Appendicitis. The discussion will follow the last paper of the series.]

APPENDICEAL PUS.*

COMPLICATIONS AND SEQUELÆ.

BY JOHN B. DEAVER, M.D.
PHILADELPHIA.

The experience of many years in treating the complications and sequelæ of appendiceal pus has led me to choose this subject as a proper and profitable one to bring to your notice, with the hope that both you and I may gain by the exchange of ideas and relation of experience. I am quite sure that many of you have seen and treated the various conditions which follow and complicate pus within the peritoneal cavity and, as a consequence, realize the peculiarly infectious and destructive nature of that variety which owes its origin to appendicitis. And from essential conditions, the case cannot be different. We have in the appendix a narrow, muscular tube, filled with lymphoid tissue; it possesses a blood-supply from a terminal artery; it is deficient in drainage; it is always in more or less intimate contact with the peritoneum; it is undergoing retrograde metamorphosis; and, finally, it is inhabited both in health and in disease by that protean micro-organism—the bacillus coli communis. As anatomical factors, we have in the right iliac fossa, or at least within reach of the appendix, the cecum, the terminal portion of the ilium and the iliocecal valve, coils of intestine, the omentum, the right kidney and ureter, the iliac vessels, the mesenteric and portal veins, and the bladder; in the female, the uterus, tubes and ovaries; the bernal openings, and beyond all, a great mass of lymphatics. With such circumstances as these in juxtaposition it needs only the application of the torch of inflammatory action to produce the ravages which we must so frequently encounter when inflammation of the appendix has been allowed to reach its limits—if, indeed, it may be said to have any. Aided, let us suppose, by the mechanical, i. e., ulcerative effect of a coprolith within its canal, there takes place a rapid invasion of micro-organisms through the mucous, submucous, muscular and peritoneal coats of the appendix; there is thrombosis of the arterial vessels, with partial or complete gangrene followed by rupture, and abscess formation—or it may be a stricture of the canal taking place after ulceration, with a small quantity of pus penned up at distal end of the appendix—or there may be simple follicular ulceration of the mucous membrane lining the appendiceal lumen; yet, whatever the condition, it is a source of danger, either local or general or both, only in so far as it represents the toxic action of bacteria. And it is in this connection that to the colon bacillus must be ascribed supreme importance, for either virulent in itself or rendered so by the chemical products or indigestion or by those of other micro-organisms, or even associated with the micro-organisms themselves, it adds by its mere presence especial threat to both the exudate and to the pus resulting from appendicitis. Though in most instances it is the only bacterium present, in the earlier stages at least, yet the colon bacillus is often accompanied and assisted in its infectious action by the staphylococcus pyogenes aureus, by the streptococcus pyogenes, or by both, by the bacillus pyocyaneus and the bacillus prodigiosus, by the micrococcus lanceolatus and some others. I have seen astonishingly rapid suppuration and infection from the combined action of the bacillus coli communis and the streptococcus pyogenes, and equally severe results from the poisonous presence of the bacillus pyocyaneus alone; but, however, often in

*Presented to the Section on Surgery and Anatomy, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June, 6-9, 1899.

a long series of cases we may meet with the deleterious influence of the various individual bacteria, it is to be remembered, nevertheless, that the bacillus coli communis gives the characteristic feature to appendiceal inflammation and pus collections resulting therefrom; this feature consisting in great virulence and an especial aptitude for transmission and pyogenic action.

We have, then, in the appendix a structure easily susceptible to high-grade inflammation and consequent destruction, not only of its own tissues but also those of the various important abdominal viscera with which, by its various positions, it may be in more or less close contact. We have in appendiceal pus a substance possessing peculiarly poisonous properties; we have about the appendix lymphatics and blood-vessels for the absorption and transmission of the toxins and transplantation of the micro-organism causing, or developing from, appendiceal inflammation. This is a combination from which only the direct results can be rationally expected, and unfortunately our experience merely confirms such expectations; for this condition exceeds even the invasion of the female pelvic organs by gonococci in risk of life by local or constitutional danger.

Of all the complications of appendicitis, peritonitis, that dreadful disease which has and is to-day carrying many a human soul into eternity, stands foremost in frequency and mortality. Now, a more or less severe inflammation of the serous coat of the appendix is of common occurrence in many cases of appendicitis, and within certain limits, is rather beneficial than otherwise, by the formation of adhesions; but, when, from infection or from extension or by rupture, the general peritoneum becomes involved in a suppurative process, the outlook is indeed unfavorable, if not hopeless. I need not enter into an extended discussion of this complication, but I shall merely say that my experience in both its operative and palliative handling has led me to believe that general purulent peritonitis is not amenable to successful treatment. I am quite aware that "successful" cases have been reported, but in such instances there has always been a doubt in my mind as to the extent or character of the inflammation. The peritoneum is so large and so full of nooks and corners that I have always felt that some parts of it must have been free from infection, and certainly no man at an operation can make an examination sufficiently thorough to enable him to prove this statement false. Personally, I have never seen a case of *genuine general purulent peritonitis recover*, and this despite hydrogen peroxid, salt solution, opium, or salts, operation or "expectant" treatment the results were the same and I have come to the belief that, when certain of the diagnosis, this condition is an absolute contraindication to operation.

Secondary abscesses of the peritoneum, more or less localized by adhesions in the vicinity of the appendix or its site, are not infrequent and are of the same importance as the original pus collection.

I may here mention that constitutional septic infection intoxication resulting from absorption of the poisons elaborated in some appendiceal pus cases, resembles in some respects clinically the appearance of typhoid, and it may present considerable difficulty in diagnosis; pathologically there may be simple follicular ulceration of the mucosa of the appendix lumen, or stricture formation with a small retention abscess as it were; or lastly a pericecal or retrocecal abscess. In these instances septic or even true croupous pneumonia is especially apt to supervene and induce a rapidly fatal termination. And in these same septic

states the occurrence of acute Bright's disease or acute endocarditis is by no means rare.

The hepatic complications arising from appendiceal pus are of extreme interest and importance. Thrombophlebitis of the mesenteric veins in a common enough process in appendix inflammation, and when we add to this a free anastomosis between these vessels and the radicles of the portal vein, the possibilities for infection of the hepatic structures by extension along the veins, or by septic emboli, are readily appreciated. Indeed, abscess of the liver, either single, or usually multiple, may so mask the symptoms of the primary affection that only by the post-mortem are we made aware of the pyogenic focus in the appendix. Formerly regarded as pathologic curiosities, pyelophlebitis and hepatic abscess are now recognized as among the most to-be-feared complications of appendicitis—and this is not only in cases with large pus collections, but also in those apparently less severe conditions, with small ulcerative or gangrenous processes taking place within the mucosa of the appendix. Sometimes, as an extension of the liver abscess through the diaphragm or as processes depending upon septic emboli from the appendiceal pus, purulent pericarditis and particularly, purulent pleurisy, may result, which, unless relieved by operation, may rupture externally through the ribs or into the bronchial tubes. Several of such cases I have personally seen.

Of nature and formation similar to the hepatic abscesses are those multiple metastatic abscesses in the kidney, lungs, and spleen, which post-mortem records prove to be of daily occurrence in acute appendicitis with circumscribed pus collections; seen in those cases especially in which operation is postponed for the favorable "interval," or where the golden hours are allowed to slip by while waiting to actually demonstrate the presence of that poisonous pus which so often robs the patient of vitality and life itself.

Having mentioned now some of the most frequent and important complications of appendiceal pus more or less remote from the source of infection, let me consider briefly the more localized manifestation of the intense activity and destructive power of this substance. Here besides the blood, and lymphatic supply, several other factors play an essential part. First of all is the position of the appendix itself, the risk of life and to the neighboring structures evidently depending upon its direction and the part affected, the danger being greater when the tip of the appendix points toward the spleen; when it points into the pelvis—in which cases I emphasize that the pain may be left-sided; or when it curls up over the ascending colon, the danger being least when the appendix lies beneath the ascending colon or when it points west. In addition we must recognize the influence of gravity, the effect of the recumbent or upright position—as it may happen—and the anatomical relations of the peritoneum, coils of intestine, etc. Ulcerative and gangrenous processes are the natural effects of both the mechanical and bacterial action of the appendiceal pus. This is often observed in the omentum, considerable areas of which are found partially or completely necrotic, and require extreme caution in their operative manipulation. Depending upon the position of the appendix or the pus from it, we may have iliac phlebitis; phlebitis with thrombosis of the iliac vein, and consequent edema of the leg affected; or one iliac vein may be the seat of a local gangrenous action severe enough to perforate and cause fatal hemorrhage. By the same means appendiceal pus, or the appendix itself

may rupture into one of the hollow viscera, the intestines, the bladder, or the pelvis of the ureter, causing a probably incurable internal fistula; or rupture may take place through the abdominal wall with the formation of an external fistula. These complications are especially prone to occur when the tip of the appendix, in close relation to one of the above-named structures, becomes gangrenous and involves its attachments. When the appendix, postcecal and pointing north, is the seat of abscess formation it is not unusual to meet with enormous collections of pus extending far up toward the liver. These retrocecal abscesses are probably the most numerous, and fortunately can be handled with less risk to the peritoneum than any other variety. I have seen cases where the gall-bladder formed part of the confining wall of an appendiceal abscess with subsequent infection and necrosis, resulting in biliary fistula. When in such instances the infective process involves the post-peritoneal connective tissue, we have the so-called lumbar phlegmon. In fact, in the absence of lesions of the spinal column, it is probable that the idiopathic perinephritic abscess of former days was invariably due to the retroperitoneal extension and septic infection of an antecedent appendiceal pus collection.

Of appendiceal pus in hernial sacs and purulent appendicitis complicating or complicated by pregnancy, I shall make mention only in so far as to state that in my opinion neither offer contra-indication to operation, as several successful cases testify. But I have left to the last, consideration of one particular of one aspect of this subject. I refer to the effect of appendiceal pus upon the pelvic structures, especially the reproductive organs of the female. When appendiceal pus occupies the pelvis it is usually the result of phlegmonous inflammation of an appendix pointing due south or southeast, of which merely the distal extremity, usually in close relation with one of the pelvic organs, is affected by an ulcerative or gangrenous process. The pain, as I have said, is commonly left-sided; the abscess formed is generally of only moderate size, so that there is more than the usual liability of confounding this condition with true pelvic disease, especially as adhesions are rapidly and solidly formed, confining the abscess along the sigmoid or the bladder, or between the two. The bladder wall and the sigmoid are often perforated, and two of the most distressing cases that have ever come under my care were of this character. One was a vesico-intestinal fistula in a young man from whom feces passed by the urethra; the other was a young girl with a similar condition, through whose urethra flatus was expelled. From the standpoint of the gynecologist, such pelvic lesions are claimed to have their origin in tubal or ovarian disease, with secondary involvement of the appendix attached thereto; from the standpoint of the surgeon, the appendix is responsible for the primary affection and its complications, causing first an infective salpingitis with later involvement of the sigmoid or bladder or both. The surgical idea seems to me to be much the more rational, because such widespread pelvic lesions are particularly encountered in young women and girls in whom no history or sign of external infection can be obtained; 2, because of the greater virulence of appendiceal pus and its especial faculty of setting up purulent processes in other organs; and, 3, because the initial symptoms point rather to appendiceal than to ovarian or tubal disease. In these cases, too, I have been impressed by the fact that there is frequently a tuberculous family taint, but without demonstrable lesions in the patient, so that the underlying condition may be not only a diminished power

of resistance to the influence of acute inflammation, but also, in some instances, at least, a mixed infection, dormant tuberculous elements being started into activity by fresh infection from appendiceal pus.

But whatever their etiology and precise formation, I would lay especial stress upon the clinical importance of these pelvic lesions in which both the ovaries and tubes, together with the appendix, are involved in phlegmonous inflammation. Surgically they offer difficulties that are at times insurmountable. The organs are covered by great quantities of exudate in which one or more smaller abscesses are to be found; dense adhesions are encountered which have so devitalized the attached organs that the slightest traction is liable to induce a rupture into the bladder or sigmoid. I have seen the pelvis practically one solid mass, and as if this were not enough, these adhesions have a particular tendency to recur beyond the power of human skill to prevent or even ameliorate. The most remarkable case of this character I have ever dealt with I shall briefly outline.

An attack of acute appendicitis in a young man was followed by apparent recovery without operation. Later his right chest filled with what aspiration indicated to be appendiceal pus; a rib was resected and he improved; this was probably a sub-diaphragmatic abscess. Still later the sigmoid was perforated and the pelvic abscess further evacuated itself by the rectum.

As far as the sequelæ of appendiceal pus are concerned we have to deal principally with the effects of adhesive inflammation and with fistula; as the result of adhesions, we may, and often do, have intestinal obstruction, the bowel having twisted itself about a ribbon-like adhesion; or the obstruction may be due to the mere contraction of adherent coils of intestine, or to the constriction exercised by the contracting wall of an abscess, especially if this has not been radically dealt with. Frequently the omentum becomes attached to the parietal peritoneum and by its efforts to free itself, as well as by certain movements—coughing, deep inspiration, etc.—intense pain is caused. Indeed in some cases only slight adhesions are necessary to be the source of considerable trouble, though, naturally, intestinal obstruction is the danger most to be feared from their presence—a danger which even operation at times can merely diminish, but scarcely remove.

As for fistula, I have already some mention of those conditions, by no means rare, in which appendiceal pus ruptures into the hollow viscera, especially the cecum, ilium, sigmoid, bladder, ureter or Fallopian tube, constituting an internal fistula. Such communications, as you know, show small tendency to spontaneous cure, and the operations necessary for their relief are apt to be so severe and so fatal that we are often obliged to withhold any surgical interference whatever. External fistula, however, offer more promising results, the simple fecal variety, seen after operations for evacuation of appendiceal pus, often healing of their own accord within a few days. However, an unhealed abscess may underlie any simple external fistula, or the fistula may be in communication with the appendix, in which event removal of this organ is absolutely necessary to effect a cure.

Of fecal fistulae two classes are commonly observed: 1, when the appendix connects with the sinus; 2, when the fistula is in communication with a part of the bowel—usually the cecum or ilium. Of these, the first variety is much the more favorable, a comparatively moderate operation sufficing for complete closure. But when the fistula involves the cecum, or ilium, a very extensive operation is required, which the weakened condition of the

person afflicted may render extremely dangerous, if not altogether impossible.

One, if not the most distressing, sequel of appendiceal abscess is a fecal fistula, the forerunner of which in not a few cases is practically an artificial anus. Can you imagine anything more capable of demoralizing, not only the patient, particularly if she be a young unmarried woman, but also the attending surgeon? When this follows the evacuation of an appendiceal abscess it usually occurs about the end of the first week. I know of nothing more distressing, not only to the patient, but the parents as well. The surgeon, too, is frequently held accountable for this terrible condition. I style it "terrible" for I know of no word that can better express it. It has fallen to the lot of the writer upon more than one occasion to account for this distressing condition, not only to the family, but their friends. In the majority of cases it is the result of a late operation we must admit, therefore why cry against the radical surgeon who practices, teaches, and begs his fellow surgeon to operate upon the advent of the initial appendiceal pain. While this is only one of the many arguments in favor of operative interference at the earliest possible moment, it alone is strong enough in the writer's opinion to influence any right thinking medical man that it is the only course of treatment to pursue.

I have apparently made a rather gruesome representation of the complications and sequelæ of appendiceal pus, but the picture has one virtue, it is an accurate one; for I have myself, together with every surgeon who operates in a fair proportion of such cases, met repeatedly with just these conditions.

I repeat, appendicitis with pus formation produces ravages of the worst description; the effects are often permanent and irremediable, and in my experience unequaled by any other affection occurring within the abdominal cavity. For me, the lesson taught by the widespread, disastrous lesions of appendiceal pus was long ago learned, in fact, these very complications but accentuate the necessity of early operation to usher in that prevention which is indeed cure.

Would that my voice were strong enough to sound the note of warning against the presence of appendiceal pus, its ravages, etc., from the Atlantic to the Pacific and far beyond the everglades of Florida to the glaciers of Alaska.

[The foregoing is one of a series of six papers on Appendicitis. The discussion will follow the last paper of the series.]

ACCIDENTAL HEART MURMURS.*

THEIR CAUSES AND DIFFERENTIAL DIAGNOSIS.

BY GEORGE W. WEBSTER, M.D.

PROFESSOR OF PHYSICAL DIAGNOSIS NORTHWESTERN UNIVERSITY
MEDICAL SCHOOL.
CHICAGO.

Every theory in physical diagnosis should be the realization, not the violation, of a physical law. Every theory in connection with the diagnosis of cardiac murmurs, to be enduring, must harmonize with the physical laws governing the mode of production, pitch, quality, intensity and conduction of sound.

It is the duty of the teacher to seek out and apply these laws and central essential truths, seeking particularly and insisting especially on those which are fundamental, at the same time giving due weight to those which are less palpable to ordinary observation and likely to escape indolent research, and to impress both upon those whom he

addresses with every embellishment that can be furnished by his knowledge, and every weight, emphasis and adornment attainable by his power.

Before considering the causes of accidental murmurs, it may be well to indicate what is meant by this term and also to indicate the purpose of this paper.

Murmurs were formerly classified as organic and inorganic or as organic and functional; the latter being again subdivided into anemic or hemic, and dynamic. The anemic or hemic murmurs were supposed to originate in depraved blood states, while the dynamic were ascribed to irregular or perturbed action of the heart muscles, quite independent of any abnormality of the blood.

This classification is faulty and inaccurate. A so-called functional or anemic or hemic murmur may be present when there is no anemia, and when important blood changes are not demonstrable and where proof of any inco-ordination or perturbed action of heart muscles is wanting. A murmur may be classified as functional, when the purist may maintain that a functional disturbance is the result of a pathologic change. Such a classification commits us to too much, as, by its terms it indicates the pathology, which is not yet a matter of agreement or is not supported by the evidence.

The chief objection, however, lies in the fact that such a classification, besides being simply a cloak with which we cover up our want of knowledge of the subject, is a bar to progress. This objection may be urged against the term "accidental," but this can be said in its favor; it commits us to no theory of causation and places no impediment in the way of investigation.

This want of uniformity in terminology, and lack of unanimity of opinion regarding the cause of accidental heart murmurs is very confusing to both students and practitioners, tending to envelop the whole subject in so much confusion that both are likely to be led to believe that out of so much contradiction and chaos, it is impossible to evolve anything practical, and that an accurate diagnosis is impossible.

This paper is not written because of the hope or belief that I can add anything new to the subject, but simply to make a plea for simplicity and uniformity of terminology, to urge the recognition of the teachings of physical science, and to attempt to show that notwithstanding our hazy, nebulous, discordant views in regard to etiology and pathology, an accurate diagnosis is, in the majority of cases, comparatively easy; and lastly, to make a plea for more careful, painstaking accurate diagnosis, because we should be more careful in condemning patients to a life of mental misery, by a wrong diagnosis.

By accidental murmurs I mean all those murmurs not readily recognized and classified as organic, but formerly classified as functional, anemic, hemic, spanemic, dynamic, etc., and would suggest the following classification.

Murmurs	{	Endocardial	{	Organic
		Exocardial		Accidental

Before taking up the accidental murmurs, a few words should be said in regard to the cause of those designated as organic.

The first satisfactory explanation of the mode of production of murmurs was made by Corrigan. He showed that when the blood flows through a constricted opening into a normal channel beyond, or flows through a normal orifice into a widened channel, or regurgitates through an orifice normally closed by valves, vibrations are produced which may ultimately reach the ear as sounds.

Chauveau supported the views of Corrigan, extending

*Presented to the Section on Practice of Medicine, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-8, 1898.

his observations and clearly demonstrating their correctness, also proving that friction caused by roughening of the interior of the tube cannot originate a murmur, and has no influence on the production of sound.

Heysius pointed out what is now generally accepted: that the murmurs have their origin in the fluid blood and are primarily vibrations in the blood itself, the vibrations being caused by the formation of Savart's "fluid veins." In other cases "eddies" are formed. The intensity and area of audibility seem to depend on the force of contraction, the quality probably depending on the rapidity of the vibrations. These vibrations are transmitted through intervening structures to the surface of the chest and may be perceived as sounds. These sounds are termed "murmurs," and are recognized as having a definite, physical cause.

It is quite generally conceded then, that organic disease is due to structural changes of a more or less permanent character, the theory being in accord with the teachings of physical science. It is quite otherwise with the accidental murmurs. Here theory, speculation and fancy have been allowed full sway, each writer or observer evolving his own pet theory accompanied by an argument more or less logical, attempting to explain the beauties of his own theory and expose the fallacies of others. The following are some of the advanced:

THEORIES OF CAUSATION OF ACCIDENTAL MURMURS.

1. The theory of Naunyn is that it is a murmur of mitral regurgitation, heard, not in the mitral area, but in the left second interspace outside the pulmonary area, just where the appendix of the left auricle comes up from behind, and as Walshe⁷ pointed out, lies in contact with the chest wall, and in some cases may even cover the pulmonary artery. This is the theory to which Balfour² gives emphatic endorsement. He says: "Naunyn's explanation is the only one consistent with the facts and is now universally received."³

"Now we know that the so-called functional murmurs of both kinds—hemic and dynamic—depend upon the dilation of the heart, due to residual accumulation from imperfect discharge of its function, by a heart, unable through debility, to cope with the blood-pressure, which is either natural or only slightly raised."

Stengel⁴ says of Naunyn's theory which Balfour advocates so warmly, "This view seems to be held by no one at the present time, and I refer to it only to express dissent."

Hoover⁵ also dissents from this view and says very pertinently: "If genuine regurgitation were the cause of a murmur in this region, the physical principles of the transmission of sound demand that the murmur should be audible at the apex of the ventricle as well as over the appendix of the auricle." He is a follower of Potain and is inclined to classify most of the accidental murmurs as cardiopulmonary, although he distinctly states that he does not wish to be interpreted as classifying all so-called functional murmurs under this head. In support of the theory of Potain, he cites the experimental evidence of Francois-Franck, who discovered, while operating on a dog, that there was a systolic murmur audible over the heart. "Without opening the pleural cavity, he introduced a tenaculum through the thoracic pleura, and withdrew a tongue of lung from the anterior aspect of the heart. Directly the murmur ceased; but the murmur returned when the tongue of lung was permitted to reoccupy its former position."

Quince⁶ relates six cases in which there was a pulmonary murmur with perfectly sound hearts and arteries, the only abnormality being retraction of the lung

from the base of the heart. He supposes that in these cases, the murmur is produced by the pressure of the heart upon the pulmonary artery during contraction, with formation of "fluid veins."

Russell and Hanford inclined to the view that the murmur heard in the pulmonary area and outside of it is caused by pressure on the pulmonary artery by a dilated auricle.

Allbutt⁷ says: "Arguments of weight seem to prove that these murmurs about the pulmonary orifice are not due to mitral regurgitation, as claimed by Balfour and Naunyn, and not due to pressure on the pulmonary artery, as claimed by Russell and Hanford."⁸

Stengel⁴ says that he is sure this is not the explanation and that the views of Naunyn and Balfour "are held by no one at the present time."

Potain⁹ maintains that the murmurs of anemia are of cardiopulmonary origin.

M. H. Sonlier¹⁰ maintains that inorganic murmurs are probably due to friction. He cites the experiment of placing the palm of the left hand over the left ear, and says that by scraping the back of the hand with the end of the finger in a rhythmical manner, a sound similar to a double cardiac murmur will be produced. He thinks that if the pericardium be dulled from any cause not necessarily inflammatory, a murmur may be induced. This is theorizing with a vengeance.

Thalma¹¹ calls attention to some experiments on dogs, made with a view of determining the influence of certain blood states. Oligemia was produced by bleeding, and hydremia by running warm saline solution into the femoral vein. He concludes that: 1, inorganic murmurs were rarely produced by oligemia; 2, hydremic plethora favored their production; 3, quinin produced a dilation of the heart with cardiac and arterial murmurs closely resembling those found in chlorosis; 4, infrequency of the heart's action, due to a marked filling of the cavities of the heart favored the development of murmurs.

At the meeting of the German Medical Congress in April, 1899, Dr. Winkler¹² of Vienna stated that sounds are sometimes heard over the mitral valve, for which no cause could be found post-mortem. This he attributed to a faulty action of the papillary muscle and a deficient insertion of the valve muscles. He impeded the action of the papillary muscles, and the post-mortem examination showed that he did not damage the valves. Both systolic and diastolic sounds continued to be heard, and mitral regurgitation occurred. He claims to have established a relationship between functional and organic mitral insufficiency.

Sansom¹³ says, "I cannot doubt that a systolic murmur, heard at the apex of the heart in anemia indicates a veritable regurgitation. The audibility of the murmur at the back fulfills the requirements of all observers for an organic mitral regurgitant murmur." He says that he cannot subscribe to the views of Balfour, Naunyn, Hanford and Sehrrwald, and that "no explanation of the systolic murmur heard over the site of the origin of the pulmonary artery can be satisfactory which does not recognize a nervous as well as a cardiovascular causation"¹⁴.

He concludes that the arterial systolic murmurs are caused by a tremor of the conus just below the valves. He also says, "it seems quite possible that the valves themselves may vibrate in the current"¹⁵. The pathogenesis is neuromuscular."

Osler¹⁶, in speaking of the heart in chlorosis says that "a murmur may be heard at the base or at the apex." He refers to Balfour's explanation when the murmur is at the pulmonary region, but offers no opinion regarding it.

Russell proposes two explanations. He suggests that in some cases it might be produced by dilation of the left auricle, which, pressing upward upon the pulmonary artery, gives rise to a narrowing of its lumen; while in other cases it is simply the systolic murmur of tricuspid incompetence propagated upward to the conus arteriosus.

Gibson¹⁷ formerly held to the opinions of his teacher, Balfour. He now repudiates his theories and states that he believes that Russell has disproved the theories of all observers previous to himself. Then he goes on to say that while Russell has disproved all previous theories, part of his own will not bear investigation. He also claims that Samson is "obviously in error." His own view here is that the systolic murmur heard in the pulmonary area is due to tricuspid incompetence, but admits that it is perfectly possible that for some of the cases, Hanford's explanation is plausible.

Anders¹⁸ seems to favor the hemic origin of these murmurs. He says, "soft blowing murmurs of hemic origin are not infrequently heard over the carotid arteries—hemic murmurs at the base of the heart in pernicious anemia." Again he says, "Keihl's work shows the dependence of the valves for their complete closure upon a normal state of the different portions of the heart muscles." And again, "the special conditions rendering these murmurs audible are the great dilatation, softening of the papillary muscle and abscess near the valves."

Musser¹⁹ says, "Anemic murmurs are generated at the pulmonary orifice or in the cone of the right ventricle." "Tricuspid and mitral valves often become relatively incompetent; mitral and tricuspid regurgitation ensues." "The vessels are dilated from artificial disease, the increased caliber favors a development of a murmur by the creation of a fluid vein." He also gives a classification of Drummond:

Functional	{	cardiohemic or anemic.
		cardiomuscular or neurotypic.
		cardiorespiratory.

Vierordt says in regard to these murmurs, "These are difficult of explanation. We think with others that the nature of the phenomena differs in different cases, and in many cases we apply Sahli's supposition that venous murmurs from the large veins in the thorax lie behind these heart murmurs."

Skoda²¹ says concerning hemic murmurs: "The opinion that they rise through any particular condition of the blood is hypothetical," and speaking of the venous murmurs, he says, "I have for many years looked upon it as a sign, neither of a watery condition of the blood nor of anemia." It exists even in the young and healthy." He was also familiar with the fact that no sound is produced by friction between the blood and the vessel walls, and freely credits Hamernik with having in 1847 called attention to this now well-known fact. Skoda also agrees with his explanation of the venous murmur: "The less the quantity of blood present in the vena cava, the more rapid will be the flow of blood through the jugular veins during inspiration, and the smaller the current of blood." "Now, the internal jugular vein is so attached at its lower part as of necessity to always retain a certain width; the diminished stream of blood can only fill this wide space by passing through it with an eddy movement." He also states that the conditions necessary for the production of the murmur exist only in the internal jugular vein, and in a much more perfect manner in the right than in the left. That he correctly appreciated the im-

portance of what we now call fluid veins is shown by these words: "A murmur also arises, when a rapid current of blood is directed against blood that is quiescent, or moves less rapidly, or in a contrary direction."²²

Whittier²³ classifies these murmurs as accidental, refers to the opinion of Sahli, who believes these murmurs are due to hydremia; to Durozies, who believes the venous murmurs may be conducted to the heart and simulate valve murmurs; also to the prize essay of Audeoud and Jacot-Descombres, who describe what they call a functional murmur of mitral stenosis in nervous irritable people affected with chloroanemia. These probably belong to the class so well described by Potain as cardiopulmonary, as do also the presystolic murmurs described by Flint and which led to the controversy between Drs. Flint and Balfour, the latter intimating that the former could not hear a murmur correctly. In regard to the cause, Whittaker says: "At the same time it must be admitted that many, perhaps most, accidental murmurs depend upon relaxation of the heart muscle, weakness of the papillary muscles, failure of adjustment of the orifice, producing or permitting a relative insufficiency with reflux of blood and eventually with some degree of dilatation."

Clifford Allbutt²⁴ calls attention to a lecture by Donald MacLain, published in 1882, in which he called attention to the diminution in size of the auriculo-ventricular orifice in complete, normal contraction, this being incomplete in muscular atony, in anemia, chlorosis, etc. In this connection it may not be amiss to recall the fact that Potain has shown experimentally that, post-mortem, the mitral valve will withstand an intraventricular pressure high enough to rupture the wall of the ventricle. On the other hand, the safety-valve action of tricuspid valves is quite generally recognized. He says again, however, "I lean to the belief that the solution will be found in some altered relation between the blood and the walls of the vessels, especially the pulmonary artery and conus arteriosus; so that an excessive vibration of the walls takes place," thus harmonizing with the views of the etiology of arterial and venous murmurs, which he believes to be due to "vibrations in the walls of veins, due to changes in the caliber of the tube at the root of the neck."

Inasmuch as these murmurs occur chiefly in chlorosis and other anemias any light on the actual condition of the heart in these conditions will be of aid in diagnosis.

Allbutt²⁵ says, in speaking of chlorosis: "The blood-vessels are slackened in tone, the beat is feeble and diffuse." "There is an increase of dullness to the right but not to the left." "The influence of respiration upon the murmurs is not constant."

Anders²⁶ says, "In chlorosis the heart is dilated." But he also says, "Murmurs are not rare and are not necessarily dependent upon dilatation."

Osler²⁷ says, in regard to the heart in chlorosis: "There is a slight increase in the transverse dullness."

Taylor²⁸ says: "The heart is dilated." "There may be fatty degeneration of the heart muscle." He also quotes the opinion of Goodheart, who says: "In the several conditions of anemia, the base of the pulmonary artery is morbidly dilated beyond the caliber of the orifice." Vierordt says: "The heart may be dilated." Musser says: "There may be dilatation, fatty degeneration or hypertrophy."

The next point to be established is the boundaries of the precordial space. In the adult, the right border of the area of complete flatness is at the left border of the sternum. The apex is in the fifth left intercostal space, two inches to the left of the sternum, or about one inch

inside the nipple line. In children, at birth and even up to 9 years of age, the apex is at or, in some cases outside, the nipple line. The apex limits the area of cardiac flatness on the left.

DIAGNOSIS.

The diagnosis of a case of organic disease of the heart is based upon the history of the case, together with an examination of the patient. The former usually reveals some antecedent disease, such as rheumatism, gonorrhea or some other infectious disease, the valvular lesion being recognized as a consequence, while the examination discloses certain constant pathologic changes, such as hypertrophy or dilatation or both, caused by the increased work of the heart, consequent upon the obstacle imposed to the onward flow of blood. In the diagnosis of a murmur we determine its character, rhythm, point of maximum intensity, direction of propagation, and area of audibility. Let us apply these methods in the investigation of the accidental murmurs.

History.—The history is that of the malady of which the murmur is at once the sign and consequence. It is that of chorea, some form of anemia, primary or secondary, some toxic condition, as alcoholism, wasting diseases, overexertion, as in young, untrained athletes or raw recruits, the febrile state, or after the loss of a considerable quantity of blood. The patient is more likely to be young than aged, and also to be of the female sex. Inspection confirms the history.

Palpation and Percussion.—These methods are of extreme value and should always precede auscultation. They show that the pulse corresponds well with the character of the cardiac impulse and is often of higher tension than would be expected, due, as Sansom believes, to the stimulation of vasomotor nerves by retained waste products. Thrills may sometimes be palpated. The cardiac impulse is commonly feeble and diffuse, the apex is not sharply defined and may be slightly out to the left, but not downward. There may be a slight increase in the dulness to the right, but there is wanting the pulsation and the impulse of a hypertrophied right ventricle at the lower end of the sternum. The left ventricle is not hypertrophied. In a word, there may in some cases be evidence of some dilatation, even of broken compensation, but not of hypertrophy, at least as a consequence of the disease of which the murmur is a sign.

Character of the Murmur.—It is usually soft and blowing, but may be harsh and rough, and is subject to considerable variation. It is claimed by some that it is influenced by posture, being louder in the recumbent posture, and thus contrasting with organic murmurs; also that it is louder during inspiration, and that sometimes it may be caused to disappear by holding the breath. Vascular murmurs may be associated with it.

Rhythm.—It is almost always systolic in time. The only exception is the one which is auricular systolic in rhythm and probably of cardipulmonary origin.

Point of Maximum Intensity.—An organic murmur usually corresponds to one of the cardiac areas, commonly has associated with it definite lesions of those valves whose normal sounds are heard in those areas, and which it either accompanies, replaces, obscures or follows. Accidental murmurs may be heard at any orifice or in any cardiac area, but usually at the base of the heart, and in the pulmonary area in the majority of cases.

Balfour emphasizes the statement that the murmur of pulmonary stenosis is heard with maximum intensity in the second left intercostal space, close to the sternum, while the accidental murmur is heard an inch outside of

this, where Walshe claims that the auricle comes in contact with the chest wall.

Area of Audibility.—Here there seems to be the widest diversity of opinion. Some observers claim that these murmurs have a very limited area of audibility, while others, equally competent, maintain that they have a wide area of audibility. Thus Sansom²⁹ says: "They are sometimes loudest at the apex of the heart, conducted into the axilla and heard at the angle of the scapula." Mackenzie says, "It is remarkable how loud and harsh the murmurs sometimes are." Again Sansom says: "The murmur of anemia can answer to all the criteria of one due to regurgitation from organic causes." However, it seems generally conceded that the murmurs heard in the pulmonary area as well as in the aortic area are limited in their area of audibility, gradually fading away in the vessels.

DIFFERENTIAL DIAGNOSIS.

In the differential diagnosis, let us apply the method of exclusion. At the four cardiac openings, eight murmurs may be generated. They are either systolic or diastolic. Let us consider the latter first. A diastolic murmur is perhaps the rarest of accidental murmurs, and for practical purposes it needs only to be differentiated from mitral obstruction. This may lead to some confusion because of the fugacious character of the murmur. In organic disease, it occurs in early life, is caused by rheumatic endocarditis, is usually harsh, rough or purring in character, may be high in pitch and is abruptly terminated by a distinct shock, the ventricular impulse and the first sound; and there is a distinct interval of time between the murmur and the second sound. There may be all the evidence of broken compensation, with hemoptysis, hematemesis, and embolism.

The left auricle is hypertrophied, the right ventricle always shares in the cardiac changes, there may be palpable auricular impulse and thrill, suddenly terminated by the ventricular systole. The pulmonic second sound is accentuated. Arrhythmia is present late in the case, and ascites may be present. When this evidence is borne in mind, a diagnosis should present no difficulties. The accidental murmur of articular systolic rhythm is probably a cardiopulmonary murmur.

The second point in exclusion is that in any case in which it can be clearly demonstrated that holding the breath stops the murmur, we are justified in concluding that we are dealing with an accidental murmur. The latter do not modify the heart sounds. This leaves us for consideration only the systolic murmurs, viz: aortic stenosis and mitral regurgitation in the left side and tricuspid regurgitation and pulmonary stenosis in the right. Mitral and tricuspid stenosis are apical murmurs, while aortic and pulmonary stenosis are basal. Of course if a murmur is heard with maximum intensity at the base, we can exclude mitral and tricuspid regurgitation.

Aortic Stenosis.—The history is one of infectious disease, atheroma, or strain, commonly in adult or late life and of the male sex. The pulse may be small, the pressure sustained, and is in strange contrast with the powerful cardiac impulse. The apex is out to the left and down, the impulse is heaving and thrusting in character and usually well defined, the pulse tracing is characteristic, the enlargement is all confined to the left ventricle, the murmur is heard with maximum intensity at the aortic interspace, is often harsh and rough, may spread laterally, is the only murmur that may be audible at a distance, or that may be perceived by the patient. The murmur is always transmitted into the great vessels. With such a condition no confusion can possibly arise.

Pulmonary Stenosis.—This is one of the most common of congenital defects, and the rarest of acquired lesions. It is the most frequent site of accidental murmurs. When a congenital defect, there is a history of having been a "blue baby," there is some cyanosis, hypertrophy of the right heart, which may here take place without dilation, murmur and the characteristic physical signs.

In addition, "arrested development, bodily and intellectual, prominent eyes, thick lips, distended veins, enlarged liver, defective development of the genital organs, clubbed fingers, cyanosis, liability to epistaxis, hemoptysis, convulsions, headache, somnolence or insomnia." (Whittaker.)

There is a strong tendency or predisposition to pulmonary and general tuberculosis, only 15 to 20 per cent. reaching adult life (Sansom), this being in marked contrast with the comparative immunity conferred by most other valve lesions. In accordance with Pascal's law, the right ventricle is hypertrophied, and may be dilated as well. The degree of the dilation determines the character of compensation, and the latter the symptomatology. When pulmonary stenosis is acquired, and due to endocarditis, it is nearly always secondary to other valve lesions, and the history, symptoms and signs will be that of the antecedent disease and the consequent valve lesion, the last link being the affection at the pulmonary valves.

The murmur itself furnishes no clue. In differentiating between pulmonary stenosis and accidental murmur at the pulmonary area, consider the foregoing, and remember Bishop Butler's advice that "probability is the rule of life."

Tricuspid Regurgitation.—Tricuspid incompetence is now rightly regarded as the most common heart lesion, and the "safety valve" action described by King is quite generally accepted. It is also generally conceded that the tricuspid regurgitation is a relative insufficiency and beneficent in its action and results, saving the valves themselves from injury, and protecting the pulmonary blood-vessels from rupture, and not generally due to endocarditis of the right side of the heart. In these cases, resistance to the flow of blood through the lungs induces tension in the pulmonary artery, distension of the right auricle and ventricle, with incomplete closure of the right tricuspid valve. At each contraction of the right ventricle, instead of the blood flowing forward into the overcharged pulmonary artery, a portion of it flows backward into the auricle, the large veins become distended, the accumulation of the blood induces and is relieved by the tricuspid regurgitation. Tricuspid regurgitation follows disease of the left side of the heart, and especially of the mitral valves, as consequence upon cause. The history will be that of an affection of the mitral valves, an acute endocarditis, emphysema, bronchitis or overstrain, and the symptoms and signs of the latter will be present. Sibson says of it: "It is a friendly sign; it warns you of inflammation elsewhere and relieves the ill effects of that inflammation. It is a danger signal, and a brake lessening the mischief."

When tricuspid regurgitation follows left-sided disease of the heart, it must be dilated in order to permit the regurgitation and the signs will be those of dilatation with broken compensation. When due to an acute endocarditis, as of gonorrhoeal origin, the murmur is a mere incident and these cases need not concern us here. Likewise in chronic bronchitis and emphysema, the disease usually dominates the cardiac lesion.

The concurrent signs will depend on whether the case

is one of acute endocarditis, relative insufficiency together with the cause of the latter; that is whether a pulmonary or mitral lesion.

In the latter the heart must be dilated in order that regurgitation be permitted. It follows therefore, that there will be the signs of that condition. The dulness is to the right of the base line, the apex is displaced, but the apex-beat cannot be felt, as the dilatation of the right ventricle prevents the left from coming anywhere near the chest wall. The cardiac impulse is diffuse and weak and will be best marked near the left sternal border. There may be systolic venous pulsation in the external jugulars and systolic venous pulsation of the liver. In regard to heart sounds, Balfour says: "The pulmonary second sound is always accentuated, as the increased pulmonary congestion which causes and maintains the regurgitation also keeps up the accentuation."

It should be mentioned in passing, that this is true in those due to relative insufficiency, but not true of those cases of acute endocarditis affecting the right side of the heart. In these cases, there is no accentuation of the pulmonary second sound. The symptoms will depend almost wholly on whether the case is of relative insufficiency or of acute endocarditis.

The murmur is systolic in time and heard best in the tricuspid area. An accidental murmur having the rhythm and point of maximum intensity of a tricuspid regurgitation, would exhibit a history of one of the conditions with which it is commonly associated, such as anemia, chlorosis, chorea, etc., there would be no antecedent conditions, such as pulmonary obstructions or mitral disease, and there are no consequent changes in the heart, with the exception already noted. It is the belief of many that this murmur of tricuspid regurgitation is the one heard in most cases of accidental murmur, when audible over the body of the heart.

Mitral Regurgitation.—This is the commonest form of valvular defect and is so familiar that a mere reference to it is sufficient.

The history of rheumatism, the hypertrophied and dilated right heart, the apex out but not down, the augmented impulse in the compensated cases, the accentuated pulmonary second sound, the apex systolic murmur with its wide area of audibility, all make up a clinical picture too familiar to need enlargement. And yet right here will be found one of the greatest difficulties. To positively distinguish between an accidental apex murmur with slight dilation of the right heart, and a slight organic lesion of the mitral valves with perfect compensation, is at times a matter of extreme difficulty and may occasionally be impossible. When an apex systolic murmur is present, together with a history of anemia, chlorosis, alcoholism, overexertion or the febrile state, with absence of history of rheumatism or other infection, characteristic appearance of anemia, want of increased relative value of the pulmonary second sound, absence of hypertrophy of the right heart, and with a fair pulse tension, we are justified in assuming that organic mitral regurgitation is absent.

In the febrile state especially, I have observed cases in which there was an apex systolic murmur, enlargement of the percussion flatness to the right, relative accentuation of the pulmonary second sound, the murmur having all the characteristics of quality, rhythm, point of maximum intensity and area of audibility of an organic murmur with compensation damaged, the impulse diffuse and weak, and I have seen these cases proceed to a perfect recovery and disappearance of the murmur; and I cannot escape the conviction that these are

cases of true relative insufficiency of the mitral valve, due to weakness of the myocardium, the auriculo-ventricular opening not being sufficiently contracted to allow the valve flaps to close, or else the distended walls cause enough tension on the chorda tendinae to draw the edges of the flaps apart, preventing perfect closure, "retraction into the ventricle of the leaflets of the valves from dilation of the cavity, thus serving to increase the distance between the point of origin of the muscles and the normal meeting place of the leaflets of the valves."³⁰

These are the cases of so-called curable mitral regurgitation. A correct diagnosis cannot always be made until the patient is cured.

CONCLUSIONS.

1. Accidental heart murmurs may occur when there is neither anemia nor fever, as in certain forms of intoxication.

2. Accentuation of the pulmonic second sound may occur in accidental heart murmurs.

3. An accidental murmur may be diastolic in rhythm.

4. The term "accidental" should be employed to designate all those cardiac murmurs which cannot, after careful examination, be clearly demonstrated to belong to the organic class, it being clearly understood that as our knowledge extends and increases, the number of "functional" maladies gradually diminishes. The latter term is simply a cloak which covers up our lack of knowledge. True, the same may be said of the term "accidental," and yet there is this to be said in its favor; it commits us to no theory of causation, indicates no pathology, avoids a discussion of the question whether functional disturbances occur without pathologic change, and above all, it erects no barrier in the way of progress.

5. While I do not believe that we are perfectly acquainted with all the physical conditions that can give origin to either cardiac or vascular murmurs, and while the error may be one of either observation or interpretation, I incline to the view that no single theory can be made to reasonably account for all accidental murmurs. I believe that there may be a relative insufficiency of either the mitral or the tricuspid valves, due to incomplete contraction of the heart, the latter due to degeneration, fatigue, or the effects of toxic agents, as in pyrexia, alcoholism, etc., and that under these circumstances, the murmur may not vary in any of its essential characteristics of quality, pitch and intensity or in point of maximum intensity and area of audibility, from regurgitation due to organic disease at the same orifice. The vibrations accord with physical laws. Tricuspid regurgitation is probably of much more frequent occurrence than mitral.

6. The theory of Potain in regard to cardiopulmonary murmurs seems a reasonable explanation of some of the accidental murmurs.

7. In all cases of organic disease, the vibrations originate in the fluid blood, due to the formation of "fluid veins." The theory that the accidental murmurs originate in vibrations in the walls of the vessels or of the conus, and are communicated to the moving column of fluid, and so not carried by it, does not seem quite reasonable but might serve to explain the limited area of audibility of some of these murmurs.

8. The wide diversity of opinion in regard to rhythm, point of maximum intensity and area of audibility would seem to indicate careful, accurate observations improperly interpreted or else an attempt to explain all accidental murmurs by one theory.

9. In many cases, especially of apex systolic murmurs, or in those heard over the body of the heart, a cor-

rect diagnosis cannot always be made without awaiting the results of treatment.

THE UTERINE FIBROID.*

WHAT SHALL WE DO WITH IT?

BY D. TOD GILLIAM, M.D.

COLUMBUS, OHIO.

If brevity is the soul of wit, it is also the essence of propriety on occasions like the present, where there is so much to say and so many to say it. But before going any further I wish to say that I have allowed myself a little latitude of expression, which it will be readily understood is not intended to detract from the dignity, nor question the motives, of that class of the profession of which I am an honored member, but rather to emphasize the points which I desire to make conspicuous. The question which appears as a caption for this paper has been asked many times before and as frequently answered according to the light and spirit of the times. Years ago, when hysterectomy and its allied operations were little less than the equations of death, the answer was: "Let it alone," and there were few who had the temerity to take up the knife in the face of hostile opinion. Then came the apotheosis of abdominal surgery. Old methods were revived, new methods devised, the death-rate was scaled down. Down, down, down, went the death-rate until, it would seem, there was no longer need of circumspection. A sudden revulsion seized the profession and was communicated to the people. The cry now went up: "Exterminate, exterminate!" and our mothers, wives and sisters moved toward the operating-table. In every land and clime men stood at the table. A knife was in every hand; on each table a woman. There was neither noise nor turmoil, nevertheless the knife went in and lives went out. It was a silent and stupendous tragedy! But many survived, and in surviving regained more than life. It was a blessed and broadcast beneficence! It was neither, it was both, we shall see by and by. At this stage a fibroid tumor to the surgeon was as a red flag to a bull; large or small, lobulated or smooth, it was odious to his senses and the signal for a furious, uncompromising onslaught. A diligent search was instituted for the

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

offender, and when one was found the unhappy possessor of it was doomed. From that moment her ears were assailed with the most harrowing and blood-curdling tales, and before her eyes a picture was held—a picture as black and revolting as ever came from the pencil of Doré, until at last the poor victim was fain to fly to the operating-table in sheer desperation.

This mighty crusade was not the offshoot of vice, neither did it betoken recklessness nor cupidity; it was the natural corollary of enthusiasm, an enthusiasm born of undreamed of success and grounded in the highest philanthropy. Was it a mistaken enthusiasm? Let us see: I give you two pictures taken from life. Mrs. P. discovers that she has a little menstrual disturbance, and being an intelligent woman, decides to call on Dr. X. for advice. Mrs. P. is a young matron of about four and thirty, and is the proud mother of two very interesting children. She has never had any sickness, in fact, has never been confined to her bed except at childbirth. She is well-formed, bright-eyed, rosy-cheeked, walks with a firm, elastic step, and enjoys a sense of perfect well-being. Dr. X. is a fashionable gynecologist, who commands a large following, does much surgery, and has an eye on the end of his index finger. In due time Mrs. P. is ushered into the cosy consulting-room and Dr. X. proceeds to explore the pelvis with that ocular finger. Suddenly he rolls his eyes upward, and with an air of extreme gravity says: "Madam I am sorry to inform you that you have a fibroid growth in the womb." "Do you think so, doctor? The doctor smiles, but deigns no reply. "Excuse me, Dr. X, I did not intend to question your skill, but the fact is I have been so well and felt so well all my life that it is hard to believe that there is anything much wrong." "Is it of much consequence?" "Of the utmost consequence." "What will have to be done?" is the anxious query. "There is only one thing to do and that is to remove the uterus." "An operation? I will never consent." "Wait until you have heard me. You evidently do not understand the significance of a uterine fibroid. You are well now, but it will not be for long. Soon you will be having hemorrhages and these will grow in volume and in frequency. Soon you will begin to suffer from pressure symptoms, the growth will impinge on and injuriously affect the bladder and the bowels. It will also press upon the ducts that carry the secretion from the kidneys. Later it will affect the liver, kidneys and stomach. The kidneys will become diseased, the heart will become diseased, the brain and nervous system become implicated, and not infrequently melancholia and insanity follow in the wake. When once these organic changes take place in these important organs there will be no redemption." "I will never consent; if I am to die, I will die a natural death, but I will never have an operation." "Very well; I felt it my duty to lay the matter before you, and now you have a duty which you owe to yourself and family which, unfortunately, I can not assume. It will not be long until your eyes are opened, but I cannot promise you that it will be in time. You will be tortured with pain and drained of blood, and will become distorted and unsightly, you will be tormented with a discharge which will not only make life miserable, but place a barrier between yourself and husband, you will grow old and haggard—" She puts out a hand appealingly and simply says: "I will go," but her lips are compressed and the color has fled from her face. In one week from that day she lies on the table, beautiful in her sleep. A red line followed the knife over the gentle swell of a faultless abdomen and

through the gaping wound the offending organ was removed. A little nodule not larger than a pigeon's egg marred the symmetry of an otherwise perfect specimen. In thirty-six hours there were two motherless children and a distracted husband. There was also desolation in one of the finest of homes. "Secondary hemorrhage" was the laconic inscription on the hospital card and the doctor took down his case-book and with a rueful face wrote in the result column a word of five letters.

But here is another picture. This time it is a woman of 43. She is not comely, whatever she may have been. She is the mother of three daughters—the eldest a girl of 20. They are poor. The patient is pale and almost cadaveric. She presents a marked abdominal protuberance. She spends much of her time in bed and has periods of flooding. In the intervals there is a profuse discharge of dirty serum. She has constant trouble with her bowels, is tormented with piles, and suffers much in many ways. Much of her little substance goes to the doctor, who, though poorly paid, is in almost constant attendance. She goes from bad to worse, though not continuously, for there are times when all the symptoms are abated. In one of these intervals she is induced to consult Dr. Y. Dr. Y. examines her in the presence of her family physician, and says: "Your doctor is right; this is a fibroid tumor. Furthermore it is of unusual size, is quite firmly impacted in the pelvis and is making serious inroads on your health." "But what am I to do; is there no help for me?" "I think there is. There are two roads open to us, either of which gives you a chance and both of which are attended with risk; one is to remove the growth, the other to leave it to Nature. In either event you will probably get rid of it, but, as I said, there is danger in both. On one hand you take the risks of a rather grave surgical operation, but should you survive you will be instantly and forever free from your affliction. On the other, if you should live until the change of life the growth will probably dwindle and in time cease to trouble you. But of this there is no absolute guarantee, and besides the change of life is often delayed by reason of the growth. It remains for you to choose." "I have chosen," she said composedly, "I want that thing taken away right off." A few weeks later, and just before the anticipated menstrual period, there was another table scene. Another red line followed the knife from epigastrium to pubis. A gaping wound disclosed an enormous distorted uterus. Deft fingers liberated adhesions, applied clamp and ligature, severed the attachments, and lifted out the mass. A month later this self-same woman returned to her home. The fires were bright on the hearthstone, but the fires of hope and joy and love were brighter in the hearts of that little group that gathered around it. A year later, and this poor, wan, suffering creature that we presented at the beginning has regained flesh and blood, health and good cheer and moved in and out among her family and friends, the happiest among them, for she had been in the depths and knew the value of life.

I cite one other case which gives us another phase of the subject. In this I shall use the first person, for there is neither that to be ashamed or proud of. The patient was a maiden lady of uncertain age, of magnificent physique and excellent mind. I found her with a fibroid of about the size of a pregnant uterus at the fourth month. I placed her on electricity, which I gave continuously and after the most approved method of the day. Despite this the tumor continued to enlarge; she had

a constant watery discharge and at intervals profuse hemorrhages. Besides, she suffered greatly from pressure symptoms. The tumor finally attained the dimensions of a seven-months pregnancy; all the symptoms became aggravated; she became exsanguinated, and of anxious countenance. I then suggested hysterectomy as the most feasible procedure, which she neither declined nor accepted, but continued to drift. She then passed out of my hands, but evidently went from bad to worse, as she was much of the time confined to her bed. After a few years she began to appear on the streets, and now she is taking an active part in club work, looks hale and hearty and has all the indications of perfect health.

What are the lessons inculcated by the illustrative cases just cited? We see in the first case the tragic taking off of a young and lovely woman, wife and mother through the overweening zeal of an overconfident gynecologist. In the next we witness the inestimable benefits from a timely operation in a bedridden woman whose social condition demanded immediate relief. In the last we are taught that even most unpromising cases may and do recover without operative interference. I claim that operative interference in cases like the first is unnecessary, unjustifiable and criminal. I am aware that in making this assertion I am stepping on somebody's corns, that some very good men take a very different view of the subject, and I am willing to accord to such honest convictions. But by far the larger number of the adherents to this policy is made up of beginners who are anxious to make a record and who are willing to take chances to further their ambitious designs. Last, there are a few, and I blush to speak of it, who are neither young nor inexperienced, who are neither wanting in skill nor intelligence, who recognize the unequal chances they are imposing on those entrusted to their charge, but who nevertheless enter the arena open-eyed and juggle with human life for the lucre there is in it. Of such is not the kingdom of heaven.

Specious arguments are adduced in favor of early interference.

It is claimed that the uterine fibroid is inherently dangerous; that aside from the distressing symptoms that attend pressure on contiguous organs, it leads to grave lesions of the kidneys, heart and brain; that the patient is in danger of fatal hemorrhage; that by sapping the vital powers it renders her an easy victim to intercurrent disease; that the fibroid growth is prone to degenerative changes and especially malignant degeneration; that it does not cease to take on growth at the menopause, but, on the contrary is apt to take on renewed vigor, and lastly, that the operation is attended with much less difficulty and danger in the earlier stages of its development. This would indeed be a specious, I might say unanswerable, argument if the premises were correct. In the first place, it cannot be shown that the uterine fibroid is naturally and inherently dangerous to life. If such cases were the cause of the mortality from this cause in times ago must have been appalling. Kolb says that 40 per cent. of the women who die after the fiftieth year are found to have uterine fibroids. According to this from one-third to one-half of woman-kind attaining to the age of 55 years must have perished from this source. Fatal hemorrhage from a uterine fibroid is one of the rarest of rare occurrences. One of our authorities—I believe it is Skene—claims that it seldom if ever occurs. I have never seen a case. Of the complications from heart and kidneys we have few instances of death, indeed it is a rare thing to see a woman die from uterine fibroid. I have been in the

practice of gynecology for many years, during which time I have had to deal with scores, yea hundreds, of cases of uterine fibroid in all stages and conditions, and I cannot now recall a single instance in which the victim succumbed to the growth or any condition attributable to the growth. Indeed, it has seemed to me that such patients enjoyed a peculiar immunity from life-destroying diseases. I have seen fearful hemorrhages, in which the patient was reduced to the last extremity, but she always rallied. I have witnessed mechanical obstruction to the bowels and bladder that threatened dire consequences, but in time they adjusted themselves, and the patient enjoyed a period of respite. I have seen the urine loaded with albumin, but have never known such to lead to a fatal issue. I have never seen one die of heart failure unless she had been on the operating-table. I have never attended one in whom death could be traced to malignant degeneration of the growth.

I did panhysterectomy for one case of enormous suppurating fibroid that must have inevitably died had she been left alone. I have removed several uterine fibroids that gave strong evidence of malignant degeneration, but these were rare as compared with the number of cases in which no such indications existed. I have seen very few cases in which the tumor continued to grow or showed increased activity after the menopause; on the contrary, I have seen many cases in which the retrogression was marked and continuous. I have seen many cases of smaller fibroids which never attained a size that gave the patient any concern. I have seen many others of various sizes that remained stationary throughout years of observation. On the whole, I have come to look on the uterine fibroid as comparatively innocent, in so far as its life-destroying propensities are concerned. I do not deny that it may, and sometimes does, kill. I do not deny that in its more aggravated forms it is capable of making life unbearable, but what I do contend for is that a very small proportion of the incipient fibroids ever attain to a size to give serious trouble, and that the growth is in a large measure self-limited. Were we to attempt to exterminate all the uterine fibroids lest they should grow and become complicated, we should have to unsex nearly one-half of woman-kind, and while we were doing this the tubal pathologist would demand the other half, and one generation would put a period to human existence. I do not know what the death-rate for hysterectomy is, but it must be vastly greater than that from the fibroid if left to itself. As a life-saving agency, therefore, we must abandon the knife except in rare and carefully selected cases. I am reminded that I held different views a few years since, and that in a paper read before the Mississippi Valley Medical Association at Detroit, I advocated a very different course. In reply I will say that the man who would not change his mind must cease to think. The changeless mind is the prerogative of fools and infallibility. But I have not changed so radically as might be supposed. I never advocated the removal of the unoffending fibroid. I did, however, go so far as to say that any fibroid that was a menace to life, health, or happiness should be removed. I do not retract that saying, but modify it. I have been in the practice of gynecology for many years, and have attempted to keep in touch with my fellow workers. I have read the same literature, discussed the same topics, have imbibed the same ideas, have been imbued with the same enthusiasm, have been actuated by the same aims and purposes. But I have also been in the same swim—

that turbulent, turmoil of waters that engages the whole soul and attention, that shuts out the horizon, the past and the future, and blinds the senses to all but that which is going on around one. In the midst of all a wail comes to my ears. It is the wail of a bereaved family, of husband and children. It is the wail of that family from whom was snatched in the full bloom of health one of the loveliest and most exemplary of wives and mothers. I pause, listen, think. I lift myself from the turbulent waters that I may collect my faculties, and now for the first time I get a bird's-eye view of the whole scene. If a man would see a battle he must not engage in it; rather must he withdraw himself to some commanding height where the eye can take a wide range. From this vantage-point I looked far backward into the remote past. I marshalled before me the hosts of women who had lived and died naturally despite the fact that many, very many, carried about with them uterine fibroids. I then cast my eye into the busy waters from which I had just extricated myself, and the words of Burns came to me:

O wad some power the giftie gie us,
To see oursel's as ithers see us.

What shall we say then; shall we lay aside the knife? By no means; in the future, as in the past, the surgeon's knife will continue to be afflicted woman's last and best friend. But the knife of the future must have a brain and a conscience behind it. What I contend for is greater circumspection and more conservatism on the part of the surgeon. Let the smaller and less mischievous growths alone. They may or may not give trouble in the future. Ten to one they will not, but if they should, it will be time enough to consider them when the exigency arises. Should you be called hence before that time, have no fear, for wisdom will not die with you, and the art of surgery will still survive. As you journey along life's path you will meet some cases, few though they be, which your judgment and experience will admonish you are inherently bad. In such it will be your privilege and your duty to urge and insist on radical measures. But in by far the larger number you will have no such assurance, and then you will be confronted with the ever-recurring question: "What shall we do with this uterine fibroid?" I hold that it is the patient's prerogative to decide. It is a right vested in the human race to incur risk for the betterment of condition. Men are continually taking such risks, and we regard them with complacency and commendation. They go down into the mines, climb steeples, grasp the throttle of the flying locomotive, toy with nitroglycerin, fight fire, brave the dangers of the deep, and in a thousand and one ways take their lives in their hands in order to better their condition or that of those dependent on them. Why, then, should woman be deprived of this same priceless privilege? Her sensibilities are more acute, her instincts stronger, her social relations closer, and her duties as imperative as those of man. But over and above all this, her capacity for loving and her yearning for love are beyond the comprehension of man, for with her love is the sum total of life. If, then, she finds herself a burden on those upon whom she is dependent; if life has become intolerable to herself and she feels that she is making it so for others; if by reason of deformity, irritability of temper, loathsome discharges, inability to perform her wifely duties, or any other cause, she finds that she has become a tax on her husband's forbearance or fortune, then I say she has a right to choose, even though that choice carries with it a degree of personal danger. And she, having chosen, knowing

the danger, it is your duty to give her the benefit of your experience and skill. The list will not be so long perhaps as under the present régime, but it will be long enough.

There is a wiser and better day coming, and succeeding generations will judge you by the light of that day. In that day your children or grandchildren will take up your musty old record-book and scan its pages. They will not appraise you according to the number of hysterectomies you have performed, but according to the character of your cases and the animus back of your work. Some will pore over long lists in which the cases mount into hundreds, but as they proceed their cheeks will burn, and should they hear an approaching footsteps they will cover the page with their hand. There will be other lists, be they long or short, which will be studied with interest and pride, and when at length they are finished the musty old book will be carefully laid on the shelf and the reader will turn away with the half audible exclamation: "Bless his old soul; he was honest." And, when life's race is run and you enter the pearly gates, which all of you will, except a few of my competitors, you will meet many scarred bellies, some of which will bear your private mark. Happy will it be for you if, in glancing over the list charged up to you, you shall find opposite each name the verdict: "Justifiable homicide."

DISCUSSION.

DR. WALTER B. DORSETT, St. Louis Mo.—This paper covers a good deal of ground and represents some very vivid pictures which possibly all of us have seen, particularly one of the first drawn, of a beautiful woman and child taken away from her family. The second case related by the Doctor is a picture we have seen occasionally, one we appreciate after having done the operation described by him, and one which gives us a great deal of satisfaction.

This question of the indications for operation for fibroid tumors is one that I have approached very cautiously and steadily, and I think we may sum it up possibly under three headings: The first is hemorrhage, which, of course, includes the dirty discharge coming away from the patient all the time, and that class of cases that are anemic, that have lost great quantities of blood, those in which the tumor has been supplying the life-blood of the patient possibly for several years. The next indication is that of rapidity of growth. Rapidity of growth usually indicates malignancy; it indicates cystic degeneration, or it indicates carcinoma. The third indication is the general inconvenience of the patient, or general discomfort of a patient who is suffering from fibroid tumor; those in which the digestive apparatus has been interfered with; those in which patients are suffering more or less from ptomain poisoning on account of constipation due to the mechanical interference with the rectum and the bowels, and those in which adhesions are formed. Many of us possibly have seen those cases in which, whether the tumor be intramural or subperitoneal, we find masses of adhesions. In a case of subperitoneal growth we will find the tumor largely nourished by adhesions. I have, in a number of instances, particularly in those cases where electricity has been tried and has failed, seen large vessels coming off from the omentum through which the nourishment of the tumor was undoubtedly kept up.

DR. C. R. REED, Middleport, Ohio.—I consider the management of fibroid tumors one of the most important subjects that comes within the province of the gynecologist. When a small fibroid tumor is discovered in the pelvis of an otherwise healthy woman whose life is not endangered and who seems to be comfortable, I do not think it wise to urge operation for its removal, nor do I think it prudent for the physician to inform the woman that she has such a fibroid. There are many women who have small fibroid tumors and do not know it. I think it is wrong to tell them that they have fibroid tumors, because the majority of women, after having received such information from the physician, magnify the effects from these growths and claim that they suffer when they really do not. If left alone, nine out of ten of these cases will gradually disappear. Let me give an instance that came under my observation; a woman of middle age, in a fair degree of health, of somewhat neurotic temperament, but well nourished, complained of some obscure symptoms. I made a vaginal examination and discovered a small fibroid tumor about the

size of a small egg. I doubted whether it had anything to do with her nervous symptoms; still, I incautiously and wrongfully told her she had a fibroid tumor. I should not have done it. She immediately magnified her symptoms, and thought she was an invalid and in danger of dying from it. She consulted a prominent gynecologist, who examined her, and said to her, "Madame, you have a fibroid tumor." She asked him how large it was, and he replied, "About the size of a cocoon," and added, "you will have to have it removed. You are in great danger, and after your next menstruation if you will come to my office, I will remove it for you." This was adding fuel to the fire. She was greatly depressed with the idea that she had to undergo an operation. She went to the hotel greatly depressed, and her husband said, "Let us consult Dr. Reed, we have known him for a long time. You have been under his treatment for your nervous symptoms." They did so, and I advised them to consult another practitioner, a man of great ability. This they did, and after a careful examination, he said, "Mrs. C, you have a fibroid tumor; it is as large as an orange, perhaps, or as large as the fist of a small hand; but it is not distressing or troubling you, and if you go to a hospital and rest for some time, you will go home better. Do not let this small tumor worry you." The woman said, "Doctor So-and-so told me that the tumor was as large as a cocoon, and advised me to have it removed." "Well," said the physician, "he is an operative gynecologist, and that is his business. You might expect such advice from him." The physician told her that he had known fifteen or twenty women who had had fibroid tumors, some of whom were operated upon, and died, and some of whom were not operated upon, and are still living. However, the woman went to the hospital, remained there for two weeks, and then came home. She has not been sick a day since. This was five years ago. She is now the picture of health. She has her opinion of those two physicians.

I have known cases similar to the one mentioned and which have come under my observation during the last twenty-five years, and the women have enjoyed a fair degree of health and are living yet.

The paper covers the ground very thoroughly; it is admirable. I wish to repeat that, when we discover a small fibroid tumor, and a woman does not know that she has it, it is our duty not to let her know it. She will be better for it; she will enjoy life better as long as the tumor is not menacing her health.

DR. W. A. TICHENOR, Chicago.—I have not very much to say with reference to this paper except to commend it. I think the Doctor has struck the keynote in outlining the cases that should, and those that should not, be operated on. I am free to confess that a number of cases have been operated on for the removal of fibroid tumors in which the entire uterus was extirpated, and, in all probability, in the present light of advanced surgery, they would have done just as well had they not undergone surgical operation. We all know that three or four years ago there was a craze for operating, but the pendulum is swinging back the other way, and we are occupied with a happy medium. We are learning better what to do, and we are acting accordingly. The Doctor spoke of the class of cases that should be operated upon, and clearly outlined the class of tumors that need hysterectomy. I do not believe he referred to myomectomy. I do not really know how many are doing that operation, but I do not believe it will become a very popular operative procedure. Tumors suitable for myomectomy are those the size of a hickory nut, a hazel nut, or a small orange, and are usually intramural or subperitoneal: They can be shelled out through the vagina. These tumors push their way from beneath the peritoneum covering of the uterus, and as soon as they get out from the uterine wall they carry the peritoneum with them. The indications for operating on intramural subperitoneal fibroids are pressure symptoms on the bladder or rectum, or hemorrhage. This character of tumor, on account of the form of its pedicle, does not cause much disturbance. When the tumor is submucous, it begins to interfere with the mucous membrane, pushing into the cavity and causing severe uterine contractions, which of themselves will cause hemorrhage. After awhile they may assume the form of polypi and you can twist them off. Then, there is the interstitial variety; the whole tumor is peculiar; it is soft, vascular, grows rapidly, and no kind of intrauterine local application seems to have any effect. It is more liable to cystic or malignant degeneration and bleeds freely. In a tumor of that character hysterectomy is the operation to do. I had occasion about five weeks ago to operate on a case that had seven small fibroid tumors the size of a guinea egg to a hazel nut, the case being complicated by an ovarian cyst. I removed the cyst; a competent surgeon was standing by, and I asked him about doing a hysterectomy or dropping the uterus back into

the abdominal cavity. He said, "I think you had better take the uterus out." As he was a man of considerable experience, I followed his advice, removed the uterus, and left the other ovary, which was normal. The patient did well, and has gone home. But I believe, if left to my own judgment, I should have left the uterus. In these cases I believe it is the consensus of opinion that if we leave some healthy uterine tissue we do not have excessive neurotic troubles follow.

The Doctor spoke of one case that went on to recovery in which he used electricity. He did not tell us if he continued its use until the patient got well.

DR. GILLIAM.—The patient passed from under my care, and I did not see her for probably a year.

DR. TICHENOR.—I do not know how much efficacy there is in electricity in the treatment of these tumors, but I am using it, although my experience is limited. I have a battery in the office; it looks well; it makes a good show, and a good many talk about it, and say it is a good thing; it makes a pretty piece of furniture. I have studied how to use the copper intrauterine electrode; I wrap cotton around it, saturated with copper salts or nitrate of silver salts, and by the cathaphoric action try to drive some of these salts into the tissues; the salts will harden the tissues, and thus prevent hemorrhage. I think in one case it benefited the woman, as she did not bleed as much. The swallow, however, does not make a summer.

DR. MILES PORTER, Fort Wayne, Ind.—I wish to thank Dr. Gilliam for having presented this matter. There is hardly anything in it with which I cannot entirely agree. This paper, together with what has been said in this Section before on the subject of uterine fibroids, coupled with the symposium on hernia, though widely different subjects, teach us important lessons. In connection with the treatment of fibroid tumors we are told by one that they should be removed under all circumstances, while another narrates cases with similar histories, in which he allows the tumors to remain, with the most happy results. This diversity of opinion amounts to this: there are no hard and fast lines which can be laid down even for the treatment of the simple cases that come into the hands of the surgeons. Each case is a law unto itself, and this is particularly applicable to the treatment of fibroid tumors. It is true, as Dr. Gilliam has remarked, that after the menopause hemorrhage is not to be feared as a general rule; yet singular as it may seem, the first fibroid I ever removed was taken away for the purpose of arresting hemorrhage which did not come on until after the establishment of the menopause. Again there are young women who are looking well, feeling well, who are the subjects of fibroids, but they do not care to carry protuberant abdomens. Such women consult doctors and desire to be relieved of their tumors. They say, "What are the chances, Doctor?" I believe a woman should be given an opportunity to have the tumor removed, if she so desires, but in giving her that opportunity the personal question comes in. To say to a woman that the mortality from the removal of fibroid tumors is so-and-so because of having arrived at that conclusion from the great bulk of cases reported is not giving the woman an answer which she deserves. She is going to Dr. Gilliam, to Dr. Porter, or somebody else to have the tumor removed and she is going to have it removed, and what she means when she asks that question of mortality is, what will be the probable mortality when you do this operation? It is unfair for us to give these women the general mortality from these operations, when, personally, our individual mortality may be only 2 or 3 per cent. The general mortality may be 10 or 15. So I believe the personal equation, in so far as it applies to the operator and individual upon whom you are going to operate, should enter into the decision of this question. After all, each case should be treated upon its merits, and the best one to judge of the merits of the case is he into whose hands the case is placed for treatment.

DR. J. D. GIBSON, Birmingham, Alabama.—I believe one of the gentlemen spoke of a case in which he thought the uterine fibroid was nourished by the use of electricity. He implied in his remarks that the original source of hemorrhage probably had been relieved by electricity and the tumor was nourished afterward entirely by peritoneal adhesions. I would like to know if it is customary, after the treatment of fibroids by electricity, for them to be nourished; those not treated by electricity, are they nourished by peritoneal adhesions?

DR. WALTER B. DORSETT, St. Louis, Mo.—I can give only my personal experience, and that is that all the cases that I have operated on which have been treated previously by competent electricians have had adhesions, and in some of them the adhesions were large, and doubtless in other cases the tumor was nourished principally by the adhesions. I operated on a physician's wife two years ago where an artery and vein came down from the omentum, nourishing the tumor. One of them was

large as the femoral; the other as large as the radial. In this case the tumor was undergoing degeneration. She had refused operation a number of times. She was treated by a competent physician for malarial fever; the plasmodium malarie were found, and the patient went from bad to worse, and finally I was called back, and the physician said: "Doctor, we are going to have an operation performed just as soon as she gets stronger. What do you think about it?" I said to him: "My dear friend, she will never be any stronger than she is to-day." She had a temperature of 102 when put on the table, and never had a temperature over 99.5 after operation. An abdominal section was made, the tumor removed, and it was found to be degenerated. There was pus found in the center of the tumor. This case was treated by electricity for five years off and on, one in which the principal amount of nourishment to the tumor came from the omentum and the bowel. It was a subperitoneal fibroid.

In regard to subperitoneal, intramural and submucous fibroids, I have this theory: These tumors are migratory to a certain extent. In other words, we may have at the beginning an intramural fibroid; later it becomes submucous or subperitoneal, and this changed condition is brought about by the peculiar construction of the muscular fibers, together with the contraction of the uterus incident to menstruation. By this mesh-like general distribution of the muscular fibers the tumor becomes changed, so far as its location is concerned. It is migratory. You can readily understand that, if you use the faradic current in a case of this kind, it produces contraction of the muscular fibers of the uterus, and while the tumor at the beginning of the use of electricity was possibly intramural, by chance, and by chance alone, it became subperitoneal. If it had been located in the beginning, it might have been found nearer the mucous than the peritoneal surface.

Dr. W. D. HAGGARD, JR., Nashville, Tenn.—The use of electricity undoubtedly gives rise to complications connected with fibroid tumors, particularly adhesions. I do not think Dr. Dorsett means to be understood as saying that all peritoneal adhesions, particularly the omentum, are due to electricity. Personally, I recall a case of huge fibroid, weighing thirty pounds, which had a pedicle nearly as large as one's three fingers, and the entire nutrition of the growth was derived from the omentum. Huge veins came down as large as fingers. This case was not treated by electricity at all.

Dr. GILLIAM, closing the discussion.—I wish to thank the gentlemen for their kind reception of my paper. I shall have very little to say in conclusion. I thought I made myself understood as well as I could considering the short time at my disposal. There are two or three points brought out in the discussion that I would like to explain. In the first place, I do not want to go on record as being opposed to operation for fibroid tumors.

I have done a great many of these operations, and I expect to do them in the future. I am opposed to unnecessary operations. An operation is more or less dangerous, no matter what we may say to the contrary. I tell a patient what I think her chances are, and in doing that I consider the personal equation Dr. Porter speaks of. If life is made unpleasant by the presence of a fibroid tumor; if she wants an operation done for its removal, I might probably advise her to have it done, but I do not insist on having it done. By this means I avoid taking upon myself the responsibility that would weigh heavily upon my conscience for the rest of my life. If she is determined to have an operation done, then I render her my best and most faithful service.

Dr. Reed spoke of one point that I desire to touch upon here. He said that women carry small fibroids, and if he finds them during the course of an examination he does not tell them anything about the matter. In the majority of cases a fibroid is going to be an incubus to the woman; it is going to make her unhappy, and there is danger of her drifting from one physician to another. You try to be honest; you give an honest opinion that you have discovered a fibroid. If you do not tell the woman this, if she is dissatisfied, she will consult another doctor. He will tell her that she has a fibroid, and urge its removal. By reason of the latter advice she either undergoes an operation or is so frightened that she will probably never get over the effects of it. Is it not much better to say to these women: "Madam, you have a little fibroid in the uterus; don't get frightened. These tumors are common; nearly all your neighbors have fibroids, and the reason I tell you is simply because somebody else will do so after a while and probably frighten you; the chances are it may not hurt you during your lifetime. If it should hurt you, consult some good conscientious surgeon, let him advise you in the case." When you speak to them in that way, they are armed for anything that may occur hereafter, and they do not worry about it.

A lady came to me a few weeks ago, who stands high; she is

a woman of brilliant intellect. I examined her and said, "you have got a little fibroid about so large." She said to me, "You told me that five years ago." I did not remember her. I do not remember the faces of my patients very well. However, she was going to Europe, and she felt a little uneasy. I happened to be writing my paper at this time, off and on, and I said to her, "let me read you a few lines of this paper, and explain some points to you." I read a little to her, and she was anxious to hear more, and before I got through her mind was relieved, and she left the office in a happy mood.

CATAPHORESIS IN TRACHOMA.*

BY GEORGE F. KEIPER, M.D.

LAFAYETTE, IND.

The word "cataphoresis" is derived from two Greek words.** The word "catalysis,"*** is often used synonymously with "cataphoresis," and incorrectly. Cataphoresis is a subdivision of the electrical process called catalysis. Cataphoresis, as now understood, is a process whereby medicinal substances are introduced into the body, through skin or mucous membrane or both, by the help of the galvanic current.

Synonyms.—Anodal diffusion, electric osmosis, voltaic narcotism, electric transportation, anaphoresis, electric medicament diffusion, and electric transfer of particles and liquids, are the synonyms in use.

History.—The process is not a new one, though it is attracting more attention to-day and has been for the last ten years, than ever before. Dr. B. W. Richardson, in 1859, wrote two articles on "Voltaic Narcotism." In October, 1858, after vainly trying to produce anesthesia in a rabbit's ear, by the electric current alone, he used a solution of morphin at the positive pole of the battery and succeeded in anesthetizing that organ. Then he used tincture of aconite at the positive pole with the same result. He used the following solution:

B. Tinct. Aconit.	3iii	3/90
Ext. Aconit. Aleh.	3i	1/30
Chloroform	3iii	3/90

He put the positive pole of the battery, wet with one-third of the above solution around the upper part of the shaven hind leg of a dog. The negative pole was applied to the ankle. Eleven minutes sufficed to produce complete anesthesia to sticking pins. Then the tendo Achillis was severed without pain. In one hour the leg was amputated without any pain, except when the bone was sawn through. Then the dog cried out once, but probably from terror. Twenty minutes later the dog ate heartily and walked around on three legs quite unconcernedly.

A nevus one inch in diameter was subsequently removed from the shoulder of a ten-weeks-old baby, after a half hour's application of a solution of chloroform and tincture of aconite, 5 drops each, applied to the positive pole. A strangulated hernia was also operated on by this method, and then a tumor of the shoulder on a patient 47 years old was removed, all of which were painless.

Richardson's work aroused a storm of opposition on the Continent and in England and for twenty-five years it lapsed into obscurity.

Wagner, in 1886, reintroduced the subject to the profession. Adamkiewicz, in 1886, described a diffusion electrode for introducing chloroform into the tissues. In 1889 Peterson called attention to Richardson's experiments and theory. Opposition and criticism again greeted its revival, but to-day it has all disappeared.

*Presented to the Section on Ophthalmology, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

**Kata, down, and Phoresis, to bear.

***Kata, down, and Aves, to loose.

Apparatus.—A good battery, say of twenty cells. For good results the plates must be clean and the zinc plate well amalgamated. The solution ordinarily used should be fresh. A switch-board in the commercial circuits is best.

2. A good milliamperemeter—the Kenelley or Weston are the best, because they are not influenced magnetically by the presence of iron in the immediate vicinity. The work previously done in this line has lacked scientific accuracy because the current has not been measured. No current should be passed through any person unless accurately measured. Many of the articles written speak of the use of from ten to twenty Grenet cells in producing the effects to be afterward described. This may mean much or little. If the battery fluid be old and nearly exhausted, or the carbon plates dirty and the zinc plate not properly amalgamated, and the connections poor and dirty, there will not be very much current, otherwise there will be. Hence there is no scientific accuracy in publishing results thus.

3. Proper conducting cords with proper tips for making connections between battery and electrodes and battery and milliamperemeter are essential.

4. Such electrodes as may be necessary. For forcing in solutions of drugs, the ordinary carbon electrodes of various sizes are best for ordinary use. Special ones will be described later.

5. Plenty of absorbent cotton to take the place of the dirty and filthy sponges now in almost general use on the electrodes is another necessity.

Theory of Cataphoresis.—If a vessel be divided into two distinct and separate compartments, by an animal membrane, and each side be filled to the same level, the one with a dense liquid and the other with one lighter in density, there will take place what is known as osmosis, whereby the lighter liquid will travel through the membrane to the denser. After a time the level of the denser will be higher than that of the lighter. Now, if the positive pole of the galvanic battery be placed in the denser and the negative pole in the lighter, the denser will be driven through the membrane into the lighter in direct opposition to the natural process of osmosis, i. e., the liquid travels in the direction of the current—from the positive to the negative pole. The effect is mechanical, for no decomposition takes place if carbon or platinum electrodes be employed.

Experiment: Take two porous cups and place them in a basin of water. Fill each to an equal height, with water. Put the positive pole of the battery in one and the negative in the other. Turn on the current and after a time the level of the water in the cup wherein is the negative pole will be higher than in the cup containing the positive pole. In fact the water will in a measure leave the cup containing the positive pole and its level may be lower than the surrounding water in the basin. Thus, with this simple experiment it is possible to make solutions travel in the direction of the electric galvanic current.

Physiology of the Process.—*Experiment:* Take a frog, keep its skin wet with a 2 to 5 grain solution of strychnin sulphate, and in a few minutes it will die of strychnin poisoning. The skin absorbs the strychnin. The skin of man and other mammals does not absorb substances readily because of the fat present in the epidermis and pores. Remove the fat with ether and the skin becomes more permeable. Massage, coupled with cutaneous medication, helps absorption by forcing the medicine into the pores. If the epidermis be removed either by abrasion, burn or blister, absorption will take place rapidly.

Experiments: Apply the positive pole of the battery to the back of the hand and the negative pole to the palm, and turn on a current of five milliamperes for from ten to twenty minutes. No anesthesia is produced.

Apply a 10 per cent. solution of cocain to the back of the hand and leave it there until the water is evaporated. Then apply more and thus continue the process until twenty minutes shall have elapsed. No anesthesia is produced.

Take a small carbon electrode, cover it with cotton and moisten it with a 10 per cent. solution of cocain. Attach it to the negative pole of the battery. Hold it on the back of the hand, grasping the positive pole in the palm thereof. Pass a current of five milliamperes for ten minutes. The result is no anesthesia, but hyperesthesia at the negative pole.

With the same electrodes as above, apply the electrode covered with cotton moistened with cocain to the positive pole. Put it on the back of the hand which grasps the negative pole in its palm. Turn on a current of five milliamperes for ten minutes, and the result is anesthesia to pain, touch and temperature.

H. Munk,¹ in a series of experiments found that he could as above introduce sufficient strychnin through the skin of a rabbit to cause it to die of strychnin poisoning in a few minutes. Quinin and potassium iodid introduced thus have been detected in the urine. What is true of cocain, quinin, strychnin and potassium iodid is also true of aconitin, mercuric bichlorid, guaiacol, metallic mercury (Massey), peroxid of hydrogen, sodium chlorid, morphin sulphate and lithium salts.

Peterson has thus summarized the physiologic action: "The galvanic current alone does not produce anesthesia at either pole, although the anode—positive pole—has a soothing effect over painful foci. A watery solution of cocain applied to the skin is not absorbed and does not produce anesthesia except, perhaps after an indefinite and long period. The same is true of chloroform and of an alcoholic solution of aconite. A watery solution of cocain is diffused through the skin and subcutaneous tissues by the anode, but not by the cathode. This is true of chloroform, aconite, strychnin, potassium iodid, corrosive sublimate, tincture of iodin and a number of other medicaments. Chloroform had better not be used this way unless a vesicant effect be desired. By this process a dermatitis is produced, the effect lasting for a week to ten days.

Haynes summarizes the effect of the direction of the current thus: "The galvanic current used to produce electrolysis on living tissues accomplishes results by utilizing three properties of current. 1. The chemical property into which the electricity is converted and manifests itself in the fluids and semifluids of the body contiguous to the electrodes—catalytic action; 2, the physical properties, due to the disintegration of the electrodes and the transference of substances through the tissues—cataphoric action; 3, the physiologic properties of the galvanic current as it produces trophic changes in the tissues."

In connection with this must be considered the solution of the electrodes themselves, and if placed at the positive pole the cataphoric action obtained by the solution of the electrode penetrating the tissues in the direction of the negative pole.

Experiments: Take a piece of fresh, juicy, lean meat, and put on one side a carbon electrode connected to the negative pole. To the positive pole attach a pure copper needle and insert into the meat; turn on the current. After a time on cutting the meat open around the needle an apple-green stain will be found. This is diffused in

the direction of the negative pole. Or, putting a blunt pure copper electrode on the surface of the meat, we get the very same stain. Chemical analysis of the stain shows it to be the oxychlorid of copper; it is a powerful germicide. In the reaction, HCl and H_2SO_4 and O have been formed, which, uniting with the copper, form the oxychlorid of copper, and this, being soluble, is diffused by the cathodic action of the current in the direction of the negative pole. It will also be seen that the needle used is difficult to withdraw after the current has been on. This is probably due to the albuminate of copper formed holding it fast. By reversing the current the needle can be easily withdrawn after a time. Not only is this true of copper but it is also true of iron, lead, zinc, and brass, which are readily soluble. Tin, silver and aluminum are less readily soluble. Carbon and gold are the least resistant of all the metals. Platinum and platinum with its alloy of iridium are not acted on at all!

THERAPEUTIC INDICATIONS.

For Relief of Pain.—In neuralgia, cataphoresis with a 10 per cent. solution of cocaine or cocaine with guaiacol, which is preferable, produces anesthesia which lasts from four to eleven hours electricity alone producing a transitory effect.

In tubercular laryngitis, by placing the positive pole wet with guaiacol on one side of the larynx externally, and the negative pole on the other side externally, relief from pain is usually prompt and the effect lasts about twenty hours. Guaiacol is to be preferred to creosote as being less irritating; in fact guaiacol is creosote deprived of its irritating properties. Lactic acid and eurentment may be abandoned.

"In cutaneous operations," Dr. Dawbarn writes, June 10, 1889: "I have recently . . . tried this method on a child's hand requiring suture of a severed tendon. The injury was an old one, and there was no wound before I made my incision. The anesthesia from 10 per cent. cocaine on the anode, continued with my chlorid of silver battery—twelve cells—for ten minutes, was very satisfactory."

In rheumatism and gout, at Edison's laboratory, a number of experiments have been made whereby lithium chlorid has been forced into the tissues. In an old man who had chronic uric acid concretions so that the joints between the phalanges were obliterated, by the cathodic action of lithium chlorid after twenty-five hours of total application the measurements made showed a distinct reduction in bulk. The pain was relieved and the patient's general condition improved. The 120-volt current was employed through proper resistance. The current strength was twenty milliamperes. Note that this is a very strong current for cataphoresis, five milliamperes is sufficient. The séance is generally five to fifteen minutes; the stronger the current the shorter the séance.

In gynecology cataphoresis is giving results which are gratifying.

In this connection permit me to bring to your attention a new method of treating affections of the tear-duct and lachrymal sac by the cathodic action of protargol. The cupped sounds are the ordinary Theobold probes in which at intervals of one-fourth of an inch cups are made into which the protargol in vaselin is placed. The probe is introduced in the usual way and after it is in place it is connected to the positive pole of the battery while the patient holds the negative carbon electrode in his hand. A current of five milliamperes is turned on and five minutes suffice to drive all the medicament out of the cups into the lachrymal passage. So far this

mode of treatment has given me better results than any I have heretofore tried.

Concerning the therapeutic indications of metallic electrolysis and the consequent cathodic action, much might be written. Massey, in a work just published on conservative gynecology, speaks of an original method of treating cancer by passing into its substance mercuric oxychlorid. He used gold electrodes into which the mercury is amalgamated by submersion. By using a large lead electrode, 12 by 20 inches, at the negative pole, he is enabled to pass through the cancer as high as 350 milliamperes. His theory is that the cancer cells possess less physiologic resistance to the interstitial attack than does normal tissue. In fact the cancer cells lose their viability without the normal tissue suffering necrosis.

In laryngology, and in tubercular laryngitis, the soluble copper electrode is of great value. The oxychlorid of copper is not only a powerful germicide but a powerful stimulant to resolution of the painful ulceration, but it is in the treatment of granulated eyelids that we have made the most distinct advance over the older methods of treatment, so that it is now possible to cure in months trachoma that would have otherwise taken many years.

In the *Ophthalmic Record*, October, 1898, after three years of earnest search for a more efficient remedy for this troublesome disease, was published a new treatment for trachoma which consists simply in the solution of a pure copper electrode in the substance of the lid, by the means of the galvanic current. The sulphate of copper pencil, which has always been our standby, produces but a superficial action. The oxychlorid of copper is a more powerful germicide than the sulphate of copper and besides it penetrates into the very substance of the granulations themselves, causing their absorption, without contraction of the eyelids. Some pain follows the operation, which is quickly allayed by the application of cold water to the closed eyelid. Three milliamperes of current are generally sufficient. When the communication was published it was supposed to be entirely new. But the wise man of Israel has said that there is nothing new under the sun, and I was chagrined at having my "discovery" disputed by Dr. Neiswanger of Chicago. Demanding his proof as to the priority of the discovery, he sent me copies of the *Alkaloidal Clinic* of three years ago, containing in a short paragraph his use of it on a Kansas physician's trachomatous eyelids before a clinic in the Post-Graduate Medical School of Chicago. But as the *Alkaloidal Clinic* is not read generally by ophthalmologists it never came to light in ophthalmic literature and was buried. However, it afforded me great pleasure in the succeeding number of the *Ophthalmic Record* to accord to Dr. Neiswanger proper credit for his priority in this valuable discovery.

In a communication to the American Electro-Therapeutic Association in 1894, Dr. W. J. Morton offered the following conclusions concerning metallic electrolysis.

1. The salts of many metals may be electrically dissolved from metallic electrodes, and at the same time be caused to permeate human tissue to a considerable depth. In the case of copper on dead tissue, with the current usually applied to living tissue, this depth is visible as an apple-green color, in the radius about the electrode of from one-fourth to one-half an inch; it probably invisibly extends much farther, shading off to a minimum.

2. The electrically formed and electrically diffused metallic salts are not destructive to tissue in the sense that ordinary electrolysis is; the effect is rather by the presence of a partially insoluble salt and by the effect of

a newly formed organo-metallic salt, denutritive or absorbing, on diseased tissue.

3. It would seem that these electrically-formed salts possess a selective affinity for diseased in preference to healthy tissue, or at least produce a more profound action on the morbid tissue, causing a favorable alteration in the nutrition of the part.

4. Electric diffusion is greatly superior to topical application, for the reason that the medicament is caused to penetrate the tissue acted on.

DISCUSSION.

DR. HUIZINGA.—As to the benefits to be derived from cupric electrolysis in trachoma, I believe that it deserves more than a passing notice. Taking for granted for the present that trachoma is the result of specific infection, and that the neutralization or destruction of this infection is a primary requisite for the cure of the trouble, it must follow that if cupric electrolysis will accomplish this it is a valuable remedy. To determine this factor I have made a large number of extensive and careful experiments in which a five-milliamper current was passed for five minutes through previously infected raw beef, the anode being an electrode made of pure copper. A piece of this electrolyzed beef was afterward placed in sterile solutions of bouillon and agar. If the excised piece was very thin, and taken from the place where the anode had been, it was found that the beef was completely sterile, thus showing that in the immediate vicinity of the anode the current passing through the copper electrode had distinctly germicidal properties. I believe a current of this kind will penetrate the conjunctiva and destroy or neutralize the cause of trachoma for about the depth or thickness of an ordinary inflamed conjunctiva, but no farther, and inasmuch as the cause of this disease may be deeply imbedded in the tissues, the usefulness of this form of treatment has its limitations.

I have estimated that the amount of copper deposited in the tissues is approximately 1-300 of a grain. This copper unites with the chlorine ions in the tissues to form the chlorid of copper. It is necessary, in order to get a maximum effect in a minimum of time, that the distance between the anode and the cathode should never be less than five inches. The reason for this is that the amount of chlorine ions between the two poles must be sufficient to meet any demands that may be made on them. To illustrate this I have repeatedly tried the following experiment: Two electrodes placed in raw meat at a distance of ten inches from each other, will dissolve one-eighth of a grain of copper wire in twenty minutes, with a voltage of 60, and an amperage of 20, while if the distance between these two poles was only three-quarters of an inch it required an hour to dissolve one-eighth of a grain of copper wire, with a voltage of 10 and an amperage of 20.

DR. L. HOWE.—At the last meeting of the American Therapeutic Society I presented a paper on an analogous subject, and in looking up the literature I found that Morton's book was the only one that contained any concise statements on the subject. I am somewhat surprised at the amperage mentioned, because one and one-half or two milliamperes will cause the patient to vince very decidedly, and three is painful in the extreme.

As to the electrode, we can get the same results by using instead of the solution of sulphate of copper, simply the crystal applied against the conjunctiva itself. In using solutions we must take into consideration that they are decomposed before entering the tissues. I have made the attempt to estimate the amount of substance which might be introduced into the globe in this way. I thought I could get the characteristic starch and iodine reaction without difficulty, and on several human eyes, just before enucleation, and in many rabbit eyes. I have applied the two electrodes with solution of iodine in various strengths and then turning on the current tested with the starch solution, but I could not get a trace of blue color. I know the amount was very small, but still I do not think there is proof that the solution enters the tissue in that manner.

DR. G. F. KEIPER.—DR. Howe spoke of the wincing of the patient. I think it is best to always use cocaine first, but still the patients will suffer some pain, and the most peculiar thing is that they have most of it after they leave the office.

Correspondence.

Medical Guild of the Misericordia.

WESTBORO, MASS., July 10, 1899.

To the Editor.—The Medical Guild of the Misericordia is a society of medical practitioners and medical students interested in the work of mercy for the sorrowing and suffering. The guild comprises an order of brothers and associate communicants of the Anglo-Catholic Church in every land, with priests as chaplains whenever their services are required. The relief it seeks to afford in corporal works of mercy is: To feed the hungry; to give drink to the thirsty; to clothe the naked; to rescue the fallen; to visit the prisoner; to shelter the stranger; to visit the sick, and to bury the dead.

Members of the guild obligate themselves to engage in any or all of the above works whenever occasion offers, and to consider it their especial duty to watch for opportunities for so doing. In a word, the object of the organization is to impress on and keep before the minds of its members the duty of doing works of mercy, both corporal and spiritual, whenever it is possible.

Wherever there is suffering there is our opportunity. The emblem of the order is the crucifix, on the reverse arms of which appears the word "Misericordia." The skull and bones and words *Memento Mori* also are used as emblematic of the fraternity. The girle of the guild is of purple silk cord with seven knots and seven silver beads, and is to be worn always, day and night the same, and around the shroud in death. In the impressive ceremonies attending membership, the candidate pledges himself with God's help that he will faithfully strive to carry out, with charity, humility and fortitude, all the public and private intentions of the Guild, and to preserve in secrecy all the works of mercy which he may be permitted to perform. He also pledges himself that he will not disclose the names of the members of the Misericordia.

We are glad to welcome to membership all who desire, for any cause, to devote the remainder of their lives to deeds of charity; all—rich or poor, saint or sinner—those whose hearts have been touched by sorrow or misfortune or who, through charity, seek to offer help to sufferers—"Darkened by shadows of earth, yet reflecting the image of heaven." Sincerely yours,

W. TH. PARKER, M.D.

A National School of Tropical Medicine.

St. ANNE, Ill., July 15, 1899.

To the Editor.—With the "Stars and Stripes" flying over the Hawaiian Islands and our new possessions abroad since the termination of the war with Spain, has not the time arrived for a more thorough and systematic teaching in our medical schools of the etiology, pathology, symptoms and treatment of tropical diseases? Returning from the west coast of Africa, last April, I was delighted to learn of the energy being displayed by the Liverpool School of Tropical Diseases, and knowing, from personal experience, what a terrible havoc malarial fever causes among the white settlers in western and equatorial Africa, and realizing how the troops and citizens in our new possessions will have to face not malaria alone, but other diseases peculiar to warm climates, I venture to advocate a more thorough course in all diseases pertaining to the tropics.

Many of the future graduates from our medical schools will take service in either military, naval or civil life in our new possessions; and the preference will undoubtedly be given to those best versed in tropical diseases. Not only would I advocate a special chair for teaching the subject of tropical medicine in every medical department of state and private institutions, but also the formation of a government school of tropical medicine, having well-fitted laboratories for research and original work. Physicians residing in tropical lands would doubtless be only too glad to collaborate with such a school, and give it the benefit of their experiences and material obtained on the spot.

Soldiers and others invalidated home would often furnish valuable clinical material. Future graduates in medicine will then be able to go forth from their college with such an intelligent understanding of tropical diseases as to justify their acceptance for service in our foreign possessions. Respectfully,

ALBERT L. BENNETT, M.D.

Presbyterian Mission, Angom, Congo Francais.

The Hopelessly Insane.

WAUWATOSA, Wis., July 13, 1899.

To the Editor.—Your journal does me an injustice in reporting a paper (JOURNAL, xxxii, p. 165) read by me on "Contagion and Infection in Nervous and Mental Diseases," at the late meeting of the American Medico-Psychological Association in New York. Your words are, "Incidentally he advocated the somewhat radical measure of judiciously ending the lives of the hopelessly insane." It would scarcely be necessary to explain that this was an error to those versed in these matters, but as many readers may be misled, I wish to say that in my paper I proposed to inquire whether various radical measures frequently advocated, among them electrocution for incurable insane, castration, etc., were practicable measures and the conclusion at which I arrived, distinctly given in my paper, was that such measures were not practicable. Please make this correction and oblige, Yours truly,

RICHARD DEWEY, M.D.

A Novel Device.

MEMPHIS, TENN., July 11, 1899.

To the Editor.—In answer to the letter of Dr. W. H. DeWitt of Cincinnati (JOURNAL, June 17, p. 1378), I would say that the "cotton capsule" is a well-known and much-used expedient for getting gastric juice. It was first used, I believe, by Max Einhorn.

AMERICAN.

1. See abstract in JOURNAL, June 10, p. 1312.
2. **Surgical Anatomy of Bile-Ducts.**—Bever calls attention to the error in description by Fenger, in the anatomy of the bile ducts, in placing the portal veins in front of the hepatic ducts and over the upper portion of the common ducts. His incision was described in the JOURNAL, June 26, 1897, p. 1225.
3. See abstract in JOURNAL, April 22, p. 882.
4. **Volvulus.**—This article is a discussion of the whole sub-

- ject of volvulus and its treatment, with reports of three cases.
5. **Inflammation of Bursa Gastrocnemio-Seminibræ-nose.**—Remarking that inflammation of this bursa is probably frequent, and on the rarity of recorded instances in the literature, Hawkes describes its anatomy, etiology, diagnosis, and the operation for its cure, as the excision is the only plan which he thinks advisable when a radical cure is expected, unless it be in syphilitic cases. The details of the operation are given with such fulness that we must refer the reader to the original article. Four cases are reported and a bibliography given.
6. **Blood Examinations in Anæsthesia.**—The following are the conclusions of Fish's paper: Safety in anæsthesia and operative procedures is dependent on a hemoglobin percentage over and above that required for the performance of its normal duties, and a normal or increased number of polymuclear neutrophils. Under these conditions anæsthesia may be produced, and operative procedures conducted with assurances of perfect safety.
7. **Diagnosis of Nervous Syphilis.**—Burt's paper discusses the general symptoms attending nervous syphilis, such as the suddenness of serious complications, headache, insomnia, the fleeting nature of certain symptoms, etc.
8. **Remote Results of Artisan's Palsy.**—Pearce divides occupation palsies into three classes: muscular cases due to over-volunt use of muscles; the neuritic type, consisting of a peripheral neuron irritability which may pass over to a subacute neuritis; the arterial cases associated with arterial or capillary involvement. The first type is hopeful as to cure, the second serious, but still hopeful, and the last form rather persistent. With the first class, stop the cause and recovery will quickly follow. In the second, if the central nervous system is not involved, the cases are not unpromising. He believes that a larger proportion of all cases recover than has perhaps been generally recognized.
9. **New Spore Producing Bacillus.**—Denny describes a bacillus obtained from sputum sent for tubercle bacillus examination. The patient died some months later, probably from a general tuberculous infection. A similar bacillus has been isolated by Dr. Hopkins, from the mouth of a healthy individual, and he is of the opinion that it is not an uncommon mouth-dweller, but neither he nor Denny has been able to identify it with any form heretofore described. It resembles the bacillus subtilis in many respects, but is broader, has a larger number of flagella, its growth on agar is more rapid and free, the spores are less resistant to heat, and the serum of animals inoculated with this bacillus does not give a clumping reaction with bacillus subtilis. A striking peculiarity of this bacillus is that well-marked clumping action was obtained with the serum of guinea-pigs which had been inoculated with its bouillon cultures, especially in connection with the fact that it is not pathogenic.
10. **Relation of Depressor Nerve to Vasomotor Center.**—It has been thought that the fall of the blood pressure, seen when the central end of the depressor nerve is stimulated, is due chiefly to the dilatation of the abdominal vessels through the splanchnic nerve, or, in other words, that the depressor nerve was connected with the vasoconstrictor fibers of the splanchnics in a different way from its connection with other vasomotor fibers. To settle this question, Porter and Beyer experimented by separating the splanchnic nerves and watching the effect of depressor stimulation. The fact that the separation causes so great a fall in blood pressure that quantitative measurements of vasomotor effects were embarrassed, was overcome by stimulation of the separated ends of the splanchnic nerves until the blood pressure again rose to the normal, then electrically exciting the depressor nerves. Numerous experiments by this method showed that the fall of blood pressure caused by depressor stimulation does not especially diminish after exclusion of the splanchnic area. The fall observed under other conditions, therefore, is not due especially to the dilatation of the abdominal vessels, and consequently there is no reason for supposing that the depressor nerve has special connection with the bulbular cells through which the splanchnic fibers receive their constrictor impulses.
11. **Influence of Dextrose on Toxin Production.**—In this preliminary note Smith notices the fact that it has been generally held that the varying and disappointing actions of diphtheric toxin, obtained from cultures made from beef bouillon

in the usual way, are referable to the presence of muscle sugar, which is promptly converted into acids by the bacillus. He has modified the method of Stronek for meeting this trouble, by causing fermentation of the beef. In further experiments for concentration of the toxins he found that dextrose could be added to bouillon from which the muscle dextrose had been removed, with the result of actually favoring the accumulation of toxin, and the details of this discovery will appear in a forthcoming article. He does not explain this difference between the reaction of muscle dextrose and the dextrose introduced in this way, but gives some of his experiments and conjectures in regard to it. He remarks that the difference in the toxicity of bouillon cultures prepared in different ways should make bacteriologists cautious in claiming actual increase of virulence when such increase may depend entirely on the environment and may be modified by changing the medium. In comparative tests of toxicity, only guinea-pigs raised under the same conditions should be used. Animals from certain sources may be twice as susceptible as those from others.

19. **Origin of Fibrinogen.**—Mathews concludes, from his studies, that fibrinogen is derived from the decomposing leucocytes, chiefly those of the intestinal area. It possibly corresponds to that constituent of the body of the leucocyte which falls into a fibrillar form during karyokinesis. Karyokinesis and the clotting of blood are possibly identical processes.

21 and 22. **Indurated Erythema.**—Dade reports, with illustrations, a case of indurated erythema of Bazin in which microscopic examinations were made showing that there was no evidence whatever of its being tuberculous, therefore rendering improbable the title of "des serofleux" given by the French author. Johnson reports a case of this disorder and reviews its histology and treatment. He thinks that climatic conditions are the chief provoking causes, and his best success in managing the trouble has been through general methods, forced feeding, life in the open air, tonics, etc. It is non-microbial and, therefore, must be toxic.

23. **Syphilitic Stricture of Rectum.**—Cooke attributes the occurrence of syphilitic disease causing stricture of the rectum to the special irritation in this part, which is greater in women, who are the chief sufferers in the proportion of from 5 to 10 to 1, reversing that of syphilis itself. The location is fortunately low down, as a rule, at the point where the impacted fecal masses would meet with their first obstruction and cause irritation. About 50 per cent. of all rectal strictures occur in syphilitics. The symptoms are described in detail and the diagnosis is generally clear, but physical examination should never be omitted. It is a matter of great importance to make a correct diagnosis, considering its possible effect on the family. The diagnosis between syphilitic stricture and malignant disease is comparatively simple, and the microscope is always available. Internal medication is useless in this condition, surgical interference affording the only means from which permanent benefit may be expected. The operation that is least objectionable and most promising is posterior linear proctotomy, which consists briefly in introducing the point of a bistoury through the opening and cutting downward and outward in the median line, completely dividing not only the stricture itself, but all the structures between it, the tip of the coccyx, and the posterior anal margin. The large triangular wound is packed with gauze and made to fill in by granulation. During healing, the dressings should be often changed and the parts frequently irrigated with an antiseptic solution. At first there will necessarily be incontinence, but as the wound heals, control will be regained and, with proper care, completely in most cases. Bougies should be passed daily during the healing process, and thereafter at such intervals as may be required. The operation should not be performed when the stricture is slight and there is reasonable hope of success by treatment with bougies alone, or when it extends so high as to render it impossible to fully divide it. Two cases are reported.

24.—See abstract in JOURNAL, June 10, p. 1320.

25.—Ibid, p. 1321.

26.—Ibid, June 3, p. 1254.

28. **Revacination.**—Payne's paper is notable in that he very decidedly objects to revaccination, claiming that it is never necessary if it has once been performed successfully.

31. **Treatment of Appendicitis.**—In any case of appendi-

ctitis the important question is whether operation is imperatively demanded, and Ladd has adopted the following rule, which he here offers in answer to this question: Operation is demanded early in any case of appendicitis where any of the symptoms are severe. For example, if repeated vomiting, especially high temperature, very rapid pulse, severe or persistent pain or tenderness to pressure are any one of them especially prominent in any one case, the indication is that there is something more the matter than a simple mucous inflammation within the appendix.

33. **Post-Operative Hernia.**—The occurrence of post-operative hernia and its high percentage of frequency have induced Shimonek to review the subject and endeavor to point out the special measures for prevention. These he sums up as follows: The careful approximation of like tissues; strict asepsis; gentle manipulation; avoidance of the use of antiseptics; avoiding the constriction of the edges of the wound; allowing sufficient time to elapse before the patient is permitted to assume the upright posture; the use of slowly absorbable or non-absorbable suture materials for buried sutures.

34. **Throat Cough.**—In this article Bach limits himself principally to the subject of coughs due to irritating adenoid hypertrophies. The most frequent of these, which he finds producing the symptoms, are those situated immediately behind the posterior faucial pillars, extending up and down for about half an inch at the junction of these with the pharyngeal walls. In this region they are subject to constant irritation and strain and are generally exceedingly sensitive and irritable. The careful application of a bead of chromic acid or the galvanocautery point will in one treatment often cure this cough. Another area only second in importance is that in the lingual, or more rarely, faucial tonsils. This form of irritation is most frequently met with in children between 4 and 10 years of age, whose general condition favors adenoid growths. A few applications of 3 or 4 per cent iodine solutions in glycerin, or better, the ablation of a portion of the growths by the cautery or snare will relieve the symptoms. The third location is the post-nasal pharynx where the same irritation through reflex action may even produce attacks of asthma.

42. **Appendicitis.**—Viewing appendicitis from the standpoint of a country doctor, Davidson holds that the appendix is not an entirely useless organ, though we may not be able to explain or determine its value, and he favors conservative treatment in cases of recent acute appendicitis. He usually begins with 1 or 2 grains of calomel, repeated every hour for three or four doses, then follows with 60 grains of sulphate of magnesia and 10 grains of soda bicarbonate, repeating every half hour until free catharsis is established, and if pain is severe he uses inhalations of chloroform. In this way he says he has kept his patients from suffering and brought them safely through in every case.

43. **Scarlet Fever in Schools.**—Robinson's article is a plea for the appointment of school inspectors to prevent the spread of scarlet fever and diphtheria.

48. **Conservatism in Gynecology.**—Mattison pleads for more conservatism in gynecology, including under this term, however, certain operations, such as amputation of the cervix and operations to restore obstructed functors.

49. **Tooth in Nasal Cavity.**—Tyler reports a case in which a tooth was extracted from the nasal septum, the root going downward but not penetrating the roof of the mouth. It extended horizontally, directly across the nasal cavity, with its crown imbedded in the inferior turbinated bone.

51. **Posture in Reading.**—The main points in this article are the importance of having the book or paper held at the greatest distance in which a clear image can be had, which, if the vision is normal, should average rather over than under eighteen inches, also having the plane of the surface of the reading matter at right-angles to the line extending from the eyes to the book. Reading in a recumbent position, Baker thinks, will be altogether harmless if these conditions are observed.

55. **Hyoscin.**—The uses of hyoscin are shown in this article by Fotheringham. He claims a wider utility for the drug than has generally been recognized, and reports five cases of senile mania, meningitis, hysteria and rheumatism in which he found it of benefit.

56. **Gynecology Among the Insane.**—Hobbs' paper is a defense against certain criticisms that have been made on the extensive gynecologic work done in the London (Canada) asylum.

57. See abstract in JOURNAL, June 24, p. 1440.

60. **Depopulation of Infected Towns.**—Hlaralson discusses the question as to the advisability of the plan of abandoning yellow fever infected towns as suggested by the United States Marine-Hospital Service, but criticises its methods, especially as to the shortness of detention in camp. The principle is correct. The disinfection of a town left to itself will require about ninety days. Depopulation, followed by rapid and thorough disinfection and fumigation, could completely rid a town of infection in thirty days, and thus save many lives and sixty days of business in the town. The time for this action is not when the first case occurs, or the first few cases if their location and sources are known and the balance of the community protected against it. In this case the disease could be stamped out. But if the disease is scattered throughout the town, without known origin, the time has come for people to move, and a thorough system of sanitation should be carried on. After the sanitation is complete—it should include everything, disinfection, cleansing, etc.—the people may return. He gives an account of his experience with Oxford, Miss., last September, in this way.
