The attorney-general of Illinois has lately rendered a decision that the courts ought not to confirm, or if they do, it will be time to correct their narrow interpretation by new and unequivocal legislation. A child aged 6 years, died in Douglas county under Christian Science treatment, and in reply to an inquiry from the state's attorney of the county the attorney-general rendered an official opinion that, according to the clause in the Medical Practice Act, "mental and spiritual" means are legalized and that the sections of the criminal code against willfully endangering the life of a child did not apply, since it was not done willfully, but in good faith. This is equivalent to saying that if the parents or others in charge of an infant are under any kind of an honest delusion that would make them sacrifice or endanger its life, the law gives it no protection. He does not even hint at the rational alternative—their seclusion in a lunatic asylum—probably recognizing the fact that such imbeciles are too numerous in these present days of popular voodooism to protect infant life in that way. While, as the *Chicago Tribune* says, according to our practice in this country, "a man or woman who has reached years of discretion" is supposed to be able to take care of himself or herself, it is no enlightened view of the law that applies the same construction of it to helpless infants, or children who can not act for themselves. If this opinion is to be the last word on the subject we may look for an extensive slaughter of the innocents, by the well-paid mercenaries of "Christian Science," "Dowieism," and other like fads. We had supposed that the premiums on murder were wiped out of the law, but according to this attorney-general we are having new ones enacted by statute. It can not be that he is right, and the opinion should be

regarded as only the individual utterance of a narrow technical official. The law certainly can not intend that the most helpless and the most deserving of our sympathy and care are to be denied its protection against bigotry and ignorance.

A POSSIBLE CHECK TO QUACKERY.

A careful study of Circular No. 12 of the Internal Revenue Department is suggestive of some possible checks to quackery under the present revenue laws. The object of the law is to tax all special proprietary, trademark, or patented medicines, druggists' popular nostrums, all "non-secret" remedies, all advertised cures, and all physicians' advertised prescriptions or medicines, the demand for which is created by post-office solicitation, as well as perfumery, etc. According to the attorney-general's opinion: "Any medicinal article will be held to be advertised on the package or otherwise as having any special claim to merit, or to any peculiar advantage in the mode of preparation, quality, use or effect, when any description of it, either on the package or otherwise, includes any statement to the effect that it has a special or peculiar merit or value over other like articles or articles of the same class; or when it has any word, phrase, or sentence, either in the title or formula, or otherwise, which indicates its superior merit over articles of its class." The repetition of the "or otherwise" after each specification of advertising in the above makes the opinion a very broad one in its practical application. It covers not only every printed claim, but the recommendations of street fakirs and counter prescribers, as well as the special remedies of the advertising quacks. Whether this will cover all the drugs used by advertising doctors is a question, but from the reported instructions to revenue collectors it appears possible that such might be the interpretation put upon it by the department. There are certainly evidences that a more rigid enforcement of the war tax on advertised and proprietary preparations is intended, and the result should be a salutary limitation of quackery. If these frauds are made generally liable to the jurisdiction of the federal courts, there will be a somewhat better chance for their restriction or extinction.

VARIATIONS IN CEREBROSPINAL PRESSURE IN ASSOCIATION WITH CONVULSIVE ATTACKS.

The epileptic attack has been attributed to various and even opposite influences, thus to both cerebral anemia and cerebral hypermia, local or general, to both increase and diminution in intracranial pressure, to accumulation and discharge of nervous energy, but no one explanation is entirely sufficient or satisfactory for all cases. Sometimes the one, sometimes the other influence appears to be effective or at least provocative. Having observed in two cases of traumatic porencephaly with epileptic convulsions that long-continued drainage of the lateral ventricle, which communicated with the porencephalic cyst, was attended with a cessation of the attacks, and a like result in a case of traumatic epilepsy, Koche¹ concluded that the increased pressure of the cerebrospinal fluid was of considerable influence in exciting the convulsive seizures, the drainage acting as a

regulator for sudden variations in pressure. Similar observations have been made by others, and Stadelmann² by means of lumbar puncture found the cerebrospinal pressure in epileptic attack to be 360 mm. of water-pressure. In a series of observations to determine the therapeutic utility of lumbar puncture with relation to the course of epileptic attacks, Nawratzki and Arndt³ first found the normal cerebrospinal pressure to be in the recumbent posture about 113 mm., and in the sitting posture 400 mm., these results corresponding closely with those obtained by other observers. In three cases of epilepsy the pressure was normal before the onset of the attacks, but at the height of the tonic stage of the paroxysm it increased enormously, fluctuating during the clonic stages, and becoming again normal at the conclusion of the paroxysm. It is, therefore, thought that the increased pressure is not a cause, but rather a result of the convulsion, the tonic spasm causing cessation of respiration, which leads to increased intrathoracic pressure and interferes with the return of blood to the heart. In consequence of this and of the contraction of the muscles of the neck and the compression of the blood-vessels stasis takes place in the veins of the head. Forced expiration, coughing, crying and the like, give rise to similar results. Even simple pressure on the abdomen was capable of inducing increased intracranial pressure. Quite analogous phenomena were observed in the convulsive seizures of hysterical and paralytic patients, although they were the more pronounced in cases of epilepsy.

THE LYMPHATIC CONSTITUTION IN IDIOPATHIC EPILEPSY.

Ohlmacher⁴, continuing his studies in the pathology of epilepsy, gives a general survey of 25 cases of epilepsy examined post-mortem, and elaborates still further his observations on the presence of the lymphatic constitution (*status lymphaticus*) in idiopathic epilepsy. He reports five additional—to three previously published—very carefully and ably studied cases of genuine grand mal which presented pronounced evidences of the lymphatic constitution. These five cases include the most typical examples of "idiopathic" epilepsy of nineteen epileptics examined post-mortem. All five met death suddenly and in a state of good general nutrition, resembling in these respects some of the features of the lymphatic constitution. Post-mortem, there was found a persistent thymus with all the evidences of lymphoid activity accompanied with a general lymphatic overgrowth and arterial hypoplasia. Three cases also showed the changes in the bones characteristic of old rickets, and in four there were evidences of morbid changes in the thyroid. From morphologic and clinical reasons, Ohlmacher suggests that there exists a certain relationship between genuine epilepsy and rickets, *celammpsia infantilis*, thymic asthma and thymic sudden death, tetany, and possibly exophthalmic goiter. As is now known, more or less well-marked and constant hyperplasia of the lymphatic tissues is found in all of these conditions, which are also

² Deutsche Med. Woch., 1897, p. 749; Mittheil. a. d. Grenzgeb. d. Med. u. Chir. 1897, p. 561.

³ Berliner Klin. Woch., 1899, p. 662.

⁴ Bulletin Ohio Hospital for Epileptics, 1898, I, Nos. 2 and 3.

¹ Deutsche Zft. f. Chir., Bd. xxxvi, H. 1, 1893.

more or less in touch with each other in many of their clinical manifestations. The exact relations between the anatomic changes in the lymphatic apparatus and the disease mentioned are as yet purely conjectural. In his remarks on this interesting phase of his subject, Ohlmacher seems to lean to the opinion that the neurotic affections mentioned are the result of autointoxications, or other conditions, departing from the changes in the lymphatic tissues. A more extended discussion of this topic from a different point of view would also be very desirable, namely, from the standpoint of the possible secondary nature of the changes in the lymphatic apparatus due, perchance, to the action of various substances present in epilepsy, exophthalmic goiter, etc. It does not appear that we are necessarily bound to assume that the lymphatic constitution must be regarded in the light of a direct or indirect cause of the strange diseases associated with it. Ohlmacher's studies are very interesting, valuable and suggestive, and it is to be hoped that the material and facilities of many other similar American institutions may be put to such good use as is now being made of them at the Ohio Hospital for Epileptics.

THE RIGHT TO DIE.

A presumably learned jurist, a law lecturer in Yale University, has, in an address recently delivered, emitted the opinion that it is wrong to prolong a life in hopeless misery by medical art. He says: "In civilized nations and particularly of late years, it has become the pride of many in the medical profession to prolong such lives at any cost of discomfort or pain to the sufferer or suspense or exhaustion to his family." He asks: "Is not this a misapplication of the healing art?" In other words, are not physicians interfering with a beneficent providence, which, if left to itself, would abbreviate suffering and really make life happier to the surviving? This address has been extensively noticed in the daily press and commented on by physicians, lawyers, and others, and it is satisfactory to see that the ethical instincts of our profession are so firmly upheld in nearly all the parts that medical men have taken in the discussion. One or two points, however, have been perhaps too much emphasized, viz., that we can not say when a disease is hopeless, and that the desire for life is universal. Every physician of any amount of practice must have repeatedly seen cases where the near fatal termination was as certain as a mathematical axiom and others where the desire for death was stronger than the love of life, to say nothing of the vast majority where disease has produced a mental apathy or indifference. In any case, the physician has no question as to his duty, and needs no such excuse to keep him to it. Doctors are not generally accused of being religious, but the ethics of our profession go parallel with the best Christian doctrine in this as in other matters. In only one case reported in the daily press has an alleged physician uttered sentiments in accord with those of the jurist referred to, and the report of his remarks reads like a criminal confession. He has, he says, in hopeless cases given chloroform at the patient's request to shorten his existence. "Suicide," he says, "is justifiable in many cases provided the suicide has no obli-

gations." He has advised suicide and specified the method, though he naively acknowledges he does not know that his advice has been seriously taken. This doctor may be safe in his own state, where the judge referred to presides in the higher courts, but his quoted remarks, if taken seriously, would make him liable to criminal proceedings in some sections of the country. They sound more like the reckless utterances of one who not only lacks principle but has times "when the wit is out," or when his desire to see his name in print overbalances any correct judgment he may possess. It is to be regretted that there is a physician whose ideas even, are based on such pagan principles as seems to be the case here.

TRANSMISSION OF BACILLUS OF TUBERCULOSIS THROUGH THE PLACENTA.

The number of observations definitely showing the transmission of the bacillus of tuberculosis from the mother to the fetus is very limited. Auché and Chamberlent¹ were able to collect 19 cases in which the demonstration of the transmission of bacilli from the mother to the fetus could be considered as satisfactory; to this number they add one of their own. In twelve of these cases there were no macroscopic or microscopic evidences of tuberculosis in the tissues of the fetus, the presence of the bacillus in the fetus having been demonstrated either by means of cover-slip preparations or by means of animal inoculations. In eight of the 20 cases definite histologic lesions were found in the organs of the fetus. This number, which excludes a number of imperfectly studied cases, allows the claim that the transmission of tuberculosis by way of the placenta is rare. The transmission is so much the more to be feared as the tuberculosis lesions of the mother develop rapidly and are widely disseminated. It has never been observed before the fifth month of pregnancy. In the cases where the placenta has been examined it has always been found tuberculous, as shown either by the aid of animal inoculations or by microscopic examination. It seems safe to conclude, therefore, that this tuberculosis of the placenta forms the first stage of the infection of the fetus, the bacilli becoming localized first in the placenta, whence they invade the fetal circulation. As noted, the tissues of the fetus may be infected by the germ of tuberculosis and not present any specific lesions, microscopically or macroscopically. The tuberculous lesions that have existed are most generally disseminated, occurring in all or nearly all of the organs. Rarely the lesions are definitely localized. In the disseminated lesions it is customary to find the bacilli in large numbers, sometimes in extraordinary amounts. In the case of Schmorl and Kockel, where the tuberculous changes in the fetus were localized in the suprarenal capsules, the bacilli were present in very small numbers. It would therefore seem that the fetal tissue cannot be regarded as a poor medium for the development of tuberculosis, and the hypothesis of the latent tuberculosis, as advanced by Baumgarten, and based on a contrary opinion, does not receive any support from the facts brought out by the study of these cases. In the personal observation of these authors an

¹ Arch. de Méd. Exp., 1896, xi, p. 321.

extensively tuberculous mother gave birth to a premature child, which died after about three weeks. The liver, the spleen and the lungs contained a large number of miliary tubercles; the peribronchial and mediastinal glands, and the glands at the hilus of the liver contained caseous tubercles, and the endocardium near the apex of the right ventricle was the seat of a tuberculous nodule about 1 mm. in diameter. This appears to be the first instance observed of a congenital tuberculous endocarditis.

OVERSUPPLY OF MEDICAL PRODUCTS.

Our English brethren are evidently suffering to as great an extent from an overabundance of ready-made medical preparations as we are. And the same determination to crowd the stuff down the throats of the physicians—figuratively speaking, of course—is as much in evidence on the other side as on this side of the Atlantic. Every week or two our English exchanges contain letters crying out against the evil of free samples, of traveling representatives of proprietary drug houses and other evidences of an oversupply of medical preparations. The last number of the *Medical Press and Circular* prints a communication which is unique in that it proposes a remedy. "I say that if a stop be not put to this"—the deluge of medical preparations—"the treatment of disease will be taken out of our hands altogether. The public come to know what is ordered and then proceed to order for themselves," is the way the writer puts it. His remedy is to have a body of experts who shall be appointed and paid by medical organizations. To this body should be entrusted the task of investigating, or superintending the investigation, of every new preparation brought out, and no physician should be allowed to prescribe anything until its precise value should be ascertained by this board. It is, he says truly, mere nonsense to allege that the busy practitioner can investigate for himself, and his certificate, consequently, can not be of the slightest value. While the suggestions sound Utopian and impracticable, and they are to a certain extent, nevertheless it seems as though some action should be taken whereby the physician could have some thing or some body, on which to depend. To make a sweeping assertion that all proprietary and patented products are fraudulent is just as absurd as to accept the say so of the manufacturers that all are good. A few of the newer products are valuable, for progress has been, and is being, made in materia medica and therapeutics, as well as in other branches of medicine. But so much fraud and commercialism is mixed up with this progress that the average physician is at sea. He is losing faith in testimonials, and his experience teaches him that he can not rely on what manufacturers state. These remarks refer not to the "proprietary" only, but to the synthetics, to the patented preparations. For all the fraud does not rest with the proprietaries any more than all the virtue with the patented products from the fatherland. If some one will rise up and tell us how to get rid of the difficulty he will confer a great blessing on a suffering profession. Our present condition is breeding therapeutic nihilism that is anything but pleasant to contemplate.

Medical News.

DR. L. BREISACHER of Detroit has assumed the medical directorship of the Ypsilanti Sanitarium.

DR. H. P. REICHE, Baltimore, while getting off a street-car, was thrown to the ground and was seriously, but probably not fatally, injured.

FOUR VOLUMES of the report of the Moscow International Congress are about completed, and the remaining three are expected to be ready by the end of the year.

ACCORDING to report, the Board of Health of Nanticoke, Pa., is much exercised over a case now considered to be leprosy. The patient is said to be an Assyrian.

A PARIS exchange mentions that "Bremount's Pride," one of the horses entered in the Autenil races, has been wearing a tracheotomy tube for some time, and won a prize of \$8000 soon after it was first inserted.

DR. J. ACKERMAN COLES, Newark, N. J., has presented to Jefferson Medical College, Philadelphia, a Carrara marble bust of William Harvey, by Horatio Stone; also a bronze medallion lifesize portrait of Abraham Coles, father of the donor, together with a number of other gifts of less value.

AN AUTOMOBILE ambulance is to be presented to St. Vincent's Hospital, New York City. It will be propelled by electricity and will be the first of its kind in the city. The donor's name has not been given.

TYPHOID FEVER has developed in and around the Guerin "fortress" in the Rue Chambroi, Paris. The accumulation of filth and disregard of all sanitary measures by Guerin and his friends are, of course, the cause of the outbreak.

AUGUSTA, ME., is suffering from an epidemic of diphtheria. At last reports seven houses were quarantined, and the inhabitants were considerably wrought up. Springfield, Mass., is also afflicted with the same disease, 37 cases having been already reported.

DR. J. J. SMITH of Chambersburg, Pa., while making investigations in regard to anthrax, which has prevailed in that section for some time, had the misfortune to inoculate himself with the disease. Within a few days an eruption appeared indicating its nature and several days later death ensued.

A RECENT fire in Apothecaries Island, St. Petersburg, destroyed the military drug factory, the chief magazine of military medical stores, whence army supplies were sent out to every part of the Russian empire. The loss, which can hardly be repaired for years, is estimated, in money value alone, at nearly \$3,000,000.

A MONTH'S imprisonment and a fine of \$200 have been imposed on the dealer in oils who frequented a Paris hospital, calling himself a retired navy medical officer and serving as assistant at times, as mentioned recently in the *JOURNAL*. He had also obtained several patients as a specialist in throat and ear troubles.

THE MEDICAL department of the University of Denver has been incorporated as the "Denver College of Medicine." The change of name carries with it no change in the relations heretofore existing between the University of Denver and its medical department, other than giving the Denver College of Medicine an independent legal existence.

AN EPIDEMIC of dysentery occurred during the month of August in the State Insane Asylum at Norristown, Pa. During the month there were sixty-six cases, six

of them among the attendants, and seventeen deaths. The disease was reported by the physician of the female department, and it is inferred that it was principally confined to that side of the institution.

DR. S. LEWIS ZIEGLER, of Philadelphia, who has been abroad for the past three months, has returned home. While in Holland he attended the Ophthalmological Congress, which recently met at Utrecht.

DRS. C. A. I. REED, Cincinnati, Bayard Holmes, Chicago, and Wm. Osler, Baltimore, are among those who have returned from Europe during the last week. The latter rented a cottage outside of London, where, with his wife and infant son, he spent most of the summer.

SOME TIME ago the subject of filters for the public schools of Philadelphia came up for discussion before the members of Councils. At the time it was believed that a satisfactory variety had been found, but new developments show that only three out of seven come up to the requirements, and so far none have been selected.

MANY MEMBERS of the Army Nurses' Association, which held its session in Philadelphia during the recent meeting of the G. A. R. were present from various sections of the country. At one of the meetings Miss Clara Barton was present and decorated each member with the insignia of the Order of The Red Cross Association.

TYPHOID FEVER is reported as particularly prevalent in Kentucky towns this fall, especially in those along the Ohio and Kentucky rivers. The health officer of Louisville is reported as saying that there are more cases in that city than he has ever known before, and circulars are being prepared to instruct the public in regard to the disease and its prevention.

A FOCUS of smallpox has been discovered, it is reported, in certain rural districts in Central Illinois, in which, as in the late epidemic in Northern Indiana, some of the local physicians apparently did not at first recognize the disease. In these days of general vaccination, when only modified varioloid is likely to occur, it is probable some cases escape detection, as seems to have been the case here.

REFERRING to the menaced invasion of Europe by the plague, one of the most atheistic, ultrascientific French periodicals remarks that the microbe is answering the question: "Who is my neighbor?" as it is teaching man that it is not a matter of indifference whether he has a neighbor at home or abroad who is poverty-stricken, filthy, immoral or diseased, as poverty, ignorance and filth breed cholera, bubonic plague and what not. The formula for the happiness of the human race, it adds, is in the hands of science, the new religion.

WAR HAS BEEN declared in Europe against rats and mice, as a preventive measure against the bubonic plague. The French Board of Public Health has issued a circular to shipowners requiring the screening of all openings by which rats can enter a vessel, and a protecting appliance fitted on each cable tying it up to the dock. Rats on board must be trapped or poisoned with the preparations sold for the purpose, and carcasses burned. Vessels must be disinfected with sulphurous acid in the haunts of the rats, and elsewhere with mercuric chlorid.

OWING to the intense heat and humidity which prevailed for several days in the city of Philadelphia during the recent G. A. R. parade, in one day 475 persons were treated, and on September 6 three deaths occurred. During the week of festivities all ambulances were kept busy constantly, and the hospitals were filled

to their utmost capacity. That more deaths did not occur was doubtless due to the extreme care exercised by the physicians appointed for the purpose, who had taken the precaution to have at convenient distances ambulances and patrol wagons to give relief in the shortest time possible.

THE THEORY that bacteria are indispensable to digestion has been laid to rest at last by Levin's research in the Arctic regions, reported in *Hygiea*, No. 2. He accompanied the Nathorst expedition and examined the intestines of various birds and animals killed. With the exception of one polar bear and two walruses, the intestines were found absolutely sterile, and in these only a few specimens of the bacillus coli were discovered. Bacteria were found in the water, one colony to 1 c.c., the number increasing with the distance from the surface. The air was found absolutely sterile. No colds nor catarrhs ever occurred among the men.

THE CONTRACT for additional dormitories for the University of Pennsylvania has been awarded, and within a few days ground will be broken preparatory to the erection of a large group of buildings for the accommodation of students. With this addition it is hoped to give the student those private advantages gained at places away from cities, and at the same time be in a position where they may be judiciously obtained. It is proposed to erect a line of buildings extending entirely around the old athletic field. The new dormitories will cost nearly \$1,000,000, and are to be finished by August 1, 1900.

REPORTS from Key West, Fla., show that 111 new cases of yellow fever with five deaths have occurred during the five days ending September 12. The total number of cases is 218; deaths, 12. One case was reported from Jackson, Miss., and there was a general exodus to higher altitudes. Quarantine has been instituted against Mississippi City, which reported 13 cases. The marine-hospital service reported one case at Port Tampa City, Fla. A. H. Doty, health officer of New York, has begun the serum treatment on two of the four cases taken from the steamship *Lampasas*. One of the Key West Refugees died at Swinburne Island, September 11.

THE LEPRO patient whose death we recorded last week, had been an inmate of the John Hopkins since April, 1897. She had lived in Alleghany City, Pa., and was supposed to have "scrofula" of six years' standing. Her disease was recognized as leprosy on her arrival in Baltimore. The Pennsylvania authorities refused to allow her to return, therefore the hospital was obliged to keep her. With regard to the origin of the disease, it was ascertained that when she was 15 years of age she went to Demerara, British Guiana, and remained there several years. It is supposed she contracted the disease there. The case at one time created much apprehension in the hospital, but as the patient was rigidly isolated, no fear is entertained that any other person has been infected.

JUDGING from the report issued by the State Board of Health of Pennsylvania, smallpox has by no means abated. The report says: "Since the disease was first reported in Bedford County in the month of November, 1898, it has made its appearance in 21 counties and more than 100 localities. The number of cases reported has been about 900, and the number of deaths 7. The fact that deaths have occurred is sufficient to exclude chicken-pox and impetigo contagiosa. The warning note issued by the State Board of Health some months in advance

of the invasion, pointing out the steady progress of the disease from Florida up along the coast, and calling especial attention to its mild character, might indeed have aroused their suspicions, but does not seem to have been generally regarded.

The *Chicago Tribune* is publishing a series of excellent articles under the caption "Nineteenth Century Passed in Review." The ninth in the series, published last Sunday, was entitled "Triumphs of Medicine," and was written by Dr. G. F. Butler. The paper is an excellent résumé of the progress of medicine during the century, and, with the illustrations, covers over two pages of the *Tribune*. We should imagine the article as couched in rather too technical language for the average lay reader, otherwise it is worthy of commendation, and certainly ought to help to enlighten those who read it, to the extent that they may see the difference between scientific medicine and ignorant and fanatical charlatanry.

A COMMITTEE on railway sanitation has been appointed by the Wisconsin State Board of Health, which has been giving the subject some special attention of late. This committee proposes to act, if possible, as advisor to the railroad officials, whose duty it is to be ready to receive suggestions as to methods that will improve the service and the safety on their lines. The resolutions under which the committee will act are as follows: That the board appoint a committee to confer with the railroad companies in the state and ask them to improve the sanitary conditions of their passenger cars in the following respects, namely: 1. To provide cuspidors containing disinfectants for all smoking cars and smoking rooms in sleeping cars. 2. To give more attention to disinfecting passenger coaches at the end of each run. 3. That better arrangements be made for the ventilation of passenger day coaches and sleeping cars." The board evidently does not mean to attempt too much, but will use its influence to improve, as far as possible, the sanitary risks of the traveling public.

Correspondence.

Compulsory Notification of Tuberculosis.

LANSING, MICH., Sept. 7, 1899.

To the Editor:—Referring to the paragraph on page 611, of your issue for Sept. 2, 1899, permit me to suggest that isolation of patients and placarding of premises need not follow notification; but notification is essential for any action by the people, that is by the state, for gaining any knowledge of the actual conditions and circumstances under which tuberculosis is spread, and it is for such purposes that the Michigan State Board of Health has taken action; and for the additional purpose of placing in the hands of persons who cough and of their friends some brief suggestions tending to teach the patient how to avoid re-infection and the spreading of the disease to others. Extensive observation at morgues in large cities has proved that even a large proportion of persons dead from other causes have recovered from tubercular disease of the lungs; this means that if a person has such disease in that part of the body only, recovery may reasonably be hoped for; but if the sputa are swallowed, tubercular disease of the bowels and general tuberculosis may result, and death is then probable. The interests of the patient as well as the interests of the public demand that the patient shall be informed of the nature of the disease, and how to avoid re-infection and the spread of the disease. In Michigan, if the patient is thus informed, he, or the householder, hotel-keeper, boarding-house

keeper, or tenant, is liable to a fine, and to imprisonment if the fine is not paid, if he or his physician does not report the fact of his disease to the local health officer; therefore, in order to protect his patient, or his household, from prosecution, the physician should report the case. And in Michigan, the law provides a small fee to the physician for every such report.

Every sanitarian knows that tuberculosis is spread by the bacilli, and, as pointed out on the same page (611) of your JOURNAL on which is the paragraph on notification, these are liable to be "deposited on the tonsil from the inspired air," and that this disease which causes most deaths is generally contracted by inhaling the germs of the disease. Therefore every person should know that there is danger in a room in which there is a coughing consumptive who does not scrupulously care for the sputa.

Every sanitarian knows that vaccination is almost a certain preventive for smallpox, and that if he is recently successfully vaccinated, as he should be, he is in no danger whatever in "being in a room with a case of smallpox." There should be no impropriety in putting before the public the exact truth on these subjects. Let us have notification of this most important disease, which is now known to sanitarians to be preventable, and which has been decreased by 11 per cent. in Michigan since the State Board of Health has been vigorously working for its restriction.

Very respectfully,

HENRY B. BAKER,

Secretary State Board of Health.

[If notification of cases of tuberculosis were simply for the purpose of obtaining data as to the disease, its spread and possible control, no one could object and every true physician would do what he can to aid in this endeavor. It is different, however, with compulsory and indiscriminating notification, and the Michigan law which requires every patient to be informed as to the nature of the disease and made liable to a fine or imprisonment for not reporting it to the local health officer, appears to us a very harsh and unnecessary one. We repeat, we do not think the time has come for such compulsory notification. The matter can be more safely left to the attending physician. As regards education of the public as to the needed precautions, it certainly should be done, but at the same time exaggeration of the dangers should be avoided. That this has not always been the case is shown by the proposition reported of the authorities in one city to prohibit public funerals of consumptives. We agree with Dr. Baker that there is no impropriety in putting before the public the exact truth on these subjects, but it should be carefully limited to that, and should not include the compulsory publication of the misfortunes of afflicted citizens.—Ed.]

London.

(From Our Regular Correspondent.)

LONDON, Aug. 26, 1899.

DANGERS IN MAKING PHOSPHORUS MATCHES.—Dr. Talbot, the medical officer of health for the "match-factory district" of East London, has just made a report on the phosphorus danger which is unexpectedly encouraging. He asserts that yellow phosphorus can be used in making matches with perfect safety, provided certain parts of the process are carried out practically in the open air. He bases this conclusion and change of view on his part on a visit recently made to a factory in his district where 500 hands are constantly employed, and yet where not a single death from necrosis has occurred in ten years, and only two mild cases of "phossy jaw." The secret lies in doing the mixing of the paste and the dipping of the matches on the roof of the factory, under little more than an awning to protect from the weather. The fumes escape so rapidly that no odor even is perceptible.

FEAR OF THE PLAGUE DIMINISHED.—The slight fear of a plague epidemic in England, fanned by the statements of certain "yellow" journals, seems to be rapidly subsiding, as the slowness of the spread of the disease, even in filthy Oporto in manifested. Great vigilance is being exercised by the Port of London Medical Officer, Dr. Collingwood, in the inspection of every Mediterranean and Oriental vessel coming up the Thames, but

so far, fortunately, not a single even suspicious case has been discovered. The plague bacillus actually needs dirt, and plenty of it, as a culture-medium, and can no more spread in its absence than a fish can live out of water. Clean and civilized communities, which means all Europe, outside of Russia, Spain, Portugal, and parts of Italy, have little to fear from it, even if a case be imported. The Portuguese, both lay and official, seem to be doing about what was to be expected—as little as possible—but other governments are taking the situation in hand and sending in experts and serum in self-defense, so that the epidemic seems likely to be “juggled.”

TYPHOID FROM SHELL-FISH.—An interesting instance of probable infection through eating shell-fish contaminated by sewage has just been reported from Exeter. A number of cases of typhoid have occurred within a few days of each other; on investigation, all were found to have been in an excursion party to Exmouth, where they had partaken of the local cockles uncooked. These cockles, it was further found, had been gathered on the bay mud-flats close to an outfall of sewage. As no other source of infection could be found, the connection is decidedly suggestive, to say the least, and the authorities of Exeter are justified in demanding the prohibition of any further sale of cockles from this bed.

A MEDDLESOME MIDWIFE.—A remarkably aggravated case of a midwife's ignorance and meddlesomeness has just come before a London coroner. An inquest was held on the body of an infant which had died in convulsions at three days of age. The cause was believed to be “moulding” of the head by the midwife. The good lady actually admitted that she “sometimes did press their little heads into shape a bit,” but denied doing so in this case.

Canada.

(From Our Regular Correspondent.)

TORONTO, ONT., Sept. 9, 1899.

CANADIAN ADDENDUM TO THE BRITISH PHARMACOPEIA.—A short time ago, Prof. J. G. Adami, as president of the Montreal Medico-Chirurgical Society, received a letter from Dr. Attfield, dated from the General Medical Council Office, England, with reference to the proposed Indian and Colonial Addendum to the British Pharmacopœia. Dr. Adami at once took the matter in hand and appointed a committee to deal with all suggestions emanating from Canadians along this line. This committee has sought and obtained statistics and information as to what non-official drugs, whether Canadian or otherwise, are most in demand. This information has been mostly obtained through the medium of responsible wholesale pharmaceutical houses. Acting also on instructions in Dr. Attfield's letter, they have indicated in their report the methods of preparation and administration of those preparations which have been found most serviceable. So far as suggested, the following are the preparations this committee would have incorporated in the addendum: Elixir simplex, emulsio olei morrhue, extractum apocyni liquidum, extractum buchu liquidum, extractum grindelie liquidum, extractum hyoseyami liquidum, extractum pruni virginianæ liquidum, extractum tritici liquidum, extractum senegæ liquidum, extractum sanguinariae liquidum, extractum viburni opuli liquidum, extractum viburni prunifolii liquidum, liquor thymolis compositum, oleum gaultheriæ, syrupus acidi hydriodici, syrupus ferri phosphatis compositus, syrupus hypophosphitum compositus, syrupus senegæ, syrupus ipecaeanhæ, tinctura arnicæ flores, tinctura jalapæ composita, tinctura opii deodorata, tinctura sanguinariae, ferri hypophosphis, hydrargyri iodidum flavum, syrupus hypophosphitum, ferri phosphas solubilis resina laricis, tinctura resina laricis, syrupus ferri iodidi. This draft report contains the information so far gathered and sifted.

HOSPITAL FOR INEBRIATES.—At the recent meeting of the Canadian Medical Association, the committee appointed at the

last meeting in Quebec City, Dr. James Thorburn, Toronto; Dr. J. G. Adami, Montreal, and Dr. W. S. Muir, Halifax, brought in a report endorsing a scheme for the establishment of a hospital for the treatment of confirmed drunkards in the province of Ontario. That scheme was outlined in the report of a similar committee which reported at the meeting of the Ontario Medical Association in June last, which advocated the appointment of an inspector of inebriate institutions by the Ontario government. This inspector is, of course, to be a qualified medical practitioner, who has made the medical treatment of inebriety a special study. After his appointment had been made, the inspector should organize in the city of Toronto, a hospital for the medical treatment of pauper inebriates of the more hopeful class, and in the other cities of the province, an inebriate department in the existing general hospitals. In the providing of this treatment, which was to be done in accordance with the tenets of legitimate medicine, alone, no “proprietary remedy” was to be used. Now that this scheme has received the unanimous approval and support of the two leading medical associations in this country, we may expect that the Ontario Government, which has endorsed the scheme, will at once take action on the lines indicated in the Ontario Medical Association's report, and then appoint an inspector to take the matter in charge. In a large measure, the credit is due to Dr. A. M. Roseburgh, Toronto, who now for many years has taken a deep interest in this question; and it was only a few months ago that he was commissioned by the Prisoner's Aid Association of Canada to visit institutions in the United States and also to interview specialists in Canada and the United States with a view of enabling him to formulate a plan for the economic treatment of pauper inebriates.

MCGILL'S NEW PROFESSOR.—The newly-appointed professor of mental diseases at McGill University, Dr. Thomas Joseph Workman Burgess, was born in Toronto in 1849, and was educated at Upper Canada College, where he received numerous prizes. He was graduated in medicine from Toronto University in 1870, winning the University silver medal and the Starr gold medal, and for a year acted as clinical assistant in the Toronto Asylum. In 1875 he became assistant superintendent to the London Asylum for Insane and in 1887 was transferred to the Asylum at Hamilton. In 1890, he was unanimously chosen from a large number of applicants, as medical superintendent of the Protestant Hospital for the Insane, at Verdun, P.Q., an appointment which he still retains. Dr. Burgess is a member of the Canadian Institute, Toronto; an honorary member of the Hamilton Association; a member of the American Medico-Psychological Association; a Fellow of the Royal Society of Canada; a member of the Torrey Botanical Club of New York, and a Fellow of the American Association for the Advancement of Science.

CHRISTIAN SCIENCE FOOLERY.—Some idea of the hold which this doctrine obtains on some mortals is well illustrated by the report of a case from western Ontario. At Benchville, five miles from the town of Woodstock, a woman, the leader of the faddists of that rural hamlet, lost her baby through her foolish conduct. When the child was first taken sick, the mother called no doctor, and as a result the infant rapidly succumbed to the illness. The mother, however, refused to believe that the child was dead, and said that the spirit had merely departed from it, so she locked herself in the room with the little corpse and prayed for a day and a night, when the neighbors ultimately broke into the room, took the child from her and gave it decent burial.

Significance of Nose Bleed as an Early Symptom of Softening of the Brain.—Kompe has observed five cases in which copious, repeated nose bleed was one of the first symptoms of encephalomalacia. He explains it on the same grounds as the cerebral affection: the arteriosclerosis of the blood-vessels of the nasal mucosa.—*Archiv. f. Laryngologic*, viii, 3.

New Instrument.

A Dissector.

BY B. BRINDLEY EADS, M.D.
CHICAGO.

The instrument, a cut of which is here given has been invaluable to the writer in his operative work and doubtless will prove to be a most serviceable one to the general surgeon. All surgeons use some form of blunt instrument, it may be a director, a dissector or the handle of the scalpel, while the instrument here presented combines the advantages of all in one. It is made from a single piece of metal, seven inches in length, consisting of a central portion, the handle and two extremities, one of which is hook-shaped and fenestrated near the end and the other, slightly curved and blade-shaped, has a single longitudinal groove in the center. The latter is used for the isolation of structures located in tissue which can be pushed aside, thus avoiding hemorrhage and keeping the field of operation

dry. This is especially valuable in breaking down adhesions, enucleation of diseased glands, exposure of important vessels and nerves. The single groove serves as a guide for the back of the knife in making the incision and takes the place of the grooved director. Therefore this extremity may be regarded as a combined grooved director and separator of tissues and resembles the well-known Kocher instrument in its construction. When greater force is required in dissection, the hook-shaped extremity is brought into use. The eye acts as a ligature carrier, the blunt extremity of the hook, which can not be forced through the wall of the blood-vessel, makes it a convenient aneurysm needle. The instrument is manufactured by V. Mueller & Co., Chicago.

Book Notices.

MASTERS OF MEDICINE. CLAUDE BERNARD. By Michael Foster, M.A., M.D., D.C.L., etc. Professor of Physiology in the University of Cambridge. New York: Longmans, Green & Co., 1899.

Accident and environment have often more to do with one's life and its successes or failures than most of us are willing to admit. Certainly it was an accident that caused Claude Bernard to take up the study of medicine, and it was the later environments which influenced him to take up the gradually widening investigations to which he afterward devoted his life.

His parents being in moderate circumstances, Claude was given only a fair education, and while yet in his teens he accepted a position with a pharmacist. During his evenings he evidently had time for writing, for after compounding drugs for two years he produced a comedy which was placed on the local stage with more or less success. Stimulated by this he made another attempt. His second effort was a historic piece in the conventional five acts. This completed, he gave up his position in the pharmacy, and with a letter of introduction to the great critic, Saint-Marc Girardin, of Paris, he went to that city. When he presented his letter and manuscript to Girardin, the latter acknowledged that the drama showed its author possessed literary ability of no mean order, at the same time he discouraged the aspirations in the young man and advised him to take up some other calling. "You have

studied pharmacy," said the critic; "study medicine, you will thereby much more surely gain a livelihood." And this advice was followed.

No better man could have been selected to write the life of Bernard, the greatest among the physiologists of the past, than Sir Michael Foster, one of the greatest of the physiologists of the present. The history of Bernard is a history of the development of the science of physiology during the thirty-five years previous to his death. Bernard's life and works were so intimately connected with this development that it could not be otherwise. Hence, while the reader will find in this a history of the life of one of the greatest men of the century, written in such a style that it is as fascinating as a novel, at the same time he will find it more a history of the work and the experiments which made our present knowledge of physiology a possibility. Very little of the private life of the man is given. The story of such a life, full of indomitable energy, of unselfish devotion to scientific investigation, crowned with success after overcoming obstacles apparently insurmount-

able, can not but stimulate those who read it to greater efforts; and also it will bring one to a realizing sense of the fact that the knowledge we have of physiology, as well as other sciences, has come to us without labor on our part, through the most self-sacrificing labors of others.

THE GROSS AND MINUTE ANATOMY OF THE CENTRAL NERVOUS SYSTEM. By H. C. Gordinier, A.M., M.D., Professor of Physiology and of the Anatomy of the Nervous System in the Albany Medical College. With 48 full-page plates and 213 other illustrations. Philadelphia: P. Blakiston's Son & Co.

The anatomy of the central nervous system has of late years become so detailed that few text-books on nervous diseases can give more than a general view of its leading features without sacrificing more space than is desirable. The present work meets the need of a special anatomical text-book devoted to the nervous system. Notwithstanding the recent publication of the translation of Edinger's work, this book will find a place and meet a want. It has an advantage of being originally written in our language and that is not a slight one, when we consider the involved and elaborate nature of its subject. Dr. Gordinier has apparently done his work in a very thorough and satisfactory manner and the book in its present form will be a boon to the student in this department. Confining itself, as it does, to human anatomy it thus gives less chance for confusion and is more readily consulted by the average student and practitioner. For students it certainly has some decided advantages, though as a volume for reference it is inferior in some respects to Edinger's work. We have compared the two for the reason of their almost simultaneous appearance and their identical and kindred subjects.

The illustrations here are largely schematic and for that reason are more instructive; for the most part they appear to leave little to be desired. There is a good index and the make-up of the book is first-class in every respect.

A MANUAL OF DISEASES OF THE NERVOUS SYSTEM. By Sir W. R. Gowers, M.D., F.R.C.P., F.R.S. Consulting Physician to University College Hospital; Physician to the National Hospital for the Paralyzed and Epileptic, Queen Square. Third edition, Revised and Enlarged. Edited by Sir W. R. Gowers, and James Taylor, M.A., M.D., F.R.C.P., Senior Assistant Physician to the National Hospital for the Paralyzed and Epileptic, Queen Square; Physician to the Northeastern Hospital for Children and to the National Orthopedic Hospital, Volume I. Diseases of the Nerves and Spinal Cord. With one

Hundred and Ninety-two Illustrations. Octavo. Price net \$4.00. Philadelphia: P. Blakiston's Son & Company, 1012 Walnut Street.

This latest addition of Gowers' standard "Manual of Nervous Diseases" will be welcomed by the profession. The changes in the present volume bring it up to the more recent acquisitions in the department of neurology. The author has apparently accepted in full in this edition the later theories of the neuron and has added a chapter on the general constitution of the nervous system, in which the neuron theory and its history are elucidated. The additions are found, moreover, in every portion of the work and aggregate a total of seventy-six pages in excess of that of the prior edition. An appendix on the muscle spindle, by Dr. F. E. Batten concludes the text. The index is only moderately complete, but as this is the first volume this can be made more satisfactory when the finished work appears.

This revised edition of the work will, beyond question, continue its deserved reputation as one of the leading recent manuals of diseases of the nervous system in our language. It is so generally thorough in its treatment of the subjects that the very few places where it might be more full and complete without unduly expanding beyond the normal compass are hardly worth mention. It might be rivalled by other recent publications as a student's textbook, but as a manual and reference work for the practitioner it is unsurpassed.

BULLETIN OF THE OHIO HOSPITAL FOR EPILEPTICS. Vol. I, Nos. 2 and 3. Published by the Hospital: Gallipolis, Ohio.

Excepting a brief introductory with statistics and remarks by the superintendent, Dr. H. C. Rutter, the whole of this number of the "Bulletin" is by the pathologist, Dr. A. P. Ohlmacher. The memoirs are all pathologic reports, fully detailed, with critical discussions of the conditions found, their etiology and relations to the epilepsy in the clinical history. The concluding paper alone, a short one, deals with the comparative pathology of tumors as illustrated by certain marked growths in the lower animals.

One of the most important memoirs here published is that on the lymphatic constitution in idiopathic epilepsy, in which Dr. Ohlmacher maintains his views previously published on the importance of persistent thymic and general lymphatic hyperplasia as having a probable morphologic and casual relation to the disease. In this publication he reports five cases—additional to those previously published—of genuine *grand mal*, presenting the anomalies mentioned above, and being the most typical examples of idiopathic epilepsy out of nineteen epileptics examined post-mortem.

In all respects the "Bulletin" is a credit to the institution and to the state that gives it its support.

ARCHIVES OF NEUROLOGY AND PSYCHOPATHOLOGY, Vol. I, No. 4, 1898. State Hospital Press: Utica, N. Y.

This issue of this scientific memoir serial is practically a monograph on acromegaly, one hundred and ninety-four of its two hundred and fifty pages being devoted to the subject. The principal article, that of Dr. Harlow Brooks, is noticed editorially in this issue of the JOURNAL, and further mention of its contents can therefore be dispensed with here.

The other memoirs are, one a collateral subject, the distortion of the optic chiasm in a case of acromegaly, by Dr. Ward Holden; one that might be considered in a sense collateral, on the normal dimensions of the pituitary fossa by Dr. Alex. Herdlioka, and one, a preliminary psychologic study of a case of amnesia. The issue is a valuable one and maintains the standard set in this publication. ♣

TRANSACTIONS OF THE AMERICAN MICROSCOPICAL SOCIETY. Edited by the Secretary. Twenty-first annual meeting held at Syracuse, New York, Aug. 30, 31 and Sept. 1, 1898. Volume XX. Lincoln, Neb. Issued May, 1899.

This handsome volume of transactions contains several papers of medical interest, some of which have already been noticed

editorially in the JOURNAL. Still other short medical papers are those on "The Micrometry of the Human Red-Blood Corpuscles," by Frank Judson Parker; "On Feeding Some Insects with Cultures of Comma or Cholera Bacilli," by R. L. Maddox; "Questions in regard to the Diphtheria Bacilli," by M. A. Veeder, and "Medical Microscopy," by A. A. Young. There are, of course, the lengthier memoirs on biology and natural history themes with elaborate illustrations. The volume is, on all these accounts, evidently a valuable contribution to scientific literature.

Deaths and Obituaries.

W. N. AYERS, M.D., of Wichita, Kans., died at the home of his son, in that city, August 30, aged 88 years. Dr. Ayers was also an ordained minister of the Presbyterian Church; and was at one time a member of the Illinois legislature.

THOMAS J. DOUGLASS, M.D., died at his home in Ottumwa, Iowa, September 2, aged 72 years. He was graduated from the University of Pennsylvania in 1853 and from Western Reserve College in 1854, and began practicing his profession in Ottumwa in 1855. He was president of the Wapello County Medical Society and a member of the Des Moines Valley and the Iowa State medical associations.

JOHN M. GRAY, M.D., of Noblesville, Ind., died at the home of his daughter, in that city, August 28, aged 63 years. He was surgeon of the 39th Indiana during the Civil War, and distinguished himself by the skill and success of his work.

JULIUS HALL, M.D., University of Maryland, 1841, of Upper Marlboro, Md., died at the home of his daughter, in that city, September 4, aged 80 years. He had been a practitioner for over 57 years.

GEORGE W. KING, M.D., Pendleton, Oregon, died August 23, of cerebral embolism. He was a graduate of the Ohio Medical College, and a prominent medical figure in the Pacific northwest. He was 55 years of age.

AUGUSTUS DELOFFE, M.D., surgeon and major U. S. A., died September 3, at Fort Sam Houston, San Antonio, Texas. He was born in France and was appointed from Louisiana in 1874. His last post was the U. S. Barracks, Columbus, Ohio.

M. A. MOSHER, M.D., Austin, Ill., died September 12, aged 80 years. He was graduated from the University of Michigan, and had practiced medicine at Appleton, Berlin and Milwaukee, Wis. During the Civil War he served as surgeon in the 20th Wisconsin Infantry.

TIMOTHY H. O'NEILL, M.D., of Providence, R. I., a graduate of Maynooth College, Dublin, and of the New York Medical College, died at his home, August 29. He was at one time surgeon-general of the 5th Battalion of Infantry, Rhode Island regiment.

MATTHIAS J. PENNYBACKER, M.D., died in Philadelphia, August 29, aged 48 years. He was an alumnus of the University of Pennsylvania, class of 1876.

JOHN H. TILFORD, M.D., Windom, Minn., died September 7, after an operation for appendicitis. He was graduated from the Northwestern Christian University (Butler College) and the Indiana Medical College. He served through the Civil War as assistant surgeon of the 79th Indiana.

J. F. WADE, M.D., College of Physicians and Surgeons, Baltimore, 1884, of Arlington, Neb., died in that city, September 3, of heart failure. He was surgeon of the Fremont & Elkhorn Valley R.R.

WILLIAM F. TROUT, M.D., of McConnellsburg, Pa., died in that city from the effects of gangrene, September 7, aged 66 years. He was graduated from Jefferson Medical College in 1856, and was a surgeon during the Civil War. He also practiced for several years in Egypt and Palestine.

P. M. HOBBS, M.D., of Wymore, Neb., September 4. . . . Webster B. Johnson, M. D., of Savanna, Iowa, August 31, aged 25 years.

... Robert J. McClure, M.D., of Sandy Lake, Pa., September 3, aged 68 years. ... William Rubey, M.D., of Macon, Mo., August 31. ... Arnold Vogt, M.D., of Fort Madison, Iowa, September 2, aged 90 years.

DEATHS ABROAD.

S. HERXHEIMER, M.D., a prominent dermatologist of Frankfurt, Germany. ... F. Gonzalez del Valle, professor of surgery at Havana for over sixty years. ... H. Klotz, professor of gynecology at Innsbruck.

Miscellany.

Mechanics and Physiology of Bicycling.—The chief advantage of bicycling over gymnastic exercises, according to Siegfried of Naheim, is that it develops the attention and innervation, and this central activity is of a great hygienic and therapeutic value.—*Deutsche Med. Woch.*, No. 33.

Fatal Hemorrhage from Lesion of an Intercostal Artery.—The artery at the point of the injury (stab) was only .5 mm. in diameter, but the aspiration of the blood at each expiration prevented the formation of a clot and led to fatal hemorrhage, the first case of the kind on record. Suture of the pleura would probably have prevented the intrapleural effusion.—*Beitrag z. klin. Chir.*, xxii, 2.

Jejunostomy.—Maydl claims that the indications for jejunostomy are as comprehensive as for gastroenterostomy, and he prefers it in case of ulcer ventriculi and duodenal stenosis. He adopts Kunn's suggestion of a Y-implantation of the central in the peripheral end to control the bile and pancreas secretion. Twenty-two cases are tabulated in the *Mitth. a. d. Grenz.*, No. 4.

Injury to Abdomen Without External Wounds.—Eichel concludes, from the study of several observations, the urgent necessity of the immediate transportation to the hospital of every person injured in the abdomen, even without external wounds, without waiting for the classic symptoms of peritonitis. The case can then be supervised and operated on as soon as the pulse increases out of proportion to the body temperature.—*Beitrag z. klin. Chir.*, xxii, 1.

Extrauterine Pregnancies.—A patient succumbing to peritonitis in the supposed sixth month of pregnancy was found to have a fetus 51 cm. long, in the left tube, surrounded by evidences of a fetus developed to term in some previous pregnancy, macerated and partially absorbed. As this left tube showed no traces of a corpus luteum, and as its connection with the uterus was entirely obliterated, the fecundated ovum must have been derived from the right tube.—*Arch. f. Gyn.*, lviii, 1.

Philadelphia Mortality Statistics.—The number of deaths occurring in Philadelphia during the week ending September 9 was 405, a decrease of 132 over the corresponding week of last year and an increase of 69 over that of last week. The principal causes of death were: Apoplexy 17, nephritis 24, cancer 11, cholera infantum 29, tuberculosis 59, heart disease 29, pneumonia 17, septicemia 6, suicide 4, sunstroke 1; infectious diseases: typhoid fever 7, diphtheria 15, cerebrospinal meningitis 1.

Physiology of the Handwriting.—Recent research by Javal has established that the most rapid and even handwriting, written with the least effort, is obtained with the paper sloping to the left at about the same angle as the slope of the handwriting, the wrist making the motions rather than the fingers, the arm pivoting on the elbow, each line thus an arc of a large circle, and no dots or crosses inserted until the page is reread. He adds that physiology sheds a bright light on expert study of the handwriting. The advantages to be derived from a sloping handwriting were divined from the

earliest ages, as evidenced for instance, by the famous "Mesa Stela" in the Louvre.—*Bulletin de l'Academie de Med.*, July 18.

Predisposition to Infection Induced by Lesions of the Tissues.—Extensive experimental tests of the influence of ligatures, crushing the tissues and other injuries, on the development of bacteria introduced into wounds at Tavel's bacteriologic institute at Berne, have resulted in establishing the advantages to be derived from moist asepsis in treating wounds, and the necessity of avoiding ligatures of muscles and crushing of the tissues during operations. Tetanus spores introduced into wounds did not produce infection, unless the muscles had been ligated, in which case the disturbances in the circulation favored the germination of the spores and development of the bacilli.—*Chl. f. Chir.*

United Twins.—An unsuccessful attempt has been made to separate the six-year-old "Rosalina and Maria Sisters," the interesting case of xiphopagism mentioned in the *JOURNAL* of August 12. We also reproduce an etching of the twins from the *Brazil Medico*. Repeated examinations in medical circles had convinced every one that the twins were distinct and could easily be separated. Radiographs, after ingestion of bismuth, enabled the entire alimentary canal to be traced in each as in

a normal subject, while the connecting band cast no shadow. But the incision revealed a peritoneum in common and a single continuous liver, forming a flattened lobe 4 cm. thick and 10 cm. wide occupying the second upper quarter of the connecting band. There were no indications of a septum of any kind, and intervention by operation was abandoned. In other respects the organs of each were found apparently independent. The twins move around easily, one walking backward, but can only lie on one side with comfort.

Seasickness.—A physician on one of the North German Lloyd steamers has contrived an apparatus to register the movements of the ship, described in the *Wiener Klin. Woch.* of July 27. It records that the ship sometimes rose perpendicularly a distance of 13 meters, at times as rapidly as 2 meters in a second. Ah, the inventor, considers seasickness

a functional affection and that it only occurs when the motion of the ship forms an element in the consciousness. The immunity of infants and the lesser predisposition of the aged, its absence during profound sleep, and also the fact that the seasickness is forgotten in moments of great danger, tend to establish the functional character of the disease.

Prevention of Suicides.—Hauviller states that in his thesis (Paris, 1899), that material causes only indirectly produce the loss of psychic balance, which is the direct cause. Rich or poor, the first step is a sense of loneliness, of isolation, and association of any kind is the most effective means of combating the tendency. Family, religious, social associations all prevent the idea of self-destruction, and the stronger the ties the less it occurs. There are fewer suicides among the Jews than among the Roman Catholics, and fewer among them than in Protestants. In the army there are more among the petty officers than among the privates. Political crises lower the number of suicides as men are drawn into closer fellowship with each other.

Favorable Effects of Alkalinization.—Injections of sodium salts were made by M. M. Charrin Guillemonat and Levaditi very gradually in a series of experiments on rabbits and kept up a long while. Another group were injected with acids. All were then inoculated with pyocyanous cultures. The control-animals died in three days; the acid animals in eighteen to forty-eight hours, while the alkalinized survived several days and the injection was much less intense in every respect. The alkalines evidently modified the soil in favor of the defense.—*Progress Med.*, August 5. (*Soc. de Biologie.*)

Double Stars of Medicine.—Janus has an interesting article on members of the profession who have become so distinguished in other branches of learning that the medical aspect has been eclipsed. Rabelias and Schüller in literature, Erastus and Servetus in theology, Averroes and Locke in philosophy. The latter name is a surprise and the article quotes at length from some unpublished MSS. in the British Museum to show that this intellectual ruler of the eighteenth century was an Oxford bachelor of medicine, physician to the Earl of Shaftesbury and others, and constantly compiling medical notes and suggestions.

Surgical Treatment of Epilepsy.—Contrary to most writers, Schär advocates intervention always when internal, dietic measures have failed to afford relief in a brief space of time. The inmates of epileptic asylums should be examined occasionally by a surgeon to decide which cases promise a successful operation. His conclusions are based on the results in Kocher's clinic, and he claims that an injury of the skull properly treated never determines epilepsy. Abstinence from alcohol is imperative and even for persons who have suffered trauma of brain or skull, with no evidences of epilepsy.—*Archiv. f. Klin. Chir.*

Therapeutic Utilization of Salivation.—Von Leube had his attention called to this subject by a case of enormous ascites which spontaneously retrogressed and was eliminated in the saliva that attained an amount of three liters in the twenty-four hours, and 300 to 1000 c. c. were secreted daily for some time, with no recurrence of the ascites. Applying this experience to several cases of pleuritis exudativa, he ordered the patients to chew on rubber tablets, and thus induce a copious salivary secretion. In 4 cases out of 5 the effusion was absorbed, and once in 2 cases of ascites. He therefore advocates alternating or combining ptyalysis with diuresis and diaphoresis when other measures fail.—*Muenchener Med. Woch.*, August 15.

Fish Eater's Tuberculosis.—This is the name suggested for leprosy by Jonas Hutchinson, who attributes the disease to excessive fish diet, and believes that it will disappear when

cereals, potatoes and meat take the place of the salt fish. Except under special conditions it never occurs in inland districts. It is especially prevalent in Roman Catholic countries, he states, which impose a fish diet on fast days. The Greek church forbids fish as well as meat, and leprosy did not follow the church into the interior. Hutchinson's theory meets with so little acceptance among physicians that he is now appealing to the general public.—*Journal of Tropical Medicine*, June.

Alcohol and Legal Responsibility.—If a person under the influence of liquor is in a condition of health, he is responsible; if in a condition of disease, he is not responsible. This is the key to the question according to De Boeck, president of the Belgian Society of Mental Medicine. Where it is impossible to absolutely decide the pathologic or non-pathologic condition, attenuated responsibility must be admitted. A person under the influence of liquor is intoxicated and hence not normal. But alcoholism being so frequent, it has become "normal" as it were, and the problem is to decide whether the reaction to the alcohol is normal or not. Unconsciousness and amnesia are important symptoms of normal drunkenness, but opinions vary as to the degree necessary. He does not consider it necessary that they should be complete, nor that the soil should be prepared by a hereditary taint, to produce pathologic intoxication. The fact of having taken but a small quantity of alcohol should not be considered a necessary indication of pathologic intoxication, nor should the benefits of irresponsibility be refused to those who have taken large quantities.—*Revue Med.*, August 2.

Russian Congress to Arrest the Spread of Venereal Diseases.—The official summary of the reports and measures proposed at this conference in 1897, has just been published in German in a special number of the *Derm. Zftf.* The tendency of the seventy measures advocated is for stricter control of prostitution, ample gratuitous facilities for treatment of venereal diseases, with special employment and diversion for prostitutes kept in the hospitals for treatment—"a prominent field for private benevolent efforts"—examination of male visitors to brothels if possible, and opportunities for post-graduate courses in venereology. A medical certificate of the absence of any contagious disease should be required of servants and factory employes on entering and leaving service. The reports show that in the smaller towns extragenital infection is the rule instead of the exception. Introduction of a uniform nomenclature and schema for registering cases is urged.

Deaths in Michigan During August.—There were 2755 deaths in Michigan during the month of August, corresponding to a death-rate of 13.8 per 1000 population. This number is 356 more than the number registered for the preceding month, and is also about 300 more than the number registered for the month of August, 1898. There were 703 deaths of infants under 1 year of age, a marked increase, due to the prevalence of diarrheal diseases, from which cause there were 501 deaths reported, as compared with 265 in July. There were 296 deaths of children aged 1 to 4 years and 551 deaths of persons aged 65 years and over. The number of deaths from certain important causes of deaths were as follows: Pulmonary consumption 145, other tubercular diseases 53, typhoid fever 50, diphtheria and croup 22, scarlet fever 9, measles 7, whooping cough 34, pneumonia 82, diarrheal diseases under 5 years 501, cerebrospinal meningitis 45, cancer 112, accidents and violence 193. There is no marked increase in mortality from any other cause than diarrheal diseases, with the exception of slight rises of typhoid fever and whooping cough.

Women Doctors in Russia.—The *Philadelphia Press*, in a recent article, gives an interesting account of the history of women doctors in Russia, the earliest accounts of which began about twenty-five years ago. It is stated that owing to the lack of facilities which existed in that country many young

women pursued their course of instruction in Zurich, but owing to the trend of liberalism which existed throughout Russia in the sixties a medical college for women was founded in St. Petersburg in 1873. At this time much opposition was encountered and the idea was combated on the ground that such condition tended toward disintegration of the family, and was opposed to the public morals. The school was an annex to the regular military medical college and the girls were admitted on the same footing as boys, each of whom required a course of instruction extending over a period of five years and passed the same examinations, but in the case of the girls the full title of physician was not granted. At the university the women students were regarded by their male comrades as equals, and, as an example of the friendship that existed between them, the following is told: One of the female students was in need of a book on anatomy and was overheard by a male companion, unknown to her, but who at once said: "I'm sorry not to have one myself, but if you wait a moment I shall surely get one for you," and a few moments later appeared with several copies loaned by her friends, and on presenting them he said: "Take whichever one you like best; take even several, if you know of others of your classmates that may be in need of them." At the time when the first girl students were to pass their final examinations war between Russia and Turkey broke out. Russia had hardly sufficient physicians; the fourth and fifth year students of the Military Medical School were ordered to the battlefield. The girls seized this opportunity, eager to prove their capability to perform the functions of physicians, and during the war the Russian women physicians made themselves generally known and turned public opinion in their favor.

Mosquito Origin of Malaria.—Bignami now asserts that the *Anopheles pictus*, as well as the *claviger*, serves as a host for the crescent-forming parasite.—*Annali de Med. Na.*

Pennsylvania Examinations.—The result of the recent examinations before the Pennsylvania State Board of Medical Examiners was as follows:

Colleges.	Examined.	Failed.	Percent, per cent of failures.	General Average
University of Pennsylvania	143	1	00.7	86.00
Women's, Philadelphia	28	0	00.0	81.22
Medico-chirurgical	93	15	16.3	79.94
Western Pennsylvania	46	7	15.2	79.01
Jefferson	34	3	8.8	78.24
Miscellaneous	74	32	29.7	76.31
Baltimore Medical	7	4	59.1	72.84
General average	425	52	12.2	80.04

Quinin in Malarial Hemoglobinuria.—The JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION bears the fact that it still reads the "assertion" that the administration of quinin in malarial hemoglobinuria aggravates the "symptom," and then asserts that very few practitioners in the malarial districts believe that quinin will produce this condition. The JOURNAL, by rules of logic which are naive, to say the least, says: "Why the hemoglobinuria of malarial origin has been singled out among all the other varieties and stated to be increased by the use of quinin, is not clear. Thus we have: 1, paroxysmal hemoglobinuria, and 2, toxic hemoglobinuria, including that due to chlorate of potash, carbonic acid, naphthol, carbon dioxide, and the poisons of infectious fevers, etc." It says further: "The bright red urine observed is not always a hematuria—in fact, a hematuria is the rare exception, for hemorrhages, of whatever nature, are uncommon in all varieties of malaria."

It is very easy to sit on the editorial tripod on the shore of Lake Michigan and, in the above *ipse dixit* style, dictate to experienced men how they should treat a "symptom," of which

the editor shows his ignorance by calling it such. Malarial hematuria—one term is as good as another, since both are incorrect—is a pathologic entity, with a symptom-complex all its own. To place it in a category with other conditions which also have one of the symptoms does not strike the ignorant swamp doctor as good logic.

Now, to begin with, the form of malarial fever accompanied by bright-red urine, we denominate hemorrhagic malarial fever. There is a distinct hemorrhage, and it is most effectually treated with quinin, and rationally so, because the malaria is in an active form and requires the classic remedy for its removal. Not so in the other condition; here the bulk of the color is due to methemoglobin, the urine is black or the color of port wine, and, the JOURNAL to the contrary notwithstanding, there is always some blood present. In this condition the malarial organism is either already absent or is rapidly disappearing from the blood.

The symptoms of icteric methemoglobinuria of malarial origin are about as follows: After a variable history of previous intermittents, treated with quinin, the patient is suddenly taken with a chill, lasting from a few minutes to an hour, the thermometer indicating from 101° to 106°, usually about 103°. This is followed by no increase of temperature and absolutely no sweating. After a short time, from a few minutes to an hour, the patient will pass, with great vesical tenesmus, from 30 to 300 c. c. of dark-colored urine; if the quantity is small it is inky-black, and the prognosis is bad. The urine is highly albuminous, and contains a variable number of blood discs, mostly bleached out; the specific gravity is from 1025 to 1040. If the patient is still under the influence of quinin, a second or third rigor may appear, without any periodicity, and each additional dose, with mathematical precision, will bring on a paroxysm, and each paroxysm is followed by darker urine, but if no more rigors appear it will gradually clear up. The patient has an anxious facies, rapid, sighing respiration, a rapid, feeble pulse, and more or less nausea. In from six to ten hours after the onset, active vomiting appears, which is projectile, the skin becomes markedly jaundiced (darker than obstructive jaundice), the bowels are obstinately constipated, and the shock becomes more marked. The blood in the beginning may contain from three to four million red cells, some plasmodia, and there may be seen some phagocytosis. In twelve hours the count may be one and a half million, and the plasmodia may have disappeared; even at the autopsy they may be absent in the internal organs.

In favorable cases, after sharp elimination, all the symptoms gradually disappear, the stools, which were at first black and tarry, become lighter and of a golden-yellow color, the urine is voided frequently, becomes more dilute, and contains epithelia and all kinds of casts. In fatal cases the rigors continue, the patient becomes delirious, suppression sets in, and he dies with "uremia." Or, there may be amelioration of symptoms, but with suppression, the patient will feel well and will not believe that he is certainly doomed, and may live eight days after complete suppression. In some few rare cases the plasmodia may persist and give rise to a febrile movement; in such we use methylene blue, some preferring sodium thiosulfate.

Now, the writer will tell the learned editor of the JOURNAL a secret; he has never seen a case treated with quinin recover; on the other hand, by the eliminative treatment the majority of cases make a rapid recovery. This is no editorial bombast, but can be attested by thousands of swamp inhabitants. If a malarial infection is promptly and scientifically treated with quinin this peculiar disorder can be positively prevented, but the dilatory and improper use of it in the face of a malarial cachexia will certainly bring on an attack of methemoglobinuria in a susceptible individual.

The writer has seen several cases of quinin methemoglobin-

uria; it has no existence apart from malarial cachexia. The editor of the *JOURNAL* can find any number of such cases in the Mississippi Valley, provided he has money enough to induce a subject to take a dose of quinin; they generally take arsenic. It seems to be a chronic condition. We admit that we do not understand it, but know, however, that in chronic malaria the hemoglobin percentage falls after quinin is exhibited, just like the pulmonary effect of a mercurial inunction in secondary syphilis.—*The Memphis Lancet*.

The Value of a Medical Defense Union.—We have referred several times of late to the great advantages of a medical defense union for the protection of the members of the profession against blackmail, charges of professional incompetence, etc. A case which has recently occurred in England emphasizes the value of such a league in so marked a manner that we can not refrain from laying the gist of it before our readers.

Dr. Kidd, a medical man in practice at Bromsgrove, whose diplomas of M.B., London, and F. R. C. S., England, mark him at once as a physician of standing, was the medical officer of the Bromsgrove sanitary district, and also of the joint isolation hospital established for the three sanitary districts of Bromsgrove, Redditch, and Droitwich. On Sept. 17, 1898, a member of the Bromsgrove urban district council made a public allegation, according to the *Lancet* for August 12, that a "patient was in the hospital one week and three days and never saw the doctor once, and all the six weeks and three days she was there she never had one drop of medicine." Further, according to the *Lancet*, it was alleged that, although a patient (a little girl) was in great agony for two days, the medical officer did not see her, and that she was frightened by a threat of being put into "boiling blankets" to make her keep quiet in bed; that the medical officer actually ordered this treatment, and that the girl died while undergoing it. Moreover, it was stated that "men, women, youths and boys and girls had to eat, drink, lie, and sleep all in one room; also that the hospital was so badly constructed that rain came into the building, and that the wind could be felt by the patients as they lay in bed.

The facts of these allegations appear to have been that the patient in the first case "was admitted (into hospital) at a late stage of the disease, that convalescence was not interrupted, that she required no medicine, that it was not true that Dr. Kidd did not see her for ten days after her admission, and, further, it was shown that she was the defendant's aunt. The little girl was niece to the woman already mentioned. Nephritis set in as a complication of scarlet fever and she died from uremia. A hot-pack was ordered as a means of treatment—hence the statement about 'boiling blankets'—but the disease was too far advanced for it to be of any avail. It was also proved that Dr. Kidd was indefatigable in his attendance on the patients. The hospital was only a temporary one—a hospital marquee tent with double canvas walls. It was well ventilated, but when there was heavy rain the water trickled down in one or two places, the beds, however, being carefully removed from the damp. The patients were mostly young children, but while the woman already referred to was an inmate there were two boys as patients, about fifteen or sixteen years old. They occupied the same large tent, but their beds were thoroughly screened off from the other beds and Dr. Kidd had heard no complaints."

It is easy to see how such charges may have arisen without malicious intent, and it is still more easy to comprehend how they might form a serious basis for malicious persecution.

It so happened that, according to Dr. Kidd's letter, published in the same number of the *Lancet*, he became a member of the Medical Defense Union five years previously, little thinking that he was himself likely to become involved in litigation. But suddenly there came upon him these damaging charges

of gross professional incompetence and negligence; charges which, as he says, he certainly would have been unable to deal with adequately on his own slender resources. He sent the facts to the secretary of the Medical Defense Union, and at once received a most careful and exhaustive letter of advice from their attorney, followed by an eminent counsel's opinion. The union subsequently took the case off his hands, bringing an action for libel against the author of the charges, entirely vindicating Dr. Kidd's character, disproving the allegations in detail, and obtaining for Dr. Kidd a verdict for £150, the foreman of the jury taking care to explain that it was only the defendant's pecuniary position which prevented them from assessing much heavier damages against him.

It is not only the cost of the proceedings, when an incriminated physician has either to defend himself against malicious or otherwise unjust action, or to vindicate his character against slanderous statements by bringing suit himself against their author—a cost which must inevitably be considerable even though he gain his case; but it is the wear and tear, the sleepless nights, the worry and anxiety, the unfitness for good work which comes from being in a state of tension, which are also saved to him by his membership in such a union. On this point Dr. Kidd says:

"During the six months over which the action was pending, the whole of the work connected with the case was taken off my hands by the solicitor to the union, without the slightest trouble to myself, and I need scarcely have been aware that I was involved in any proceedings at all; but the work was being done nevertheless with an amount of skill and care and unwearied labor which it would be impossible to praise too highly, and which could not have been exceeded if I had been the most wealthy and exalted client in the land, instead of a humble country medical man. When I think," adds Dr. Kidd, "of what the union has done for me in this trying case and of what I should have suffered without its powerful and kindly aid, and when I reflect that such advantages are open to every member of our profession at the cost of 10s. 6d. yearly, it becomes a matter of surprise to me that the membership roll of the Medical Defense Union is not identical with the *Medical Register and Directory*."

In addition to these considerations, the fact must not be lost sight of that the existence of such an association would act as a strong moral power in checking ill-advised and unwarrantable actions against physicians; for not only would the knowledge that the physician had the association at his back act as a deterrent, but further, the necessary preliminary examination of his case by the union before espousing his cause would of itself testify that he stood well with the profession, and be, moreover, a presumptive cause for his assailants to expect failure.

In this country, we believe, slanderous charges are more prevalent, actions for malpractice more common, and attempts to extort blackmail from physicians more frequent than in almost any other. We are constantly reading accounts of such in medical and lay journals. It does, therefore, seem extraordinary that no organized effort of any magnitude or universality exists in this direction; and while we question if it would be wise to impose upon the AMERICAN MEDICAL ASSOCIATION additional functions of a nature so divergent from those with which it is at present fully occupied, we do think that the initiative in organizing such a league might, owing to the far-reaching influence of the ASSOCIATION, wisely take its rise from that body. But from whatever direction it comes, we would urge that such a league be formed, and that it be national, with state branches, and not so many isolated state leagues. For the principle of the stronger helping the weaker will apply as much between one state—or all the states—and another as between individual medical men.—*Editorial N. Y. Medical Journal*, September 9.

Christian Science Legal.—Attorney-General Akin has rendered an official opinion to the effect that the treatment of disease by so-called spiritual or mental methods is not an offense under the criminal code of Illinois. This is an additional reason why the next legislature should pass a law forbidding such treatment for infants or children. A man or woman who has reached years of discretion is supposed to be a competent judge as to what treatment he or she shall have in case of illness. If some adults think they can get any benefit from Christian Science, or mind cure, or the prayers of Dowie, they have a right to risk their lives under this sort of treatment if they so desire. But small children should be protected from the ignorance or charlatanism that deprives them of skilled medical treatment in case of dangerous illness. Whatever virtue there is in mental or faith cures arises out of the faith of the patient and the power of autosuggestion. Infants can get no benefit from these methods.—*Chicago Tribune.*

Queries and Minor Notes.

THE TUBERCULOSIS CONGRESS.

KANSAS CITY, MO., Aug. 28, 1899.

To the Editor:—Can you inform me where I can obtain the Proceedings of the recent Tuberculosis Congress in English. The information will be appreciated.

J. C.

ANSWER: The JOURNAL is not aware of any publication of the proceedings of the recent Tuberculosis Congress in English other than the abstracts given in correspondence and otherwise in the medical periodicals. We presume such publication will be made. Probably some of our readers may be able to enlighten our correspondent, as well as us.

BILIARY CALCULI.

EVANVILLE, IND., Aug. 31, 1899.

To the Editor:—I wish to put on record a case of biliary calculi that came under my observation and was operated upon by me July 15, 1899. The gall-bladder contained 331 distinct calculi, the largest as large as a good-sized marble, and the smallest as large as a grain of wheat. I have not seen or heard of a case with so large a number of stones. Perhaps you or some of the JOURNAL readers have, if so I would like to know it.

A. M. HAYDEN, M.D.

The case of our correspondent is certainly of interest, but not unprecedented. Others of equal or greater numbers have been published; for example, Meiseubach's of 1100 calculi, in the *Medical Mirror*, 1885, vi, p. 92. Naturally, with these excessive numbers the calculi must be very small, and some of them may have been counted that were not nearly so large as the smallest mentioned by Dr. Hayden, "as large as a grain of wheat," and that would have been overlooked by other observers.

The Public Service.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., to and including Sept. 7, 1899:

Lewis Balch, major and surgeon, Vols., from New York City to San Francisco, Cal., for duty in the Department of California.

William E. Borden, captain and asst. surgeon, U. S. A., member of an examining board in Washington, D. C., vice Major William F. Lippitt, Jr., surgeon, relieved.

Robert Boyd, acting asst. surgeon, leave of absence extended, to Louis Breckin, major and surgeon, U. S. A., from duty in Porto Rico to post duty at Fort Logan, Colo.

George L. Cable, acting asst. surgeon, from New York City to Athens, Ohio, for annulment of contract.

Christopher C. Collins, lieutenant and asst. surgeon U. S. A., sick leave extended.

John B. Darling, acting asst. surgeon, to temporary duty at Fort Snelling, Minn.

William B. Davis, major and surgeon, U. S. A., leave of absence extended.

John Ryan Devereux, acting asst. surgeon, leave of absence granted.

Marion O. Fulcher, acting asst. surgeon, from Waynesboro, Ga., to duty at Camp Meade, Pa.

William W. Gray, major and surgeon, U. S. A., relieved from further station at Fort Huachuca, Ariz.

Philip F. Harvey, major and surgeon U. S. A., member of an examining board in San Francisco, Cal., vice major E. B. Mosely, surgeon, relieved.

George L. Hicks, appointed lieutenant and asst. surgeon, Vols., August 17, 1899, and assigned to the 35th Inf. Vols.

Aubrey F. Higgins, acting asst. surgeon, from Germantown, Pa., to Governor's Island, N. Y., for duty in the Department of the East.

John Sturgeon Hill, acting asst. surgeon, from Alleghevy, Pa., to San Francisco, Cal., for duty in the Department of California.

D. J. Johnson, acting asst. surgeon from duty with the 47th Inf. Vols. at Camp Meade, Pa., to post duty at Fort Strong, Mass.

Franklin M. Kemp, lieutenant and asst. surgeon, U. S. A., leave of absence granted.

Thomas R. Marshall, captain and asst. surgeon 41st Inf. Vols., from New York City to join his regiment at Camp Meade, Pa.

Clarence B. Millhoff, lieutenant and asst. surgeon, U. S. A., member of an examining board in San Francisco, vice Captain Isaac P. Ware, asst. surgeon, relieved.

Curtis E. Munn, major and surgeon, U. S. A., from Fort Logan, Colo., to his home to await retirement.

John C. Orr, acting asst. surgeon, from Fort Strong, Mass., to Camp Meade, Pa., to accompany the 5th Inf. Vols., to Manila, P. I.

William O. Owen, captain and asst. surgeon, U. S. A., member of a board at St. Louis, Mo., to fix responsibility for certain horses.

John W. Thomas, acting asst. surgeon, from Washington, D. C., to duty at Key West, Fla.

Compton Wilson, acting asst. surgeon, revocation of recent orders directing him to proceed from New York City to Washington, D. C.

Movements of Navy Medical Officers.—Changes in the medical corps of the U. S. Navy for the week ending Sept. 9, 1899:

Surgeon E. H. Marsteller, ordered to duty in connection with recruiting rendezvous, Buffalo, N. Y., to report at the New York Navy Yard, September 4.

P. A. Surgeon B. R. Ward, Asst.-Surgeon J. F. Chaffee, are detached from the *Boston* when put out of commission and ordered home to await orders.

Surgeon J. C. Decker, detached from the *Monadnock* and ordered to the *Monocacy*, at own expense.

P. A. Surgeon J. Staughton, detached from the *Monocacy* and ordered to the *Monadnock* at own expense.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended Sept. 8, 1899:

SMALLPOX—UNITED STATES.

California: San Francisco, July 31, 5 deaths.
Florida: Jacksonville, September 3, 1 case.
Kentucky: Louisville, August 31, 2 cases.
Massachusetts: Boston, August 25 to September 2, 2 cases.
Ohio: Cleveland, August 19, 7 cases, 2 deaths.
Pennsylvania: Altoona, August 26 to September 2, 7 cases.
Texas: 16 points in State, August 26 (71 cases and 2 deaths have, except in two instances, been traced to a hospital at Sedalia, Mo.)

SMALLPOX—FOREIGN.

Belgium: Antwerp, August 19, 1 case, 1 death.
Brazil: Bahia, July 29 to August 7, 3 cases, 1 death; Rio de Janeiro, July 21 to August 1, 55 cases, 22 deaths.
Greece: Athens, August 19, 7 cases, 2 deaths.
India: Bombay, August 8, 6 deaths.
Mexico: Chihuahua, August 26, 3 deaths; Nuevo Laredo, August 26, 1 case.
Russia: Moscow, August 11, 2 cases, 2 deaths; Odessa, August 12 to 19, 11 cases, 3 deaths; St. Petersburg, August 19, 3 cases, 1 death; Warsaw, August 12, 1 death.

Straits Settlements: Singapore, July 15, 2 deaths.

YELLOW FEVER—UNITED STATES.

Florida: Key West, September 2, 96 cases, 7 deaths.

Louisiana: New Orleans, September 2, 2 cases, 1 death.

YELLOW FEVER—FOREIGN.

Brazil: Bahia, July 22 to August 12, 3 cases, 2 deaths; Rio de Janeiro, July 21 to August 1, 5 cases, 3 deaths.
Colombia: Panama, August 22, 20 cases.
Costa Rica: Port Limon, August 14, 1 case, 1 death.
Cuba: Christo, August 19, 1 case; Sancti Spiritus, August 24, 2 cases.
Mexico: Tuxpan, August 21 to 28, 9 deaths; Vera Cruz, August 24 to 31, 19 cases, 14 deaths.
Salvador: San Salvador, August 1, 2 cases.

CHOLERA.

India: Bombay, August 1 to 8, 2 deaths; Calcutta, July 22 to 29, 53 deaths.
Japan: Osaka and Hiogo, August 12, 4 cases, 1 death.

PLAGUE.

China: Amoy, July 22 to August 8, 425 deaths; Hongkong, July 22 to 29, 37 cases, 39 deaths.
Egypt: Alexandria, August 7 to 13, 45 cases, 39 deaths.
India: Bombay, August 1 to 8, 75 deaths; Calcutta, July 12 to 29, 16 deaths.
Formosa: Tamsui, July 25 to August 10, 13 cases, 20 deaths.
Russia: St. Petersburg, August 12 to 21, 1 case.
Straits Settlements: Penang, July 14 to 22, 49 cases, 39 deaths; Singapore, July 15 to 22, 3 cases, 5 deaths.

CHANGE OF ADDRESS.

Brillingham, J. D., from 1823 So. 17th St. to 4205 Girard Ave., Philadelphia, Pa.

Butler, G. F., from 103 State to 794 Adams St., Chicago, Ill.

Daly, J. J., from LaGrange, Ill. to Charles City, Iowa.

Daly, V. M., from Chicago to Pontiac, Ill.

Griffin, O. A., from Fayette, Ohio to 812 E. Washington St., Ann Arbor, Mich.

Hull, G. S., from Mt. Alverno, Pa. to Pasadena, Cal.

Hartman, J. C., from Keown to Box 156, East Pittsburg, Pa.

Herr, A. W., from 440 to 230 Euclid Ave., Cleveland, Ohio.

Heston, H., from Columbus to Baltimore, Ohio.

Krebs, L. L., from Philadelphia, Pa. to 1406 11th St., Des Moines, Iowa.

Lawson, T., from Mountain Grove, Mo. to El Reno, O. T.

McCready, H., from New Concord to Brice, Ohio.

Noble, C. P., from 1637 Broadway to 1509 Locust St., Philadelphia, Pa.

Patterson, C. L., from Marango to West Side, Iowa.

Small, J. W., from New York to North Tarrytown, N. Y.

Schabinger, C., from Felton, Del. to S. E. cor. 11th and Brown Sts., Philadelphia, Pa.

Tifschitz, A. H., from 1010 Milwaukee Ave. to 11018 Michigan Ave., Chicago, Ill., Pullman Station.

Original Articles.

DOES THE REMOVAL OF THE OVARIES EXERT BENEFICIAL INFLUENCE ON THE SUBSE- QUENT PROGRESS OF MALIGNANT DISEASES?

BY E. E. MONTGOMERY, M.D.,
PHILADELPHIA.

No class of cases has stimulated a greater variety of methods for treatment than malignant disease of the genital organs, including the mammary gland. In combating this dreadful disorder medical and surgical therapeutics have been exhausted. In searching for new agencies it is not surprising, in this day of organo-therapy, that the animal secretions and extracts should have found employment. Thyroid extract has found its advocates. The well-recognized, and frequently demonstrated influence of the ovaries on the circulation of the genital glands naturally led to the consideration of the influence of their ablation on the preexisting malignant disease.

To G. Thomas Beatson of England belongs the honor of being the first surgeon who deliberately removed the appendages for the relief of mammary cancer. To him he did, June 15, 1895, on a woman aged 33 years, from whom in the preceding January the entire breast, including the pectoral muscle and the axillary glands, was removed for undoubted cancer, an operation which was so extensive on the skin surface as to require parallel incisions to permit the closure of the wound. Three months later the wound reopened and there was general involvement of the scar. Thyroid extract was then tried for its influence on mucoid degeneration, but without appreciable influence on the progress of the disease. Then, in June, as already stated, oöphorectomy was done. The right ovary was healthy, the left slightly cystic. The improvement in the diseased mammary region was immediate, though the use of thyroid extract as a powerful lymphatic stimulant was resumed at the end of a month and continued subsequently. The improvement was uninterrupted, and eight months later he could report the patient in good health with a healthy cicatrix. In his subsequent cases—two in number—while showing improvement, the result was not so gratifying as in the first case. In a recent discussion, Dr. Stites mentions having seen Beatson's first case, which was regarded as a cure, and asserts that the disease is returning.

Stanley Boyd reports seven cases in which he has performed oöphorectomy for the relief of inoperable cancer of the breast with appreciably favorable results in the majority of cases. His first case, two years after the

operation, was almost free from true cancer, but this was a patient in whom the disease naturally ran a slow course. He attributed the beneficial influence in both his and Beatson's cases, to the oöphorectomy, and asserts that the patients of the latter would have done just as well had thyroid extract been omitted from the subsequent treatment.

In order to explain the beneficial influence of oöphorectomy, Beatson finds it necessary to construct a new theory for the etiology of cancer. His theory is based on the natural reproductive power of the body cells as especially exemplified in the lower forms of animal life. In the hydra, on the division of its stricture into separate portions, each portion will develop into a new and complete hydra. In the higher forms of life, the cells of the embryo are arranged into separate layers, and by subsequent differentiation, these cells are specialized into separate organs and tissues. One very marked group retains its power, the special function being the reproduction of the species. The setting aside of these cells for the special function does not deprive the other cells of their reproductive power, but so long as they are healthy, the ovaries and testicles exert an inhibitory influence by which such power is checked or controlled; in other words, special reproductive organs, rather than the nervous system are more potent in the regulation of processes of metabolism. An altered ovarian secretion or migration of ovarian cells which become parasitic may be the source of origin of cancer. He quotes Klebs as having come to the conclusion that cancer epithelial cells are transformed into ovum cells, probably due to the fructifying influence of the leucocytes on the cancer cells, causing them to multiply. Oöphorectomy, thus far, has been addressed to the treatment of malignant disease of the mammary gland, but if disease of the ovaries originates malignant disease, and their removal is serviceable in the one form, then the treatment should be applied to all forms of cancer and wherever situated, the extirpation of the ovaries should accompany the removal of the uterus in every case of uterine cancer, and the advisability of oöphorectomy should be considered in every case of inoperable cancer of the genito-urinary canal; as well as of the mammary gland and digestive tract.

Such conclusion opens the gates to operative procedure so widely that it is extremely important this theory should be carefully considered and its results thoroughly weighed before the conclusion is promulgated. The theory is a new one, but where all is speculation, that one which best harmonizes with the subsequent progress of the disease is most worthy of credence. If, however, the healthy condition of the special reproductive organs is necessary to control and keep in check the latent reproductive action of the various cells, and cancer is a result of the loss of this action through

*Presented to the Section on Obstetrics and Diseases of Women, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

disorder of their function, how much more must we expect the tissues to run riot, when inhibition is entirely removed. If the patient is liable to the genesis of cancer when inhibition is partially removed, will she not be much more subject to its ravages when inhibition is entirely destroyed? If we accept this control view, may we not explain the greater frequency of cancer at or following the climacteric to the decline of this inhibition, and further the apparently increased frequency of malignant disease in women who have had both ovaries removed as demonstrated by the statistics of Spencer Wells' individual work?

It would seem, then, that our theory carried to its logical sequence would contraindicate rather than render advisable the removal of the ovaries for malignant disease. While the theory of inhibition would seem to forbid the removal of the ovaries for relief of cancer, empiricism may demonstrate that the practice is more correct than the theory. An analysis of the results, however, does not in my judgment assure such a conclusion. The results of some fifteen operations in the hands of different operators show but one case in which the cure seems effected, and in this one a late report indicates a return. Many other cases appear temporarily benefited, but sooner or later the degenerative processes resume their fatal progress.

Every surgeon who has had an opportunity to operate on a large number of cases of malignant disease has been impressed with its erratic course. There are some cases in which the limits have been reached, in which it seems inadvisable to operate, and operation is followed by cure or delay in its progress for years. In other cases the involvement is so slight as to make us feel assured that operation must be associated with complete relief and yet a thorough, careful operation associated with removal of the ovaries is followed by early relapse.

My experience with the extirpation of the uterus for cancer has not impressed me with the fact that the individual enjoyed any special immunity against relapse on the removal of the ovaries. It does not seem unreasonable, however, that the ovaries may exert an influence on the circulation in the vicinity of the reproductive organs through the vasomotor system. Nature is economic of her forces. With the removal of the ovaries and the cessation of need for their performance of special functions, the unused organs are no longer so liberally supplied with nutrition, and hence temporary relief, but the history of cancer does not prove that it can be starved out, so relief must be at best but temporary.

A careful consideration of the subject forces us to the conclusion that the apparent relief is afforded through the vasomotor nervous system; that further experience is required to demonstrate not curability, but sufficient palliation and delay in the progress of the disease to compensate the patient for the discomfort of the additional operation; and that such an operation will only be of service if done during reproductive activity.

THIS SIGN—"Dr. Sylvester, American Dentist"—at the entrance to his office in a French city resulted in the condemnation of the dentist on two indictments: 1, for practicing under a pseudonym, as his name was in reality Sylvester Baumgartner; and 2, for neglecting to append the source of his medical diploma, the court asserting that dentistry being a branch of medicine, the derivation of the title of "Dr." must be stated on the sign to conform to the French law in respect to aliens practicing in France.

CLINICAL AND MICROSCOPIC DIFFERENTIATION OF SCLEROCYSTIC AND CIRRHOTIC DEGENERATION OF OVARIES AND CHRONIC OVARITIS.*

BY WM. H. HUMISTON, M.D.

Associate Professor of Gynecology in the Medical Department of the Western Reserve University; Gynecologist-in-Chief to St. Vincent's Charity Hospital; Consulting Gynecologist to the City Hospital.
CLEVELAND, OHIO.

It has been, and is still, the custom to regard the condition of the ovaries as termed cirrhotic and sclerocystic degeneration as merely a sequence of an acute ovaritis. No pathologist, so far as I have been able to learn, has attempted to separate these primary degenerations from those occurring secondarily to inflammation.

ETIOLOGY.

The etiologic factor is unknown. In speaking of arteriosclerosis, Osler says that the tendency to this affection, which shows in entire families, can be explained in no other way than that "in the makeup of the machine bad material was used in the tubing." And it does seem that in these cases the connective tissue elements throughout the economy are of "bad material." The same authority recognizes an independent primary cirrhosis of the kidney.

A cirrhotic ovary is smaller than the normal; is hard and inelastic, and usually deeply corrugated. A sclerocystic ovary, however, is two or three times the size of the normal organ, and is globular rather than ovoid. The surface is smooth and glistening and studded with slight elevations caused by enlarged Graafian follicles beneath the tunica albuginea. These follicles vary in number from five to twenty or thirty. The largest are found near the surface. On section numerous smaller ones are usually seen nearer the center. The tunica albuginea is always greatly thickened, and is firm and unyielding. The hilum also is usually the first portion of the ovary to show corrugations. In a smaller portion of the cases the vessels within the folds of the broad ligament are sclerosed.

In a simple case there are never any signs about the tube or the ovary indicative of past inflammatory action. It is otherwise in the secondary degenerative changes. It is also true that there is not the marked contraction in the latter as in the primary, and this corresponds exactly to the gross appearance of the kidney of interstitial nephritis, which usually is differentiated from the small granular contracted kidney by the term subacute interstitial nephritis. In the secondary form the tunica rarely, if ever, is involved to the extent to which the primary is subjected.

The microscopic differences between the primary—non-inflammatory—and the secondary—inflammatory—degenerations are especially quite marked. In the secondary we invariably find, in a section taken from some portion of the ovary, a small round-celled infiltration, or the connective-tissue elements in some of their various stages of development. Also, however advanced the stage of fibrosis may be, the numerical relation of nuclear to cellular elements in this variety is always greater than in the primary form. And the microscopic appearance of the vascular system is also different.

In the inflammatory group we have primarily a dilatation of the vessels with secondary contractions of their greatly thickened walls, and a lessening of their lumen.

*Presented to the Section on Obstetrics and Diseases of Women, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1895.

In the primary group there is usually no thickening of the vessel-walls; there is never any dilatation, and contraction occurs so early that the poor blood-supply is immediately noticeable, particularly to the periphery of the organ. In those cases of arteriosclerosis of the vessels within the broad ligament, we usually find the condition extending to the vessels entering the ovary—not otherwise. And, lastly, in the primary group the epithelial cells of the ovarian stroma are diminished in number, and usually in size. In some sections they are hard to distinguish from the connective-tissue elements, and appear to be undergoing a process of reversion. I would not state this as a fact, as yet, but it does frequently so appear.

These several microscopic differences are so constant and so decidedly marked, that I have no hesitation in separating them into two distinct pathologic groups.

In the chronic state of ovaritis the chief complaint is dysmenorrhea with intense neuralgic-like pains in one or both ovarian regions which are usually relieved with the commencement of the flow. Usually there is almost an entire subsidence of pain between the menstrual periods—at least, no exacerbations. Menorrhagia is also a constant symptom, undoubtedly due to the affection of the endometrium. The history of the early menstrual epoch is usually negative. In the primary or non-inflammatory, one will find that the dysmenorrhea has existed, usually from puberty, and that this symptom has gradually increased in severity, unrelieved by the flow, and occurring a number of days before, and lasting beyond the cessation of the flow.

A clinical symptom of the greatest importance in the making of a differential diagnosis is the occurrence of intermenstrual pain. The patient will state that she is

NORMAL OVARY (WALDEYER.)

SYMPTOMS.

The clinical history of the inflammatory group is well known and easily recognized. Usually there is a distinct history of infection of the endometrium and a subsequent salpingitis with extension to the ovary by contiguity of parts, or, as is more frequent in puerperal infection, the ovary is involved through the lymphatic system. Infection is accompanied by a chill or rigor, with an elevation of temperature, and an increase of the pulse-rate. Pain and localized tenderness are constant symptoms.

not only never free from pain, but has exacerbations between her periods, which sometimes are even more severe than dysmenorrhea—a poor term. A not infrequent symptom, too, is amenorrhea, or at least delayed catamenia. This prolongation of the usual prodromal stage is attended with most severe mental and physical suffering. And lastly the wear and the constant nervous tension to which these unfortunate patients are subjected lead to some of the most serious functional nerve disturbances. I will presently relate a few cases which more clearly define my meaning.

DIAGNOSIS.

I wish to allude briefly to an interesting discussion by Olshausen and Hegar, on the indications for castration. Olshausen says: "The difference between Hegar and me consists only in the fact that the former when he finds a few prominences on the ovary, or feels that it is firmer and somewhat thicker, or, on the contrary, smaller than usual, satisfies his anatomical conscience, while I, after having ascertained in the same way the dependence of the symptoms on the ovaries, at the most regard the often minimum anatomical changes as a corroborated

Hegar repeatedly declares as indispensable to the indication?"

Olshausen, then, castrates for neurotic symptoms without regard to pathologic changes. Hegar expresses astonishment when he relieves his patient after the removal of—to him—practically a normal organ. It is evident that both fail to appreciate the pathologic and clinical significance of these primary degenerations.

For the clearer understanding of the several points in making a differential diagnosis between the primary and the secondary groups, I arrange them in two columns.

PRIMARY OR NON-INFLAMMATORY SCLEROSIS. DIAGRAMMATIC.

- A —Germinal layer somewhat flattened and with small nuclei.
 B —Thickened fibrous tunica.
 C —Follicle which fails to break through the tunica.
 D —Absence of round-celled infiltration—only a few connective-tissue cells with increase of fibrous elements in the stroma.
 E —A few scattered epithelial cells of the stroma.
 U —Vessel-wall slightly thickened.

tion of my opinion, but recognize the fact that similar symptoms may develop without any changes in the ovary which are clinically recognizable. But an indication can not be offered by changes which are only recognizable on the post-mortem table or in the extirpated organ. That the dilatation of a few follicles, the hyperplasia of the stroma and cirrhosis, may produce such an array of symptoms—as the various neuroses—is entirely unproven and a priori very improbable." He also says: "We have several times obtained permanent results from castration in cases in which careful examination showed merely hyperplastic conditions of the ovary. I then ask what remains of the anatomical basis which

PRIMARY.

Non-inflammatory.
 No history of infection.
 Occurs in early life. (From puberty to thirty.)
 Often dysmenorrhœa since puberty.
 Intermenstrual dysmenorrhœic pains.
 Endometritis not constant.
 Amenorrhœa or delayed catamenia.
 Cystitis, a rare complication.

SECONDARY.

Inflammatory.
 History of infection with peritonitis.
 May occur at any period.
 Dysmenorrhœa after infection.
 Not so marked, or wholly wanting in some form.
 Always accompanied by endometritis. Menorrhagia or premature catamenia.
 Often a cystitis dating from the infection. (Particularly if gonorrhœal.)

Evidences in not a few cases of a granular and contracted kidney.

In a large per cent. of cases a marked arteriosclerosis can be found in some portion of the arterial system. No evidences of pelvic peritonitis.

Ovaries (one or both) usually prolapsed, firm, unyielding, globular in form, or small and exceedingly hard, but not adherent. Tubes usually not palpable.

Neurasthenia develops early, but is quickly superseded by one of the various neuroses.

Sometimes a subacute nephritis due either to a prior septic condition or extension from cystitis.

Evidences of a pelvic peritonitis.

May be prolapsed, bound down by peritonic adhesions. Mobility of uterus impaired. The tubes usually palpable, and found increased in size.

Neurasthenia common. Neuroses rare.

supporting the prolapsed appendages by the use of tampons or pessaries. I have administered the desiccated ovary without obtaining the slightest effect on the symptoms, and no effect whatever on the condition. A great deal of stress is being placed to-day—especially by Continental writers—on the internal secretion of the ovary and its effect on the metabolism. I am as yet incredulous. I know of no way to relieve this class of patients except by castration.

CHRONIC OVARITIS.

A great deal may be done for a chronic ovaritis by general medical supervision, and by gynecologic treatment. Often attention to the general health is sufficient to relieve these patients of much suffering. Pelvic massage and galvanism with tampons soaked in ichthylol and glycerin carefully applied to exert a slight

SECONDARY OR INFLAMMATORY SCLEROSIS (DIAGRAMMATIC.)

- A—Germinal layer usually absent and replaced by round cells or connective tissue.
- B—Tunica not much thickened nor fibrous.
- C—Round-celled infiltration with increased nuclear elements as compared with the primary form; few fibrous elements also.
- D—Epithelial cells of the stroma.
- U—Thickened vessel-wall and seen near the surface.

TREATMENT.

For cirrhotic degeneration the internal administration of mercury and the iodids, together with general tonics, has been tried. Local application of poultices and blisters to the abdominal walls in the iliac regions; the painting of the vaginal vaults with iodine; faradization and galvanization to the cavity of the uterus, together with all sorts of almost indescribable methods have proven of no avail. There is some relief afforded by

pressure, will, in a few cases, greatly increase the mobility of the adherent uterus and its adnexa, and relieve to a great extent the dysmenorrhea and the ovarian pain. If the patient is nearing the climacteric, an attempt should be made to tide her over the remaining period of sexual activity, when her symptoms will gradually decline with the cessation of the periodic congestions of the pelvic organs. But if the examination proves that the inflammation has been extensive

and its results of some magnitude, operation alone will avail.

The following cases illustrate these points:

Mrs. B. M., aged 38 years, has had two children, the youngest 8 years old. She has had two miscarriages, both prior to birth of the last child. There were no instrumental deliveries nor puerperal fever. The menses first occurred at the age of 18 years, and were at first irregular, but later were regular without pain, lasting four days. The quantity varied but little, and was never profuse. Her general appearance was good. She weighed 140 pounds. A general examination proved negative, as was also her family history.

Six years ago she was suddenly taken ill, with intense pain through the abdomen, and chills followed by a high fever. Just prior to that acute attack, she had considerable leucorrhœal discharge, and urination was very painful and frequent. She was ill in bed for a number of weeks, but again gradually resumed her routine household work. Ever since that time she has suffered intense pain at each menstrual period. She has been compelled at these times to stay in bed during the first two days. The menses occur every three weeks, the flow being usually prolonged and increased in quantity over that of her earlier years. While her general physical condition has remained good, she has become extremely nervous, irritable and hypochondriac. She is easily depressed, and in these states loses control of her nerves—that is, she becomes hysterical. Urination is at times painful, the bowels are regular. Her digestion is much impaired, and she has frequent attacks of palpitation of the heart. The uterus was in retroversion, and could not be replaced: both appendages were prolapsed, and imbedded in firm inflammatory exudate. Slight manipulation occasioned severe pain.

In July, 1895, I removed both appendages, freed all pelvic adhesions, and suspended the uterus. Both tubes were enlarged, the walls thickened, and the fibrinated ends occluded. Both ovaries were imbedded in dense tissue, and were in a state of chronic inflammation. She has since passed through a series of severe trials, both of domestic and business nature, and has remained in most excellent condition.

Such is the history of all this class of cases. Your familiarity with them allows me to proceed to a report of several cases of the other variety—the non-inflammatory or primary cirrhotic and sclerocystic degenerations.

Mrs. L. S., aged 30, though married nine years, has had no pregnancies. The first menses occurred at 16 years. They were regular but painful, lasting seven to eight days, and at first profuse in quantity. Later she has been irregular, missing one and two successive periods, and suffering great distress at such times as the flow should have appeared. She has constant, never-ceasing pain in both ovarian regions—but particularly the right—with excessive exacerbations occurring at no stated period, but usually two or three times each month. She states that these pains are at times even greater in severity than the pains accompanying the flow, and are quite similar in character to the latter. She appears to be quite emaciated and of sallow complexion. She weighs ninety pounds, having lost much during the last two or three years.

Her mother died of cancer of the uterus. She had scarlet fever when a child, and has never been robust. A general examination was negative. She has been in poor health since 1887, for which she can assign

no cause. She complains of backache, frequent attacks of migraine and pains in the right groin, extending down to the thigh. She is much reduced in weight, and is still losing flesh and strength. She is unable to do the general household duties, but spends most of her time, when not confined to bed, in china-painting. She is morose and taciturn, though naturally of a lively disposition, and is ready to submit to any measure which promises a chance of relief.

I found on examination an enlarged and cystic cervix; and the body of the uterus was tender but not enlarged. Both ovaries were prolapsed and double the size of the average normal organ. She complained bitterly of pain during this examination.

June 28, 1895, I first curetted the uterus. The cervical canal was dilated, and both the external and internal uterine mouths were stenosed. The mucosa lining of the body was normal; that of the cervix indicated a hypertrophic glandular inflammation. Through a small incision in the abdominal wall I removed both ovaries and tubes. The tubes were normal; the left ovary was treble the normal size and completely occupied by numerous cysts varying greatly in size. Microscopic examination showed the framework to be composed of a dense fibrillary network with none of the epithelial or ordinary connective-tissue stroma remaining. The right ovary was about half the size of the former, and was of the type of sclerocystic degeneration.

It has invariably been my experience that the most pain is on that side in which the cirrhosis is most marked, and not dependent on the degree of prolapse of that organ.

In the fall of that same year she made an extended trip up the lakes, during which time she gained fifteen pounds in weight, and, better yet, regained all of her former cheerfulness of disposition. She is now in most active life.

Mrs. F. F., aged 25, a widow, has one child 5 years old, and has had no miscarriages. She was 16 years old when her first menstrual period occurred. They have always been irregular, attended with much pain, in duration from three to four days, and the quantity has always been scant. She had amenorrhœa for five periods during the past year. She is anemic and very thin, weighing 92 pounds, though she measures five feet and seven inches in height. Her general condition is very poor. She has a weak, rapid, arrhythmic, irregular pulse. A marked sclerosis of the radials, temporals, and right popliteal arteries is observed. There is an enlarged, tender, prolapsed right kidney, and a suspicious sound is heard in the apices of both lungs during expiration. The slight amount of expectoration showed no trace of the existence of tuberculosis. Examination of the urine was negative, though she complained of a frequent desire to urinate. She also complained of frontal headache, and tenderness of the eyeballs, which was relieved by Dr. Brunner, oculist.

She complained of backache, pains in both groins, and soreness over the entire abdomen, dysmenorrhœa and "spells of pain" during which she remained in bed usually two days. These "spells" came on as frequently as two to three times each month. Formerly she weighed 130 pounds, but has been losing during the past two or three years. She is easily fatigued and discouraged, and at such times usually "gives way to crying spells." Three years prior to the time of the taking of this history she had had a lacerated cervix

repaired. Pelvic examination shows a slight perineal tear, a roomy vagina, a small cervix, an enlarged and partially retroverted uterus, and both ovaries prolapsed—enlarged and globular in shape, tense and unyielding. There is no evidence of peritonitis.

She was under general and local treatment for three months, during which time she was fitted with glasses. A proper bandage was made for holding up the prolapsed kidney. The uterus was kept forward by a pessary, and congestion relieved by hot douches and boroglycerin tampons. Attention was given to the diet, and the regulation of bowel movements, and general tonics were administered. She gained five pounds in weight. Her headache and backache were relieved, but there was no cessation of the pains in the pelvis, which were, in her opinion, the source of all her ills. Accordingly, in July, 1895, I first curetted the uterus, and immediately opened the abdomen. I found no adhesions; both tubes were normal; both ovaries were sclerocystic. In both broad ligaments I found arteries and veins with greatly thickened cirrhotic walls, especially so on the right side, corresponding to the most painful side. Both appendages were removed.

During her convalescence particular care was given to massage of the right kidney. She rapidly gained in weight and in general health. She married again shortly after her operation, and has been able to carry out the duties of a mother to a number of children.

Miss F. McG., aged 20, had her first menses at 14, which were irregular during the first year. They have since been irregular. There was no severe dysmenorrhoea until two years ago, since which time this symptom has steadily increased in severity. There has been a scanty flow, lasting usually two or three days only. She is poorly nourished, weighs 98 pounds, having lost ten pounds during the last few months. She is very costive. Urination is normal. A general examination proved negative. She had typhoid fever in 1895, and since then all her symptoms have been much aggravated. She complains of general lassitude, great weakness after the least exertion, severe pain in the right groin, constant but aggravated, preceding and during each period, and backache. The appetite and digestion are fair. There is constipation and leucorrhoea. Her family say that she has become peevish and fretful, and altogether changed from her former usually happy nature.

The general examination was entirely negative. On pelvic examination the cervix was found eroded, the uterus in retroversion, both ovaries palpable, the left very much enlarged, spherical, tense, though not painful, the right ovary larger than normal, and giving the characteristic feel of a sclerocystic degeneration. In June, 1897, I curetted the uterus. On opening the abdomen I found a thin-walled ovarian cyst, the size of a hen's egg, and on the right side a much degenerated ovary of the sclerocystic variety. Both were removed.

Although on the second day an acute hepatitis developed, and she lay very ill for a number of days, she gradually recovered. She left the hospital in six weeks, and during the past summer has led an active, open-air life, indulging her heart's desire in cross-country riding on horseback.

I am indebted to Dr. Spence for drawing these beautiful charts from the microscopic slides submitted to him, and I feel that he has aided me greatly in bringing out the subject in so clear a light.

RELATIONS OF HEADACHE TO AFFECTIONS OF THE EYE.*

BY S. D. RISLEY, A.M., M.D.,

Attending Surgeon to Wills Eye Hospital; Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine.

PHILADELPHIA.

I am not unmindful of your courtesy in requesting me to speak to the Neurological Section on the ocular phases of headache. I have not accepted the honor, however, without many misgivings. The ophthalmologist, in common with a large portion of the profession, holds his breath, and treads with great circumspection when he approaches the mysterious precincts of the nervous system, that region in which his neurologic colleagues hold high carnival, and disport themselves in lighter vein. The subject chosen for your symposium, however, is one of great interest to the ophthalmologist, since so large a percentage of his patients suffer from headache. In the last one thousand private eye patients applying for treatment for all causes, 50 per cent. complained of this symptom, and a considerable percentage of this number came by the advice of the physician, or through the persuasion of some friend, complaining of headache alone, and were unconscious of any ocular defect. It would not be surprising, therefore, if the ophthalmic surgeon should be in danger of overestimating the significance of the ocular apparatus in the etiology of pain in the head.

It is now very generally recognized that eye strain and certain diseases of the eyes are, in a large number of persons, the sole and sufficient cause for headache. It is probably less generally recognized that ocular affections may be the unsuspected cause. Extended experience, however, has shown that, in other groups of patients who suffer from headache, there may be no necessary relation between existing ocular defects and the pain in the head. It is not an unusual experience to remove the eye strain by glasses, to the great relief of ocular symptoms, without any appreciable result in relieving the headache; or, certain kinds of pain in the head may be relieved, and others still persist. Moreover, it is quite common to find patients who suffer greatly from impaired vision, chronically inflamed and painful eyes, who never have headache or other reflex symptoms. Therefore, I very highly esteem this opportunity to discuss the possible relations between the ocular conditions and headache, together with certain other associated phenomena.

The subject should be approached with a feeling of marked conservatism. It is not unusual to have under treatment at one and the same time two patients with similar or identical ocular defects, one of whom has no symptoms other than weak, painful, or inflamed eyes, lowered sharpness of sight, and a blurred page; while the other is constantly in the slough of semi-invalidism, from constant pain in the head and other reflex symptoms, which, from exposure to light or persistent use of the eyes, or after some unusual exertion, culminate in more or less frequent and violent explosions of so-called "sick or nervous headache," both of whom find complete and lasting relief from glasses so nearly the same that they might be used interchangeably.

It is obvious, therefore, that in searching for an explanation of such phenomena we must look for individual peculiarities not directly referable to the eyes. It is

*Presented to the Section on Neurology and Medical Jurisprudence, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

true that difference of vocation or environment may, in such cases, be a sufficient explanation. That is to say, in one case persistent use of the eyes may be unnecessary, and in the other compulsory. One patient may be in good general health, the other the victim of some complicating diathesis, as for example, lithemia. Ambition to excel or the sanguine temperament may drive one into constant activity in spite of the pain occasioned by use of the eyes, while the other rejects the goal of ambition, unwilling to secure success, or to woo fame at the sacrifice of pain. But even here we see indications of difference in temperament; a suggestion of the phlegmatic individual in the one, and the neurotic in the other. I do not wish to trespass on the domain of the neurologist at this point, but simply to state the proposition that, given certain abnormal ocular conditions causing eye strain, other things being equal, the neurotic individual is more likely to suffer from headache and associated phenomena, than are those who can not be called nervous people.

Although it is now quite generally recognized that eye strain may be the cause of headache, the truth that ocular affections may be the unsuspected cause still stands in need of wider recognition. I am still seeing patients who have passed into middle life, having from youth been the victims of headache, who are cured of their life-long malady by the correction of ocular defects, the real cause of their suffering never before having been suspected by themselves, or by their physician. It is an interesting fact in this connection, in a large number of eye-strain patients, that the symptoms fall with great stress on the eyes without giving rise to headache or other reflex symptoms. That is to say, the eyes are painful, vision is more or less defective, they have blepharitis ciliaris, sympathetic conjunctivitis, styes, partial lachrymal retention, etc., but do not suffer from headache. It is true that pain in the head may also be present, but these patients do not, as a rule, belong to the headache group. I take it, however, that this group of patients is not the one which will most interest you as neurologists, since they so obviously fall into the hands of the ophthalmic surgeon. Those who suffer most severely from headache, demonstrably due to ocular defects or diseases, are often quite free from local symptoms, and frequently suffer for years without suspecting their eyes as the source of their trouble. If there are ocular symptoms, they occur *pari passu*; or come on after the reflexes, and are regarded by the patient as due to the headache. Patients have often told me that their "eyes were weak because they had a bad head," and submit quite reluctantly to eye treatment since they recognize no primary ocular disturbance.

The location of the pain in the head is usually suggestive. Vertex pain is comparatively rarely due to the eyes. In optic nerve disease, as in retrobulbar neuritis and atrophy, there is, in many cases, pain in the front of the head on top, but it is not a vertex pain. The pain, when associated with eye affections, occurs in the brow, occiput, back of the eyes, as a hemicrania, or in the temples, and in point of frequency in the order named. Simple eye strain due to error of refraction particularly in children, will usually give rise to brow pain. If associated with some abnormality of ocular balance, as insufficiency of the interni, esophoria, or a hyperphoria, there will usually be occipital pain also. If there is at the same time marked turgidity or inflammation of the choroid, with retinal irritation, or macular disease of the retina and choroid, there will be a tense postocular pain which shoots to the occiput, nape of the neck, even down

the spine and radiating to the shoulders. Temple pains are not infrequent. I have in a number of instances witnessed the relief from pain in the region of the heart, which had caused much anxiety, follow the use of glasses, or the tenotomy of an ocular muscle.

There is a wide variety of manifestation in different patients. Many suffer almost constantly from brow and occipital pain. It disturbs their rest at night, and they awake in the morning with a dull pain in the occiput or nape of the neck. One patient remarked that he always woke in the morning feeling as though he had a billet of wood for a pillow. Although rarely free from pain, they suffer more or less acute exacerbations produced by exposure to light, from prolonged use of the eyes, or by general fatigue, but the symptoms are never violent. Others, while like the first, are rarely free from pain, are subject to a steadily progressive aggravation of all the symptoms until they culminate in violent onsets of "sick or nervous headaches," which drive them to bed in a darkened room, from which they emerge after twelve or twenty-four hours with a dull, sore head, red and weak eyes, which are tender to palpation, and unduly sensitive to light. The explanation for the advancing symptoms, up to the point of crisis, is found in the steadily increasing hyperemia and turgescence of the vveal tract of the eyes coming on under use, or by exposure to light. The relief comes from the subsidence of the congestion which results from the confinement in a darkened room, the emesis, the administration of saline cathartics, the cold compresses over eyes and brow, etc., which are the means of treatment ordinarily adopted by the patient. They return to their usual vocations, only to pass again through the inevitable cycle of suffering. Many persons through a large part of their lives suffer these constantly recurring torments once a week, or more or less frequently. Some recognize the effect of exposure to strong light, or the extraordinary use of the eyes as factors in causing these violent onsets of pain, but others never do, and ascribe their suffering to "biliousness," to overfatigue, hunger, and many other things, never suspecting their eyes as the cause.

Many regard their recurring sick headache as hereditary, since one or both parents or other members of the family suffer in the same manner. They think that therefore it is useless to seek permanent relief. While it may be true that the neurotic tendency is a family trait, it is equally true, even more probable, that the anatomic defects on which errors of refraction or ocular imbalance depend are hereditary. The regularity with which defective eyes, e. g., hypermetropia with astigmatism, are handed down from parent to child is one of the most striking facts in ophthalmology. It is highly probable that the defective form of the eye-ball which produces both the ametropia and the abnormal attachment of the ocular muscles to the globe, and is the cause of faulty binocular balance, is the direct result of defects in the shape of the bony orbit, and this in turn is due to distortion in the skull. It is to the form of the skull that family resemblances are largely due, hence the great frequency of heredity also in ocular defects. It is in a word another example where disease and impaired function has a congenital anatomic basis for its existence.

While the nausea and emesis together with the ensuing general relaxation seem to afford more or less speedy relief in the cases of so-called "sick headache," there are others who suffer what they call "nervous headache," and who are rarely nauseated, but have violent pain, and find the coveted relief only in opiates, or analgesics. I recall

the case of a merchant, the head of a large mercantile establishment, who had a high degree of hypermetropic astigmatism, and right hyperphoria, who was rarely free from a dull occipital pain. Suddenly, while at his place of business, he would be attacked by a right hemicrania, preceded by phosphenes. Taught by many experiences, he would summon a cab to take him home. His wife described one of these exacerbations to me. Arrived at home, his fortitude entirely exhausted, he would ring the door bell violently, enter the house holding his head between his hands, and, unable to reach his bed, would throw himself on the parlor or hall floor in despair, perfectly beside himself in an agony of suffering, when he would burst into a flood of tears, roar with pain, making the most violent manifestations, alarming his wife, and children and servants, until the doctor came and relieved him by a hypodermic injection of morphia. These attacks were relieved by the correction of his refraction error, and a subsequent tenotomy of the right superior rectus, but he still suffers from dull occipital pain "after a hard day." Since the attacks often came on after some fancied indulgence at the table, or at his club, or after an evening at the theater followed by a supper, he ascribed them to deranged stomach and liver, and was, as a consequence, a victim of the cathartic habit.

Another illustrative patient of this type was sent to me by the late Dr. William Pepper, under whose care he had been for "epileptic seizures." He also suffered the sudden violent onsets of headache very similar to those suffered by the case just related, but the paroxysms culminated in total loss of consciousness, convulsions, frothing at the mouth, and wounding of the tongue, after which he would fall into a profound sleep, often lasting for several hours, from which he could not be aroused. I found a hypertrophic astigmatism with exophoria, and marked choroidal disease due to eye strain. He received suitable correcting glasses after the prolonged use of a mydriatic, and returned to his home in one of the interior cities of Pennsylvania. I heard no more from him for eight years. He then returned for some change in his glasses, and much to my surprise related that he had not had a single return of his headache or convulsions after the treatment of his eyes.

There is a group of patients, of whom I have seen many examples, who suffer attacks of severe headache after journeying by rail, or in a carriage, or after a shopping expedition, the unsuspected cause of which is some ocular defect. They are usually women, and the paroxysm is ascribed to fatigue. I recall the case of a woman who wrote by the advice of her physician from a distant city, for an appointment for the examination of her eyes, stating that she would not be able to come to my office for a day, or possibly two days after her arrival in Philadelphia, as she would be compelled to pass that time in bed in a dark room suffering from "sick headache." Would I not see her at the hotel? I did so, and found her as she had predicted, in the throes of a violent headache; nervous, exhausted, suffering from nausea, and fruitless attempts at emesis. I immediately instilled a mydriatic, directed cold compresses to the eyes and brow, and gave her bromid of potassium. She was completely relieved in an hour, rose, ate a hearty meal, and came to my office the following day. She had a very high grade of hypermetropic astigmatism, which was corrected by glasses. She returned to her home wearing them and on her arrival at once wrote to me that for the first time in her experience she had been able to enjoy a railroad journey, and had reached home in perfect comfort.

The facial twitchings of school children, with brow pain, irritability of temper, restlessness, inability to sit quietly for a moment, disturbed sleep, precarious appetite, all of which makes them the despair of their mothers or teachers, I have many times seen relieved by a pair of glasses. Whether these cases are to be classed as petit chora or not, it is certain that the eye strain was for them "the thorn in the flesh" which produced a constant irritation of the nervous system.

Ocular symptoms or headache not infrequently manifest themselves for the first time after an attack of acute illness, e. g., measles, scarlatina, or pertussis, and are not infrequently ascribed to the lowered vitality consequent upon disease. The ocular participation is therefore overlooked. Observation shows that even in adults the eye strain consequent upon a congenital defect or refraction may be borne without recognized symptoms up to a certain day which the patient fixes quite definitely as the time of breakdown. Not infrequently the breakdown comes with the depressing influence of an acute cold, after which the eyes and head are never comfortable, without correcting glasses, notwithstanding the fact that no trouble had before been experienced; or, he has his first headache after some extraordinary strain upon his physical endurance, and never finds relief except in a pair of glasses.

There is a considerable group of patients, usually men of affairs, between the ages of 40 and 50, who suddenly develop headache. As representing this group I recall the case of an eminent clergyman, aged 50. He not only had the care and responsibility of a large and influential parish, but often occupied the lecture platform, was the author of a number of books, and a frequent contributor to religious periodicals. He began to suffer from insomnia, and almost suddenly became the victim of severe occipital pain for which he sought the advice of his physician. He received a grave prognosis based on the theory of "cerebral hyperemia," and was advised to abandon his work for a year and seek relief in foreign travel.

Quite disheartened, he called upon me socially and related his condition. In detailing his symptoms it occurred to me that the occipital pain might be due to his eyes. He was to all appearances in perfect health, and was a remarkable example of stalwart manhood. At 50 years of age he had never worn a glass, notwithstanding the enormous amount of his literary labor. He received a pair of working glasses. His headache and insomnia disappeared at once, and although arrangements had been made for a long vacation, they were cancelled, and he went on with his work. In this case there could be no suspicion of a neurotic element entering as an etiologic factor. His symptoms were unquestionably the result of his neglect to neutralize by glasses the physiologic loss in the range of accommodation. A less vigorous man would have recognized the need of reading glasses at 43 to 45, instead of at 50 years of age.

There are many persons who have violent headaches not due to eye strain, but associated with pathologic conditions of the fundus oculi, as, for example, cases of retinitis macula lutea, hemorrhagic retinitis, or optic neuritis. It is not always clear in these patients whether the disease is a purely local one. That is to say, the condition seen with the ophthalmoscope, may often be regarded as an indication of intracranial disease, to which the headache may be reasonably ascribed.

Standing in marked contrast to the groups of patients already described is another group, members of which wander from one consulting-room to another, receiving slight changes in their glasses, each time enjoying tem-

porary relief from their complaints. It is quite true that many persons with delicately poised nervous systems are greatly benefited by the correction of very low degrees of astigmatism, since any attempt to abandon their glasses leads promptly to a return of their headaches, but I am convinced that in others the glasses afford relief by a species of suggestion, precisely as they would be relieved by the mummeries of a bonesetter, a "Christian Scientist," or Osteopath. As an illustration of this class of patients I recall the history of a patient, referred to me by Dr. H. C. Wood, who displayed marked reflex phenomena apparently due to eye strain. She had a nearly emmetropic right eye and a significant degree of astigmatism in the left which I sought carefully to correct. During one of her consultations in which she had made the most of her symptoms, she claimed such a dread of light that she could not bear to look at the table of test letters. This I knew was not true, and simply directed her positively to open her eyes and look at the letters, that there was no sufficient reason for her not doing so. She obeyed at once, and the subjective examination was made without further difficulty. This over, she took a chair near me as I sat at my desk to write a prescription for glasses. She placed herself on the very edge of the chair, sat erect while a tense expression came into her face, a far-away look in her eyes. Her fingers were clenched tightly into the palms of her hands, every muscle was tightly fixed, and she said, "Doctor! don't you think it would be a good thing to send me away from home on a journey? somewhere! anywhere! I am oppressed, I am stifled at home. My husband is an excellent man, but plain, stolid and matter-of-fact. He can't comprehend me. I am not like other women. I am like a delicate, tightly-strung harp, the vibrations of every string causing the most exquisite sensations. A beautiful poem or painting, the odor of flowers, the stars at night, an exquisite strain of music drive me wild with a delight that borders on pain." She received a pair of glasses which she has not been able to neglect, but I am convinced that the relief she experienced was not so much due to her glasses as to a few weeks of "rest cure" in the hospital. Certain it is that she returned to her home with the tightly strung "harp strings" relaxed to such a normal tension that their vibrations gave only such sensations as cause pain or pleasure to ordinary mortals.

The following conclusions may be regarded as established by clinical experience:

1. Abnormalities of the ocular apparatus are in a large group of patients the sole and sufficient cause of headache.

2. These abnormalities of vision may be the unsuspected cause, and therefore, the absence of symptoms obviously referable to the eyes does not exclude them as an etiologic factor in headache, insomnia, vertigo, petit chœra in children, and certain stomach derangements.

3. The recent or sudden development of symptoms, after attacks of severe illness, as typhoid fever, the exanthemata, etc., or in association with more or less acute exacerbations of some general dyscrasia, is not sufficient evidence against ocular participation in causing the symptoms.

4. The participation of the eyes as an etiologic factor in headache can be positively excluded only in the absence of ocular disease or after the most painstaking correction of any existing error of refraction or abnormality of binocular balance.

5. For the relief of reflex symptoms accurate corrections are essential, and these can be secured only by the more or less prolonged use of a strong cycloplegic.

6. Immediate relief by these corrections in a large group of patients is not to be expected, since the pain is frequently due to associated pathologic conditions of the fundus oculi, and these require time for cure.

HEADACHES OF GASTRO-INTESTINAL DISORDERS.*

BY FRANK BILLINGS, M.D.

CHICAGO.

Gastro-intestinal disturbance is a very common cause of headache. The gastric disturbance which may give rise to headache may depend on organic stomach disease, or may be associated with the many functional disturbances of the stomach and bowels. The gastro-intestinal disturbance which apparently causes headache in some individuals is manifest in others by some other form of nervous or bodily distress. Organic disease of the gastro-intestinal tract probably does not primarily cause headache. The resulting dyspepsia fermentation, constipation and lessened antiseptic action of the stomach secretions are the probable source of an auto-intoxication, which may result in a disturbance of the nervous apparatus, and headache may be one of the symptom expressions of the toxemia.

In functional disorders of the stomach, like the dyspepsia due to hygienic errors, the neuroses of the stomach associated with general or local nervous disorders, like neurasthenia and tabes dorsalis, and the gastric neuroses manifested often in pelvic disorders of women, in floating kidney, etc., are marked by many of the symptoms; constipation, pyrosis, flatulence, epigastric fulness and tenderness or pain as in organic gastric disease, and headache is quite as common if not more constant than in organic disease.

Disturbance of function with or without organic disease seems to be the main causative factor of headache in gastro-intestinal troubles.

There are many conditions of the body which may disturb the stomach which are themselves the chief causes of headache, but for which the stomach receives the blame. In all conditions of the body associated with marked anemia, with cardiovascular disease, with functional or organic diseases of the nervous apparatus, with disease of the excretory organs—kidneys, skin, etc.—the nervous apparatus is much disturbed and perception of pain may be so exaggerated, that headache may result from any slight cause—"a last straw" to the overburdened irritable nervous apparatus. In short, in many such cases the headache is, like the stomach disturbance, a result of some bodily condition. On the other hand, the dyspeptic or the individual with chronic gastritis may, in consequence of dietary errors, suffer, in time, from malnutrition including anemia and a resulting nervous apparatus and headache.

It is sometimes very difficult to assign the headache to the proper cause when there are present, with the gastro-intestinal disorder, conditions of malnutrition, anemia, neurasthenia, etc. Heredity and the personal equation play an important part in many of these mixed cases. One finds a history of stomach disturbance with headache in families, and apparently quite as much an inheritance of poor digestive organs as the unstable nervous apparatus of neurotic families. The individual equation is also apparent in stomach disturbance and it must be confessed that the patient is usually a hysteric or a neu-

*Presented to the Section on Neurology and Medical Jurisprudence, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

rastrhenic and the headache and the gastric trouble therefore due to the same general condition.

Fundamentally, headaches due to gastro-intestinal disorders are probably toxic. Of this we have no exact proof. The clinical conditions which exist in all headaches associated with disturbance of the stomach and intestine are most easily explained on this theory, and further emphasized by the therapeutic management, which gives the greatest relief to the patient.

An acute toxemia may occur in a perfectly healthy individual, from the overingestion of food, from the ingestion of indigestible food or from food contaminated by preservative chemicals or from food contaminated by toxins of decomposition. The epigastric pain and tenderness, the nausea and vomiting, the diarrhea or constipation, the depressed nervous apparatus; the cold extremities, small pulse, headache, dizziness, etc., during the acuteness of the attack, are typical of intoxication. We presume that the headache sometimes associated with cases of atony, dilatation and ptosis of the stomach is due to a toxemia by the poisons absorbed from the fermenting or decomposing contents of the stomach.

Not headache only, but weariness, melancholia, tinnitus, vertigo, sleeplessness, palpitation of heart, syncope and tetany or convulsions may occur. Atony, dilatation and ptosis may occur in cancer, ulcer, chronic gastritis and in constitutional states, and the above-named phenomena in the diseases named.

"Bilious" attacks with nausea, vomiting, constipation, heavily coated tongue, foul breath, with headache, nervous depression, etc., are conditions apparently of chronic recurrent intoxication usually associated with gastro-intestinal dyspepsia, imperfect oxidation and assimilation by the liver and aggravated by defective excretion by the skin, liver and bowel. The idea of intoxication by bile, to which these characteristic symptoms were thought to be due and which gave it name, is no longer accepted as causative, inasmuch as headache and many of the other phenomena named are not often present in real cholera.

Chronic constipation may cause headache, and when it occurs it is doubtless toxic. However, in many cases of severe constipation, especially among women, no headache, or indeed no other nervous symptoms may appear. We have all seen individuals who were perfectly comfortable with constipation, the bowels moving only once a week or even at a longer interval. Again, constipation is such a common occurrence in so many other bodily conditions that it is fair to assign the nervous phenomena, including the headache, to the combined effect of the general or local state plus the effect of the toxemia due to the constipation. In some individuals constipation apparently produces depression of spirits, irritable temper and headache, and the symptoms disappear with a thorough evacuation of the bowels.

The toxic substances causing headache are really unknown. Bunge's theory, that the stomach is an organ of protection, rather than an organ of nutrition, by disinfection of the ingesta before they pass on to the intestine, where the digestion properly takes place, is worthy of much consideration. The acid contents of the stomach we know protect one against infection from cholera and typhoid. The presence of acids also prevents the formation of toxins from albuminous foods. It is possible, therefore, that the acidless contents of the stomach in atony, dilatation, etc., may allow the formations of ptomaines, Brieger's peptoxin, acetones, diacetic acid and other poisons which the normal acid gastric juice would not permit.

Senator, Bamberger, Lorenz, Haig, von Jaksch, von Norden, Bouchard, Rachford and many others have presented theories of auto-intoxication in gastric-intestinal disease and ascribed the intoxication to leucotoxins—uric acid, paraxanthin and xanthin—ptomaines, peptoxin, acetone, diacetic acid, etc. Some of these poisonous principles have been found in the decomposed stomach contents, and others have been found in the urine during toxic seizures. Furthermore, the isolated poisons injected into the bodies of animals have produced toxic symptoms similar to the phenomena associated with the gastro-intestinal disease.

Headache due to gastro-intestinal disturbance is said to be located definitely. In my experience this is not true. The brow of the whole frontal region is the most common seat, but may be occipital, vertical or general. It may be dull or sharp in character, with or without a sense of fullness or throbbing, and is usually aggravated by noises, bright light or by mental or physical effort. In acute attacks, nausea and vomiting usually occur. In the more chronic forms nausea may occur and rarely vomiting.

The diagnosis of headache due to gastro-intestinal disease or disturbance may be difficult. One must remember that gastro-intestinal disturbance, including constipation, is frequently secondary to states of general malnutrition and anemia, also to neurasthenia and other neuroses, to local disease of the skull, meninges or brain, to disturbances of the eye, ear and nose, to pelvic disorders, etc., and that the headache is due primarily to one or more of these conditions aggravated by the secondary gastro-intestinal disturbance. Indeed, the increasing experience of years has constantly narrowed the writer's cases primary of gastro-intestinal headaches and constantly broadened and increased the cases of headache due to general conditions of malassimilation, malnutrition and faulty excretion in which the gastro-intestinal condition was recognized as one of the results of an unhygienic life; a result which doubtless does aggravate the pre-existing poor general conditions and therefore becomes a secondary causative factor of headache.

Decomposed stomach contents, the presence of gastric ulcer, or cancer, chronic gastritis, duodenitis with intestinal indigestion and constipation with headache, and especially when the history and examination show no other abnormal conditions, will justify the diagnosis of headache due to primary gastro-intestinal disease.

Migraine or a condition much resembling it may sometimes be due to gastro-intestinal auto-intoxication. The diagnosis can be verified only by the cessation of the attacks after the removal of the gastro-intestinal cause.

TREATMENT.

Treatment of headaches of gastro-intestinal origin is palliative and curative.

Palliative: Remove the source of the poison by emptying the stomach, by emesis or lavage; move the bowels by cathartic or by colonic flushing; promote excretion of the poison from the blood by diluent drinks to aid skin activity and diuresis, and relieve the pain by small doses of the bromids combined with caffeine, or by the cautious use of phenacetin or some of the other petroleum derivatives or, in very severe cases, by a small dose of morphia hypodermically. In incurable organic disease of the stomach palliation will be the limit of treatment.

Curative treatment will consist of the application of the laws of hygiene, modified to suit the individual case; a selected diet for each individual; the free use

of pure water as a diluent drink; recreation in the form of physical exercise or physical rest, commensurate with the mental activity or physical tire of the individual; the correction of irregular habits of sleep, of time of taking food and of exercise; the withdrawal of tobacco, tea, coffee and alcoholic drinks, which is usually necessary, and especially in the patients who suffer from the neurosis. Lavage the stomach when necessary and overcome the constipation by hygienic measures, if possible without drugs. In the conditions of malnutrition and anemia, give restorative tonics and an abundant simple diet. In short, a sensible hygienic life will not only prevent the headache, but will usually remove the gastrointestinal disease or cause.

100 State Street.

QUANTITATIVE ESTIMATION OF ALBUMIN IN THE URINE.*

BY CHAS. W. PURDY, M.D., LL.D.
CHICAGO.

Our present lack of a uniform method of expressing quantities of albumin in the urine detracts much from the value of all our methods; indeed, it renders the subject very confusing. As commonly employed, the term "percentage of albumin" is applied indifferently to gravimetric and volumetric measurements, as though they were synonymous, when, as a matter of fact, the two possess the most widely different significations. Thus, we commonly hear and read of percentages of albumin in the urine ranging from 20 to 40, etc., without further qualification. Such amounts expressed by actual weight would be a physical impossibility, since the proportion of albumin in the blood-serum itself never exceeds 9 per cent., and it would therefore be clearly impossible for the proteid contents of a fluid derived directly from the blood—such as the urine—to exceed that in the blood itself. As a matter of fact, the albumin in the urine expressed gravimetrically, rarely rises above 2 per cent., and perhaps never exceeds 3 per cent. It would therefore seem beyond question that at present we greatly need for clinical purposes some rapid, accurate, and ready method for estimating albumin in the urine, coupled with a more definite and exact method of expressing results obtained.

The author of this paper claims to have recently supplied this want, but before entering into a description of his method a brief survey will be taken of the more prominent methods heretofore employed.

THE GRAVIMETRIC METHOD.

The process consists in coagulation of the albumin, which may be accomplished either by boiling, or by means of a chemical agent; the succeeding steps being filtering out the albumin, collecting, drying and weighing.

Coagulation by Heat.—In this process a certain quantity of urine is taken—say 100 c.c.—a few drops of acetic acid added until the urine is distinctly acid, and then it is filtered. The urine is then put into a flask and gradually heated to boiling. The boiling should be continued for a half minute, and the urine then passed through a filter, the weight of the latter having been first ascertained and noted. The flask is next washed with distilled water, to secure all the adherent particles of albumin, and the contents of the flask are then again thrown on the filter. Next, the albumin is washed with boiling distilled water, by means of a pipette, the jet

being directed so as to wash the albumin toward the center of the filter. The washing should be continued until the albumin becomes perfectly clean and white. Sometimes it is necessary to use hot alcohol to cleanse the albumin. The filter is next placed in an oven, the temperature of which is 100 C. (212 F.), and then left until desiccation is complete. Drying is known to be complete when two weighings at an interval of an hour are identical. From the whole weight that of the filter is deducted, and the difference represents the weight of albumin in 100 c.c. of urine, from which the whole amount may be readily calculated. The tediousness of the process is its chief drawback for clinical purposes, since it can not be carried out in less than five or six hours.

TITRATION METHOD OF TANRET.

This method consists in precipitating the albumin by means of double iodid of mercury and potassium solution, and estimating the amount of albumin by the amount of mercuric solution required to precipitate all the albumin. Thus, one drop of the precipitating solution delivered from a pipette of standard size precipitates exactly 0.005 gm. of albumin. Therefore as many drops as it takes to precipitate all the albumin in a given quantity of urine represents that number of times 0.005 gm. of albumin present.

The formula for the precipitating solution is: Potassium iodid 3.22 gm., hyd. bichlorid 1.35 gm., aqua destil. to 100 c. c. The formula for the confirmatory solution is hyd. bichlorid 1 gm., aqua destil. to 100 c.c.

Process.—It will be more convenient to always conduct the test with a certain quantity of urine—say 10 c. c.—as in such cases the number of drops of the solution it takes to precipitate all the albumin in 10 c. c. of urine will represent so many half grams of albumin per liter. Thus, if it takes 10 drops of the precipitating solution to precipitate all the albumin in 10 c. c. of urine, then we have 0.05 gm. of albumin in the 10 c.c. of urine, which gives us 5 gm. albumin per liter. We proceed by then taking 10 c.c. of the albuminous urine and adding to it 2 c. c. of acetic acid, and stirring well with a glass rod. Next the precipitating solution is added, drop by drop, stirring thoroughly each time. After the addition of each drop of the precipitating reagent, a drop of the urine is placed on a porcelain dish or tile and a drop of the confirmatory solution is brought into contact therewith. As soon as a yellowish-red color appears all the albumin is precipitated, and the process is completed. The amount of albumin may at once be determined by taking the number of drops of the precipitating reagent employed, subtracting 3 as having been used in excess to make the color development perfectly apparent, and considering the remainder as so many half grams of albumin per liter, or so many 0.005 grams in the 10 c. c. of urine.

So long as any albumin remains in solution in the urine, the precipitating reagent will not form red iodid of mercury when the bichlorid solution is added, but it immediately does so when all the albumin is precipitated, therefore the bichlorid solution constitutes a perfect and beautiful indicator.

The above test is a fairly ready and rapid method which might be made available for practical clinical work were it not for the fact that it can not be depended upon in point of accuracy. As is well known, Tanret's reagent precipitates all known proteids in the urine, and unless corrected by means of heat, many of these would often be estimated for albumin. All alkaloids likewise are thrown out by this reagent. In short, if this test

*Abstract of paper presented to the Section on Practice of Medicine, at the Fifteenth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

be employed cold, as directed by its author, it can not but prove entirely untrustworthy and misleading.

DIFFERENTIAL DENSITY METHOD OF LANG, HOEBLER AND BORNHARDT.

This method is based upon the difference in the specific gravity of the urine before and after coagulation and removal of the albumin. According to Haebler, the difference must be multiplied by 210; and according to Bornhardt, it must be multiplied by 415 in order to find the percentage of albumin in the urine. Neubauer states that his observations show that Haebler's quotient is absolutely false, and, moreover, that Bornhardt's number with careful manipulation yields only tolerable results when the amount of albumin in the urine is not too small: but in small amounts the limit of error is very great. Halliburton says of this process: "The supposed constant factor is from its very nature a variable one, and a simple algebraic demonstration of this will be found in a paper by Huppert and Lahor!"

THE OPTICAL METHOD.

The principle of this method, proposed by Vogel, consists in gauging the amount of albumin by the degree of transparency of the urine after precipitation of the albumin. Various modifications of this method have been proposed, among the most simple of which is that of George Oliver. Thus, standard lines have been adopted by Oliver, of different thickness or width; corresponding to the different percentages of albumin, according to their degrees of visibility through a certain stratum of urine.

CIRCUMPOLARIZATION.

If the amount of albumin in the urine is not very small, and the urine is not too dark in color, and if it is rendered perfectly clear on filtering, the albumin may be estimated by means of the polarizing apparatus of Soliel-Ventizke. An observing-tube 200 mm. long is employed, and after filling and placing in the apparatus, by turning the compensator, the two halves of the field of the double plate are made exactly isochromatic. The zero point of the nonius now lies on the left side of the zero point of the scale, and each division, with a tube 200 mm. long corresponds to 1 gram of albumin in 100 c.c. of urine; and each division of the nonius to 0.1 gm.

ESBACH'S VOLUMETRIC METHOD.

For clinical purposes this method has attained very great popularity, chiefly on account of its simplicity, rather than from its accuracy. The process is simple in the extreme, although it takes twenty-four hours to complete the process. This method is based upon the fact that picric acid precipitates all the albumin in the urine at ordinary temperatures, and the assumption that the precipitate deposits in a uniform state and degree of density through gravitation, permitting volumetric measurement which corresponds with gravimetric measurement. The fact is incontestable, but the assumption is far from accurate.

The apparatus consists of a tube not unlike an ordinary test-tube in shape and size, but much thicker and graduated on the side so as to indicate the amounts of deposits, representing in grams and fractions thereof the albumin per liter of urine. The standard reagent is composed of 10 grams pure picric acid, 20 grams citric acid, distilled water to 1000 c.c.—1 liter.

Process.—The urine is poured into the albuminometer to the mark U, and the reagent is added to the letter R; the tube is then closed with a stopper and in-

verted a number of times until the urine and the reagent are thoroughly mingled. The tube is then stood in a rack for twenty-four hours, when the amount of albumin may be read off as indicated by the scale in grams per liter of urine. If it be desired to know the percentage of albumin in the urine, instead of the number of grams per liter, remove the decimal point one figure to the left—thus 5 grams per liter would be 0.5 per cent.

This method is simple and convenient; but, unfortunately, the results are only approximately accurate for the following reasons: In the first place, the reagent—picric acid—throws out and measures peptones, albumoses, nucleo-albumin, and practically all proteins met with in the urine in addition to alkaloids if present. In the second place, the force of gravitation, which is depended on for securing uniform packing of the albumin, is inadequate to overcome the lesser forces which often arise from varying conditions in the test itself and its physical surroundings, thus the slow chemical changes in progress between the reagents, or between the latter and the urine, or even in the latter alone, are often sufficient to liberate sufficient gases to completely overcome the force of gravitation, and the albumin often arises *en masse* to the surface. In a less degree the quantity of albumin itself, the specific gravity of the urine, and the surrounding temperature furnish opposing forces to that of gravitation, which disturbs uniformity of results and defeats the accuracy of the process. Observations in the writer's laboratory have shown conclusively that Esbach's method, with every precaution, is subject to constant and sometimes very wide errors.

THE AUTHOR'S CENTRIFUGAL METHOD.

It will be seen from the brief glance at the various quantitative methods just considered that the clinician demands something more accurate and ready for practical work than at present is available. The method herewith brought forward and recommended for practical clinical work is the result of five years' experimentation, with the details of which I will not take your time: The process in brief consists of the following steps: Precipitation of the albumin in carefully graduated percentage-tubes of 10 c.c. of the urine by means of 2 c.c. of 50 per cent. acetic acid and 3 c.c. of 1 to 10 aqueous solution of potassium ferrocyanid; after mingling the urine and reagents, the tubes should stand for ten minutes to ensure entire precipitation of the albumin. At the end of ten minutes the percentage-tubes are placed in a centrifuge, the radius of which with tubes in position must be exactly $6\frac{3}{4}$ inches. The tubes are revolved for exactly three minutes, at a uniform speed of 1500 revolutions per minute. The tubes are next removed and the amount of albumin is read off in bulk percentage, which, by the aid of accompanying table, is converted into percentage by weight and grams per fluid ounce. It will be observed that the time necessary to carry out this test need not exceed fifteen minutes, and as a result of many observations in the writer's laboratory in which the results were compared with the gravimetric method it has been found that the errors arising by this method need never amount to more than 0.01 per cent. Such minimal errors are of no practical import, being in fact no greater than ordinarily claimed for the gravimetric method itself.

To insure the most accurate results the following details should be observed: The urine should first be filtered and its chemical secretions ascertained, and if found to be neutral or alkaline it should be rendered frankly acid by the careful addition of a few drops of

acetic acid, great excess being avoided. Next, if the quantity of albumin be excessive the urine should be diluted with one or more volumes of water until the volumetric percentage does not exceed 10 or at most 15 per cent. Observations conducted in the writer's laboratory have determined the fact that accurate and uniform volumetric measurements of albumin in the urine are only possible when the volumetric percentage does not exceed 10 per cent., and this applies both to gravitation and centrifugal force.

With regard to the reagents: the 2 c.c. of 50 per cent. acetic acid should be added to 10 c.c. of the urine, the tubes should be inverted a number of times to insure thorough mingling of the acid with the urine; then 3 c.c. of the 1 to 10 ferrocyanid of potassium should be added, the tubes again inverted till all are well mingled, and lastly the tubes should be stood aside for ten minutes to insure entire precipitation of the albumin. Lastly, with regard to packing and measurement: The first and most important essential is an efficient centrifuge. The Purdy electric centrifuge possesses all the essentials for exact work. If this is at hand very few additional suggestions are necessary. If not, then a centrifuge must be employed that possesses certain essential features or is capable of such modification as will include these essentials, which are as follows: *a.* The percentage-tubes must be accurately graduated in tenths of a c.c. up to .15 c.c. *b.* The arm of the centrifuge should possess a radius of exactly $6\frac{3}{4}$ inches, that is to say, the linear distance from the center of the axle to the tip of either tube must be just $6\frac{3}{4}$ inches. *c.* The motor must be capable of an even and sustained speed of 1500 revolutions per minute, with the required radius, and carrying one ounce of urine. *d.* Lastly, some reliable method of gauging the exact speed of the motor must be employed. Any centrifuge that fulfils the above named requirements will give accurate results, as indicated by this method and the accompanying table.

PURDY'S QUANTITATIVE METHOD FOR ALBUMIN IN URINE.
(CENTRIFUGAL.)

Showing the relation between the volumetric and gravimetric percentage of albumin obtained by means of the centrifuge with radius of $6\frac{3}{4}$ inches; rate of speed 1500 revolutions per minute; time three minutes.

Test—2 c.c. of 50 per cent. acetic acid and 3 c.c. of 10 per cent. solution of ferrocyanid of potassium are added to 10 c.c. of the urine in the percentage-tube and stood aside for ten minutes, then placed in the centrifuge and revolved; rate of speed and time as stated at head of the table. If albumin is excessive dilute the urine with water till volume of albumin falls below 10 per cent. Multiply result by the number of dilutions employed before using the table.

This method has now been in daily use in the writer's laboratory for the past six months, where it has afforded the greatest possible satisfaction. The advantages claimed for this method over all others are its rapidity, simplicity, accuracy and comprehensiveness in expressing results, the volumetric percentage, the gravimetric percentage, the number of grains per ounce and the total amount by weight in twenty-four hours all being apparent by a single glance at the table.

57 East Twentieth Street.

ACCIDENTAL OR SPURIOUS ALBUMINURIA.*

BY CHARLES G. STOCKTON, M.D.

BUFFALO, N. Y.

The term accidental albuminuria as here used relates not only to the presence of albumin in the urine exclusive of disease of the kidney, but also of the various conditions aside from recognized kidney disease, which permit of the passage of serum albumin through the renal parenchyma into the urinary tubules. In other words, the term is employed to include those cases of albuminuria in which albumin finds its way into the urine from the pelvis of the kidneys, from the ureters, the bladder and the genitalia.

Albumin thus appearing possesses indirect interest to the student of internal medicine, because he must be able to exclude albumin arising from the sources above mentioned before he can affirm that he has to deal with albumin coming from the kidneys. As a matter of exclusion, therefore, the question must be made a familiar one.

Accidental albuminuria is of direct interest to the physician, because it is one of the diagnostic data for the recognition of pelvic renal diseases, urethritis, and cystitis. The occurrence of albumin in pyelitis is almost constant while, in quantity, it varies with the character of the inflammation. It seems to bear direct ratio to the extent of pus formation in the pelvis of the kidney. When there is an inflammatory edema of the pelvis of the kidney, the exudation of albumin may be considerable. Occasionally in tubercular disease of the pelvis albumin may appear in small amount, but as the disease advances the albumin is more abundant, though this may be frequently explained by the fact that the parenchyma of the organ is at the same time involved. In

* Presented to the Section on Practice of Medicine, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

calculus of the kidney, albumin at least in traces is rarely absent, nor is it seen in very large amounts.

In all these affections we expect to find the urine acid in reaction, sometimes sharply so, and the appearance of pus, blood and mucus either by macroscopic or microscopic examination, and very often by both. Upon these facts, and on the fact that the tube-casts are absent, we are able to infer that the albumin is derived from a point below the parenchyma of the kidney.

Not enough attention seems to have been called to the undoubted fact that traces of albumin are generally found in that really important affection, ureteritis. This condition, sometimes mistaken for appendicitis, salpingitis, or irritable ovary, is extremely common in victims of lithuria and oxaluria, especially in females. Very often there results an irritable bladder with frequent urination of very acid urine, containing traces of albumin, epithelium, and mucus. Pus-cells are common and also a few red blood-corpuscles.

I have twice seen this affection, in an acute form, produced in the right ureter following parturition in women having floating kidney. In each case there was evidence of irritation of the pelvis of the kidney, and it is believed that this trouble was induced by transient hydronephrosis occasioned by pressure of the fetal head on the right ureter. Both cases were seen by my colleague, M. D. Mann, who concurred in the view that there was no infection in the genital tract, and that the chills, high temperature, headache and profound nervous excitement resulted solely from the trouble with the ureter and renal pelvis.

These cases were both severe; the temperature in one reaching 106 degrees, and the other going above 104; the febrile paroxysms not altogether ceasing after ten days. In these instances the urine drawn with the catheter contained sufficient albumin to cause a slight precipitate with heat and acid, large numbers of pus cells, red blood-corpuscles and epithelium, but at no time were any tube-casts observed, nor was the quantity of urinary solids diminished. In both cases the patient made a perfect recovery, and at no subsequent time showed evidences of renal disease save such peculiarities of urine as are commonly associated with nephropoiesis.

We have all seen albumin accompany the escape of a renal calculus into the bladder. A calculus having found its way into the bladder excites sufficient irritation to evoke a slight exudation of albumin from that organ. Here also we find pus-cells and mucus, as well as bladder epithelium, in the urine. There should be little difficulty in recognizing the albuminuria of cystitis. The well-known symptoms of the disease, together with the abundance of pus and mucus, bladder epithelium and alkaline reaction point at once to the source of the exudation. The error of assuming that because there is a cystitis there is not at the same time a pyelitis is more likely to be made, or a real nephritis. Particularly is this true of paralytics. I well remember a lesson taught me years ago by Gouley, in this pregnant sentence: "Most victims of paraplegia die from uremia secondary to infection of the bladder." According to my observation this is true. It can never be considered safe to allow urine containing albumin to go without frequent microscopic examinations.

In the male it is not uncommon to find albumin associated with inflammation of the prostatic urethra, the prostate, and the seminal vesicles. Needless to say, such conditions usually accompany or follow gonorrhoea. Everyone has seen instances of men occasionally showing traces of albumin in the urine, generally associated

with pus, sometimes traces of blood and always mucus, and occasionally some one has been so unwary as to pronounce this affection to be albuminuria and probably Bright's disease. Victims of spermatorrhea not infrequently show traces of albumin in the urine. It is surprising that this is not more frequently the case. Its presence is probably owing to catarrh of the seminal vesicles and irritation of the prostate. It seems hardly necessary to call attention to the vagina as a source of albumin in the urine. If one makes the blunder of filtering the urine before microscopic examination, as I have known to be done, it is possible that he may be led astray. I find that it is the part of wisdom to request women who show albumin in the urine, accompanied by pus, to thoroughly irrigate the vagina and external genitalia before voiding the urine that is to be preserved for examination.

In closing, it should be stated that accidental albuminuria is not to be disregarded, and the source of the albumin should always be most carefully examined into. It should also be reiterated that when albumin is found originating in the bladder, the ureter or the pelvis of the kidney, the urine should be frequently studied to make sure that infection is not invading the more important structures of the kidney.

DISCUSSION.

DISCUSSION ON PAPERS OF DRs. STOCKTON AND PURDY.

DR. ARTHUR ELLIOTT, Chicago.—The significance of albumin in the urine in organic kidney disease has become lessened during recent years, and has been deposed from the position it once occupied in clinical esteem. Had Dr. Musser's paper been read, reference would doubtless have been made to cases of nephritis unaccompanied by albumin in the urine. These cases are, I am sure, more frequent than is generally supposed. Examination of the twenty-four hours' collected urine, with determination of urea and other urinary solids, and microscopic examination of the urine sediment, constitute in conjunction with the information elicited by physical examination a far more reliable basis of diagnosis than does the mere presence or absence of albumin. In cases of interstitial nephritis, albuminuria may be disregarded in arriving at a diagnosis, for its inconstancy in this lesion is notorious, the urine of quiescence being frequently free from albumin, but not so during activity. A point in the clinical aspect of albuminuria, which might be referred to, is the albuminuria accompanying gastro-intestinal disturbances. The urine under such circumstances is of high specific gravity, contains excesses of indican and throws down acid elements. I am inclined, as the result of such observations as I have been able to make, to believe that the albuminuria is the result of irritation of the renal secreting structure by certain toxins of intestinal derivation. This form of albuminuria, although as a rule slight, is contemporaneous with the gastro-intestinal dyspepsia. The albumin, centrifugally estimated, ranges from a faint trace to 2 or more per cent. bulk.

Dr. Purdy's method of estimating the amount of albumin in the urine is a very accurate and beautiful one. Personally I have been using the centrifuge for a number of years, following the original directions given by Dr. Purdy for the approximate determination of albumin. This I have found to be readier and quite as satisfactory as any of the mechanical means. It has been, however, of little value except for clinical and comparative purposes, because of the impossibility until now of converting the bulk percentage into definite quantitative amounts. This procedure is rendered easy by Dr. Purdy's table, and correct estimation is possible.

DR. A. L. BENEDICT, Buffalo, N. Y.—I want it distinctly understood that I do not come here to furnish wisdom, but to obtain some. In connection with albuminuria we occasionally find so-called peptonuria, and yet there is no true case of peptonuria on record. The only cases published were based on a test which was not correct. Thus, instead of peptonuria, we should say albumosuria. A definition of peptonia, "that soluble proteid which is not thrown down by ammonium sulphate." In testing for albumin it is wrong to use cold nitric acid, which throws down a mixture of albumin and albumose; if heat be used, pure albumin is thrown down. I wish to refer to four cases of albumosuria out of two hundred examined. One was acute inflammation of the bladder, combined with a

subacute gastroenteritis. This patient had been on a long journey and had drunk much ice water. He had albumose in the urine, which cleared up in a day or two. The second was a case of diffuse nephritis, with mitral regurgitation and hepatic sclerosis, and he had been under observation for some time. The albumose persisted for many months and then disappeared, reappearing when the renal function failed. In the third patient it was impossible to make a thorough physical examination on account of obesity. The urine was free from casts, but there was present a small amount of albumin and albumose; the latter cleared up before the former—a phenomenon which is quite characteristic. The fourth was a case of subacute inflammation of the bladder. The primary condition was a colitis which was catarrhal or a mixed infection. The patient presented all the symptoms of typhoid, but the blood test was negative. The urine gave a doubtful Ehrlich's sign. It was a question in my mind whether it was typhoid or not. All these cases had albumosuria and not peptonuria. In some of these cases, also globulin was present. This is something about which we know but little. Peptonization by bacteria might be considered, theoretically, an explanation of albumosuria, but many of the latter cases occur in sterile urine. I have never found albumose to develop in albuminous urine that had been allowed to decompose. In other words, ordinary saprophytes have no peptonizing power.

DR. E. R. AXTELL, Denver, Colo.—We are indebted to Dr. Purdy for the work he has done for us in urinalysis. The test he has presented is in the way of accuracy, without loss of time. There are but few objections that could apply to it. It requires Dr. Purdy's electrical centrifuge. For many of us this is impossible of attainment, because we can not procure the motor force. I may mention the fact that with my centrifuge, having a radius of $11\frac{1}{4}$ inches, I have had to do some original work of my own in getting normal deposits. I find that if I revolve my hand centrifuge two hundred times, my readings are about those laid down by Dr. Purdy. If I take a solution of albumin or chlorid of known strength, and precipitate them by proper reagents, I get a proper reading after the revolution, proving that my results are accurate.

With albumin precipitation, there is a source of error in using a centrifuge. The albumin does not pack down evenly and on a level, but accumulates to a slight extent on the glass of the tube. This is certain to modify the reading. Possibly some little plan can be found to remedy this. I am indebted to Dr. Stockton for the term "uroteritis." I have called such cases renal colic.

DR. CARROLL E. ENSON, Denver, Colo.—I wish to call attention to a paper on "Albuminuria of Adolescence," written within the year, by Dr. Clement Dukes of England, who for many years has been studying this subject of occasional albuminuria in adolescence. Dr. Dukes made observations on school-boys, at either Eton or Rugby. I have forgotten which, and he found a large number of cases in which there were at the period of adolescence, small traces of albumin occasionally present; this amount of albumin was influenced largely by the time of day, by exercise, etc. In this paper he called attention to the fact that he could not speak of conclusions until the lapse of a certain time and the collection of a large number of statistics. He also speaks of having found a considerable number of cases, where the albumin cleared up under rest, and the albumin remained absent during school life where the lads were under control. But, subsequently, when they reached adult life, they developed albuminuria which was quite serious. He recently had a case in consultation, of an adult, where he could trace, back the records to the adolescent period, and he found that the patient had been passing albumin at that time. This fact should put us on guard. Certain statistics of Dr. Dukes are sufficiently numerous now to warrant him in bringing it to our attention. This is not the accidental or spurious albuminuria, but cases of albuminuria of adolescence in which all spurious sources of albumin were ruled out.

DR. GEORGE DOCK, Ann Arbor, Mich.—Dr. Purdy's series of investigations are of great value. It might be worth while pointing out that the use of this method in practice is not necessary for proper treatment. The variation in the amount of albumin within small limits is very common and to be expected, from a number of causes. It is more important in practice, so far as albumin goes, to know the approximate amount than to be able to state it within minute fractions, and the examination of the sediment is, after all, of much greater importance. In regard to the matter of functional albuminuria, it is extremely important that we should look on every case of albuminuria, as Dr. Stockton has suggested, as possibly being the earliest stages of kidney disease, therefore, to tell a patient he has functional albuminuria is a dangerous thing to do. Repeated examinations of the urine should be urged. I also

wish to speak of certain forms of albuminuria which come on in persons taking exercise in undue amounts. I have, during the past three years, been making observations on bicyclists and other athletes, and I have found, in a large number of cases, that even a moderate amount of exercise brings on albuminuria, and occasionally casts. In many cases there is not more than a trace of albumin, but a distinct sediment and casts of various kinds, sometimes hyaline, and sometimes blood and blood casts. It will be interesting to find out later if disease follows in these cases. It does not do to use the term nephritis too loosely; very often the condition is not a nephritis but a superficial degeneration. So far, I have not carried the observations far enough to see whether they suffer any permanent damage to the kidney. These observations are important enough to speak of now and they certainly are interesting.

DR. CHARLES E. MINOR, Asheville, N. C.—I was glad to hear such an authority as Dr. Dock dwell on the fact that the exact amount of albumin is not of such great importance. I do not wish to be understood as belittling this admirable work of Dr. Purdy's, but I feel that what we want is the more general adoption of less complicated methods of rapid diagnosis. To be of the greatest use an apparatus for clinical diagnosis must be such that it can be generally adopted, not only in laboratories, where the conditions for Dr. Purdy's instrument are obtainable, but by the general practitioner throughout the country. Those of us who possess laboratories should remember that we are an insignificant minority and will for years remain so; we should not, as Dr. Purdy seems to do, discourage, but rather encourage the use of apparatus which, like Eschbach's tube, is simple enough for easy use by the general practitioner, and which does not demand an electric current and an expensive machine whose price will certainly prevent its general adoption; it is hard enough in any case to get a majority of the profession to use the methods of precise diagnosis, without making it harder by discrediting the simpler, if not absolutely accurate, ones. What we want in the present state of the profession in the country is a more general adoption of clinical diagnosis in the profession at large, and if we are to make any progress we must not begin by discrediting the simpler apparatus or demanding too elaborate or expensive a one in its place. We will be lucky if we get 50 per cent. of the doctors of the country to give any attention to the quantitative estimation of albumin; there is some hope of getting them to use Eschbach's tube, none at all of getting them to purchase Purdy's form of centrifuge. I repeat, therefore, that while glad of this addition to our means of precise diagnosis, I regret that the author has seen fit to discourage the use of the older and simpler method.

DR. JUDSON DALAND, Philadelphia—So far as Eschbach's method is concerned, it has been, in my experience, entirely unsatisfactory; it is exceedingly incorrect, in spite of the great commendation given it. A trace, moderate amount and large amount of albumin are terms usually employed by clinicians; but instead of these terms we should use percentages, which is the only accurate method of noting the quantity of albumin. The former terms have been used from necessity. I believe that if Dr. Purdy's instrument be used with these tables, greater accuracy will be secured. So far as the profession is concerned, it is quite impossible to carry on the laboratory work and to attend to a general practice. If you have assistants, they can attend to this work. But that is no argument against the instrument's precision. So far as the centrifuge is concerned it is a simple matter to secure 1500 revolutions per minute, and it is a procedure that occupies but a few minutes. Dr. Purdy's paper deserves a very careful consideration, and to the employment of this method I look forward with pleasure.

I was much interested in Dr. Stockton's paper on "Accidental Albuminuria." Occasionally, a cystitis is accompanied by renal disease. The question, therefore arises, as to how much of the albuminuria is due to liquor puris and how much is of renal origin. If some method could be adopted by which this differentiation could be made, accuracy in diagnosis would be increased. Not infrequently the amount of albumin seems disproportionately large when the small amount of pus is considered. Of course, when tube casts or cylindroids are present the diagnosis is simplified.

I recall an instance, which occurred lately, of a floating kidney, which was exposed and secured by three ligatures. A careful examination showed no albumin immediately before the operation, but immediately after there appeared an amount of albumin, an amount equal to one-half of the bulk of urine; there was also a moderate amount of blood and a number of blood casts. The urinary evidence was that of an ordinary acute nephritis. In the course of two days the albuminuria rapidly diminished and, in the course of three weeks it had entirely

disappeared, and the urine was normal. This case is interesting as showing the effects on the urine, of three suture tracks in one kidney.

So far as the occurrence of nephritis without albuminuria is concerned, it seems to me that this has been demonstrated, and it also is quite clear that many cases of this form of disease where albuminuria is present are frequently overlooked. In the majority of instances the cause for this is the injudicious employment of light. If the test-tube is held before the window, the trace of albumin is frequently overlooked; but where it is held against a black background, and the light passes through the urine obliquely downward, the smallest trace may be detected. This particular technic is of practical importance.

Dr. SCOTT of Indiana—I wish to express satisfaction with the use of Esbach's instrument; its estimation of albumin depending on the specific gravity. As stated by Dr. Purdy, the alkalis and other substances are thrown out and measured when the picric acid is added, which makes an erroneous reading of the sediment. It is the sentiment of the society that a uniform radius and uniformity, at least to a certain extent, should be obtained. The centrifuge is indispensable. It seems to me that in the analysis of urine, there is too little attention paid to it. Two things should be considered, the analysis and the interpretation of the analysis. It is important to determine just what the result of the analysis will be. In the question of urea, there is no positive way of estimating the urea. The instruments are all erroneous because they depend so much on the barometric pressure, which varies so. Doremus' ureometer is a good instrument, but it is open to objections.

Regarding the question of albuminuria of adolescence, it is certainly not always true that we have disease of the kidneys or a nephritis. In any case it is impossible to tell which individual illness may not give rise to a nephritis from simple irritation or congestion of the kidneys. And yet it certainly is not wise to report to companies that a true albuminuria is present without determining, by means of the microscope, whether there is present blood or epithelial cells, which would call attention to a diseased condition of the kidneys. Albuminuria alone should not be considered evidence of a nephritis.

Dr. GEORGE W. WEBSTER, Chicago—I wish to record two interesting observations. I have recently had two internes who had been assigned the duty of giving anesthetics. They were employed from four to seven hours each day in the administration of the anesthetics, and usually ether was the one given. In one instance there appeared a large percentage of albumin, blood, and casts. After resting for ten days, all this entirely disappeared. On resuming his duties at the hospital, he worked seven hours, and at the end of that time there appeared a large percentage of albumin, together with blood in the urine. After another absence from the hospital, for one month, he again reported and the albumin and blood had disappeared. It is a difficult question to tell where irritation ends and inflammation begins. The explanation may be the same as in typhoid fever, where albuminuria occurs in 25 per cent. of all cases examined.

Dr. ARTHUR R. ELLIOTT, Chicago—I do not think Dr. Minor is warranted in arriving at his conclusions in reference to Dr. Purdy's paper. Dr. Purdy has said that he has endeavored to supply us with an accurate and simple mechanical means by which the results can be arrived at in the short space of fifteen minutes. To substitute a simple mechanical means for a complicated and tedious chemical procedure is certainly not calculated to introduce any confusing element into clinical work.

Dr. CHARLES G. STOCKTON, Buffalo, N. Y.—I feel with Dr. Daland that, as a rule, the albumin found bears a relation to the amount of pus present. This is not invariably, but is the rule. One peculiar feature in cases of spurious albuminuria is that, in traces, albumin is frequently found associated with ureteritis. The intense acidity of the urine and the increased irritation exercised on the tissues of the ureter explain the occurrence of albumin in that condition. It is small in amount but important enough to call attention to it. Cases called nephritis are often not true nephritis, but simply albuminuria arising from the ureters. I would like very much to discuss the general subject of albuminuria, but I feel it would not be right to discuss it when the chief papers on that part of the topic have not been read.

IN A RECENT charge to the grand jury, convened in Newark, N. J., a justice rendered a decision in the case of accidents due to bicycle riding that: "The law does not create the ringing of the bell as a signal that will exonerate from responsibility."

OBSERVATIONS ON TONSILLECTOMY*

BY J. HOMER COULTER, M.D., Ph.D.

Professor of Rhinology and Laryngology in the Chicago Clinical School and in Harvey Medical College.
CHICAGO.

There is yet a lamentable uncertainty and want of precision in the terms used generally by the profession in reference to the pharynx and larynx, this, too, notwithstanding the great amount that has been written and spoken on this particular subject. Such indiscriminate use of terms is not alone by the general practitioner, but in many cases by those who in other respects maintain their standing as specialists in the line of nose and throat work. These facts are in all probability due to the comparatively short history of the specialty as a distinct line of work, and the consequent somewhat limited amount of original investigation that has been made. We note as an instance that many presumable authorities indiscriminately use the terms tonsillitis and quinsy; or that the removal of any portion or of the entire gland is alike termed a tonsillectomy; how little is positively known of the function of the pillars, or indeed of the tonsillar gland itself.

I wish in the beginning to posit as the most important element in the following argument and deductions the opinion that a pathologic tonsil demands entire removal. The exceptions to this rule are few, and are ordinarily not difficult to differentiate. We may maintain as most important exceptions, some cases of malignancy; cases of known or strongly suspected hemophilic tendency; the rare but possible condition of aneurysm in the region of the tonsil; in unusually severe cases of tubercular or syphilitic infection, with special manifestations in or about the tonsil. These, however, it will be observed, are only such conditions as would naturally be inhibitory indications to any operations at any time, and consequently very proper exceptions to the rule laid down above: admitting that there are oftentimes conditions and circumstances which make the case a rule unto itself in a surgical aspect.

I maintain that the above rule is one strictly in consonance with the best practice of the most successful surgery, and that its violation is, as of any other well-established fact in medicine or surgery, unwarranted, injudicious, unscientific and unsurgical. What would be thought of the modern surgeon who would voluntarily and without further excuse than that they were difficult to reach, amputate a breast and leave enlarged axillary glands, or of one who would do a simple mastoid and leave untouched a severe middle-ear involvement, or one who would remove pus tubes and leave a retroverted uterus in situ because the adhesions were difficult to get at or break loose? Yet I believe such argument is applicable to the cases under discussion.

Dr. Goodale, in a recently published monograph on the pathologic histology of acute tonsillitis, has conclusively demonstrated that there are quite sufficient bacteria and other pathologic conditions present to warrant the conclusion that the doubtless resultant chronic condition is one not only demanding careful attention, but also is necessarily a pathology more or less diffused throughout the entire gland. The process of natural or spontaneous repair in cases of acute tonsillitis is yet to be demonstrated conclusively. Certainly, however, the almost universal experience would lead us to anticipate that the acute condition was quite likely an impor-

*Presented to the Section on Laryngology and Otology, at the Fiftyeth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

tant etiologic factor in the various chronic pathologies met with so frequently.

It is unfortunate that as yet we do not know what is the function of the tonsillar gland. A dissection will demonstrate little beyond the fact that there is not a very intimate relation, anatomically, between the gland and the surrounding tissues; aside from the blood and lymph-vessels none of the fibers from the palatoglossus or palatopharyngeal muscles leave the striations of those muscles and branch off into the body of the tonsil, nor do they anastomose with each other until they have passed below the triangular space occupied by the tonsil, thus apparently favoring as much as possible the enucleation of the gland when desired. The conclusions arrived at by Goodale in his extensive and careful investigations may be again referred to: "1, absorption exists normally in the tonsils, and takes place through the mucous membranes of the crypts; 2, the path of the absorbed substances is in the interfollicular lymph channels in the direction of the larger fibrous trabeculae at the base of the organ; 3, during the process of absorption, foreign substances encounter phagocytic action on the part of the polynuclear leucocytes situated in and adjoining the mucous membrane."

Admitting these deductions of Goodale as true, it does not alter the truth of the statement that the crypts quite frequently extend almost the entire depth of the gland; indeed, enucleation of pathologic tonsils will in more than half the cases demonstrate the existence of abscesses and other debris in the depths of these crypts, quite on the other side of the tonsil from that presenting in the throat. If the lymphatics of the tonsil do anastomose to any great extent with those of the lateral and posterior pharynx, then might we not expect that more frequently an infection in the tonsils would be conveyed to the peritonsillar tissues? Or if the action of the tonsillar lymphatics was not alone absorptive, but expulsive as well, would it not be expected that the bacteria would become lodged deep in the plexus within, and we would much more frequently anticipate a phlegmonous condition therein in evidence of the correctness of our etiologic theory? The comparative absence of these evidences, however, must indicate that either the lymphatics in the so-called "lymphoid ring" are not very ready bearers of bacilli, or else the intimate connection, presumed by some authorities between the lymphoid tissue at the base of the tongue, between the pillars and in the vault of the pharynx is an imaginary one.

If it be true, as some have claimed, that the normal secretion of the tonsil is one of nature's leucocytic antiseptics, destroying each microbial intruder within the precincts of the crypts, then we are not warranted in removing a tonsil which is capable of producing this secretion. But I do not apprehend such surgery will be advocated by any member of this ASSOCIATION. It is not the question at issue once in a hundred cases, as to whether or not the tonsil is a pathologic one; it is rather the character and extent of the pathology, or the method of removal which we consider.

A careful and studious dissection of a number of pathologic tonsils will, I believe, prove the truth of the following statements:

1. The most violent pathologies are not always presented in the most hypertrophied tonsils. An overlapping pillar may so confine pyogenic germs as to force them into the surrounding areolar tissue. These pillars are then often hypertrophied to a considerable extent; the tonsil projects but little if any above the pillars, is firmly attached to them, and we have the so-called "sub-

merged tonsil." This leads me to the additional fact that:

2. Such continuity of tissue formed by the pillar overlapping the tonsil, is distinctly pathologic, and being such, demands surgical interference, theoretically at least, in all cases, excepting only those mentioned earlier in this paper.

3. In all probability the gland has an absorptive action, but it is a much more popularly known fact that many pathologic tonsils do constantly emit from the mouths of the diseased crypts and follicles quantities of odoriferous pus cells, pyogenic germs and cheesy masses of debris into the throat; so also will be found numerous abscesses usually emptying into the lacunæ, to be conveyed to the throat and stomach.

4. It will furthermore be observed that the force and action of the muscles in deglutition has kept the surface of the gland well freed from these products of decomposition, and that consequently the most serious condition is to be found in the deepest crypts. The truth of this statement can only be determined by a considerable number of post-mortem dissections, or by a bloodless process of enucleation on the living.

5. The tonsil will frequently be found firmly adherent to both pillars, and when so, either from repeated inflammatory conditions or as a result of a previous tonsillotomy, or from any other cause leaving a cicatricial bridge, they will be found firmly bound together, their independent action being prevented. The importance of such inhibition of function will be the better appreciated if our experience has led us to observe the results obtained by the removal of such cicatricial stumps from the throats of professional vocalists. The unanimous testimony of such patients, whom I consider much above the ordinary in intelligence and whose judgment must in a large measure be competent, is to the effect that they can, after the removal of these stumps, by the same effort at vocalization produce a much better quality of tone than before.

6. A more perfect incubator of disease germs can not well be imagined than is found in a pathologic tonsillar crypt. The chances are that the very fact of its being pathologic precludes to a great extent, if not entirely, the possibility of the antiseptic action of the leucocytes. We have here warmth, moisture and mechanical protection; can it be a matter of wonder why so many cultures can be so easily made from the deep crypts of a pathologic tonsil?

7. It will be found that the larger end of the gland is uppermost, frequently quite imbedded beneath the pillars, although to the casual observer the opposite would seem to be true. This can be easily demonstrated by having the patient gag, when it will be seen that the gland bulges out prominently from underneath the pharyngeal aponeurosis. I desire to call attention at this time to two points: one is, that it is often in this hidden portion of the tonsil the most serious pathology is found; and a second is that in such a condition a tonsillotome or any similar instrument, short of one adapted to a dissecting process, will fail of success to the extent to which it leaves a portion of the pathologic gland remaining in the throat.

What then are the general results of tonsillectomy, as compared with those obtained by the usual operation of tonsillotomy, as is ordinarily done by the general practitioner or most specialists as well?

1. It gives a cosmetically perfect throat. It gives a throat practically precluding the possibility of a return of the tonsillitis. It gives a throat in which there can

be no absorption of the toxins or bacilli into the lymph-channels at that point; at the same time it certainly offers to the patient a better chance for recovery should they subsequently be subject to an attack of any disease affecting the throat, such as the exanthemata, diphtheria or quinsy.

2. It liberates and allows a perfect action of the pillars and soft palate, the same result holding whether the pillars were adherent from inflammatory action or bound together by a cicatricial stump the result of a former tonsillectomy.

3. It removes a mechanical obstruction to the sound waves. This, in the case of those professional people who are compelled to use the voice in singing or speaking, is a matter of no little importance.

4. The operation, thoroughly and properly done, is more likely to be effectual in relieving a reflex disturbance when such neurosis is due to a pathologic tonsil than is the more simple operation of tonsillectomy.

5. If thoroughly and properly done, and the case receives the proper subsequent care and treatment, it will leave a perfectly smooth surface in place of the tonsil, which result can not as certainly be attained by a tonsillectomy, and with ignipuncture it is a practical impossibility. With singers this becomes an important matter.

6. Pillars, which were for any reason previously hypertrophied, will ordinarily, after this operation, promptly retract to a more normal contour and size.

7. It is in some cases a practical operation where another would be almost or quite impossible; for instance in those tonsils which on the surface are so soft and degenerated that a firm hold on them can not be obtained by any instrument; to obtain satisfactory results these must be dissected out entirely.

I take it as a sufficiently established fact which practically every operator will admit, sooner or later, plainly or by inference, that total ablation of the entire gland is the indication in all cases where malignancy, lues or tuberculosis is eliminated with a reasonable degree of certainty, and even in these cases such is very frequently highly advisable. It is equally axiomatic that in chronic pathologic conditions of the tonsils local applications are practically useless, and that constitutional treatment, aside from those cases in which a special and well-pronounced indication for such treatment exists, is a wasted effort.

In a large number of cases where complete removal is performed, those evidences of follicular involvement which are so frequently seen in the pharynx and about the base of the tongue, and even an old adenoid, will disappear as if by magic. Indeed, it would seem that the marked improvement which so universally follows a tonsillectomy, or even very often a tonsillectomy, should be sufficient confirmation of the baneful influence such a pathologic condition may and usually does produce. It is not unusual for patients to voluntarily speak of the relieved condition of the throat even after the removal of a single gland has been accomplished.

The dangers of tonsillectomy, as compared with other operations for the relief of tonsillar hypertrophy, are greatly exaggerated by the profession generally. In an experience reaching over three and one-half years past, during which time I have removed the entire glands, by cautery dissection process, over three hundred times, I have not been unfortunate enough to meet with a single untoward accident. One of the most frequent objections urged against the removal of the entire tonsil has been the added dangers of hemorrhage; I am convinced, however, that this is a danger more imaginary than real.

I have thus far had but one single case which required the least attention on account of hemorrhage. In that case ordinary styptics served to control the bleeding quite promptly. Such result I attribute, aside from a kindly fate, to the care taken in avoiding the wounding of the muscular tissues in the least possible degree, and as well to the fact that the cautery was always the instrument employed in effecting the removal. I have in this way fearlessly removed a number of large fibrous tonsils which I confess I would have long hesitated before attempting with either the guillotine or knife. I have on a previous occasion referred at some length to this process of operating, and I will consequently not enter into the details of the method as now employed.

To me a most convincing proof of the value of tonsillectomy as an operation is the unanimous satisfaction it affords the patients; and that after all is the ultimate criterion which must be the measure of our success in any practice.

That the removal of enlarged tonsils in children is advisable is a generally admitted fact, and requires no argument; but that even in these cases a partial removal of the gland is often advisable I must deny. If no other means be possible, then thoroughly curette the same after the use of the tonsillotome, scissors or knife.

The object of the paper is to call your attention to the fact that we will get by the removal of the entire gland when pathologic, in adolescence and adult life even more marked and surprisingly satisfactory results than in childhood. We will in addition be more closely following the precepts of consistent scientific surgery.

103 State Street.

DISCUSSION.

DR. F. J. QUINLAN, New York City.—As the essayist detailed the results of his observations, it occurred to me that we could mention the use of the cold snare, which I think a very valuable and safe adjunct to our present armamentarium. Some years ago Dr. Roe of Rochester gave us a very excellent paper in which he spoke of an affection of the tonsil unattended by hypertrophy, which is likely to at times give us much trouble. This small amount of glandular tissue gives rise to inexplicable symptoms and it is difficult to get at the cause. It is only by repeated examinations and by carefully separating the pillars that we can see this stroma, or rather this hardened tuft of tissue. This is the kind of tonsil that affects not only phonation, but frequently deglutition, and throws the soft tissues out of gear, so to speak. This small lymphoid collection, unless it is removed, may bring about acute and subacute conditions. The cold snare is of value in removing this, more especially since the introduction of the suprarenal extract, which we are all using today for its hemostatic effect. The use of the galvanocautery does not seem to me justifiable in these cases, but by simply throwing this tonsillar mass in view and getting the cold wire well down, then drawing it forward with the forceps, you can with this loop excise this tissue. The greatest amount of benefit often follows the enucleation of these little fibrous tufts. It is in these cases that you may inspect the fauces and be able to detect the cause of the trouble. The little crypts are often visible only on ablation of the tonsil. I only wished to mention the cold snare, though my experience in tonsillectomy does not warrant me in emphasizing its use and advocating it when other measures can serve us with safety.

DR. A. DEVLIRISS, Toledo, Ohio.—I would like to ask whether the gentleman could make a tonsillectomy, as suggested by the Doctor, with the cold wire.

DR. QUINLAN.—I referred to tonsillectomy, Mr. Chairman.

DR. C. M. COBB, LYNN, Mass.—The snare that is made for tonsillectomy is rather large and heavy. It carries a No. 10 wire, and it is quite possible to do a tonsillectomy with it if you bend the wire around so you get a curve that falls behind the tonsil, and then work it carefully in. The caution I wish to give is that this instrument being so heavy, you are very likely to make some traction on the tonsil with it, and if you do you are very likely to have the neck filled with extravasated blood. The instrument is heavy and has to be handled with care.

DR. T. R. CHAMBERS, Jersey City, N. J.—If I understand the gentleman correctly, all his cases are tonsillectomies now in-

stead of tonsillotomies. I have done a great many tonsillotomies and a few tonsillectomies. After tonsillotomy I find many of these patients have as good singing quality as they had before. And I think issue may be taken with the writer in regard to all the tonsils that are hypertrophied being pathologic. I think it is very doubtful whether we can say that a tonsil, because it is a little enlarged, is a diseased tonsil. If it fits so much space that it gives us difficulty in breathing, then tonsillotomy is indicated. The operation of tonsillectomy, Dr. Coulter says, is not a serious one, but there are conditions under which I think it might be a serious operation. The tonsil must be put there for some purpose, and if it is partly taken away it still may serve its purpose, but that is not true if it is entirely removed.

Dr. H. W. LOEB, St. Louis.—This paper is an exceedingly timely one, especially in view of the work that has been done in the past three or four years, by which demonstration has been made of the fact that certain diseases enter the body through the tonsils. I believe it is claimed that muscular rheumatism as well as the acute articular form is due to toxins that find entrance in this way. There are cases going around the country to-day in which partial tonsillectomy has been performed and acute attacks of tonsillitis have been observed for years afterward. I recall a case of tonsillitis that occurred after every vestige of the tonsil was supposed to have been removed, and finally a small mass of tonsillar tissue was found to be remaining. In this case the dissection of the small remaining mass and the removal of practically all of it has caused the attacks to be lessened in duration and number, so that the patient has had only one attack in four months, whereas before they occurred every ten or twenty days. I found the only portion of the throat affected was the portion on which the small mass still remained. In 1892 I presented to this ASSOCIATION the first snare which I had the opportunity of devising. Since that time this electrocautery snare has been very much improved, until the present snare, mentioned by Dr. Coulter, which should be used whenever it is practicable, uses only a No. 5 wire. A complete tonsillectomy can be made without any particular danger to the patient. I thus save my patients, or think I do, not only the possible tonsillitis in the future, but also those who may find entrance through the tonsils. It is only necessary to use a pair of forceps and pull the tonsil from its bed and take out the entire mass with the snare so the whole bed is as smooth as the rest of the palate. The healing is rapid. I am sure if this operation were more often used with instruments that have sufficient precision to warrant their use, the condition Dr. Coulter mentions would not be seen so often. I rise at almost every meeting of this ASSOCIATION to say about the same thing, and I have not had any reason for changing my opinion.

Dr. J. A. STUCKY, Lexington, Ky.—I have been trying to agree with Dr. Coulter for two or three years. I have only done two or three tonsillectomies, and have not had the courage to do any more, for I have seen two or three people who have had the operation performed by men far more skillful than I, and they are sorry that they had it done. They complain of soreness and stiffness, and one declares that his voice is not of as high register as before. Whether there is anything in that I do not know. But I have found that when all the tonsil that could be engaged in the tonsillotomy was removed, that has given relief. But I have not met any cases of recurrences when the gland was thoroughly removed with the guillotine. It does seem to me that we run some risk in removing the entire gland, and when there are adhesions I question whether we can do it without harm.

Dr. JAS. H. FARBER, Dayton, Ohio.—In many cases of enlarged tonsils, in fact those which most commonly present themselves to us, we find the tonsil scarred from repeated attacks of quinsy, irregular in form, its outline lost in the pillars, and adjacent structures hypertrophied so that it is difficult to determine which is tonsil and which is pillar. On close inspection we find several crypts; these I remove with scissors, trimming out as much tissue as the case will warrant. I would like to ask Dr. Coulter whether or not he believes there is a place for the snare in the cases.

Dr. G. V. WOOLEN, Indianapolis, Ind.—I had the temerity to say before this Section, at the meeting of the ASSOCIATION in Cincinnati, in 1888, that I did not believe there was any such thing, anatomically or physiologically speaking, as a tonsil. I have since thought that I might have been mistaken at that time. I have made a persistent study of this subject. When we met in Philadelphia I again announced my belief that there was normally no such thing as a tonsil. Some gentlemen from Philadelphia took me to task and said that comparative anatomy taught that there was such a thing. The statement was rather a "stunner" to me, because I had not made a study

in that direction. I am doing so now, and I do not know where they find proof unless possibly it be from a more extensive study of embryology than I have made. But in the study of comparative anatomy and physiology, which I am prosecuting now, I am becoming confirmed in the belief that we do not have, physiologically speaking, such a thing as a tonsil. If this dictum be true, then there can be no objection to tonsillectomy. As a matter of fact, I have yet to regret once having made a tonsillectomy. It has been my practice to remove all of the tonsillar tissue. I do not always succeed in removing all of it, but I always feel disappointed if I do not. All the ill effects supposed to be due to removing the tonsil are attributed to, and result from, disease in the nose. Thus, we often have pharyngeal trouble after removal of the tonsil, which has no relation whatever to the removal of the tonsil. If the nose is first put in good condition, we will not have any difficulty with these patients, if tonsillectomy is subsequently made.

Dr. E. J. BERNSTEIN, Baltimore, Md.—I was rather surprised to hear the Doctor say that he did tonsillectomy with a guillotine and had no return. Am I right, Doctor?

Answer: Yes, sir.

Dr. BERNSTEIN.—Well, I have done the operation with the guillotine a number of times, and I have had a number of recurrences. I believe the tonsil to be an unnecessary and dangerous organ, and then the fact that the tonsil may be a focus of infection has been brought home to me in a very terrible manner during the past winter. I had a patient with a very mild tonsillitis, so mild in fact that she would hardly have paid attention to it at the time if I had not been treating a relative of the family. All that could be seen on one tonsil was only a slight erythema. I treated it with nitrate of silver. In a day or two she returned, saying the throat was as bad as ever. I made a culture and found the streptococcus. That is not surprising, for we often find the streptococcus when the throat is normal. But the young woman developed a streptococcal infection in a short time, and notwithstanding the use of the antistreptococcus serum, she died in a few days. In Baltimore, Dr. William Welch said, "There are streptococci and streptococci, as far as antistreptococcus serum is concerned;" the fact I got very little benefit from the antistreptococcus serum is not surprising, since it is usually prepared from the streptococcus of crystals and the streptococcus we had in this case was not of that variety.

Dr. A. DEVLILHS, Toledo, Ohio.—The essayist said that tonsillectomy should not be made with the knife. I do not believe the operation can be made complete with the cold snare, and I believe that tonsillectomy will usually suffice.

Dr. L. C. CLINE, Indianapolis, Ind.—I would like Dr. Coulter, in closing, to explain what he means when he says that his method will never cause bleeding. If there is a method not occasionally followed by bleeding, I would like to be familiar with it. In either operation we should group our patients and not rely on any single method, but select the method that best fits the case. We can often get good results with tonsillectomy followed by the use of the canterly knife to destroy any crypts that may be left; at least, that has been my experience.

Dr. J. C. McALLISTER—I wish to ask the age at which that was done.

Answer: Seven years.

Dr. McALLISTER.—It is perfectly proper to do a tonsillectomy as well as a tonsillotomy. I find many persons who need a tonsillectomy or tonsillotomy, where there are adhesions between the tonsil and the anterior pillars. One of the speakers spoke of the use of the hot snare in removing these. I can not imagine, for my part, how he is going to do the snaring without previously dissecting the tonsil from the anterior pillar. For myself, I have a set of knives for use in these cases, to dissect the tonsil from the anterior pillar, and then I do a tonsillectomy.

Dr. J. F. BARNHILL, Indianapolis, Ind.—It seems to me that the diversity of opinion as to whether we shall do a tonsillotomy or a tonsillectomy can be greatly simplified by remembering what we do the operation for. To my mind we do it to accomplish two things, viz., remove the obstruction that may be present, and remove the crypts that are always present. When the obstruction is great, or even considerable, and we wish to free the upper air tract, there is no other method simpler, safer or certain in results than tonsillotomy. The patient is almost certainly cured. In the second class of cases requiring the operation, where the tonsil is small, the kind that has been particularly referred to by the essayist and some of the speakers, we do not remove the tonsil on account of obstruction, but for the purpose of getting rid of the crypts. Any other method, as I take it, that will remove the glands beyond the bottom of these crypts will do all the good that can be done. I do not believe,

as has been intimated by some of the gentlemen, that it is necessary to leave any part of the tonsil in place. The tonsil is simply a part of the system of lymphatic glands, of which there are five or six hundred left if we remove this completely, and they are freely able to perform all the work that is done by the tonsil that we are at work on. So I always feel satisfied, and that my patient is cured, when I go to the bottom of these crypts and remove them.

DR. J. H. COULTER, Chicago.—If I undertook to answer all that has been said it would occupy much more than my allotted time. In regard to the remarks by Dr. Barnhill, which I believe are positively incongruous with his practice and with his ideas of surgery, in that he says he will get perfect results by destroying a diseased crypt or portion of the tonsil, when the crypt runs up well under the pharyngeal aponeurosis, where you often find your greatest pathologic focus, how can you destroy that thoroughly, and yet leave a smooth pillar that will be free in its action to perform its function well, either in voice production or deglutition? I can not accomplish it. It would require a man with greater dexterity than I can display. Dr. Loeb and one or two others rather misinterpreted the purport of my paper, inasmuch as I had intended and had hoped that little or nothing would be said concerning the method to be employed. I am simply contending for a surgical principle. I do not use the snare very frequently. Dr. Loeb uses the snare, and uses it successfully. I have seen some of his patients, and he does get beautiful results from it. But certainly Dr. Loeb does not attempt to use the snare without first separating an adherent tonsil from the pillars.

You can not draw the tonsil into the snare if it is adherent to the pillars; it must first be loosened and made to stand out as a separate gland. I thoroughly agree with Dr. Woolen that normally there is no gland discernible. I can show you in this city, although I do not live here, a person on whom there has been no knife used, and yet I defy any of you to discover a gland there.

A MEMBER.—You can see that in my throat.

DR. COULTER.—Well, there are two instances. If now our proposition be true, and I believe it is, then if that tonsil does become discernible it is hypertrophied, and hypertrophy is a pathologic condition. One of the speakers asked if all enlarged tonsils are pathologic? I say yes, emphatically, because even if the crypts are not diseased the tonsillar tissue itself is diseased. I do not want to enter into a lengthy discussion of the method at this time, but Dr. DeVillias and Dr. Cline have forced the question so that I must say a single word. My method of doing tonsillectomy is with the cautery blade, because by that method I have an absolutely bloodless operation. By this process in over three hundred cases I have never yet had a very serious hemorrhage, and only one requiring attention. Time and time again I have removed an enlarged fibrous tonsil almost reaching the median line of the throat, and not had twenty drops of hemorrhage.

I remember all the objections to tonsillectomy, and I appreciate the criticisms that have been made, because they have brought out the fact that tonsillectomy is the proper surgical procedure if we adhere to the very first principles of modern surgery. There is no question about it. There is not a member present here who has advocated tonsillectomy, who would be willing to go before the surgical section and advise leaving a portion of the pathologic tissue intact in the body where it can produce such deleterious effects, as it is almost certain to do if left. I repeat it as a perfectly practical and feasible proposition that every operator who will begin the practice of removing the entire gland when pathologic will get results surprising to himself and gratifying to his patient, and will not soon return to the unsurgical operation of tonsillotomy.

DISEASES OF THE ANTRUM OF HIGHMORE: A STUDY OF ONE HUNDRED AND FIFTY CASES*.

BY L. C. CLINE, M.D.

PROFESSOR OF LARYNGOLOGY AND RHINOLOGY, MEDICAL COLLEGE OF
INDIANA.

INDIANAPOLIS, IND.

My apology for presenting the often discussed subject, "Diseases of the Antrum of Highmore," is the confusion among observers regarding the etiology and pathologic conditions found in these cases, as well as the discrepancy of opinions as to treatment. After an experience with

150 cases, 140 of which were in my own practice, I feel warranted in calling attention to a few points noted under my observation.

My cases have all occurred between the ages of 20 and 70. Forty-eight occurred in females and 102 in males. The disease did not predominate with any particular class of people—doctors, lawyers, ministers, teachers and tradesmen—in fact, all the callings and conditions in life were represented. Of the 140 cases, 6 had sarcoma, 3 in women and 3 in men. Two of these were operated on by the late Dr. J. W. Marsee, and in one of them the entire superior maxillary bone was removed, the other only partially, which gave only temporary relief from pain. The other four, when apprised of the nature of the disease, refused operation and finally succumbed to the malady. These cases all gave a history of suffering from their teeth prior to the development of the disease, which fact leads me to believe that the long-continued irritation from an abscessed root discharging into the antrum is a factor in the production of sarcoma.

Four cases of empyema of the antrum have come under my observation. The symptoms were the same as those described by Dr. D. B. Kyle in his cases—that of escaping gas from abscessed and carious teeth into the antrum, producing a sense of nasal pressure with paroxysms of a dull, heavy, sickening headache. These were all relieved by extracting or treating the diseased teeth.

The etiology of my cases could all be fairly well traced to three sources, viz: dental, nasal and la grippe. As nearly as I can estimate, 50 per cent. were due to diseased teeth, 40 per cent. to sequelæ of la grippe and teeth combined, and 10 per cent. to ethmoiditis and the various nasal obstructions. Probably a greater percentage should be assigned to la grippe complications. My estimates have been placed on the clinical history as given, which is often misleading.

Twenty cases were acute, complicated with influenza, and all subsided without operation. Of the other 120 all were chronic, suppurative cases of from two months' to seven years' standing. Operation revealed a marked swollen edematous condition of the mucous lining of the antrum in 16 of these. In none did I find true polypoid growths, as described in some of the text-books. Curettement was done in 6, and packing with iodoform gauze in 4 cases. The others yielded to hot astringent douches. Five cases were bilateral. Of the rest, 75 per cent. were on the right side. In trying to account for this, dentists and dealers in dental supplies tell me that a large percentage of the teeth and plates that are broken occur on the left side, which goes to show that there is more biting and chewing on the left side, thus favoring decay on the right. Ethmoiditis was observed as a complication in 11 cases, all of which were preceded by la grippe. Two cases that were carefully diagnosed would not submit to operation, and, so far as I know, they are still suffering from the disease.

The zeal of some of our dental brethren in crowning, building and maintaining bridge work, I am led to believe, is a cause of empyema, in some cases at least. The thought was suggested in 6 under my observation, having had to remove diseased roots under expensive bridge work before a cure could be effected. A purulent discharge from the antrum, when due to dental origin, is carious and fetid, but when its cause is from other sources, like the ethmoid and frontal sinuses, it is creamy and almost without odor.

For diagnosis I rely principally on the use of peroxid of hydrogen and the position of the head. After cleans-

*Presented to the Section on Laryngology and Otolaryngology, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

ing the nose and cocainizing, a few drops of peroxid are injected with a small syringe armed with a canula, the point of which is bent at a right angle and carried into the ostium maxillary. If pus is present, it will be manifest by the characteristic reaction. In cases of nasal obstruction or a deflected septum, I make an exploratory puncture with a small, sharp-pointed drill, through which peroxid is injected.

Illumination is less reliable and more complicated than the above method, although it is a useful aid in determining the condition of the roots of the teeth. I have come to believe, after trying the different methods of opening the antrum, that entering through the alveolar route is by far the best, for the reasons that the after-treatment is less painful, and the drainage is more complete, and the patient can, with greater ease and facility, keep the antrum clean.

Of the 118 cases operated on, all but two had one or more carious teeth, or they had already been removed. So that the objection to opening through the alveolar process on account of the teeth was reduced to a minimum.

My experience in puncturing the antrum from the outside under the gingivomoid fold has not been flattering. In every instance I had a swollen cheek from purulent infection from the discharge. The plan now followed in operating is to first enter the antrum with a small, pointed drill run by an electric motor, then insert a bit of cotton saturated with 10 or 20 per cent. solution of cocain well through the hole, which soon enables me to enlarge the opening to any required size. When a tube is required to keep the hole open, or food from entering, I use one made from silver wire turned to form a shoulder on the end to prevent its entering the antrum. The tube I now show you will remain where it is placed without anchorage, and the patient can remove and replace it at will. Some cases do better without a tube, using a plug of cotton instead, frequently changing it.

The time required to cure a case depends on the size of the opening and the thoroughness of the operation in removing all the carious teeth and nasal obstructions, together with thorough cleansing, curetting, packing and stimulating to healthy granulation. My cases have varied in the time required to effect a cure, from three weeks to one year, the average being from three to six months. Many cases will relapse and require reopening, after closing, on taking cold. For this reason, tonics and attention to the general health must not be neglected.

My practice has been to have the antrum thoroughly cleansed twice a day until the discharge lessens, then once daily until the discharge ceases, first using a little peroxid in water, followed by a solution of hot boric acid, or salt water; once or twice a week a solution of silver nitrate or iodine of sufficient strength to make an impression on the mucous membrane is injected. In the boggy, swollen, edematous cases the best results were obtained by using hot water injections three times a day with a little boric acid or salt added.

The so-called dry treatment by insufflating powders has not come up to expectations. The best results observed from the use of powders were by first washing the antrum clean, and then covering the membrane with equal parts of finely powdered boric acid and lactopeptin.

In tabulating cures, I find it difficult to keep track of all cases, as they are scattered over a large territory, some changing location. But, from my knowledge of the cases, a large percentage have been cured.

To summarize: The points I wish to emphasize are: 1. The great number of cases that are traceable to la grippe. 2. The absence in my cases of polypoid growths. 3. The greater predominance on the right side. 4. The importance of a good-sized opening, and the removal of all diseased teeth. 5. In my experience, to open through the alveolar process is by far the best. 6. Hot douching to relieve the edematous conditions. 7. The dry treatment alone after a first washing has not been a success in my hands.

224 N. Meridian Street, Willoughby Building.

DISCUSSION.

DR. J. A. STUCKY, Lexington, Ky.—I do not think Dr. Cline need offer any apology for bringing this subject before our notice again. He has certainly given us an excellent paper. I am sorry he said nothing more than he did about the consequence of antral trouble. Most of the patients complained a little of pain in the cheek. I have had more patients complain of a peculiar heavy grinding pain in the occipital region than I have had complain of pain in the cheek, and nearly all of them complained of some nasal trouble. I am surprised to hear him say that in the chronic cases he has met with very little true polypoid degeneration in the antrum. I nearly always find it in these cases. I approve of the method he mentions of entering the antrum, going through the alveolar process and removing a tooth if necessary. As a rule we have a decayed tooth which we can remove, but if not I am in favor of removing a sound tooth. As to the cause of suppurative in the antrum, dental caries has a great deal to do with the production of this trouble, and next to this has been chronic trouble in the nose. In my experience, usually I have found a polypoid condition of the middle turbinate, and the secretion was simply dammed up without any drainage whatever. In nearly all the chronic cases, too, I have found that there is suppuration in the ethmoidal cells.

I recently had a very interesting case of osteosarcoma of the superior maxilla which puzzled several of us for five or six days, and I would like to report it. A coal driver was emptying coal into a cellar and a man received a shovelful of coal in the face. Two weeks afterward his face was swollen, and disease of the antrum was suspected. With the trocar and canula I found pus in the antrum. The man was etherized and the second and third molars removed without trouble, and about one-half an ounce of pus evacuated. I found the whole wall had undergone absorption, and microscopic examination showed the presence of an osteosarcoma. A week afterward a general surgeon removed the maxilla entirely and the patient died.

Now as to the dressing in these cases, I would be afraid to allow a patient to keep the opening closed with cotton. I object to a tube; I prefer gauze. In this connection I want to mention a case, for we learn by experience. I operated on a patient two years ago for antral empyema. The patient kept her antrum closed with gauze, but in a hurry one morning she put in too small a piece of gauze, which slipped into the cavity and she had a reinfection as the result. There was acute suppurative from the ethmoidal sinistis following, and reopening of the antrum was necessary in order to remove the gauze tampon.

DR. T. H. CHAMBERS, Jersey City, N. J.—I would like to ask the Doctor if this is the average diameter of the tooth. In my experience that diameter is less than it should be in ordinary cases.

DR. JOHN H. McCASSEY, Dayton, Ohio.—Dr. Cline has certainly given us a very interesting paper. I would mention the use of peroxid of hydrogen in closed cavities or in small deep cavities to condemn its use. We know the peroxid of hydrogen in closed cavities causes gaseous formation and pressure on the adjacent tissues, and too often results injuriously. I would condemn the use of iodoform in this kind of practice—eye, ear, nose and throat. We regard iodoform in surgery as the skunk of surgery. Surgery would not suffer if iodoform was entirely abolished. I have long since dropped its use. Boric acid and nosophen and other drugs have taken the place of it. Last summer I had a case in which a man was upset in the river while crossing it with a horse and cart, and the horse kicked him on the upper jaw. He had a canine tooth that was diseased and I had it extracted. I could readily pass a probe up into the right antrum of Highmore, and I permitted it to drain through that opening. I wanted to operate on the other antrum, but the patient refused and went away a few months. When he returned I found the upper part of the malar bone was necrosed. I was able to bring away a large portion of the malar bone. There was an opening from the left antrum

through the cheek. I operated, scraping away all necrosed bone and the patient got well with five after-treatments. I mention reaching the antrum of Highmore through the canine tooth, which was only accidental, because the patient wanted the tooth out in order to get a new set of teeth. The shape and location of the antrum varies greatly. The portion of malar bone necrosed and removed was $1\frac{1}{2}$ inches wide, and extended back over one inch. This space has been bridged over with fibrous tissue and the patient wears a plate nicely.

Dr. C. R. HOLMES, Cincinnati, Ohio.—Although I arise to not exactly agree on the point of operation, I do so with all due deference for the writer, for whom I have the greatest respect and of whose beautiful work I have long known. I am one of those who do not make the opening through the alveolar process, although I have done so in the past. I have no such record as Dr. Cline, and the number of cases he has treated is of importance. But when you can look into the antrum with a mirror, and curette it at any time, it is desirable. Instead of using gauze I have had flexible rubber plugs made, which are introduced into the opening. These are shaped like a wedge and cause almost no inconvenience to the patient. They can be taken out and sterilized by the patient as often as he chooses. My treatment is practically the same as Dr. Cline has given. I do not favor the introduction of gauze, when we can use flexible rubber plugs, because gauze is not so likely to remain in position. I am exceedingly glad to see this flexible wire drain of the Doctor's, but I am not willing to let the opening be made through the alveolar process. I would like to ask how the Doctor secures closure of the opening.

Dr. E. J. BERNSTEIN, Baltimore, Md.—I would like to ask where the Doctor got the plugs?

Dr. HOLMES.—I had a dentist make them for me in Cincinnati.

Dr. S. E. ALLEN, Cincinnati, Ohio.—We have two classes of antrum trouble, the acute and chronic. In the acute cases I suppose an opening anywhere, maintained for a few days or months, will bring about a cure. As to chronic inflammation of the antrum of Highmore, I have not been sure in my cases that the patient was cured, that is, that the cure would be positive and that there would be no necessity for again cleansing the cavity. It seems to me the only rational way, and that which makes the nearest approach to a cure, is to make a big opening into the antrum and clean it out and make a big opening into the nose. Even then suppuration may go on. But if you have a big opening into the nose, that cavity after a time becomes a part of the nose and you get the nearest approach to a cure. But even then, in my experience, these cases may have trouble afterward. I would like to know what percentage of old chronic cases make a really permanent recovery?

Dr. Geo. C. STOTT, Philadelphia.—I want to say a word in regard to the etiology of these chronic cases. I differ from Dr. Cline and rather lean to the side of Dr. Holmes in that I do not believe that these cases are due to carious teeth. In support of this view, a Russian in 500 post-mortems found 212 had carious upper teeth, but only two of these abscesses of the molars penetrated through the periosteum into the antral cavity. There are a few cases that are caused by carious teeth. Most of my cases have been caused by hypertrophied conditions of the nasal mucous membrane. Dr. Cryer has a very good specimen showing how a carious tooth might cause trouble in the antrum. The carious tooth is surrounded at its root by an osseous wall, formed there in the regular process of Nature to make a cure, and preventing any of the unhealthy material from entering the cavity itself. As to operation in the chronic cases, I prefer going through the canine fossa and then putting in a hollow tube, instead of a solid plug such as Dr. Holmes describes, the upper lip or cheek acting as a valve to prevent food particles entering the antrum.

Dr. L. C. CLINE, Indianapolis, Ind.—There are some points I would like to make a little more clear. As to Dr. Stucky's suggestion as to the details of the symptoms, I took it for granted that most of you knew the symptoms and that we had gotten to the point where we knew we had trouble in the antrum and wanted to get rid of it. We could spend a whole hour on the symptoms alone. The first point is to make a diagnosis, and if there is any doubt about the case I put a hole into the antrum and inject a few drops of peroxid of hydrogen. As to injecting peroxid of hydrogen into a closed cavity, I do not have a closed cavity after I have made a hole into the antrum. It would be a mistake to use peroxid of hydrogen in a cavity containing pus, unless there were an opening into it. I have not attempted to present anybody's theory, but only my own observations. These cases have occurred in my practice and I have not found certain things that I have heard of being in the antrum, such as polypoid growths, etc. I did not find polypoid growths in any of the cases. There were edematous

conditions found in some of them, which were relieved by hot astringent treatment. As to the size of the opening and the size of the tube I use, I made this tube only to show what it is. If I make a large opening I make the tube to fit the opening by using large wire, or if the opening is very large I do not need to use a tube. It is only in the smaller openings that the tube is needed. As to the position, I have tried these various methods and it may be my fault that I did not have success in opening through the canine fossa. My cases have gotten along very much better with the opening where the patient can clean it. My great difficulty has been to get patients to keep the antrum clean. By using an ordinary Davidson syringe, such as is commonly sold in the drug stores, by putting on a tube, they can pump through a sufficient amount to keep it thoroughly clean.

OPERATION FOR UNDESCENDED TESTICLE AND CONGENITAL INGUINAL HERNIA.*

BY ARTHUR DEAN BEVAN, M.D.

Surgeon, Presbyterian Hospital; Professor Surgical Anatomy and Associate Professor of Surgery, Rush Medical College.

CHICAGO.

During the last year I have developed an operative procedure, first in connection with congenital inguinal hernia, and later in connection with undescended testicle, which has been very satisfactory in the few cases in which I have employed it, and which I believe is of sufficient value to warrant my reporting and urging its general adoption. As malformations in connection with the descent of the testicle, we find: 1, the rather common condition of congenital inguinal hernia, due to failure of closure of the vaginal process of peritoneum, and 2, the malpositions of the testicle, which might be divided roughly into three groups—*a*, within the abdominal cavity; *b*, in or about the inguinal canal, and *c*, in the perineum.

Cryptorchidism is not very uncommon, although the condition is usually concealed. Statistics of the Austrian army show one case in each five hundred men drafted for military service. Little attention has been paid to the operative treatment of this deformity in America. Formerly, when a cryptorchid presented himself to me for advice, I dismissed him with the statement that nothing could be done to correct the malposition, and I found from reading our standard surgical works and from conversation with my colleagues that this was the position almost universally taken. This deformity brings with it both mental and physical distress and dangers which warrant surgical interference for its relief—mental disorders, such as hypochondriasis and hysteria; physical dangers, such as hernia, inflammations from trauma, twisting of the cord and gangrene, and a great susceptibility to malignant degeneration.

For some years the teaching of most surgical authorities has been never to interfere with this condition unless urgent symptoms were present, and then to castrate. In the pre-antiseptic and pre-Bassini days, this teaching was undoubtedly correct. To-day, however, our ability to secure normal wound healing and the knowledge of the region involved, obtained from our experience in hernia work, has made this position no longer tenable, and I shall endeavor to show that the rule now should be to operate and transplant to its normal position in the scrotum every undescended testicle which can be palpated, whether it causes symptoms or not.

The malposition of the testicle is often complicated with hernia, and hernia of a very dangerous and distressing type. When the testicle is retained high up in the

*Presented to the Section on Surgery and Anatomy, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

abdomen and does not reach the internal abdominal ring, a hernia is not very apt to coexist, but in one-half of the cases, where the testicle is in or about the inguinal canal, a hernia is present. It is difficult to retain such a hernia with a truss because the pressure on the testicle is unendurable and such pressure is apt to produce traumatic inflammation of the organ.

The malposition of the testicle appears from statistics to make it prone to malignant degeneration in a far greater percentage of cases than in the normal testicle. Zymanowski, who investigated this subject most thoroughly, comes to the conclusion that all retained testicles should be removed because of this danger alone. He was himself a monorchid and died of carcinoma of the retained testicle.

Statistics seem to show that carcinoma of a retained testicle is peculiarly malignant, as no cases of cure have followed removal, all cases dying within a short time of recurrence. I have had but one case of malignant disease of a retained testicle, a case of sarcoma. Castration was followed rapidly by a great sarcomatous mass in the abdominal cavity, metastases in the brain, and death.

A retained testicle in or about the inguinal canal is peculiarly liable to injury, both external injury from its exposed position and also injury from bodily movements, exercise of any kind in which the abdominal muscles are strongly contracted, sneezing and coughing. I have had one case in which the patient was compelled to remain in bed whenever he had a slight cold, because the pain of coughing and sneezing was excruciating. These injuries are followed, when severe, by the sickening sensation peculiar to a trauma of the testicle, nausea and sometimes syncope. Swelling and traumatic inflammation of the testicle may follow, and, if infection from without or through the circulation, occurs, suppuration and sloughing may result. As rarer complications of undescended testicle, hydrocele and twisting of the cord, followed by necrosis, might be mentioned.

One of the accompaniments of undescended testicle, which is seriously distressing to the individual in whom both testicles have failed to descend, is the fact that, as a rule, such testicles are sterile. Why this should be so is difficult to state, because in many animals the intra-abdominal position is normal; the fact remains, however, that most undescended testicles fail to develop and produce living spermatozoa.

I have very briefly stated the dangers and discomforts of the condition of undescended testicle simply to claim, as I do know, your consent to the statements that they are as great, if not greater, than those of ordinary inguinal hernia. We do not hesitate to offer a patient the benefits of an operation for hernia. Why should we refuse the cryptorchid the benefits of a surgical procedure which, if properly done, is as safe and as sure as a Bassini hernia operation, and which is of more value to the individual both from a physical and mental standpoint?

In pre-antiseptic days the treatment of undescended testicle was mechanical. An attempt to bring the testicle into position by pulling and pressing the organ into the scrotum, or the continuous pressure of a truss above the testicle when this could be employed; or when these means failed, which they almost always did, either dismissing further effort, or castration. A few attempts were made to transplant the testicle into the scrotum by a cutting operation, but these failed because of ignorance of the surgical anatomy necessary to unravel the malformation and malposition, or because of infection. Such treatment did not find adherents, because of

the bad results, and was never admitted to the position of a standard procedure.

Soon after the general introduction of antiseptic surgery into German clinics, Max Schuller, then in Greifswald, published in the *Centralblatt*, and also in the *Annals of Anatomy and Surgery*, the description of an operation which he had made for undescended testicle, in which he laid the foundation of a surgical procedure, correct anatomically, in that he recognized the chief factor which prevented the drawing of the testicle down into the scrotum and the factor which drew the testicle back into the old position after operation. This factor was the peritoneal prolongation extending from the general peritoneum to the tunica vaginalis; that after division of this vaginal process it was possible to bring the testicle down into the scrotum without tension. He stitched the testicle to the bottom of the scrotum. His patient made a good recovery and, as he reports, the small undeveloped testicle rapidly increased in size.

Following Schuller, Nikoladoni, Kocher, Czerny and Ziebert in Germany, and Tuffier, Richelot, and a number of other French surgeons have developed the operative treatment of undescended testicle. In Great Britain and America little work of this kind has found its way into the literature, so little in fact that my attention had never been called to the work already done along this line until after I had developed the technic which I am about to report.

In the first place, I desire to refer briefly to the best method of handling the vaginal process of peritoneum in operations for congenital inguinal hernia. I have until recently been in the habit of obliterating the vaginal process in these cases by a purse-string suture at the internal ring, and by whipping up the peritoneum around the cord with a continuous catgut suture, leaving enough to form a tunica vaginalis. I did this because of the great difficulty I had experienced in separating the vaginal process from the cord. I found in one case in which I had done this, that the testicle was dragged high up, almost out of the scrotum, by the subsequent contraction of the vaginal process.

In a careful dissection of the case of inguinal hernia, I found that although it was very difficult to separate the vaginal process from the cord proper, when I opened the inguinal canal widely, so as to expose freely the internal ring, I could very easily separate the peritoneum from the cord just where the cord separates into its constituent elements, i. e., where the vas turns inward and downward and the spermatic vessels pass upward. Here I could readily separate and cut off the vaginal process and close the abdominal cavity as in treating the sac of an acquired hernia. Further, I found that by following the vas and spermatic vessels inside of the abdominal cavity with my finger, and freeing them from the peritoneum covering them, I could pull them a surprisingly long distance out of the abdominal cavity. Since that time I have had the opportunity of operating on four cases of congenital inguinal hernia which I have handled in this way, by an incision three inches in length over the inguinal canal, splitting up the entire length of the canal, freely exposing the internal ring, opening the vaginal process, freeing the vaginal process very high up where the vas and spermatic vessels separate, ligating the vaginal process with catgut at the internal ring and dividing half an inch below the ligature, then, without stripping the vaginal process from the entire length of the cord and without removing any of it, throwing a catgut ligature around it and ligating it so as to close it, forming a large tunica vaginalis.

In operating on undescended testicle, whenever it is palpable above the canal, I have pursued the following technic: Incision three inches long over the canal; the incision should never involve the scrotum. It should never extend farther inward or downward than the external ring. If the testicle is in the canal, split the canal open the entire length by division of the external oblique, draw out the testicle by dividing all the covering over it down to the peritoneum, run the finger along the vas and carefully separate the peritoneum from the vas for two or three inches within the abdomen, run the finger along the spermatic vessels, and in the same way carefully free them from peritoneum. Now separate the vaginal process from the cord high up, ligate the peritoneum of the internal ring, and divide the process half an inch below the ligature, remove all the coverings from the cord, so that the testicle hangs suspended by the vas and the spermatic vessels. It is surprising to find how movable the testicle now becomes. It can be readily laid on the thigh several inches below Poupart's ligament. The index finger is now carried into close contact with the external oblique over the crest of the pubis into the scrotum, and with the blunt dissection of the finger a large pocket is made on that side of the scrotum for the reception of the testicle, great care being taken to make the opening of the pocket only as large as necessary to admit the testicle. The very freely movable testicle is now carefully slipped into the scrotal pocket, where it remains without tendency to retract. The testicle is not sutured to the scrotum, such suturing being of no value in preventing retraction, simply adding the risk of complications. If the testicle has been properly freed, it becomes at once evidence that such suturing is superfluous, and if the testicle has not been freed sufficiently and can not be retained in the scrotum without suture, then one may be sure that it will retract in spite of such suturing. The inguinal canal is now restored as in a Bassini operation for hernia, or what is probably better a Bassini operation without transplantation of the cord, which Semm advocates as preferable to a Bassini and which Ferguson of Chicago described as the typical hernia operation. After the closure of the canal and external ring there still remains one of the most important steps of the operation, i. e., the sewing of the deep layer of the superficial fascia to the aponeurosis of the external oblique by means of fine buried catgut. This is done throughout the operative field, over the inguinal canal, and well down over the pubic crest to the neck of the scrotum. The object of this step is to obliterate the areolar space between the superficial and deep fascia in front of the external ring. It is in this space that the testicle retracts in case of recurrence of the malposition.

I have in this manner operated on four undescended testicles, one double and two single cases. In all of these cases the freeing of the testicle was easily accomplished after the manner above described. In all cases the testicle could be laid on the anterior surface of the thigh three or four inches below the external ring. All of the cases had open vaginal processes practically, therefore congenital inguinal hernia. In but two, however, was the existence of hernia made manifest by symptoms. In the two single cases there was an abundance of scrotal tissue and no difficulty was experienced in making the scrotal pocket. In the double case, however, there was absolutely no scrotum, in the sense of a pouch, before the operation. The skin was perfectly flat from the root of the penis to the perineum, but was thrown into transverse ridges by the muscle tissue of the dartos. After freeing the first testicle it was found that this

tissue could be very freely stretched and a good-sized pocket was made with the blunt dissection of the finger. After the double operation had been completed—in this case the testicles were almost normal in size—the scrotum looked like some of the cases where a very extensive amputation of the scrotum is made for varicocele. The operative wound in all cases healed by first intention, and in none has there been any tendency to retract. The three patients operated on were about the same age, one 20 years old, two of 21. I believe that the age of selection for this operation would be about 15, or, better, let us say, immediately after the age of puberty. It is possible, however, that a more extended experience will select the period before puberty, from 8 to 12. Not one of these was more difficult to perform than a simple Bassini hernia operation. The results have been satisfactory. I might add, I have never had more grateful patients. The condition for which the operation was performed was certainly of more moment to the individual than the existence of a simple inguinal hernia.

As results of the operations, the patients were freed from hernia and dangers of hernia. The testicle was placed in its normal position where it is probable it will develop into a normal testicle. The testicle was removed from an exposed position where it was subject to trauma and inflammation, and it is probable that after such an operation the testicle will be less likely to become the site of malignant degeneration than if allowed to remain in a position where it was constantly subjected to trauma. This operation is to be preferred to castration, as it saves the testicle for the individual. Aside from the mental value of such saving, it is not improbable that the addition to its function of producing spermatozoa, the testicle, like all other glandular organs, produces certain compounds which are of value in the normal life processes.

Because of the benefits produced by this operation; because of its safety; because of the dangers incident to the deformity, I would urge the general adoption of the operative treatment for the relief of these patients. Certainly, in the light of our present knowledge and skill we can assure these patients that an operation holds out to them a reasonable prospect of cure, and that the dangers of a properly conducted operation are far less than those of the continuance of the deformity.

DISCUSSION.

DR. SAMUEL E. MILLIKEN, Dallas, Texas.—I am glad to have heard Dr. Bevan's paper, as the subject of undescended testis is one of particular interest to me. At the Detroit meeting in 1892 it was my pleasure to report a case and demonstrate the operation, which was performed on a patient suffering from congenital hernia. Dr. Bevan goes a step further in that he enters the abdominal cavity for the purpose of loosening up the attachments to the spermatic cord. This operation is thoroughly scientific and justifiable. The ages of the patients on whom I have operated range from 8 to 20 years, but I prefer to operate at about 12 or before puberty. The case reported to this Association in 1892 was one of retained testis and strangulated hernia. Bassini's method of reconstructing the inguinal canal was employed, and after all the cremasteric fibers had been relieved, the testis was easily brought into the scrotum and anchored by passing a single catgut suture through the partially obliterated tunica vaginalis and scrotal walls. The organ remained in the scrotum and the patient was subsequently presented to my class at the New York Polytechnic.

DR. J. P. LORD, Omaha, Neb.—Those who are in the habit of attending medical meetings are wont to state that it always pays financially. I shall go home now and will enter into correspondence with a number of cases of this kind which I have turned off, thinking that operative interference was not practicable. I want to call attention to an etiologic factor in the production of this condition. I have in mind a case that came to me a couple of years ago, a man of 42 years of age, who reported that he had normal testes, as he supposed, that is, they

were normally located until he had a very severe attack of parotitis, with metastatic inflammation of the testicles. At that time the testicles retracted to within the canal; they continued to remain there and because of their presence in that locality he was continually subjected to attacks of inflammation which rendered him perfectly incapable of pursuing his vocation as a farmer, it being necessary for him to remain in bed. This man consulted me for an operation. I laid the matter before him, stating that I thought the removal was the only feasible thing, if he would consent to it. I think this operation of Dr. Bevan's would be applicable to that man, that there would be relief for him. This case was entirely novel, as far as I know, in producing these anomalies independent of the congenital conditions.

DR. M. L. HARRIS, Chicago.—The main point on which I wish to say a few words is the time that the operation should be done. There are two factors here involved—the first one is the necessity of an operation, and the second is the functional capacity of the organ. I do not think it is advisable to operate on these cases previous to the age of puberty. It is well known that the testicles may remain in the canal until puberty and then descend. It is impossible to say when a testicle will descend previous to the age of puberty. Lauenstein has reported a very interesting case in this connection. In a youth with double retained testicle, one side was operated on previous to puberty. The patient left the doctor, returning after puberty, when much to his surprise he found that the testicle on which he had not operated had descended into the scrotum nicely; the testicle he had operated on and replaced had again retracted, and he had in addition an inguinal hernia on that side, which had not previously existed. So I can not agree with Dr. Milliken that these cases should be operated on before puberty. These testicles do not lose their functional capacity because they are retained, but they are retained because there has been imperfect development from the beginning. I have removed a number of retained testicles after puberty in patients from 20 to 30 years of age, and in every case that had gone beyond the age of 25 no living spermatozoa could be found in these testicles; every one of them had become incapacitated for producing living spermatozoa. Such has been the experience of a number of observers who have made microscopic sections of these cases. This means that if cases are to be operated on at all it must be done early, that is, immediately after the age of puberty. At this time many of these testicles do retain some functional capacity, and the aim should be to preserve, to every extent possible the little functional capacity which these organs possess. Therefore, I would make the point that these cases should not be operated on until the age of puberty, and then operated on as early as possible.

DR. L. L. MCARTHUR, Chicago.—I have under my care three cases that I have operated on for this trouble, one with double and two with single undescended testicle. No testicle should be extirpated until a reposition of that testicle in the abdominal wall, extraperitoneally, has been tried; if it is feasible when the testicle can not come down, that such a testicle should be dropped into the pouch outside of the peritoneum within the small pelvis. This is easy of accomplishment for all these in which we have to do a Bassini to correct the dilated inguinal canal any way, and would be easy of performance where the dissection had been made. The presence of such an organ is possible and it is inexpedient to remove it until reposition has been tried. In two cases in which I found it was impossible to bring it down satisfactorily, even by loosening up the epididymis from the testicle and dropping the testicle down, still the length was not sufficient to bring it with the hope of its remaining in the scrotal position, and in these cases I have put them back, and after a lapse of two or three years there has been no complaint on the part of the patient.

DR. R. C. DUGAN, Evota, Minn.—Would Dr. Bevan make no distinction as to time of operating between those cases attended with and those without hernia? In other words, would he put off a hernia operation to a later date on account of an undescended testicle?

DR. F. C. SCHAEFFER, Chicago.—The remarks of Dr. Harris are well taken. I recall the cases of four children who had undescended testicles, between the ages of 7 and 11 years, two accompanied by hernia. They were kept under observation, and in all of them, by the age of 18, the testicle had descended and the hernia also disappeared. Judging from this experience, I am satisfied that the operation should not be done until the time of puberty, excepting for special reasons.

DR. A. D. BEVAN, Chicago.—I had a case two weeks ago illustrating the anomalies of position of undescended testicle. I do not know that you would class it as an undescended testicle, because it had descended through the inguinal canal, but had been displaced on to the abdominal wall in the groin. There

was an accompaniment of a congenital hernia. This patient was a typical hypochondriac; and completely incapacitated from doing any work. At one time there had been an attempt made to retain the hernia with a truss, and you can appreciate what the effect was on the testicle resting on the external oblique muscle. I wish to mention it to condemn the practice of applying any truss to a hernia accompanied by a supposed undescended testicle. They are not all undescended testicles, but simply a testicle that failed to descend into the scrotum, as this case demonstrated. In this particular case I was very much pleased to find what could be truly said to be a beautiful appearance of a normal development of the vas deferens with a displaced testicle, fully three inches of the vas deferens knotted up in a condition like a varicocele; the different coils had to be dissected apart. The operation was made not unlike that of Dr. Bevan's, and the testicle was readily placed into the scrotum and retained there. The peculiar position is one which should not be overlooked.

DR. THOS. H. MANLEY, New York City.—One word has been suggested to me by the remark of Dr. Bevan, and it is one of very great importance, that is with reference to the application of a truss in these cases. Dr. Harris has spoken about the etiologic factors in operation. In the most of them his position is, no doubt, correct. The causes of ectopic testicle are dependent on arrest of the descent of the testicle. My experience is that it is dependent on other causes also, and that the most prolific in many is an improperly constructed or a prematurely adjusted truss. As a matter of fact, during the first year in a great many children the vaginal process is not completely closed. The cremasteric muscle possesses the power of dragging the testes up into the inguinal canal. You take a case of this kind, complicated, at least, early in life, with a small hernia, the testis with a tendency to glide up and down the inguinal canal, and you apply a truss and lock the testis in the canal, and you provoke an adhesive inflammation, you may reduce the hernia but you have fixed the testis, you have artificially brought about a condition of monorchism. My experience has led to the opinion that if the hernia is not large, in those cases we had better leave them alone until after puberty, because, there is no doubt, a considerable number of the cases tend to undergo spontaneous cure. If we have an enlarging hernia present, however, and we perhaps will in a certain percentage of these cases, then comes the question as to what to do. Then, unless there is a large or irreducible hernia, we would better not do anything but wait, as the tendency of infantile hernia is to undergo a spontaneous cure, the hernia tends to ascend and the testis to come down. If the case has gone along until after 21 or 23, and there is no disturbance, it is a question in my mind whether we are justified in doing anything. On the other hand, if we have evidence of irritation, the testis possibly taking on degeneration or malignant changes, it is another matter. Then, the thing to do, assuming that the position taken by Dr. Harris is correct, with those passing beyond the age of puberty—the functional capacity of the organ *nil*—is not to bring the organ down, but do a castration. The operation recommended by Dr. Bevan is one involving an extensive dissection, one that should not be undertaken by a person not well skilled in anatomy, and one which, if not performed with great care, would be apt to leave a tendency to hernia—a hernia very difficult to manage. I would like to have Dr. Bevan tell us how he does a Bassini operation. He says those cases can be treated by the Bassini operation without obliterating the inguinal canal.

DR. R. HARVEY REED, Rock Springs, Wyo.—The sum and substance of this matter is: What benefit are we going to get from an operation of this kind or for any operation for the relief of a retained testicle? My experience has been that in the large majority of these cases, the organ has become atrophied and worthless. It seems to me that the principal object in surgery is to give not only relief, but to derive some benefit, and the only benefit that I see in the majority of these cases, if operated on after puberty or after the age at which there is recognition of the existence of a testicle, is to convey to the mind of the patients that they still retain their testicle. As to the actual benefit derived, I question it very much. In the majority of cases in which I have operated for undescended testicle, I have found many of them degenerated beyond all hope of restoration. In others I was unable to bring the testicle down on account of a contracted and thickened cord, which would not permit the testicle to descend. It has always been my rule to bring the testicle down if possible, but, if I failed to do so, I removed it, for in many of these cases the surrounding tissues would become thickened and give pain to the patient, subsequently requiring a castration for the relief of the pain.

DR. A. D. BEVAN, Chicago.—I desired in reading my paper to present the subject and emphasize the surgical connection

of the parts involved. It is quite difficult to describe any operation clearly as in a hernia operation, with words, and I have a number of plates which I believe will give one a better idea of the operation than any description. I recommend the age of 15 or roughly putting it in that way, just after puberty, and I am glad to find that the majority of the gentlemen agree with me in adopting that age, because of the possibility at any time up to 15, or after 15 of the testicle itself descending. I would not delay an operation for hernia until 15; if the undescended testicle was accompanied with hernia we should do the operation at once. As to the statement of extensive mutilation, the operation involves practically just the same region and almost the same structures as are involved in a Halsted hernia operation. We do not consider that a very extensive operation. The cases that I have operated on have a small hernia occurring high up on Poupart's ligament, just as in a modern hernia operation. Dr. Manley asked me in regard to doing this operation as a Bassini operation, without transplanting the cord. I should say to him that Dr. Ferguson, in his description of a typical operation, does what I described as a Bassini operation, without transplanting the cord—opening the canal, leaving the cord in place, stitching the conjoined tendons of Poupart's ligament over the cord. The cord is left below the conjoined tendons in the normal position. Then over this closure of conjoined tendons and Poupart's ligament, the suture of Poupart's ligament and the external oblique as in a Bassini operation. This is done by a number of men to-day.

CHLORETONE¹: A NEW HYPNOTIC AND ANESTHETIC.

BY E. M. HOUGHTON, PH.D., M.D.

Lecturer on Experimental Pharmacology in the Detroit College of Medicine,
DETROIT, MICH.

AND

T. B. ALDRICH, PH.D.

Late Associate in Physiologic Chemistry in the
Johns Hopkins University,
BALTIMORE, MD.

Chloretone, acetonechloroform, or trichlor tertiary butyl alcohol, has, according to Willgerodt, the following formula:

It is formed when caustic potash is slowly added to equal weights of chloroform and acetone, and may be isolated from this mixture, after the removal of any excess of acetone and chloroform, by distilling with steam. Obtained in this manner, it is a white crystalline compound, having a camphoraceous odor. When freed from water by melting, and allowed to cool, the camphoraceous odor is more pronounced and its general appearance resembles camphor more closely. It is very soluble in chloroform, acetone, strong alcohol, ether, benzine, and glacial acetic acid, sparingly soluble in cold water (1 per cent.), more soluble in boiling water. Dilute acids and alkalis are apparently without effect; concentrated sulphuric acid decomposes it. When purified by distillation with steam or when recrystallized from water, it melts between 80-81 C.; when freed from water, readily accomplished by distilling, it melts between 96-97 C.; and boils at 167 C. (Willgerodt). At body temperature it sublimates in the form of beautiful white needles.

If chloretone crystals or the tablets containing the substance are administered to animals, per stomach or rectum; if a solution is given per stomach, per rectum, subcutaneously, intravenously, intra-abdominally, or if the animal be confined in a tight box and compelled to inhale air saturated with its vapors, all degrees of hypnosis to complete anesthesia may be produced, lasting from a few hours to several days, depending on the

amount of the substance entering the system, the animal finally recovering in excellent condition if the dose is not too large. However, when an extremely large quantity of the drug is administered the animal remains completely insensible for several days, the respiration becomes slower and weaker, finally ceasing altogether, the sleep of anesthesia terminating in the sleep of death. When administered per stomach, more quickly when followed by considerable water, chloretone passes rapidly as such into the circulation, and is distributed as such throughout the body. The spectroscope fails to show any effect of the drug on the hemoglobin of the blood even after exceedingly large doses have been administered.

The pulse-rate is slightly lessened, but the action of the heart, under the influence of chloretone, remains excellent until the organism begins to suffer from a lack of oxygen. Frogs are very quickly overcome by the action of the drug when it is applied in vapor or liquid form. The local application of aqueous solutions of chloretone to the laid-bare frog's heart produces slowing of the rate and a more complete contraction of the organ, reminding one of a digitalis heart.

Kymographic tracings taken from the carotid artery of dogs show that blood-pressure usually remains unaffected, in several instances the pressure being a little higher at the end of an experiment occupying six hours than at the beginning.

The amplitude of the contractions of the ventricle as recorded by the myocardiograph remains constant for many hours. (See tracings.)

The main action of the drug is confined to the central nervous system, it being essentially the same as that of the other anesthetics and hypnotics of the fatty acid series, differing from most of the members of this group in not depressing the circulatory system. Chloretone, besides its central action, possesses local anesthetic properties in a marked degree, resembling cocaine in many respects. Indeed, it will probably be found a useful substitute for the last-named drug, as the small amounts introduced subcutaneously to produce insensibility to pain in surgical work are entirely harmless.

Experiments seem to warrant us in making the statement that chloretone has a selective action for the central nervous system—more chloretone having been found in the brain in several instances than in any other organ of the body.

Blood serum and other organic fluids are preserved for an indefinite time if saturated with chloretone, a little more than .5 per cent. of the substance being dissolved. Culture experiments with various kinds of bacteria also prove that chloretone possesses considerable antiseptic properties.

We would naturally expect, since chloretone is volatile at even ordinary temperature, and since it circulates in the blood, that it would be eliminated by the lungs. Carefully conducted experiments thus far have failed, however, to detect it in the expired air. In any case it must be eliminated in very small quantity. Even after very large doses have been administered, chloretone has never been positively recognized in the urine of animals, neither has acetone nor chloroform been detected with certainty. The chlorids in the urine of a dog fed on a fixed diet are markedly increased after the administration of chloretone, and remain high some days after the discontinuance of the drug. It seems probable that chloretone is decomposed—or burned down in the body—this view would accord best with the facts that we have already observed.

¹ In order to avoid confusing this subject with "acetone chloroform" (a name which has been applied to chloroform made from acetone), we have deemed it advisable to use the name "Chloretone."

During the past few months chloretone has been quite extensively employed clinically. From our own experience and that of numerous other observers, we may briefly outline its therapeutic properties as follows:

In cases of lacerated wounds, burns, etc., it is very efficacious in lessening pain when the injured parts are freely bathed in aqueous solutions of the drug. Owing to its antiseptic properties, it may be used independently as a surgical disinfectant, or if a strong antiseptic action is desired it can be employed in conjunction with mercuric chlorid, carbolic acid, etc. Pain and uncontrollable vomiting of gastric origin may frequently be relieved very quickly by its internal administration. In one instance the drug proved especially useful in checking the persistent vomiting of gastric carcinoma. It may be possible that the drug will prove to be a useful therapeutic agent in preventing or controlling sea-sickness, vomiting in pregnancy, etc. Laboratory experiments quite conclusively show that it renders the mucous mem-

count. Chloral is quite irritating to the stomach and depresses the heart's action. Chloretone does not possess any of these disadvantages, being only rarely followed by disagreeable after-effects. Occasionally, when large hypnotic doses have been given, drowsiness occurs on the following day.

In general we may summarize our claims for this drug by stating that its action on the central nervous system is similar to the anesthetics and hypnotics of the fatty acid series without depressing the centers of the medulla; locally, it acts like cocain, as a peripheral anesthetic.

It is too early to prophesy what position chloretone will take in medicine, but the results as a hypnotic and local anesthetic are very encouraging. As high as 60 grains have been given at one time, without producing any untoward symptoms. From 6 to 20 grains given in tablets at a single dose, followed by a drink of water or milk seem to be quite sufficient to produce the desired results. Possibly the drug will prove to be a useful gen-

9:30 A. M.

5:30 P. M.

brane of the alimentary canal insensible to irritants. Mustard, when given in an aqueous solution of chloretone to dogs, fails to provoke emesis, the animal usually going quietly to sleep. That the mustard produces the usual amount of irritation is shown by the fact that if on the following day the animal is killed and the intestine examined, its walls are found much inflamed, the parts coming in contact with the mustard in some instances being nearly vesicated.

As a hypnotic, chloretone is frequently efficacious in various conditions. Especially good results have been obtained from the exhibition of the drug in cases of persistent insomnia in the aged; cardiac disease with renal complications accompanied by high arterial tension. In many instances where morphin, chloral, trional, etc., have been unsatisfactory, chloretone has been successful. Morphin, as is well known, increases the excitability of the nervous system when administered in large doses, and is frequently objectionable on this ac-

eral anesthetic when administered in large doses; or it may be given before chloroform or ether and allow complete anesthesia to be produced by the use of a minimum amount of chloroform or ether. Perhaps such administration may prevent the annoying vomiting that so frequently occurs when a patient is being anesthetized. Chloretone is nearly an ideal anesthetic for use in experimental surgery, physiology, pharmacology, etc., as has been abundantly demonstrated by Abel of Johns Hopkins, Cushny of Ann Arbor, and our own experience in the laboratory for several years past. About .2 gr. per kilo body weight is the proper dose for dogs, where it is intended to keep the animal alive; if, as is frequently the case in physiologic and pharmacologic work, the animal is not allowed to recover, much larger doses may be given without interfering with the experiment. We have nearly completed an exhaustive systematic investigation of the chemical and pharmacologic properties of chloretone, which will be published in detail in the near future.

THE DOUCHE.

ITS RISE AND DECLINE, BUT PRESENT RESTORATION.

BY FRANK A. STAHL, M.D.

INSTRUCTOR IN OBSTETRICS, RUSH MEDICAL COLLEGE,
CHICAGO.

Until 1894 obstetric opinion scarcely doubted that the douche was advantageous as a prophylactic measure. Till then the clinician pointed to his improved statistics as proof positive. Döderlein and others reported, from bacteriologic examination, that the vaginal secretions contained micro-organisms, pathogenic, non-pathogenic but corrective, and some whose functional possibilities could not be interpreted. The conclusions followed that the prophylactic douche of the clinicians seemed also to be substantiated by the bacteriologists. For they stated that the vaginal secretions were not sterile, therefore were not sufficiently bactericidal in function; auto-infection, its probability more especially, seemed proven, and in no small degree, because of the presence of these latter non-interpretible germs. It could not be said they were indigenous, or of external origin, or that they were external germs arrived in the vagina, and had given origin to a new form, which remain in this quiescent, uninterpretable state, waiting for a favorable occasion, like labor, to develop into a more mature organism with probable pathogenic properties.

These questions could not then be answered, nor were they afterward, nor have they as yet been successfully solved. Clinically and bacteriologically, until Krönig appeared in 1894, Ahlfeld's auto-intoxication seemed justified; the prophylactic douche, though questioned by some, was quite generally adopted.

Similar in tone and conclusion to Gönnér, who had previously (1887) reported that "the vaginal secretions of thirty-two pregnant women did not contain pathogenic organisms usually found in puerperal infection, that auto-infection was not possible, that the prophylactic antiseptic douche was not necessary," came Krönig's articles in 1894, with the startling assertions that the other fellows were all wrong in their conclusions, because they were based upon incorrect technic in bacteriologic research; that the vaginal secretions of pregnant women, acid, alkaline or neutral, were free of pathogenic germs; that the secretions possessed bactericidal properties; that to remove them was unwise and harmful; therefore, the obstetric world was woefully in error that it continued to douche; last, but not least, Ahlfeld was disproven. Shortly afterward Menge reported a similar testimony as to the properties of the vaginal secretions of non-pregnant women, that they were bactericidal, but to a less degree than in the pregnant, and showed with experimental vaginal inoculations of pathogenic germs that such germs, without the douche, met with a more timely neutralization in the non-pregnant vagina than when the douche was previously used.

From Döderlein to Williams these assertions were indeed startling; they stunned. Before this statistics; discussion in congress and society; technique, all and everywhere, scientific expression vied with each other to testify to the beneficial effects of the douche. Auto-infection, championed by Ahlfeld, though struggling in the throes of doubt, had held its own among the probable probabilities. Alas for all this heralded philanthropic achievement on the part of the obstetrician, Krönig's conclusions, apparently supported by Menge's

work, seemed to act like a cyclone, uprooting previous doctrine. The majority of obstetric thought fell prostrate before them. This is no reflection on the majority or their weak-kneedness, or of the profundity of their previously asserted comparative clinical observations and deductions. No, they were all that; I envy only Krönig and his wonderful victory! For by one man, controlling but a comparatively speaking not-great clinical field, coming upon his opponents in the full daylight of scientific struggle, as if with a breath of air, like Sennacherib's hosts, they were laid prone, paralyzed—but few remaining to bear the tale, all embarrassed to hold high the head!

Whether right or wrong—for this year's (1899) German Gynecological Congress throws great doubt upon the accuracy of his views—Krönig must ever be complimented with the laurel of so successful a *coup d'état* in the amphitheater of scientific controversy, and that, too, in the presence of overwhelming antagonistic scientific thought; a stroke rarely offered and rarely achieved! As a gladiatorial feat, bravo, Krönig!

Döderlein, the mighty, wavered; he surrendered the prophylactic douche; he seemed bewildered as to the judiciousness of the douche as a whole. He was not alone. Williams accepted Krönig's suggestion that his bacteriologic investigations of 1893 were technically wrong—naturally his conclusions. In his new series, reported¹ in 1898, he, truly gentle, acknowledges his error, and again offers a new series of conclusions, that vaginal douches are not necessary, and are probably harmful; auto-infection is possible from bacteria in the vagina in very rare instances, etc. All this because of a *single* charge of "error in bacteriologic technique." Where was their strength, which was theirs by right of comparative clinical results? Judging from previous bacteriologic experience, who knows that the morrow will not bring forth another bacteriologic David, whose sling will contain a mightier bacteriologic technic, which will again lay prone? Verily, verily, consistency, thy name is not alone gynecology.

The majority soon discarded the douche—at first, the prophylactic, then the douche altogether, reserving its use for operative and necessary cases only. Now, it appears to the writer that the moment the new departure did so reserve its use for the operative cases, they acknowledged as true all they claimed was not true. Why, then, so consistently douche, when operating with forceps, turning or other hand and instrument-invading operations, where skin and instrument contact with infection possibility, is a prolonged one, if secretion is sterile and bactericidal; douches harmful; in rare cases only can there be auto-infection. Does not the very fact that they recommended the douche in these cases prove their lack of faith in their own conclusions? The very fact that they recommended the douche in operative and necessary cases shows that they admitted that the douche does possess virtues? If the douche is harmful, why did they wash away the protecting secretions? For here, in the operative labor, exists a far greater test of virtues than in the normal labor. Explain, you who objected to the douche.

Notwithstanding all this departure from the previous methods, here and there there remained a few, erect and fearless, whose presence proved their worthiness to survive, by the fact of their unaffected strength. Ahlfeld remained unshattered. Throughout obstetric realms this minority, willing to, but with the evidence

¹ Williams: The bacteria of the Vagina; Amer. Jour. Obstet., Oct. 1898. Here also may be found a complete bibliography on this subject.

in hand could not be convinced that previous clinical experience was all wrong, injurious and injudicious. Comparative clinical results spoke not in such a tone, neither so loudly nor so impulsively.

In 1898, notwithstanding Williams' position and positivism, before the American Gynecological Society, even alongside the fulsome praise most justly rendered his careful efforts, we find Reynolds stating that as "practical surgeons, however, we could not allow a laboratory demonstration of the innocuousness of the vaginal secretions to justify us in acting as though that innocuousness were a certainty, until it had been backed up by abundant clinical observation." In this expression may be seen reflected a sentiment felt in the main by all of that minority who had not been convinced. It is but a few months since a similar pro-and-con discussion occurred in the Chicago Gynecological Society; search will reveal a like disparity in thought in many such obstetric discussions.

It is admitted at the outset that the need of the douche to-day is not so broadcast as twenty years ago. Such denial would be tantamount to saying that all clinical and moral instruction passed between obstetrician and patient this many years had been without permanent effect. This is not so. Throughout the civilized world gynecologic physical expression is more hygienically perfect to-day than ever before; mortality proves that it never can be perfect, or without destructive influences. Ethics, hygiene, environment, all teach this to-day and not without avail.

So far as the charge that the douche² can harm is concerned, the clinician has always asserted that it, like any other means, can do harm, can inflict injury; we have, and there is, no means, however good, however harmful, but may be made to have a beneficial or an injurious effect. It is the intelligence of the one who employs it that determines the desired result.

The douche can harm only if repeated too often; if its force and volume be too great; if its temperature is too high; if a many-opening point be used. This latter is of the greatest importance. Argue as you may, no complete flushing occurs before the end of the many-opening point; as a consequence those parts in front of the point remain without the cleansing advantages of the douche; with the many-opening point there is only a backward flushing, not a forward and then a backward, like in the single-opening point. This will explain the many cases where, notwithstanding douches were given, cervical and high diptheritic-looking puerperal patches still presented.

The clinician has maintained that to douche the parturient canal like judgment should be exercised as with an open surgical wound. Formerly excessive sponging (rubbing) and irrigation, even during the operation, interfered with primary union, by rubbing and washing away the physiologically exuded serum, and irritated the severed surfaces. To-day a better technic exists where these, the first-night errors of primary Listerism, have been corrected. He does not douche so often nor does he believe he need or can destroy all the germs with his solution; to him even now,

practically, it is immaterial what the germ is; if he can but obtain good drainage from the genital tract he feels confident that his douche will do here what the douche will do in a surgical wound anywhere—it will remove the undrained retained discharges, and lead to a more clean and rapid restoration. By douching the wound he stimulates the cells to a healthier activity, he encourages the normal contractility of the parts, thereby assisting the fibers to express and expel any foreign material, as exudation, retention, pus, etc., there may be in their interstices, for in all parts of the body there is a functional contractility that determines toward an external expulsion. In the abscess, like in secretion, there is external determination by this contraction in the direction of the least resistance. Surgical drainage is but the artificial amplification of this natural expression.

Another argument which the antidouchist uses and which is often heard: Regard the Indian woman; she does not douche. No, neither do the many other aborigines. Admitted he is correct. Inquiry elicits that neither do the Chinese, nor the great multitudes of aboriginal women in both Asia and Africa use the douche or bath. Does this strengthen his position? Decidedly not, for where will you find such an antidouchist who will charge himself with the assertion that the woman of the aborigine is the equal of the woman of the Anglo-Saxon of to-day—physically, intellectually and morally? Further, the relative position in influence of the races but accentuates this point. Comparative anatomical and intellectual study of contemporaneous woman disproves that the douche, a localized bath, used with discretion, injures. Compare even the Anglo-Saxon woman of any strata one cares to choose. Among the socially most elevated or most modest, whom do you find the highest typed? She who is well groomed—judiciously and rationally. Do not the grand physical and mental pictures of the presidents of our great women's bodies betoken the careful grooming of bath, food, and method? This is the type Oliver Wendell Holmes referred to as the mother of the American Brahmin. Regard the farmer's wife; the one who is careful in grooming, the one who is slovenly; where lies physical strength and mental power, and vigor of offspring?

In the masterpiece of the Oriental harem, conveying the story of the slaves assisting at the bath, does not the artist hint, as delicately as subtle blending of color and shade render possible, by the gentle inclination of the slave's hand upon the robe, that those parts too are of no minor importance in the bath? Synthetically, with his brush, the master expresses whole volumes of critical gynecologic anatomy, hygiene, psychology, and social economics of the period. Science of to-day can only try analytically to explain and fill in the detail of determining cause, so perfectly appreciated and expressed by the master. And in his detail of the inclination of the hand was it but to serve as a fig leaf? What do the eyes of mistress and slave say? The one gratification in possession, the other gratification in the artistic preparation.

The Talmudic injunction to the Hebrew women: There shall be abstention for seven days subsequent to cessation of menstruation—which is to-day rigorously held by the orthodox, and which for all races would be an excellent law, solving many suggestions outlined in Bulwer Lytton's "The Coming Race"—when this period of separation shall be ended and before she may discontinue the separation, she shall dip herself even be-

² Concerning the douche as a routine measure in the puerperium, it is stated: "In several (among how many?) cases the writer has seen infection in a later period of the puerperium the use of dirty syringes in the hands of the nurse."—Obstetrics, page 358. This observation may be extended, and with equally great force, to all surgical irrigations. The conclusion here intended must be that the reflection is not upon the douche, *per se*: it can only be upon the individualism of the user. Nor should it be overlooked that the exception does not break the rule; the exception proves the rule. Again, what traveller is there who has not observed that even the great men, the masters of the arts and in all climes, exceptionally err. Is, therefore, the conclusion justified that the exceptional and individual error annihilates all general and intrinsic merit?

pond the hair of the head three times in *running water*. Is it not here suggested, among other good suggestions, that the infective probabilities of the secretions were well known; does not this ancient ceremonial cleansing suggest the modern douche?

Likewise the ancients knew of the tendency of the lochia to grow in unclean and infective quality from day to day. Again, she was separated thirty-three or sixty-six days "to continue in the blood of her purifying." (Leviticus, xii.) Later the clinician explained this growing infectiveness on the ground that external causes worked upward, and that this pathogenicity declined in proportion as two important factors were present: 1, the neutralizing effect of the physiologic resistance, both local and general; 2, assisted by the neutralizing effect of the stimulation from the cleanliness, for the latter increases the former. This beneficial effect of cleanliness must have influenced the theologian, the clinician to the first prophylactic douche, though possibly he knew nothing of bacteriology (Leviticus, xii-xv), the phenomena alone directing him. A good illustration of this ascending infection was to be seen in the usual course of Cesarean section anterior to the perfected operation of to-day, when the open uterine wound was the rule. The secondary ascending putrefactive uterine juices infected the uterus—the old uterine inflammation—and the abdomen; this was more fatal in effect, in lowering the vitality and favoring secondary hemorrhages and sepsis than the primary operation.

That the upper and vaginal secretions are bactericidal must be admitted; all physiologic secretions of the body, like the serum, are inimical to invading influences, but let some change in stimulation occur, a like change will occur in secretion and function; their properties will be increased or diminished. That we can not rely on the vaginal secretions as always possessing essential sterile-producing qualities, as the bacteriologic conclusions of Krönig, Menge and Williams would seem to convey, is proven beyond a doubt by the primary and secondary venereal and other bacterial tissue changes produced by their micro-organisms upon the cervix and in the higher vagina. Another clinical suggestion as to the unreliability and variability in the apparently sterile properties of the non-pregnant or pregnant vaginal secretion is as follows:

Two friends, innocent of any previous glaring expression, visit the same hetera. In the interval she bathes, but because of the urgency of the moment, she takes time only to bathe the externals. A few days after Friend B, embarrassingly, but with full confidence, asks Friend A if he is all right. A smiles at B's discomfiture, and congratulates himself that he was not second best man. B, crestfallen, hies himself away for diplococci treatment. This is no uncommon clinical experience. The explanation is simple. A met with a secretion inert, apparently sterile; possibly some diplococci may have shown on bacteriologic examination; if so, their influence was *nil*. But due to the stimulation of A's presence, a newer, fresher secretion appeared, poured out from the deeper mucosa, which,

³ It is interesting to note in connection with this subject of the variability and unreliability of bactericidal and infective properties of secretions where apparently sterile that: "In a recent controversy between Behrens, Berliner, Kili, *Wochenschrift*, 1888, No. 6, chief of official examiners of hetera in Berlin, and Neisser (*Ibid.*, No. 9), it has been demonstrated that for the diagnosis one can not depend solely upon Behrens' assertions that there may be a permanent or intermittent disappearance of the gonococci with a continuance of the clinical symptoms, or the latter may subside with a persistence of the gonococci, or both may disappear simultaneously. According to the official instructions to the medical examiners of Berlin, hetera are to be held under surveillance so long as they are capable of transmitting infections."—*Progressive Medicine*, Vol. 11, June, 1899, p. 182.

when B was received, left an impression of bacteriologic character, whose unsterile intensity soon made itself manifest in its higher color of the next seven to seventy days. There is no doubt that B's skepticism—for he was no medical student—of secretional sterility was based upon good grounds, for had the vaginal prophylactic douche replaced the external bath, most probably B's tender reminiscences would have struck a less pathetic chord.

Krönig and Menge must admit that their laboratory probabilities of results in inoculation and cultivation are not the laboratory probabilities of the everchanging functional susceptibilities of the vagina of the non-pregnant or pregnant. That the prophylactic and protective douche is injurious, even to Menge must appear more than doubtful.

Again, consider a practical business, and one founded on commercial and competitive lines; it can not be fostered by methods having injurious and harmful probabilities. If there were no virtues in the douche, even to the non-pregnant, the dermatologist of experience, when requested for his experience upon this subject, could not testify to the fact that, even prior to the certificate, the presence of the douche-bag in the chamber of the successful commercially inclined dispenser of Schopenhauserian pleasures, suggests a vaginal hygiene conducive to the more happy preservation of the clients' physical and mental state, even to the felicitous degree where all disturbing doubt is fully eradicated. Vaginal-secretion sterility to the contrary, it is a well-known fact that more cases of skin trouble are traceable to the non-professional than to the professional, caused by this professional lack of vaginal hygiene.

(To be continued.)

Therapeutics.

Angina Pectoris Gravior.

Sir R. Douglas Powell discusses the treatment of this disease in the seventh volume of Thomas Clifford Allbutt's "System of Medicine," as follows: "Taking first the anginal paroxysm, there are certain prominent symptoms that call urgently for relief, if relief be possible, namely: 1, pain; 2, arterial spasm if present; 3, stenocardia and cardiac muscle failure; 4, shock and air hunger.

"Pain is almost always due to one or both of two conditions, namely, distention or muscular cramp of the ventricle. When first called to a patient in the midst of a paroxysm there is no time for careful examination, even did the condition of the patient permit of it. A tightened, thready pulse, with obviously laboring or it may be paralyzed heart, urges upon us the immediate use of the vascular antispasmodics, nitrite of amyl or nitroglycerin. Five to twenty minims of nitrite of amyl may be inhaled, or one to five minims of a 1 per cent. solution of trinitrin given. If there be violent or forcible heart action, stimulants are better avoided; but if there be flaccid distention, a draught of aromatic ammonia, soda, cardamom, and chloric ether may be given with the amyl inhalation or the nitroglycerin drops; if such means be not to hand, some very hot water with a little peppermint essence or brandy may be sipped slowly.

"In cases where there is marked heart failure, ether by preference, or brandy, in doses of 20 drops to 5i., in which one to two minims of trinitrin (1 per cent. solution) may be dissolved, should be injected hypodermically. When the pain is not relieved by this treatment, arterial spasm having thus been eliminated as its cause, the use of subcutaneous morphia is in-

indicated; due care being exercised with regard to the dose in view of the possible presence of kidney disease; if the factor be excluded, the degree of pain would regulate the dose, and the combination of atropin would be useful as a heart stimulant.

"The free use of oxygen inhalation is of very great value in all cases in which cardiac failure is a marked feature. The remedy has a double value in satisfying and relieving the air hunger—due to impaired circulation through the lungs—which is often so marked a feature; and in securing the circulation through the usually constricted coronary vessels of overoxygenated blood, which stimulates nutritive changes in the muscle and secures the removal of effete and half-changed material which embarrasses its function. In administering the oxygen, however, all personal co-operation on the part of the patient must be avoided; the naso-oral muzzle must never be used, but the gas must be directed over the mouth and nostrils by means of a glass funnel attached to the tubing, held a few inches away, so as to leave the patient to breathe a highly oxygenated air at his case. Oxygen inhalation is particularly indicated in those cases in which morphia is found necessary; and, when the paroxysm is over and sleep induced, the gas should be allowed from time to time to fortify the air immediately about the patient's mouth and nose. It is best to let the patient choose his position for himself, and to adopt that which is most comfortable and helpful to him. When the heart is large, wanting in power, and embarrassed in action by fatty depositions about its surface and fibers, and is laboring against a high arterial resistance which is prone to acute increase, the line of treatment is a restricted but fairly nitrogenous dietary in three regular moderate meals; root vegetables, sweets and starchy foods and all sweet wines and beers being avoided. Fluid should be taken very sparingly at meal times, and supplemented by a draught, preferably of hot water, taken between meals or shortly after food, and again either at bedtime or in the early morning, with a view to the excretion of effete materials.

"Regulated open-air exercise is of the utmost importance—beginning with regulated level walks, proceeding to gentle inclines, and so on, but never overstepping the limits of cardiac power. The most important drug treatment of these cases consists in the judicious administration of mild mercurial laxative and saline aperients to reduce arterial blood-pressure; potassium iodid is also sometimes valuable to this end. It is in this stage of the disease that Professor Bradbury advises the use of erythrol tetranitrate, which he finds to exercise a more persistent influence on the blood-pressure than other preparations of the kind. In addition, strychnia and acid tonics, taken once or twice a day only, are sometimes of value.

In cases of valvular disease of the heart appropriate remedies must be employed. When digitalis is employed it is often advantageous to combine with it small doses of nitroglycerin (1/200 to 1/100 gr.), or of erythrol tetranitrate, to slacken the arterial resistance.

"Arsenic is the most appropriate drug in these cases—coronary disease and consequent secondary nutritional changes in the heart—and oxygen inhalations from time to time, and especially in the night, are very valuable in those where respiration becomes shallow and inclined to the Cheyne-Stokes type during sleep. In the latter case strychnia is the most valuable cardiac tonic. Small doses of digitalis or strophanthus are indicated when the cardiac power is much reduced and its rhythm irregular; caffeine is also of great value, especially when the urinary secretion is scanty. The liver function must be stimulated from time to time by mercurial laxative. Let it be said in fine, that he who would treat angina pectoris in its multiform degrees with all the success that can be looked for must take the case in hand on broad lines in accordance with the well-defined principles of medicine, pursuing such lines into such detail as may be appropriate to each case."

Water Treatment of Gastro-Intestinal Disturbances.

Marfan advocates an exclusive diet of water for infants with diarrhea or other gastro-intestinal disturbances, the amount corresponding to the usual amount of milk ingested. (See *JOURNAL*, xxxi, p. 186.) A number of our Southern and European confrères have found this treatment extremely effective and a communication in *El Progreso Medico*, for August describes cases of diarrhea during the war in Cuba cured in three to five days with nothing but water taken freely, boiled and cooled to the temperature of the room.

Epilepsy.

- R. Lithii bromidi
Potassii bromidi
Sodii bromidi
Caleii bromidi, aa.
Syrupi aurantii corticis.
Aqua, q. s. ad.
- M. Sig. Teaspoonful in water after meals to prevent recurrence of convulsive seizures.

EPILEPSY WITH WEAK HEART.

- R. Potassii bromidi.
Syrupi acaciae.

Acidi tannici.
Boroglycerini.
- M. Ft. suppositoria No. vi. Sig. One by vagina each night after douche, useful in subacute and chronic cases with profuse discharge.

For Catarrhal Affections Following Measles and Whooping Cough.

Hock advises the employment of creosote, prescribing as follows:

- R. Creosoti
Saccharii
Olei morrhue.
- Ft. emulso. Sig. From 2 teaspoonfuls to 3 tablespoonfuls a day.

Antipyrin in Dysentery.

Ardin-Delatt has employed antipyrin in the dose of seventy-five grains to eight ounces of water as a rectal injection in dysentery, given three times a day and retained for fifteen minutes. He claims that the relief from pain and tenesmus is immediate, that the number of stools is decreased, and that convalescence is speedily established.—*Therap. Gaz.*

Alcohol in Puerperal Endometritis.

In eighty cases after laborious delivery or indications of septic infection of the uterus, F. Ahlfeld injected a 50 per cent. solution of alcohol into the uterus, with promptly favorable results; the fever vanished after one or two injections and serious uterine affections were prevented.—*Semaine Med.*

3. **Care of the Insane at Farm Dwellings.**—Blumer reports his experience with the treatment of the insane in detached farm-houses at the Utica Asylum, and advocates the extension of this method.
4. **Psychology.**—The relation of psychology to the medical profession, especially as regards the field of hypnotism and other psychic symptoms, is treated by Dr. Sidis. He criticises the neurologist for neglecting this, and claims that the alienists have taken a step in advance in this regard.
6. **Puerperal Insanity.**—Tomlinson analyzes some 60 cases of puerperal insanity as regards their causation, symptoms, etc., the most important consideration, of course, being the prognosis, and he concludes as follows: The history of the cases recorded in this paper, and of one hundred and fifty others, from among which they were selected, would indicate that the prognosis in any given case of insanity connected with maternity was dependent upon the heredity of the patient; and further that those cases having a heredity of insanity alone are most likely to recover; while those having a heredity of consumption, alcoholism, syphilis or cancer, are the most certain to be the victims of progressive degenerative changes. Or to express the same conclusions in another way: The children of the insane are unstable, but the children of those suffering from somatic disease which seriously impairs vitality are defective.
7. **Wound Infection in Insanity.**—The subject of Hobbs' paper is the same as that of some other recent communications by him—the insanity connected with gynecologic conditions. He mentions, however, insanity from erysipelas infection, but the main part of his paper is based on 98 alleged puerperal cases admitted into the London Asylum since the year 1870. Twenty-three of these he has personally examined, and in 22 of them he found pelvic lesions. In 21 of these surgical interference was followed by recovery in 8 cases and improvement in 4. In the past four and a half years they have treated in the London institution 187 women and found lesions in 163. Eighty had inflammatory lesions of the pelvic organs that he thinks can be best credited to sepsis at the time of the puerperium. The surgical treatment of these 80 produced physical recovery in nearly all, mental recovery in 45 per cent., and mental improvement in 25 per cent. He concludes by emphasizing the importance of care on the part of the obstetrician in protecting his patients from septic infection, and of the necessity of removing pelvic lesions in the insane.
9. **Difficulties in the Retraction Theory.**—Worcester notices certain difficulties in the acceptance of the retraction theory of the terminal filaments of the neuraxones. The first is the rapidity of the movement that is required by the quickness of the mental action, which is not parallel with any physiologic condition. Next, the power of selection attributed to the nerve-cells seems to him hardly credible. He also notices a phenomenon which it seems to him impossible to explain by this hypothesis. When a patient affected with hysterical amblyopia is made to look into the apparatus of Flees for the detection of simulated blindness, in which, by an arrangement of mirrors, only one object can be seen by each eye, and that seen by the right appears to the left of that seen by the left eye, she sees only that which is visible to the amblyopic eye. Thus, if the right eye is the one affected, she will see only the object apparently situated to the left, which is, in fact, invisible to the left eye. It will be noted that, in such an experiment, the subject does not know whether she should see one object or more, or what the relative positions of the objects seen should be. On the supposition that there is an actual interruption of connections, the patient should see only one object, namely, that which is visible to the left eye, and, having nothing with which to compare its position, would have no reason to suppose that she saw it with the other eye. Why, under such circumstances, should there be a reversal of the connections and interruptions previously existing?
12. **Pseudo-Dementia Paralytica Uremica.**—Berkley reports a case which he considers as distinct from parietic dementia but due to uremic intoxication. The case is very elaborately reported with pathologic findings.

15. **Intrascapulo-Thoracic Amputation.**—The author of this paper finds ten different methods have been used for dealing with the hemorrhage in intrascapulo-thoracic amputation, and the last, disarticulation of the sternal end of the clavicle with ligation of the arteries and the veins, is the one adopted in the case he here reports. The operation was done for sarcoma involving the shoulder-joint. The method consisted in: 1. Incision from the sternal end of the clavicle along this bone to about its middle and curved downward to the anterior axillary fold. The skin and fascia are dissected up, exposing well the inner two-thirds of the clavicle. 2. Disarticulate the clavicle by severing the sternal attachment and the rhomboid ligament, cutting the attachment of the sternomastoid muscle close to the bone and separating the clavicular portion of the pectoralis major with the finger from the costal portion of the muscle of the anterior axillary fold. 3. The clavicle is now pulled outward and upward, and if the subclavian muscle does not readily strip off, its attachment to the first rib is divided. This exposes the pectoralis minor and it is divided and the coracoid portion reflected upward with the clavicle, thus exposing the axilla and the vessels. 4. The sheath of vessels is opened and the vein dissected away from the underlying artery. Two ligatures are tied around the artery. The arm is then held up to empty it of blood, while two ligatures are passed around the vein but not tied until the arm is blanched. This renders the use of an Esmarch bandage unnecessary. Unless the cephalic vein has joined the axillary below this ligature, a separate tying of this vessel is required. 5. The vessels are now severed, together with the brachial plexus of nerves and the costal portion of the pectoralis major, completing the division of the anterior attachment of the arm. 6. A posterior incision is made from some point on the anterior one, as near the tumor as advisable, directly downward and backward to the inferior angle of the scapula, and up again to the posterior axillary fold. The skin and superficial fascia are dissected up for a short distance—half an inch to an inch. 7. The trapezius is now severed and the transversalis colli or posterior scapular artery is secured. The omohyoid muscle is cut and the suprascapular artery is secured, and the muscles attached to the inner border of the scapula are rapidly divided close to the bone; then the serratus magnus and latissimus dorsi are cut, the latter at the posterior axillary fold. The arm is then held to the body by the skin of the axilla alone. If there is sufficient flap to cover the wound, the anterior and posterior incisions are joined through the axilla, but if more skin is needed, a flap may be raised from the under surface of the arm. The wound is then closed with suitable provisions for drainage. The advantages of this operation are summed up as follows: *a.* It gives the widest and fullest possible exposure of the vessels, and decreases the accidents of ligation to a minimum. *b.* The disarticulation of the clavicle is simpler, quicker and easier than the resection of the bone, and the danger of wounding important vessels is less, because these structures are well protected by the sternothyroid muscles. *c.* The elevation of the arm, after securing the artery and before the vein is tied, makes a practically bloodless amputation. *d.* The suprascapular and posterior scapular arteries—the only vessels that can bleed—are easily picked up before being cut. *e.* In malignant growths, where the outer end of the clavicle is involved, there is less risk of a return if the entire bone with its periosteum is removed. *f.* It removes everything in one piece, a more surgical procedure when dealt with malignant growths.

16. **Resection of the Liver.**—After referring to a former paper, Keen reports a third case of resection of the liver for a large tumor. The operation was done entirely with a Paquin cautery and the hemorrhage was comparatively slight. The packing was removed in 48 hours. There was no hemorrhage, but an escape of bile from the fourth to the twelfth day. In spite of this, if he should hereafter have to deal with a small charred surface after removing a hepatic tumor, Keen says that he will be sorely tempted to test the absorbent powers of the peritoneum by immediate closure of the wound without drainage. He analyzes the literature and appends a table of 17 cases, including the present one, making a total of 76 which he has collected. A pathologic report by Drs. Coplin and Tinker is appended. The tumor appears to have been a cylindrical cell cancer.

17. **Neoplasm of the Liver.**—Thompson reports a case of removal of a hepatic gumma and analyzes the literature on the treatment of hepatic neoplasms.

18. **Compound Fractures.**—LeBoutillier's paper is a critical analysis of 55 cases of compound fracture of the long bones treated at the J. Hood Wright Memorial Hospital during the three years ending Jan. 1, 1899. A number of the cases are reported in brief detail. He believes that the treatment most likely to give the best results is one with the least possible operative interference. Free incisions, immediate excision of tissues badly damaged, whether by violence or by soiling, drainage of pockets without packing of the wound, the removal of as little as possible of the fragmented bone, the suture of bone or muscle in clean wounds only and with the amplest drainage, may in appropriate cases supplement the most thorough and painstaking mechanical cleansing of the wound. He has not seen medicated solutions or dressings at this time followed by any better results than the use of sterile gauze. For irrigating he believes a physiologic salt solution to be as efficient as any other, and less liable to do further harm to bruised or partly devitalized tissue. What bacteria remain in the wound after thorough mechanical cleansing can not be reached by antiseptic solutions or dressings, for they are probably imbedded in tissues and inaccessible to germicides, without damaging viable tissue. The limb should be put in proper apparatus; that one being the best to use in the particular case, with which the operator is most familiar in simple fractures. During the next few hours and days careful watch for the occurrence of symptoms of inflammation should be kept up, and at their advent there should be no delay in inspecting the wound and taking what further measures the individual case may require. Where free incisions are made, at the primary dressing, the circulation of the wound is less embarrassed by the swelling so apt to occur as a result of traumatism, and the tissues are better able to protect themselves from the harmful influences of bacterial multiplication, as they are better nourished. Absorption of toxic products is also less likely to occur, and give rise to severe constitutional symptoms.

21. See abstract in *JOURNAL*, Sept. 9, p. 657.

23.—See *JOURNAL*, May 6, p. 101, p. 991.

25. **Alopecia Areata.**—Bowen describes two epidemics of alopecia areata that occurred in an asylum for girls in the city of Boston. In the first it seemed to start in one girl, but four months later it was found that 63 of the 69 children in the institution were more or less affected. Two months later the areas began to fill in, and at the end of six months a few patches only could be found. The girl in whom the affection was first observed left the institution and was away three years. It was not certainly known whether she perfectly recovered and it is not at all unlikely that some small areas of baldness existed. Six years after the epidemic she re-entered the school at the age of 17. There had been no cases during her absence. A month or six weeks later patches were observed on the head of one of the children and four or five months after her return 26 of the 45 children were found to have spots of baldness of the same dotted and angular character as those of the first epidemic. He has not seen reported any similar experience in this country, though there has been observed in France.

30. **Athletics in Their Relation to Genito-Urinary Organs.**—Several matters of importance in regard to athletics that are not altogether noticed as such as they should be are here referred to by Lydston. He believes that athletic exercises within physiologic limits are perfectly healthy and that they have frequently good effect on the sexual irritation in youth. As regards strain or friction on the groins, genitals and perineum, it is well known that they may set up irritation, and in this connection he speaks of bicycling, which is injurious in case of existing troubles of the urethra, prostate and bladder. He does not, however, believe that it can set them up in an originally healthy individual. As regards accidents, the professional athletes are safer than the amateur. In conclusion he calls attention to the possibility of deranging metabolism by training. In the case of uric acid diathesis, physical exercise may be necessary. When the systematic exercise is discontinued, however, the body can not care for the proteids, and a lithemic crisis may be induced. He can assure anyone who

contemplates entering active training that he will thereby acquire a physiologic habit that may be embarrassing in later life.

32. **Albumosuria.**—Benedict discusses the subject of albumosuria and its possible significance. Its test is so simple that it should be a matter of routine in urine examinations. His method is to float the suspected urine over the alkaline copper solution used in testing for sugar. On warming carefully a lilac band develops in the presence of albumose or pepton. He reports six cases, the first due to cystic trouble and the second probably; the third connected with a remote pathogenic process, and in the fourth a possible relation with the liver and abdominal viscera, but the diagnosis was obscure. In the fifth case the albumose was essentially renal, and in the last there was a tumor of the liver. He asks for criticism and suggestions on this subject in regard to which our knowledge is so imperfect.

33. **Movable Kidney.**—Halstead's paper is almost monographic on the subject of movable kidney and not easy to abstract.

34. **Fibrinous Peritonitis in a Child.**—Cumston and Hastings report a case of tubercular fibrinous peritonitis in a child two and one half years of age, which was operated upon with success except that a troublesome fistula was left. A second operation to close the fistula was attempted, but without good results, a second fistula being formed. The child survived the operation only a few weeks, dying from exhaustion. The case is of interest in the uncharacteristic development of the affection, the extent of the lesions and as showing how much the abdominal cavity of a child will stand in the way of operation.

35.—See *JOURNAL*, June 3, p. 1263.

36.—See *JOURNAL*, May 27, p. 1172.

37. **Reflex Symptoms from Rectal Disease.**—Watkins calls attention to the puzzling reflexes occasionally observed from ulceration of the rectum and which lead to serious gynecologic mistakes. He reports 3 cases and states that his object is only to put the general practitioner on his guard against advising ovariectomy, etc., in such cases.

38. **Prevention and Treatment of Tuberculosis.**—Brush's paper treats at length of the cause of consumption and methods of its prevention. Admitting it to be one of the most fatal diseases, and yet one that has been found to be curable in its early stages, the chief points to be borne in mind are: 1. That it is an infectious disease transmissible from person to person through the respiratory and digestive tracts or through wounds of the skin and mucous membranes. While all who come in contact with the disease may not develop it, no one can determine when the system is in a condition favorable to do so. It is reasonable, therefore, to apply all necessary precaution in any case. 2. Inasmuch as it can be conveyed through infected food, the present law for checking the disease in cattle should be enforced. It appears too that food displayed upon street stands is also a source of danger as not being protected from street dust, and some regulation requiring better security in this respect should be demanded. It having been shown that wherever intelligent measures of prevention have been adopted, the disease has decreased, it will be criminal for the state to neglect its duty in this regard. He also speaks of the necessity of prohibiting expectorations in street and public conveyances, and also of the danger of promiscuous kissing.

39. **The Metric System in Prescriptions.**—Bartley advocates the more universal use of the metric system in doctor's prescriptions. Calculation of doses has been the principal deterrent, and he suggests a simple rule to render this less troublesome. It is as follows: A dram of the two-ounce mixture will contain as many grains or minims of any ingredient as there are grams or c.c. of that ingredient in the whole two ounces. By keeping this rule in mind the calculation of doses becomes easy and simple.

41.—See *JOURNAL*, May 27, p. 1173.

42.—*Ibid.*, p. 1173.

43.—*Ibid.*, p. 1172.

44. **Atypic Malaria in Children.**—The irregular course of malaria in children is noticed by Engelmann, who reports a case that first suggested typhoid infection, but showed malarial origin after blood examination. The case was of interest from its unknown mode of infection; the irregular and masked course of the disease; the peculiar type of the protozoön; the

disappearing leucocytosis, and the existence of a limited area of lung consolidation with low temperature curve, pulse and respiratory ratio. The patient did well under quinin treatment for chronic malaria.

45. **Treatment of Chronic Malaria.**—Maxwell describes his method of treating malaria cases in special malaria regions, which is, for an adult, as follows:

- R. Hydrarg. chlor. mite.
 Sodii bicarb., $\bar{a}\bar{a}$gts. x
 M. S. At bedtime.
 R. Quinin sulph.....gts. xx
 Fiat capsula No. iv.

Sig. Two hours apart, the last dose 12 hours before chill time.

- Then
 R. Elix. quin. strych. et ferri..... \bar{v} iv

Sig. Spoonful three times daily. But it does not always do in practice. A certain per cent. of the patients will have chills while taking the medicine right along.

Finally he stumbled upon this, to be used as a tonic after the calomel and quinin had been given as above, and to his surprise and gratification he had no relapses.

- R. Quinin sulph..... \bar{v} i
 Acidi nit. dil..... \bar{v} ixiiss
 Spts. frumenti..... \bar{v} iv

M. Sig. Spoonful just before eating, three times daily.

He thinks the prescription given above containing the spirits is the best thing he has ever tried and that the patient can be assured in the most dogmatic manner that this medicine will cure him.

47. **Healing Frauds and Superstition.**—This article is of interest as being the publication of a sermon in a medical journal. The preacher's views are such as any physician can indorse, and it appears that in the locality where the sermon was delivered the ministers are generally up in arms against certain frauds which make their headquarters there.

53. **The Family Physician and the Middle Ear.**—The author of this paper writes to call attention to the great necessity of the general practitioner paying attention to ear troubles in their early stages, as in the treatment of these cases prevention is better than cure. In the beginning of tubal catarrh, great relief will result from inflation of the middle ear, and he describes the method. Many times a child suffering from earache can be immediately relieved by taking out the Politzer bag and inflating the middle ear, instead of dropping oils, extracts, etc., into the outer auditory canal.

55. **Local Anesthesia.**—Heiueck's paper gives the technic of full anesthesia in full detail, stated in such a manner that nearly the whole article would be required to be given in an abstract. The reader is referred to the original.

56. **Albuminuria.**—Wilson sums up his paper as follows: 1. We should know our tests and their fallacies so as to detect a true renal albuminuria. 2. If we have a true renal albuminuria we should by repeated microscopic examination of the sediment, well concentrated by gravity and the centrifuge, satisfy our minds that casts are or are not present. It may take several hours to attain this result. 3. True renal albuminurias, functional in nature, must be looked upon as cases of increased susceptibility to nephritis, though many of them are comparatively innocent. It would seem from the foregoing that with many of these cases it is largely a matter of degrees of the same condition and that many cases of incipient nephritis cure up under proper conditions, just as incipient tuberculosis frequently is overcome by a natural tendency toward recovery.

57. **Suprarenal Extract.**—The writer gives his experience with suprarenal extract, of the value of which he was at first skeptical. He usually precedes it with cocaine, though he can not affirm that it counteracts the poisonous effect of the latter as some have stated. He now never operates on pterygii without using it, and he finds it of great value in other minor operations, such as tenotomy. In the ear it has but a limited effect, but in all operations within the nasal cavity it is, next to cocaine, most valuable. In the throat the same conditions exist as in the nose only in a lessened degree. It aids in galvanocautery operations by enhancing the effect of cocaine, and the same may be said of it in tonsillotomy. He has not ob-

served that it materially lessens the hemorrhage. Aldrich sums up his experience with it as follows: 1. The extract of suprarenal capsule is one of the most powerful of vasoconstrictors, and is, in addition thereto, an erectile tissue contractor. 2. As such it allows a deeper and more perfect anesthetic action from the local use of cocaine, enabling the surgeon to have highly anesthetized surfaces and tissue for operation. 3. The ischemia from such action is so profound as to act as a prolonged hemostatic, giving thereby a clear field for operation, and preventing secondary hemorrhage. 4. Its action can be depended upon, in every case. It is in no way deleterious to tissues operated upon, nor does it interfere with aseptic healing.

59. **Sulphocarbolates in Typhoid.**—Remarking first that intestinal medication in typhoid fever has of late years been going apparently out of date to some extent, Church states that resort to drugs must be had in many cases where all the appliances and trained nurses are not at hand. It is often imperative that something must be given and he believes that we must do something to prevent a toxemia not directly due to the typhoid bacillus, which takes place if the bowels are not treated with antiseptics and kept in proper activity. He, himself, would use the sulphocarbolates were he the subject of the disease. There is nothing difficult in their administration. In cases with constipation he would give in the beginning small doses of calomel, frequently repeated until moderate catharsis has resulted, to be followed by 10 grains of sulphocarbolate of sodium every 2 to 4 hours, in the average cases. In ordinary cases with diarrhea the zinc salt is preferable on account of its strong astringency, and he speaks especially of the value of the administration of these drugs in reducing the offensiveness of the diarrhea. In diarrhea generally, especially those due to fermentation, in enteritis and in dysentery or any condition where intestinal antiseptics are required, these drugs are extremely valuable.

61. **Malaria in Children.**—Moncorvo continues his article on infantile malaria, noticing the bowel symptoms, the associated secondary infections, endocarditis, pericarditis, the abortive forms with neuralgic symptoms, irregular fever, vertigo, syncope, hicough, dermatoses noticed by Boiesoco and others, abdominal swelling, rectal prolapse, etc. He remarks on the diagnosis, the differentiation from various disorders like tuberculosis, etc., and he says that any fever of irregular course without noticeable antecedents to account for it in a young child must give rise to a suspicion of paludism, especially in a country where malaria exists. As regards prognosis, the practitioner must ever be on his guard when the disease has once obtained a foothold, no matter how mild it may appear. The younger the child, the more careful should we be, and it goes without saying that the need of an early diagnosis is imperative.

63. **Morbus Ceruleus.**—The comparative infrequency of blue disease and the lack of literature on the subject appear to have been the stimulus for the present article by Mapes. In it he goes over the literature quite thoroughly, using as a text a case recently reported by Gossett. The paper, as a whole, is a useful discussion of the subject, though not original.

64. **Belladonna in Infantile Bronchopneumonia.**—Beginning with the report of a case of a child in which other remedies had failed, and improvement rapidly followed the use of belladonna with calomel, Hodghead describes his experience with this remedy, covering 25 cases, and 5 cases observed in the practice of other physicians. He claims that belladonna has just such a physiologic action as is suitable for the disease for which it is here recommended. 1. In small doses it is mildly narcotic, producing a slightly sedative influence upon the nervous system, and having a tendency to make the child less irritable, and its condition less uncomfortable. 2. It is, in small doses, a heart tonic, raising the arterial tension, and increasing the circulation by stimulating the cardiac sympathetic, and in a corresponding manner depressing the pneumogastric, the inhibitory nerve. 3. It is a respiratory stimulant, influencing in some degree the diaphragm, but more especially does it affect the accessory respiratory muscles, although its action in this regard, it must be confessed, is not yet fully understood. 4. Belladonna produces a dilation of the superficial capillaries, and in a corresponding degree, and in the same manner, relieves the congested lungs. It might also be remarked that it produces an increased secretion of urine

and of bile. 5. The most important influence, however, which the drug exerts, and the one which bears directly upon the question at hand, is to diminish secretion in the bronchial tubes and pulmonary tissues. The water-logged condition of the lungs is overcome or prevented. Its effects, in such instances, seem almost mechanical, as well as marvelous. The superabundant and dangerous secretions are diminished in quantity, and the threatened asphyxia, which becomes completed when these secretions increase so abundantly that the child is unable to rid its lungs of them, is averted. He has found it necessary to give it in quite large doses every hour, or two hours, until the desired results are obtained. Children are not very susceptible to this drug and readily bear it. In the case reported he gave it in 1 and 2 drop doses every half hour. He says that if it will prove as effective in the hands of others as it has in his, where the mortality has been reduced from 60 to 80 per cent. to less than 10 per cent. it will be as useful as antitoxin has been in diphtheria.

70. Incipient Pulmonary Tuberculosis.—Considering consumption in its beginning as a curable disease, Penn believes that dissemination of information among the public is desirable. The best results in treatment, he thinks, will be obtained in a sanatorium. He is doubtful as to the value of operative methods like those of Murphy. Out-of-door life and elevated situation are desirable. He believes egg albumin to be one of the most efficient nutrients in this disorder. As regards drugs, the best to be relied on is strychnia; it should be carried to the limit of tolerance, and creosote given for the relief of cough and fever.

71. Cerebrospinal Meningitis vs. Malaria.—Burns reports a case with the symptoms of fulminant malaria, including the development of the estivo-autumnal parasite in the blood, with also some symptoms strongly suggesting cerebrospinal meningitis, and a tough, elastic secretion in the nose containing what was believed to be meningococci. Recovery.

78. Tuberculin as a Diagnostic Agent.—After noticing the defective measures formerly in use, and giving the facts of the tuberculin reaction as best understood at the present day. Head gives the results of 487 recorded cases of tuberculin injection given for diagnostic purposes, as collected by himself from the literature and elsewhere. Of the 487 cases, 54 per cent. reacted and 46 per cent. failed. In 136 cases 83, or 61 per cent. were demonstrated as tuberculous by operative, post-mortem and bacteriologic evidence. In 83 undoubtedly tuberculous cases, nearly 5 per cent. did not react, and this failure was due in at least one case to the small doses given and to the establishment of a tolerance. The tuberculous cases which failed to react were, so far as he could ascertain, far advanced in the disease. In 12 apparently healthy individuals, 1 reacted. In 64 supposedly non-tuberculous diseases, 18 per cent. reacted. From a study of these cases, Head thinks it probable that no pathologic state reacts to tuberculin in any marked per cent., if at all, except those caused by the tubercle bacilli, and that 92 per cent. of pulmonary tuberculosis shows the reaction. In 71 per cent. of the cases of enlarged cervical glands; in 88 per cent. of the cases of acute pleurisy; in 100 per cent. of the cases of chronic pleurisy; in 91 per cent. of the cases of tuberculosis of the joints; in 100 per cent. of the cases of tubercular peritonitis; in 100 per cent. of the cases of Addison's disease, and in 100 per cent. of the cases of lupus, the reaction occurred.

79. Bladder Drainage Through the Catheter.—The conditions in which Cabot has found catheter drainage of advantage may be classed as follows: 1. Injuries of the urethra, either the result of accident or of operation, in which it is desirable to conduct the urine past the seat of injury in order that it may not by its irritant qualities interfere with the process of healing, and to prevent the absorption and toxic effects of the urine. 2. Hemorrhages in the urethra, in which the catheter assists in checking the bleeding. 3. Obstructive lesions of the urethra, which lead to inflammatory conditions of the bladder and kidneys, and in which systematic catheterization does not bring relief. The action of the catheter after an operation on the urethra or any injury to its walls is twofold. 4. It acts as a core or stem around which the urethra re-forms itself, a very desirable effect. The more important action, however, is to protect the wounded surface from con-

tact with the urine and the dangers of its absorption. In order that this shall be satisfactorily effected, it is necessary that the outflow of urine shall be constant. The catheter should never be obstructed. He points out the value of this method also in cases of hypertrophied or obstructed prostate and the quick improvement of the urine under this method. It is useful also in cases where the gradual emptying of an overdistended and partially paralyzed bladder is required. If the urine is drawn off too rapidly, hemorrhagic cystitis may follow and extend itself to the kidneys. He thinks the soft red rubber catheter is the best. If it can not be introduced or the caliber is too small and a stiffer instrument is required, he thinks the English gum elastic catheter with wire stylet the most satisfactory. One thing of the greatest importance is that it shall be properly adjusted so as to produce constant drainage.

80. Auto-Intoxication and Epilepsy.—The title of Futeher's paper, "What Evidence Have We in Support of the Theory that Epilepsy is Due to an Auto-Intoxication?" indicates its scope. It is simply a statement of the theories on this subject without a positive expression of opinion.

81. Membranous Conjunctivitis.—McDavitt reports 4 cases in one family, of membranous conjunctivitis with more or less inflammatory symptoms and weakness, without detection of the diphtheric bacillus. Two, at least, of the cases were treated with antitoxin and these appeared to be the most profoundly affected systematically.

82. Early Recognition of Catarrhal Disorders.—The necessity of early recognition of catarrhal disorders in children is emphasized by Scheppegrell. The pathologic conditions most frequently found requiring attention are the enlargement of the pharyngeal tonsils and the various forms of rhinitis, and the earlier these can be treated when treatment is necessary, the better. Of course, not every case requires treatment and it may tax the judgment of the physician to decide. The condition which presents the greatest possibility of injurious after-effects in children is purulent rhinitis. The mucus secreted is often retained in the nasal passages and by its irritation, directly and indirectly by forming a culture-ground for pathogenic germs, it causes serious injury to the normal structure of the nasal passages. Scheppegrell holds that it is frequently a forerunner of atrophic rhinitis and similar conditions. Aural affections of insidious development are often started by these conditions and serious injury to the hearing may follow. While adenoids in the nasopharynx atrophy toward adult life, they can in the meantime produce irretrievable harm. Parents should be instructed as to the importance of this matter.

83.—See JOURNAL, August 26, page 548.

84. Yellow Fever in New Orleans.—Souheon reviews the past records of yellow fever in New Orleans and especially the management of the disease in 1879. Here begins the first period, with the exception of that from 1861 to 1865, when there was practically no intercourse with yellow fever regions, in which yellow fever was not endemic every summer in the city of New Orleans. From 1880 to 1884 outside intercourse was free, but yellow fever failed to appear. He asks: "Is it not just and reasonable to say that this result was the effect of sanitation, crude and primitive though it may have been?"

85.—See JOURNAL, August 26, p. 548.

86. Atypical Forms of Pneumonia.—The types of pneumonia that sometimes occur with symptoms that baffle the diagnosis of the experienced practitioner are discussed by Pailer. He considers them under six heads, illustrating each form by detailed cases: 1. As to gastric pneumonia, in almost every case of inflammation of the lungs there is more or less disturbance of the abdominal viscera, but in some few these are so prominent as to give the impression that the main trouble is situated lower down in the abdomen. The case reported is of interest on account of complications with empyema and the severe abdominal disturbances. Both of these complications are discussed at length, and the author remarks that when in some disorders the symptoms are out of proportion to the extent of lungs involved, as in this case, empyema may be thought of, and diagnosis by the hypodermic needle is advisable. As regards the abdominal disturbances, he suggests a theory that the involvement of the pneumogastric, through reflex irritation of the medullary centers, is responsible for both abdominal disturbances and

cardiac failure in pneumonia. He thinks this a more plausible theory than the toxic one, attributing the cardiac failure to toxins acting on the cardiac nerve-centers. 2. As to cerebral pneumonia, Palier remarks that there is not much new to be said on this subject, since cerebral symptoms have been described by various authors, but one of his cases resembled tubercular meningitis so closely that it could easily have led to a false diagnosis. 3. Under "wandering pneumonia," he mentions cases in which exacerbation of symptoms occurred after a crisis and a period of desiccation, the pulmonary inflammation passing over to a new region and starting a secondary attack. 4. Under the designation, abortive pneumonia, he refers to cases lasting only a few days and terminating in recovery before full manifestations of the physical signs. In only one case has he seen a fully developed pneumonia terminate on the third day, and he rather doubts the claims of those who specify any form of treatment that will abort the disease in that time. In these cases, the physical evidence not being sufficient, the diagnosis of pneumonia is often very uncertain and, as recovery is the rule, post-mortem verifications are out of the question. 5. Under the head of chronic pneumonia he refers to the croupous and catarrhal pneumonias, subacute from the onset and lasting for months and sometimes for years, and very frequently ending in recovery. Sometimes these cases are attended with hemoptysis, and they frequently simulate pulmonary tuberculosis so closely as to be mistaken for it by competent physicians. He reports two cases that he thinks must be regarded as subacute or chronic cases of croupous pneumonia of this type, and mentions others. The other points of difference between this subacute chronic croupous and catarrhal pneumonia and tuberculosis of the lungs is the emaciation which is always present in the latter and not well marked in the former. Microscopic examination of the sputum is required to make the diagnosis certain. He alludes also in connection with this condition to the unresolved acute pneumonia in which the resolution after the typical acute attack is sometimes delayed for weeks. 6. As to masked pneumonia, while ordinarily the physical signs in pneumonia do not appear until some time after the fever, there are cases in which they do not show themselves until after the crisis, and even then imperfectly. He reports a case in which all the appearances were those of the disease, so that even the women in the house recognized it, but careful and repeated examinations did not detect the physical signs until the seventh day, and the patient was well on the ninth. A case in which the physical signs appeared on the sixth day is reported by Francis Minot and then they were distinct. As regards prognosis, he takes a favorable view in children in whom most of his cases occurred. He believes that croupous pneumonia involving not more than two lobes of the same lung will naturally terminate in recovery if not too much interfered with. Considering that most of his patients lived in unhygienic surroundings, and were without the elaborate nursing that is sometimes considered necessary, this is a favorable showing. The duration of the disease in his ordinary cases was from six to ten days. The treatment was liq. am. acetatis combined with sweet spirits of nitre in minimum doses; no coal-tar antipyretics unless the temperature rose above 104 degrees, and then a few small doses of phenacetin to reduce it a degree or two; calomel in tablet form in small doses, for constipation; about the fifth day, if there was much prostration, small doses of tincture of nuxvomica repeated as required. In adults, tincture of strophanthus and digitalis may be added as needed. In delayed resolution and difficult cough, etc., carbonate of ammonium is given with the nuxvomica with advantage. Washing the body with alcohol and water frequently reduces the temperature without drugs. No local application was used on the chest and very little alcoholic stimulant except when prostration was great, and then with doubt as to its efficacy when used. The diet consisted of boiled milk, barley or oatmeal water, according to the condition of the alimentary canal. Palier believes that the golden rule in the treatment of pneumonia in children is to interfere as little as possible except when interference is absolutely necessary.

87. Hysterical Blindness.—Muzzy remarks, in commencing

his article, that he has found much difference of opinion as to the frequency of hysterical affections of the eye. Most writers say that young girls are the most frequent victims, but experience does not support such a statement. Two points, not mentioned by de Schweinitz, are the suddenness of the onset and the anesthesia of the conjunctiva and cornea. The most frequent form is concentric contraction of the visual field, and the next most frequent is disturbance of the color sense. Functional paralyses have been described, also diplopia and in a few cases hemianopsia. One author, Lagrange, elaborately describes hysterical binocular diplopia. This may occur in two ways, in most cases, from spasms of accommodation causing two images, of which in a few cases irritation of the visual centers is the cause. It must be remembered that hysterical manifestations may complicate actual organic diseases of the brain and embarrass the diagnosis. Treatment is generally unsatisfactory.

88. Seasickness.—Remarking that the amount of suffering from seasickness renders the subject one of some importance, DeVries says that it is clearly a functional disease of the nervous system due to shock produced by the motion of the ship. The common notion that it is beneficial is altogether wrong, as it is decidedly injurious. Vomiting is a symptom of concussion of the brain; seasickness is a series of mild concussions. One of the first symptoms mentioned by the author is not often described as such, namely, an inordinate appetite developed as soon as rough water is encountered, to be quickly followed by the different stages of seasickness. As regards treatment, in some slight cases a prolonged even inspiration as the vessel rises, followed by expiration during descent, thus controlling the movements of the diaphragm, is efficacious. He does not speak well of the bromid treatment recommended by Beard and others. The plan he recommends is thorough purging before embarking, followed by 20 grains of sodium bromid at 7 a.m. on the day of sailing, and repeated one hour before the vessel sails. Keep on deck during the voyage, except at meals and during sleep. Indulge freely in Vichy and Apollinaris water. In those who have not undergone this preliminary treatment, aromatic drinks, lemonade, champagne and ginger ale are of great value. The horizontal position is generally most agreeable. Substantial and succulent food easy of digestion, and stimulants, are indicated. Avoid cold food. Nitrite of amyl has been tried with success and should be given in full doses and repeated if necessary. He has not found cocaine beneficial, though it has been recommended. In very severe and obstinate cases, after everything else has been tried without success, the patient's very feeble condition and the constant vomiting call for morphia, but it must be administered with great care. The patient should be kept under its influence at least twenty-four hours.

89. Epiphyseal Separation of Ends of Humerus.—Lucid describes the condition of epiphyseal separation of the ends of the humerus, which is liable to occur in young people. After noticing the anatomy and mechanism of the displacement, he speaks of the diagnosis. The first symptom notable in separation of the upper epiphysis, and distinguishing it from fracture, is the abrupt projection about one inch beneath the coracoid process, caused by the upper end of the lower fragment of the bone. Next comes crepitus of a softer nature than in fracture. Thirdly, the end of the shaft is round and smooth, not sharp, having the form of a low cone. Again, there is the immediate recurrence of the deformity when the means employed for its reduction cease to be in operation. The most important practical point is that the accident is apt to be followed by arrest of development, if not properly reduced. The common error in treatment is the severe and protracted extension used to reduce the relaxation, which is effective only as long as it is maintained. The most effectual mode of reduction is by carrying, with moderate extension, the humerus forward and upward. The head will roll upon the glenoid surface in any motion of the arm until restrained by its capsule. Now, then, while the humerus is still back of the central line of the body, the head is rolled upward, and long before the humerus is brought up perpendicularly, the capsule at the lower border of the head has become tense, thus holding it firm; while the humerus, being thrown up

and restrained by its muscles, slides the diaphysis backward, producing a coaptation of the corresponding facets. In other words, the reduction is effected by carrying the arm forward and upward, using moderate extension to the perpendicular line with the body.

The retention is effected by moderate extension while bringing the arm down to the side, and maintaining this slight extension until dressings for the purpose of continuing it are applied. Moore's method, which consists of a wooden splint fastened to the outer side of the arm, resting its lower end in a strip of adhesive plaster, while the upper end projects two inches above the shoulder, with a notch through which a bandage is passed under the axilla for extension, fulfills easily and promptly the indications.

The diagnosis of separation of the epiphysis at the lower end of the humerus is easy on paper, but very difficult in practice, owing to the swelling. In this condition, the X-ray, when available, offers the most valuable aid in early diagnosis. Lucid recommends the use of an Esmarch bandage starting at the hand and going slowly but firmly up the forearm over the swollen elbow-joint to the arm-pit. Leave it on for ten or twelve minutes, and then gently remove it, beginning at the hand and leaving a few turns at the top still in place. The elbow thus exposed will be pale, bloodless and no longer swollen, and the diagnosis can be made with ease. The lower end of the upper fragment will be tilted forward and the elbow-joint pushed seemingly backward with limited flexion and extension of the forearm. The lower end of the upper fragment has greater width than any fracture at the base of the condyle, and the line of separation is nearer the end of the bone. For reduction, grasp the forearm and make extension with the knee in the bend of the elbow, adjusting the fragment with the free hand. Now remove the remaining bands of the Esmarch bandage and apply a posterior and anterior splint with pressure anteriorly over the seat of separation. Passive motion should be resorted to about the seventh or eighth day, by the surgeon himself, then about the twelfth day and after that every other day until the twentieth. The fragments should be held in apposition and motion made very cautiously. If after the twenty-second day complete fixation and extension can not be produced, the adhesion should be broken up under anesthesia. It is often advisable after provisional callus formations and the fragments are in position, to bandage the arm, one day extended and the next day flexed.

91. **Epileptic Eye Strain.**—Capps reports two cases of epilepsy relieved by the use of atropin and suitable glasses; no return of the epilepsy in one case for a year and in the other for five months at the date of writing. He insists on the importance of consulting an oculist in epilepsy in children.

93. **Roentgen Ray in Incipient Tuberculosis.**—Williams reports the results of examinations of 165 patients with incipient tuberculosis, by the Roentgen ray. The diagnosis of tuberculosis was confirmed by the discovery of the bacillus or the reaction of the tuberculin test. He groups his patients into two classes: those with slight physical signs but no rales, and those without physical signs. He reports cases of each. He thinks that the value of the Roentgen test is that it gives an early warning when other signs are not prominent, and in some cases it may correct a mistaken diagnosis of tuberculosis from apparent physical signs. It is also of value in cases of tuberculosis with pleurisy and effusion, with bronchitis and emphysema. In two cases the X-ray failed, though the other tests demonstrated the disease, but generally it is the most efficient means of diagnosis. The fluorescent screen is more reliable and convenient than photographs in these examinations.

94. **Climate in Renal Diseases.**—The causal condition that has been recognized in certain kidney troubles is here discussed by Walker, who finds that the principal element is soil dampness, and he suggests a residence in a dry sandy soil as one of the most valuable means of treatment.

95. **Inguinal Hernia, a New Operation.**—In spite of the excellent results of Bassini's method, it has occasional failures, and Beck here attempts to improve on it by still further fortifying the abdominal walls. His method is as follows:

The incision is made down to the internal surface of Poupart's ligament alongside the outer margin of the rectus muscle, exposing its lower third down to the shelving portion of Poupart's ligament. The sac is isolated from the cord, and ligated and cut off within the internal ring. While the cord is held away the cut aponeuroses are dissected backward and an oblique incision is made which divides the lateral fibers of the rectus muscle transversely, to the extent of about one-third of its width, a little below the lower third of the muscle. The incised fibers are then so far severed from the remainder of the muscle that their upper portion, when turned downward, will reach Poupart's ligament without any considerable tension. This turned flap is now fastened to the conjoined tendon at one side, and to Poupart's ligament on the other, with formalin catgut, after the cord has been placed on it so that the cord rides, as it were, on the muscular flap. The gap caused by the resection of the flap is now covered by uniting the outer margin of the rectus muscle with the broad abdominal muscles. Then the cut aponeuroses are united above the cord by a continuous suture, thus forming a very strong posterior muscular wall, which in large and direct hernias may be of importance. It may also be that the removal of the sac may thus be rendered unnecessary in small hernias.

In the cases in which he used this method the results have been exceedingly satisfactory. As he says, however, the real value can only become evident after more experience and observation. The question of the gap as well as that of the division of the nerves and of cutting off some of the blood-supply has been well considered, and the objections seem to be only theoretic.

96. **Concerning Colorado.**—The climate of Colorado, and its advantages in consumption, are very fully stated.

97. **Cheyne-Stokes Respiration.**—The value of Cheyne-Stokes respiration as a diagnostic sign of the early stages of interstitial nephritis is here pointed out by O'Donovan. He has records of three cases in which these symptoms occurred during sleep, at a time when there was no albumin in the urine, or other evidence of any departure from perfect health, and in all three interstitial nephritis was developed later. The phenomena occurred irregularly and only at night and were not influenced by any particular posture of the individual. He asks for observations in large hospitals for this symptom occurring in the early stage of disorders, as there night nurses have opportunity for observation.

99. **Floating Liver.**—Floating liver is defined by Einhorn as a liver that has fallen downward and can be replaced by manipulation. Its etiology is obscure. He discusses it at some length, reviewing various alleged causes. He thinks that an enlargement of the abdominal cavity is of great significance, but it must be combined with other causes. As to the frequency of the condition, he has found it in 30 out of 804 patients suffering from digestive disorders, or about 3.7 per cent. It appears to be more frequent among women than men, their percentage being about 5.6 to 2 per cent. for the male sex. The conditions of floating liver and floating kidney often coincide. In about one-half of his female patients this was true. As regards the symptomatology, he divides it into five groups: those in which no disturbances are noticed; dyspeptic cases with indefinite digestive symptoms and feeling of weakness and nervous symptoms; cases of hepatalgia with almost constant pains in the right side of the abdomen, often radiating toward the back and shoulder-blades, and sometimes subsiding with the recumbent position—sometimes drawing and tearing pains are felt; cases of hepatic colic with symptoms like those of gall-stones, but seldom jaundice; and lastly, asthmatic cases in which a feeling of fulness and constriction in the upper abdominal region associated with slight dyspnea is especially prominent. He reports cases of some of these different groups. The diagnosis by palpation is described in detail and the differential diagnosis discussed. The condition may be mistaken for renal tumor or hydronephrosis, or it may be diagnosed when the real disturbance is liver enlargement or other conditions filling up the abdominal cavity. It must be shown in the diagnosis that no intrathoracic organ is disordered so as to force the liver downward. The treatment resembles, on the whole, that of floating kidney; the use of well-fitting abdominal bandages

to support, gentle massage, diet, exercise, etc. He does not favor surgical treatment. In conclusion he speaks of the possibility of mistakes in the diagnosis from appendicitis, gallstones, etc., and states that the appropriate treatment is usually crowned with brilliant success.

100. Typhoid Fever.—The practical treatment of typhoid fever, according to Taylor, is: first of all, rest; avoidance of purgatives; care as to diet, none at all being given for the first twelve or twenty-four hours, especially if the patient is nauseated. After this feed three times a day with soft food. Never allow your patient to eat anything he is obliged to masticate. When the temperature rises above 101, he gives anti-febrin, and if restless at night, bromidia. If the tongue is dry, he gives for a day or two small doses of turpentin in capsules, or creosote and carbolic acid and tincture of iodine. He has the patient's mouth cleansed three or four times a day, and directs him to chew *tolu* an hour or two every day until the tongue becomes moist, and take as much water as his stomach can conveniently absorb. Use colon irrigation with warm sterilized water, or if diarrhea is present, add a little boric acid or permanganate of potassium. Sponge the patient's body once or twice a day with warm water, or if a bath-tub is available, immerse for ten to twenty minutes. He does not use cold water and fluids warm water sufficiently antipyretic. If not enough water is taken by the stomach, he gives an injection, into the colon, of about a pint of decinormal saline solution, after it has been irrigated. The above is for treatment of typhoid without complications. When it occurs in patients suffering from other troubles, the treatment is slightly modified, especially when gastric disturbances pre-exist. Digestion must be carefully watched. The food must be small in amount, easily digested, and slow to ferment. He thinks the white of an egg suits this class of cases better than any other food. Milk is inadvisable for patients with weak digestion. Antiferments may be given if necessary. If the stomach is irritable and there is hyperchlorhydria, give sedatives just before food. A cup of hot water and a large dose of bismuth will usually prove efficient. Colon irrigation and baths are used as in the former case. The author concludes as follows: By promoting digestion and preventing indigestion, and keeping the alimentary tract from the stomach to the anus free from absorbable toxins, we will have no necessity for an average temperature of over 100-101 F., and a pulse of 72 to 80 per minute. The sum total is, favor digestion, prevent absorption of toxins, and promote thorough elimination of the toxins unavoidably absorbed.

101. Facts and Fallacies of Urinalysis.—The fallacies pointed out by Schaefer are the dependence on the boiling test for albumin, which he gives reasons for believing misleading; the importance attributed to phosphoric and uric acid elimination, and also that of calcium oxalate. He also speaks of the difficulties of the sugar test and the need of skill in making it, and the overestimated significance of tube casts. Only the true casts, consisting of a uniform, transparent, gelatinous matrix, to which other elements, such as epithelial cells, red blood-corpuscles, leucocytes and crystalline or amorphous forms, may accidentally have been attached, should be regarded as of great diagnostic value. He agrees with von Jaksch that Ehrlich's diazo reaction has little clinical significance.

102. Intussusception.—After discussing the subject of intussusception and operation for its relief, of which he thinks dissuagination and reduction is the ideal operation and the one promising greatest success, Munro analyzes the reported cases of resection and reports two personal ones, in one of which recovery took place.

104. Carcinoma.—Councilman describes the mode of growth of carcinoma, and says that as regards its cause, we enter the domain of theory. The influence of trauma he rejects, as also the theory of Thiersch, that it is due to a degeneration of the connective tissue. Cohnheim's theory of its being due to embryonic residues included in the normal growths has more in its favor, but he evidently does not accept it fully, nor the parasitic theory which is now so much to the front. He points out the fallacies of statistics of carcinoma, from which its excessive increase has been inferred, and says that the more accurate statistics of life insurance do not give evidence of its

increase. It is not improbable that carcinoma may be due to parasites, but if so the invasion must take place in the latter half of life, in places least exposed to ordinary invasion. The parasite must enter every cell, causing it to proliferate, and must be carried with the cell to other parts of the body to repeat the process. He thinks this theory must be taken up and definitely proved by investigation, or set aside.

108. An Emergency Obstetric Case.—Young reports a case of pregnancy terminating in eleven months, the child's head being so large as to require symphysiotomy. The operation though done under difficulties, was a success.

110. The Rocky Mountain Region.—Van Zant sums up the advantages of the Rocky Mountain region for the treatment of tuberculosis, especially in its incipient stage. Cases where cavities have occurred are not well suited to this climate. He notices also the following other disturbances, as affected by the climatic conditions: "Inflammatory rheumatism is quite rare here, whereas muscular rheumatism and neuralgias are quite common. The latter are apparently due to the sudden changes of diurnal temperature. Malaria is never seen except in imported cases. Asthma, frequently though not by any means invariably, disappears as if by magic. Among those reclaimed from this dread disease are some of Denver's most prominent doctors. Pneumonia, while no more prevalent here than elsewhere, runs a much more rapid course, the crisis often being reached in two to four days. Gastrointestinal disorders among infants are very much less prevalent than at lower altitudes. Sunstrokes are unknown."

111. Suicide.—Sweringal notices the increase of suicide, and lays it to the social conditions, which he thinks should be reformed.

114. Contagion and Infection.—Grigg discusses the significance of these two terms, quoting various authorities as to their usage, and concludes that from his standpoint "an infectious disease is produced by a pathogenic micro-organism that lives and propagates in a suitable soil on the outside and independent of man, but when taken into the system and absorbed is capable of producing certain diseased conditions which are not directly transmissible from patient to host; while a contagious disease is produced by a pathogenic micro-organism that propagates in the afflicted patient and which, after escaping from said patient without undergoing further change and on being taken into the system of a prospective host and being absorbed, is capable of producing certain diseased conditions and is transmissible from patient to host either directly by contact or indirectly as by fomites." He thinks it is of some importance to make this distinction clear.

115. Nervous Hemorrhages.—Toms reports a case of a man 33 years of age, with neurotic antecedents, who had been injured by an assault and by accident, who suffered from attacks of hemorrhage, apparently originating somewhere in the buccal cavity. There were various nervous symptoms and there was a history of delirious spells in the past. There were hysterical stigmata. Physical examination was negative, as was also urinalysis. He reports the case as of interest on this account.

117. Inheritance.—Conklin discusses the subject of heredity from the point of view of a zoölogist, and maintains, in general, Weismann's theory that acquired peculiarities are not inherited.

Progres Medicales (Paris), August 10 and 26.

Nature of Acute Leukemia. F. RAMOND.—The present state of our knowledge in respect to acute leukemia is summarized by Ramond from the communications to recent congresses, etc., as follows: The infectious stamp of the syndrome of acute leukemia is apparent. Everything about it suggests an infection invading first the ganglia and then spreading rapidly to all the viscera. But on the other hand, the composition of the blood and the histologic lesions of the organs are not all like those observed in an infection in general. The changes in the blood have been frequently described. The hypertrophied ganglia are formed of a sort of hyperplasia of the normal reticulum with a multitude of small mononuclear cells in the meshes, associated or not with a few large mononuclears, with or without granulations, according to the variety of leukemia under consideration. The liver and kidneys have nothing of

the embryo infiltration so common in infections, but present more complex formations, recalling in every respect His' lymphoid tissue; small nodules with the structure of embryo lymphatic tissue, that is, a delicate reticulum with an infiltration of small cells in the interstices. This formation of lymphoid tissue, characteristic of lymphatic leukemia, is encountered in most of the viscera, also in the bone-marrow, subcutaneous cellular tissue, etc. Myelogenic leukemia differs by a few secondary peculiarities. These anatomic lesions bespeak a non-infectious origin, but we must not be too absolute, as it is possible that we are not yet acquainted with all the reactions to infection, and that certain micro-organisms may influence the organism in a special manner. Recent research on the sporozooses shows that besides the bacterial infections there are others, due to the invasion of the organism by sporozoa, which differ materially from the former. Cultures and inoculations in leukemia have resulted negatively or conflictingly. The writer himself experimented with aerobic and anaerobic cultures on every known medium and with every animal in the laboratory, colloidion-saes, etc., without any results suggesting the presence of a bacterium or sporozoon in any manner.

Septicemia of Otic Origin Without Thrombophlebitis of the Sinuses. STANCULEAUNE AND BAUP.—Two observations of suppurative otitis of the middle ear and mastoiditis terminating in fatal septicemia, are described in this communication, noticeable on account of the fact that trephining and évidement, and ligature of the jugular had no effect on the course of the infection unless perhaps to give it impetus. In both cases the liver showed degeneration, tumefaction of the cells and fatty degeneration of certain lobules. An extremely virulent streptococcus was found in the blood; no lesions in the venous system nor in any sinus. The cases suggest as etiology the possible passage of the microbes through the walls of venules or sinuses into the circulation, with a hepatic predisposition to infection.

Annales de l'Institut Pasteur (Paris), June.

Role of the Leucocytes in Immunization Against Arsenous Acid. BESLEDKA.—Rabbits can be immunized against fatal doses of arsenous acid by accustoming the leucocytes, which is accomplished by fractioning the fatal dose or by injecting a small dose of the poison twenty-four hours before the fatal dose. The serum of these animals has preventive and antitoxic properties against a dose of acid fatal in forty-eight hours. The antiarsenin is probably not an arsenical compound; the arsenic is not dialyzable. The antiarsenin acts on the toxin by the intermediation of the leucocyte system. Suppressing this, as when the poison is injected into the brain, the action of the antiarsenin is paralyzed.

La Parole (Paris), No. 6.

Practical Applications of Experimental Phonetics. ROTSELOT.—The movements of the tongue and larynx in speaking are registered by a simple apparatus consisting of a rubber olive held in the mouth, a tube, drum and an index. The subject can see for himself in what way his movements differ from normal, and corrects them with a little exercise. This method has proved extremely effective in overcoming defects in pronunciation, teaching languages, and curing stammering, paresis of the vocal chords, etc., combined with open-air life and the use of the spirometer to test and increase the breathing capacity. In pronouncing *tar* for instance, with the olive in the mouth, the index springs quite a distance, but does not move when *car* is pronounced. The larynx signal is a small sleigh-bell held by a weak spring against a thin metal plate, the bell tinkling when the plate is applied to a vibrating larynx. Another contrivance is a wire bent into the outline of a small hoe, which is placed over the under teeth to teach the pronunciation of the liquid *n* as in *onion*, the tongue kept in contact with it.

Revue Herb. de Laryngologie, etc. (Bordeaux), August 10.

Ozena and Sinusitis. P. JACQUES.—"Idiopathic ozena is a myth," the writer declares. Ozena is merely the secondary consequences of sinusitis of one or more of the nasal fossae. All therapeutic measures for ozena to date merely respond to the symptomatic indication to combat the atony resulting from sclerosis of the pituitary body due to irritation from sinus secretions. Moure has noted 32 cases of verified sinusitis in 114 of ozena and if we were able to examine the sphenoid

ethmoidal system as easily as the frontomaxillary, this coincidence would probably be found the rule. Each sinus should be minutely interrogated in turn, he concludes, in every case of ozena.

Annales de la Societe Med.-Chir. de Liege, June.

Autovaccination in Treatment of Pneumonia with Digitalis. G. CORIN.—Six years of successful experience leads Corin to affirm that "expectant treatment of pneumonia is illogical and dangerous when we have in digitoxin a safe, reliable specific to abort the disease." Digitalis is unreliable, but digitoxin, in spite of its formidable name, can be depended on to strengthen the heart and prevent stasis in the lung and thus check the morbid process. The reinforcement of the activity of the heart prevents any considerable absorption of the toxic products secreted by the pneumococcus, which thus dies poisoned by its own excretions. Or possibly the small amounts of the toxic products which the digitoxin allows to be absorbed vaccinate the subject from the focus of infection, while the pneumococcus culture becomes less and less virulent to final extinction. Corin compares the action of digitoxin to that of Pane's serotherapy and considers them probably identical in the autovaccination produced. Three milligrams of digitoxin is the dose he gives an adult, and the effect is not apparent for twenty-four, possibly thirty-six to forty-eight, hours, afterward. The fall of the pulse is the first expression of the action of the digitalis, and it precedes the fall of the temperature, the first expression of the action of the vaccin.

Berliner Klinische Wochenschrift, August 7, 14, 21.

Technic and Hardening of Sections of Brain. E. SIEMERLING.—With a microtome specially constructed Siemerling cuts series of sections in any direction and hardens with the Mueller-formol mixture; two parts of the 40 per cent. solution of formal to 100 parts Mueller. Study of sagittal sections throughout the entire brain shows great variation in the number of tangential and especially of horizontal fibers in the cortex. They are most numerous in the convolutions of the temporal lobe, and next in the central convolutions and the convolutions at the calcarine fissure. This fact should be borne in mind in studying fiber disappearance in paralysis.

Primary Retroperitoneal Echinococcus in the Abdomen. F. KAREWSKI.—In one of the two observations of this rare localization reported, obscure symptoms resembling lumbago had existed for years, and a tumor finally appeared during pregnancy, in the left kidney region, with evidences of catarrh of the bladder. Operation disclosed a suppurated echinococcus sac which had developed on the kidney and extended behind the descending colon. In the other case the sac had developed at the emerging point of the plexus ischio-cruralis and had been the cause of ischialgia during twenty-five years. Complete recovery in each followed after extirpation of the sac.

To What Extent Can We Sterilize Our Hands? GOTTSCHEN and BLUMBERG.—"Three years of tests and experiments have established that asepsis of the hands can only be realized in about 75 per cent. of the attempts, and that in tincture of soap we have the most effective disinfectant for the hands yet discovered." (See JOURNAL, July 8, p. 100.) Triclot gloves, frequently changed during aseptic operations, are the best guarantee of asepsis. They act as a filter, and frequently changing the filter removes the accumulated germs from within and without. Rubber gloves are too easily torn for general surgical operations but are indispensable in septic conditions.

New Method of Applying Long-Continued Powerful Galvanic Currents Without Injury to the Skin. FRANKENHAUSER.—This is a preliminary communication from Senator's clinic, and describes a method by which the current can be applied to the tissues with none of the cauterizing effect which has been such a disadvantage hitherto in long-continued applications of electricity. The corrosive substances are washed away as they are generated, by a continuous stream of physiologic salt solution. A still simpler method is to have a sodium solution at the anode and a hydrochloric acid solution at the cathode, or any sodium or chlorine salt respectively, in which case no corroding ions are generated. Metallic electrodes are discarded on account of their chemical action and sheets of a prepared felt are used. By this means with an electrode of twenty square centimeters 580 coulombs can be applied at one sitting.

[*Deutsche Medicinische Wochenschrift (Berlin)*, August 17, 24 and 31.

Rheumatic Mental Disturbances with Acute Rheumatic Chorea and Study of Choric Movements. M. JASTROWITZ.—In the two extremely severe cases studied in detail, it was evident that the agent causing the disease had directly attacked the portion of the nervous system to which Jastrovitz ascribes the various forms of choric movements, that is, the entire motor part of the central nervous system, weakening and irritating it. In one, the cortex was first affected (first stages of the psychosis), then the joints, and then the motor centers and tracts (chorea), and the clinical phenomena varied as the various regions became involved in turn. In the second case the course was more rapid and violent, and there was mixed infection with the streptococcus pyogenes, which may possibly have favorably influenced the psychosis and chorea, but induced malignant endocarditis and thrombosis of the femoral artery. Both recovered. He also ascribes the choric movements in idiocy to a "weak brain life," a general condition affecting the motility.

Extirpation of Cancerous Rectum and Sigmoid Flexure. K. SCHUCHARDT.—The coccyx method followed by our Stettin confrère allows the complete extirpation of all the parasacral tissue with its possibly infected lymphatic glands along with the rectum, to the promontorium and beyond. The patient being on his back in a modified, exaggerated Trendelenburg position, buttocks extremely elevated, legs drawn up and fastened, the coccyx is divided with a Gigli saw and the rectum mobilized and excised with ease and no hemorrhage proceeding as for a hysterectomy, after a circular incision. With a ring carcinoma he makes a lumbar colotomy a few weeks previously. Not until the entire field has been inspected, drain inserted and small gauze tampon left in the sacral space does he cut into the rectum and suture the central end to the skin. He does not attempt to save the sphincter, and in case the vagina is involved he proceeds to a bilateral paravaginal incision such as he advocates for hysterectomy, extending it through the musculus levator ani on both sides as high as required. In one case he succeeded in mobilizing 40 cm. of the rectum, extirpating 30.

Dyspepsia From Motor Insufficiency of the Urinary Apparatus. O. ROSENBACH.—In these days of specialism there is danger of attributing to the organ which appears most affected disturbances which are primarily due to an insidious morbid process elsewhere. This is especially liable to occur with the dyspepsia which careful observation will trace to a motor insufficiency of the urinary apparatus—nokinetic dyspepsia—as Rosenbach establishes in this study concluded from the two preceding numbers. The cases are always men at the end of the fifties or in the sixties. Disturbances in the digestion appear at intervals, first noticed as a distaste for meat, a disagreeable, stale taste in the mouth, frequent pyrosis or eructations of odorless gases, efforts to vomit, an uncomfortable sensation in the jaws and salivary glands, sometimes involving the head. There is usually lassitude and great weakness in the lower extremities, progressive debility and emaciation from lack of nourishment. In some cases chills are noted at irregular intervals, usually in the evenings; temperature low, no fever except in advanced stages; frequent desires to urinate, especially during the night. Some complain of a sensation of oppression in the lower abdomen, desires for, and incomplete, defecation. The tongue is seldom coated, usually only in severe cases, when there is a blackish discoloration at the rear of the tongue and slight fever. Subjects who used to smoke much have a distaste for tobacco and liquor. Salivary secretion is diminished and gums are dry. Stomach contents are negative; there is occasionally absence of free HCl. Palpation discloses nothing abnormal, except that occasionally in certain positions, the bladder is noted reaching to the navel, long and tapering. The urine contains no albumin and has merely the slightly darker color and higher specific gravity usual in digestive disturbances. But a special characteristic is that it decomposes with exceptional rapidity and disengages ammonia with a strong odor. Also, as the urine stands, quantities of mucus are deposited in the sediment, and the microscope shows a remarkable abundance of white corpuscles. The subject finds it impossible to retain urine long and even when the bladder reaches to the navel, the amount contained is not over 200 to 300 c.c. The prostate is usually enlarged

at this age; the essence of the affection is a paresis of the motor system of the urinary apparatus. An important point in the differentiation is that catheterization is easy and painless. The bladder disturbances are so slight that patients never even refer to them. If neglected and long continued, serious nephritic complications may appear, but in the early stages, when the sphincter is alone involved, treatment is invariably successful. It consists in a general tonic and kidney-resting régime, warm baths, rest in bed, refraining from liquids and light, cautious massage of the abdomen, ureters and bladder region. Faradization and ice-bags, nau vomica or ergotin have also proved useful. Beer and sour wines must be strictly avoided.

Zeitschrift f. Geburtshilfe u. Gynäkologie (Stuttgart), xii, 1.

Etiology of Paralysis of the Upper Arm From Injury at Birth. J. SCHIEMAKER.—Experimentation on infants' cadavers has demonstrated that "Erb's point"—the emerging point of the sixth cervical nerve between the scapula, where the roots of the brachial plexus lie—can be directly injured by compression with the forceps, and also by traction on the head or on the lifted arm during version, indicating the necessity of special caution.

Wiener Klinische Wochenschrift, August 17.

Molluscum Fibrosum. P. MERKEN.—The argument in favor of the congenital nature of this affection, advanced by Merken, is based on the facts that seventeen cases are on record which are known to be congenital and that the influence of heredity is unmistakably apparent in many others; also that by far the largest number develop in youth and especially in early childhood; also its frequent coincidence with pigmented patches. He calls attention to the frequency of coexistent mental disturbances. In his opinion it is a deformity similar to nevus in many respects, but differing by its progressive character, which stamps it as a neogrowth—generally benign but with a tendency to malignancy—the congenital deformity consisting in the tendency of the connective tissue to unlimited proliferation.

Centralblatt f. Nervenheilk. u. Psych., No. 1.

Continuous Baths for the Insane. E. BEYER.—The experience at Heidelberg has been very favorable to these baths or water-beds, transferring the patient from bed in the morning to the bath—temperature, 23 K.—and from the tub to bed again at night, with no other procedures or examinations. It is especially beneficial for the rapid curing of decubitus, phlegmons, etc., and is indicated for all uncleanly, restless, destructive or menstruating patients. It has proved invariably successful in mania. No mechanical means are used, but a dose of hyoscin at first may be found useful. Each ward should have its separate bath-room with tub and attendant to each two or three patients. Cells and isolating-rooms will then be found unnecessary.

Zeitschrift f. Hygiene u. Inf. (Leipzig), xxxi, 1.

Ray Forms of Tubercle-Forming Organisms. LUBARSCH and SCHULTZE.—Research in respect to the "modified tubercle fungi," streptothrix, etc., has demonstrated that the actinomycetes forms which until recently have been considered peculiar to and characteristic of a certain distinct species of disease germs, in reality belong to a long list of fungi of the streptothrix group. The ray and club shapes are not the expression of degeneracy but are rather deformed specimens, due to arrested development. This group of micro-organisms should not be classed with the schizomycetes nor the hyphomycetes, but should be considered independent transitional forms between these two forms. The principal cause of the formation of radiating foci is the reaction of the living tissue, the barrier formed around the invading bacilli by the leucocytes; the bacilli can only spread at the weakest points of the encircling barrier. Comparing this actinomycetotic form of the tubercle bacillus with the actinomycetes, he observes that the analogies are greater than the differences that separate them.

Bacteriologic Enzymes as the Cause of Acquired Immunity. EXNERICH and LÖW.—"The substance resembling an enzyme, secreted by bacilli, not only destroys its own bacilli in time but is also bactericidal to certain other species and neutralizes their toxins." Experiments with the enzyme derived from the bacillus pyocyaneus—"pyocyanase"—proved that not a single culture would develop after two hours, out of

nearly five millions of anthrax bacilli to which the pyocyanose had been added *in vitro*. Tests on animals were still more conclusive; pyocyanose given with over a fatal dose of anthrax cultures or five hours later, saved the animals and no bacilli could be found in the blood.

The Anthrax Bacillus Does Not Form Toxins. CONRAD.—“We have no evidence to prove the general assumption that the anthrax bacillus generates a toxin. On the contrary everything tends to indicate that the anthrax bacillus is a typical infectious micro-organism.”

Clinica Medica Italiana (Geneva), March.

Pernanganate of Potassium an Antidote for Nux Vomica. E. PARATORE.—Drinking a solution of fifty centigrams of potassium permanganate in one liter of water will transform the strychnin in the stomach into a harmless compound. Follow with lavage of the stomach with the same at 1/5000; chloroform if convulsions have appeared.

Importance of Local Reaction in Genesis of Immunity. G. CASTRIGNUOVO.—Extensive experimental tests have demonstrated that immunity to intoxication with abrin or ricinin can be secured in animals, and that it is more certain and more extensive in proportion as the primary local reaction is intense and lasting. The gradual disappearance of the local alterations is an index of the degree of immunity attained. Animals immunized against one are partially immunized against the other. If the local reaction is very energetic and lasting it can, *per se*, produce a considerable degree of immunity. It was also established that an intense local reaction produced by cantharidin confers a greater resistance to intoxication with bacterial toxins—Koch's tuberculin or diphtheria toxin—or analogous toxalbumins (abrin), but never sufficient to arrest the fatal course of tuberculosis.

Revista Medica de S. Paulo, June and July.

Liver and Spleen in Ankylostomiasis. P. MAGALHAES.—Hypertrophy of these organs in this disease is usually ascribed to malarial infection, but Magalhaes describes three observations in detail out of a large experience, in which the liver and spleen were much enlarged but no evidences of malarial infection could be discovered in the anamnesis nor blood, not even a trace of melanic pigment. The red corpuscles were diminished in number and varied from extremely large to extremely small, with some deformed specimens. In one case the leucocytes contained no trace of melanic granules. The leucocytes were diminished in number in all, and only one eosinophile was found in all the preparations.

Revista Medica de Bogota, March and April.

Hysterical Pseudotypoid Fever. ALGANDONA AND CALDERON.—Suggestion proved the only means to control and cure the case described in this communication: a hysterical young woman who for six weeks presented the clinical picture of severe typhoid fever, utterly rebellious to baths and therapeutic measures, with several peculiar features, such as the exacerbations every seventh day, frequent abrupt rise and fall of the temperature and pulse, convulsions, discordance between and alternate occurrence of dyspnea and tympanism, fetal pulse and enterorrhagia, evidently aberrant menstruation. With suggestion, the temperature dropped two degrees and the pulse from 132 to 120 in five minutes, at one time. It also controlled and arrested the convulsions every time. The writers mention the difficulty encountered in the countersuggestion of the family.

Revista Medica (Mexico), August 1.

New Syndrome Consecutive to Wound of Spinal Cord. URRUELA.—The symptoms produced by Mott by hemisection of the spinal cord in monkeys were typically reproduced in a case of stab-wound of the spine, that evidently severed the cord as in his experiments. The tip of the knife must also have injured the pyramidal tract beyond on the other—left—side, as lax paraplegia occurred at once, with the hemiparaplegia on the right side. During the two years since, the right side has regained its function, but the left only partially, and the left limb is much contracted. There were no vasomotor nor trophic disturbances at any time. Rectal and bladder functions were regular after three days of retention.

Societies.

COMING MEETINGS.

American Association of Military Surgeons of the United States, Kansas City, Mo., September 27-29.
Mississippi Valley Medical Association, Chicago, October 3-6.
Idaho State Medical Society, Lewiston, October 5-8.
Utah State Medical Society, Salt Lake City, October 6-7.
Wyoming State Medical Society, Laramie City, October 10.
American Academy of Railway Surgeons, Omaha, Neb., October 12-13.
Vermont State Medical Society, Burlington, October 12-13.
Medical Society of Virginia, Richmond, October 15.
Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, October 24-26.
New York State Medical Association, New York City, October 24.
American Public Health Association, Minneapolis, Minn., October 31.

Idaho State Medical Society.—The annual meeting of the Idaho State Medical Society will be held at Lewiston, October 5 and 6, postponement from September 5 and 6 having been made to accommodate the State Board of Medical Examiners.

Douglas County Medical Society.—This Wisconsin society elected officers at its recent meeting, as follows: President, J. A. Rene; Vice-President, Dr. Saunders; Secretary, H. J. O'Brien; Treasurer, H. J. Orchard; Censors, Drs. Sheehan, Ground and McGill.

Kankakee Valley District Medical Society.—Twenty-two physicians met at North Judson, Ind., September 12 and completed the organization of this Society (see JOURNAL, August 26, p. 544) by the adoption of a constitution and by-laws and the election of the following officers: President, I. B. Washburn, Rensselaer; Vice-Presidents, W. A. Noland, North Judson, and R. B. Short, Union Mills; Secretary, N. W. Cody, Logansport; Assistant Secretary, H. B. Hill, Logansport; Treasurer, Wm. Kelsey, Monterey. After the organization was completed, Dr. Geo. W. Thompson read a paper on "Anesthesia," which was discussed by Drs. Short, Kelsey, Davis, W. H. Thompson, Thomas and others. The next meeting will be held in North Judson, Dec. 5, 1899.

Mississippi Valley Medical Association.—The next meeting of this Association will be held in Chicago, October 3 to 5. The general sessions will be held in Handel Hall, 40 Randolph Street; the Section meetings in the lodge rooms on the eighth floor of the Masonic Temple, and the exhibits in Commandery Hall, same floor. The following is the program:

GENERAL SESSIONS.

Address of the President. Dr. Duncan Eve, Nashville, Tenn.
Address in Medicine—"Typhoid Fever." Dr. J. A. Witherston, Nashville, Tenn.
Address in Surgery. Dr. Lewis McMurtry, Louisville, Ky.

MEDICAL SECTION.

1. Enzymes and Immunity. Chas. T. McClintock, Detroit, Mich.
2. Recent Physicochemical Researches as to the Physiologic Action of Lecithin and Other Organic Phosphorus Compounds. L. H. Warner, Brooklyn, N. Y.
3. Communal Hygiene. Ernest B. Sangree, Nashville, Tenn.
4. Some Phases of Malaria—Quinin in. Wm. Britt Burns, Deekerville, Ark.
5. The Treatment of Cystitis. M. F. Lee, Columbus, Ohio.
6. Diabetes and Its Constitutional Treatment. Elmore S. Pettyjohn, Alma, Mich.
7. The Treatment of Pulmonary Tuberculosis by Inhalation of Antiseptic Nebulae. Homer M. Thomas, Chicago, Ill.
8. The Management of Cases of Pulmonary Phthisis at Health Resorts. Charles F. McGahan, Aiken, S. C.
9. The Treatment of Acute Lobar Pneumonia. Ramon F. Garcin, Richmond, Va.
10. The Art of Diagnosis. E. L. Larkins, Terre Haute, Ind.
11. The Successful Treatment of a Case of Graves' Disease as an Antidote. Charles L. Minor, Asheville, N. C.
12. Do We Need to Think? Wm. O'Neill Mendenhall, Richmond, Ind.
13. The Evils; Their Causes, and the Remedy That Will Edify Medicine in the United States. A. M. Osnes, Dayton, Ohio.
14. Two Cases of Typhoid Fever with Unusual Complications in Very Young Children. E. B. Montgomery, Quincy, Ill.
15. Further Observations on the Treatment of the Abdominal Viscera Through the Colon. Fenton B. Turek, Chicago, Ill.
16. Report of a Case of Complete Hernia of the Pregnant Uterus. W. V. Anderson, Toledo, Ohio.

17. Leptomeningitis. Frank Parsons Norbury, Jacksonville, Ill.
 18. Pathogenesis of Functional Nerve Diseases and Its Prophylactic Indications. John Puntun, Kansas City, Mo.

SURGICAL SECTION.

1. Vesico-Rectal Anastomosis. J. Frank, Chicago, Ill.
 2. Intercostal Ulceration of the Rectum, with Report of Five Cases. Sterling B. Taylor, Columbus, Ohio.
 3. Modern Surgical Treatment of Hemorrhoids. Gustavus M. Blech, Chicago, Ill.
 4. Hemorrhage from the Rectum and Its Varied Importance As a Symptom. Leon Straus, St. Louis, Mo.
 5. Treatment of Certain Ocular Diseases by Excision of the Cervical Sympathetic Ganglia. James Moores Ball, St. Louis, Mo.
 6. Urethral Endoscopy. W. R. Blue, Louisville, Ky.
 7. Inflammation of the Vermontanum. J. Rilus Eastman, Indianapolis, Ind.
 8. The Technic of Abdominal Incision, Peritoneal and Extra-Peritoneal. S. E. Milliken, Dallas, Tex.
 9. Mammoth Ovarian Cysts. Reports of a Tumor Weighing 245 Pounds. Jas. B. Bullitt, Louisville Ky.
 10. Some Causes of Death After Abdominal Section. Louis Frank, Louisville, Ky.
 11. The Value of Prostatic Examination. J. Leland Boogher, St. Louis, Mo.

12. Intestinal Obstruction from Gall-Stones. J. Wesley Bovée, Washington, D. C.

13. Obstructive Growths of the Pylorus, with Report of a Successful Case of Pylorotomy. J. E. Allaben, Rockford, Ill.
 14. What Becomes of the Medicinally Treated Cases of Appendicitis? Louis Schooler, Des Moines, Iowa.

15. Appendicitis from a Medical Standpoint. I. N. Love, St. Louis, Mo.

LICHEN RUBER PLANUS.

DR. MEYER HELDINGSFELD presented a case of this disease with a universal distribution, of only seven weeks' duration. The eruption began on the flexor surface of the forearms, and extending over the arms, trunk and lower extremities. The papules were small, polygonal and waxy, aggregated here and there into plaques, purplish red in color, sharply defined and accompanied with pruritus. Papules were also present on the mucous membrane of lips, cheeks and palate. Two weeks of arsenic treatment had already induced reparative changes, and many of the large plaques showed central atrophy and a sepia-brown dis-

coloration. The sister of this patient was also presented and showed a lichen ruber eruption of three years' duration, on the lower extremities, and of the verrucosus type.

SPLENYMYELOGENOUS LEUKEMIA.

DR. MARK BROWN presented a patient afflicted with this disease. The patient was a man 40 years of age, and, as far as he was able to state, his trouble had begun suddenly about fifteen months previously with sharp lancinating pain in the splenic region. This pain had resisted treatment for nine months. He had noticed no enlargement of the abdomen until New Year's day, 1898, but the tumor mass had steadily increased in size since that time. He absolutely denied venereal disease and had never had an attack of malaria. He has lost about forty pounds in weight since the onset of his disease, but has regained a little, since the institution of treatment about a month ago. On examination, the patient did not appear to be very anemic, but he was considerably emaciated, this condition contrasting greatly with the protruding abdomen. The heart revealed a basic hemie murmur, which became lost toward the apex. The apex-beat was pushed slightly upward. The liver was enlarged to between two and three inches below the costal border. The most important point was the enlargement of the spleen, which extended as far downward as the anterior superior spine of the ilium and laterally several inches beyond the umbilicus. The splenic notch could be readily detected. The tumor was firm and hard, painless on palpation, and without nodules on its surface. There was some enlargement of the submaxillary and inguinal glands, but no others were involved. There had not been swelling of the feet at any time. The only signs of anemia that had been present were a general weakness and shortness of breath on slight exertion. Ophthalmoscopic examination was negative aside from pallor of the discs. The red and white corpuscles were counted in the same pipette, Toisson's solution—1 to 200—being the diluent. dilution reds were 3,300,000; whites, 400,000; the hemoglobin was not estimated, as the test is not very reliable, the presence of the large number of leucocytes altering the color to such an extent that the resulting color becomes untrustworthy for comparison. Differential count; small lymphocytes 10 per cent.; large lymphocytes 6 per cent.; polymorphonuclear leucocytes 35 per cent.; eosinophiles 6 per cent.; and myelocytes 43 per cent. The myelocytes at 43 per cent. would count up about 175,000 corpuscles per cubic mm.

It has been claimed that the myelocytes were not distinctive of this disease as was once thought. This was admitted, but the claim was made that the greatest number of myelocytes found in any other disease was far less than the least number found in any case of splenomyelogenous leukemia. In addition the blood showed marked irregularity, both in the size and shape of the red corpuscles, numerous nucleated reds, both normoblasts and megaloblasts, and a few "mast" cells. It was difficult in many instances to distinguish a large lymphocyte from a myelocyte, and the personal equation had often to be relied on. The speaker thought that, on account of the similarity of the two leucocytes, the myelocyte was derived from the large lymphocyte in this disease at least. A stained specimen of blood was shown under the microscope and the field chosen demonstrated large and small lymphocytes, neutrophiles, eosinophiles, nucleated red corpuscles, and the great irregularity of the reds. The treatment consisted entirely of arsenic, administered as Fowler's solution, commencing with three drops three times a day. He has been taking this medicine, gradually increased, for about a month, until now he is taking nine drops three times a day, without any toxic manifestations. Patient stated that he has gained several pounds in weight during that time and that he thinks the swelling in his abdomen has somewhat diminished. In response to a question the speaker stated that excision of a leukemic spleen has been performed twenty-four times with but one recovery: out of 105 splenectomies there had been 48 deaths; 16 of these latter cases were of floating spleen, of which 15 recovered.

INTOXICATION.

DR. OPIEUS EVERTS presented this, the paper of the evening. It dealt entirely with alcohol, and its defense in small quantities as a food. The writer's enormous experience enabled him to deal authoritatively with the question as to what part this drug plays in the etiology of nervous diseases, and he decided

that less than 10 per cent. could be assigned to this cause. He cited other statistics to this effect. The paper was discussed by Drs. Langdon, Taylor Mitchell and the essayist.

September 11, 1899.

SPECIMEN OF APPENDIX.

DR. EDWIN RICKETTS presented a specimen of an appendix taken from a boy, aged 17, who had had four attacks of appendicitis within the past year. On opening the abdomen he had twice punctured the superficial epigastric vein. The operation was somewhat difficult on account of the numerous and strong adhesions that existed. He was also compelled to remove a large piece of omentum to get at the appendix. The latter was found in about its normal position, but subperitoneal. The appendix was found to be doubled on itself.

DR. C. A. L. REED was interested in the statement that the appendix was subperitoneal. He himself had had a number of cases in which the membrane had seemed to be peritoneum, but was afterward found to be adventitious membrane.

DYSPNEA FROM GLANDS IN LARYNX.

DR. S. E. ALLEN reported the case of a boy 4 years of age, who had been brought to the Cincinnati Hospital the latter part of March. For four months previously the child, whenever handled or irritated, had suddenly developed severe attacks of dyspnea. Examination of the larynx was negative. An esophageal bougie passed readily into the stomach. A tracheotomy was done, but nothing found. The wound healed readily and the child was sent home in practically the same condition as when it entered. He died suddenly about one month later. Post-mortem examination showed a large mass of glands about the trachea, one of which had greatly softened and had ulcerated into the trachea.

MASTOID DISEASE.

The second case reported by Dr. Allen was one of mastoid disease. The patient, an adult male, gave a history of a discharge from the ear since infancy. Eight months ago facial paralysis developed. There were no mental symptoms. On opening the mastoid he had found this bone necrotic, the entire top of the tympanic cavity and of the antrum wanting, so that a probe could be passed upward in the cerebral cavity for a considerable distance. Anteriorly the necrosis continued as far as the sheath of the carotid, which was opened. Bleeding was readily controlled by a small piece of gauze. The man died four days after the operation.

GUMMA.

DR. ED. SHIELDS presented a girl about 11 years of age, with a small tumor formation at the left sternoclavicular junction. The patient had just come under his observation that day. Four years before he had treated the mother for serpinginous syphilide. He thought that the tumor was a gumma. At any rate, he proposed to treat the child on that line and will report the result to the Academy at some future meeting. He intends giving 1 gr. of blue ointment in capsules three times daily.

DR. ALBERT FRIEBERG some years ago encountered a similar condition, but on operating found a tubercular caries which had necessitated removing a considerable portion of the clavicle.

AMPUTATIONS IN THE VERY AGED.

DR. J. C. OLIVER read the paper of the evening. Several cases were reported. The first, aged 80, had met with an injury to her left shoulder, supposed to be a dislocation. Six weeks later spontaneous fracture of the upper third of the humerus occurred, and on examination a tumor was found which was diagnosed as an osteosarcoma. Chloroform was used and the patient to all intents and purposes withstood its effects as well as a much younger person would have done. Amputation of the arm and of a considerable portion of the shoulder was made, with good recovery.

The second patient was aged 88, and was afflicted with gangrene of the great toe of the right foot. Gradually the gangrene spread to the other toes of the foot and was soon followed by a line of demarcation. Amputation at the metatarsophalangeal joint was made under 2 per cent. cocaine anesthesia, and the stump closed perfectly after seven months. The essayist was inclined to the view that "a man is as old as his arteries," and believed these patients to be much younger physiologically than was determined by their years of life.

Cleveland Medical Society.

September 8, 1899.

COMBINED SARCOMA AND EPITHELIOMA.

DR. O. T. TROTMAN exhibited a specimen which had been diagnosed before operation as epithelioma of the cervix with fibroid uterus. Microscopic examination of the cervix, after hysterotomy, showed combined sarcoma and epithelioma, a very rare condition. The body of the organ contained an adenocarcinoma in the endometrium, and within the walls an almost pure myoma which showed beginning sarcomatous degeneration. He exhibited one other specimen which had before operation been diagnosed from its softness and rapid growth as possible sarcoma, but which proved to be almost pure myoma.

DR. W. H. HUMISTON gave the history of the case from which the last-mentioned tumor was removed. There had been metrorrhagia for the previous nine months, together with symptoms of a tumor. Abdominal hysterotomy was performed, practically bloodlessly, by means of clamping the ovarian and uterine vessels. There was no shock and recovery was prompt. He thought these tumors should be removed as soon as they attained perceptible size, because of the risk of malignant degeneration.

DISTENDED STOMACH.

DR. C. F. HOOVER reported a case of a man, aged 19 years, who suffered from pain in the cecal region and vomiting. Diagnosis of appendicitis was made, but after four or five days in bed the tenderness diminished and the fever disappeared. However, severe thirst persisted, the tongue was very dry and he vomited large quantities of thin green fluid. There was abdominal distension, more marked on the left side, with considerable prominence of the hypogastrium. The prominence on the left side was dull on percussion, and by pressure a very distinct succussion sound could be elicited. A day later the symptoms became very much worse and death occurred. At the necropsy the tumor was found to be simply a distended stomach which practically filled the whole abdominal cavity. The appendix had sloughed off and lay up behind the cecum. There was no free pus in the peritoneum, but some along the ascending colon. No anatomic basis for the dilation of the stomach was found. A few cases of acute dilation of the stomach without apparent cause have been reported.

DR. R. J. WENNER remarked that Dr. Hoover's case furnished a strong argument for operation in appendicitis within twenty-four hours after the diagnosis was made. He reported a case of dilation of the stomach in a young man who had been shot through the dorsal region of the spine, and two other cases which followed directly on an attack of typhoid and in which stenosis of the pylorus existed.

DR. H. L. SPENCE quoted a recent report of a case of acute dilation of the stomach without apparent cause, which was followed in a few days, in spite of all treatment, by death in collapse. No mechanical cause could be found.

DR. C. F. HOOVER remarked that stomachs are generally contracted in typhoid, and that he had never seen dilation mentioned as a sequel of that disease. He also noted a case in which the patient died of collapse a short time after the passage of a stomach-tube, and said that it was perfectly clear that a stomach-tube should never be passed without some clear indication, as the sudden inhibition of the vagus may cause death.

RUPTURED ECOTIC GESTATION.

DR. CHARLES TANNER of Wilkoughby reported a typical case of ruptured ectopic gestation with sudden death.

DR. HUMISTON gave it as his opinion that it was never too late to operate in such cases, and reported a grave case in which a successful outcome was possible by immediately finding and clamping the ruptured tube just as soon as incision was completed.

HIP DISLOCATIONS.

DR. C. A. HAMANN presented a case of a boy, 8 years old, who had fallen from a wagon, striking on his hip. He was able to walk after the accident, but in a day or two went to bed because of severe pain. When seen at the end of two weeks the leg was held in a flexed position, with the arch of the lumbar spine that is seen with coxitis. There was considerable fever and emaciation. The leg was extended with weights, and allowed to remain in this position for five or six days. There was no

improvement and the temperature still rose in the evenings. An abscess then formed in Scarpa's triangle. The pus was not that of a cold abscess. The case was found to be one of acute osteomyelitis of the inferior spine of the ilium and of the pubis. There was no evidence of hip-joint disease. After curettement the abscess rapidly closed. Staphylococci were found in the pus, but no tubercle bacilli.

Dr. W. E. WITT remarked that hip-joint disease could be eliminated from the diagnosis of this case because of the complete flexion of the limb. Even if the joint had been affected the opening of the capsule would not have been justifiable, because of the danger of fresh infection of the joint.

Dr. C. A. HAMANN also showed a case of dislocation upward of the outer end of the clavicle, caused by a fall from a freight train, the man striking on his head and shoulder. He noted that, while this dislocation is easily reduced, it is difficult to retain in position, and considerable deformity usually results. The best treatment is to apply a compress and then strips of adhesive plaster firmly bound over the chest anteriorly and posteriorly, covered by a posterior figure-of-eight bandage.

Dr. C. J. ALLBRIGHT had had poor results in treating these dislocations. He noted that the chief feature in the deformity was contraction of the trapezius muscle and that placing the patient prone on his back relaxed this muscle entirely and aided in securing a good result.

Dr. WERT reported four instances illustrating the necessity of making a complete examination in every case. The first had been referred to him as one of infantile paralysis, but on examination proved to be congenital dislocation of the left hip. Another supposed case of spinal disease proved to be congenital dislocation of both hips. The third case of supposed Pott's disease was found to have the same condition. In these cases, where there exists an acetabulum and a head of the femur, a good result can be obtained, but in many cases these structures are absent and cure is practically impossible.

RENAL CALCULUS.

Dr. L. B. TUCKERMAN reported a case of removal of a renal calculus (when determination of the organ affected had been made by the ureteral catheter).

Dr. R. J. WENNER noted that the segregator would probably have performed the same service equally well without danger of infecting the sound kidney.

Detroit Medical and Library Association.

Sept 8, 1899.

SURGICAL TREATMENT OF INTERNAL HEMORRHOIDS.

Dr. W. F. METCALF, in a paper on this subject, said in part: The surgical treatment of internal hemorrhoids is satisfactory, but to secure the best results all abnormal conditions of the genito-urinary organs and of the whole digestive tract must be corrected, and in many cases the habits of living must be changed; hemorrhoids are frequently an important etiologic factor in disease, and the methods advocated by many authors are unnecessarily painful. The objections to the method of ligation en masse are that sloughing is produced, that the subsequent pain is too great, that it is unnecessary. The following method in uncomplicated cases is preferable: Thorough physic two days before, and a gentle physic the day before operation should be given, also a high enema the night before and an ordinary one the morning of operation. The patient should be thoroughly anesthetized and placed in the dorsal position, when any genito-urinary work required may be done before the rectum is touched.

The author favors the Pratt speculum. After adjusting the speculum so that a pile tumor presents between the separated blades, the mucous membrane covering the dilated vein extremities is removed with a sharp-pointed scissors curved upon the flat. These vein extremities are then clipped off. If there be but a small amount of fibrous tissue, this is all that is necessary. If the tumor contains much fibrous tissue, it should be cut off smoothly from the surface of the muscle. If a vessel spurts, an artery forceps is placed on it. The other tumors are treated in the same manner. All forceps are now removed, the sphincters gently but thoroughly dilated and the denuded surfaces examined for arterial bleeding. If any points are found they are again secured by fine-pointed artery forceps, and ligated with fine catgut. This ligation is seldom necessary

as the artery freed from the fibrous tissue retracts, and its intima being wounded by the forceps, its lumen is closed. The tags of redundant skin about the anus are then clipped off. A plug of iodoform gauze or of wool covered with silk and dusted with iodoform or other antiseptic powder is inserted. This plug should be removed as soon as the patient is conscious of any pain. Its presence lessens capillary hemorrhage and its removal clears away any small clots which may have formed. Sterile gauze wrung out of water as hot as can be borne should be pressed against the anus until the patient is comfortable, when a larger compress should be secured firmly by a T-bandage. If the patient be a woman, morphin is seldom required after this operation. This method leaves strips of membrane longitudinal to the gut, attached to the skin margin and to the membrane above. From these strips new membrane will develop to cover the entire circumference in about a week. After the first day comfort and cleanliness are ensured by letting a stream of a saturated solution of boric acid play on the parts, the patient being placed on the side, on a rubber pad, and instructed to strain down slightly. Water need not be thrown within the sphincters. It is better not to pass anything into the rectum, until healing is well nigh complete, unless colic is troublesome, which may and should be relieved by passing a sterilized rectal tube. Stool is forced on the fifth day. When this is desired three ounces of carbolized sweet-oil is thrown into the rectum, a seditiv powder given at the same time, and two hours later an enema of a saturated boracic solution. Any irritable tags found around the anal margin at this time should be clipped off after injecting cocaine solution. Where the whole circumference of the rectum is diseased and prolapses, amputation of the redundant mucous membrane by the American modification of the Whitehead operation is advisable. The points necessary to be observed in the operation are: 1. Thorough dilatation of rectal sphincters. 2. Removal of all diseased tissue. 3. Line of incision at skin margin at such a point that mucous surface will not be exposed or skin drawn within the grasp of the external sphincter when healing is complete. 4. Cutting of longitudinal fibers of membrane to be brought down. 5. Freeing and pushing upon the circular fibers which form the internal sphincter. 6. Sutures of catgut which do not pierce the epidermal layer of skin, thus lessening tendency to spasm of underlying muscles. 7. Avoidance of crushing of edge of membrane to be attached to the skin. 8. Dilatation subsequent to complete healing. Observance of these points will insure a satisfactory result.

Methylene Blue As a Sedative in Insanity.

The history of the use of methylene blue in general therapeutics is similar in many respects to that of other auiline compounds. Early reports, backed by commercial interests, were indicative of its value as a general panacea for many of the ills of the flesh, but of recent years it has found an established though restricted field in a limited number of affections. Its value in malaria admits of little doubt and in migraine and other nervous affections evidence is slowly accumulating that will give it a recognized position among the hypnotics.

Recent studies by P. Bodoni of the University of Genoa (*Klinische Therapeutische Wochenschrift*, No. 21, 1899, p. 666) seem to show its wide applicability as a sedative in excited mental states. He reports some fourteen cases in which the remedy was tried; these included such conditions as simple acute mania, mania with furor, periodic mania, chronic mania, and the mania of chronic alcoholism, periodic melancholia, paranoia with delirium, hysteroclepsy, and puerperal mania. In all of these cases the remedy was administered by hypodermic injection into the gluteal muscles, in amount varying from one to one and one-half grains. Its sedative action became manifest within from three to six hours and usually persisted a day or, in some of the cases, even for three to four days. The quieting action was not attended by any narcotic effect and there were no unpleasant after-symptoms observed.

The cause for its action is not definitely understood. By analogy, bearing in mind the use of this substance in technical microscopy by reason of its affinity for nerve tissue (methods of Ehrlich, Nissl, etc.), it would appear that it has a specific action on these tissues during life. This, however, has been denied by some observers who are inclined to class the drug with the blood poisons, acetanilid, etc., and thus explain its pharmacologic action. The author believes that it should take its place with others of the hypnotics, such as chloral, amphenhydrate, trional, and even hyoscyamus.—*Medical News*.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting, of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Those new members of the Association should send their annual subscription direct to the Treasurer, Dr. Henry P. Newman.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street Chicago.

Original communications are accepted with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, SEPT. 23, 1899.

THE MANNER OF INFECTION IN BUBONIC PLAGUE.

The occurrence of epidemics of the plague in various places and the possibility that it may reach our own shores—a contingency which may come to pass at any day—shows clearly enough that this disease has much more than only a historical significance even for us.

Since the recent appearance of plague in India and China, the opportunities presented for thorough and scientific study of the disease have been used to exceedingly good advantage. We know that bubonic plague is caused by a bacillus which is pathogenic for animals, and that some of these animals, especially the rat, play an essential rôle in the local spread of this terribly fatal disease. While it is the accepted opinion that the disease is carried long distances by man himself, either in the person of patients or in infected articles of various kinds, yet the manner of extension in the epidemics thus started does not depend so much on direct contagion as on the intervention of certain of the lower animals.

According to the investigations of Hankin and of Simond¹ the rat certainly is the carrier of infection. The irregular extension in the cities and villages of India can not be explained as due to infection through the air and water. Cases will appear in houses both far and near from original centers of infection, and at the height of epidemics the spread is very capricious. In certain parts of Africa the onset of an epidemic is foretold by the natives from the death of large numbers of rats which then occurs, and when these animals begin to die the natives leave their huts. In Formosa the term "bubonic plague" literally means a disease of rats.

The identity of the disease in rats and in man in such cases has been established bacteriologically. Simond has found that in two cases plague developed in men after epidemics among rats on board ship. Simond also hopes that the recrudescences characteristic of plague epidemics depend on the appearance of new generations of rats.

The next question is: How does the disease spread from rat to rat and from rat to man? While an absolutely satisfactory explanation can not be given at the present time, there are a number of facts which speak in favor of the flea being the principal direct agent of infection. According to Simond, fleas abound on rats sick with plague; bacilli, like the bacillus of plague, have been found in the intestinal contents of such fleas; and the disease has been communicated experimentally to healthy rats through fleas from plague-stricken rats. The flea theory explains satisfactorily the partiality of plague for the inhabitants of the most unhygienic parts of cities, and also the manner in which infection may be carried in wearing apparel.

While this seems to be the usual mode of infection there are also other possibilities to be considered. It has been shown by suitable experiments that infection may occur through the digestive tract, although not readily. But the plague bacillus does not live long in water, and Childs² shows that the mesenteric glands are not enlarged in cases of plague in man. These facts argue against the digestive tract as the usual seat of infection. In the so-called plague pneumonia the infection is generally held to occur through inhalation, because of the principal localization of the bacillus in the lungs, but it has also been shown that the bacillus is readily destroyed on exposure to the air. Hence, it may be concluded that, in the vast majority of cases, infection with the plague bacillus takes place through the skin, the flea and possibly other insects being the most likely immediate carrier of the infection.

Viewed in the light of our present knowledge of the manner of infection it is quite apparent that certain districts of our cities, especially the larger, offer favorable conditions for the spread and maintenance of the plague should it ever be introduced. The preventive measures are to be directed against rats, parasites, and man. Simond recommends that ships should be fumigated so as to asphyxiate the rats, which should be treated with boiling water before removal and then other familiar methods of disinfection should be thoroughly employed.

INSUFFICIENCY OF THE LIVER.

The results of recent investigation would seem to indicate that the metabolic function of the liver is far more important than its secretory function—to make a literal rather than a scientific distinction. The pancreatic juice, in conjunction with the gastric and the intestinal juices, seems fully capable of satisfactorily

¹ Annales de l'Institut Pasteur, 1898, xii.² British Med. Jour., 1898.

affecting the processes of digestion without the aid of the bile, but failure in the metabolic activity of the liver results at once in the development of symptoms of intoxication. These disturbances are, as a rule, unattended with appreciable anatomic alterations, and are thus beyond actual demonstrative proof. In addition to the secretion of bile, the liver stores up glycogen, takes an active part in the formation of urea, and removes or neutralizes poisons contained in the portal blood and largely derived from the gastro-intestinal tract.

In a suggestive communication on hepatic insufficiency, Pick¹ discusses four states that he considers dependent on this condition: catarrhal jaundice, cholelithiasis, the uric acid diathesis and diabetes.

With regard to catarrhal jaundice, it has been assumed that functionally deranged liver-cells may return to the blood biliary constituents that they had previously secreted, and it has been thought that such a state of affairs might be brought about by either abnormal irritation of the secretory nerves of the liver or the presence in the circulating blood of toxic substances derived from without or generated by intestinal or pathogenic bacteria.

The formation of biliary calculi, which consist principally of cholesterin and biliary coloring matter in combination with calcium carbonate, is attributed to secretory disturbances, as it has been experimentally found that such concretions can—on long exposure to the action of the bile—be dissolved in the gall-bladder of dogs after ligation of the cystic duct.

Many cases of the uric acid diathesis may be viewed as an expression of hepatic insufficiency, from failure of conversion by the liver-cells of ammonium carbamate into urea, in consequence of the presence in the portal blood of toxic substances, derived from the intestinal tract. This explanation, also, may be applicable to many cases of neurasthenia attended with increased elimination of uric acid; and to the transitory or alimentary glycosuria and even mild diabetes occurring under like conditions, and attributable to failure on the part of the liver to retain its glycogen. Cases of diabetes in which the amount of sugar in the urine increases on a nitrogenous diet, with restriction of carbohydrates, may be looked on as dependent on hepatic insufficiency.

It is thought that hepatic insufficiency may be congenital or acquired, and that in the development of the latter variety intoxication from the intestinal tract plays a most important part. The ability of the liver to neutralize this intoxication is limited, and will vary with the character and the amount of the poisons generated. Insufficiency of the liver may be due also to organic disease. When due to intoxications from the intestinal tract and manifested by catarrhal jaundice, cholelithiasis, diabetes and the uric acid diathesis, alkalies yield most useful therapeutic results, and among these sodium salicylate has especially proved of service. Mineral waters may be taken with advantage, and further in-

toxication is to be prevented by making the diet a mixed one and restricting proteids in favor of carbohydrates, and increasing the motor activity of the intestine by mechanical and chemical means.

EOSINOPHILOUS BRONCHITIS.

The establishment of an eosinophilous bronchitis, by Hoffmann of Leipzig, rests on the occurrence of a bronchial catarrh in which the sputum is exceptionally rich in eosinophilous cells. The condition is now described somewhat more fully as a more or less distinct disease, by Teichmüller¹. Nothing is as yet known concerning its pathologic anatomy, because the disease is not fatal, and opportunity to study the morbid changes can only be secured through some accident. The real cause and the exact nature of this disease, as well as that of asthma, are unknown. The disease is a form of chronic bronchitis which, when undisturbed by treatment, is characterized by intermissions of good health; the patients do not suffer very acutely, and consequently they do not as a rule seek the aid of a physician until some time after the beginning of the symptoms. The complaints then made resemble wholly some of those characteristic mild degrees of asthma and of emphysema, or of any other form of bronchitis. There may be a more or less well-marked dyspnea. Whistling rhonchi associated with prolonged expiration are said to be frequently present over both lungs. Cough is rarely absent. The expectorate is transparent, slimy, rather thin and it does not resemble the thick, viscid asthmatic mucus. The especially characteristic peculiarity of the sputum is the presence of numerous eosinophilous cells, not only in but also between the little masses of mucus which have been spread out on the slide. In suitably stained preparations (0.5 per cent. alcoholic solution of eosin and saturated solution of methylene blue) these cells may be so numerous as to form red foci which are visible under very slight magnification; the only other disease in which they occur in such numbers is asthma. Typical Curschmann's spirals are not present, but rudimentary spirals without the central thread are occasionally observed. Fever is rarely present. The patients commonly complain of general weakness.

The diagnosis is easy for the physician who is in the habit of examining the sputum of all patients who present symptoms pointing to the respiratory tract. He who has no time for examining the sputum can not with certainty diagnose eosinophilous bronchitis; such cases, as well as cases of beginning tuberculosis will often pass through his hands under an erroneous diagnosis. The differential diagnosis between eosinophilous bronchitis and asthma is not difficult provided the conception of asthma be limited to attacks of dyspnea with peculiar expectoration and emphysematous distension of the lungs.

The prognosis is good in all cases that live under reasonably good hygienic conditions. Gymnastic and

¹ Wiener Klin. Wochn., April 8, p. 697.

¹ Deutsche Arch. f. Klin. Med., 1899, 63, 444.

hydrotherapeutic directions suffice for treatment. Short, cold douches or warm baths followed by cold sheets must be used. The only drug to be used is iodid of potassium in those cases in which there is reason to believe that the bronchitis in some way rests on a luetic basis. Teichmüller emphasizes the necessity of measures to improve the general physical condition of the patients.

UNIFORM MEDICAL LEGISLATION.

Last June the Wayne County Medical Society—Detroit, Mich.—appointed a committee for the purpose of initiating a movement looking to the creation of a national board of health or, in some way, to secure uniform legislation in every state. The committee made its report on September 14, and in its report says that it sent circulars to fifty-one states and territories, in which replies were asked to seven questions—the most important of these being as follows:

“Would you be inclined to favorably consider the plan of entering into a state of reciprocity with other states which have practically the same requirements for the license of practicing medicine as your state has?”

“Would you join in the efforts in working out a memorandum to be presented to the legislative bodies of the different states with the view of introducing a bill as to the subject-matter, and would your secretary co-operate with us?”

The committee received answers from thirty-six states and three territories. Thirty-four of the answers were favorable, showing almost unanimity. The unfavorable answers were accompanied by explanations which made it not at all impossible to overcome the difficulty. While the committee recognizes the existence of the National Confederation of State Medical and Examining Boards, it believes that the state medical societies of the country ought to act separately, at least at the beginning. As the committee was instructed to continue, we hope it may be able to accomplish its object so that all states shall have like medical laws, with reciprocity. There is certainly a need of a different system of licensure for the control of medical practice than the unequal one that now exists in the different states. It seems hardly just to compel a physician who desires to move from one part of his own country to another, to pass an examination when that move happens to carry him into another state. Few men, no matter how well qualified, are able to pass a fairly good examination in all the fundamental branches. A technical knowledge—that which can be expressed in words—of all such fundamental branches as anatomy, physiology, chemistry, etc., is held by but few men. Men in special lines of work are more decidedly liable to get rusty in other branches, and would make sorry work of passing an examination that would have been easy in their early professional life. The possibility of doing away with this anomaly in our system of regulating the practice of medicine is not hopeless. It must come, however, through concerted action on the part of the different

states, national legislation on the subject being probably unattainable. To accomplish this reform a central body must be created, through which the different state bodies shall act, and this central body must be created by the states themselves. The first thing to be done, therefore, is to get each state to take action, and this, as we understand it, is what the Wayne County Medical Society is attempting to do. One thing must be recognized at the beginning, however, and that is that the united action of the states will only come by raising the standard in those states that have now too lax a law, and not by a retrograde movement on the part of any. It might be well to here call attention to a resolution adopted by the AMERICAN MEDICAL ASSOCIATION at its meeting in 1894, viz.: “That we request the state societies to unite in establishing a uniform standard of professional requirement for admission to the practice of medicine, and to aid, as far as possible, in advancing the scientific status of the same by the appointment of state examining boards independent of the teaching faculties of medical colleges.”

BOVINE VS. HUMAN TUBERCULOSIS.

Dr. Edward Moore, a prominent veterinary surgeon of Albany, N. Y., published in the last two issues of the *N. Y. Medical Journal*, a rather long article on human and bovine tuberculosis. In this he takes a position directly in opposition to that of leading sanitarians of the day, in that he holds that bovine tuberculosis is not transmittable to men, and vice versa, and that the bacillus has become so modified by habitat as to become specifically distinct. In support of this view, besides his own experience and observation for many years, he quotes Dr. Theobald Smith, certainly no mean authority, who has expressed himself as recognizing, at least provisionally, a distinction between the respective germs of human and bovine tuberculosis. Dr. Moore denies that there has been any positive or satisfactory evidence of the transmission of bovine tuberculosis to man, or from man to cattle. Dr. Cooper Curtice, in 1897, examined some 210 cattle in the vicinity of the Saranac Lake Sanitarium, feeding in the pastures where the aggregated consumptives took their exercise, and found no tuberculosis. He also published letters from various persons of wide experience and observation, including the veterinarian of the Massachusetts Agricultural College and the director of the New Jersey Agricultural Experiment Station, who testify in accordance with his views. Dr. Moore's publication is likely to call attention to the need of more thorough study of this subject, and to the fact, if it is such, that satisfactory evidence of intraspecific transmission of tuberculosis between man and cattle is still lacking. It is surprising, indeed, if this is so, since physicians and public health authorities have been acting constantly and consistently as if the reverse were true.

HOW SHALL THE NEW REMEDY BE RECEIVED.

The new remedy, to be of value to the busy practitioner, must be accompanied by the report of careful

studies as to its mode of action and its therapeutic indications. Who shall furnish this? The pharmacologists alone after painstaking experiment may authoritatively report on the physiologic action of the new product. These are not numerous, and, excepting a few now finding a place in the schools, can hardly thrive beyond the confines of the laboratories of the great manufacturing pharmacists. As a rule the profession may safely rely for pharmacologic information on the reports of the experimenters employed by the large manufacturers. In the future, however, the laboratories of the schools will contribute largely to unbiased pharmacology. The physician with an extensive hospital service is best able to effectively determine the therapeutic value of the new drug. It is the rule to look askance on the laudatory clinical report from the unknown practitioner of the small village. This is not because the small place has a monopoly on cupidity, for it is well known that the venal of all ranks tend strongly to congregate in the cities, but unfortunately because experience teaches that the majority of these testimonials come from obscurity. At times this is due to the non-existence of the accredited writer, again to the overwhelming need of some who are not overscrupulous, and again to the vanity of the would-be shining light. Obscurity nearly always indicates lack of adequate opportunity to render judgment of value, even when the requisite ability to draw valid conclusions from well-established observations is not lacking. Hence, the only reports of the properties of new remedies to which the physician should give heed are those emanating from pharmacologists of established reputation and from clinicians of known wide opportunity and unquestioned probity. By adhering to this rule the profession will compel the manufacturer to produce such evidence and the common and outworn testimonial will be condemned to well-merited oblivion.

THE PRESENCE OF DIPHTHERIA BACILLI IN HEALTHY PERSONS.

The statement that a micro-organism can be regarded as the cause of a definite disease only when it is found exclusively in the disease in question, which must then be present, has long ago been modified. We know that the presence of the cause of a disease does not necessarily mean development of the disease, because there are conditions which prevent this. A bacterium may therefore be regarded as the cause of a certain disease when it is constantly found in connection with the disease, and as a rule only in this disease. It is assumed that the occurrence of the bacterium without the development of the corresponding disease is relatively rare. This question has rapidly come to the fore in connection with diphtheria. We know that the bacillus of diphtheria is found in the bodies of patients free from diphtheria, as well as in absolutely healthy persons. Recently Kober¹ reviewed the literature bearing on the distribution of the diphtheria bacillus on the mucous membrane of the mouth and pharynx of healthy persons. The facts reported in the literature show that the dip-

theria bacillus has been found in persons who have not come in contact with diphtheria patients—in 7 per cent. in the investigated cases. Kober studied 600 persons and found the diphtheria bacillus present in 2.5 per cent. In 15 of these, close examination revealed that the persons had come in more or less intimate contact with diphtheria patients, so that the occurrence of diphtheria bacilli in the oral cavity of individuals who have not come into contact with diphtheria patients is reduced to 0.83 per cent. All the cultures from the first set of cases were pathogenic to animals, none of the last set were. The observations recorded in the literature would indicate that diphtheria bacilli occur in the oral cavity of 18.8 per cent. of persons associated with diphtheria patients. Kober carefully investigated 123 persons who were in more or less close relation to the disease, and found the bacillus only ten times, that is to say, in 8 per cent.

PUBLIC ACCUSATIONS AGAINST HOSPITALS.

A medical officer in New York City has recently made a public accusation against the surgical staff of the local hospitals, that operations are needlessly and carelessly performed in these institutions. The charge has naturally been resented, not only by the accused surgeons but by at least one of the leading lay papers, which editorially takes up the gauntlet in favor of the hospital staffs. The accusation appears to have been a general one, though, so far as stated, it is based on the coroner's physicians' interpretation of a case where he claims the diagnosis was wrong and the operation unnecessary, and another where he charges neglect in a case of fractured skull. It would seem, at least, an inconsiderate act for a physician holding an official position to offer general criticism involving, as it were, the professional character of men whose standing in the profession is certainly higher than his own, without ample proof to support his assertions. There does not appear to be any very adequate grounds so far as the facts have been published for even suggesting any mistake, much less any needless recklessness on the part of the operating surgeon. If the criticism is aimed at the regular visiting staff of the great hospitals of a medical center like New York City it has of itself little weight, for it is the condemnation by a comparatively obscure medical man of the leaders of the profession. Much more than his mere assertion will be needed to give it credence. If it is aimed at the house staffs, the same is true, for they are under the direct supervision of these leaders, and a derogation of the one implies that of the other also. The apparently wholesale character of the accusation also makes it really undeserving of serious consideration, except in so far as it is likely to have the effect of impairing public confidence in the public and private charitable institutions. Where these are not demoralized by the political control, one may naturally question the unfavorable opinions of a political appointee in regard to them. It is, as Dr. Shradz says in a published interview, not only unprofessional but also against public policy that the confidence in our hospitals and in the ability of the hospital attendants should

¹ Zft. f. Hygiene und Infektionskrankheiten, 1896, xxxi.

be inconsiderately questioned. In no other country is it so common to exaggerate faults and "wash dirty linen" in public as it is here, and there are some, we regret to say, that appear to consider it meritorious to besmirch and defile, in order, it would seem, only to exploit their own self-righteousness. Reckless accusations, generally applied, can sometimes be thus best interpreted.

QUARANTINE OF THE TUBERCULOUS.

The California State Board of Health has, it is stated, unanimously passed a resolution to the effect that it consider the propriety of quarantining against the entry of human beings or domestic animals suffering with tuberculosis. It is to be hoped that this consideration will be thorough and deliberate, and that no hasty action will be taken. At the present time many of us can hardly be said to be in a judicial state of mind on the subject of tuberculosis. The pendulum has swung nearly or quite to the extreme in one direction, as shown by the statements made in the lay and medical publications of the day, in regard to the excessive contagiousness of the disease and the ratio of deaths from this cause in the general mortality. We have repeatedly seen it stated that consumption is the most contagious of diseases, that it is responsible for one-third of all deaths from all causes, that it did not exist in various regions until carried there by health-seekers, that trained nurses would rather care for smallpox patients than for consumptives, with other still more extreme utterances given out from time to time. The result is a sort of medical panic which is being transmitted to the public, and the consequences of which may be serious injustice and hardship to an already afflicted class. So far as we have been able to ascertain, consumption is not in the proper sense of the word *highly* contagious. We find that in most civilized countries its mortality does not exceed from 9 to 12 per cent. of the total, and, considering all things, more nearly the smaller than the larger figures; that it has existed more or less in nearly all regions; that its increasing death-rate in health resorts is largely due to the immigration of diseased individuals, and would be mostly confined to them if ordinary reasonable precautions were observed, and we have never yet met a nurse who preferred the contagion of smallpox to that of tuberculosis, even though protected by vaccination. Consumption does not spread from well conducted sanatoria, as is shown by experience. Why should the residents in a climate like that of California, where those infected with tuberculosis go to recover, suffer unduly from the disorder unless they neglect the needed precautions? And if this be so, why should they deny the benefit of it to those to whom it is supposed to be physical salvation? The resolution is not in the line of medical progress or philanthropy, nor do we believe it to be in the line of true sanitation. To make an effective quarantine against tuberculosis, not only the openly manifest cases of tuberculosis must be excluded, but the incipient and latent ones also, and this would be a task beyond the abilities of any state authorities. It would be more effective as well as humane to regulate unsanitary habits and conditions, prevent indiscriminate expectorations in public conveyances and rooms, use proper methods of disinfection,

where needed, and instruct the public as to the proper care of themselves, than to create a panic by proposing wholesale quarantine and exaggerating the danger and contagiousness of the disease. We have learned that it is contagious or infectious, or both, to a certain degree, but we have also learned that its contagion or infection is ineffective in nine cases out of ten, or we should all be its victims. Perhaps we should better say it is ineffective in 999 cases out of 1000, for we must all be almost daily exposed to it in our large centers of population. Under such circumstances, while doing everything that is reasonable to check the scourge, why should we excite exaggerated fears and call for inconsiderate and panicky legislation. If California is really becoming dangerously infected with tuberculosis, its authorities can publish the fact and save the expense of quarantine: the publication would be just as effective as the other. Heretofore it has only disseminated far and wide the accounts of its glorious climate for pulmonary invalids, and the course now suggested will, if adopted, seem to the world a surprising change of front.

Medical News.

THE HEALTH Board of Detroit, Mich., is endeavoring to suppress faith healers in that city.

THE SPANISH *Illustracion* suggests supplementing the military cordon around Oporto with a cordon of cats.

PROFESSORS Froesch and Kossel of Berlin have been sent by the German Government to study the plague at Oporto.

THE EVANSTON (Ill.) hospital has established a training school for nurses in connection with the regular work of the institution.

DR. A. RAVOGLI, Italian Consul for Cincinnati, Ohio, has just returned from Europe. While abroad he was knighted by King Humbert.

It is reported that the managers of the Chester County (Pa.) Hospital have started a movement for the erection of a home for nurses, to cost \$5000.

BY THE will of Philip Gruner, whose death recently occurred in Germany, a provisional bequest of \$1000 has been left the German Hospital of Philadelphia.

THE NEW chapel of the St. Joseph's Hospital, Bloomington, Ill., was formally dedicated September 14. The cost of the building with its furnishings was \$9,000.

THE AUTUMN maneuvers of the French army have been omitted this year on account of a serious epizootic of foot and mouth disease prevailing in the regions selected.

DR. JOHN C. WISE, fleet surgeon to the command under Admiral George Dewey, will be the guest of honor at the eighth annual convention of army surgeons, Kansas City, September 27-28.

DR. L. M. ALLEN, for the past six years connected with the Maryland University Lying-In-Hospital, has been appointed associate professor of obstetrics in the University of Maryland School of Science.

OWING to the resignation of Dr. Charles B. Penrose, as professor of gynecology in the University of Pennsylvania, last spring, this chair is still vacant. There are said to be sixteen applicants for the position.

A GERMAN daily states that Professor Quincke of Kiel sent in his resignation as chief of the medical clinic.

because the faculties and accommodations are so inadequate and his repeated protests have been persistently ignored.

THE **FREDERICK DOUGLASS** Memorial Hospital—colored—Philadelphia, has issued an appeal for subscriptions looking toward the purchase of a site and the erection of a larger and modern hospital building. The sum asked for is \$75,000.

UNIFORM nomenclature of the causes of death was one of the subjects exhaustively discussed at the Biennial International Congress of Statistics, which opened at Christiania, September 4. The chief address on the subject was by Bertillon.

A **DESPATCH** states that Ambassador Choate has advised the State Department that Her Majesty's Secretary of State for War has accepted the invitation of the Military Surgeons of the United States, and has deputed Mr. McWaters, R.A.M. Corps, to attend.

A SINGULAR case of death, illustrative of the danger of keeping household pets in living rooms, is reported from Washington, D. C. A parrot of mischief-making proclivities removed the lava tip from a gas burner and as a result caused the asphyxiation of a young woman of 23 years.

THE **MEXICAN** Academy of Medicine has offered a prize of \$500 for the best work on either exploratory laparotomy or tuberculosis, or both. Competing articles must be in Spanish, and be received by the secretary, L. T. Alcalá, Cuadrante de Santa Catalina, 12, before October, 1900.

A SUITE of rooms has just been completed at the University of Pennsylvania Hospital, specially constructed and equipped with all the modern apparatus necessary for operations. The suite consists of an operating-room proper, a recovery-room, and one exclusively for the surgeon's use.

THE **NEFF** Home for Convalescents, situated at Price Hill, Cincinnati, Ohio, has just been opened. The accommodations are limited to twenty. It is purposed to carry out the principles of the Weir-Mitchell rest cure. Dr. Frank Hendley, late superintendent of the Cincinnati Hospital, will be in charge.

WE NOTE that *El Progreso Medico* of Havana, Cuba, speaks most enthusiastically of the great work accomplished by Dr. C. K. Furbusch of the American army, in reorganizing the hospitals of Havana and founding a training-school for nurses, in the short space of three months before he was transferred to Manila.

DR. DANIEL R. BROWER of Chicago addressed the Buffalo (N. Y.) Academy of Medicine, September 12, by invitation, on the "Medical Aspect of Crime." There were present, as guests of the Academy, a number of prominent lawyers and clergymen. The doctor urged the asexualizing of the habitual criminal.

PROF. SIMON FLEXNER, who recently severed his connection with the Johns Hopkins to assume the chair of pathology in the University of Pennsylvania, as noted in the *JOURNAL* at that time, and who for the past few months has been studying tropical diseases in the Philippines, has returned to Philadelphia to assume his duties at the opening session.

BY THE WILL of the late Judge Richard Prendergast, Chicago, a "rest-cure home" will be founded for the benefit of persons suffering from nervous disorders. The institution will occupy the former summer residence of the donor, consisting of 150 acres at Wheaton, Ill., and will be in charge of a community of Sisters of Char-

ity. It will be known as St. Winifred's Rest, in honor of the wife of the testator.

TO ESCAPE the strict quarantine measures, the captain of the *Albertville*, arriving at Antwerp from the Congo, had a couple of negroes suffering from smallpox thrown overboard. A passenger reported the occurrence to the authorities, but the captain managed to escape to England. The Belgian Government has requested his arrest.

THE SIXTH annual meeting of the Detroit (Mich.) Physicians' Protective Association was held September 12, and reports submitted showing the organization in a very satisfactory condition. Officers were elected as follows: President, Guy L. Kiefer; vice-president, D. L. Walmsley; secretary, A. P. Bidde; treasurer, S. H. Knight.

THE EIGHTEENTH annual session of the College of Physicians and Surgeons, Chicago—Medical Department of the University of Illinois—opened September 19. Other medical institutions which have begun their winter's work are the Kansas City Medical College, and the University Medical College, Kansas City, Mo., and the Medico-Chirurgical College of Philadelphia.

DR. JOHN G. REED, Cincinnati, Ohio, has issued a letter to the Cincinnati and Hamilton County medical fraternity, calling on physicians to band together and demand representation in the legislature, declaring that there should be one doctor elected to the legislature for every lawyer sent there. Dr. Reed advocates a political-medical organization with the hope of securing to the profession and the people the wise legislation so long contended for by the leading physicians of the state.

A BOLD robbery took place at the St. Joseph's Hospital, Philadelphia, during the past week. Owing to great improvements now going on at that institution, and the large number of employees about a burglar gained entrance to the office during the noon hour, broke open the office desk, and appropriated \$45. The man was seen entering the building and told one of the employees that should anyone inquire as to his whereabouts, he could be found on the roof, and so passed as an employee.

A PRELIMINARY meeting has been held and officers elected, the purpose of which is to form an association having for its object the erection of a hospital for orthodox Jews in Philadelphia. The initial meeting was composed for the most part of contributors to an orphan asylum now in existence in the lower section of the city, in which locality the proposed building will be erected. It is now proposed to hold a mass-meeting for the purpose of bringing the subject more properly before those who sanction the movement.

IN AN address before the recent German-speaking congress of anthropology, Virchow called attention to the dangers of substituting the "traditions of opinions" for the "traditions of facts," observing that they are especially misleading in anthropology and the sciences to which it is the handmaid. He ridiculed the way in which anthropology seems to have concentrated and restricted its attention to the skeleton, as if there were no nobler parts of the organism: "mutability of the type is far more important in respect to the brain and muscles than to the skeleton," adding that pathology is merely physiology under difficult circumstances.

DR. BRANDETH SYMONDS, medical examiner of the Mutual Life Insurance Company of New York, suggests that a course of six lectures be given in medical

colleges on "Instruction In Life Assurance Medicine," as follows: 1. Some instruction in vital statistics and the fundamentals of life insurance. 2. The relation of the examiner to the company and the applicant. 3. The facts concerning each disease, which are of importance from a life insurance standpoint. 4. Habits, occupations and employment. 5. The family record and heredity. 6. The physical examination, particularly with reference to the distinction between essentials and non-essentials. 7. The relations of examiner to the agent. 8. Frauds and fraudulent practices.

A MOVEMENT has been started among Philadelphia women, the aim of which is to wage war on disease, and its prevention by practical rules of hygiene. A meeting has been held, organization effected and a charter applied for. The organization will be known as the "Woman's Sanitary League of Pennsylvania." Its purpose is the advancement of sanitary science, the promotion of public health and good government, and the forming of country and local auxiliaries to extend the beneficial work. It is stated that the action of the St. Louis Board of Health in requiring the disinfection of all such materials as second-hand books and clothing is the precedent with which the committee presents its plan to the Philadelphia authorities. The subject of schools and school children, expectation, and the summer diseases of childhood will all come in for their share of consideration.

AS A RESULT of a series of experiments on dogs, turtles and frogs, Dr. Richard H. Cunningham of the Vanderbilt Clinic, New York City, has, it is said, come to the conclusion that death in the case of the electrocuted is not due to paralysis of the heart, but to fibrillary contraction of that organ, which results in collapse of the nervous system. In all cases of this character, it is claimed, death is preceded by a period of consciousness, during which the recipient of the shock feels, but without the sensation of pain. In seemingly sudden death from shock due to powerful currents, it is stated that the thorax in the case of the lower animals has been opened and the heart found still beating. From these experiments one would be led to the belief that persons coming in contact with charged electric wires might be resuscitated by appropriate remedies, "such as creating artificially a temporary circulation of a fluid capable of sustaining the heart and the nervous system until the heart has recovered sufficiently to maintain the circulation in the normal manner."

ACCORDING to the *Gazette Médicale de Paris*, Dr. Jorge, the director of the bacteriologic institute at Oporto, reported to the government early in July what he believed to be cases of the plague, and officially informed the authorities of the existence of the plague in Oporto, the 28th, but the epidemic was not announced by the government until August 15. Telegrams despatched by Spanish physicians resident in Oporto were not received by the addressees, and it is supposed they were detained by the authorities. The schools have been closed and all the navy medical officers who have had experience with the plague have been ordered to Oporto. The merchants and populace are furious against Dr. Jorge, and he has been obliged to be protected by a military escort when he appears on the street; several persons have been wounded in the manifestations against him. He has received more than fifty threatening letters. Dr. Heppenitz has been sent from Russia, by the Russian Plague Preventive Society, with 2000 vials of plague serum, and offers to establish a "serum fac-

tory." Despatches from St. Petersburg also announce that the plague has broken out in Samara, in south-eastern Russia, and the town of Tsarytzine has been surrounded by a military cordon.

Correspondence.

The Third International Periodical Congress of Obstetrics and Gynecology.

(Delayed Correspondence.)

AMSTERDAM, Aug. 16, 1899.

This delightful metropolis of the land of the sea has been the scene of interesting events to those who, during last week, were attendants on the Third International Periodical Congress of Gynecology and Obstetrics—a stately title, and one which everybody of course immediately contracts into "the Gynecology Congress," as it should be in this age of telegraphic brevity. But stately and solemn-sounding as was its title many came from many lands. It was interesting here, as in all similar international events, to see Kieff and Chicago, Tokio and Toulouse, Manchester and Madrid, Helsingfors and Rome, Stockholm and Nice, Paris and New York, Bucharest and Brussels, to say nothing of Barcelona and Cincinnati exchanging greetings with each other, and thus widening that amity which places the great profession of medicine above personal and political considerations. It was pleasant to feel that the civilized world as represented by the most advanced nations exemplified this lofty conception—and yet Germany was not there. Germany, the next-door-neighbor, sat on the fence and made faces while the splendid procession was marching to the tune of progress. Amsterdam and Griefswald did not exchange greetings. It seems that some time some Germans had been selected to fill some vacancies in some universities in Holland. Then some more Germans became candidates. Then some Dutchman had the temerity to intimate something about the propriety of Dutch professors for Dutch universities. This seemed to be very offensive to German professors, who could not understand why, if German interests so demanded, every professor of every other nationality should not quietly and smilingly remove himself from the face of the earth. Well, it so happened that the Dutchman who said something about Dutch professors for Dutch universities was selected by a Dutch committee on organization, to an important official position in a congress to be held in the Dutch metropolis. *Voilà!* Germany was in a huff. Everybody in Germany was personally offended. What would appease this righteous wrath? Could it be done? Yes, and easily. Holland might retain the congress and pay the expenses, but the Holland Committee on Organization and the Holland president would kindly efface themselves and Germany would confer on the *Paye Bas* the great distinction of furnishing the entire official personnel of the congress. It was about this time that a few of the corpuscles—good red blood-corpuscles of William of Orange—were found floating around in the little kingdom of the beautiful Wilhelmina, and Holland went on with the task herself, laboring all the while under the freezing frown of German disfavor. Well, never did a country extend to a scientific gathering such hospitality; never were better papers presented or more thoroughly discussed; never was there more enthusiasm; never were absentees missed so little.

The Congress was opened in the classic halls of the Ancient University of Amsterdam, with a scholarly address delivered in French, German, English, and Italian, by the learned president, Professor Treub, the trend of whose remarks was in the direction of conservatism. The audience was made up of representative men from practically every advanced country in the world. There were numerous representatives from the United States, among whom I noticed Drs. A. and E. A. Vander

Veer, Albany, N. Y.; Janovin, New York City; H. Gordon, Portland; A. Palmer Dudley, New York City; J. H. Carstens, Detroit, Mich.; J. M. Baldy, Philadelphia; G. J. Engelman, Boston; E. P. Davis, Philadelphia; L. H. Dunning, Indianapolis, Ind.; Clinton Cushing, Washington, D.C.; J. M. Withrow, Cincinnati, Ohio; A. F. A. King, Washington, D.C.; A. Goldspohn, Chicago; Geo. M. Edebohls, New York City; Henry D. Fry, Washington, D.C.; Ernest Laplace, Philadelphia, and H. Tuholsek, St. Louis, Mo. It is doubtful whether any other country outside of Holland and France had a larger delegation or a more interested one.

ALEXANDER'S OPERATION.

It is not within the purpose of a letter, such as this, to give a detailed account of the proceedings of the Congress, or to anticipate the publication of any of the valuable papers by giving a résumé of their contents. It may not be improper, however, to state that one of the earliest events of interest was the discussion of the paper by Dr. Goldspohn, in the course of which there was a free debate as to the present status of the Alexander operation. The special point of interest was the personal participation of Dr. Alexander himself in the debate. Tall, unostentatious, frank and commanding, this splendid type of the honest professional man quite captured the convention, by stating in effect that Alexander's operation was devised at a time when opening the peritoneal cavity was a more serious matter than at present, and that, therefore, much of the reason for its performance had passed away. He stated further that it ought not to be performed in irreducible retrodisplacements of the uterus, nor in those cases in which clearly reducible displacements are complicated with organic disease of the uterine appendages. In cases that fall within these limitations the comparatively simple operation is quite sufficient to effect a cure. It is needless to say that this clear statement of the purposes and limitations of the operation by its author served to place it on a more definite footing than it has heretofore enjoyed. I can not recall any person who has so much excuse as Dr. Alexander to plead for rescue from his friends, particularly from inconsiderate imitators in America, who are daily perpetrating a misapplication of his principles while they and the world are naturally holding him responsible for the unfortunate results.

OVARIAN PREGNANCY.

A very interesting report on the much-disputed ovarian pregnancy was presented by Mlle. Catherine van Tusschenbroek of Amsterdam, who also demonstrated a specimen which she had procured from the clinic of Professor Kouwer of Utrecht. The operation had followed rupture, with extensive hemorrhage into the peritoneal cavity, which occurred six weeks after the patient's last menstruation. At the time of the operation the uterus was found enlarged, the left ovary and tube normal, while at the right ovary was found a tumor as large as a walnut, to which blood-clots adhered. The right ovary and tube were removed. The tube was quite normal; the fimbriae were somewhat conglutinated, but the lumen was free. Pathologic adhesions between the ovary and the tube did not exist. The tumor and the ovary showed, near the top, the place of rupture, from which a ruddy fringe came forth. After being hardened the specimen was opened by a median section going through the fringed opening. By this section the gestation sac in the tumor was cut in two halves and an embryo appeared of about 12 mm. in length, fixed by a short and thick umbilical cord. Macroscopic inspection left no doubt that the case was one of ovarian pregnancy. Microscopic investigation showed that the impregnated ovum had developed within a Graafian follicle. That was proved by the fact that the wall of maternal tissue which surrounded the ovum showed the structure of the ruptured Graafian follicle—the well-known corpus luteum. Decidual transformation of the connective tissues in the ovisac was nowhere to be found. The fetal ele-

ments were quite the same as in normal uterine placentation. The fetal villi showed the plump and irregular forms which belonged to this early stage of pregnancy. Their epithelial investment consisted of two layers—Langhans' cells and the syncytium. The latter was in many places ciliated. The conclusions which Mlle. van Tusschenbroek came to were as follows: 1. Ovarian pregnancy was a fact. 2. Ovarian pregnancy meant pregnancy in a Graafian follicle. 3. The wall of the pregnant Graafian follicle not being transformed into decidual tissue they must conclude that for the implantation of the ovum Webster's decidual reaction was not a *conditio sine qua non*. 4. One piece showing a regular development of characteristic syncytium, they had a new and incontestable proof that syncytium had nothing to do with uterine or tubal epithelium and was an offspring of the fetal ectoblast.

FIBROMYOMATA, ETC.

The questions formally discussed were fibromyomata, antiseptics and technic, influence of posture on the size of the pelvis, and comparative indications for symphyseotomy, Cesarean section and artificial delivery. None of the Germans were present to read their promised addresses, but the gaps thus caused were easily bridged. There was a general chorus in favor of the abdominal route for operations, except for incipient cervical cancerous lesions, etc. Symphyseotomy found several champions. Doyen delivered one of the addresses on the surgical treatment of fibromyomata. He considers phlebitis, albuminuria, intestinal occlusion and malignant degeneration of the fibromatous uterus, imperious indications to operate. He restricts the vaginal route to a mobile uterus in multiparæ or extremely obese subjects. Since he has been using his crushers and substituted ligatures for forceps he has performed hysterectomy 52 times for fibromyomata: 27 vaginal, all recovered; 25 abdominal, all recovered but one, with complicating phlebitis of the limbs and calculus appendicitis. Schauta restricts the vaginal route to tumors which do not extend beyond the umbilicus and can be pushed down into the small pelvis. He operates only after failure of all other means to arrest accidents due to the tumors, and discountenances all curteting, supravaginal amputation and ovarian castration for fibromyomata. Delagenière reported five cases effectively relieved by the simple process of ligating the uterine arteries: no recurrence of the tumors during the three to one year since. The tendency of the Americans, Baldy, Carstens, and Tuholsek seemed to be in favor of supravaginal amputation in certain conditions, in which Treub and others concurred. Gordon expressed his disapproval of myomectomy as an insufficient operation. Treub reported a number of successes attained with injections of ergotin and electricity alone, which he advocates for more general adoption. He considers supravaginal ablation with a buried elastic ligature, the chosen method, and has followed it in 31 cases, with three failures.

POSTURE.

The addresses on posture were by Pinzini, Bué, and Walcher. The latter claims to have been the first who ever noted the influence of position on the size of the pelvis, and especially in the position with the legs hanging, or hyperextension. But Bué traces the first study of the subject to Crouzat. Pinzini reported tests with 102 parturient women, which established that assuming, in turn, the lithotomy position and then hyperextension, the promonto-subpubic diameter increased from 2 to 17 mm., averaging 7.5. Changing from the lithotomy to the obstetric position, the increase was 0 to 5 mm., and from the latter to hyperextension, the increase was from 2 to 12. The increase in the conjugate diameter from the obstetric to hyperextension, is larger with a deformed pelvis, averaging 8.7. The coccygo-pubic diameter in cadavers decreases 5.6 mm. on an average, changing from the first to the second position, and 9.2 from the second to hyperextension, a total of 9 to 26 mm. Pinard's experience has been that in 10 per cent. hyperextension does not enlarge the pelvis, and that in the rest the average

increase in the diameter is but 3 mm. Pestalozza observed that the small average of 5 mm. increase attained by hyperextension in his experience does not account for the undeniable clinical benefit derived from it, and he suggests that possibly the lowering of the symphysis, which he measured on cadavers and found averaged 3 cm., may be a factor in the result attained.

TECHNIC AND ANTISEPSIS.

In the discussion of technic, Doyen stated that after operations when he anticipated infection, he covered the patient with ice from the nipples to the pubis. He disinfects the region with very hot water, soap, sublimate and phenol at 2.5 per cent., and now uses glutol exclusively for his dusting powder. Richelet used to ascribe certain deaths, he stated, to "lack of resistance of the subject," but he now rejects this excuse and considers them all due to infection.

SYMPHYSEOTOMY, ETC.

The several addresses on symphyseotomy, etc., were by Pinard, Pestalozza, and Fancourt Barnes—the last-named not being present. The former observed that the most numerous cases of contracted pelvis are those with a promonto-pubic diameter not less than 6.5, and in these circumstances he prefers symphyseotomy as less dangerous than opening the abdomen and uterus, citing a case in which it was successfully performed on an open country road. He utterly rejects premature artificial delivery, embryotomy of a living child and any use of forceps or version involving a struggle between the fetal head and bony resistance. "Since antiseptics has come in, all these procedures should be abandoned." Pestalozza allowed certain conditions in private practice justifying premature artificial delivery, especially in young primiparæ. Symphyseotomy, on the other hand, he considers counterindicated in private practice, and that it should be reserved for multiparæ. With a pelvis under 7 cm. the dangers rapidly increase for mother and child. Between 8 and 8.5 it should only be preferred when the fetal head is rigid and forceps repeatedly used in vain. Under 7 cm., Cesarean section and embryotomy are the only operations to be considered, and the indications for the latter are becoming constantly more restricted, although in private practice it is at times still advisable, and also in case of fever, albuminuria, hematuria and eclampsia. Treub and Nijhoff consider symphyseotomy more dangerous than section, on account of the difficulty of keeping the region aseptic. Stijn Parve asserted that he had had only four fetuses die in fifty artificial deliveries, between the thirty-fourth and thirty-eighth week. Fancourt Barnes, in his communicated address, mentioned the extreme rarity of contracted or deformed pelvis at London, and declared that surgeons now lauding symphyseotomy would probably abandon it later. Jouin recommended, as an effective palliative operation for cancer of the uterus, singeing—"flaming"—the cancerous surfaces with alcohol for thirty to ninety seconds after curetting and thermocauterizing them, the vaginal walls protected with a thick coating of vaselin. Rapin called attention to a method of preventing threatening asphyxia of the child during difficult labor by introducing 500 to 600 c.c. of air filtered through cotton, into the amniotic cavity, through a rubber tube or urethral sound. In the three cases thus treated the child was born without any mucous accumulations or amniotic fluid in the respiratory passages, and he urges general adoption of the method, possibly using oxygen. The uterus is so protected at the time that he does not think there can be any danger of embolism. Van de Velde confirmed the value of subcutaneous injections of methylene blue in eclampsia and albuminuria, for both diagnosis and prognosis. Duret reported three cases of *inversio uteri* successfully operated on by his method (described in the *JOURNAL*, xxxii, p. 132). Doumer also confirmed the benefits derived from high-frequency and high-tension currents in congestive hyperplasia of the uterus, in which they promote resolution to a marked extent in addition to their action on the pains and amenorrhea.

LAPLACE FORCEPS IN INTESTINAL ANASTOMOSIS.

Dr. LaPlace of Philadelphia made a hit with his ingenious forceps for intestinal anastomosis. It is difficult to describe this device, which its inventor, with the assistance of Doyen, demonstrated to the open session of the Congress, and, during the succeeding days, privately to all who were interested, which seemed to include everybody.

OVARIAN TRANSPLANTATION.

Another American paper that attracted a vast amount of attention, but no discussion, was offered by Palmer Dudley of New York. It was short and consisted in the report of a case in which he had transplanted and implanted an ovary, not merely with the object of perpetuating the menstrual menses, but the fecundity of the patient. The procedure consisted in opening the fundus of the uterus and implanting into the incision thus made the normal ovary, which had been removed from its original site. This implantation was carried so deeply as to permit a zone of the ovary to project into the uterine cavity, the idea being that ovulation occurring from this disc of ovarian surface would subserve the purposes of fecundation. The sequel of the case has not yet been told, but there is every evidence that the surgical procedure is a *fait accompli*. The world will look forward with interest to the outcome of this meritorious experiment, and the hope that it may be the means of preserving the prospect of maternity of the unfortunate victims of destructive tubal disease.

It is impossible to even allude to all the valuable work presented at the memorable meeting—contributions that will enrich the literature of gynecology and abdominal surgery for more than a day.

The question of the next place of meeting was left in the hands of a committee. Bucharest's invitation was presented by Dr. Jonnesco, Barcelona's by Dr. Zargas, London's by Dr. Jessett, and that of the United States by Drs. Engelman and Reed. It seemed impracticable to settle the question at the time. The *ad interim* organization of the Congress in the United States, as determined by the Executive Body of Founders at Amsterdam, consists of Geo. F. Engelman, L. S. McMurtry, J. Whitridge Williams and Charles A. L. Reed, committee, and A. Palmer Dudley of New York City as secretary.

A serious question relating to the future character of the Congress is under advisement by the various national committees, and is to be disposed of by an *ad interim* international conference. It is practically a question of an open or a closed-door policy, and embraces a plan for the more definite organization of the Congress. The matter is in the hands of judicious men, and will be disposed of in accordance with the best interests of the Congress and of the status of gynecology and abdominal surgery in the scientific world. The splendid fruition that has been reaped at the three congresses already held leads to the hope of subsequent harvests.

CHARLES A. L. REED, M.D.

London.

(From Our Regular Correspondent.)

LONDON, ENG., Sept. 4, 1899.

SANITARY CONGRESS.

An interesting and valuable organization has just closed its session at Southampton. This is the annual congress organized by the Sanitary Institute—the great semi-official representative body of popular sanitary interest and progress. It has established a small museum of hygienic and sanitary apparatus, named in honor of the great sanitarian, the Parkes Museum, in London, where courses of lectures and demonstrations on hygienic subjects are given and examinations held to qualify for the post of sanitary inspector. As the guileless Neapolitan yearns for a fruit-stall, so almost every professional or semi-professional organization in England, medical, legal, commercial and educational, hankers after the control of some "pass"

public service examination—and the fees attaching thereto. One or two most prominent organizations might be mentioned both medical and educational, which, organized originally for the good of the profession, now regard the profession as existing chiefly for their benefit and exploit it accordingly. And the Sanitary Institute, invaluable as it is as a means of popular education in hygiene, seems to have fallen somewhat into this rut, if one may judge by the strong “permanent official” flavor of crudity and superficiality about some of its courses of lectures and of the speeches and discussions in the recent congress.

Some of the papers and the discussions following were admirably adapted to increase an intelligent public interest in sanitary measures, notably those of Prof. Percy Frankland, on water-supply; Dr. Arthur Newsholme, on the prevention of consumption, and a symposium on the re-housing of the poor displaced by the destruction of London slums.

LONDON'S WATER-SUPPLY.

But there were a few things which were crude to the verge of rankness. The address of the president, Sir William Preese, for example, began by alleging that Moses was not only the originator of all sanitary legislation, but one of the ablest and most advanced sanitarians the world had ever seen! Indeed, he doubted whether all our boasted progress had succeeded in bringing us up to his level. And, as a triumphant illustration, he declared that Moses directed garbage to be burned outside of the camp, and our most modern garbage crematory was only a tardy and incomplete fulfilment of this.

After asserting that Moses “invented” the idea of pure water, he took up the burning question of the water-supply of London, and calmly announced that the Thames would furnish an abundant supply of the purest water for fifty years to come. On what ground he bases this astonishing statement, other than that Moses did not forbid a city of 5,000,000 inhabitants—as his gift of prophesy would have easily enabled him to do if it had been necessary—to take its water-supply from a thirty-seven-inch trout-stream, does not appear in his address.

The man who will say this will say anything. The Thames valley is already practically one continuous village for thirty miles above London, and during the past month the water companies actually drew out of the river between one-half and two-thirds of the total flow of the stream. The water, by the mercy of Heaven and the luck of the British army, has remained fairly pure so far, but a simple sewage “leak” from some river town, village or even farm-house might at any moment escape the vigilance of the authorities and poison the metropolis before it was discovered, and even waiving all this, if a river has to be sucked half-dry to-day to supply a rapidly growing city, what will become of it fifty years hence? It is a simple problem in arithmetic. After this we are barely even surprised to find Sir William throwing contempt on the London County Council's masterly scheme for a supply from the Welsh Mountains, by an idiotic piece of clap-trap about “robbing gallant little Wales of her water.”

MEAT INSPECTION.

One of the papers in the Section of State Medicine, at the recent Portsmouth meeting of the British Medical Association, was an admirable review of the questions and methods of meat inspection, by Dr. Manby, health officer of Liverpool. He strongly urges the total abolition of the private slaughter-house, and instanced the German regulations as a model of their kind. In place of the original public slaughter-house, divided into small rooms or stalls, each of which was rented to a separate butcher at a fixed sum, the most modern arrangement is now to have one large hall in which all the slaughtering is done, each butcher simply using the space which happens to be vacant at the time. All this work is under the immediate supervision of a single official, any possible trickery is avoided, and the ventilation and cleansing arrangements are immensely simplified and

approved. The feature which at first would strike both English and American consumers somewhat strangely is the establishment of a “Freibank” or municipal meat market, to which is sent all meat which is distinctly inferior in general quality, on account, say, of the age of the animal, leanness or non-essential defects of that description, but which is not so dangerous to health as to require its absolute condemnation. The method is said to have worked extremely well and furnished a supply of sound and unobjectionable meat to the poorer classes at barely half the market price. To prevent any possible re-selling of the meat, not more than six pounds will be issued to any one person.

INSPECTION OF SCHOOLS.

Another excellent proposition made in this Section was that of Dr. Sydney Marsden, that all schools, not only public but private, should be placed under the control of the medical officer of health for inspection as to ventilation, air space, drainage arrangements, etc., in just the same way as factories. He pointed out that while a certain amount of supervision was now exercised over the public schools, there was practically none, except by purely voluntary arrangement, over the private schools, many of which being held in private houses and in rooms extremely ill-adapted for the continuous occupation of large classes of children were serious offenders in this regard. In Germany these schools are under state supervision and regulation, not only in these but in many other regards precisely as the state schools.

MEMORIALS.

A most excellent custom in respect to memorials is about to be followed at Newcastle, in memory of the late Dr. Nesham, who for many years occupied the chair of midwifery in the University of Durham. The form to be taken by the memorial will probably be a new hospital or the addition of a pavilion to the present building. The action is taken by the governors of the Hospital and some of the leading men of Newcastle, and is an excellent precedent for future extension. As a rule memorials to members of our hard-worked profession exist either in the hearts and memories of their patients or in the form of some chair, lectureship or ward for which they themselves have been devoted enough to furnish the funds. When the laity begin erecting monuments to us, it really looks as if our day is at last coming.

MEDICAL ATTENDANCE OF THE POOR.

A curious condition of affairs, of some practical interest to the profession, exists in regard to the medical attendance of the poor in Whitechapel. Some years ago the local guardians, in consequence of a scandal arising from grave delay in obtaining the services of the district medical officer, passed a regulation permitting any urgent case, which was unable to secure the services of the officer, to call in any practitioner in the neighborhood and send the bill for his visit to the Board of Guardians; accompanied by a statement of their previous call on the regular officer. This looks like a reasonable and even liberal arrangement, and the Guardians make a pompous report to the effect that it has worked admirably, has been “of immense advantage to the poor and no abuse has been made of it.”

LEAD-POISONING.

A curious survival of an ancient, but we had supposed practically extinct, cause of lead-poisoning, has recently put in an appearance in Paris. Symptoms of mild plumbism have been rather common and wide-spread of late in the French capital, and for some time the profession was quite at a loss as to either the character or cause. A few, however, proved so strikingly characteristic, that an energetic investigation was set on foot as to the source of the lead salts, and it was found that the bakers of the city were in the habit of using old building timber, floors, etc., for the purpose of heating their great ovens, and by the persistent use of large quantities of this sort of dust-containing material it is believed not merely lead but also copper and creosote has found its way into the in-

terior of the ovens. Loaves which are then placed in the ovens manage to rub off enough of these deposited materials from the floor and walls to, by long-continued ingestion, set up accumulation poisonings in those who eat them. The older form of this sort of contamination, it will be remembered, used to be the ancient Dutch oven, where the fire was lighted in the oven itself, and then after a sufficient heat had been obtained, the ashes swept out and the loaves put in their place. In this way much larger amounts of lead and copper were introduced and some of the poisonings were very severe, so much so that the use of such fuel was forbidden by law in many Continental cities. The regulation has now been revived by the Paris Council and extended to the use of such wood or boards anywhere about ovens or furnaces.

Canada.

(From *Gaz. Regular Correspondent.*)

TORONTO, Sept. 16, 1899.

TO STUDY BERI-BERI.

It is said that Dr. Hamilton K. Wright—McGill '95—has received through Mr. Chamberlain, Colonial Secretary, an appointment as pathologist to the Straits Settlements, with specific instructions to more especially study beri-beri. Shortly after graduation, Dr. Wright received the appointment of medical registrar at the Royal Victoria Hospital, and in 1897 gained one of the exhibitor's grants of the British Medical Association for his researches on the pathology of the nervous system. He also obtained, in the same year, the John Lucas Walker exhibition in pathology, at the University of Cambridge. With the assistance of these, he further undertook valuable researches in the nervous system in Cambridge and Heidelberg, and in the following year received the appointment as pathologist to the Claybury Asylum in Essex, England, the largest institution of its kind in Great Britain, if not in the world. His work in that institution and its good results brought him to the attention of the medical advisers of the colonial office, who recommended him for his recent appointment.

MEDICAL COMMISSION IN CAPITAL CRIME AND INSANITY.

Dr. James Russell, medical superintendent of the Insane Asylum, Hamilton, Ont., contends for the appointment of such a commission, in a recent article, read before the Ontario Medical Association, on "The Plea of Insanity in Medical Jurisprudence." This is the outcome of long thought and a careful study of the whole subject and an experience extending over a considerable number of years in giving expert evidence in these cases. This commission should be composed of men of high standing and long experience in their profession, appointed by the Crown, for the purpose of examining all prisoners charged with a capital offense, and for whom the plea of insanity has been entered. Dr. Russell also thinks that when insanity is alleged, a sufficient period of time should be allowed to elapse between the perpetration of the criminal act and the trial of the accused, so that the examiners may be enabled to study the nature and progress of the case, on which to base conclusions that will not be subject to any doubt. Were these suggestions followed up, all unseemly conflict of medical evidence would be abolished; and the public mind would be satisfied that justice had been done and the law vindicated. There is a growing feeling in the public mind of Canada, that too many of these criminals escape merited punishment by the successful manner in which the insanity plea is urged in court, and any measure such as the appointment of a medical commission of this character and scope that would tend to increase confidence in the integrity of our courts, should receive all due consideration.

OVERCROWDING OF THE INSANE IN PRINCE EDWARD ISLAND.

Both the professional and lay minds in this staunch little province are being considerably agitated over the construction

of an "annex" to the Provincial Asylum for the Insane. Some 7½ years ago, the grand jury of that Province, directed attention to the overcrowded state of the asylum building, but the government did nothing until about four years thereafter when it placed a number of the inmates of the poorhouse under the same roof with the insane. Very recently tenders were called for the erection of an "annex," but the authorities move so slowly in the matter of awarding the contract that the people are very much incensed at their dilatoriness and at the fact that the poor lunatics are to be left in the conditions described by the grand jury of Queen's County, to endure the rigors of another winter, huddled together, sleeping ten in a room, quartered in the attic, cold and shivering. This is the treatment meted out to these helpless and unfortunate ones by the representatives—or as one writer describes them—by the misrepresentatives of a Christian people. Pressure ought to be brought to bear on the governments of the different provinces at once, where these conditions of affairs exist—as Prince Edward Island is not alone in this matter—other provinces being known to be notoriously negligent in the same regard, in order that this crying evil be speedily remedied.

PRESCRIPTIONS WITH SCRIPTURAL QUOTATIONS.

The newly-appointed detective of the Ontario Medical Council, is rapidly getting into harness. From St. Thomas, Ont., comes the report that he has instituted proceedings against the "Rev." J. G. Evans, "M. D.," whose professional card bears the following: "The Nazarene," Medical Mission, Jericho, Syria. In writing his prescriptions, the pseudo-practitioner is alleged to have issued the following scriptural injunctions, which were printed on the top of his prescription blanks: "And He sent them to preach the kingdom of God and to heal the sick." "And heal the sick that are therein, and say unto them the kingdom of God has come nigh unto you." "Heal the sick, cleanse the lepers, raise the dead, cast out devils: freely ye have received, freely give." Following the written prescription, no doubt as an adjunct "signature," appearing in bold strong type was: "Ask the Lord to bless this as you take it." Subsequent information from Detective McPherson has elicited the fact that the "divine healer" has decamped; probably he has gone to Jericho.

Deaths and Obituaries.

ROBERT B. CRUCE, M.D., Philadelphia, while making a professional call, September 15, died suddenly, at the age of 61 years. He was born in Ireland, came to this country in 1850, and was graduated from the University of Pennsylvania in 1859. In July, 1861, he was appointed assistant-surgeon to the 38th Regiment, Pennsylvania Vols., and later, with the 12th Cavalry, at the battle of Chancellorsville, he was taken prisoner, but subsequently escaped and joined his command. Owing to an injury received by the fall of a horse, he was retired from the army in 1863, and in September of that year was appointed house surgeon to St. Joseph's Hospital, Philadelphia; in 1867 he became physician and surgeon in charge. In 1875 he was elected visiting surgeon, and, on the death of Dr. William V. Keating, in 1894, succeeded him as president of the medical staff. At the time of his death he was a member of the College of Physicians of Philadelphia, of the Philadelphia County Medical Society, the Philadelphia Medical Club, and the AMERICAN MEDICAL ASSOCIATION.

CHARLES THOMAS ROBINSON, M.D., Columbia University, N. Y., 1895, died from cardiac disease, at his home in New York City, September 11, aged 26 years. He spent a year as house surgeon in St. Catharine's Hospital, Brooklyn, N. Y., after which he began practice in Harlem, New York City.

THOMAS C. WORTHINGTON, M.D., died at Laurel, Md., September 15, after a month's illness. He was 80 years of age, and

a widower without children. He was graduated from the medical department of the University of Maryland in 1840.

ALFRED BROWN, M.D., HELLERTOWN, Pa., died in that city on September 11, aged 34 years. He was graduated from the University of Pennsylvania in 1871, and had practiced in Hellertown for the past twenty-seven years.

J. H. Cook, M.D., Dardanelle, Ark., died September 14. . . . R. H. Culbertson, M.D., Brazil, Ind., September 12, aged 69. . . . Hosea A. Little, M.D., Linton, Ind., September 9, aged 30. . . . M. D. Raiford, M.D., Waller, Texas, September 30.

New Appliances.

An Instrument for Intratracheal Medication.

BY ALBERT C. HEATH, M.D.
ST. PAUL, MINN.

The only excuses for offering this instrument are simplicity and efficiency, two essentials which are not always found in medical and surgical appliances. I have used it for the past two years, and find it suits its purpose, i. e., to inject solutions into the trachea and bronchus. The instrument consists of an ordinary Davidson oil atomizer bottle and cap, but having in place of the ordinary atomizing canula a much longer one without the small inner tubing which delivers an unbroken stream: this canula is so curved that one can easily bring its point over the opening to the larynx, or even between the vocal cords, if necessary. I use this instrument with a Davidson cut-off under about twenty pounds air-pressure, and am in the habit of using it in the following way: Under illumination with the laryngoscope in position, the tip of the instrument being placed within the oropharynx vertically over the opening to the larynx in its axial plane, having previously observed the

rhythm of the breathing, injection is made with the inspiratory effort. After a little practice one can gauge the amount of the medicine to be injected by the touch of the thumb on the cut-off. Intratracheal medication can be accomplished without touching the tissues, and with no discomfort to the patient except that which the medicine produces after it is in the trachea. Intratracheal injections can be given even without the use of the laryngoscope, by placing the tip of the instrument in the oropharynx just above and posterior to the epiglottis, then at the same time with forced inspiration the injection is made. This can be done with the most intractable patient. This instrument is made by the Davidson Rubber Co., Boston, Mass.
140 Lowry Arcade.

Suggestions for an Antiseptic Suit.

BY JESSE HAWES, M.D.
GREELEY, COLO.

The antiseptic suit is usually made of common blue denim. Seven yards is enough for the average person. Stretch the cloth from the floor up one side of the person, loosely over the crown of the head, and down to the floor on the opposite side. Cut arm-holes opposite the shoulders. Pin the whole width of the cloth about the legs, from the floor to the perineum.

Sew the edges as pinned. This forms the legs of the suit. Sew double thicknesses of denim over the lower end of the pants legs. Lap the two front edges over the chest and abdomen, six or eight inches, and pin in this position. Pin the denim from the back of the head to the nates. Remove surplus cloth. Leave enough cloth in the suit to loosely envelop the person, when wearing an ordinary suit of clothes. Gather the front edge down, over the forehead, level with the eyebrows, and pin. Place a flap 5x10 inches, across the face below the eyes. Sew one end of the flap, and fasten the other with strap and buckle. Sew in loose sleeves, fasten with strap with buckle around the sleeve at wrist. Attach two rows of buttons, eight inches apart, down the right side of the front: one row should be just at the edge, the other eight inches to the right of the edge.

Dr. Hawes' Antiseptic Suit for use in Contagious Diseases.

Fasten a belt with buckle, around the hips. Sew a pocket on the left breast for handkerchief and thermometer. When the suit is complete, soak it, a pair of cotton gloves, and pocket handkerchief in breast pocket, in a 1 to 500 bichlorid solution.

Lay the suit away for use when needed. When called to a recognized case of contagious disease, dampen the suit lightly all over with any clean water on leaving your office. Put on the dampened suit at the door of the patient; remove it on coming out of the room; wipe the face with the bichlorated handkerchief. Roll up the suit and put it under the buggy seat loosely, or in a little cloth bag. Every germ that has come in contact with the damp suit will be destroyed. Remember that the corrosive salt does not leave the suit, nor grow weak with age. The suit is ready for use at any time, by being lightly dampened with clean water.

An occasional dampening with the 1 to 500 solution, while almost unnecessary, will render the suit more strongly antiseptic. Cost of material for suit, less than \$1.00.

Parrots and Psittacosis.—A French navigation company, the *Compagnie des Chargeurs-Renais*, has forbidden the transportation of parrots on its vessels, as a preventive measure against psittacosis.

Miscellany.

Delivery of Association Buttons.—Owing to the great demand for the A. M. A. buttons during the past week, we have been unable to fill all orders, but as soon as a new consignment is received from the manufacturers, probably within a few days, orders will be filled.

The American Association of Obstetricians and Gynecologists met this week at Indianapolis. The following officers were elected for the ensuing year: President, Rufus B. Hall, (Cincinnati); Vice-Presidents, L. H. Dunning, Indianapolis, and T. J. Crofford, Memphis; Secretary, W. W. Potter, Buffalo, and Treasurer, X. O. Werder, Pittsburg, were re-elected. The next meeting will be held in Memphis, Tenn.

Preservation of Meat.—A Danish zoölogist, Fjelstrup, has suggested a method of preserving meat, founded on the principle that the decomposition of the blood is the cause of the putrefaction. At the moment the animal is slaughtered the heart is exposed and a ventricle opened for the complete evacuation of the blood, after which the venous system is injected with a solution of salt through the intact ventricle. The experience of three months has been very favorable.—*Magasin Pit.*, July 1.

Fedoroff's Extracapsular Abdominal Hysterectomy.—The special features of this method are that the uterus is extirpated with its peritoneal covering—hence the term extracapsular—and that the posterior and anterior cul-de-sac are in turn exposed and reached through the abdomen and opened with the scissors. Forceps are then introduced through the vagina and these openings to clamp the broad ligaments. The bottom of the pelvic cavity is not sutured nor separated from the vagina. Four observations of cases thus treated are described in the *Medicinske Obozrenje*, v. 51, the results justifying the recommendations of the author.

Serotaxis with Solutions of Caustic Potash, a New Method of Diagnosis.—The fact that caustic potash dissolves the tissue with the production of a clear serous fluid, suggested to Frickenhaus that this outward stream of serum might sweep bacteria out with it and ensure a correct diagnosis. In cases of lupus he was thus able to derive tubercle bacilli, and in lupus erythematosus a hitherto undescribed micro-organism. He also applies a 1 to 3 per cent. solution of caustic potash to lupus nodules, painting the surface every second or third day, and finds that the nodules heal well under this treatment. He urges further research with "serotaxis" in favus and trichophytosis.—*Derm. Zbl.*, August.

Queries and Minor Notes.

COMMERCIALISM.

WAUSEON, OHIO, Sept. 12, 1899.

To the Editor—Enclosed I send you a circular letter which I received from your city. I use you are speaking of commercialism. What do you think of this one?

P. J. L.

ANSWER:—This time it is a woman who offers to divide her fees with the doctor who will send her cases. She "cures cancers." Her circular is made up of "hogwash," self-laudation and brag. She uses the old-time humbug about the "busy practitioner" who has no time to study the "etiology, pathology or the latest or best methods of treatment of such maladies" (cancer). Being a specialist, she tells us she has made a deep study of all these, and also of the latest methods of treatment: "In cancer I have a method of treatment which is wholly original with me, and known only to me." But she is not as liberal as some evidently are, judging from a letter we published three weeks ago: "I shall give you fifteen per cent. for all cases sent me amounting to \$300 or less, for all over that amount twenty-five per cent." However, she evidently has her eyes open to the necessity of "cash down" policy for she instructs her patrons to let the patients know they must be prepared to pay cash in advance. "and then your fee as well as mine will be secure." And then here is another wise soteeche: "When you are sure that a patient has fully made up his mind to come for treatment, kindly tell me how much he is able to pay, and about what he is safely considered worth." But for brazen assurance, this is hard to beat: "It would be well to inform the persons who have the bills to pay, that the treatment, of necessity, must come high, as I am the only one anywhere who does the work by this method."

We would not have our readers imagine that the sender of this circular

is among the reputable physicians of this city, her name not being in the list of members of any of the societies, but she evidently does belong to those who believe in this phase of "commercialism" in medicine. Further, her name is not in the list of practitioners as published by the Illinois State Board of Health, while Polk's "Med. and Surg. Register of the United States and Canada" gives Missouri Medical College as her alma mater. The 1898 "Chicago Medical Blue Book" gives St. Louis Medical College, while the 1899 Blue Book puts her down as "ecclectic, no information"; and Connor's "Medical Directory" has her credited to Hahnemann Medical College, Chicago, 1884. Possibly she has forgotten where she did graduate.

NURSE AS ANESTHETIZER.

JOLIET, ILL., Sept. 7, 1899.

To the Editor—Kindly inform me whether certificates or diplomas issued by the State Board to graduate nurses allow them to administer anesthetics, or does their training-school diploma cover that? The case is this: One of our graduate nurses here has taken a special course in the administration of anesthetics, and has become very proficient, and wishes to announce her ability in this respect on her cards, etc., she wishes to know whether she would be allowed to do so, or would a certificate issued to her by the physician under whom she has been studying be recognized and protect her?

J. H. W.

ANSWER:—The Illinois medical practice act apparently makes no provision for anesthetizers other than qualified medical practitioners who have obtained certificates from the State Board of Health. This is obtained only by passing an examination, and the wording of the act is: "No person shall hereafter (after July 1, 1899) begin the practice of medicine or any of the branches thereof or midwifery, in the state, without first applying for and obtaining a license from the State Board of Health to do so." A training-school diploma carries with it no legal rights to practice, it is simply the statement that the holder has passed through the course, and a statement of fitness to act as a nurse under a physician's direction. A certificate from a physician would have no more value. The printing and circulation of such a card as mentioned by our correspondent would, therefore, not be advisable.

The Public Service.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., to and including Sept. 14, 1899:

James A. Alexander, acting asst.-surgeon, from the Department of the Province of Havana and Pinar del Rio to Monroe, La., for assignment of contract.

Frank E. Artand, captain and asst.-surgeon, from New York City to join his regiment, the 45th Inf. Vols., at Fort Snelling, Minn.

Edward G. Benson, lieutenant and asst.-surgeon, 39th Inf. Vols., from recruiting duty at Des Moines, Ia., to Vancouver Barracks, Wash., for duty with his regiment.

Joseph L. Bell, lieutenant and asst.-surgeon, Vols., assigned to the 34th Inf. Vols.

Frank S. Bouras, major and surgeon, Vols., resignation accepted, to take effect Sept. 30, 1899.

Alfred E. Bradley, major and surgeon, Vols. (captain and asst.-surgeon U. S. A.), resignation of volunteer commission accepted to take effect Oct. 1, 1899.

Louis Brechemin, major and surgeon U. S. A., sick leave extended.

Julius M. Cabell, major and surgeon, Vols., from San Francisco, Cal., to Washington, D. C., for instructions.

Charles A. Cattermole, acting asst.-surgeon, to duty with troops en route from San Francisco, Cal., to Manila, P. I.

Walter Cox, lieutenant and asst.-surgeon, U. S. A., from the Department of Porto Rico to post duty at Fort Leavenworth, Kans.

Charles F. Craig, acting asst.-surgeon, from Camp Columbia, Cuba, to temporary duty at Fort Hamilton, N. Y.

Thomas E. Evans, appointed major and surgeon Vols., Sept. 9, 1899, and assigned to the 49th Inf. Vols., at Jefferson Barracks, Mo.

John J. Gihluey, acting asst.-surgeon, to duty with troops en route from San Francisco, Cal., to Manila, P. I.

Charles S. Grant, appointed captain and asst.-surgeon, Vols., Sept. 9, 1899, and assigned to the 49th Inf. Vols., at Jefferson Barracks, Mo.

Howard A. Grube, captain and asst.-surgeon, Vols., to join his regiment, the 48th Inf. Vols., at Fort Thomas, Ky.

Charles F. Kieffer, major and surgeon, Vols., to join his regiment, the 48th Inf. Vols., at Fort Thomas, Ky.

Henry S. Killeen, major and surgeon, U. S. A., to inspect the transport "Patrick J. McKeogh," Pa.

Charles E. Marrow, lieutenant and asst.-surgeon, U. S. A., sick leave extended.

Donald P. McCord, acting asst.-surgeon, from the Department of the Province of Havana and Pinar del Rio, Cuba, to report at Washington, D. C., to the surgeon-general.

Patrick J. McKeogh, lieutenant and asst.-surgeon 34th Inf. Vols., resignation accepted to take effect Sept. 8, 1899.

Franklin A. Meacham, major and surgeon, Vols., from New York City, to duty in the Department of California.

William Grey Miller, acting asst.-surgeon, to duty with troops en route from San Francisco, Cal., to Manila, P. I.

Thomas K. Mullins, acting asst.-surgeon, from Troy, Ala., to duty in the Department of California.

Fred W. Palmer, acting asst.-surgeon, from Jackson, Mich., to the Department of California.

William W. Purcell, appointed lieutenant and asst.-surgeon, Vols., Sept. 9, 1899, and assigned to the 15th Inf. Vols., at Fort Thomas, Ky.

Edward A. Romig, captain and asst.-surgeon, Vois., to join his regiment, the 40th Inf. Vois., at Fort Riley, Kan.

William E. de Salazar, acting asst.-surgeon, from duty in the Department of the Province of Havana and Pinar del Rio, Cuba, to report for annulment of contract.

Hugh L. Taylor, acting asst.-surgeon, from the Department of the Province of Havana and Pinar del Rio to report to the surgeon-general at Washington, D. C.

James S. Wilson, lieutenant and asst.-surgeon, U. S. A., now under orders for Manila to report on arrival for examination for promotion.

William H. Wilson, captain and asst.-surgeon U. S. A., from duty with recruits at the Presidio of San Francisco, Cal., to Angel Island, Cal., for post duty and to command the company of instruction to be established there.

Movements of Navy Medical Officers.—Changes in the medical corps of the U. S. Navy for the week ending Sept. 16, 1899:

Surgeon M. H. Crawford, detached from the marine recruiting rendezvous, Chicago, Ill., and ordered to the marine recruiting rendezvous, New York City.

P. A. Surgeon E. S. Bogert, detached from the marine recruiting rendezvous, New York City, and ordered home and to wait orders; directed to be ready for orders to sea duty.

Surgeon C. M. Moore, detached from the *Vermont* and ordered to the marine recruiting rendezvous, Chicago.

Asst.-Surgeon M. S. Elliott, detached from the marine recruiting rendezvous New York City and ordered to the *Vermont*.

Asst.-Surgeon W. M. Garton, detached from the *Franklin* and ordered to the Washington navy yard.

Surgeon P. A. Lovering, ordered to duty at the recruiting rendezvous, Honolulu, N. Y.

P. A. Surgeon W. F. Arnold, ordered to the Pensacola navy yard.

P. A. Surgeon H. N. T. Harris, detached from the Pensacola navy yard and ordered home to wait orders.

Asst.-Surgeon J. S. Chaffee, resignation accepted.

Medical Director J. R. Tryon, detached from duty as general inspector of naval hospitals and ordered home and to wait orders.

Asst.-Surgeon E. C. Parker, detached from the *Penwood* and ordered to the *Harford*.

Medical Director J. R. Tryon, retired September 21.

P. A. Surgeon L. L. Von Wedekind, granted sick leave for three months, when discharged from naval hospital, Mare Island, Cal.

Marine-Hospital Changes.—Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine-Hospital Service, for the 21 days ended Sept. 14, 1899.

Surgeon J. H. White, directed to proceed to National Soldiers' Home, Va., for special temporary duty.

Surgeon G. M. Magruder, to proceed to Port Tampa, Florida, for special temporary duty.

P. A. Surgeon C. P. Wertenberger, granted leave of absence for fourteen days on account of sickness.

P. A. Surgeon A. C. Smith, to proceed to Tortugas Quarantine, for special temporary duty.

P. A. Surgeon Charles H. Gardner, granted leave of absence for one day.

P. A. Surgeon H. W. Wickes, leave of absence extended four days.

Asst.-Surgeon L. D. Fricks, to proceed to Key West, Fla., for special temporary duty.

Asst.-Surgeon G. M. Corput, relieved from duty at Egmont Key Detention Camp, Fla., and granted leave of absence for 30 days on account of sickness.

Asst.-Surgeon Walter W. King, relieved from duty at Reedy Island Quarantine, and directed to New Orleans, La., and report to the commanding officer for duty and assignment to quarters.

Asst.-Surgeon F. J. Thornbury, relieved from duty at Baltimore, Md., and directed to proceed to the Immigration Depot, New York, and report to the commanding officer for duty.

Asst.-Surgeon F. E. Trotter, relieved from duty at Immigration Depot, New York, and directed to proceed to Mullet Key Detention Camp, Florida, and assume command.

Acting Asst.-Surgeon L. C. Bean, granted leave of absence for one day.

Acting Asst.-Surgeon B. J. Brown, Jr., granted leave of absence for three days.

Acting Asst.-Surgeon Francis Duffy, granted leave of absence for two days.

Acting Asst.-Surgeon B. W. Goldsborough, granted leave of absence for one day.

Acting Asst.-Surgeon A. W. Smith, relieved from duty at Cape Charles Quarantine, and directed to rejoin station at Baltimore, Md.

Hospital Steward F. H. Peck, relieved from duty at Hampton, Va., and directed to proceed to Mullet Key Detention Camp, Fla., for special temporary duty.

Hospital Steward E. T. Olsen, to proceed to Tortugas Quarantine for special temporary duty.

Surgeon H. K. Carter, to proceed to Key West, Fla., for special temporary duty, thence to New Orleans, La., and assume charge of service matters.

Surgeon G. M. Magruder, to proceed to New Orleans, La., for special temporary duty.

P. A. Surgeon T. B. Perry, relieved from duty at San Francisco, Cal., and directed to proceed to Stapleton, N. Y., and report to the commanding officer for duty and assignment to quarters.

P. A. Surgeon J. M. Eager, to proceed to Saginaw, Mich., as inspector.

P. A. Surgeon M. J. Rosenau, detailed as temporary quarantine officer at Havana, Cuba.

P. A. Surgeon J. A. Nydegger, relieved from duty at Marine Hospital, New Orleans, La., and directed to report to Surgeon Magruder for special temporary duty.

P. A. Surgeon Rupert Blue, granted leave of absence for one month and eight days from Oct. 6, 1899.

Asst.-Surgeon J. McMullen, to proceed to Memphis, Tenn., for special temporary duty.

Asst.-Surgeon R. H. von Ezdorf, relieved from duty at Hampton, Va., and directed to rejoin station at New Orleans, La.

Acting Asst.-Surgeon F. B. Adams, granted leave of absence for ten days.

APPOINTMENTS.

Edward J. Agnewly of New York, to be junior hospital steward.

BOARD CONVENED.

Board convened to meet at New York, Oct. 4, 1899, for the examination of candidates for appointment as assistant-surgeon in the service and officers for promotion. Detail for the board: Surgeon H. W. Austin, chairman; Surgeon G. W. Stoner; Surgeon C. E. Banks, recorder.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the surgeon-general of the U. S. Marine-Hospital Service, during the week ended Sept. 15, 1899:

SMALLPOX—UNITED STATES.

Florida: Jacksonville, September 2, 1 case.
Massachusetts: Fall River, September 2 to 9, 1 case.
Ohio: Cincinnati, August 25 to September 1, 6 cases; Cleveland, September 1 to 8, 4 cases.

Pennsylvania: Philadelphia, September 9, 1 death.
Texas: San Antonio, August 31, 1 case, 1 death; Sixteen places, August 5 to September 2, 76 cases, 4 deaths.

Virginia: Portsmouth, September 9, 1 case.

SMALLPOX—FOREIGN.

Belgium: Antwerp, August 29, 3 cases.

Brazil: Rio de Janeiro, July 28, 54 cases, 34 deaths.

Cuba: Casilda, August 1 to 31, 1 death.
Greece: Athens, August 25 to 28, 11 cases, 2 deaths.

India: Bombay, August 15, 11 deaths.

Mexico: Chihuahua, September 4, 4 deaths; Mexico, August 20 to September 7, 9 cases, 6 deaths; Tuxpan, September 4, 2 deaths.

Russia: Moscow, August 12 to 23, 1 case, 1 death; Odessa, August 19 to 26, 1 case, 1 death; Orel, August 19 to 26, 1 case, 1 death.

Spain: Valencian, August 25 to 29, 4 cases, 5 deaths.

Turkey: Erzeroum, August 2 to 12, 2 cases; Smyrna, August 13 to 20, 1 death.

YELLOW FEVER—UNITED STATES.

Florida: Key West, September 9 to 12, 92 cases, 3 deaths; Port Tampa City, September 11, 1 death.

Louisiana: New Orleans, from outbreak to September 11, 7 cases, 2 deaths.

Mississippi: Jackson, September 10, 1 case; Mississippi City, September 10, 1 case.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, July 28, 5 cases, 2 deaths.

Cuba: Havana, August 24 to September 3, 5 deaths.

Colombia: Barranquilla, August 20, 1 case, 1 death; Colon, September 4, 1 case, 1 death.

Mexico: Orizaba, August 15 to 26, 6 deaths; Tuxpan, September 4, 2 deaths; Vera Cruz, August 24 to 31, 16 cases, 11 deaths.

CHOLERA.

India: Bombay, August 15 to 17, 1 death; Calcutta, August 15 to 17, 27 deaths.

Japan: Yokohama, July 16 to 29, 2 cases, 2 deaths.

China: Karachi, August 12, 14 cases, 17 deaths.

PLAGUE.

China: Karachi, August 12, 1 case, 2 deaths.

Egypt: Alexandria, August 20, 2 cases, 1 death.

India: Bombay, August 15 to 17, 71 deaths; Calcutta, August 15 to 17, 25 deaths.

CHANGE OF ADDRESS.

Arons, W. C., from Detroit, Mich., to 82 3d St., Fond du Lac, Wis.

Becker, B. A., from Silver Lake, Wis., to 2612 W. Main St., Louisville, Ky.

Blackbear, E., from Jocassee Valley, S. C. to 624 Green St., Augusta, Ga.

Bennett, F. R., from Urbana, Ohio, to Dayton, Fla.

Boyd, D. A., from Platt to Whittier, N. C.

Beem, E. D., from 1301 E. 8th to 705 Main St., Kansas City, Mo.

Covington, J. M., from Rockingham to Wadesboro, N. C.

Cotton, G. E., from Park, N. C. to 1606 Eutaw Pl., Baltimore, Md.

Cono, C., from Green Park, N. C. to 1616 Eutaw Pl., Baltimore, Md.

Clements, J., from 1113 to 915 W. 17th St., Kansas City, Mo.

Curtis, W. H., from Columbus to 528 S. 2d St., Lafayette, Ind.

Drummond, P. B., from Chillicothe, Ohio, to York, Neb.

Engstedt, A. B., from Omaha, Neb., to 2319 Broadway, Galveston, Texas.

Fuson, A. N., from Lapaz, Ind., to Stockton, Cal.

Giffin, C. W., from Waterloo to Iowa.

Hopkins, E. G., from Richmond to Glen Allen, Va.

Hardy, J. A., from Kilmarnock, Va. to Welch, W. Va.

Horton, R. W., from Waxahatchie, Texas to Wynne Wood, I. T.

Halley, J. J., from Benton City, Mo., to Fort Collins, Col.

Harris, G. D., from Columbus to Indianola, Miss.

Hackett, R. K., from 1318 Washington St. to Carrollton Ave. and Elm St., New Orleans, La.

Jones, G. E., from Connorsville to 1003 1st Ave., Evansville, Ind.

Kaumlheimer, G., from 508 to 577 3d St., Milwaukee, Wis.

Ruhn, B. F., from North Webster to Elkhart, Ind.

Lyster, T. C., from Ann Arbor, Mich. to Chief Surgeon's office, Div. of Cuba, A. A. Surg., Havana, Cuba.

McDuggall, G. T., from Eau Claire to 284 Washington St., Milwaukee, Wis.

McMasters, H., from Memphis, Tenn., to Pryorsburg, Ky.

Munford, from 507 to 504 Penn Ave., Pittsburg, Pa.

McJahan, C. F., from Bethlehem, N. H., to Aiken, S. C.

Motter, M. G., from Lake Park, Md. to 2144 Conn. Ave., N.W., Washington, D. C.

Medill, O. E., from Persia to Defiance, Iowa.

Paulin, N. O., from 1232 Euclid Ave. to Box 42, Station B, Cleveland, O.

Post, H. H., from Shappano, N. H., to 306 Adams Ave. St. Louis, Mo.

Rummond, W. B., from Mt. Pleasant, Mich. to Brazil, Ind.

Sessums, J. R., from Duffan to Carlton, Hamilton Co., Texas.

Short, J. L., from 214 W. 15th to 116 Holmes St., Kansas City, Mo.

Shlars, A., from Roseport to Ruston, La.

Smith, F. C., from Rowan to Waterloo, Iowa.

Woodward, J. H., from Long Lake, N. Y., to Brandon, Vt.

Werner, C. A., from St. Paul, Minn. to Box 62, Marathon, Iowa.

Wright, H. G., from Marshalltown to care Drake Unit, Des Moines, Ia.

SURGICAL TREATMENT OF ABSCESS OF THE LUNGS.

BY D. S. FAIRCHILD, M.D.
CHIEF SURGEON ST. JOSEPH'S HOSPITAL,
CLINTON, IOWA.

Pulmonary abscess is said by Osler to be easy of recognition, but for my own part I have to confess that I have met with cases in which grave doubts existed in my own mind as to the question of differential diagnosis between abscess of the lung and encysted empyema. I have also met with cases in consultation in which the attending physician was in error touching the existence of any abscess at all. It is no doubt true that an abscess discharging through a bronchial tube may be recognized without much difficulty, but previous to this time I am quite certain it may be easily overlooked.

Pneumonia is now generally recognized to be an infectious inflammation of the lungs, due in the majority of cases to the influence of the diplococcus pneumoniae of Fraenkel. The disease generally pursues a well-defined course marked by certain pathologic changes; once in about fifty cases it is said the pathologic changes result in the formation of an abscess. The consolidation which results from the inflammation appears to impair the resistance of the lung to a degree which, under favorable conditions of infection, may lead to the formation of pus, and the extension of the infection leads to an accumulation of pus to the extent of forming an abscess of greater or less size, or to more than a single abscess. In view of the fact that pneumonia is a disease due to a microbe which sometimes has the faculty of setting up pyogenic processes, it is quite a matter of surprise that in this disease abscesses of the lungs do not more frequently occur. A considerable number of conditions may lead to the formation of pus in pulmonary tissue, but the most frequent causes are pneumonia and tuberculosis. The complicated character of abscesses or cavities in tuberculosis or other diseases of the lungs than pneumonia, or the inflammation following injuries or foreign bodies renders surgical procedures of doubtful utility, except in rare cases. My experience being confined entirely to abscesses following pneumonia renders it hazardous for me to go outside of pus accumulations arising from this cause.

In a case of pneumonia, if after the end of two or three weeks there is still fever and absence of improvement in the respiratory murmur, or if marked improvement in the general condition of the patient has taken place at the usual period of convalescence, together with an improvement in the respiratory condition of the affected lung, the fever reappears, and the area of consolidation extends, it may be assumed that some complica-

tion exists. Among the complications may be found consolidation of the lung, hydrothorax, empyema or abscess. Which of these conditions we have to deal with I am confident can not always be determined. If bacteriologic investigations show the tubercle bacillus, it is of course significant. The absence of bacilli is not conclusive. The usual symptoms of fluid in the pleural cavity may be looked for, and if discovered the nature of it can be determined by the use of the aspirator needle. It is usually possible, however, to determine the nature of the fluid by the clinical symptoms; the presence of chills, morning and evening temperatures, rapid pulse, and the general symptoms of septic infection are significant, but it is best not to rely on this alone, for in some cases the presence of pus may not be revealed in this way and the exploring trocar should be used to determine the facts absolutely.

Encysted empyema will not reveal itself by the ordinary symptoms of fluid in the chest cavity and it is often difficult to distinguish between this and an abscess in the lung. An examination of the lung may show that the air enters the anterior or posterior surface—more particularly the anterior in my practice—while the opposite surface is solid, showing an entire absence of vesicular or bronchial respiration. While the air may enter the anterior or posterior surface, the respiratory murmur is abnormally feeble. I have a patient on whom I operated some time ago, where well-marked but rather feeble respiratory sounds were found on the anterior surface of the right lung, but the posterior was absolutely solid; this condition had existed for about eight months, large quantities of pus being discharged through the bronchial tubes every morning. This differed from an abscess of the lung only in the absence of an offensive odor and the absence of a cavity. The diagnosis was confirmed by the introduction of an aspirating trocar between the ribs at the lower border of the scapula. A portion of rib was resected and the cavity drained. An exploration of the cavity by the finger revealed the encysted empyema.

An abscess of the lung is a much more serious condition than an empyema, on account of the difficulty of surgical drainage. In an abscess of the lung, after discharge through a bronchial tube has taken place, the drainage is frequently so unsatisfactory that after the first discharge of pus, it continues to partially fill and discharge for a considerable length of time or until the patient is exhausted. In cases where it is possible to drain by surgical means better results may be obtained. It will sometimes be observed in abscesses of the lung that a single abscess forms, discharges, the cavity gradually contracts, and finally the patient is cured. In other cases several abscesses form and discharge at different times; this will occur when several foci of pus infection appear in a lobe which has been damaged by the intensity of the inflammatory process, even in cases which are not of embolic origin. These cases are no doubt more serious than where a single abscess forms.

*Presented to the Section on Surgery and Anatomy, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

The remainder of the products of inflammation are removed by absorption or by expectoration, but the case is more protracted.

Two cases treated surgically by myself will illustrate this fact. About seven years ago I was called in consultation to see a man weighing 250 pounds, who had been attacked by croupous pneumonia two months previously. The pneumonia had pursued the ordinary course, and apparent convalescence occurred. About two weeks subsequent to this, the fever began to rise and soon after an expectoration of exceedingly offensive pus occurred. The discharge was through a small bronchial tube and the cough was almost incessant, interfering seriously with sleep or comfort. When I saw him this condition had existed about three or four weeks; it was not quite clear to our minds whether we had to deal with an abscess of the lung or an encysted empyema.

The respiratory murmur was quite clear over the anterior surface of the right chest, although somewhat feeble. The posterior surface was quite solid; not even bronchial respiration could be discovered and the area of consolidation did not change on account of the position. The patient was placed under the influence of chloroform. The posterior surface of the chest was prepared for an operative procedure and an aspirating trocar introduced deep into the chest, first between the sixth and seventh ribs just posterior to the axillary line, with negative results, again between the fifth and sixth ribs, a little farther back, with the same results. The needle was introduced a third time, between the fourth and fifth ribs, in the angle between the scapula and the vertebral column, and obtained a free flow of pus; leaving in the trocar, as a quite free incision was made through the thick mass of muscles down to the ribs. The space between the ribs was not sufficient for satisfactory work and $1\frac{1}{2}$ inches of the fifth rib was resected. Following the needle I found that the two pleural surfaces were united and, thereby, the pleural cavity was protected from pus infection. I pushed a pair of straight, broad-ligament-forceps boldly over the needle through an inch of lung substance into the abscess cavity, separated the blades freely, introduced a large rubber drainage-tube, and a large quantity of pus escaped. The cough and expectoration of pus at once ceased and the patient made a rapid and uninterrupted recovery. In this case the discharge through the bronchial tube was only sufficient to remove the constantly forming pus, and therefore no cavity was permitted to form and one of the classic symptoms, the existence of a lung cavity, was absent. The point of differential diagnosis in this case lay between abscess of the lung and an encysted empyema communicating with a bronchial tube. The only symptom of value indicating an abscess was the offensive odor of the pus expectorated.

Another case more recently under observation was that of a young man who passed under a rather severe attack of pneumonia. Convalescence became partially established, but soon the fever began to rise, consolidation of the lung persisted, and it became evident that some serious lesion existed; cough and expectoration was slight; sputum was examined for tubercle bacilli, but with negative results. I saw the case in consultation, June 18, 1898. The lower lobe of the left lung was solid, except the anterior surface, in which the respiratory murmur was feeble; heart displaced toward middle line; temperature ranged from 101 to 103; no cavities; no expectoration of pus. After a most careful examination I could not make a complete diagnosis of the path-

ologic condition, but believed that pus existed in the lungs or in the pleural cavity as an encysted empyema. To clear up the doubt I introduced an aspirating trocar under aseptic precautions, between the fifth and sixth ribs, just posterior to the axillary line, and withdrew a large syringe of pus. A free incision was made in the track of the needle and the pleural cavity opened, but no pus was found, only a quantity of serous fluid. My finger, which had been carefully prepared, was introduced and the surface of the lung explored. The space between the ribs was wide, and no resection was necessary. It had been determined beyond doubt that an abscess of the lung existed, by the deep exploration of the needle, and as the pleural cavity was exposed I did not feel justified in incising or puncturing the lung for fear of infecting the pleura. I therefore packed the wound lightly down to the lung, with iodoform gauze.

A few days later a free discharge of pus occurred through the wound, with the result of bringing down the temperature to 98.5 in the morning and 100 in the evening, with a corresponding reduction in the pulse. For seven days the improvement was marked. The discharge of pus gradually lessened. At the end of this time the temperature began to rise. Fearing that the drainage was not sufficient the patient was again anesthetized, June 27, and my finger forced through the chest wound. It now entered an irregular cavity of considerable size, in the lung, but no accumulation of pus was found, showing that the drain provided for the discharge of all the pus formed. Any further operative procedures were deferred under the hope that if the pus was again forming it would soon find its way into the old abscess cavity as the evidence seemed to show that we were already in the area of infection.

Six days later, July 31, the temperature, which had ranged from 101 to 103, fell to 99.6, with a corresponding improvement in his general condition. Under these circumstances it was deemed best to defer operative procedure; nevertheless, a point on the posterior surface of the chest between the fifth and sixth ribs was selected for exploration providing the patient did not continue to improve.

Three days later, however, the temperature began to rise and ranged between 101 and 104. It now became certain that another collection of pus existed and that further operative procedures were necessary. Accordingly, on July 15 exploration was made between the fifth and sixth ribs on posterior surface—at the point selected on the previous visit—and a large amount of pus found; resection of a portion of the fifth rib permitted an exploration of the cavity of the lung.

We now had two lung cavities separated by a mass of lung tissue, no doubt in condition of consolidation, offering a degree of resistance which did not permit the pus of one cavity to enter the other. The irregular outlines of both cavities could be determined by pushing the finger deeply into the wound. The improvement which followed the last operation did not continue long. Three days later the temperature rose to 104 and on July 19 I found a bronchopneumonia in the right lung. This condition had no doubt arisen from the insufflation of pus germs during chloroform narcosis, for, during the few days previous to the last operation a small quantity of pus had escaped through a bronchial tube. The condition appeared to be desperate, but fortunately the bronchopneumonia subsided and the patient made an uninterrupted and rapid recovery, thanks to the skillful care of Dr. Ruml of Cedar Rapids, Iowa.

While it may be difficult or impossible to differentiate

¹ Reported Chicago Med. Rev., May, 1893.

in a considerable percentage of cases between abscess of the lung and an encysted empyema, it may be said that the means of absolute diagnosis is the same, viz., puncture of the suspected area by an aspirating needle. If pus is found it should be evacuated by free incision, resecting a rib if necessary, to obtain sufficient drainage. If on entering the chest cavity no pus is found, the finger should be introduced for the purpose of exploration. The failure to obtain pus after its presence has been demonstrated by deep aspiration may be taken as evidence that the abscess is in the lung itself. If the finger reveals the fact that the pleural membranes are not adherent, then gauze may be lightly packed against the pleural pulmonalis to invite adhesions and thus protect the pleural cavity from the danger of infection, when subsequently the abscess is opened. There are no doubt cases where the immediate danger is so great as to warrant the surgeon in ignoring the risk of infecting the pleural membranes and opening the abscess at once, but I can not agree that this is the safest course when a few days' time can be spared. In the case I have referred to may be mentioned the fact that there was serous effusion sufficient to hold the pleural surfaces apart and thus prevent the adhesions which would otherwise probably have taken place.

I do not think it is a good practice in cases of either pulmonary abscess or empyema to use irrigation; it can do no good and often causes distressing irritation of the lung. In my earlier practice I resorted to injections of solutions of boric acid, but I have not done so of late years. As to the administration of medicines, very little can be said. It is true that certain means may be employed with great advantage for the purpose of supporting the strength of the patient, but these are indicated on general principles, regardless of the fact of a pus accumulation. It is no doubt true that if the pus is due to the pyogenic action of the pneumococcus degeneration and absorption may take place, but if it is due to a mixed infection or to the streptococcus, as is usually the case, no such fortunate result can be expected. The disease then becomes certainly a surgical disease and should be treated by surgical means adapted to the individual case, always having in view the necessity of drainage. In a certain proportion of cases the abscess discharges itself through a bronchial tube and a spontaneous cure is accomplished in this manner. While this can not be looked on as a scientific termination of a case, it is, however, the best that can be looked for in a certain number of cases.

DISCUSSION.

DR. A. H. LEVINGS, Milwaukee, Wis.—I am very much interested in the subject which the Doctor has so well placed before us, and think it is one which has not received the attention its importance merits. Some noted clinician has said, "Before treating a pulmonary abscess one must make a diagnosis, and not only make a diagnosis, but must locate the abscess." A reliable diagnosis of abscess of the lung will depend on the history, the symptoms, the character of the sputa and a thorough physical examination of the chest. An abscess of the lung is usually a secondary process; its symptoms will be more or less intermingled with, and marked by those of the original disease, in common with other acute affections of the lungs; there is pain, disturbed respiration, fever and cough; on percussion, there will be circumscribed dullness, provided the area affected be of sufficient size and superficially situated, with bronchial breathing and more or less rales. With the formation of a cavity, if the process be superficial, a portion of the dull area will have changed to tympanites, and if the costal pleura be implicated, there will be the friction sounds of pleurisy.

In a case under my observation, the percussion-note was ob-

erved to alternate over a circumscribed area between dullness and tympanites. After a severe fit of coughing and the expectoration of a quantity of pus, the area which had previously been dull would become tympanitic, following this, if the patient did not cough much for twenty-four hours, and allowed the cavity again to fill, the percussion note would change to dullness. If the cavity be in full communication with a bronchus, the percussion-note will be higher with the mouth open than with it closed.

Gerhardt has called attention to the fact that if the cavity be longer in one direction than in another, and contains fluid, change in the patient's position will change the pitch. This interrupted change in pitch is considered pathognomonic, that is, with the mouth open a rise of pitch is noticed upon percussion only in a certain position, as in sitting up. While the location of the abscess is determined as nearly as possible, by a physical examination, this finding must be proved true, or corrected by the aspirating needle. If one fails with the needle to locate the abscess, then I believe it is imperative, if the symptoms are pronounced, to make a resection of one or more ribs, and patulate the lung.

DR. J. B. MURPHY, Chicago—I wish to speak of one condition in connection with the operation. In abscess of the lung, where we have pleural adhesions, is not difficult to operate. One can expose the lung, divide it with the scalpel, which is the best means, down into the abscess cavity, but we have an additional danger, and I paid for the knowledge, by sacrificing a patient a few days ago. It was a case of abscess of the lung following the inhalation of a peanut. The abscess was located under the angle of the scapula. There was a paroxysmal cough; expectorations of a half ounce every two or three hours. The abscess cavity could not be emptied by placing the patient in any particular position. There appeared to be no excursion of the lung. We believed there were firm adhesions of the pleura at the time of operation and did not carry out a plan which I have devised, demonstrated experimentally and which I shall always do in the future, regardless of adhesions, and that is determining the presence of adhesions by injecting into the pleural cavity a quantity of air, which should be done without force. If there be no adhesions, the air will be aspirated into the pleural cavity with each inspiration. What then happens? If adhesions exist, the dullness will remain and respiratory sounds will not change. If adhesions do not exist, the lung will collapse and respiratory sounds in that side will cease. In my fatal case, after resecting the ribs and exposing the pleura, I found very friable adhesions, with an increase in respiration, and the lung receded. The result was that several ounces of pus escaped from the mouth. He was resting on his healthy side. He inhaled some of the pus into the healthy lung and he died of infective pneumonia of the previously healthy lung, about forty-eight hours after the operation. I drew the infarcted portion of the diseased lung out into the incision, sutured it in the incision and had it ready for secondary opening with the scalpel or cautery, thoracoeic. I knew I could easily open it secondarily, as I had the diseased portion of the lung exposed, but he died of aseptic inhalation pneumonia produced by the pus inhaled during the anesthesia. I could have avoided that by putting the air into the pleura while he was awake and could expectorate it.

DR. D. S. FAIRCCHILD, Clinton, Iowa—I have only a word in addition to say and that is in relation to physical examination. I have to confess that I am not sufficiently skilful in making a physical examination to determine whether its consolidation is due to abscess or to other causes, and I can do better if I introduce a needle. I should use the short—the smallest—needle consistent with ascertaining the real fact. I spoke of the long needle and deep exploration because we had a very large man, weighing 250 pounds. The fact in this case I did not offer as being a rule in guiding me in the matter of the long needle. I would not use a longer one than was necessary. The reason why I used a pair of forceps in pushing my way into the lung, where the abscess was located, was because I was too timid to use a sharp instrument. I used the forceps in this case and would use them again under similar circumstances.

Exophthalmic Goiter.—Dr. Pitres of Bordeaux reports that 1 c.c. of iodofomed ether injected into the parenchyma of the thyroid body at eight-day intervals for several months has cured six cases of exophthalmic goiter, and the cure has persisted two years. Six other cases were improved to such an extent that they were satisfied with the results of partial treatment and did not return to complete the course. He has thus made 120 injections and never observed any accidents.—

SOME OF THE RARE FORMS OF HERNIA AND THEIR RADICAL TREATMENT.*

BY R. HARVEY REED, M.D., (UNIV. PA.)

President Wyoming State Medical Society; Member Association of Military Surgeons of the United States, The Rocky Mountain Interstate Medical Association, The Western Surgical and Gynecological Association; Medical Director Wyoming General Hospital; Division Surgeon Union Pacific R.R., Surgeon-General of Wyoming, etc.

ROCK SPRINGS, WYO.

The writer does not propose to review the anatomy of hernia, or enter into its etiology or pathology, neither does he propose to discuss or report cases of the more common forms of hernia, with which medical literature on this subject is already overburdened.

GASTRIC HERNIA.

It has always seemed strange to me that our textbooks, old and new, should refer to hernia of the diaphragm with such mathematic precision, and at the same time ignore the presence or attempt a description in the most meager manner, of gastric hernia. Certainly it is not because the authors have not seen it, or that it does not exist, or that it is not more common than hernia of the diaphragm. One thing is certain, it is much more amenable to surgical interference with more successful results than the former. In the writer's opinion, it is much more deserving of a place in our textbooks from a practical standpoint than hernia of the diaphragm.

In my experience gastric hernia has been the result of direct violence, usually over the larger curvature of the stomach, causing a solution of the continuity of the abdominal walls overlying that particular anatomic region; like ventral hernia, it is seldom if ever congenital, but is usually, if not always, traceable to direct violence.

To illustrate: Case 355, A. N., was admitted to the Wyoming General Hospital, Jan. 14, 1898, at which time we found a tumor about the size of a fist, immediately over the larger curvature of the stomach. We also found the patient suffering not only from pain, but from indigestion, and frequent vomiting, and on further investigation found this tumor varied in size, sometimes disappearing altogether, at other times being not larger than a walnut.

The patient was an unusually large muscular Swede, aged 42, and a professional coal driller, and had charge of one of the large drills in the U. P. Coal Company's mines. This drill was run by compressed air, and he was in the habit of pushing the drill into the rock or coal by pressing the one end of it against the pit of the stomach; continued pressure at this point, with a sudden lurch of the drill one day produced a tear in the linea alba, which on physical examination could be readily felt underneath the skin, and it was with little or no difficulty that I could thrust my three fingers into the opening through the abdominal wall. At times a portion of the stomach would protrude through this opening, and could be easily felt, and with little or no difficulty replaced, thus giving relief for the time being. The patient became so expert at this that he kept on with his work, and when the stomach would protrude through the opening, would stop and replace it, and go on about his business.

Becoming weary of this, he entered the Wyoming General Hospital for a radical operation, which I performed on Jan. 15, 1898. It consisted in making an incision in the median line about three inches in length, carefully

dissecting down until we came to the ragged edge of the opening which had been torn through the abdominal walls in the line of the linea alba. These edges were freshened and carefully brought in apposition by the so-called "base-ball" suture. The first, second and third rows of sutures were of pyoktanin catgut, while the last row was of silkworm gut. The first row included the peritoneum only, the second the muscle and peritoneum, the third the deep fascia and the muscle, and the last row the integument and deep fascia.

The patient made an uninterrupted recovery by first intention, and was discharged Feb. 2, 1898, just eighteen days after his operation, and up to the present time has had no evidence of a return.

Again, Case 701, J. K., a strong, healthy Finlander, aged 39, miner by occupation, while lifting a prop in one of the mines, had his foot slip, and in trying to save himself caught hold of another prop, but finally fell, striking heavily on the bottom of the mine. He at once experienced intense pain in the region of the stomach, and, noticing a lump, came to my office. On examination I found a tumor immediately over the larger curvature of the stomach, about the size of a walnut.

He was admitted to the Wyoming General Hospital, and operated on, Jan. 20, 1899, after the method described in Case 355, making an uninterrupted recovery, with the exception of an attack of acute cystitis. He was discharged from the Hospital, February 19, thirty days after his operation, which was prolonged twelve days more than in the former case on account of the cystitis. He is now at work in the mine, and complains of no inconvenience.

UMBILICAL HERNIA.

This is not considered as a rare form of hernia, but I take the opportunity of presenting a case of unusually large umbilical hernia and, as will be observed by the accompanying photographs, taken before and after operation, one of more than ordinary interest. The patient—Case 404—Mrs. M. L., was admitted to the Wyoming General Hospital, March 20, 1898, where she was operated on, March 24. She was born in Scotland 43 years ago, married, weighed 260 lbs., but for a woman of her size and weight was exceedingly active, doing her own work, and acting in the capacity of the so-called "granny nurse" when and wherever needed.

About one year previous to her being admitted to the Hospital, she noticed a tenderness about the umbilicus, which she thought might be a boil. This tenderness gradually increased, and at the same time a tumor appeared, which also continued to increase in size. She consulted a physician, who told her it was an *abscess*, and wished to lance it. To this she did not give consent, and in February, 1898, called at my office, when I found a tumor so large that when she was sitting down on an ordinary chair the anterior portion of the tumor was even with the knees when the legs and thighs were flexed.

My diagnosis was umbilical hernia, involving the omentum, stomach, and the small and large intestines, and I advised her going to a hospital. On March 24, I operated and found my diagnosis correct. The opening through the abdominal wall was large enough for me to pass my closed fist through it without touching either side. I removed about two pounds of omentum, and returned the remainder with the intestines and stomach to their normal positions. After thoroughly dissecting off the fibrous ring, which surrounded the opening through the abdominal wall, and removing an elliptic

*Presented to the Section on Surgery and Anatomy, at the Fifteenth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

piece of skin from each side of the abdominal incision, each one of which was about three inches in width, at its widest point, and about six inches in length, in order to make the integument conform with the reduced size of the abdomen, I proceeded to approximate it with the continued pyoktainin catgut suture. My first row of sutures included only the peritoneum; the second, the muscular structures and peritoneum; the third, the deep fascia, being careful to include the muscle, and lastly, I carefully approximated the integument with interrupted silkworm gut suture which included the deep fascia.

She made an uneventful and uninterrupted convalescence and was discharged with a complete recovery. Before she left the Hospital I made careful measurements and had a double-legged Hamilton supporter made for her, so as to prevent the return of the hernia. After returning home, she attempted to improve the supporter, but in her efforts to do so, destroyed its usefulness and threw it away, and went without any support whatever. She continued her duties as housewife,

BEFORE OPERATION.

but after some months the hernia partially returned, but not to such an extent as before and does not pain her as it did prior to the operation. We feel, however, that this was due to her immense size and to the fact that she did not carry out the instructions regarding the use of the Hamilton supporter, which, I think, had it been used, would have prevented her from having any further trouble. As it is, however, she is able to do her ordinary duties with little or no inconvenience, her health is good, and if anything, her weight is greater than before the operation.

VENTRAL HERNIA.

While ventral hernia is most commonly found at some point along the linea alba, yet it is not infrequent that it may be found at other points in the abdominal walls. To illustrate this, I will refer to a case which came under my observation in Columbus, Ohio,—a male, between 50 and 60 years of age, who had served his country in the Civil War. While in the service he sustained a ventral hernia which protruded through the muscular structures

of the left side, and at times became as large as the crown of an ordinary hat, and from the symptoms set forth involved not only the large and small intestines, but the left kidney. I was called to see him in numerous acute attacks and found not only constipation of a character indicating complete obstruction of the bowels, but also partial suppression of the urine, neither one of which was relieved until after the contents of the hernial sac were evacuated and the viscera which it contained were returned to the normal position. I suggested an operation a number of times, but he always objected, and said he would take his chances rather than have an operation, although the last time I attended him, which was nearly two years ago, it came very near costing him his life, and no doubt will, sooner or later, if he is not relieved by surgical interference.

The most common case of ventral hernia at the pres-

AFTER OPERATION.

ent time is the sequel of an abdominal section. A good illustration of this kind is shown in Case 121. Mrs. A. C. S., age 36, born in Scotland, married, and who was admitted to the Wyoming General Hospital April 16, 1898, gave the following history:

About five years previous to her admission to the Hospital she was operated on for a supposed ectopic pregnancy. In order that the operator might have a complete view of the abdominal cavity he made an incision which began at the ensiform cartilage and extended to the os pubis. This was followed by a large ventral hernia, which allowed almost the entire contents of the abdominal cavity to protrude through the opening which had been made in the abdominal wall, and which had never been closed, and for years had made such continued pressure on the integument that it was thinned down so as to leave a very fragile partition between the abdominal viscera and the outside world.

She was again operated on, April 18, 1898, which necessitated my making an incision almost the entire

length of the former opening. After making the incision through the integument, I found a very large opening through the abdominal wall, which measured nine inches in length and about three at the widest point. The muscles had become contracted, and around this opening was an oval, fibrous non-elastic band which I was obliged to dissect out completely, after which I brought the abdominal walls together with pyoktanin catgut, by the method already described, excepting that I used the interrupted instead of the continued suture.

This patient made an uneventful recovery, and was discharged May 10, 1898, after having been fitted with a double-legged Hamilton supporter, and so far as I have any knowledge, up to the present date has had no further trouble, but is able to continue her usual duties, and "trip the light fantastic toe" with ease and grace.

LABIAL HERNIA.

In looking over a dozen or more of the modern text-books I was very much surprised to find that labial hernia was seldom referred to, excepting where the viscera passed between the vagina and the ramus of the ischium. The case which I am about to report does not constitute one of this class, but is one in which the bowel broke through the abdominal ring, passed down the canal of Nuck, and descended into the labia majora. It is as follows: Case No. 561. Mrs. J. B. Z., married, white, age 22, born in Germany, when about four months pregnant, while doing a large washing, lifted a heavy tub of clothes and immediately afterward felt an intense and smarting pain along the line of the canal of Nuck, and this was followed by a tumor in the labia majora.

She was admitted to the Womans General Hospital Sept. 19, 1898, and was operated on the next day. An incision was made over the tumor, which was found to consist of small intestines which had found their way down through the abdominal ring and along the canal of Nuck, which was laid open to the external abdominal ring, after which the viscera were returned to the abdominal cavity; the redundant sac was amputated and the stump sutured with pyoktanin catgut in the external abdominal ring, after which the canal was subcutaneously closed with a continued suture, including the labia majora. This was followed by closing the integument with interrupted silkworm gut suture, after the manner already described in my former operations.

Notwithstanding the pregnancy, this patient made an uneventful recovery and was discharged from the Hospital on Oct. 5, having fully recovered.

She went on to her full term and was delivered of a large child, by my assistant, Dr. Chamberlain, without any return of the hernia, and is now in her normal health and suffers no inconvenience whatever. Her general health is good, and to all appearance there is no indication of the return of the hernia.

Deductions.—Notwithstanding that our text-books are filled with discussions on the various methods for operating on the more common forms of hernia, and that nearly every operator has his own method for repairing breaches in the abdominal cavity occurring in the inguinal and femoral region, yet, the report of the few cases given in this paper, of the rarer forms of hernia, shows conclusively:

1. That all cicatricial tissue must be completely removed.
2. That the most perfect apposition of the separated parts must be secured.
3. That strong, flexible, thoroughly sterilized and absorbable animal tissue should be used for subcutaneous

sutures, and that non-absorbable thoroughly sterilized suture should be used for approximating the integument.

4. That great care should be taken to avoid the possibility of necrosis, by shutting off the normal blood-supply, and thus not only preventing the absorption of the animal suture, but eventually causing the breaking down of the adjacent structures, thus deprived of their normal blood-supply, which is bound to complicate the case.

Remarks.—After having tried different kinds of animal tissues, prepared by different methods, for subcutaneous suture, I have obtained the best results from pyoktanin catgut, which I have prepared, by my chief nurse, under my personal direction. For over two years I have purchased my catgut in the raw form from a firm in New York, which experience has taught me, furnished a most excellent and reliable form of catgut. This is prepared, first by immersion in ether for not less than four days, after which it is wound on glass spools and immersed in a solution of 1 to 1000 pyoktanin in absolute alcohol, after which the jar containing the alcoholic solution of pyoktanin with the catgut is sterilized for one hour under pressure. It is my custom to have the catgut sterilized in this manner each time after it has been opened for use; this, however, will in time cause the catgut to become fragile, when it is thrown away and a new supply is prepared.

Catgut prepared in this way is not only strong, but very flexible, and, as a rule, is absorbed in from seven to nine days.

My objection to some of the other methods of sterilization is their overhardening of the animal tissues, thus preventing absorption of the suture after the parts have become repaired, when the catgut or other animal suture becomes a foreign body, and unless removed is sure to produce suppuration, if not promptly removed, very greatly to the annoyance of the operator and the patient.

By preparing catgut as above described, I have had the least amount of trouble in this direction. There are other methods for preparing it which make it pliable, but unfortunately when these are used it is absorbed too soon, and allows the wound to gap open before it has had time to repair, hence it has been my aim to adopt a method for the preparation of animal suture that will insure proper sterilization and at the same time will perform the services required, with as little additional demands on the economy as possible.

Conclusions.—It has been the writer's aim in the preparation of this paper to present only facts, and cases, which have come under his personal observation, and to report a few cases for illustration, and, briefly, the method by which they were operated on, and the results, in the belief that we should study the rarer forms of hernia, and their methods of repair just as well as the more common forms which are of every-day occurrence to all practical operating surgeons.

DISCUSSION ON PAPERS OF DRs. REED AND FERGUSON.*

DR. F. W. McRAE, Atlanta, Ga.—The cases which I shall report—I have not prepared a paper and did not intend to present one—of hernia of the diaphragm are unusual, and of such interest that I should like a few minutes to present them to the Section.

In 1894 I operated deliberately for hernia of the diaphragm. The patient had received a stab wound six months previously, that penetrated the chest and the diaphragm. The wound was treated without stitching the diaphragm. About six months later I was called to operate on him for acute obstruction of the bowels. There was a tympantile tumor presenting

*Dr. Ferguson's paper appeared in the Journal of July 1.

at the old scar. The operation was undertaken in the possible hope of giving relief. At the time of the operation I found the whole transverse colon, part of the stomach and small intestine in the left thorax. The lung was pressed up until it was not larger than my fist, occupying the apex of the thorax. This case I reported in detail elsewhere.

The other case occurred a few weeks ago; a negro woman, aged about 50 years, who gave the history of having had severe attacks of constipation for several years. She had been in the hospital on the medical side, for four or five days, with absolute obstruction of the bowels, before she was transferred to the surgical side. This obstruction had existed for two days prior to her having been brought to the hospital. As soon as the case was turned over to the surgical side, I had the woman prepared, and I operated at once, without any idea as to what the condition was. On opening the abdominal cavity, I found, tracing the distending bowel, that there was a knuckle of the colon which had passed through a small opening in the diaphragm. This was apparently a congenital opening, no larger than my finger; no hernial sac, only a small knuckle of the transverse colon—splenic flexure—passed into the opening. There was absolute obstruction. On enlarging the opening slightly, which was done without difficulty and without shock or interference with respiration, I was enabled to liberate this knuckle of intestine. This woman had had stercoraceous vomiting for several hours, and was vomiting when put on the table. The mistake I made here was that her stomach was not washed out. After withdrawing the hernial protrusion I was enabled to stitch the opening in the diaphragm with a continuous suture, without difficulty. This closure was done without any difficulty. There was no depression; respiration went on properly, but I killed the patient a few moments later.

The stomach and intestines were distended; she had taken all sorts of narcotics to make the bowels move, when it was absolutely impossible for them to move, and the whole upper intestine was filled with fluid feces. After the operation had been completed, without opening the intestine, which I should have done to let out this material, I attempted to press those intestines back into the abdominal cavity, and instantly there was a reurgitation and inhalation of the liquid; the woman was practically drowned; there was a large quantity of this material immediately taken into the lungs. I made two mistakes, in not washing out the stomach—it was an emergency case—and in not opening up those distended intestines and allowing that pent-up material to escape. I believe life might have been prolonged for a time. I am sure the woman might have been saved if an early operation had been done. There were no surgical difficulties present. I was surprised at the ease with which I was able to insert the suture and to close the opening in the diaphragm. The post-mortem showed that there had been a perfect closure of the opening in the diaphragm. The cure to operation in my first case was taken from Dr. Marcy's book on "Hernia," recommending operation.

CHAIRMAN—We have with us one of the pioneers in this sort of work, Dr. Marcy of Boston, and I would request that he come forward to the platform and open the debate on these excellent papers on hernia.

DR. H. O. MARCY, Boston.—Dr. Ferguson very properly called attention to the infundibular process, which unfortunately has usually been described as pertaining to the normal anatomy. This is not true, and in the well-developed man is only made to appear as a depression at the site of the internal ring by making traction on the cord. We are indebted to Clouet of Paris, who carefully describes it. He dissected over four hundred subjects having hernia in different stages of development, and not unimportantly describes the earlier conditions, where the internal ring was relaxed and the peritoneum depressed as anatomically normal. Quite to the contrary, I have satisfied myself that this is due to a defective closure of the parts case of the passage of the testicle through the inguinal canal. This leaves an inherent weakness of the parts, predisposing to hernia, which may not take place until even late in life. In the development of a hernia, as usually formed, the internal ring is depressed from above downward, leaving the cord in its lower border, forming a funnel-shaped depression, and, little by little the hydrostatic intra-abdominal pressure dilates the canal until the hernia is complete. Very naturally it becomes evident that the rational way of curing the hernia would be to reconstruct the parts to their normal anatomic condition, and this can only be effected by restoring the inguinal canal to its oblique passage through the abdominal wall, so that the intra-abdominal pressure is brought to bear at or near to, a right-angle with its long axis. The only other illustration of this rational closure of a canal in nature is the passage of the ureter through the wall of the bladder, from which, indeed, I obtained my first suggestion, which

taught me the necessity of the reconstruction of the inguinal canal for the cure of hernia, which necessitated two radical departures from that which had been hitherto taught as permissible. A free dissection, a separation of the peritoneal sac, quite within the border of the internal ring—the cord having first been carried upward, toward the median line—and sutured evenly across its long axis, and resected. The peritoneum thus freed should be as no depression at the site of the suture.

The internal ring is now closed. From below upward, quite on the cord, which lengthens the inferior border of the inguinal canal, to normal length. The cord is replaced and the external structures sutured over it, re-forming the external ring. It will be noted that in order to accomplish this the deeper layer of the sutures must necessarily be buried, that is, cut off and left in the structures. This was the first use ever made of buried animal sutures in surgery, and I deliberately applied them for this very purpose, after experimenting with them for a considerable time, in a long series of studies on the lower animals.

My first publication on the use of buried sutures for the cure of hernia was in 1870. Repeated publications on the subject followed in this country, catgut having been used for the buried suture. In 1881, at the International Congress in London, I read a paper on the subject, advocating the use of the tendon suture obtained from the moose and caribou. In 1884, at the International Congress in Copenhagen, I still further reported my experiences in the cure of hernia and there exhibited specimens of suture material, obtained from the tail of the Kangaroo, which I have since used in all my work, believing that well-selected and prepared tendon is superior to any other suture material. Bassini's first work for the cure of hernia, embracing the essentials as above outlined, was in 1886, and his first publication was made in 1888.

Our profession very justly demands of its members a free contribution of every advancement in science, making double the honor accruing to the contributor, since he may not profit in any other way. Names signify comparatively little, but I am not quite content that the operation for the cure of hernia, which I devised and have so long practiced in all its essentials, should not be at least accredited to American surgery.

Dr. E. D. Ferguson of Troy, N. Y., in a paper entitled: "The Operative Cure of Hernia in Men," reviews the subject with judicial fairness, and in this paper I refer any who may ask an investigation of this subject.

I am quite sure that the contribution of Dr. Ferguson is of value more from calling attention to the fact of the defective condition of the structures with which we have to deal, than from the importance of the obliquity of the external incision which he advocates. Most operators are more or less aware of these conditions, and the suturing of the structures which go to form the posterior wall of the canal must correspondingly vary. The atrophy resulting from the long wearing of a truss is a well-recognized cause. It is hardly possible to overestimate the importance of the proper reconstruction of the posterior wall of the inguinal canal, since on this depends, more than on any other factor, the permanency of the cure.

As you are aware, several operators have gone so far as to advocate the transplantation of the cord, even closing all the strong structures of the abdominal wall beneath the cord. This is especially faulty, in that the internal ring is no longer buttressed at its point of exit, and a direct hernia is likely to occur here.

I have operated on several such cases where the attempted cure had been made in this manner. Experience now warrants that hernia almost without exception admits of safe and permanent cure, and that its practice may be commended to every practitioner who is a master of aseptic surgery, and am I not addressing to-day an association whose members are competent practitioners of the science and art of modern surgery?

DR. LEONARD FREEMAN, Denver, Colo.—I wish to mention another case of hernia of the diaphragm. Some time ago I had a patient in my charge who, in cleaning a snoutgun, discharged the weapon so that the ball entered in the left axillary line and emerged near the sternum. The charge seemed to pass beneath the skin only; but he was not severely shocked, and said that he did not think there was very much the matter with him. I incised through the skin and found a large opening in the chest wall, through which I could insert my fist. I could catch the heart and hold it in my hand. I did not know at first what the condition was, but after examining carefully, I found, as Dr. McPhee has also stated, that there was a large portion of the stomach, colon, and intestines, in the pleural cavity; the lungs were up under the clavicle and considerable hemorrhage was going on. With considerable difficulty I succeeded in replacing the abdominal viscera and sewing up the wound in the diaphragm, which was three or

four inches long. There was no interference with respiration or with the heart's action. I could pull the diaphragm almost out on the chest wall in making the sutures. The patient recovered from the operation without serious symptoms. However, during the course of the night, about twelve hours, perhaps, after the operation, bleeding from the lung took place and the patient died of internal hemorrhage.

DR. H. A. KELLY, Baltimore, Md.—So much work is done in original lines in Baltimore, I wish, with Dr. Marcy, to urge very strongly the propriety, no, the decency, of considering American claims first when American publications are prior to those of foreign authors. (Applause.) When it comes to the transplantation of the cord in hernia, getting rid of the weak point, I want all to speak not of the Bassini, but of the Halsted operation, and if you will take a little bit of trouble and consult the records you will see that Dr. Halsted's publication antedated that of Bassini's. In bad cases, in Baltimore, we find that the ordinary suturing operation—and we always use non-absorbable sutures, in spite of my good friend's (Dr. Marcy's) claim that the absorbable is necessary—in bad cases, is not satisfactory; that the only operation which gives us a guarantee of success is transplantation of the muscle—muscle-plasty—bringing over the rectus muscle, as devised by Dr. Bloodgood. It sounds like bringing a bit of distant tissue from the neck over the ring, but you will notice that the border of the rectus muscle is close at hand and can be brought over the ring. Where we have had recurrences after the most careful operation was performed, they have been cured by this method, and we have had no relapses when the rectus has been drawn over the ring and used to close this.

DR. D. W. CUSHAM, Chicago—Since the question of priority and dates seem to be the order of the day, I think it both proper and right for me to state here that I claim to have first proposed the use of the sartorius muscle to strengthen the inguinal region in certain cases of old hernia; for I see Dr. Ferguson claims the idea as original with him, and has so labeled it in his printed paper. It is proper to state also, that the idea was suggested to me by reading of a cadaver experiment by a Dr. Kelly of New York, in which he used the fascia connected with the tensor vaginæ femoris muscle for this purpose. It occurred to me that the sartorius muscle might be utilized to better advantage and with more promising results. My opportunity came in April, 1895, and in May of that year, when the subject of hernia was under discussion at the annual meeting of the Illinois State Medical Society, I reported the case with details of the procedure. I withheld the report from the Transactions of the Society for the reason that I wanted to improve the technic and add other cases before publishing or recommending the method to the profession. I have not had a case since in which the procedure was indicated, and in which I could get the consent of the patient. As a plastic operation, the one I reported was only a partial success, because of avoidable technical faults, the chief one of which was hemorrhage occurring after the wound was closed, which caused the stitches to break away and the end of the muscle where it was sewed to the border of the rectus to slough. The patient was a man of about 60, with a very large inguinal protrusion and defective abdominal muscles. He had already been operated on three or four times by other surgeons, but without benefit.

DR. J. P. LORD, Omaha, Neb.—Apropos to Dr. Reed's paper, in which he speaks of ventral hernia, and hernia of the linea alba, I want to state this experience. In operating on a case of very large umbilical hernia in a woman weighing 300 pounds, who had had repeated pregnancies, the last of which resulted in twins, I found, in addition to this very large umbilical hernia two large hernie of the linea alba in addition, one with a tumor of the omentum, the size of a Bartlett pear, and the other the size of an ordinary hen's egg. These were between the umbilical hernia and the ensiform cartilage. I do not recall having seen in my researches reference to multiple hernia of this kind.

DR. J. B. BULLITT, Sr., Louisville, Ky.—Overlooking, for the time being at least, all questions of priority and the various operators, American and otherwise, I would like, for a few minutes, to discuss the papers, especially that presented by Dr. Ferguson. The curved incision seems unquestionably to afford some points of advantage, which have been already pointed out by Drs. Thomas and Lee incidentally. Concerning, however, the further procedure as mentioned by Dr. Ferguson, I fail to see that it accomplishes the restoration which he seems to believe it does. As Dr. Marcy and Dr. Kelly have mentioned, referring to the method practiced by Halsted, of transplantation of the cord, the cord, instead of being restored to its original oblique anatomic position high up, is depressed downward by bringing the internal oblique muscle to Poupart's

ligament above this cord. The valve-like structure at this point, instead of being restored by Dr. Ferguson's principle, has been prevented from recurring. On the other hand, Bassini's operation does just the reverse of this; it closes the lower portion of the ring where this depressed condition of the cord has occurred, transplants the cord above to exactly the position where Halsted would place it, and restores the parts as Dr. Marcy has shown us on the blackboard, beautifully and simply, to their proper anatomic relations. Concerning the question of suture, I must agree that while my experience is very limited as compared with Dr. Marcy's, and with many other gentlemen's, I must say that this incident of breaking down of the tissue underneath the suture or with the buried cumul suture does occur and is a most distressing one. This has not always been caused by direct infection. I believe that hemostasis is not always complete and that a blood clot forms here; if any bacteria are introduced along with the sutures, they find fertile soil for development in this blood clot. Therefore, I agree with Dr. Lee that the radical cure of hernia would seem to offer a very reasonable and hopeful method of closing these wounds. Concerning the question of the buried silver-wire suture, despite the authority which we have from Baltimore—which is one of the Meccas of American pilgrimage in our day—the majority of the profession will scarcely come to adopt this method. In Louisville we are still taking out the sutures put in in Frankfort.

DR. FRANK WARNER, Columbus Ohio—I wish to emphasize the early operation on hernia. I believe too many of the works hamper you with a lot of suggestions that you will operate on a hernia when there are certain conditions this, that way and the other, but I believe the sooner we come to perform an early operation, aside from children and perhaps in old age, when they can get along by the use of a truss, the better we are going to be; the more sure we are going to be in having a satisfactory termination in our operations for hernia, in operating before hernia have become so large on the one hand that the parts are distorted and all of them weakened by the disturbance of nutrition, circulation, enervation, and so on, and the sooner we emphasize the matter to operate earlier, the greater success we will have.

DR. THOS. H. MANLEY, New York City—For some years I have given special attention to surgery of hernia, and there is no other subject that has had greater fascination than the history of the surgery of hernia. What strikes me particularly is the fact that practically all the modern operations had been done in pre-antiseptic times, one after the other, to be gradually dropped and displaced by another. It appears that in the last ten years, there have been something like 150 operations recommended for the cure of hernia. I was somewhat amused this afternoon in the discussion on the technic of operating for hernia, and our claims about the operation known as the Bassini, because I certainly was taught that Bassini's operation de-troyed the inguinal canal, while the aim of Marcy's original operation was to restore it. As I understood the Marcy operation, the clinching feature of it was that he restored the inguinal canal.

The Bassini operation destroys the whole thing. If they can prove the contrary to what Dr. Ferguson has so well brought out this afternoon, that the functions of the testes are greatly impaired by displacing the spermatic cord, I will agree there is a very serious objection to the Bassini operation. There are some very important points which the reader has entirely failed to take up. You notice in the beginning that this operation, as described, applies to only one type of hernia, to the complete inguinal in the adult; and the majority of our operations which are being done for hernia nowadays, are on infants and children. The infant has practically no inguinal canal. The key to the whole situation, in operations for inguinal hernia, in my experience has been, and I have had no reason to change it one iota, that the best operation for the so-called "cure" of reducible hernia is that which should be the simplest, which is attended with the least mutilation of tissues, with the least loss of blood, and performed with the greatest rapidity.

DR. SAMUEL E. MILLIKEN, Dallas, Texas—At the time I read my first paper on Bassini's operation, before the Texas State Medical Association (*Med. Record*, 1892), there were many skeptics as to the possibility of a radical cure. When I began the reconstruction method ten years ago I employed catgut, but some years later my friend, Dr. Marcy, got me to using kangaroo tendon. It has been my misfortune to have been compelled to remove these stitches three months after an operation when primary union had been obtained.

DR. MARCY—You ought to have left it alone.

DR. MILLIKEN—It came to the surface.

DR. MARCY—You didn't bury it properly.

DR. MILLIKEN—The buried suture has always been a diffi-

cult problem, and I hope the longitudinal silver wire solves it for all time. Catgut, I am convinced, does not last long enough and offers an additional danger of infection. I wish to congratulate Dr. Lee and Dr. Harris for offering us a satisfactory suture material for the deeper structures in hernia work.

In 1892 I called attention to the method of dividing the aneurismosis of the external oblique by passing the grand director into the external abdominal ring almost longitudinally, instead of running parallel with the fibers—this for the purpose of giving a longer external or lower flap, at the same time caused the various layers of sutures to be in different lines and not directly over each other.

Dr. J. E. MOORE, Minneapolis, Minn.—In the matter of umbilical and ventral hernia, mentioned by Dr. Lord, I wish to bear testimony to the fact that it quite frequently occurs above the umbilicus. I have operated on patients who had been treated for years for dyspepsia and all sorts of intestinal disturbances, who were really suffering from small omental hernie, sometimes so small that they were not larger than the end of my small finger, and many times they were unknown to the patient. I have generally found those hernie in the median line, quite frequently a little to the left; I never found any to the right. I have found, too, on examination, that the patient knew nothing of it. I would call his attention to the fact that there was a little lump there and he would say that he never would have known it. They come through the small opening and they can be sewed up, as you know. I have been interested here, because we have a multiplicity of operations, which I believe is very desirable. As one has said, it is not well to limit ourselves to one operation. Who is there here who would always perform a hysterectomy or a simple amputation by the same method? Why should we always undertake to perform a herniotomy by the same method? We have a multiplicity of methods and we should consider, in performing any radical cure of hernia, the sole idea of doing that particular patient the most good. (Applause.) You can not always bring that about in the same method. In the matter of suture, my patients in whom I have buried nonabsorbable material, have stayed at home and I have been removing those sutures myself. When we perform an operation for hernia, either we get primary union or we do not. The success of the operation for hernia depends on the presence of asepsis. If our wound is aseptic, union will take place in a very few days. It does seem to me that sutures are not needed to hold four and five weeks. As I say, either you get union or you do not. Taking, as a matter of illustration, a simple amputation wound, if you get primary union you are satisfied; if your stitches will hold for six days you get a good result; if you fail to get primary union, you remove your sutures, because they are a nuisance and they are doing harm. Why not apply the same principles to the same operation for hernia?

Dr. A. J. OSCHNER, Chicago.—I think that Dr. Ferguson's paper is worthy of careful consideration and discussion, because it is based on very careful and extensive anatomic study. His diagrams bring out the conditions present, with great clearness, and on this foundation he has developed an operation which is logically superior to most of those heretofore described. I saw Dr. Adams of Glasgow use the same curved incision in 1895. In 1897 I saw Dr. William T. Bull, New York, perform the operation Dr. Ferguson has just described, with the exception of the external incision. He obtained most satisfactory results by this method. I do not know whether it was original with him, nor how long he had practiced it, but the fact that several eminent and thoughtful surgeons have developed the same method speaks well for it. This method seems to me to have some advantages over the Halsted operation, from the fact that it does not disturb the tissues to so great an extent, and leaves them more nearly in a normal position after the operation has been completed. In the Bassini, as well as in the Halsted, there is often a tendency in the fibers above the internal abdominal ring, to separate and to permit the development of a recurrence at this point, while the remaining portion of the abdominal wall remains perfectly intact. Our distinguished president, Dr. Mayo, has overcome this difficulty by placing a stitch through the tissues just above this point, before beginning to suture the conjoined tendon to Poupart's ligament. A most important point in all hernia operations consists in not drawing the sutures too tightly, because the pressure necrosis which results from tightly drawn sutures always leaves a comparatively weak scar, and predisposes to suppuration.

Dr. C. E. RUTH, Keokuk, Iowa.—The large number of diagrams which we have had here and the number of papers tend to put us about in the same predicament that we are in with the long list of remedies recommended for the cure of diseases—that either of them are worth anything or altogether are valueless. If we look closely at this, however, and the methods

of the men advocating them, we will find that underlying all of these incisions and methods of suture there are the same principles almost identically. We have the statement that men, whose veracity we can not question, accomplish certain results almost invariably with an absorbable material, and men who are just as careful in their work, so far as we know just as skillful, fail to get primary union; they have suppuration, and they use the same material, and so we are led to form our own conclusions as the result of our own experiences. We must each come to the point that we can not expect to follow, unvaryingly, the method of any one man, but that method which in our hands gives the best results. I must say that, despite all care that I have been able to exercise with absorbable and non-absorbable material, I have had considerable trouble, occasionally with infection, either early or late, and every one of these methods has its little advantage. But I want to thank the gentlemen, especially for myself, who have advocated so nice and timely a method which will enable us to use a removable, non-absorbable material that will do no harm.

Dr. F. W. McRAE, Atlanta, Ga.—I have had occasion lately to look up the statistics of inguinal hernia, and it seems to me that where one individual surgeon, whose veracity is unquestioned, has done 514 consecutive operations with one death and 5 per cent. of recurrences, he uses a pretty good method of procedure. Dr. Coley has had such results; and Dr. deGarmo's and Dr. Marcy's results are practically identical. They all use the same suture material—Kangaroo tendon. My personal experience is practically limited to the use of kangaroo tendon for closing the deeper layers. I have used silk and catgut only a few times. I have never had suppuration follow the use of kangaroo tendon, except in three cases recently operated on in the Grady Hospital. I am sure that the infection in these cases was not due to the suture material. Unfortunately I had in my service at that time several cases of intense streptococcal infection. We did not wear gloves, and I do not believe it is possible to thoroughly sterilize hands that have been bathed in intensely infectious material, only a short time before the operation, by any known method. The external surface of the skin may be rendered sterile, but prolonged manipulation brings the infection from the deeper layers of the skin, and suppuration is the result. Another important point is the size and kind of kangaroo tendon used. If very large stiff kangaroo tendon, such as is sold by many dealers, is employed, trouble will result sooner or later in many instances. But if the small tendon from the young kangaroo is used it will be absorbed in a reasonable length of time, but still give sufficient support. Non-absorbable deep sutures give trouble in a certain proportion of cases. I have had to remove both silk and silver-wire sutures that had been buried for many months. I think silkworm gut much worse than either silk or silver wire.

Dr. J. B. MURPHY, Chicago.—I wish to mention a method of closing openings in diaphragmatic hernia, the same as I devised for a case of bullet wound, viz.: open the thorax posteriorly, by an osteoplastic flap of the chest wall, which allows a fine exposure of the convex surface of the diaphragm. The hernia is then reduced and the opening in the diaphragm closed with catgut sutures, the flap replaced and the air aspirated out of the pleural cavity. I am now in competition with my associate, Dr. Lee, as to who will get the best result. Dr. Lee is using the deep non-absorbable, subsequently withdrawn silkworm gut suture. His results have been beautiful. I am using Marcy's kangaroo tendon, and I am going to try to overcome him if I can.

Dr. M. L. HARRIS, Chicago.—Early infection is due to the introduction of germs at the time of the operation; late infection to the transmission of germs along the sutures from the skin to the deeper structures. In the buried absorbable sutures we have two difficulties: 1, the aseptic suppuration of Poppert; 2, the hyaline degeneration which occasionally occurs about absorbable sutures. While these conditions are not dangerous to the life of the patient, they do weaken the line of union. All methods which transplant the cord are objectionable, as they have been followed in a large percentage of the cases by atrophy of the testicle. The value of the silver-wire longitudinal suture has been demonstrated by the remarks made by most of the gentlemen. It secures the most perfect coaptation, it produces the least possible amount of connective tissue and hence the greatest strength of union. The cord should, when possible, be re-tored to its oblique position, as this gives, anatomically, the greatest strength to the abdominal wall.

Dr. A. H. FERGUSON, Chicago.—When this Temple of Hernia is complete, and when we are all gathered home to dedicate it, then we shall give distinction to the man who laid the first stone and the different stones. It is now looking for priority, but looking for that which fulfills indications that is stimulating us to bring forward the best methods for the radical cure of

hernia. The imbecilic assertion that a certain man does not do a semilunar incision with the idea of the hernia returning should not be laughed at. No one operates on a hernia with the idea of the hernia returning—it matters not what the incision is. The transplantation of the cord is bad. There is no possible reason for transplanting it, except that it fills a gap where the origin of the internal oblique muscle is deficient. If the origin of the oblique muscle is sutured where it belongs, then, there is no reason for raising the cord out of the bed. I have had bad results; I have had plastic inflammation of the testicle following atrophy and destruction of one testicle. That cord should be left alone. The recommendation of splitting the sheath of the rectus muscle and bringing it over is an excellent thing in certain cases—a small percentage—and Dr. Bloodgood, who invented that method, is not as sanguine of bringing it forward as the gynecologists are. It should be used when there is a deficiency, but not when the typical operation can be performed. The typical operation for the radical cure of hernia leaves all structures where they belong. It is surprising, the lack of knowledge as to the presence of the internal ring. It is only a small percentage when it is pushed downward. When you have tied off your sac you have the internal ring at the epigastric vessels, and almost invariably in normal cases; in sixty cases out of 100, you will find—that is the kind I operated on—that the internal ring, after tying the sac, is in its normal place, and then all you have to do is to restore the structures. The obliquity of the canal is restored by tying the sac. It is not necessary to bring the structures underneath the cord. There is another objection to that. There is neuralgia in the region of the hernia on account of the constriction of the nerve sometimes. When the cord is left in its bed, there is no neuralgia.

DR. R. HARVEY REED, Rock Springs, Wyo.—It seems to me that the papers and the discussion which we have heard this afternoon have developed this difficulty, if they have developed anything at all, that is, that it is absolutely necessary—it matters not what kind of suture you use, whether it is animal, silver, iron, silk, or silkworm gut. It is necessary to approximate the parts perfectly, it is necessary to have a complete and thorough blood supply; it is necessary to get rid of your foreign material at the earliest possible moment. If you do not obtain this, you are going to have a foreign body which will, sooner or later, produce irritation, followed by suppuration, and the result of that operation is going to be a failure. Then it remains as to the character of the operation—the nature and the condition of the parts on which you are going to operate—as to which one of these particular sutures or methods of suturing is to be used, but you have to carry in your minds, distinctly and clearly, the principles that underlie the repair of wounds, and when you have done this, brought the parts to their proper place and held them there until Nature restores them, then your suture is of no further use. To get a suture that will do this is one of the most difficult matters to determine, because we may purchase from the very same manufacturer the same quality of catgut, as far as we are able to tell, and the result is different when sterilized in the same manner. You purchase the kangaroo tendon and you sterilize that as before, and one time will have union by first intention and the next time you will have suppuration. I have seen cases in which there was not vitality enough to have a foreign body absorbed, and others where the catgut is absorbed too soon; one instance I remember very distinctly, in which the kangaroo tendon was used when the sutures dissolved and were not absorbed, but remained there as gelatinous material, resembling melted glue.

DR. E. H. LEE, Chicago—I am pleased to hear that so many surgeons acknowledge that they have more or less trouble—more or less infection. At the present stage of modern surgery, I do not believe that anybody can say that he is master of aseptic surgery. It is impossible to say positively that you are going to operate "clean." During the college year of the College of Physicians and Surgeons, Chicago, Dr. Murphy and myself operated on several hundred cases at the West Side Hospital, and during this period of time I do not remember having seen infection in clean cases, this including several hernias, yet the time may come when we will have a series of infections; this can not be avoided. We can not always avoid the unpleasant complications which may follow an infection. It is for this reason that I have advised this method of suture.

DIPHTHERIA and scarlet fever are becoming quite prevalent in Chicago, especially since the opening of the schools. The health authorities say that the outbreak is a result of neglect of the school authorities, while the latter deny this.

FIBROSARCOMA OF ABDOMINAL WALL.

DESMOID FIBROMA BEGINNING IN POUPART'S LIGAMENT AND EXTENDING AROUND THE ILLIAC VESSELS INTO THE PELVIS—REMOVAL WITH RESECTION OF THE ABDOMINAL WALL AND EXTENSIVE DISSECTION OF THE ILLIAC VESSELS—REPAIR OF DEFECT IN ABDOMINAL WALL BY PLASTIC OPERATION^o.

BY ALBERT I. BOUFFLEUR, B.S., M.D.

Assistant Professor of Operative Surgery, Rush Medical College; Chief Surgeon, Monroe Street Hospital; Attending Surgeon, Cook County Hospital; President International Association of Railway Surgeons, etc.

CHICAGO.

Tumors of the abdominal wall are comparatively rare, and of the varieties found, fibroma comprises nearly 90 per cent. Fibroma of this locality presents some peculiar features which make it a subject of much interest to the pathologist and to the surgeon. According to the collection of Guerrien, as given by Senn¹, nearly 93 per cent. occur in women. It usually follows childbed, and trauma is the common determining cause. The tumor usually begins in the fascia in the lower segment of the abdominal wall and particularly about the crest of the ilium and the sheath of the rectus muscle. It has a marked tendency to extend inward; and may readily be mistaken for an intra-abdominal growth.

This tumor presents certain characteristics which make it difficult of classification. The tumor itself presents the histologic characteristics of a fibroma, but it manifests a marked tendency to infiltrate adjacent tissues and to recur after enucleation, but complete excision usually effects a permanent cure. Some authors classify these tumors as fibrosarcomata, while others consider them as a peculiar variety of fibromata. Nélaton early recognized their peculiar features, as did Mueller, who, to distinguish them from simple fibromata, designated them as "desmoid fibromata." The term "desmoid" would, according to our standard dictionaries, indicate a tumor springing from a fascia or a ligament. Senn, in his work on tumors, again calls attention to the peculiar features of these fibromata, and advises the retention of the term "desmoid" as a special designation for those tumors which begin in the fascia of the abdominal wall, which present histologic structure resembling fibroma, and which seldom recur after total extirpation, but which manifest a tendency to infiltrate adjacent tissues and to return after simple enucleation. Many will readily recognize in this description some of the characteristics of sarcomata, and, I believe, all will agree that the tumor occupies a peculiar indefinite position on the border line between the benign and the malignant. It probably represents a transitional stage in the transformation of a fibroma into a sarcoma, and the degree of infiltration would seem to indicate the extent to which that transformation had progressed. While most desmoids occur in the abdominal wall, they may occur in other localities. Professor Le Count has informed me personally that he has examined two specimens of desmoid fibroma taken from the male breast and the one from the neck.

The case upon which this report is based is as follows:

Miss —, 20 years of age, a well-proportioned lady of nearly six feet in height, and weighing about 250 pounds, was brought to me by the family physician, Dr. J. A. Crowell of Iron Mountain, Mich., for examination.

^oPresented to the Section on Surgery and Anatomy, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

¹ Pathology and Surgical Treatment of Tumors.

The following meager history was all that could be elicited. Between two and three years previously she had noticed a drawing sensation in the right side. Upon stooping, she experienced pain in the right inguinal region, which was also noticed after long walks, and especially during menstruation. Her principal, in fact only, marked pain was during menstruation, which was invariably referred to the right side of the lower abdomen. She had never been pregnant, and did not remember having sustained traumatism of the parts.

In about June, 1897, nine months previously, she first detected a swelling deep in the groin, and about two months later a physician examined it, at which time it was apparently the size of an orange. It had not been particularly painful upon manipulation, at any time. During the last three months there had been a rapid increase in the size of the swelling and the pain had also increased.

Upon inspection, a large protruding swelling could easily be observed, with the patient in either the erect or recumbent posture. By palpation we were able to determine a very firm, fixed swelling, apparently of the size of one's head, situated in the right inguinal region and projecting into the hypogastric region. The unusual obesity of the patient made the size of the swelling appear much larger than it actually was. The upper border was well defined, while the lower border seemed continuous with Poupart's ligament. The surface was generally smooth and regular, but a slight nodular irregularity was noted.

Vaginal examination was quite unsatisfactory, on account of the size of the patient and depth of the pelvis. A somewhat indefinite, irregular and tender swelling was detected in the right pelvis near the brim. No direct connection with the uterus could be determined at the time of the examination. Examination of the lower limbs failed to detect any disturbance of the circulation or nutrition of the corresponding one. No glandular enlargement was detectable anywhere.

Dr. Crowell had made a careful examination of the patient and had diagnosed the condition as one of probable sarcoma or fibroma. From the clinical history and examination we concurred in the diagnosis, and from the location and peculiar features of the case we believed that it was one of those quite rare cases of fibroma of the abdominal wall, classed as desmoid. From its primary location the tumor had begun in Poupart's ligament and gradually extended inward and upward, involving all the ligament and a large section of the abdominal wall, and completely filling the iliac fossa, with a portion projecting into the pelvis. The extreme thickness of the natural abdominal wall of this patient precluded a definite outline of the growth.

In view of the very rapid growth of the tumor within the preceding three months, the transformation of a fibroma into a sarcoma was suspected, while the size and attachments of the tumor impressed us with the great difficulties which would be encountered in its excision, and notwithstanding that there was a strong probability of our being unable to completely remove the tumor, we decided, in view of the perfect health of the patient and the absence of any edema or other evidence of disturbed circulation in the limb below, indicating involvement of the blood-vessel walls, that there was a possibility of its successful removal and that the patient should be given the benefit of the possibility.

The seriousness of the situation, which had already been presented by the attending physician, was again stated to the patient and relatives, and the operation

decided upon. As the hospital was full at the time, the patient returned to her home and a week later we operated, with the assistance of Drs. Crowell, Wescott and Cameron, and with Drs. Carpenter, Lockett and Menistrana present. Schleich's anesthetic compound of ether, chloroform and benzoin was skillfully administered by Dr. Cameron. Preparation of the operative field and the hands was thoroughly made by soap and brush, and alcohol only. No other chemical disinfection was made.

An incision 10 inches long was made over the most prominent part of the tumor parallel to Poupart's ligament and just below the lower abdominal fold. Upon dividing the exceedingly thick layer of adipose tissue, nodules of the tumor were observed, involving and projecting through the aponeurosis of the external oblique muscle from the indefinite creases of Poupart's ligament upward for about five inches. The projecting masses were smooth, dark in color, and very vascular. Having in mind that the principal element of success in the operative treatment of such tumors was the complete, even more than complete, removal, we made an incision vertically from the anterior superior spinous process and carried it in a curved direction above and around the tumor to the pubic spine. The whole thickness of the abdominal wall was incised. The attachments of the tumor seemed very slight below the muscles, and extirpation progressed rapidly.

Our hopes for a rapid enucleation of the deeper portion were dispelled by encountering a large lobe of the tumor in the depth of the iliac fossa, which was of larger size than the superficial portion, and which was separated from it by a deep furrow corresponding to the location of the lower abdominal fold. The inner end of the tumor was firmly connected with the pubic bone at the attachment of Poupart's ligament, with which structure it was inseparably connected throughout its whole length. To remove the deeper portion of the tumor, it was found necessary to resect an oblong section—more than 5½ inches—of the peritoneum, which was intimately attached to the inner lobe. The great thickness of the abdominal wall made separation of the deeper portions exceedingly difficult, and as the tumor dipped into the pelvis the dangers of a blind dissection can readily be appreciated. It was impossible to view the deeper parts of the wound with the tumor *in situ*, and when the tumor was elevated the femoral pulsation would cease, which confirmed our fear that it surrounded the vessels and that enucleation was impossible. As our attempt at its removal *en masse* was unsafe, and, as I believe, impossible, a *horizontal* section was made, and the greater part of the tumor, with all of Poupart's ligament and part of the fascia lata was removed. Fig. 1 shows the outline of the tumor and its relation to Poupart's and the round ligaments, and to the peritoneum.

Upon investigation we found that the tumor had extended along the iliac fascia and that the lower part of the iliac fascia and the outer part of the right broad ligament were occupied by the remaining portion of the tumor. The iliac vessels were completely surrounded by the tumor for a distance of five inches. From the soft, friable and vascular character of the tissues remaining we feared that the tumor was no longer a simple fibroma, but instead a more rapidly growing sarcoma. From an operative standpoint it was also evident that the difficulties of the operation had only begun. The complete removal of the tumor was considered by those present as practically impossible, and the danger of

damaging the vessels was so imminent in a wound of such great depth, that one would have been justified in abandoning the attempt. With the conviction, however, that the growth would return, unless completely removed, we decided to continue the extirpation as long as the patient's condition would permit. We accordingly rapidly dissected away the iliac part of the tumor including the iliac fascia, and began the tedious work of dissecting out the iliac artery and vein, whose walls were infiltrated throughout their whole extent by the tumor. You will recall the absence of any circulatory disturbance in the record of the examination, which must be accounted for by the fact that the lumen of the vessels had not been encroached upon.

The room in which we operated was lighted by low south exposure windows, and it was necessary to turn the patient on her side, and to allow the sunlight to fall directly into the wound to light up its deepest parts. While rapid completion of the operation was desirable, it was, as you will readily appreciate, absolutely impossible and palpably unsafe under these circumstances.

We succeeded in removing every particle of the tumor, and in doing so it was necessary to remove considerable of the external coat of the external iliac artery throughout nearly its whole length. Only a slight hemorrhage was encountered, and that was due to the necessary division of the circumflex iliac vein and the small arterial branches to the psoas muscle, as we had previously ligated the internal epigastric and internal circumflex iliac arteries.

DESMOID FIBROMATA OF ABDOMINAL WALL.

1. Muscular fibers of internal oblique. 2. Point of attachment to ant. superior iliac spine. 3. Poupart's ligament, attenuated. 4. Fat in groin. 5. Cut edge of aponeurosis of ext. oblique. 6. Dup. lobe of femur partially curved by peritoneum. 7. Portion of femur projecting into pelvis. 8. Round ligament. 9. Attachment of Poupart's ligament to spine of pubes.

The ovary of the right side was found to be large and to contain one cyst the size of a small hen's egg. As the operation wound was already of startling size, we did not care to add any additional and avoidable elements of danger to the case. The condition of the ovary would certainly have justified its removal, but under the circumstances I believe its being left alone was the best surgery.

With the tumor removed and an immense excavation in the side extending down into the broad ligament and presenting the iliac fossa and Scarpa's triangle as one space, the last difficulty was encountered—how to close the large defect in the abdominal wall. We did not have time for meditation and the formulation of any elaborate method of closure, and, therefore, decided to simply follow the same principles as I do in hernio-

my: 1, close the peritoneum; 2, restore muscular continuity; 3, secure tendinous or aponeurotic support; and 4, close the skin over the deeper structures, but not to utilize it in any way as a supporting element in the closure of the defect, nor to include it in the deep sutures.

The peritoneum was closed from the side of the bladder to near the crest of the ilium. While the closure in the pelvis below the vessels was difficult, the great protection to the dangers of a possible infection made it seem imperative to close it absolutely. This procedure transferred the iliac and part of the pelvic fossa from intraperitoneal to extraperitoneal cavities. As a large resection of the muscles of the abdominal wall had been made, we split the fibers of the rectus abdominalis and the sartorius and sutured them across the defect, connecting them externally with the divided internal oblique.

To fortify this delicate muscular layer I split the remaining aponeurosis of the external oblique parallel to and about four inches above the line of resection and slid it downward so that its lower edge occupied the position of the removed Poupart's ligament, and fixed it there by sutures. This gave us normal muscular support without aponeurosis of the external oblique above and artificial muscular support with normal aponeurotic support below. In addition to these elements of support we calculated that the large cavity would be filled

DESMOID FIBROMA, RESULT OF PLASTIC OPERATION.

with scar tissue which would directly support the abbreviated peritoneal wall and would also lessen the pressure on the overlying support which we had constructed. The skin was sutured and a gauze drain inserted, to be left for two days.

The wound healed promptly within ten days. The patient maintained the recumbent posture for four weeks, and wore an abdominal support for six months. The result has been much better than we anticipated; in fact it is absolutely perfect, both as to contour and as to support.

I examined the patient three months after the operation and could find no return of the tumor and absolutely no evidence of a ventral hernia or any weakness of the abdominal wall. When the patient stands up now there is no deviation from the normal contour noticeable, and even the scar is practically out of sight in the abdominal

fold. Lateral exposure also fails to show any bulging of the abdominal wall. Fig. 2 shows perfect Poupart's fold and appearance of scar on raising of pendulous part of abdominal wall. The cyst of the ovary has practically disappeared.

The absence of the return of the tumor within fifteen months warrants the conclusion that the radical operative treatment was perfectly successful, and the absence of a ventral hernia evidences the fact that even extensive defects of the abdominal wall can be successfully repaired by plastic utilization of the remaining normal structures.

Microscopic examination of the various portions of the tumor have kindly been made by Professor Le Count, who confirmed the clinical diagnosis of desmoid fibroma, and submitted the following histologic examination: "From the section of the entire tumor, which was cut in a fresh condition, a number of small pieces were selected. These exhibited small variations in color and consistency, but histologically were all found to contain essentially the same features, viz., well-fibrillated cells with scanty amount of intercellular substance. Such blood-vessels as were encountered resembled sinuses with atypical hyaline walls. The above-mentioned variations were judged to be due to difference in the amount of blood and to edema."

CHRONIC VOLVULUS PRODUCED BY ABSORPTION OF A MYOMATOUS TUMOR AFTER SALPINGO-OOPHORECTOMY: A CLINICAL NOTE.*

BY JAMES F. W. ROSS, M. D.
TORONTO, ONT.

I intend to place on record my experience with a rather rare disease, a disease that has not been much written of and certainly is rarely seen. It is not my intention to discuss the subject of acute volvulus nor of acute intestinal obstruction, but the subject of chronic volvulus, chronic intestinal obstruction lasting over a considerable period of time, an obstruction partial, not complete, and an obstruction that may at any time become complete, and set up symptoms of acute intestinal obstruction.

I find a record in the *British Medical Journal*, of a case reported to the Manchester Pathological Society, by Dr. Ashby. He showed the pathologic specimens removed from the abdomen of a man, 19 years of age, who had been subject to attacks of vomiting for two or three weeks from the time of his birth. He had frequently vomited large quantities of fluid during a single night. The exhaustion of these vomiting attacks was sometimes very great, and appeared to be almost fatal. Errors of diet seemed to invariably bring on the attack. After one of these attacks of vomiting he had acute obstruction of the bowels, peritonitis supervened, and he died. The post-mortem examination showed the immediate cause of death to be an acute volvulus involving nearly the whole of the small intestine, the last few feet of the ileum being twisted from right to left around the upper portion of the jejunum below its junction with the duodenum, the latter being twisted on itself in axis. The stomach was found immensely distended and hypertrophied; the duodenum, also dilated, like a second stomach. The lower part of the duodenum and the upper part of the jejunum were surrounded and in part constricted in front by fibrous adhesions, with some

cretaceous deposit, the result of old—probably fetal—peritonitis. About six inches were thus bound down. There was no complete obstruction, as a forefinger could be readily passed through the narrowest part.

We have here a case of chronic volvulus producing an obstruction of the bowels lasting over a number of years. A little extra twist may at any time make such a volvulus acutely felt so that the result may be disastrous to the patient. I have two cases to record, one of which suffered from volvulus on several previous occasions, and was operated on by me during an attack of acute volvulus, made a good recovery and has never since had a recurrence. The second case is one to which I wish especially to draw attention:

CASE No. 1.—Mr. F. A. G., aged 35, was seen by me in consultation with his physician, Dr. Webster of Toronto, on Feb. 15, 1897. I diagnosed the case as one of acute volvulus. The diagnosis was based on the peculiar appearance of the abdomen. Beneath its walls could be distinctly noticed a tense, curved mass, looking like a piece of bologna sausage hanging over a line. I learned on questioning the patient that he had on previous occasions suffered with similar attacks, but that after the administration of high enemata he had obtained relief. In this attack he stated that he had been taken sick five days before I saw him. While lifting a box he felt a sudden pain in the abdomen. The doctor was not called in until the next morning. No movement of the bowels could be obtained. Purgatives were administered, but were ineffectual. Two professional nurses endeavored to give enemata but could not get the water to pass up beyond the rectum, owing to some obstruction. A small amount of blood and slime came away per enema. The doctor thought the case might be one of intussusception, but I differed from him, owing to the peculiar contour of the abdomen. I advised immediate operation, and operated in the afternoon of the same day.

The abdomen was opened in the median line, an enormously distended and very much lengthened sigmoid flexure popped out of the incision and protruded from the abdomen from twelve to sixteen inches, and stayed straight up like the finger of a glove blown up with air. It appeared to be almost as large as a man's arm at the curve of the elbow with the point of the elbow upward. I turned the volvulus from left to right and undid two twists. I then had an assistant pass up a rectal tube, guided by my hands above, through the untwisted opening and the bowel was thoroughly washed out with water. An enormous collection of seeds of different kinds, pieces of undigested food, grape skins, and pieces of corn were in this way dislodged. After the bowel had been thoroughly emptied it was placed back in the abdominal cavity. I then fastened the left side of the mesentery of the abnormally lengthened bowel, to the peritoneum in front on the left side and the large muscular band of the intestine to the peritoneum on the right side of the abdomen. The abdominal wound was then closed. The patient made an uninterrupted recovery, has remained in good health, and has never had any recurrence of his former attack.

CASE No. 2.—Miss C. was referred to me in October 1894. On examination I found her suffering from a fibroid tumor growing in the left broad ligament, and advised operation, not knowing before operation whether the tumor could be removed or not.

At the Pavilion of the Toronto General Hospital, in the presence of a number of medical men, I opened the abdomen in the median line, found the growth growing in the left broad ligament and determined that it could

*Presented to the Section on Obstetrics and Diseases of Women, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

not be removed with any degree of safety. Both ovaries and tubes were therefore taken out. The patient made an uninterrupted recovery and went home but continued to menstruate. Her health was good for a year or more. The menstrual flow became excessive at times. She suffered considerably from backache. The chief symptoms, however, that subsequently set in, appeared to be those of indigestion produced by pressure on the rectum by the tumor. I made an examination and found, to my surprise, that the tumor had increased in size. I felt disappointed, because a large percentage of these cases have been entirely cured in my hands by removal of the ovaries. I was forced, therefore, to the conclusion that this was one of the unsuccessful cases. She complained of a continual aching in the abdomen, with a continual pain, chiefly toward the right side. I watched her carefully for a length of time and found slight elevation of temperature. She came to my office at intervals for a period of about three months. The tumor still remained as I had first found it, and the patient was evidently suffering from more pain than she could be expected to bear. She therefore determined to have the tumor removed at all hazards. I thought I knew what to expect and consequently held back, but eventually operation was forced on me.

On Jan. 18, 1899, I operated on her, in the Pavilion of the Toronto General Hospital. Dr. A. H. Wright of Toronto assisted me. The abdomen was opened in the median line and the old scar was entirely removed. A large tumor could be made out, filling the pelvis; it looked peculiar. I had never seen a tumor look just as this one did. It did not appear to be a fibroid tumor, but looked more like the tumor found when dealing with a suppurating ovary. After more careful inspection I concluded that it must be distended intestine. Even supposing the tumor to be distended intestine the case was not at all clear. The patient's bowels had moved several times in response to the usual purgative given before celiotomy. There were no definite evidences of obstruction of the bowels before operation. On feeling around in the left loin, the descending colon was encountered and was found filled with scybalous masses. These scybalous masses could not be made out by external palpation. They were found to extend onward into the transverse and descending colon. A great deal of difficulty was experienced in isolating the bowel, owing to the adhesions of one coil to the other. The operation was a prolonged one. It was found impossible to get anything up with which to anastomose any superior portion of the intestine. The tumor filling the pelvis proved to be nothing but a sigmoid or omega flexure packed tightly with fecal matter and half twisted on the narrowing portion of the omega flexure. A half turn of this flexure caused all the trouble. A full turn would no doubt have produced acute volvulus from which the patient must have lost her life long before. The finger could with difficulty be made to reach and pass up through the rectum through the constricted portion. The masses of feces were almost as hard as rocks. The tip of the finger passed through the anus would barely enter at the site of the twist. I separated the small intestines from around the mass, isolated the coils of large intestine, but owing to the shock could do nothing more. The patient left the table with a pulse of 140. Every effort was made to relieve her, but without avail, and she died next morning.

I regret the termination of the case, but can scarcely see that I could have done otherwise than I did. The condition could only be made out after a great amount

of searching, and this searching could only be carried out by breaking down dense adhesions. I fear that some portion of the bowel may have been torn into and that this contamination of the peritoneum brought about the fatal issue. I have never seen such an amount of fecal matter collected in any patient and have never seen fecal matter attain such a degree of hardness as it did in this case. The tumor of the uterus was found to have dwindled down until it remained about the size of a small orange. The only theory I can offer as an explanation of the condition is that the tumor filling the left broad ligament diminished, after the removal of the ovaries, from the size of a man's head down to that of an orange, and that during this diminution, the rectum, which is so closely attached to these tumors growing in the left broad ligament, was stretched and its mesentery lengthened, and that after the tumor had undergone a reduction in size, the bowel, as a consequence of this increase in length of bowel and corresponding mesentery, was allowed to take a half turn on itself.

Since meeting with this case I have come to the conclusion that there is one other condition that may simulate fibroid tumor and may deceive even the trained finger, and that condition is a collection of scybalous masses in a distended and partially twisted intestine, or in other words, a chronic volvulus of the omega flexure.

In November, 1898, I received a letter from the doctor in the country into whose hands the patient had recently fallen. He writes me as follows: "Dear Doctor:—I write you regarding Miss C., on whom you operated two or three years ago (in reality four years) in the General Hospital, for some ovarian trouble. She has been in very poor health for the past few months and now has some growth in the uterus on which an operation is necessary." To the letter I replied, "Your patient called yesterday. I believe you are in error regarding the nature of the trouble and, as a consequence, there must be some variance in our opinions. On examination now one would naturally think that our patient is suffering from a uterine tumor. At the operation four years ago I found that she had a fibroid tumor growing from the left broad ligament and, as a consequence, causing fixation of the tumor. The uterus was then over to the right side and somewhat elongated. Both ovaries were removed, as the operation of enucleation of such a tumor is accompanied by such a high mortality. I hoped at the time that oophorectomy would put an end to the growth of the tumor and that its presence would not give rise to much subsequent suffering. The whole question to be decided on is: Is the amount of suffering present great enough to demand interference, and the removal of the growth at all hazards? In some of these cases, after the removal of the ovaries menstruation continues for four or five years and then an early menopause is induced. If this patient demands operation I am prepared to perform it. Her recovery after removal of the growth would be complete and satisfactory."

After the operation had been carried out I wrote to the Doctor again as follows: "We have both been entirely mistaken in the case, as well we might be. The tumor has almost disappeared. After its diminution the omega or sigmoid flexure of the rectum must have taken a half twist on itself and have produced a volvulus. This volvulus was not sufficiently twisted to give rise to symptoms of intestinal obstruction nor even to send the patient to bed, but it constricted the intestine sufficiently to cause an enormous accumulation of scybalous masses above. The scybalous masses filled the twisted omega flexure of the rectum and were found away up in the

transverse and the ascending colon as far as the ileocecal valve. I never felt such hardened fecal matter before; it felt like pieces of broken stone inside the intestine. I passed a finger up into the rectum while the patient was thoroughly anesthetized and with the hand in the abdomen and the finger in the rectum I was able to make out the constricted portion. The tip of the finger would just barely enter at the site of the twist. After thoroughly exploring I separated the small intestines from their adhesions but could do nothing more. The patient's pulse by this time had reached 140. I am now in hopes that I will be able, should she survive, to wash out the scybalous masses. If this is impossible colotomy will be the only other recourse. The mass you felt on examination was fecal matter, the two lumps that slid about above and that felt like pedunculated fibroids growing from the main body of the tumor were pieces of hardened fecal matter in the bowel."

I give the quotations at length because the letters themselves give a better picture of the progress and circumstances surrounding the case than a bare recital of facts.

There is only one kind of a man whose fore-sight is as good as his hindsight, and that man is a fool. We can all learn by the mistakes of others, and it is easy to suggest what might have been done in a given case, but it is difficult for us to say exactly what we ourselves would have done had we been dealing with that given case. I think my finger has been fairly well educated by a number of years of experience, and I feel fairly competent to give an opinion regarding the nature of a pelvic tumor.

I have elsewhere published a case treated with electricity for two years on the supposition that the patient was suffering from a fibroid tumor, while, in reality, on performing an abdominal operation I removed a pair of pus-tubes with walls solid and thickened and cartilaginous and almost two inches in diameter. Among the hundreds of pus-tubes I have removed I have never seen another pair exactly like these. In lecturing to my class I have always claimed that one of the diagnostic features of a fibroid tumor was the separate nodules so frequently found more readily movable than in the main mass of the tumor. These nodules were noted in the case under discussion. In the days when electricity as a cure for fibroid tumors was absorbing the attention of a certain portion of the profession and a large portion of the public, it was no uncommon thing to hear of the complete subsidence of a pelvic tumor under the magic influence of the electric current. When a few of us ventured to suggest that many of these masses were not fibroid tumors, but that they were entirely inflammatory, we were supposed to be using this as unfair argument in the discussion of the question. But when one has lived to mistake a collection of fecal matter in the distended bowel of a patient having regular evacuations, it is easy to understand how many of these fibroid tumors may have been nothing but hardened intra-intestinal contents.

Time has not permitted me to make a very thorough search through the medical literature for information regarding this peculiar disease, chronic volvulus. In the slight search that I have made I find nothing except the reference given at the beginning of my remarks. There can be no doubt that a half turn of the intestine on the axis of its mesentery may produce chronic volvulus. Perhaps many cases of troublesome constipation may be explained in this way. It is evident that chronic volvulus may exist and the patient may live for years

with the condition, but not without discomfort. It is also evident that chronic volvulus may be cured by operation and the danger of acute volvulus may be thus avoided.

From the three cases referred to it is evident that chronic volvulus may occur in either the small or large intestine. When the omega flexure of the rectum is very fully developed, it is easy to understand how it may be twisted where the two branches of the omega approximate one another. That acute volvulus occurs at this spot more frequently than anywhere else is not to be wondered at. This elongated and apparently over-developed omega flexure seems to be a congenital condition. In the case of the man successfully operated on, I was amazed to find the mesentery of the omega flexure and the omega flexure itself of such enormous dimensions. When an attack of volvulus has occurred and recovery has taken place after a resort to high enemata, it seems to me that the abdomen should be opened and the bowels should be so fixed that volvulus cannot recur. It is only in this way that the patient can be placed in a safe condition. A resection of intestine might be done so as to shorten the portion of intestine inflicted with a long mesentery, but this procedure must necessarily be somewhat severe and scarcely justifiable if the minor measure carried out in my case will answer the purpose.

There are cases of volvulus of Meckel's diverticulum occurring in infants on record. While I have never yet met with such a case, I have recently had a peculiar experience in connection with Meckel's diverticulum. An infant was born and no fecal matter passed per anum. A few hours after birth I saw the child and it was evidently in great pain. Vomiting had set in and was persistent, so I opened the abdomen and found a coil of congenuous intestine forced through under a band produced by adhesion of a partially obliterated Meckel's diverticulum, to a spot of the peritonum near the spine. I presume that the bowel had been forced through under this band as a consequence of the pressure exerted during childbirth. There were evidences of acute peritonitis, the abdomen being filled with a seropurulent collection of fluid. The infant, but a few hours old, and already greatly shocked, soon succumbed.

DATA CONCERNING DEFORMITIES OF EXTRAUTERINE GESTATION.*

BY ANDREW F. CURRIER, M.D.
NEW YORK CITY.

The subject is one which, at first thought, would seem to be narrow in its scope, and yet the proper apprehension of it involves the examination of many disconnected reports of cases of extrauterine gestation, some of which devote no attention at all to the consideration of the physical condition of the fetus, while in others the details are aggravatingly meager. The deformities which are alluded to are in almost all cases, if not in all, consequences of the latter months of fetal development, since in those fetuses which are removed during the first half of gestation I have observed no record of deformity, and in those which I have examined personally, the upper and lower extremities have appeared to be normal. The subject derives importance from the fact that the number of fetuses developed outside the uterus and born alive by extraction through an abdominal incision, is not inconsiderable, and this number is increasing, year by year, as the means of diagnosis and

*Presented to the Section on Obstetrics and Diseases of Women, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 4-9, 1899.

surgical technic become more perfect. This means that the consideration for the welfare of those beings who have had the misfortune to be developed under exceptionally unfavorable conditions will increase in the future, and that they will probably have better opportunities for existence than have been conceded to them heretofore.

The sum of our efforts in the past has been to endeavor to extricate the mother from a plight which is most perilous, even under the most favorable conditions, and we have all been more or less prejudiced by the fact that most of the children in these cases have been born dead, or have died within a few hours or days, or have been deformed to a greater or less extent. The largest tabulated collection of cases in which a living child has been born through an abdominal incision, in the condition which is under consideration, has been made by the late Dr. R. P. Harris, whose table¹ contains details of 77 operations performed between the years of 1809 and 1896. From his well-known persistency and accuracy in gathering statistics, we may regard this table as fairly reliable, and as a basis from which certain inferences may fairly be drawn. Unfortunately he has made no statement in regard to the physical condition of the children referred to in his table. In another communication, which bears on this subject, he has stated, however, that only 4 children had survived at the time when his statement was published, 2 of them being then 4 years of age, 1 being 5, while 1 was 7½ years old. One of these children, as I infer, is a girl, delivered by Savage of Birmingham, and was 14½ years of age, and in good health when last heard from. The question as to the mortality in this class of cases is therefore, up to the present time, not a very brilliant one.

Champneys has collected a series of 19 cases of operations in which the child was born alive. The immediate mortality as to the fetus was 11 cases—61.1 per cent. There was deformity in 4 cases. The details of those who survived among his cases are as follows:

Operator.	Date.	Period of gestat. n.	Condition.	Duration of life.
Heim	1843	Term.	Healthy boy.	Not stated.
Haufl	1842	35 wks.	Deformed limbs.	Fifty hours.
Jessop	1877	34 wks.	Normal.	11 mos. Death from croup.
Spiegelberg.	1876	Term.	Normal.	3 mos. Death from inanition
Tait.	1880	Term.	Normal.	Well when reported at 7 months.
Schroeder . .	1879	34½ wks.	Normal.	Well at 6 months.
Wilson	1880	39 wks.	Normal.	Well at 3 months.
Litzmann . .	1880	38½ wks.	Deformed by pressure.	Fifteen minutes.

The following cases in which deformity of the child was observed at birth have been collected from various sources.

1. Champneys²: The child was a seven-months fetus when born, was fifteen inches in length, weighed 2 pounds 10 ounces, and had not been dead very long when delivered. Its face was compressed, the nose was flattened, and the head deformed. Champneys' remarks concerning such cases are as follows: "The number of children which are ill-developed, sickly or deformed in cases of extrauterine gestation is so large that the value of the child's life is much reduced and appears to be insufficient to justify additional risk to the mother."

2. John Williams³: The child was mature, was dead when born, and was deformed by pressure.

3. Olshausen⁴: The child was mature, was much deformed, and died 1½ hours after birth.

4. Rein⁵: The child was born at the thirty-seventh week, weighed 6 pounds, was asymmetric, but was living and well in 1892, being then 2 years old.

5. J. W. Taylor⁶: The child was mature at birth, weighed 7 pounds; the head was asymmetric, the larynx and neck depressed; the right foot had talipes-calcaneovalgus; the condyles of the femora were prominent. It died from convulsions, at 6 months.

6. Werder⁷: The child was born in 1894, was mature, and had asymmetry of the head and face, clubfeet, ulceration from pressure of the elbow on the left side of the thorax, and died on the fifth day.

7. Martin⁸: The child was born in 1881, with encephalocoele and clubfeet. It died soon after birth.

8. Frommel⁹: The child was mature at birth (1891), and had a deep impression on the left parietal bone from pressure on the brim of the pelvis. It also had a contraction of the right sternomastoid muscle, and died in two weeks, from gastro-intestinal catarrh.

9. Pinard¹⁰: The child was born in 1898, at 7½ months. It had asymmetry of the face, which disappeared. It was still living when the report was made.

10. Guéniot¹¹: The child was born alive, weighed 6 pounds at birth, but died in a few days with abscesses of the neck. Infection had probably been acquired from the placenta, which was attached to the intestine.

The following cases have been collected of children who were not deformed when born and who lived for varying periods:

1. Hardie¹²: This child was born at the eighth month, in 1896, and lived six hours.

2. Treub¹³: The child was born in 1887, three weeks before term, and weighed four pounds; a year later he was a strong healthy boy.

3. Lusk¹⁴: The child was born in 1893, at the sixth month, and lived twenty-four hours.

4. Cullingworth¹⁵: The child was born in 1894, at the end of the eighth month, weighed five pounds, and died at nine months, from poverty and neglect.

5. Eastman¹⁶: The child was born at the eighth month, in 1888, weighed four pounds, and died in 8½ months, from pneumonia.

6. Breisky¹⁷: The child was born in 1887, at term, weighed 5 pounds, and died in three weeks.

7. C. Braun¹⁸: The child was born at term, in 1889, weighed 6 pounds, and died in seventy-two hours, from lobar pneumonia.

Werder¹⁹ has made an interesting study of this subject, that is, from the standpoint of the fetus, and has collected forty cases, some of which have been mentioned in the foregoing pages. Of the forty children who were born alive, 18 died within one week from birth; 5 within 1 month; 1 at 6 months, of bronchopneumonia; 1 at 7 months, of diarrhea; 1 at 11 months of croup; 1 at 11 months, from an unknown cause; 1 at 18 months, from cholera infantum. Of the remainder, 5 lived after the operation, but their subsequent history is not known; 1 was strong and healthy at 3 weeks; 1 was well at 6 months; 1 was well when last heard from; 2 were living and well at 1 year; 2 were living and well at 2 years; 1 was well at 7 years, and 1 was well at 14½ years.

An examination of the foregoing cases shows that the cause of deformity was pressure on the hard portions of the pelvis and abdominal walls, due to an absence of amniotic fluid. The fetus in such cases usually lies free in the abdominal cavity, the membranes which at first enveloped it having been digested by the peritoneal secretion. The tissues of the fetus are therefore without their usual protection, hence those parts which are most in motion and most firm are most likely to show the deleterious effects of pressure. No remedy is at present

apparent for such mishaps prior to birth. After birth, should the child survive, the asymmetry of the head and face is likely to disappear the same as in children with large heads and who are delivered through narrow pelvis. The deformities of the lower extremities are susceptible of orthopedic treatment the same as are those born by the natural passages.

Does not the study of these cases teach us that the time has come when more regard should be paid for the welfare of these unfortunate beings who may, in many instances perhaps, be spared for useful existence by greater consideration and care during the early period of life?

ASSOCIATION OF PELVIC DISEASES AND INSANITY IN WOMEN, AND THE INFLUENCE OF TREATMENT OF THE LOCAL DISEASE UPON THE MENTAL CONDITION.*

BY H. A. TOMLINSON, M.D.

SUPERINTENDENT ST. PETER STATE HOSPITAL.

AND MARY E. BASSETT, M.D.

ASSISTANT PHYSICIAN ST. PETER STATE HOSPITAL.

ST. PETER, MINN.

In January, 1894, there was begun in the St. Peter State Hospital a systematic inquiry into the relation between insanity in our women patients and whatever disturbance of function or disease of the generative organs there might be present. In order to accomplish this purpose, a careful record was made of the incidents of the menstrual period in each case; with reference to the amount and character of the discharge, the length of the period, the presence or absence of pain, headache, or general disturbance; and finally as to whether there was any change or exaggeration of the mental disturbance during the period. Then each patient was subjected to a careful physical examination and a record made of the conditions found. In all of the cases where pelvic disease was present and apparent, and in those cases in which there was menstrual disorder, a systematic study of the conditions found, in relation with the mental disease, was made, and where any doubt existed a competent surgeon was called in to give us the benefit of his advice. It was soon found that the weak point in our investigation was the absence of a complete and reliable history of the case before coming to the hospital. In the meantime all of the women suffering from menstrual disorder or pelvic disease were placed on appropriate treatment, and in those cases in which operative interference was indicated the necessary operation was done, whenever

the consent of the family could be obtained. This special treatment was carried out without regard to the apparent relation between the pelvic disorder and the insanity of the woman, as we believed that the most reliable evidence of the utility of this special work would be furnished by the careful study and treatment of all cases, rather than those alone whose condition suggested an apparent relation between the insanity and the disease of the generative organs.

This preliminary study included the 450 women then in the Hospital and those admitted up to Jan. 1, 1897. The first result of our investigation was the statistical evidence furnished by the observation of the effect of the menstrual molimen on the mental condition of the patient. In only ten out of the 450 women was there any exaggeration of the mental disturbance during the menstrual period, but 50 per cent. of all of the women had more or less physical discomfort during the period. Profuse or scanty flow with headache was the most common departure from the normal, and only a very small number suffered from pain; while the ten cases in which there was an apparent relation between the menstrual period and exaggeration of the mental disturbance; only two of the patients complained of physical discomfort at all. Among the married women, 58 per cent. had some pathologic condition in the pelvis, dependent on labor and its accidents. The commonest of these were tears of the perineum and cervix; next came subinvolution with endometritis, then disease of the tubes and ovaries. There were only two cases of uterine fibroma and two of cancer. One of the cancer cases was decided to be inoperable. The woman became cachectic, emaciated and was apparently going to die. However, she rallied, gained in weight, the discharge became less profuse and fetid, she did not complain of discomfort, lived in the Hospital for eighteen months, then left somewhat improved mentally and in fair physical health. We heard from her about one year afterward and she was still in fair physical health. Two of the women in whom there was apparently a direct relation between the menstrual disorder and mental disturbance, also presented evidence, of pelvic disease. Both were young and unmarried. One had been in the hospital for five years, having been committed a few weeks after landing in this country from Germany. The other was a clandestine prostitute and had had gonorrhoea, from the infection of which she had developed a double salpingitis and her ovaries were cystic. The former had sclerotic ovaries and suffered from severe dysmenorrhoea. In both cases an operation was done with the definite object of trying to modify the mental condition by removing a constant source of irritation in the pelvis. The uterus and ovaries were removed in both cases; but unfortunately the result of the operation was not satisfactory and there was not only no improvement in the mental condition, but a distinct increase of disturbance after the direct effect of the surgical procedure had subsided, and of course the more rapid determination of dementia followed the artificial establishment of the menopause. The most unexpected result of our investigation was the finding of so large a number of women with serious pelvic disease, in whom there was not only no apparent relation between the pelvic disease and the mental disturbance, but there was no complaint or evidence of physical discomfort. Many of these women have since been operated on and all needing local treatment received it. The general result has been a more or less well-marked improve-

ment in the physical condition of those treated. In some there has been a slight amelioration of the excitement or irritability present, but in the majority of the cases the relief of the pelvic disorder has been practically without influence on the mental condition of the women.

I now turn to the consideration of the more interesting because more carefully studied recent cases. From Jan. 1, 1897, to Jan. 1, 1899, there were admitted, subjected to examination, and treatment so far as was

cases there was laceration of the perineum, in 80 laceration and in 54 erosion of the cervix; 75 had cystocele and 68 rectocele. In 17 there was hyperemia of the uterus, while in 30 cases the uterus was hypertrophied and in 25 cases there was prolapse. There was 1 case of cervical fistula, 1 of rectovaginal fistula, 12 with prolapsed ovaries, 3 with enlarged ovaries and 5 with enlarged tubes; 2 cases of cervical polypus and 7 of fibroid uterus. There was leucorrhœa in 77 and gonorrhœal infection in 11 cases. In 38 of the cases the mental

MAJOR OPERATIONS.

Case No.	Mental Condition.	Pelvic Condition.	Nature of Operation.	RESULT OF OPERATION.	
				Mentally.	Physically.
1	Periodic excitement.	Dysmenorrhœa, ovarian pain, cystic and sclerosed ovaries.	Removal of ovaries and tubes.	Unimproved.	Pelvic symptoms relieved by operation.
2	Chronic excitement.	Dysmenorrhœa, salpingitis, cystic ovaries.	Removal of tubes and ovaries.	Unimproved.	Pelvic symptoms relieved by operation.
3	Chronic excitement.	Laceration of perineum and prolapse of fibroid uterus. Did not complain of any pain or discomfort.	Vaginal hysterectomy and perinorrhaphy.	Unimproved.	Cured.
4	Chronic delusional insanity.	Subinvolution, prolapse, retroversion and adhesions of uterus. No direct symptoms.	Removal of right ovary and tube, ventrosuspension of uterus.	Improved.	Cured.
5	Acute depression.	Lacerated cervix, endometritis.	Amputation of cervix and curettement.	Improved.	Cured.
6	Chronic delusional insanity.	Laceration of cervix and perineum, endometritis.	Curettement, repair of cervix and perineum.	Unimproved.	Improved.
7	Chronic delusional insanity.	Retrodisplacement of uterus, adherent laceration of perineum.	Ventrosuspension of uterus, repair of perineum.	Unimproved.	Improved.
8	Chronic delusional insanity.	Subinvolution, uterus retroverted and adherent cystic ovaries.	Removal of uterus and appendages.	Unimproved.	Cured.
9	Dementia.	Fibroid uterus.	Abdominal hysterectomy.	Unimproved.	Cured.
10	Chronic depression.	Retroverted, adherent uterus, cystic ovary.	Ventrosuspension of uterus, removal of right ovary.	Improved.	Cured.
11	Confusional insanity.	Endometritis.	Curettement.	Improved.	Cured.
12	Circular insanity.	Laceration of perineum. Endometritis.	Curettement, perinorrhaphy.	Improved.	Improved.
13	Chronic delusional insanity.	Retroverted and adherent uterus, laceration of perineum.	Ventrosuspension of uterus, perinorrhaphy.	Unimproved.	Improved.
14	Chronic delusional insanity.	Retroverted and adherent uterus, cystic ovaries, laceration of perineum.	Removal of ovaries and tubes, ventrosuspension of uterus, perinorrhaphy.	Unimproved.	Cured.
15	Circular insanity.	Retroverted and adherent uterus.	Alexander's operation.	Unimproved.	Cured.
16	Chronic delusional insanity.	Retroverted and adherent uterus, laceration of perineum.	Ventrosuspension of uterus, perinorrhaphy.	Improved.	Cured.
17	Chronic delusional insanity.	Prolapse of uterus, laceration of cervix and perineum.	Anterior colporrhaphy, repair of cervix and perineum.	Unimproved.	Died of uremia.
18	Chronic delusional insanity.	Retroverted and adherent uterus, laceration of perineum.	Ventrosuspension of uterus, perinorrhaphy.	Unimproved.	Cured.
19	Chronic delusional insanity.	Retroverted and adherent uterus, laceration of cervix and perineum.	Amputation of cervix and perinorrhaphy, ventrosuspension of uterus.	Improved.	Cured.
20	Chronic delusional insanity.	Subinvolution, retroverted and adherent uterus, double hydrosalpinx.	Removal of uterus and appendages.	Improved.	Cured.
21	Chronic delusional insanity.	Laceration of perineum.	Perinorrhaphy.	Unimproved.	Cured.
22	Chronic delusional insanity.	Laceration of cervix and perineum, endometritis.	Curettement, repair of perineum and cervix.	Unimproved.	Cured.
23	Dementia.	Endometritis, lacerated cervix.	Curettement, repair of cervix.	Unimproved.	Improved.
24	Chronic delusional insanity.	Mobile prolapsed uterus.	Alexander's operation.	Unimproved.	Improved.
25	Dementia.	Prolapsed uterus, laceration of perineum.	Abdominal hysterectomy.	Unimproved.	Improved.
26	Chronic delusional insanity.	Retroverted and adherent uterus, endometritis, lacerated perineum.	Alexander's operation, curettement, perinorrhaphy.	Unimproved.	Improved.
27	Dementia.	Gonorrhœal endometritis, lacerated cervix.	Curettement, repair of cervix.	Unimproved.	Died of uremia.
28	Chronic delusional insanity.	Subinvolution prolapse, laceration of cervix and perineum.	Curettement, repair of cervix and perineum.	Improved.	Cured.
29	Chronic delusional insanity.	Retroverted uterus, laceration of perineum.	Alexander's operation, perinorrhaphy.	Unimproved.	Cured.
30	Dementia.	Prolapse of uterus, lacerated perineum.	Amputation of cervix, ventrosuspension of uterus.	Unimproved.	Died of uremia.
31	Acute depression.	Retroverted and adherent uterus, laceration of perineum.	Ventrosuspension.	Unimproved.	Improved.
32	Acute confusion.	Uterine fibroid, rectovaginal fistula.	Hysterectomy.	Unimproved.	Died of uremia.
33	Acute excitement.	Laceration of perineum, endometritis, uterus retroflexed, enlarged ovary.	Curettement, repair of perineum.	Unimproved.	Improved.
34	Acute depression.	Laceration of perineum.	Repair of perineum.	Improved.	Cured.
35	Acute depression.	Laceration of perineum, endometritis.	Repair of perineum, curettement.	Improved.	Cured.
36	Chronic delusional insanity.	Fibroid uterus.	Hysterectomy.	Unimproved.	Cured.

practicable, 231 women. Of this number 61 menstruated irregularly; in 30 the discharge was scant, while in 63 it was profuse; 17 suffered from dysmenorrhœa, 6 from menorrhagia, 4 from metrorrhagia; 8 had headache during the period and 26 suffered from abdominal pain. In 28 there was some increase of mental disturbance during the menstrual period. In 49 of the cases there was retrodisplacement of the uterus, in 57 retroversion, in 19 retroflexion, and antelexion in 7, while in 11 cases the uterus was mobile. In 91

disturbance of the patient was apparently increased by the pelvic disease, but in the other 173 cases no relationship could be made out between the mental disturbance and the pelvic condition. There were 70 cases in which there was serious pelvic disease, in which operative or other treatment was instituted for the definite purpose of studying its effect on the mental condition of the patient. In 22 of this number the pelvic disease was cured, and in 12 of these the mental condition was improved. In 26 cases the pelvic condition was im-

order during the menstrual period is as common among the insane as among the sane, and what disturbance there is gives rise to but little apparent evidence of its presence, for as a rule we have to search for it. Now, when we take further into consideration the fact that the physician is consulted only by those who are ill, we can find an explanation of the comparative discrepancy between the results obtained by the gynecologist in his study of the cases of menstrual disorder or pelvic disease associated with nervous disturbance, which come within his purview, and those apparent in a large number of women aggregated in one place on account of their mental disturbance. There is the natural tendency in both cases to interpret the evidence found in the terms of the conclusion sought for. However, I am impressed with the tendency of the gynecologist to overlook the large number of women suffering from nervous and mental disease who do not consult him and who are not conscious of the presence of menstrual disorder or pelvic disease. While a considerable number of the women admitted to the hospital during the time included in this study were, as shown by the figures, suffering from pelvic disease or menstrual disorder, these conditions and their influence on the mental condition of the women seldom formed a part of the clinical history of the case before coming to the hospital. Even in those cases where the patient had been under treatment for menstrual disorder or pelvic disease, the fact of her coming to the hospital afterward would indicate either that there was no relation between the disease of the generative organs and the insanity or that the treatment had been of no avail in curing the mental disturbance. But when we consider the intimate association between the nervous system and the functional activity of the generative organs in women, and the further fact, referred to in the figures given, of the association of arrested development in the generative organs of women with instability or defect in the general nervous system, it is easy to understand why these disease conditions should apparently stand in causative relation to each other. This is frequently so marked among primary degenerates that the uterus and appendages present all the characteristics of senility, while menstruation is either scanty, delayed or sometimes absent for long periods. Again, in this class of cases, it is the rule for the advent of puberty to be delayed, the average being 17 years, and we have the record of one case where menstruation did not begin before 22 years of age, and yet no one at all familiar with insanity would think of attributing the mental disturbance accompanying the progressive degenerative changes in the nervous system in these cases to menstrual disorder. However, it is not uncommon to see young women, primary degenerates, whose uteri have been curetted or their ovaries removed with the object of curing a condition dependent on progressive degeneration in the nervous system; because the physician, while recognizing the intimate relation between the nervous system and the generative organs, failed to see that the pelvic symptoms were dependent on the degenerative process in the nervous system and that both were due to defective development. I can not do better than to here quote from a paper on a closely related subject, recently read by me before the American Medico-Psychological Association. "In this end of the century when women are warring against their natural position in relation to the reproduction of the species; while the competition of social and industrial life and the growing desire to avoid any responsibility which

interferes with material advancement or social opportunity is so strong; it is not surprising that we should find so many disturbances of the nervous system associated with the bearing of children; or that this originally physiological function and process should be credited with the untoward results which so often accompany and follow it. . . . To my mind the various disturbances associated with maternity simply prove what we know as a physiologic fact; that is, the intimate association between the function of reproduction and the activities of the rest of the organism; while the greater instability of the nervous system in women renders conspicuous and prominent those changes which the concentration of her vital forces in the process of reproduction makes possible and renders apparent; because under modern social conditions, the nervous system is not equal to the task of controlling its own manifestations and meeting the extra demands upon it."

When we come to consider the second subdivision of the question—as to whether menstrual disorder and pelvic disease do or do not of themselves cause insanity, we have to carefully weigh the evidence for and against the contention. In conducting this study I have considered first the family history of the patient and then her personal history, including the condition of her mother and father at the time of conception; of the mother during gestation; the character of the labor; the infancy and childhood of the individual, with especial reference to disease accompanied by prolonged high temperature, great exhaustion; convulsions from any cause; manifestations of disturbance of nervous equilibrium during the period of second dentition; the establishment of puberty, the history of the menstrual function during the period of adolescence, and finally the record of maternity in those women who have borne children, and of the menstrual molimen in those who have not. From the data obtained I have been enabled to divide the women into two general classes: those who have an unstable nervous system and those who have a defective nervous organization. The former are generally the children of the neurotic and insane; the latter the offspring of the consumptive, alcoholic, and syphilitic. Dipping into both classes come those children who have been born after prolonged labor, have suffered from disease accompanied by prolonged high temperature or great exhaustion, or have had convulsions from any cause during infancy. These causes operate to arrest development and limit the potentiality of the nervous system, either by mechanical interference with the nutrition of the brain, or general trophic influence. Among the class grouped as unstable there is practically always a history of disturbance during the establishment of puberty and through the period of adolescence, manifested by either amenorrhea or dysmenorrhea. Among the defective, however, there has been practically no evidence of a departure from the normal in the establishment of puberty or the process of menstruation. Among the unstable the history of the onset of the mental disturbance, which in this class is usually acute, practically always shows the insanity to have followed on some mental or physical strain due to disease, overwork or worry, which has overtaxed the limited cerebral potentiality of the individual. It is true that if the patient is the victim of dysmenorrhea, this acting as a source of irritation may exaggerate the mental disturbance and, besides, the causes which operated to produce the mental and physical exhaustion on which

the intensity is engrafted, will also almost certainly increase whatever menstrual disorder may be present; so that the outbreak by which the insanity becomes apparent may make its appearance during a menstrual period; but I do not believe that because of this we are warranted in saying that the insanity was caused by the menstrual disorder, and the same holds true with regard to pelvic disease. Anything which reduces the vitality of the individual will exaggerate whatever pelvic disease may be present, or even make apparent by local symptoms a condition not before felt or complained of. We often have young women, committed to the hospital, in whom there is a history of severe menstrual disorder, which disappears entirely in a comparatively short time under the régime of hospital life, with the relief of constipation, indigestion and insomnia, but without any measures directed against the menstrual disorder itself. The history of the menstrual molimen thereafter shows no evidence of exaggeration of the mental disturbance, nor do the manifestations of the insanity necessarily or commonly improve with the relief of the menstrual disorder. Among the women of the defective class, which furnishes the largest proportion of our primary degenerates—that is, those women who become insane during the adolescence and lapse into dementia—it is the exception to find any menstrual disorder, and those among them who have borne children, although subject to the accidents of labor, septic infection during the puerperium and the ill results of subinvolution, rarely bring with them a history of pelvic disease or complain of discomfort after coming to the hospital.

This naturally leads to the last subdivision of the question. How may that class of cases of insanity be recognized which offers hope for relief or cure by the treatment of pelvic disease, either operative or otherwise? Judging from my own experience and observation no case of insanity dependent on a degenerative process in the nervous system will be benefited mentally by operative treatment, but on the contrary may, and in the majority of cases does, have the degenerative process hastened by the shock of the operation or the production of a premature climacteric. In all cases of insanity among the unstable class, where there is serious menstrual disorder which the history of the case shows to have grown worse since the onset of insanity, the patient will be benefited by local treatment; provided her delusions do not in any way relate to the sexual function or the condition of the reproductive organs. Such treatment timely begun may be the starting point for recovery; yet it is only fair to say that I have often been disappointed and, on the other hand, have seen cases, apparently seriously in need of treatment recover promptly without it. However, neither of these exceptions disproves the general rule. In the presence of pelvic disease operative treatment is required for the very same conditions that would demand it among the sane, and the relief of the physical disease may and often does materially aid in recovery from the insanity. Even when this is not accomplished the life of the woman is made more comfortable and her mental disturbance lessened. The greatest risk to the mental integrity of the woman from operative interference is, strangely enough, in that class of cases where the temptation to operate has been the greatest. I mean in young degenerate women with infantile uteri, small sclerosed or cystic ovaries and who have explosive outbreaks during the menstrual period; or women who have borne children, who have a slight

perineal or cervical tear and an enlarged and tender left ovary and slight subinvolution, but with a symptom-complex out of all proportion to the amount of disease present. Operation in such cases practically always means the determination of dementia. The following conclusions seem to me to be warranted by our study of the data furnished by our examination and treatment of the women committed to this hospital.

Menstrual disorder and pelvic disease, while quite common among insane women, in the majority of cases bear no apparent relation to the insanity; nor is the intensity of the mental disturbance in proportion to the gravity of the physical disease.

In cases where the insanity has existed for more than a year, or the patient has a defective nervous organization, treatment of the disease of the generative organs is practically without effect on the insanity, and in such cases operative interference resulting in the establishment of an artificial menopause almost invariably hastens the onset of dementia.

Operative interference is called for in the treatment of pelvic disease among the insane for the same reasons that would determine the necessity for such treatment among the sane.

In order to determine whether or not treatment of the disease of the generative organs will have a curative effect on the insanity, it is important to know the family and personal history of the patient with regard to the presence or absence of evidence of unstable or defective nervous organization, the length of time the insanity and disease of the generative organs have existed, and to what extent the general health of the patient is affected by the pelvic disease independently of the insanity.

CHOLECYSTITIS.

ITS RELATION TO ANGIOCHOLITIS AND CHOLELITHIASIS.*

BY CHARLES G. STOCKTON, M.D.,

BUFFALO, N. Y.

In the etiology of cholecystitis, what rôle is played by biliary calculi, trauma, exposure to cold, and what by invasion of the gall-bladder by pathogenic bacteria?

To explain the various painful and obstructive disturbances of the biliary passages by attributing them to gall-stone has been so simple and natural that such pathology went for a long time unchallenged. The suspicion that the process was vastly more complex than we have imagined has long been held, and during the past ten years our knowledge on the subject has so much widened that the pathologic position of the calculus in so-called gall-stone attacks has undergone a radical change. There were series of ascertained facts that were not to be disposed of by the simple statement that gall-stone was present, and for some unknown reason took upon itself to migrate from the gall-bladder. Here are a few of these facts:

1. In a large number of post-mortems, gall-stones are found present without any history of jaundice, hepatic colic, or other liver trouble.

2. In post-mortems of those dying from biliary obstruction there sometimes have been found no calculi in the biliary ducts, but one or two very large calculi in the gall-bladder, quite too large to engage in the cystic duct, and, therefore, not directly guilty of the attack.

3. Obstruction of the biliary passages is not infre-

*Presented to the Section on Practice of Medicine, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

quently found to be complete when no gall-stone is found present in any of the biliary passages.

4. A calculus is sometimes found in the common duct without jaundice, colic or other symptoms of obstruction.

5. When gall-stones are found post-mortem, or in operations *in vivo*, and there have been recent symptoms of hepatic colic and jaundice—whenever these have been searched for, evidences have been found of cholecystitis, or angiocholitis, or both.

These observations would seem to point to the fact that gall-stones may be innocent tenants of the gall-bladder; that attacks of hepatic colic may occur when there are no gall-stones at all; that an inflammatory process of the biliary passages seems in some way related to the attacks of gall-stone colic.

What then is the pathologic position of the gall-stone, and what the secret of its formation? What rôle does it play in the evolution of hepatic colic and biliary obstruction?

The belief has been held from time immemorial that some changed condition of the secretion of the liver, the result of diathesis or dyscrasia, led to the precipitation of the solids of the bile and the formation of calculus. This belief has had support in the fact that the gall-stone is more often seen in women than in men; in age than in youth; is more often present in those who lead sedentary lives, and in those who have obesity and the uric acid diathesis. On the other hand it has been long suspected that the gall-stone had its origin in local conditions, and that it was not so much dependent upon a systemic state.

In 1891, Naunyn, at the German Congress of Physicians and Naturalists, sounded a clear note on the nature and formation of biliary calculi. First, he showed the constant and unchanging presence of cholesterol and lime in the bile, without any relation to the food ingested. Next, he showed that there were present substances in the bile which hold in solution the cholesterol in far greater quantity than is necessary to prevent this precipitation in the bile. He also showed that dogs, when fed upon lime in large quantities, had no increase of lime salts in the bile. Thus, while experience shows that certain habits of life tend to favor the development of calculi, these experiments of Naunyn, which have been verified, prove that that tendency is not to be found in the amount of cholesterol or lime in the bile, contrary to the reasonings of Bouchard. It upheld the theory that the origin of gall-stone lay in some particular condition of the gall-bladder which favors the precipitation of the solid constituents of the fluid, thus supporting the contention of Frierich, Niemeyer, Barth, and a host of others who were committed to a strictly local origin, as opposed to the systemic or dyscrasic origin of the calculi. These conclusions have been well stated by Stanislaus Pechkrane¹ as follows: "Modern investigations and teachings show that the disease is but a local one, the result of a morbid condition of the bile-ducts and gall-bladder, and that it is uninfluenced by any disturbance of nutrition."

Various observers have found that the center of gall-stones consists of bilirubin and lime salts, and that about this center the cholesterol is deposited. Naunyn has shown that this formation of the center of the calculus, and also of the precipitation of the cholesterol about it, follows almost invariably from an inflammatory process in the gall-bladder. In other words, given cholecystitis and a free supply of bile—although Naunyn holds that this free supply of bile is unnecessary, which view,

I think, has been disproven by Mignot—and precipitation occurs in the order above described. The same reasoning holds true of the calculi formation in the other biliary passages.

It now remains to explain the origin of the cholecystitis, and this, it would seem, has been satisfactorily accomplished by Mignot, Gilbert, and others. While exposures to cold, trauma, obesity, age, and bodily inactivity favor the development of cholecystitis, there has been wanting some common factor to complete this explanation. This missing link in the chain, in the light of recent investigations, seems to be found in infection. This belief has not been reached without much painstaking effort, and we owe a debt to the French investigators for this step in advance.

It was formerly believed that bile possessed active antiseptic properties. This has been disproven by Vignal, Copeman, Winston and Bernabel. Naunyn proved that in the terminal portion of the ductus choledochus living organisms are usually found present. In 1891, Latiene showed that the presence of micro-organisms in the biliary passages always brings about the precipitation of various compounds of the bile. Mignot² and Gilbert³, with the assistance of Dominici, and later, Fourniers, have shown not only this result of the presence of micro-organisms, but they have traced the process step by step to the origin of the calculi and have disclosed the nature of the organisms usually concerned in the work. It is the colon bacillus that is most often responsible for the biliary catarrh; but the typhoid bacillus, the proteus vulgaris⁴, staphylococcus, streptococcus, and others are occasionally found. The colon bacilli are present, either dead or alive, in one-third the number of cases (70) investigated. It was shown that the calculi containing the living micro-organisms were of recent formation, while old calculi were sterile. Mignot, in 1896, showed that foreign bodies, when sterile, could remain in the gall-bladder for an indefinite time without inducing inflammation of the mucous membrane or precipitation from the bile. It is thus seen that the gall-stones may be innocent tenants of the gall-bladder, that their origin is secondary to infection of the gall-bladder, and that they are mere incidents of an inflammatory process and not themselves the cause of the inflammation, and that they may have no influence in producing inflammation of the bile-passages except when they exercise pressure upon the inflamed surface or, in escaping, cause abrasion of the delicate mucous membrane or, when held fast in the bile-ducts, they offer obstruction and thus favor the extension of the infection already present.

It is an interesting fact, as shown by Mignot, that the more virulent organisms do not give rise to gall-stones, but that only those having the properties of producing a slight inflammatory reaction are concerned in calculus formation. He also demonstrated that in the condition of atony of the gall-bladder, and in complete stasis of the bile, the formation of true stratified calculi is impossible. It is necessary for the biliary passages to be open so that the bile renews itself, in order to have the proper conditions for the formation of gall-stones. It is regarded as improbable that there is any increase in the size of the calculus after the death of the micro-organisms present. It is known that in man, under ordinary conditions, these organisms die in a comparatively short time; and thus is explained the fact that sterile calculi are found in sterile gall-bladders without attacks of biliary colic having ensued. The fact that the precipitation of the bile compounds occurs

when there is catarrh of the mucous membrane of the bile-passages, associated with the presence of micro-organisms, and that without this association, the gall-stones become inert, throws light upon the results of certain methods of therapeutics that hasten the death of the pathogenic bacteria, the subsidence of the catarrhal inflammation, and the disappearance of biliary sediment. On the other hand, the mere removal of the gall-stone by surgical intervention without other methods of treatment may not do more than afford temporary relief, and another calculus may at once form, as the infection and the cholecystitis may continue. It is a fact that in two-thirds of the cases of cholelithiasis in man, the bile is found to be sterile; in which cases the calculi are old and, as before stated, when the calculi present evidence of recent formation, infection and inflammation of the bile-passages are present. In passing, it should be mentioned that some experimental work supporting the views of the French observers has been done in this country by M. W. Richardson⁵.

W. Hunter⁶ attributes the catarrhal condition of the bile-passages to a toxic condition of the bile, resulting from faulty digestion and other causes of dyscrasia before referred to. He does not regard it as positively necessary that the biliary ducts should become infected. This view apparently rests on the fact that gall-stones are found present under sterile conditions; but, as has been shown, the bile under favorable conditions rapidly becomes sterile, and although infection sometimes continues for years, it is, after a short time, frequently absent. Instances of gall-stones, surrounded by mucopurulent fluid which is perfectly sterile, have been recorded.

It is very probable that the calculus acts as an irritating foreign body in the presence of inflammation, and the removal of the gall-stone unquestionably exercises a beneficial influence on the course of the cholecystitis. Indeed, it is held by Riedel⁷ and by S. Mintz that the more serious symptoms of gall-stone colic are the result of what Riedel calls "perialienitis," that is to say, an inflammation of the structures immediately surrounding the gall-stone. Riedel looks upon the inflammation about the gall-stone as a cause of the pain and spasmodic contraction of the gall-bladder, and holds that without this spasmodic contraction it would be impossible for the calculus to escape from the gall-bladder, believing the normal muscular activity of the organ to be quite sufficient. In the same way a gall-stone incarcerated may intensify the existing angiocholitis. Thus we have explained dropsy of the gall-bladder, pain, fever, jaundice, toxemia, as well as ulceration of the walls of the bile-passages that permits the escape of the gall-stones into surrounding parts. But we must not lose sight of the fact that the process, from beginning to end, hangs upon inflammation, and the inflammation upon infection. The question of dyscrasia, so long held and re-suggested by Bouchard and Hunter, may be explained by admitting that these conditions lessen resistance and thus favor infection and the formation of calculus.

Let us now look at the matter from the standpoint of the second question in this paper: "What relation does cholecystitis bear to angiocholitis, jaundice, enlargement of the liver and hepatic colic?" In other words, we are to take a different view of the same process. The question has already been answered in part. Usually when there is cholecystitis, there is more or less angiocholitis. The passage of the gall-stone increases the inflammation. There is swelling of the mucous lining of the bile-passages

and closure of a sufficient number of them to lead to the retention of bile in the liver. Jaundice necessarily follows, enlargement of the liver succeeds, the organ sometimes reaching twice its normal size, becoming dark in color, tender on pressure, and sometimes painful. At such times the gall-bladder becomes distended with bile unless there happens to be closure of the cystic duct. But even then, distension quite frequently results from inflammatory exudate into the gall-bladder, which may be felt as a distinct rounded tumor. At other times it is concealed by the enlarged right lobe of the liver; or, the gall-bladder may become thickened or shrink into an insignificant space. In some cases it is difficult to say how much of the pain is attributed to the pressure of the stone, and how much to the inflammation. Naunyn⁸ holds that not only is distension of the gall-bladder due to cholecystitis, but also that the pain, cholangitis, and the symptoms of obstruction are thus to be accounted for. Of course, when the gall-stone acts as a distinct plug in the ductus communis choledochus, an icterus would result, but this is a rather unusual state of affairs. He points out that there are cases of cholecystitis that give the picture of gall-stone colic, but which, on operation, show the absence of calculus. As a rule in such cases, the pain ceases, the swelling, the gall-bladder, icterus and fever subside. There may be recurrences, and eventually, through accidental increase of the virulence of infection, the symptoms may become very prominent, metastasis may be formed, and death result from sepsis or prostration. Or, there may result a chronic cholecystitis, with hydrops or empyema of the gall-bladder, or, coincident with the escape of gall-stones, the patient may improve, and recovery will ensue. Naunyn reiterates the statement of Mignot, that cholecystitis and angiocholitis are infectious from the beginning.

In a recent contribution to the Berlin Medical Society, March 15, 1899, Pollatschek takes a very similar position, holding that biliary colic may arise solely from inflammatory processes without the presence of any gall-stones whatever, and that even in severe cases of cholelithiasis icterus may be wanting. In this connection he points out the frequency with which the pain of biliary colic is mistaken for cardialgia, and calls attention to the fact that in the latter condition swelling of the liver is present. The contrary is almost always true of cholecystitis or angiocholitis with or without calculus. He speaks highly of a method of palpation suggested by himself, the value of which I can from personal experience vouch for. It consists in placing the four fingers of the left hand lightly over the edge of the liver while the necessary pressure is given to them by the four fingers of the right hand placed upon the dorsal surfaces of the fingers of the left. The tactile sense of the finger tips is far greater when there is absence of muscular contraction in the examining hand.

Pollatschek also draws attention to the fact that in instances of cardialgia there are almost always present well-defined stomach diseases, whereas in cholelithiasis we have merely a sympathetic gastric condition; also in hepatic colic we nearly always have the accompanying peritoneic symptoms so different from those seen in simple gastralgia.

I have recently seen two cases of obstinate cholecystitis and angiocholitis in which a single gall-stone was incarcerated at terminal extremity of cystic duct, in which was seen a beautiful illustration of inflammation of the surrounding parts, which Riedel calls "perialienitis." In these cases the swelling of the hepatic duct was sufficient to produce intense jaundice and enlargement of the liver.

In both cases the gall-bladder was small and much thickened. These cases also illustrated very strikingly the results of long-continued localized peritonitis, so commonly present in cholecystitis. The numerous adhesions, binding down into a mass of scar tissue the regions about the gall-bladder, are not only a great embarrassment to the surgeon, but give abundant evidence of the seriousness of the affection.

Let us now turn to the third question: "How far may the course of cholecystitis and the prognosis be modified by treatment other than surgery?" We can not turn our backs upon the experience of the ages that points to the fact that certain habits of life predispose to the formation of biliary calculi. Just how obesity, a sedentary life, gluttony, etc., invite infection of the gall-bladder, we may not be able to explain. In some way immunity seems to be lowered. The experiments of Naunyn would seem to show that this does not depend upon the constituents of the bile. These experiments are apparently conclusive so far as lime, cholesterol, and coloring matter are concerned; but there may be other elements in the bile of those individuals leading unhygienic lives that favor irritation and inflammation of the biliary passages. On this very important point some light would seem to be shed from a therapeutic standpoint. The treatment adopted at Carlsbad has long been famous for the relief afforded such cases. This plan of treatment is not limited to drinking of Carlsbad waters, but it is a carefully worked out plan of hygienic living, including diet, baths, exercise, recreation, and the administration of drugs.

Bearing on this treatment, A. Hermann⁹ reports his valuable observations. He admits in the beginning that the treatment has no influence in the expulsion of the calculus, and says that such migration is a purely accidental matter. Nevertheless, he shows that attacks of hepatic colic are comparatively rare in the patients under treatment. Of 114 cases of cholelithiasis that came under his observation at Carlsbad in 1898, hepatic colic occurred in 19 only. Now, if the calculi remained in the gall-bladder without producing colic attacks, it would seem that the tissues must be so modified by the treatment that the inflammation disappears, and it is highly probable that at least a portion of the benefit lies in the modification of the character of the secretion of the liver. Herman reports that in 1886 there were in Carlsbad 34,320 cases of cholelithiasis, and only 18 died of the disease; 21 died from other diseases secondary to cholecystitis, such as abscess of the liver and peritonitis. He also reports that colic often returns after operation and removal of calculi. He cites 15 cases that were operated on in which the colic returned in 7. This can not be fairly construed as an argument necessarily against the proper practice of surgical intervention in cholelithiasis, but it goes to show that the disease is really an infection of the biliary passages, and that until these parts become free from infection there is a reasonable probability of the reappearance of the calculus.

A review of the benefit derived from a well-known plan of medical treatment is believed to be timely when surgical treatment of the affection is coming to be so generally advised. The benefits obtained from surgery are not merely owing to the removal of the calculus. Indeed, Riedel ventures the opinion that 95 per cent. of the calculi migrate from the gall-bladder and are discharged without provoking true icterus, or serious obstruction. This seems like a very strong statement, but at any rate it points to the fact that the gall-stone,

either in the gall-bladder or in its spontaneous passage from that organ, creates comparatively little disturbance as long as inflammation is not present.

Riedel believes that as soon as the diagnosis of cholelithiasis is made, the calculus should be removed by operation, and yet he admits that 80 to 90 per cent. of so-called attacks of hepatic colic are merely the symptoms of cholecystitis. In other words, the operative procedure, including the removal of the gall-stone, has for its object the cure of the cholecystitis. As has been shown, operation, even though offering temporary relief, offers no assurance that the disease may not recur. Undoubtedly in a certain proportion of cases the inflammation includes the dangerous complications of chronic angiocholitis, hepatic abscess, and peritonitis, which with the assistance of surgery might have been prevented; but even in the cases in which operation is demanded, a carefully considered plan of medical treatment should be applied, not only to assist in recovery, but to prevent recurrence. In the great majority of cases, if the patient can be put under proper control for a sufficient length of time, the inflammation of the bile-passages will disappear, the calculi, although retained in the gall-bladder, will cause no trouble, and the patient is likely to continue thereafter in good health.

DISCUSSION.

DR. GEORGE DOCK, Ann Arbor, Mich.—When a case of cholecystitis presents itself, the physician should call in the surgeon in consultation, especially one who has had experience in diseases of this kind. I think, however, that the physician should not give up the case entirely to the surgeon. The after-treatment is of the greatest moment, and the patient should be watched for a long time. Such cases offer a fruitful field for experimentation. The importance of calling in a surgeon depends on the fact that in a small proportion of cases serious complications, such as adhesions and perforations, are likely to occur unexpectedly, and might be dangerous to the patient.

DR. JUDSON DALAND, Philadelphia.—I desire to refer to two cases recalled by Dr. Stockton's paper, and by the remarks of the last speaker. In one case the patient had recurring attacks of jaundice with pain, and the case looked like one of ordinary gall-stone with obstruction. The autopsy showed the difficulty to be cancer of the head of the pancreas. The mass, pressing against the opening of the common bile-duct, produced an obstructive jaundice, and from time to time the softened center of the cancer discharged into the duodenum, the pressure on the common bile-duct thereby being relieved, and the jaundice disappeared. Again the opening closed and the jaundice reappeared. This recurred several times. I also recall a case seen three years ago similar to the one described: in this instance a gall-stone was removed from the gall bladder and the patient rapidly recovered from the operation and there was no return of the attacks of biliary colic for three months when they recurred and in six months attained their original severity. It was believed by the surgeon that he had removed all the stones, and the symptoms were looked on as due to other causes; a second operation was performed and a stone was found in the common bile-duct, which, judging from its size and appearance, probably existed at the time of the primary operation.

The common bile-duct is often found with difficulty by the surgeon, especially in patients with large abdomen and in the obese. If the head of the pancreas is grasped by the thumb below and the middle finger above, in the long axis of the body, and the index finger be allowed to fall downward, it will press against the region occupied by the ductus communis chole-

DR. T. B. FURCHER, Baltimore—*I wish to refer to the importance of the typhoid bacillus as an agent in forming the nucleus of gall-stones. A number of years ago Dr. Welch, of the Johns Hopkins Hospital, demonstrated that a clump of these organisms may form a nucleus about which calcium salts may be deposited. Such cases have been operated on, the calculus cut into under strict antiseptic precautions, cultures made from the center of the latter and the typhoid bacilli grown out in pure culture. This shows that typhoid bacilli may form a nucleus about which cholesterin and lime salts may be deposited. Recently, a case in Dr. Kelly's department was operated on for cholecystitis and suspected gall-stones. The cultures taken from the fluid in the gall-bladder at the operation showed the presence of large numbers of typhoid bacilli, subsequently grown out in pure culture. The patient, a woman, had typhoid fever eighteen years previous to the operation, and there was no history of any subsequent attack. A gall-stone came away with one of the pieces of gauze later on when the case was being dressed. Whether the typhoid bacilli formed the nucleus of the calculus in this case is not known, as the stone was not saved, but this instance shows how long the bacilli may remain in the body and finally give rise to an acute cholecystitis. The patient's blood-serum agglutinated typhoid bacilli from another source and also the typhoid bacilli grown out in pure culture from her own gall-bladder.*

DR. HORACE D. AENOLD, Boston—*At a meeting this spring I had the pleasure of hearing Dr. Mark Richardson report an instance where there was injected into the gall-bladder of a rabbit, typhoid bacilli; this injection was made under the usual antiseptic precautions; as a result of such injection a calculus was formed. This is only one case, but it is in line with the evidence given by the last few speakers.*

DR. CHARLES G. STOCKTON, Buffalo, N. Y.—*The surgeon should not only be called in cases of cholecystitis, but he should be associated with the physician in the study of the case. In each case I referred to, as you may have noticed, a surgeon was called and calculi were removed. It is not always a clear matter to decide when an operation is indicated or when an inflammatory process is present. I had a remarkable case under my care this past winter. The patient, a woman, about 30 years of age, had always been healthy; she had typhoid fever last autumn, which ran its usual course; about six weeks later she was seized with severe pain and it was at first supposed to be simply a gastralgia. Later the pain was referred to the liver, and there was jaundice with distension of the gall-bladder. After the sickness had lasted about three weeks, a leucocytosis became marked and it was the opinion of Dr. Park that an operation was indicated. Operation was decided on for the following morning, but the leucocytosis declining, we decided to wait longer. She made a recovery that was remarkable, but not until after she had passed gall-stones on three separate occasions. Since that time she has been well. This case is interesting in pointing out the close relationship existing between gall-stone development and cholecystitis. Typhoid bacilli are reported as surviving long in the gall-bladder, but not so the colon bacilli. Dr. Daland remarked, I believe, that when there is obstruction in the bile-ducts or the radicals of the biliary passages, this obstruction may develop an immediate infection. This is not so true of the cystic duct as of the common bile-duct. When the obstruction is at the outlet of the common duct, we almost invariably find jaundice following, and often pain. The jaundice, in this case, is not merely the result of obstruction caused by the angio-cholecystitis. The latter is excited by the calculus, but without inflammation jaundice would, of course, continue.*

RESPONSIBILITY OF THE PHYSICIAN IN VACCINATION.*

BY JULIA W. CARPENTER, M.D.,
CINCINNATI, OHIO.

That smallpox has ever been a fearful scourge in the world is known to but few outside of the medical profession, and the full extent of this scourge in the past, unless it has been portrayed in undying colors in the class-room, is not a vivid picture even now with the majority of physicians.

So quickly does the world become accustomed to the absence of a once dreaded disease that its reappearance is needed to force again a study of its history, its rav-

ages, its cause, its prevention and obstacles to its prevention. Its history tells us that since the days of the immortal Jenner there has been a grand transformation scene on the face of the earth. This change has been almost incredible. Before the days of vaccination the ravages of smallpox were beyond belief. Two millions have sometimes died in one country in one year. Now the majority of physicians have never even seen a case. To those who died of the smallpox must be added also a long list of those who recovered from it, but died of some other disease for which smallpox was the predisposing cause. For instance, smallpox predisposes to tuberculosis. The statement has been made by one observer that of 360 persons who recovered from smallpox and were kept under observation, only four escaped tuberculosis. Those that now die of smallpox can not be classed with any noble army of martyrs, for these deaths have been proved to be unnecessary.

The subject of vaccination is of vital interest to us at this moment for several reasons: 1. On account of the recent epidemic of smallpox. 2. On account of the discussion for and against the propriety of legislation one way or another on the subject. 3. On account of the growing sentiment against vaccination and the industry with which its opponents are working.

The epidemic of smallpox in the United States during the past year could not have existed if the proper precautions had been taken, and vaccination had been universal. Why it was not, can be accounted for in two ways: 1. Out of sight out of mind, is a true adage. Absence of the disease without law to insure its prevention is the forerunner of its reappearance. 2. Ignorance on this subject among the people furnished good soil in which the enemy sowed tares, and the anti-vaccinationists arose on the scene.

The vital point in it all is: What is the cause of the opposition to vaccination, and what are the means to overcome this opposition? The strongest weapons in the hands of these enemies are facts, but these facts do not need to be repeated, if great care is exercised by the physician in the manner of vaccination and care of the patient afterward. The manner of vaccination has now been reduced to a nicety. The responsibility for the purity of the vaccin no longer rests with the physician. We now have co-workers who make its preparation their specialty, and on their faithfulness and conscientiousness depend our success and their pecuniary reward; for any impurities traced to one firm would at once turn the demand in another direction. At present the hermetically sealed tube of glycerized vaccin outranks all other forms for safety. It is a little more troublesome, but so is everything that is done in the best way possible. The ivory points, though coated with the same pure vaccin, are more or less exposed to the air and contamination by germs.

As to the place for vaccination, there is certainly room for good judgment. In recent vaccinations one still sees with girls, as well as boys, large scars on the arm midway between the shoulder and elbow. Why put a scar in a conspicuous place when it is not at all necessary? Our office is to remove all traces of disease, not to put them forever before the eyes. This gives the bearer of such a blemish an occasion to blame, and also gives another physician an opportunity for just criticism. One young lady was vaccinated in four places an inch apart, making four corners of a square just in the middle of her arm; fortunately only one took; if all four had taken, such an immense cicatrix might have prevented the author from ever being sent

*Presented to the Section on Practice of Medicine, at the Fifth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

for afterward. Many girls and women prefer the mark on the leg, but why any physician would select the calf of the leg for that operation would be hard to tell. One young lady vaccinated at that point and receiving no care afterward was unable to leave her room at the end of two months. Other similar instances could be mentioned, but these are sufficient to show one kind of a mistake that adds to the ranks of the antivaccinationists.

Vaccination is no trivial matter, and does not allow itself to be treated as such. If treated as a matter of little importance, it is a wave started out that inevitably returns to the sender, as action and reaction are equal. Carelessness always gives a return blow to its author. Any one who vaccinates a patient and lets him go without some instruction and a positive promise to return runs the risk of that patient becoming an opponent to vaccination for two reasons: 1. There may be some untoward result which could have been prevented by a little oversight. 2. The patient can easily mistake an ordinary sore on the arm for a typical "take" and if he has smallpox afterward he concludes very naturally that vaccination is no prevention, hence he joins the ranks of the antivaccinationists. He spent his dollar for nothing and had smallpox besides. Every vaccination should be cared for as a case of mild sickness, which it is, and for perfect safety the patient should be kept under supervision until the case is over, that is until the crust is off. Ordinarily one should refuse to vaccinate unless the patient will come for inspection at least once before the ninth day, and the physician himself should pronounce on the result as to whether it is sufficient to afford immunity.

The following is the after-treatment that I have found gives the best results. After vaccination, extreme cleanliness within as well as without, should be enforced. That is the chief thing to prevent untoward results. Begin with a laxative not later than the third day, sometimes on the first, or even the day before, as a necessary preparation with some. Perfect sewerage of the human body is little known to the people and has to be taught to each patient. A bath every day when possible is an important adjunct, and the entire arm should be washed twice a day with hot water and soap, of course not touching the point of vaccination. The heat and irritation in the surrounding inflamed area is greatly relieved by a little vaselin. This treatment, which is easily carried out, will prevent those results that swell the ranks of our enemies. If further purification or rebuilding of the system is necessary, I have found tinct. of chlorid of iron most effective, but give it always in capsules to save the teeth, and give no cause to patient or dentist for future blame. We should be as careful of the teeth as of the eyes or ears.

When this treatment was carefully carried out during the epidemic of the last year, I was often surprised to find that instead of the height being reached on the usual tenth day, at that time all the symptoms had been on the wane for twenty-four hours or more. With that exception they ran the typical course and left the characteristic cicatrix.

Surgeons did not reach their marvelous results until they found out what absolute cleanliness really was and how to apply it. When those same principles are used in the treatment of disease there will undoubtedly be a corresponding success.

To insure this care for all, there are some difficulties in the way with two classes of people: those who are unable, and those who are unwilling to pay for this extra

care. The laity do not know that any care is necessary, as the idea is current that vaccination is such a trivial affair that they might even vaccinate themselves. To insure the co-operation of these two classes, and for the protection of the physician, I have made it a rule to charge for the vaccination, and state that it will include subsequent visits to the office to insure that all is right. This is, of course, less compensation for faithful service in vaccination than for anything else, but with the present state of enlightenment of the public mind on this subject it seems to be the only method to protect both the people and ourselves. It is simply one more gratuitous benefaction added to the already long list to the world by our generous and noble profession.

To enlighten the people is to scatter the army of antivaccinationists, and to prevent unsightly scars, subsequent sickness and mistakes as to a "take" is to rob them of all their ammunition. With the physician rests the responsibility of keeping the people informed on the subject. A physician should in a few words give some information to each person vaccinated, and impress him with the value of the operation. To appear wise to a patient is not so much in the physician's favor as to make the patients feel they have learned something themselves. As the enemies of vaccination are wide awake and on the alert, and their weapons are results that can be avoided by care on the part of the physician, we have only to conclude that the price of the safety and universality of vaccination is eternal vigilance.

DISCUSSION.

DR. JUDSON, Wheeling.—This subject is trite, and doubtless physicians think they know all on the subject. As an officer of health for ten years, I find that although physicians may know everything there is to know about vaccination, they do not place in practical operation the knowledge they possess. The discussion on vaccination during the past few years has tended to prejudice people against vaccination. Whose responsibility is this? I believe the profession is more largely responsible than any one thing. I would, perhaps, be going a little too far in stating that accidents resulting from the introduction of the poison into the system by the operation of vaccination is the result of the carelessness of the operator. How many physicians take the trouble to watch the arm. How many physicians use the capillary tubes containing the glycerinated virus? I believe that no other virus but the glycerinated virus contained in these tubes is justifiable. I believe the profession should discard all other forms, because other forms expose the individual to infection.

As to the matter of dressing the wound, absorbent cotton properly placed can do no harm, but a better method is to place several thicknesses of antiseptic gauze over it, and to treat the wound as you would treat any surgical wound, and so protect it until cicatrization has become complete. In the Section on State Medicine there was reported a death from tetanus. Dr. Sternberg was present and said that the germs of that disease were not injected into the system by the operation, but taken into the system during the subsequent healing of the wound. I hope this will be impressed upon all.

As to the size of the vaccination, it is better to have three or four small cuts than one large one.

DR. JULIA W. CARPENTER, Cincinnati, Ohio.—Two persons have asked me where I vaccinate. When anyone prefers it, on the leg, but I do not select that situation, on account of the motion there. I believe the best place is on the arm, quite near the shoulder. If done at the insertion of the deltoid it is not so easily concealed.

DR. GEORGE C. WORTHINGTON, Baltimore, Md., charged with causing the death of Clara Lockerman, by a criminal operation, was acquitted after a jury trial at Ellicott City, Md., September 20.

RELATION OF URIC ACID TO MIGRAINE.*

BY JOHN A. LICHTY, M.PH., M.D.
PITTSBURG, PA.

It is not strange that the causal relation of uric acid to migraine has repeatedly suggested itself to the minds of physicians, for the etiology of migraine has always been to the clinician what the origin and significance of uric acid has been to the physiologic chemist—a matter of speculation.

The enthusiasm which has arisen in the past decade or more in the study of the secretions and excretions of the living organism, has again awakened investigations referring to the effect of uric acid on the human body, and its relations to disease. So thorough has been this awakening that the foundation principles of pathology and therapeutics seem to have been threatened. Diseases, the etiology and pathology of which were thought to be beyond question, are now considered with reference to uric acid formation. Remedies which were formerly given because they overcame disease, are now given because they counteract the formation, and increase the elimination of uric acid.

Among the many diseases which have been etiologically considered with reference to uric acid, may be mentioned rheumatism, gout, migraine, epilepsy, asthma, and melancholia. Some investigators have become so impressed with the effect of uric acid on the human system that they have attempted to account for a man's disposition, his emotions, and even his character, by referring to the amount of uric acid which he retains in his system. It would seem from the writings of some that philosophy and religion, as well as medicine, would have to be considered anew from the standpoint of the uric acid diathesis.

The study of the relation of uric acid to migraine has, probably, received the most attention. Migraine has been called "the uric acid headache," because examinations of the urine, during and after the attack, seemed to show that the normal relation of uric acid to urea had been disturbed. That is, the amount of uric acid excreted, relative to the urea, is increased during the attack, while after the attack it is normal in quantity for a time, or diminished. "The greater the relative excess of uric acid, and the greater its absolute excretion per hour, the more severe the headache." (Haig.) From this it is concluded that uric acid is the cause of migraine.

With this theory in mind, I have for the past three years turned my attention to the study of the urine with special reference to the relation of uric acid and urea, in the cases of migraine which have come under my observation. In order that there may be no misunderstanding in reference to the results obtained, it will be necessary for me to describe briefly the methods employed in this study.

For the estimation of urea, Liebig's method was employed, which, though not as reliable as Kjeldahl's, for clinical purposes is deemed sufficiently accurate. The uric acid was estimated according to Hopkin's method, described by Von Jaksch, in his "Clinical Diagnosis," with this modification, however. Instead of titrating with the unstable potassium permanganate solution, a decinormal solution of sulphuric acid was used, with methyl orange as the indicator. This was suggested to me by a private student from the laboratory of physiologic chemistry, directed by Dr. E. C. Herter, of the

University of Berlin, and has been found to be reliable.

The urine was collected at the severest period of the headache, and quantitative estimates were made for uric acid and urea. After the headache had entirely disappeared, the urine was collected for the same length of time as before, and subjected to the same analysis. Comparisons were then made between the relation of the uric acid and urea of these two analyses.

The patient was instructed when the headache began, to save the urine of each urination in separate vessels during the entire period of the attack. From these numerous specimens, the one which was voided at the time of the greatest intensity of the headache, was selected for chemical investigation. After the headache had entirely disappeared, the second specimen was collected.

It was thought that if these headaches were due to a uric acid disturbance, it ought to be manifest in the urine at the height of the attack; and, on the other hand, that if the uric acid disturbance which so many investigators have found associated with the headaches, was a result of the attack, it ought to be manifest immediately after the headache had disappeared.

Of the investigations conducted in this way the report of three cases will be sufficient.

CASE I.—Miss H., aged 40, a bookkeeper, has had dull, constant headache from childhood, which, at about 20 years of age, developed into paroxysms beginning over the right eye. The headaches, which are very severe, seem to be induced by overwork, or by slight colds. They are likely to occur during the menstrual periods, which have been frequent and profuse for the past ten years, but occur also at other times. Aside from the headaches, she gives symptoms of neurasthenia, but more of digestive disturbance. She has never had a serious illness. Her mother was subject to headaches, though not of the same nature, and had rheumatoid arthritis, slightly. She is pale, and sallow and weighs 138 pounds, but has no physical signs other than relaxed abdominal walls, and a right movable kidney. Blood examination: hemoglobin, 45 per cent., red blood-corpuscles, 4,600,000, numerous poikilocytes.

A mixed diet, and also nine glasses of milk a day, were prescribed, and phosphate of soda was given three times a day. At the end of a month there was no abatement of the headaches, and the anemia was increased: hemoglobin 10 per cent., red blood-corpuscles, 4,000,000. The milk was then discontinued and salicylate of soda and Bland's pills prescribed. At the end of three months the headaches were not as frequent, nor nearly so severe. The anemia had disappeared, hemoglobin, 87 per cent., red blood-corpuscles, 6,160,000.

The patient then took up her work as bookkeeper, and at the end of a year the headaches had increased in frequency and severity. The blood again showed a slight degree of anemia. A diet, consisting almost wholly of vegetables and cereals was then prescribed, and continued for four months, but the headaches were more frequent than before. A milk diet was then prescribed,

*Presented to the Section on Neurology and Medical Jurisprudence, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

with most disastrous effects, the headaches being more severe than ever.

URINE ANALYSES.

Time.	Am't. Acid. Sp. Grav.	Reac-tion.	Color.	Urea, gm.	Uric Acid, gm.	Ratio.
Feb. 16, 1899, height of attack.	100 1002	Acid.	Pale.	0.26	0.0584	1-30
Feb. 16, 1899, directly after attack.	100 1002	Acid.	Amber.	0.48	0.0285	1-16

The patient was again given a wholly vegetable diet, and salicylate of soda was taken three times a day. This was continued for two months, during which time the headaches were as severe and as frequent as when first seen two years previously. The anemia also increased: hemoglobin, 68 per cent., red blood-corpuscles, 5,140,000. A mixed diet, meat two or three times a day, was then proscribed, when the headaches became decidedly less frequent, and the patient improved greatly in general health. This condition has continued up to the present time.

Case 2.—Mrs. R., aged 54, a society woman, has had sick headaches all her life, coming on every week or ten days. The headache always begins on the right side, and is accompanied with nausea and vomiting; she gives a typical description of migraine. Ten years ago she had a double ovariectomy on account of a uterine fibroid, and has not menstruated since. The headaches have continued as before the operation. Her father had similar attacks of headache and a brother is also so afflicted. A physical examination of the patient showed no abnormal signs. Examination of blood: hemoglobin, 100 per cent., red blood-corpuscles, 5,920,000.

URINE ANALYSES.

Aug. 8, 1898, height of attack.	100 1018	Acid.	Pale.	2.058	0.0419	1-49
Aug. 23, 1898, height of attack.	100 1008	Acid.	Pale.	0.92	0.0672	1-136
Aug. 23, 1898, after attack.	100 1014	Acid.	Amber.	1.54	0.0436	1-35

This patient was allowed to take a vegetable diet. Salicylate of soda in 5-grain doses was given three times a day. At the end of two weeks a second headache occurred, which was mild; in two weeks more, a third attack, very mild; in two weeks again, only suggestion of a headache, and thereafter, no headache at all. At this time the blood examination was as follows: hemoglobin, 93 per cent., red blood-corpuscles, 5,840,000. This condition continued for six months. Social duties were again undertaken, and the headaches became almost as frequent as before, though not nearly as severe.

Case 3.—Mrs. F., aged 40, complains of a frontal headache, accompanied with nausea and vomiting. The attacks occur every seven or ten days. She has had these headaches since early childhood, has always had obstinate constipation, but no hereditary history of migraine. The patient is pale, and very nervous; tongue, heavily coated; pulse, 96; no valvular heart disease; has hemorrhoids and retroversion of the uterus. Blood examination: hemoglobin, 83 per cent., red blood-corpuscles, 5,520,000.

The patient was allowed a vegetable diet, and salicylate of soda was prescribed in 5-grain doses three times a day. Owing to sickness in the family, which called the patient away, no further observations were made.

It will be seen from the study of these cases: 1, both uric acid and urea were diminished during the height of the headache, but their relation was not disturbed; 2, that after the headache, the urea increased to about what it was between the attacks, while the uric acid increased much more, thus changing the former ratio.

These results differ from those on which the uric acid theory of migraine has been founded, in that the urea has not been found so stable a quantity as the results of other investigators show; and that the uric acid has not been increased during the headache, but, on the other hand, greatly diminished. Immediately following the headache, however, there was a great increase of uric acid.

When in these cases, however, the urine was collected during the whole period of the headache, and after the headache the urine was again collected for the same length of time, and quantitative analyses made of these two collections, the results were found to correspond exactly with those on which the uric acid theory has been founded.

From this it was concluded that the uric acid wave which is immediately associated with migraine does not appear until the latter part of the attack, and is really at its height when the attack is passing off. In other words, the time of the greatest severity of the headache precedes the highest point of the uric acid wave by a period of from two to three or four hours, as the case may be.

If this be true, and all my investigations have confirmed it, then it would seem that the increase of uric acid which is associated with migraine, is the result and not the cause of the headache. This conclusion does not seem unreasonable, when one recalls the decided digestive disturbances which take place during an attack of migraine. Digestion seems to be stopped at once, and nausea and vomiting follow. There is a disgust for food, and the appetite does not return for several days.

The uric acid theory of migraine does not alone depend on what is believed to be an absolute fact; namely, that uric acid is excreted in larger amount, absolutely and relatively to urea, during an attack of headache than at other times, but it is supported by a number of hypotheses which recent research has proved to be untenable.

It is supposed that migraine, being the sensory equivalent of epilepsy, must be due to the same cause as epilepsy, and, partially from the results of chemical analyses, and partially from analogy, it is concluded that epilepsy is due to a uric acid condition. But those who have studied epilepsy more recently from this standpoint, have come to the conclusion that the idea that the epileptic seizure is in any way caused by uric acid poisoning is wholly incorrect, and that the increased uric acid is an entirely secondary phenomenon, dependent on disturbances of digestion and metabolism due to the seizure itself.

It is stated that during an attack of migraine there is an excess of uric acid in the blood, and, as the same condition exists in an attack of gout, therefore migraine and gout must be due to the same cause, uric acid. But recently in the study of sixteen cases of gout by Adolf Magnus-Lövy¹, he found that while uric acid in the urine was distinctly increased in nearly all cases of

¹ Zeitsch. f. Klin. Med., B. xxxvi, H. 5-6.

gout, especially during the first day, there was no diminution of alkalinity of the blood, but, in some cases, there was a slight increase of alkalinity. Until such a careful study of the blood is made in migraine, it will be a mere guess to say that there is more uric acid in the blood during the attack than at other times.

Because there is a leucocytosis, similar to that in uric acid diathesis, often present in attacks of migraine, it is concluded, according to the theory of Neusser in reference to the perinuclear basophilic granules, that migraine belongs to that class of diseases commonly called the uric acid diathesis. But a study of fifty cases having the uric acid diathesis, by Charles E. Simon², showed that there is no constant relation between the presence of the basophilic granules, and the elimination of uric acid or even of xanthin bases.

In accord with the uric acid theory of migraine, the vasomotor phenomena, the angiopastic, and the angioparetic conditions described by Mollendorf and Latham, have been attributed to a "blocking up of capillaries by colloid uric acid." This is certainly a very ingenious explanation, but failing to confirm it by ophthalmic studies, and by every means at one's command, it is an unsatisfactory explanation of migraine as the vasomotor neurosis theory, itself.

From these refutations of the hypotheses, on the validity of which depends in a great degree the uric acid theory of migraine, it is concluded that whatever foundation there is for it, the theory must be based on the chemical investigation of the urine. But, as stated heretofore, in studying the urine closely through the attacks of migraine, it was always found that the highest period of the wave of uric acid excretion followed by several hours the period of greatest intensity of the headache. From this it seems evident that the increase of uric acid secretion which is associated with migraine must be the result of the headache, and not the cause of it. It can not be denied that through these studies of uric acid and certain by-products in the urine, we are coming to a closer knowledge of the causation of migraine, but Gower's statement is still applicable: "When all has been said that can be, mystery still envelops the mechanism of migraine."

MIGRAINE*.

BY SAMUEL J. WALKER, M.D.
CHICAGO.

Migraine and headache are commonly considered synonymous terms. Migraine is, however, a distinct disease, the headache being its most pronounced and distressing symptom. In rare cases we may even have migraine without headache. It is undoubtedly the most frequent of all neuroses.

It is my desire to record some of the more striking manifestations of the disease as gathered from an unusually rich clinical experience. I shall base my remarks on the notes taken on fifty consecutive cases, the majority of which are taken from the neurologic clinics of Dr. H. T. Patrick, Chicago.

In looking over the notes, the first important item is the family history, the usual entry being "mother migrainous," "mother and two maternal aunts migrainous," "mother and mother's mother migrainous," "mother and father migrainous," "mother and two sisters migrainous," etc., the disease showing itself in six or seven mem-

bers of a family in some instances. To be exact there is a distinct history of direct heredity in 40 of the 50 cases. Of the 10 remaining cases, 8 knew little or nothing of parents and family; 2 explicitly said that neither mother nor father had headaches. Throwing out the 8 cases of uncertain history, we have 95.2 per cent. of the cases showing migraine in the family. Such figures are extremely significant. Thus we see that direct heredity easily plays the star rôle in the etiology of migraine. We might almost say that heredity was the *sine qua non* of the disease, the exceptions being only sufficient to prove the rule.

How the disease is transmitted, whether through the blood, or through instability of nerve-cells leads at once into the domain of theory, which has no place in this paper. The whole question of heredity is little understood and vague, and need not be touched on here. Suffice it to say that the pathology of the disease is unknown, no theory so far advanced being able to sufficiently explain all the phenomena of the disease. Moebius, in his monograph on migraine, says that 90 per cent. of his cases—87 in number—gave a history of migraine in the family. With such figures confronting me it is difficult to see how the other conditions so frequently ascribed as causes of migraine can assume any prominence, such as eye strain, deviations of septum, adenoids, pelvic disturbances, gout, rheumatism or lithemia. Because we sometimes see in the same patient adenoids and migraine, eye strain and migraine, indigestion and migraine, pelvic disturbances and migraine, hemorrhoids and migraine, etc., does not prove anything. They are simply coincident conditions. In England, where gout is very prevalent, much weight is ascribed to gout and lithemia as etiologic factors in migraine. In Germany, where there is little gout, Moebius states that he has never seen a case of migraine with gout, or with a family history of gout. Any of these coincident conditions may act as exciting causes, precipitating attacks, making them more severe and frequent.

It goes without saying that all such depraved conditions must be corrected as the first step in any plan of treatment. No modern medical man would to-day think of treating epilepsy, for instance, without first eliminating, so far as possible, all abnormal conditions, which might act as exciting causes of attacks. The best authorities, however, do not claim for an instant that the underlying cause of epilepsy is reflex in character.

With figures so overwhelmingly in favor of direct heredity as the etiologic factor of migraine, the so-called reflex causes assume insignificant proportions. I believe that these figures will assume even larger proportions, the more thoroughly and carefully family histories are elicited. A history of severe paroxysmal headache, extending over a number of years, is highly significant of migraine. Add to this a family history of migraine and the diagnosis is assured. Ophthalmic symptoms and vomiting are unnecessary for the diagnosis. It is always to be remembered, however, that brain tumor, chronic Bright's disease, glaucoma, or any organic lesion may develop in migrainous patients, and are to be excluded by the usual methods.

Authorities differ largely as to the part sex plays in the etiology of the disease. All agree, however, that females are more frequently affected. In Moebius' cases 60 per cent. were females. In Henschens' 140 cases 90 per cent. were females. In my series of 50 cases 80.4 per cent. are females. Of the 10 cases giving a distinct history of direct heredity, in 82 per cent. the inheritance is from the mother's side. Gowers says that in epilepsy

*Presented to the Section on Neurology and Medical Jurisprudence, at the Fiftieth Annual Meeting of the American Medical Association, held at Columbus, Ohio, June 6-9, 1899.

² Am. Jour. Med. Sci.

more females suffer from the disease when the inheritance is from the mother's side, more males when from the father's side. If the same is true of migraine—the two diseases are certainly closely allied in many respects—it would account for the preponderance of females in my cases.

I now come to what I consider the most striking and practical item elicited from my series of cases. I refer to the age element. According to the notes the first attack occurred at the following ages: 1 to 5 years, inclusive, 4 cases; 6 to 10 years, inclusive, 26 cases; 11 to 15 years, inclusive, 10 cases; 16 to 20 years, inclusive, 4 cases; 21 to 30 years, inclusive, 4 cases; over 30 years, 2 cases. We have then 60 per cent. of the cases beginning at 10 years of age and under; 80 per cent. at 15 and under, and 88 per cent. at 20 years and under. Gowers states that 33 per cent. of the cases begin under 10, and 73 per cent. under 20 years. Mœbius, in his monograph, presents a table showing 56 per cent. of 59 cases beginning at 10 years and under.

The most frequent replies to the question as to when the headaches began are: "Ever since I can remember," "since early childhood," and "since childhood." All such cases I have classed as beginning at 10 years or under. Two of the 4 cases classed as beginning at 5 years and under are at present writing only 5 and 3½ years of age, respectively. The other two gave explicit history of beginning at 5 years of age. Such figures are significant and important. They help us understand the nature of the disease, they help us in the diagnosis, and in therapeutics.

When we remember that migraine is exquisitely inherited, and occurs in early childhood in the majority of cases, we certainly have valuable data for diagnosis and treatment. Migraine in children is frequently unrecognized. I saw a case two years ago in a girl 8 years of age. The attacks were frequently ushered in by scintillating scotoma, and were usually concluded by nausea and vomiting. The child's mother and four maternal aunts suffered from severe migraine. Yet this patient had passed through the hands of two competent men without having the nature of the trouble recognized. If such typical attacks are sometimes unrecognized, what becomes of the atypical and rudimentary cases.

Migraine in very young children is an interesting disease. It is my belief that the cyclic vomiting described by Holt, in his recent work on "Diseases of Infancy and Childhood," is migraine. Holt himself says it has many points of resemblance to an attack of migraine. He describes cyclic vomiting as follows: "The disease is characterized by periodical attacks of vomiting, recurring at intervals of weeks or months, without any adequate exciting cause. The vomiting is severe and uncontrollable, and usually lasts from twelve hours to three days. It is attended with symptoms of general prostration, which may be alarming. The children who are subjects of it may show in the interval nearly all the signs of perfect health." He then cites the following case: "The patient was a well-nourished boy of 6 years when he first came under treatment. He belonged to a neurotic family, and the attacks dated back to infancy. From this time they had recurred usually at intervals of a few months; occasionally five or six months would pass without one. The symptoms in all the attacks were similar in kind, differing only in degree. I observed three of them. They were preceded by a prodromal period, lasting from twelve to twenty-four hours, marked by languor, dulness, dark rings under the eyes, loss of appetite, and a general sense of discomfort in the epigastrium. At this time the tem-

perature was generally, but not always, elevated, sometimes to 103 F. The vomiting then began suddenly. It was attended with great retching and distress; it was forcible and often repeated every half hour or hour for two days. On one occasion it occurred seventeen times in a single night. Vomiting was immediately excited by the taking of any food or drink, but it occurred when nothing was taken. The vomited matter consisted of frothy mucus and serum, frequently streaked with blood, apparently from the violence of the emesis. The reaction was strongly acid; sometimes there was bilious vomiting. The temperature usually fell to about 100 F. when the vomiting began, and continued at or below this point throughout the attack. By the end of the second day the exhaustion was very marked—so severe, in fact, as to apparently threaten life. The child lay in a semi-stupor with eyes half open, lips and tongue dry, rousing at times to beg for water. The pulse was rapid and weak, and sometimes slightly irregular. There was no distension of the abdomen; it was usually flattened. By the third day the vomiting became less frequent and then ceased entirely. Convalescence was rapid and by the end of the week the boy was as well as usual."

The neurotic family history, the paroxysmal character of the attacks, extending over a period of years, the prodromal period of languor and loss of appetite, followed by vomiting, mark this history, in my opinion, an undoubted case of migraine. The well-known susceptibility of a child's nervous and physical systems would explain the rise of temperature and the rather prolonged attack.

I also believe that the gastro-enteric lithemia as described by Rachford, in the "American Text-Book of the Diseases of Children," is migraine. Rachford cites the following cases to illustrate the gastro-enteric symptoms of lithemia: The patient, a boy aged 4 years, had a gouty ancestry on both sides. After stating that this little patient had had periodic attacks since infancy, very similar to the attack in Holt's case just cited, Rachford goes on to say: "The point of special interest in this boy's case is that these attacks have changed in character. At the present time vomiting is no longer a prominent symptom. They are now characterized by headache with nausea, and followed by a more or less prolonged narcotism, during which the child falls into a deep sleep, from which he awakens somewhat improved. In brief, one may say that the gastro-intestinal paroxysms of his infancy are being transformed into true migraine. This substitution of one form of lithemic paroxysm for another is quite characteristic of the disease." From this description it is very evident that Rachford considers migraine a symptom of lithemia, a relation which I think needs further evidence to fully substantiate it.

In connection with the above cases the history of the two following cases from my own notes is interesting:

CASE 1.—H. S., male, aged 31½ years; mother has severe migraine and very nervous, father migrainous. For the last two years the baby has had periodic attacks of prostration, complete anorexia, followed in about twelve hours by uncontrollable vomiting; even whey and egg-water were not tolerated by the stomach. In the beginning of the attack there was moderate temperature, 100 to 103 F. The recovery was rapid and complete. Between attacks the child is the picture of health. The attacks are less frequent in spring and summer, the family spending about five months of the year in the country.

CASE 2.—H. F., female, aged 3 years; mother migrainous and very neurotic; father migrainous up to five

years ago. This little patient has had periodic attacks of vomiting and diarrhea for the last eighteen months. The vomiting is preceded by a short period of complete anorexia and prostration, and followed by narcotism that is sometimes alarming, i. e., in the last attack the patient lay in a semi-stupor all one day, a slow convalescence beginning on awakening. The temperature in this case usually ranged from 100 to 102 F. for the first twelve or eighteen hours of the attack; after sleeping, normal.

I consider both these cases migrainous in character, for the following reasons: Mother and father are migrainous in both; in both the attacks are paroxysmal; in both there is unusually good health enjoyed in the intervals; in both no apparent cause for the attacks could be elicited; in both there is prostration and vomiting, and in both the attacks are self-limited. In my opinion the diagnosis of migraine is more than justified; it is assured. It will be interesting to follow these cases, to watch for the development of headache, as occurred in Rachford's cases. In the light of the above illustrations it seems to me that the more carefully we study such cases, the more often will we find manifestations of migraine.

Several other forms of atypical migraine remain to be mentioned. I have in mind a case with the following history: Mrs. W., aged 30 years, mother migrainous. For the last six or eight years has had periodic attacks of weakness, accompanied by dull, deep headache in eyes; no nausea and no vomiting. The slightest noise or jar aggravates the symptoms; even walking makes the patient distinctly worse. She has marked pallor during the attack. Another case of rudimentary form has the following history: A boy, aged 9 years, family history unknown, had sudden periodic attacks of dimness of vision, accompanied by zig-zag flashes of light, lasting about fifteen minutes; this scintillating scotoma ushered in a feeling of discomfort "deep in eyes," lasting a few hours; no headache; no vomiting. Long-continued use of cannabis indica markedly diminished the frequency of the attacks. These are undoubted cases of rudimentary migraine, with the weakness in the one, and in the other the scintillating scotoma as the principal symptoms.

Gowers says that visual disturbances occur in at least one-half of the cases. In my series of 50 cases, only 30 per cent. gave a history of ophthalmic symptoms. The ophthalmic symptoms met with in the 15 cases referred to presented all the variations from simple scotoma to complete hemianopsia with scintillating scotoma. Gowers and Mochius say that the disturbance never amounts to a true hemianopsia, i. e., that the loss of vision in the affected areas of the retina is never absolute. They also say that the apparent hemianopsia or scotoma is always double. As this can only be proven in the attacks, my experience is too limited to be of value. Patients usually say the vision is affected in only one eye. The double-sided nature of the disturbance can easily be proven by instructing patients to cover or close the apparently affected eye during an attack.

I report the following interesting history of ophthalmic migraine, through the kindness of Dr. Patrick:

T. C., male, aged 23 years, mother migrainous and one brother with history of headaches, gives a history of severe paroxysmal headache since boyhood. At 17 he had his first attack ushered in by hemianopsia; attacks gradually grew worse. He woke up one night with a feeling of discomfort in the eyes; then distinct hemianopsia developed, right one-half of field gone; added to this was a scintillating scotoma, shaded with color "some-

thing like a rainbow." This lasted about twenty minutes, then nausea developed with pain deep in the eyes, through to the occiput and top of the head. Another attack was the same as above, except that the hemianopsia was followed by numbness and tingling in the right hand and elbow; this lasted about fifteen minutes, then the right half of the tongue, lips, and pharynx became numb and tingled; this lasted about five minutes, then the pain grew worse and was followed by vomiting. Finally this patient had an attack similar to the last described, with aphasia added; the aphasia was complete for about one minute; then he began to stutter and speak slowly; as he expresses it, "the words came in crossed." "Thinking one thing and saying something entirely different."

Such severe attacks are fortunately rare. They serve to show, however, the distinct cerebral nature of the disease, and also emphasize the relation between migraine and epilepsy. The relation between the two diseases is obscure, but they certainly have much in common. In both 75 per cent. of all cases begin under 20 years of age. In both the majority of victims are females. In both the pathology is unknown. In both the attacks are paroxysmal in character, and, finally, we not infrequently see cases of migraine pass over into epilepsy, the migraine attacks ceasing altogether, or becoming less frequent and severe. Sometimes the epileptic attacks pass over into migraine, the fits ceasing altogether or becoming less frequent and severe. The following history is one of five such occurring in my 50 cases, and well illustrates the relation: Mrs. B., aged 38 years, mother migrainous, was a victim of severe migraine, beginning at 5 years of age. From the twenty-seventh to the twenty-ninth year attacks were unusually severe. About this time she had her first epileptic fit; since, migraine is much less frequent; now, idiopathic epilepsy.

Our routine treatment for migraine is the fluid extract of cannabis indica¹. The drug is begun in small doses, and gradually increased until some physiologic effect is obtained. It is then continued at a dosage just below that causing physiologic effect for a long time, at least several months or more. There is nearly always some amelioration of symptoms following the exhibition of cannabis indica thus given. If, in addition, patients have the benefit of fresh air and country life, one may promise, of course with reservations, marked diminution in the frequency and severity of attacks. Of course, as touched on before in this paper, all abnormal and depraved conditions must receive their appropriate treatment. No plan of treatment is complete that neglects as unimportant the so-called reflex causes of the disease.

In conclusion I want to make a plea for the more careful study of this most interesting disease, especially of its manifestations as occur in early childhood, and of other atypical types.

DISCUSSION.²

EDWARD D. FISHER, New York City.—I would begin the discussion of this subject by drawing attention to the importance

¹ It is absolutely necessary that the preparation used be of known activity.

² The papers of Drs. Billings and Risley, in the symposium of which this discussion is a part, appeared last week. Dr. Zenger's paper was printed in abstract, in the JOURNAL of August 25, part 127, p. 557.

of two essential conditions in headache, i. e., a persistent continuous headache and an evanescent, paroxysmal or periodical headache.

The first form, that is, one which is ever present, although it may be subject to paroxysmal exacerbations, is always indicative of an organic lesion as the cause, or to permanent blood changes or diatheses, as syphilis, gout, uremia, lead, etc., while the latter or paroxysmal type is indicative of transitory physical conditions, as overfatigue, indigestion or auto-infection, excesses, as in alcohol, tobacco, etc.

In the first class, therefore, we are considering a symptom of far greater importance as to the ultimate result to the patient's future than in the second class, as in the former death may be the only possible result; whereas, in the latter, while the suffering may be as intense or even more so, the danger to life is small.

The significance of persistent headache is the fact, therefore, that it points to a fixed organic disease somewhere in the system. The most important and those which we learn daily to take into consideration are diseases of the dura mater, i. e., pachymeningitis. The pia mater, unless it involves the dura mater, causes no pain when the subject of disease. The primary disease may indeed be of pial origin, but if pain is of a marked character, it necessarily implies that it has involved the dura mater secondarily.

The commonest causes of headache due to pachymeningitis are suppuration of the cranial bones, either following injury or disease, as syphilis, tuberculosis, tumor or, again and especially, otitis media.

In epidemic cerebrospinal meningitis, simple and tubercular meningitis, we have sufficient exudation thrown out to explain, by pressure, the presence of pain. Outside of such conditions and localized injuries to the skull, involving its membranes near the surface, the localization of the headache is rarely indicative of the site of the disease or lesion.

Tumors of the brain can not usually, except under the conditions I have referred to, ever be located by the situation of the pain. Occipital pain does not necessarily mean, with all the other symptoms of cerebral tumor—abscess—present, such as general convulsions, stupor and optic neuritis, a tumor of the cerebellum. In a case reported by me some years ago, with the general symptoms of cerebral tumor as above given, the pain was most intense and agonizing over the frontal lobe, and as this was the only localizing symptom as to the situation of the tumor, we operated at this point, yet post-mortem revealed the tumor in the cerebellum.

More important to the general physician as diagnostic of organic disease of the brain than, as shown by injury, suppuration, car disease or tumor, as these give other symptoms which often naturally lead to a diagnosis, is the importance of persistent headache as pointing to arterial disease, i. e., arteriosclerosis, dependent on some dyscrasia as Bright's disease, diabetes, gout, syphilis, lead, etc. In these cases we rarely have a localized cephalalgia. It is usually general and more subacute than acute, combined with a feeling of compression. This form, unless in the very young, where anemia is the most frequent cause, almost invariably points to degenerative changes in the blood-vessels. It is the premonitory symptom of apoplexy or cerebral softening.

Persistent headache, therefore, is always of great importance, as indicating organic disease of the brain and membranes. In children, as in adults, its significance should never be lost sight of. It always means, in the young, either anemia, meningial or brain disease, eye strain, or again some chronic inflammation of the middle ear. In the so-called functional headaches, characterized by their being paroxysmal, periodical and short-lived in their attacks, we must always look for some local cause.

Here come in the factors of heredity with lithemic states, temporarily brought to a point of excitability by too free use of certain articles of diet, as sugar, nitrogenous food stuffs, etc., or again by retention in the blood of certain poisons, the result of auto-infection. The headache of acute uremia is an example of this form, or the sick headache or migraine. The douloureux I do not include in this list, as here we are probably dealing with degenerative neuritis.

I have only tried to emphasize the importance of the presence of a persistent headache as always indicative of organic changes. As a symptom, it should never be ignored, and especially is it of importance in the chronic conditions represented by diseases of the cerebral vessels. It is in this class of cases that the general practitioner is most apt to see it, and the one also which he is especially calculated to take under his own care.

Headache is too often referred to the specialist on nervous diseases, while it more properly belongs to the student of gen-

eral medicine. While the so-called nerve specialist is more in touch with the general practitioner than any other of the so-called specialists, being called on to study all diseases of the various organs of the body, still I, in closing, must emphasize the fact that headache is not a disease per se, as pneumonia, but is simply a symptom of a variety of diseases of the body as a whole, which the general practitioner is best fitted to understand.

DR. NORMAN BRIDGE, Los Angeles, Cal.—The papers have covered the subject of headache very thoroughly, in most particulars, and leave very little to be desired.

I assume that Dr. Fisher did not mean to say that any headache was utterly and completely continuous. I believe that is not the case anywhere, except for a little time. The migraines are not continuous; certainly the headaches due to meningitis are paroxysmal, the headaches due to nephritis are certainly paroxysmal, and so on; but I presume that he used the word "continuous" in that sense. I was a little surprised that Dr. Fisher, in speaking of headaches produced by things swallowed—by things imbibed—referred only to the different foods, excess of food, etc., as being capable of producing headaches. What he said is true, but it seems to me that most of such headaches are produced by tea, coffee and tobacco.

Dr. Billings referred to that fact in his paper. What Dr. Billings said is certainly correct, that the headaches produced by gastro-intestinal troubles are less due to disturbances of the gastro-intestinal mucous membrane than to the predisposition. People who have no predisposition to headache, hereditary or otherwise, may indulge in great excesses in the way of eating and drinking, and great irregularities, and have excessive gastro-intestinal irritation without having any headaches at all. The hereditary predisposition, as Dr. Walker said, is the larger part of the causation.

I was glad to hear Dr. Walker say that headache is only one of the symptoms of migraine. I do not think he emphasizes so much as he might safely have done, the various changes that take place in migraine during the march of time. In cases of this kind there is a change in the symptomatology of the migraine every half day. A symptom may be absent for the first fifteen years of migraine, only to occur for five or ten years, and then disappear again. Then the headache phase may be very pronounced in the early period of migraine, to grow less as the years go, and disappear entirely toward the middle period of life, and the paroxysms be represented by various other explosions, like diarrheas. It may also be shown, and is occasionally, in these patients, by the sole symptom of increased urination—diuresis.

Ninety-five per cent. of all cases of migraine are helped somewhat by stopping the use of tea, coffee and tobacco, and I should say that the agent that is most responsible for the aggravation of the symptoms is coffee, next would be tobacco, and the least of all is tea. But the migrainous patient may, after a period of susceptibility to the influence of coffee and these other agents, pass out of that susceptibility, and be able to take these substances regularly without any discomfort or harm.

The thing that did surprise me in Dr. Walker's paper was that he characterized so positively the relation that he assumes to subsist between migraine and epilepsy. Analogy I concede; it is clear and certain; each is a disease that is paroxysmal, and each is a disease that is largely incurable, and so on; but that they are convertible one into another is certainly new in my observation of migraine. I have searched for a long series of years, without success, for a case that illustrated it in any degree whatever. The case related by Dr. Walker does not seem to me sufficient to prove any nexus between the two diseases. It does seem to me that patients with migraine are especially free from tendencies toward epilepsy; that the disease somehow apparently protects them from other diseases of the body. That is the only comfort that the migrainous patient can have that I know of.

The paper on the relation of headache to the uric acid theory is certainly a most interesting and instructive one. My own belief has been heretofore that there was no relation between migraine and uric acid diathesis. I know that expression is not very scientific; at any rate, it is an expression for a condition about which doctors and the best pathologists seem to be in more or less dispute. Certainly the theories of the English authors quoted by Dr. Liehty have very little weight, for Haig is a great doctrinaire, and I can not make his theories seem rational to my mind.

This, however, is true: he shows in his paper that salicylate of soda lessens the headaches in some of these patients; he showed how various other treatments did not lessen them. Salicylate of soda he would call an anti-gouty medicine, and I would suggest that he try simple bicarbonate of soda in these

cases, and see if it does not produce just as wonderful results, and if it does, as it has under my own observation, it seems as if it gives us warrant in believing in the existence of a diathesis of some sort that is amenable to this kind of treatment; whether it is to be called the uric acid diathesis, whether the mischief is in the particular directions that these authors say or not, there is some diathesis of that sort that can be treated in these ways with benefit to the patient. I confess that I have rarely given the alkaline treatment in the pure migraines, but in the headaches produced or aggravated by gastro-intestinal disturbance I have in the last two or three years given considerable doses of bicarbonate of soda with marked improvement. The doses were taken half an hour before a meal, and the meal was selected that was most likely to be followed with acid eructations; usually the largest meal in the day. These patients have had less headache and gastro-intestinal disturbance. There is no question as to the relation between their feelings and the medicine; the only question is whether the alkaline treatment improved the digestion, improved the condition of the stomach by enabling it perhaps to manufacture better gastric juice or better peptic properties for digestion, or whether the alkali actually corrected, in some degree, this suppositive diathesis. Not only have I seen the headaches improved, but in a few instances I have tried this in those curious recurring diarrheas that are migrainous, that is, occurring in migrainous patients at a time in their life when the headache paroxysms have ceased to exist, and while the patient knew from experience that when a diarrhea had come on it would last from two to three weeks; in spite of all the regulation and diet possible, and in spite of bismuth and other remedies for irritation of the bowels, it promptly improved on giving the patient these large doses of bicarbonate of soda. I am bound to say that in addition to this some saline laxative was given at the same time; not enough to cathartize the patient, but enough to give a slight laxative effect; it did not seem to matter which laxative was used. The alkaline treatment seems to have a pronounced effect on these cases, and a most interesting suggestion as to the so-called uric acid diathesis, not merely as to the diathesis per se, but the diathesis as perhaps influencing the headaches, and possibly the migrainous headache.

What Dr. Zenner of Cincinnati said in reference to the mental effects in the headache is certainly very interesting. I would only say that it seems to me that it is not entirely necessary to assume that the surgical operations relieve the headaches in the cases referred to by mental impression. They may have done so in the cases related. But we know that a surgical operation does interrupt and intercept various nervous phenomena for a limited time, unexpectedly, and frequently under circumstances that make it impossible and perhaps unfair to assume that mental impression is instrumental in producing symptoms. The patient takes ether or chloroform; he suffers a wound, and when he comes to himself he has a dressing on, and he is in bed, and he has, perhaps, before the operation received extensive catharsis, and afterward is kept on a low diet, and kept quiet and free from disturbing circumstances, and so in this way the surgical operations may produce these changes without assuming that the effect is a mental one. I believe that a patient may be taught to ignore, to a considerable degree, a moderate headache, to be philosophic about it and pay no attention to it, and thus soon cease to feel it. We should always encourage the sick to do this as far as possible.

DR. L. B. TUCKERMAN, Cleveland, Ohio.—I came here for a personal interest, for further back than I can remember, I have been a sufferer from paroxysmal headache. I am in doubt yet, even after this full discussion, whether it is rheumatic headache, or hereditary headache, or due to eye strain, or intestinal complications, or what not. When I first had it as a child it was called a bilious headache, and it was my father's habit to administer Ayer's pills to me when it came on. I had an idea that it was hereditary, my mother, my mother's mother, my mother's mother and grandmother had it. My mother's grandmother died at the mature age of 102; her mother at 82, and my mother is still living. In relation to epilepsy, although every member of my mother's family has had headaches as I have them, there is not a member of the family, so far as I know, who has ever been the subject of epilepsy. There has not been a generation in the family, however, but what in certain conditions of headache or fever are sleep-walkers or sleep-talkers. I can remember as a child that, as the paroxysm came on, although I did not fall asleep, it seemed to me that the bed was aching, and my desire was only to get the bed into a more comfortable position! To-day, in the paroxysms of headache I can not lie down until it is over. I have thought that this headache was rheumatic, because

my father and mother had rheumatism, and I have occasional attacks of it, and I have noticed that when the headache or the pain passes into the back in a sort of lumbago, the headache ceases, but the attacks come on pretty promptly.

When this question of eye strain came out, I got glasses, but I have headache yet. There is one symptom that I have noticed that has not been mentioned; at the expiration of every attack of headache, so far as I can remember, the critical point in the subsidence of the headache was the discharge from the bowels of an intensely acrid, scalding substance, which has been producing pain which is almost dysenteric. I have settled now on sitting up with my feet to an open fire, if it is winter, and drinking all the hot water I can get down, and it does as well as any remedies I have thus far tried.

DR. CURTIS, Chicago.—I must express my gratification that the question of migraine has been thus handled, because it is important that it be recognized as something distinct from a headache. It strikes me that it is of all the neuroses the one which is the most true to itself in its manifestations. It has an intimate connection with epilepsy. The cases reported by Dr. Walker, and a similar case reported by the doctor from Philadelphia, half a dozen reported in *Brain*, last year, half a dozen which I have seen myself, have left in my mind not the slightest doubt that there is a genuine relation between these two neuroses. It is not unusual to find, in the same family, certain individuals presenting migraine and others presenting epilepsy. The onset of epilepsy in the developmental period of life, and the onset of migraine in the same period, serve to confirm this idea. In women, at the cessation of the menstrual activities, migraine almost invariably ceases. In men there is, as a rule, in my experience, and from the best recollection of my case-book, a tendency for migraine to cease after the age of 60. It is one of the manifestations of a stress of life acting on an organization not quite up to bearing these strains.

I have observed that migraine is likely to occur during the period from 5 to 8, when the eyes are first used in learning to read; but many of those cases present no difficulties in the eyes, or the correction of such difficulties does not relieve the symptoms. I was surprised to hear Dr. Bridge say that he had not noticed this relation between epilepsy and migraine, because there is scarcely six months passes in which I do not see an instance of this sort.

In reference to the action of the mind in regard to the management of headaches, I feel, as Dr. Bridge has already expressed, that in the two cases of cerebral tumor subjected to operation, there were many elements entering into this besides the actual operation. The opening of the bowels, the surgical blood-letting, and so on, might have that effect, just as a number of doses of iodid might have it.

DR. CHARLES H. HUGHES, St. Louis, Mo.—I wish to record my skeptical views in regard to the attributed causes of migraine or headache. I do not believe that any of the theories are tenable for the development of headache symptoms that we ordinarily encounter. I do not believe that headache and epilepsy are at all associated diseases.

In regard to the longevity of headaches, headaches have been common in my family for several generations back; my father used to have headaches, my mother, my mother's mother and father, my grandfather and my great grandfather. There are, however, no records of any epilepsy in the family, or any other neurosis. All the members of the family have attained a very advanced age.

I had headache recurring during every month, the result of brain strain, because I paid no regard to the laws of psychic recuperation. It was my custom to drink from one to three quarts of strong coffee a day, far into the night, in order to prevent sleep, on the old supposition that the brain was not dependent on the organization, and that the amount of labor you could perform was a question of will-power. My headaches came on one day in the month, and disabled me for one whole day. I had to retire to a darkened room, and wait until recuperation came about, and it was one of the most conservative processes of nature that I have ever had the good fortune to have before me, for it saved my life in that way.

I do not believe the uric acid diathesis has any more to do with migraine than any other case. It is certainly not the exclusive cause; it may be one of a number. Migraine is dependent on the sources of irritation and nerve exhaustion, and these may be as varied as the causes of pain in any other part of the system.

DR. JOSEPH V. KORROK, Cleveland, Ohio.—I have had a little experience in headaches in children. I particularly remember one case in which I was called after the family physician had been away for some time, to see a girl about 8 years old, and they told me she had headaches very often; every two weeks she had to lie in bed a day or two, and the doctor gave her a

cathartic, and she was all right again. It occurred to me to look into the throat of that child, although she did not complain of it at all. I found a very inflamed tonsil, which I treated, and she has had no headaches for six months. She still, however, has occasional attacks when she does not feel well, probably for a number of hours during the day.

It struck me that in some of these cases where there had been fever, which we notice is particularly high in tonsillitis, and vomiting and other severe symptoms, tonsillitis might be the cause. Personally I feel that tonsillitis is often the cause of headache in children.

DR. A. E. STERN—It seems to me that we can not generalize too much on this subject. I believe that almost every individual class of cases can be separated, and some cause found for the existing headache; yet even after that cause has been removed there is a secondary state following this, old chronic state, whether it is dilatation of the blood-vessels, or whether the stretching of the blood-vessels has gone to such an extent that the vital rubber loses its contractibility, it is a matter of experience that the headaches persist, and it takes a long time for them to disappear. Headaches are usually due to a lack of oxidation. This will seem plain when we consider the complex formula of uric acid.

It seems to me that we have to do here with a lack of oxidation. Whether that is a general metabolic disturbance, whether the metabolism is intrinsically disturbed, or whether we have to deal with split products in the one case, or with chemical change due to certain kinds of invasion, toxic or ptomainic or leukemic or otherwise, is a matter beside the question at the present time.

DR. F. SAVARY PEARCE, Philadelphia.—To my mind there is no doubt about heredity being a predisposing cause, and then in addition to that we have the exciting cause, whatever that may be. There are numberless exciting causes for which the broad physician must be on the lookout in order to get the best results. If it is the eye, that should be corrected. The gastro-intestinal tract should receive attention, and every other possible source of irritation should be considered, including the existence of uric acid excretions. In the case mentioned by Dr. Tuckerman, it would be well to have the stools examined, and see whether there is an excess of uric acid or not.

DR. EVANS—The papers on migraine have been extremely interesting, but if they demonstrate one fact it is that the medical profession to-day is in a state of extreme uncertainty as to the causal factors, or at least the most prominent causal factor, in the production of migraine. I do not think that arriving at such a conclusion, even though it should be practically unanimous, should describe the study in a special line. The young, and the older members of the profession, show alike a disposition to find some particular cause along the line of their own special work to explain the production of disease, or to ferret out the real causal factors in the production of certain diseases which afflict the human race. The efforts in this symposium have been along this line.

I am very much interested in the study of epilepsy, and, like migraine, I know very little about the causation; but I am inclined to think that it is a little over-enthusiastic for us to claim that there is such an important relation between migraine and epilepsy. When we take into consideration the fact of the great prevalence of migraine, and how our highly neurotic patients, or patients who are given to various forms of neuropathic manifestations, are likely to have other more serious forms of nervous disease; or, in other words, that since migraine prevails so largely, and there are numerous nervous troubles which are looked on as being developed along with it, we are not justified in saying that we shall have cases of epilepsy coincident with migraine. This is especially true when we consider the large number of cases seen by neurologists in their practice, and then take into consideration the small number of coincident cases.

DR. HENRY T. PATRICK, Chicago.—The statement made by Dr. Fisher, that constant headache is generally due to organic disease of the brain or of its envelope, is true. The only modification I wish to make is this, that there are many patients who come complaining of constant headache which, on careful investigation, is found not to be a constant, agonizing headache at all, but rather the neurasthenic discomfort, which is a rather inaccurate phrase to describe the rather multitudinous collection of symptoms known to neurotics.

I should like to support the assertion of Dr. Walker, that there seems to me some relation between migraine and epilepsy. Whether that be simply a community of cause and a similarity of expression, I think none of us can at this time attempt to define. But when one sees in fifty cases of migraine five cases of alternation, or substitution, or partial alternation, that certainly means something. Take for instance a case like this:

A woman brought a boy with epilepsy. In inquiring into the family history I found that the mother had had typical attacks of epilepsy to the age of 25, as I remember it now. From that time on, without any treatment, the epilepsy spontaneously ceased. From that time on she began to have what she had never had before, repeated typical attacks of migraine. One case is not much; but when you have seen perhaps half a dozen of these it makes one more thoughtful.

In regard to what Dr. Tuckerman said of his father having died at a very advanced age, still having his migrainous attacks, so far as I know I can not claim the credit of having cured a case of migraine. I will take off my hat any time to the man who can cure migraine. I believe that the oculists successfully cure it by the correction of ocular defects. Aside from that, I can not recall at this moment an authenticated case of cure of migraine. Women, of course, very frequently lose their pain at the menopause.

I feel it my duty to caution against taking the statements of Haig's book. I feel it my duty, because I hear them repeated so frequently by persons who have not read his book or have read it carelessly, and have taken his assertions for facts. Dr. Haig is under the same obligation that all of us are to prove his assertions, and I submit that so far he has not done so.

DR. E. D. FISHER, New York City—I simply endeavored to speak of the diagnostic importance of headaches. The weight that I wanted to give to my part of the discussion was the distinction between the so-called continuous or strain headaches, and a paroxysmal headache. There is such a thing as a continuous headache, a constant one, which is present in such cases as I referred to, as Bright's disease or nephritis, and again I wanted to insist on the point of the continuous quality of headache in arterial disease. In all of these continuous headaches, of course, we have exacerbations of pain. We must look to the diseases underlying such conditions whenever we have a continuous headache. There is some fundamental disease, like diabetes, or Bright's, or some growth.

In regard to the relation of epilepsy and migraine, I never could see any distinct connection. The class of patients subject to migraine and those that are subject to epilepsy are absolutely distinct. We are not dealing with the same thing, but the discussion of the point is very valuable.

I wish to emphasize what Dr. Patrick said in regard to Dr. Haig's conclusions. I never have agreed with them.

DR. S. J. WALKER, Chicago—I think it unnecessary to advert again to what I have said in my paper in regard to the relation between epilepsy and migraine. I simply suggested that there might be some such relation, and made no positive statement.

As for the explanation of fever in several of the cases I reported in young people, children react more easily to all sorts of influences, and this would account, in the case which I reported under 5 years, for the temperature. Gowers says that frequently in children migraine is accompanied by fever.

DR. J. A. LICHTY, Clifton Springs, N. Y.—I am very glad Dr. Patrick has made the explanation in regard to continuous headache, for I have had several cases of a similar character.

As to Dr. Haig's book, I can readily indorse all that has been said as to its character. It reads almost like a novel. I studied it carefully before I began my investigation, and the more I studied it the more I found that he did not prove his point.

As to the menopause and migraine, Dr. Haig proves his position against everything by saying that, because during the menstrual period there is an excess of uric acid, hence after the cessation of menstruation the migraine disappears.

In reference to the treatment, Dr. Bridge probably attached more to my treatment than I intended. I simply gave salicylate of soda, because Haig had said it would do such and such things; I had no confidence in it at all. The first case in which I put the patient on the diet of Haig got worse and when I changed the diet, and gave most anything, he improved. In the second case I gave a low diet without reference to uric acid, and also salicylate of soda, and the headache improved and, in fact, disappeared. I do not believe that the salicylate of soda had very much to do with these cases; I think that in nearly every case it was the hygiene and the diet. While I think Dr. Patrick is right in saying that migraine can not be cured, yet in about twenty-five cases which I have watched in the last few years, I have had very satisfactory results by watching the diet and paying attention to hygiene. I had a patient come to me two months ago, who had a severe attack of migraine. I gave her no medicine at all, but I told her to drink lots of water. She was away from her family, who seemed rather irritating to her, and she has not had an attack since.

DR. PHILIP ZENNER, Cincinnati, Ohio—As regards those two

cases which we referred to several times, my only object was to show that one is often mistaken in the supposed cause and manner of treatment of headache, but that the mental element was really the cause in those two cases was shown by their being very susceptible to suggestion. For instance, one of the patients could be relieved of her pain by a drop of sugar water, and so on. All those things indicated the power of suggestion, and it is quite probable that that was also the result of suggestion. My object was to show how one is led astray in a conclusion of that kind.

One word as to the relation of migraine and epilepsy: I suppose there is some relationship between all nervous diseases: I can hardly believe there is a greater relationship between these two. The two are so different; the one is a benign disease, the other is malignant: the one terminates in recovery, it does the patient no harm, it does not interrupt the patient's mental processes; the other, with few exceptions, continues to get worse until the end, and usually, in the great majority of cases, damages the mind. Now that the two might occur together is not surprising, both being such very common ailments, and that with the occurrence of epilepsy migraine should cease is not astonishing, because the occurrence of epilepsy itself has an effect on other disease. It may be that there is in some instances, in rare individuals, a closer relationship. It was said for some time, and possibly is believed yet, that some forms of migraine are directly related to paresis, that they finally terminate in paresis, and that may be true in some instances. It may be that it shows either an existing disease or a tendency in those individuals, and it is just possible that in certain individuals such a relation between epilepsy and migraine occurs. But the more clinical aspects as they appear to us, do not indicate such a relation to my mind.

THE DOUCHE.

ITS RISE AND DECLINE, BUT PRESENT RESTORATION.

BY FRANK A. STAHL, M.D.

INSTRUCTOR IN OBSTETRICS, RUSH MEDICAL COLLEGE,
CHICAGO.

(Concluded from Page 781.)

So far as bacteriologic conclusion may be an index, the following table from Krönig's paper is of interest. Of his 221 cases, 103 were neither examined internally nor douched. Of these he tells us 59 had pathologic secretions, 44 had normal. Now, it would seem that the 59 pathologic-secretion cases would show the greater morbidity; but not so, for of the 59 cases with pathologic secretion, 18 sickened, 30.5 per cent.; and of the 44 cases with normal secretion, 20 sickened, 45.3 per cent. *One can conclude either way.*

There is another point that must be considered. Some maternity gentlemen speak of their cases as if without the douche. Yet every patient, before she goes into labor, is bathed, soaped, and cleansed, in many cases as never before. Have not the genitals partaken in the process? Certainly, for upon the externals special effort is spent; whether or not it is intended, as she breathes in the bath the vagina is flooded; like in the Talmudic dipping, there is an involuntary douching of the vagina. It is not the large quantity of soap or antiseptics that is essential, it is the large amount of water, clean and changeable, running water. The cleansing, stimulating bactericidal action of running water is a fundamental principle in hygiene, seen in all nature.

Though this may be a digression, yet it is opportune. The celebrated Pettenkofer recognized these purifying qualities of running water, and by directing the mountain stream, the Isar, through his system of multiple canals in Munich, he thus successfully overcame the blighting municipal problem that had for many years cost Munich so dearly from the ravages of sicknesses, like the fevers, and for like reasons the financial and social loss of the large English colony, now in Dresden.

In the douche it is the running water that is of superior value; chemical antiseptics play but the minor assisting rôle. Antiseptics can not be used without the

water, they would destroy; but the water alone or with the ancient ash soap will suffice, where chemical antiseptics are not to hand.

As a rule, upon important issues, bacteriologic conclusions based upon bacterial investigation, can as yet show a greater number of errors for therapeusis in oracle than verification. More than once the bacteriologist has startled the clinician with his assertions. The outcome has been that the bacteriologist is gladly heard of in research work, but when he concludes in therapeusis the clinician good-humoredly looks skeptical, but gives him a chance, only too often to be disappointed. In practice and in discussion we have maintained that:

1. The douche is a benefit* and to be recommended, both as a prophylactic and as a preventive measure. It cleans; it stimulates; to the genital economy it is bactericidal, for though it may not destroy, it washes away multitudes of micro-organisms; the patient feels refreshed and strengthened after it; it is a splendid antipyretic.

2. Less injury has been done by the douche than by the non-douche principle. Further, ophthalmia neonatorum is surely discouraged by the douche.

3. Repetition, temperature, force, and quantity of the douche must be regulated by the demands of the problem.

4. Perforating wounds of the cheek and lip, continually bathed in the secretions of the mouth, mammary abscesses, these, like the wounds of labor, will heal and will recover; but neither so pleasantly, so perfectly, so promptly, nor with so little systemic reaction as when the douche is intelligently applied.

5. Its beneficial efficacy in the early labor, the abortion, is a fact. Contrary argument would prove but a boomerang.

6. The dangers of the douche have been exaggerated. The extreme danger of possible air emboli in practice bears the same relation to its reported theoretical possibility as is so correctly suggested in the figure of exaggeration, viz., as the molehill to the mountain.

7. The 1894 departure has not overcome; on the contrary, to-day it but strengthens Ahlfeld's auto-infection.

The above expression of position where thought is divided, and which is but a compilatory effort of previous practice and discussion, taken alone certainly would seem individualistic, carrying with it no greater force than appertains to the individual. But this force, surprisingly added thereto by the authentic reports from the last German Gynecological Congress, held in Berlin, May 24-27, 1899, and from so high an authority of scientific thought, and which but a short time before had doubted and now changed from its 1894

*Though the hygiene of society may vary with field, town, city, density, etc., individual hygiene is usually the same, that is, he who fosters (or otherwise) cleanliness and freedom from infective quality, if this is true of the individual in the field or the city, that individualism is maintained however the environment may change, therefore, I use the douche as follows:

Antepartum.—In the clean cases, as they are already clean, one douche is given as a prophylactic. I have never seen a case where such a douche normally given, induces dryness of the walls. In the unclean cases, or suspicious cases—douche as indicated.

Intrapartum.—Follow indications. In a short and clean labor, usually nature, in a tedious, prolonged labor, where secretion is at first increased by the activities of labor, followed by a hot dry vagina, a douche is cleansing and refreshing; where meconium is in the vagina, or products of maceration; where secretion at first apparently clean, becomes unclean; all unclean or suspicious cases and operative cases—douche as indicated.

Postpartum.—I use the douche twice daily, at 8 A.M. and 8 P.M., as a routine measure for the first three days of the second week. The postpartal douche is best usually either cool or tepid, with about a four-pint volume, always douching the externals first, then introducing the point. Hot water douches in obstetrics, like in gynecology, are to be avoided where possible, because they exhaust. Restriction is indicated by the systemic reaction.

departure, becomes conclusion of considerable weight, and food for more profound consideration than mere desire to controvert.

To avoid extending the limits of this article to too great length, my excerpts of the abstracted Transactions⁵ are short, so as to present each individual's position, and to show the individual and general trend of thought and therapeutics. There were presented two principal themes for discussion on the subject of puerperal fever. The first was by Ahlfeld, the champion of auto-infection; the second by Bumm, a champion of the opposition.

THEMES.

Ahlfeld of Marburg states that the definition of puerperal fever can not yet be established, neither from a bacteriologic nor from a clinical standpoint. Besides the streptococcus, there are other micro-organisms able to induce fatal infections, which clinically are not to be differentiated from streptococcus puerperal fever. Without doubt many streptococci may be found in the uterus without betraying the least evidence of their presence. With free drainage the endometrium can purify itself. The knowledge that besides the etiology of a direct invasion of virus into the tissues, another, a "2 form" of origin of childbed fever exists, the development of a disease process outside of the assistance of doctor and midwife, commences to force for itself more recognition.

He refers to the superiority of warm-water, soap and alcohol hand-disinfection over other methods. With the experienced and conscientious application of that method of hand-disinfection, internal examination is without danger. Forms of puerperal fever occur in cases where no examinations were undertaken. The causing germs were either present in the vagina at the time of labor, or had invaded the vagina; like the gonococci, their virulence may be increased after labor. Finger-coats are nothing for general practice. How the germs of the vagina ascend and under what circumstances they carry out their deleterious effects is to be studied. He states that for the last five years, thanks to the introduction of hot-water-soap-alcohol disinfection, he must consider the fever in the main as a consequence of an ascending of vaginal germs. With the preliminary vaginal douche, pathologic vaginal secretion has no importance. If, further, a series of operative labors determines the fact that thereafter the number of temperature-free puerperae does not materially increase, the thought lies near, that the careful, thorough cleansing of the vagina and frequent repetition of the same is the principal cause of this favorable result.

Bumm of Basel stated that childbed fever is wound fever. It seems of importance to maintain the difference between wound-intoxication and wound-infection. He raises the question as to why the same germs at one time attack the mucous membrane, the next time wander farther, and the third time extend only through the blood. There is as yet no satisfactory knowledge. The severity of the sickness depends especially upon the quality of the infecting agent. The streptococcus which causes fatal sepsis is the same as that one which causes the local endometritis. In comparison we now know that the streptococci of wound infection possess *the faculty of changing their biologic properties and their form of growth*. From a clinical standpoint the type of auto-infection maintained by Ahlfeld is open to

objection. The danger comes from without. If from contact with septic material highly virulent germs cling to the hands, then even the most thorough disinfection is unreliable. In the rubber gloves, therefore, we possess a most valuable addition to our antiseptic instruments. Our antiseptic methods have had no influence in the development of putrid endometritis. The greater probability here is of an external ascending putrefaction; for this speaks the day-to-day increasing germ contents of the lochia during the puerperium, and the often directly observable ascending of the putrefaction. Therefore, douches during parturition will likewise not be of assistance against later putrefaction⁶ because an open wound treatment is not to be avoided.

DISCUSSION.

Döderlein of Tübingen differs from Ahlfeld as to the possibility of disinfecting the hands, especially those of the students. In the lisle operating-gloves, the germs accumulate rapidly. He formerly believed that the germs came from the air, but he feels compelled to rectify this and admit that, in part at least, they come from the fingers. On the virulence of the germs depends the ability of the body to cope with them. Bumm is inclined to the opinion that a part of the infections are due to ascending of germs, supported by the observations of Burckhardt that the germ contents of the uterus increase in the puerperium. Winternitz examined 86 cases, and, in 80 per cent, found the uterus germ-free in late childbed. The healthy uterine cavity must be therefore germ-free. For all that, germ contents indicate no disease.

Bumm of Basel said that it is true that the results of bacteriologic investigators often contradict each other, yet it is to be remembered that these examinations are unusually difficult, and often undertaken by beginners. Concerning the abdominal cavity, Bumm obtains the same results as Döderlein; the longer the operation, the more germs were present everywhere; the air was found germ-free; all pointed toward the fingers. Bumm, even after alcohol and bichlorid treatment, warns against positive hand-disinfection. Personally, he has returned to antiseptics. The oftener during an operation the hands are washed in sublimate, the better. The body can not overcome the introduced germs if they are septic; if the wound conditions are bad; if operative technic be an imperfect one.

Franz of Halle reported results of bacteriologic examinations to determine the cause of slight increase of temperature in the puerperium. The influence of the gonococcus could not be determined, for in no case could the gonococcus be found alone, without the presence of other bacteria. From his examinations he concludes that in many cases the germs alone can not "condition" the fever, that rather the incomplete discharge of the uterine secretions in connection with the germs is the cause of the fever. As to attributing the slight temperature increases to infection during parturition, bacteriologic investigations hardly afford a satisfactory footing for explanation of temperature increases. The explanation becomes easier if one accepts an infection, less during parturition, rather one during the puerperium, therefore a secondary infection of the cavity wound, which the uterus and vagina present in the puerperium.

Fehling of Halle called attention to the little prog-

⁵ In the mammary abscess, during the labor of expelling the pus would the same logic hold true that the douching during its (mammary abscess) parturition would likewise not be of assistance against later putrefaction? Certainly not, if guided by *etiological* facts.

ness that bacteriologic investigation had made in the knowledge of puerperal fever in the past ten years. Of importance in the origin of these slight temperature increases is the clinical examination; this is shown in the 5 to 10 per cent. lower morbidity during the vacation than during the active semester. Examinations with boiled finger-cots during two semesters resulted in a slightly higher morbidity than without the finger-cots. The difference between vacation and semester morbidity, the results of glove examination, suggest that insignificant mechanical conditions in the genital tract must be of importance in the slight temperature increases.

Krönig of Leipsic, like Bumm and Döderlein, finds that alcohol is not a disinfectant; contrary to Bumm, he is of the opinion that the difference between intoxication and infection can not be maintained.

Menge of Leipsic concluded that from the reports of vaginal anaërobe streptococci of obligate nature the justification of douche is not yet to be deduced.

Schauta of Vienna said: "Permit a clinician, after twenty-three years of experience, to mention his conclusions and results. You are acquainted with the poor locality of the Vienna Klinik, its large number of obstetrical cases; because of the large number of clinicians, it necessitates intense utility of the material. If, notwithstanding this, the results can be placed alongside those of the best maternities, it speaks very highly for the antiseptic regulations which are here customary. Out of 20,805 labors, from 1892 to the end of 1898, 1664 febrile (7.9 per cent.); of these 420 were caused by internal disturbances, leaving 1241 puerperal sick (5.9 per cent.). The mortality was 101 (.4 per cent.); of these of non-puerperal causes 47 (.186 per cent.); the remaining 54 (.213 per cent.)." His regulations are disinfection according to Fürbring, debarring students for the whole semester from pursuing anatomical courses; isolation of all suspicious cases; vaginal douches with 1 per cent. lysol solution, the latter, not to remove the vaginal germs⁷, rather to remove the vaginal mucus, replacing this with a layer of disinfecting fluid.

Prochownick of Hamburg stated that the bacteriologic secretion examination *ex utero* is unreliable, of little value for therapeutic, and therefore to be given up in private practice. He mentions his bacteriologic researches with seriously sick puerpera, some of whom died. Among his results he mentions that even in early severe cases, Marmorek's serum proved wholly negative. He likewise recommends digital cureage to remove retention.

Koblank of Berlin held that all authors are a unit that streptococci are found in the vagina of pregnant women. Krönig and Menge believe that these are not the usual fakulative anaërobe, but obligate anaërobe bacteria. It is worth remarking that according to Krönig and Menge, obligate anaërobe streptococci are found in the vagina, as also in the pus of purulent peritonitis.

Hofmeier of Würzburg said that one can not blame the clinicians for regarding bacteriologic results with want of confidence, as they are full of contradictions.

The bacteriologists seem to possess a short memory. Krönig, a short time ago, stated that there existed no germs in the vagina that can induce fever. Now he finds the obligate anaërobe streptococcus, that may become very dangerous. The premises that the vagina is germ-free, is not proven.

Von Rosthorn of Graz, in a case of apparent sepsis, performed vaginal hysterectomy. At the post-mortem it proved a case of typhus abdominalis. The differential diagnosis was difficult; Widal's test is of great importance. The examination at the time showed streptococci in the cervical secretion, so that the diagnosis, puerperal fever, seemed verified. Marmorek's serum always rendered negative results.

Opitz of Berlin believes also that the glove bacteria originate from the skin. Yet it is likely that one can not attribute the temperature increase in singly examined puerpera to skin germs. Even though it is impossible to make the skin bacteriologically germ-free, it is certain that immediately after the alcohol disinfection the skin surface is germ-free, and with simple short touchings, germs from the deeper parts of the skin can not reach the surface. Probably there are concerned germs carried up from the vulva. It would be wrong to give up our present disinfection technic, so long as we have none better.

Krönig of Leipsic certainly believes that germs from the vagina in the puerperium can induce infection and does not believe he has stated the opposite.

Von Franqué of Würzburg believes in the possibility of auto-infection, though, contrary to Ahlfeld, he regards it as occurring relatively seldom. From the standpoint of protecting the parturient from the possibility of harm, douches must be given. Attention is called to coitus shortly before labor; of cases examined by the husband and others. The vaginal douche characterizes itself as a prophylactic measure.

Döderlein of Tübingen thinks the question of judicial (legal) responsibility is certainly very important. In a court case he took the ground that of a personal responsibility on the part of the defendant midwife there could be no question, since we possess no positive disinfecting methods.

Olshausen of Berlin said that clinical experience must be considered. In bacteriology we have experienced too many disappointments. He recommends, therefore, preliminary vaginal disinfection. An auto-infection is to be admitted, though only for few fatal cases.

Bumm, in closing, remarked that the question of hand disinfection is to be decided. To date there is none such. Further, all agree that various forms of streptococci reside in the vagina. Contrary to Hofmeier, Bumm emphasizes the bacteriologic diagnosis. Opposed to Krönig, he maintains a difference between intoxication and infection. The introduction of rubber gloves is not to be insisted upon. Yet they are a valuable acquisition; moreover, they were used by Bischof of Basel twenty-five years ago. Formerly he was an enemy of douches; to-day he acknowledges the more antisepsies the better.

⁷ It is a pleasure to note, that in my "Treatment of Antemature Labor" (American Gyn. and Obs. Journal, May, 1898) there is expressed a similar sentiment: "Irrigate with _____ solution, not especially for its germicidal effect, but for its cleansing, stimulating and alterative qualities." I still prefer a mild—5 to 1 per cent.—carbolic solution, as it is not irritating, not opaque, and is stimulating without the irritation necessary for a like stimulation with lysol; this I attribute to its (Carb.) soapy nature or of a coagulative nature, as do some other antiseptics; this should be avoided, as it hinders external excretion and expression; like the emulsifying overcoating property of creolin, it hinders capillary drainage from the deeper tissues.

DR. NELSON M. BLACK, who has been with the Eighth Army Corps as captain and assistant-surgeon in the Philippines, returned with his regiment, 1st North Dakota Vols., August 1. He is now associated with Dr. H. V. Würdemann, Milwaukee, Wis., with whom he practiced before entering the army.

Therapeutics.

The Use of Iron in Chlorosis.

With reference to the use of iron in the treatment of chlorosis Nothnagel prefers Bland's pills and the tincture of chlorid of iron. It is the opinion of the majority of clinicians, however, that the preparation of iron employed will depend largely on individual conditions.

The following is an outline of treatment strongly advocated by Sir Andrew Clark. With careful attention to the diet and a tepid sponge bath, followed by brisk toweling night and morning, he prescribed the following mixture:

R. Ferri sulphatis.....	gr. xxiv
Magnesi sulphatis.....	3vi
Acidi sulphurici aromati.....	5i
Tinct. zingib.....	5ii
Infusi gentian comp. vel quassie.....	5viii

M. Sig. One-sixth part twice daily, about 11 and 6 o'clock.

Occasionally this acid mixture produces nausea, dries the skin, and is otherwise ill borne. In such cases the following alkaline mixture is employed:

R. Ferri sulphatis.....	gr. xxiv
Sodii bicarb.....	5iii
Sodii sulphatis.....	5vi
Tinct. zingib.....	5ii
Spiritus chloroformi.....	5i
Infusi quassie.....	5viii

M. Sig. One-sixth part twice daily at 11 and 6 o'clock.

The large doses in both of the above prescriptions will hardly be acceptable in this country, but they can be reduced by using less of the infusion, which will but slightly change the therapeutic value of the formulae.

In case neither mixture agrees with the patient, a sulphate of iron pill is given with each meal and a saline aperient on awaking in the morning, while two or three times a week the patient should take a pill of aloes, myrrh and iron.

Quincke, writing in *La Presse Med.*, some time ago, said that in the treatment of this disease with ferruginous remedies, the preparations of iron might be divided into five groups: 1, the ferrocyanides, which have no action; 2, the blood from an organism of the same species, which may be useful during a certain period; 3, hemoglobin in solution, which probably penetrates rapidly into the circulation and is assimilated; 4, the ferruginous salts of vegetable acids, which, at least by subcutaneous injection, are taken up by the circulation and deposited in the liver; 5, insoluble preparations and ferric-oxid salts, which dissolve in the stomach and later form albuminates and absorbable iron. Bland's pills and acid lactate of iron have seemed to be most active in chlorosis. A daily dose of 1 to 1½ grains is sufficient. For hypolemic injection a 5 per cent. solution of ferric citrate may be used, a quantity containing from 1 to 1½ grains being injected daily.

It is our opinion that chlorotic cases could be divided into three classes; those in which iron is absolutely useless; those in which it is fairly valuable, and those in which it is an absolute necessity.

THE INDICATIONS FOR BITTERS.

Nearly all chlorotics are dyspeptic and the mere administration of iron is insufficient. Bitters should be administered before meals; combinations similar to the following are useful:

R. Tinct. gentiane.....	3vi
Tinct. calumbæ.....	5v
Elixir calisayæ. q. s. ad.....	5viii
M. Sig. Dessertspoonful before each meal.	
R. Tinct. gentiane.....	5iiss
Tinct. cardamomi comp.....	5ii
Tinct. nucis vomice.....	5iii
Infusi quassie q. s. ad.....	5viii
M. Sig. Tablespoonful before each meal.	

At the end of the meal or half an hour after it, the patient should take a wineglassful of hydrochloric-acid lemonade—3 or 4 parts to 1000.

INTESTINAL ANTISEPTICS.

P. le Genre advises the administration of intestinal antiseptics in chlorosis accompanied by gastric dilatation. Apropos of this idea may be quoted the interesting results of Townsend, published in the *Boston Med. and Surg. Jour.*, May, 1896: "Summary showing the average gain in hemoglobin per week from the use of various agents: Betanaphthol, 2 grains, three times daily—antiseptics—30 cases, 1.85 per cent.; Bland's iron pills, 5 grains, three times a day, 31 cases, 5.07 per cent.; cathartics alone, 7 cases, lost 1.50 per cent.; twelve cases treated with Bland's pills after a course of betanaphthol showed an average weekly increase of 6.70 per cent.; 19 cases treated with Bland's pills without betanaphthol showed an increase of but 4.50 per cent. Series of 28 cases treated during an average period of 4.3 weeks, with 2 grains of betanaphthol, in tablet form, and 5 grains of Bland's iron pills three times a day. The average gain in hemoglobin per week was 7.9 per cent., the maximum gain being 20 per cent. per week for two weeks in one case, 14 per cent. for three weeks in another, 13 per cent. for four weeks in another, while another patient averaged a gain of 11.4 per cent. per week for five weeks. The average amount of hemoglobin possessed by the patients before beginning the treatment was 48 per cent. After 4.3 weeks of treatment it was 82 per cent. Conclusion: The results of combined treatment are considerably better than those obtained with iron alone, and much better than those obtained with betanaphthol alone."

To Remove Indurated Patches After Eczema and Psoriasis.

When the patches are limited, Uina uses the following formula:

R. Zinc oxid paste.....	
Resorcin, aa.....	5xi
Ichthyl.....	
Vaselin, aa.....	5xx

When the patches are very extensive, a less energetic mixture is applied:

R. Zinc oxid paste.....	5ix
Resorcin.....	
Vaselin, aa.....	5xx

A little of this salve is spread on the patch every morning for one or two days until the epidermis commences to loosen, when it is suspended and the fall of the flap awaited or an anodyne salve applied.—*Semaine Med.*

Pneumonia.

The following discussion of the treatment of this disease is taken from *Progressive Medicine* for March, page 386:

Pilocarpin.—Rosenthal after using pilocarpin in nine cases of pneumonia, comes to the conclusion that the drug is not only of no value, but, further, that it is sometimes actually harmful in its effects. Its use is, therefore, contraindicated.

Diuretics.—Rensner, believing that the critical sweat in pneumonia has a weakening effect on the organism, endeavored to obviate this by giving diuretics at the time of the crisis. He believes that by the use of caffeine with camphor or digitalis he has been able to diminish materially the sweating, the crisis occurring in association with marked diuretics.

Use of Cold.—Mays pleads for the more general use of cold, particularly as local applications, in the treatment of pneumonia. Fussell finds that cold baths give great relief in marked hyperpyrexia. The local application of cold is also of value in relieving pain.

Counter-Irritation.—Stengel, in cases of pneumonia with delayed resolution, advises counter-irritants, active pulmonary exercises, and mentions the fact that there is some evidence to suggest that the production of aseptic abscesses resulting in a leucocytosis may exert a favorable influence on the condition.

Blood Letting.—Maragliano discusses bleeding in pneumonia. Liverato has shown that when there are limited foci of pneumonia, bleeding is followed by a diminution in the oxygen ab-

sorbed, but when the foci are extensive the oxygen absorbed and the arterial tension are considerably increased. Bleeding is particularly indicated in grave toxemia and where there are mechanical disorders of the circulation owing to the consolidation. Toxemia may be combated by digitalis, which antagonizes the bacterial poisons, and with De Renzi's (Pariè's) serum, which neutralizes them; but when the toxemia is marked and these means are not at hand, patients should be bled, and the amount of fluid in the circulation increased by intravenous salt injections. When the circulation is disturbed bleeding is also a good remedy, and one need not be hindered from doing this because the pulse is small and irregular; according to Niemeyer, it is just in these cases that it should be employed. Bleeding, then, is an occasional and not a regular method of treatment. The quantity of blood taken at each bleeding should vary from one-fiftieth to one-tenth of the total amount.

PNEUMONIA IN CHILDREN.

A discussion upon the treatment of pneumonia in children was held before the New York Academy of Medicine, which is reported in full in the *Medical News*, vol. lxxxiii, pp. 641-650. Only a few points can be touched here. Chapin points out the fact that the temperature is not always a true indication of the degree of poisoning in the child. The best means for treating the fever, when treatment is necessary, is by the external application of cold, by ice poultices, or by applying to the chest compresses which have been dipped in water at 75 to 90 degrees. The treatment may be employed until the temperature falls to 102 or 103, and then discontinued until it rises again. He believes that the fear and prostration incident to the giving of cold baths contraindicate them. Holt makes an excellent communication, in which he lays considerable stress upon the necessity of saving the child as far as possible from the worry excited by too much attention. His conclusions are as follows:

1. No depleting measures are ever admissible.
 2. Hygienic treatment, including fresh air, proper feeding, and intelligent care, is of the utmost importance.
 3. No unnecessary medication should be permitted.
 4. Many annoying symptoms may be relieved by local treatment, such as the cough by inhalations, pain by counter-irritation, restlessness by the ice-cap or sponging.
 5. Stimulants should be deferred until demanded by the condition of the pulse.
 6. High temperature is much more safely and effectively controlled by the use of cold than by drugs.
 7. Greater caution is necessary in the use of powerful stimulants than is generally observed.
 8. Rest is quite as important as in other serious diseases.
- Koplik believes that baths may be more frequently used, but advises great care in their administration. Almost all of these observers lay particular stress on the *necessity of good ventilation*, a point which the reviewer would also insist on. The manner in which patients with respiratory affections are still shut in close, ill-ventilated, overheated apartments should be combated by every intelligent physician.

Carr, discussing the treatment of broncho-pneumonia complicating measles, lays stress also on the same fact, advising that the patient be kept in a freely ventilated room, between 65 and 70 degrees. In these cases he advises that the diet should be of about the same quantity as that given to a healthy child; peptonized milk, beef-juce, eggs, custards, jellies, etc., are the best foods. Baths from 85 to 90 degrees are the best antipyretics.

Baruch discusses the methods of giving baths and packs, and lays particular stress on the necessity of employing vigorous friction throughout. Baths are not always necessary—treat the child and not the disease.

Not the Correct Formula.

THE Resinol Chemical Company writes us that the formula purporting to be that of resinol, which we printed in this department August 12, "does not contain one single ingredient that is contained in unguentum resinol" and that "the statements therewith made are absolutely false from start to finish."

AMERICAN.

1. Blastomycetic Dermatitis.—Holtken's paper describes the results of the histologic and biologic examination of a case of this affection, seen with Professors Hyde and Bevan, in the Presbyterian Hospital, Chicago.

2. Hemochromatosis.—Opie reports a case which he considers as representing an intermediate state between the hemochromatosis of von Recklinghausen and the bronzed diabetes of Hanot and other French authors. The clinical history is brief. The patient had symptoms indicating typhoid, with deep pigmentation of the skin, no jaundice, no sugar in the urine. Death occurred from gradually increasing weakness. Typhoid

bacilli were present. The post-mortem and pathologic findings are reported in full detail and the condition discussed at length. His conclusions are: 1. There exists a distinct morbid entity, hemochromatosis, characterized by the wide-spread deposition of an iron-containing pigment in certain cells, and an associated formation of iron-free pigments in a variety of localities in which pigment is found in moderate amount under physiologic conditions. 2. With the pigment accumulated there is degeneration and death of the containing cells, and consequent interstitial inflammation, notably of the liver and pancreas, which become the seat of inflammatory changes accompanied by hypertrophy of the organ. 3. When chronic interstitial pancreatitis has reached a certain grade of intensity, diabetes ensues and is the terminal event in the disease.

3. **Action of Body Cells on Phenol and Indol.**—The object of Herter and Wakeman's paper is to report experimental observations of the action of various animal cells toward these substances, made with a special view to studying the natural defense of the organism against chemical agents. The experiments were made in two ways: by direct contact of the prepared cells with this substance, and by making intravenous injections of their solution. In the contact method the mixture, after a certain period, was subjected to distillation and the distillate tested for indol and phenol. In twenty-seven observations by this method, the activity of the liver was found to be greater in reacting on phenol than any other organ treated. Next to this came the kidneys. There was less uniformity in this respect as regards indol, but the same general results were obtained. By the infusion method the liver and kidney cells were also more active than other body cells. The authors venture the opinion that the capacity of the cells to act on phenol is only one expression of a function that can be exerted on numerous allied aromatic substances, and possibly on some non-aromatic substances. In order to test the activity of these organs under pathologic conditions, tests were made on rabbits poisoned by various substances, alcohol, ricin, ammonium chromate, staphylococic infection, morphin, etc. The differences were not marked under these conditions, and some of these agents appeared to have no effect whatever on the power of the cells to convert phenol.

5. **Diploccoid Form of Colon Bacillus.**—The author concludes, from observations on rabbits: 1. That the colon bacillus injected into the circulation is rapidly taken up by both the liver and kidney. 2. That within fifteen minutes after inoculation some bacilli are already ingested by the endothelial cells of the liver, this process of ingestion continuing until some of the cells are full of bacilli. 3. That in this process of ingestion the bacilli are broken up into shorter lengths, and that these short stumpy bacillary forms may already, within the endothelial cells, present themselves as two deeply-staining dots, and may thus resemble diplococci. 4. That already in two hours the modified bacilli may be discharged outwardly from the endothelial cells, and be taken up by the underlying liver cells. 5. The exact stages of this discharge we have been unable to follow. In the liver cells the modified bacilli are to be recognized as small diplococci of a size varying from that equal to the diplococci seen in the endothelial cells, down to points of extreme tenuity; evidently these forms are undergoing destruction. In the first place, they lose their power of staining; in the second, if the destruction is not too rapid, they assume a brownish tinge. The causation of this brownish tinge we have not yet determined, but it is to be made out in the unstained sections, and our studies on the human liver indicate to us that not a little of the fine pigmentation common in liver cells is brought about by the existence in these cells of these minute elements of material destruction. During this process of destruction the modified bacilli lie in digestive vacuoles, and the frequent appearance of the halo around these forms is in great part due to the existence of the vacuole. We have occasionally been able to make out what appear to be these vacuoles in the liver cells, without the evidence of the contained microbe, and having apparently been digested. We have also seen the same appearance in peritoneal leucocytes nine hours after intraperitoneal inoculation with modified colon bacilli. 6. In the kidney the same process is at work—we have recognized the diploccoid form within the cells at the expiration of two hours after inoculation, and have also seen the vacuoles within the

cells and convoluted tubules, and have there occasionally met with the two dots just visible as final indications of the process of digestion of the bacillus.

6. **Dextrose and Diphtheria Toxin Production.**—The inhibitory action of muscle sugar in the production of diphtheria toxin, noted by Spronek and von Eurenhoff, started investigation on this point by Park and Williams, Cobbett, Blumenthal, and others. Smith here reports investigations by new methods with which he finds a contrary condition of things from that reported by many of these authors. The methods can not well be abstracted here, but the conclusions are as follows: 1. Dextrose is not in itself injurious, but rather favorable to toxin production. When added in quantities not exceeding 0.2 per cent., to peptone bouillon, freed from fermentable acid-producing substances—muscle sugar—it leads to a maximum accumulation of toxin by utilizing the available peptone to the best advantage. 2. The different courses taken by cultures of diphtheria bacilli in ordinary unfermented peptone bouillon containing muscle sugar, and in peptone bouillon made from fermented infusion to which 0.1 to 0.2 per cent. dextrose has been added, are manifested by an increased production of toxin in the latter as well as by a rapid return from an acid to an alkaline reaction. In the former an acid reaction may prevail even under most favorable conditions. 3. These differences may be explained either by assuming that the acid products of the muscle sugar are different from those of dextrose and non-utilizable, or else that the bouillon contains certain other unknown inhibitory substances removed during fermentation. The use of synthesized media, and an analysis of the acid products in fermented bouillon plus dextrose, and in unfermented bouillon, would aid in explaining the differences. 4. Among the accessory conditions which favor the toxin production in unfermented bouillon as pointed out by Park and Williams, are increased quantities of peptone, well-developed surface growth of the diphtheria bacilli, and a low initial acid reaction—phenolphthalein. In fermented bouillon these accessory conditions are also favoring, though of less importance.

9. **Blood Cultures in Septicæmia, Etc.**—The conclusions derived from examination of ninety-two cases of sepsis, pneumococic pneumonia, cerebrospinal meningitis, and various severe chronic and fatal cases, together with a study of the literature, have led White to the following conclusions: 1. Blood for bacteriologic examination during life should be taken directly from the veins and in considerable quantity. 2. Resorption of toxins is the most important feature in cases of sepsis; pyogenic bacteria invade the general circulation in a rather small proportion even of severe cases, and, as a rule, late in the course of the disease. 3. A general infection of the pneumococcus can be occasionally demonstrated in the late stages of acute lobar pneumonia. 4. The value of blood cultures as a means of diagnosis in obscure cases of sepsis is limited by the fact that invasion of the blood by the specific organism can not be demonstrated during life in the majority of cases. Positive cultures are very valuable; negative cultures do not exclude local septic infections. 5. The detection of specific bacteria in the blood of cases of sepsis and of pneumonia gives a very unfavorable prognosis in most cases. 6. General terminal infections with pyogenic cocci occasionally occur as an immediate cause of death in chronic disease. Local infectious processes play this part more frequently. 7. As far as our experiments have shown, invasion of the blood by bacteria during the death agony, with subsequent distribution of the germs to the organs by the circulation, is a rather uncommon occurrence. 8. Owing to the relative infrequency of agonal invasion, we believe that in the majority of cases where the autopsy is performed promptly after death, the bacteria which are found in the organs succeeded in reaching these organs previously to the death agony, and are associated with the course of disease. 9. The presence of bacteria in the organs of the late autopsies is due in many cases to post-mortem extension from one organ to another, and in some to the post-mortem growth of small numbers of germs which were distributed to the organs by means of the circulation.

11, 12 and 13.—**Antistreptococic Serum in Puerperal Infection.**—The report of the committee of the American Gynecological Society, consisting of Drs. J. Whitridge Williams, Pryor, Fry, and Reynolds, sums up the results of their study and observations as follows: 1. A study of the literature

shows that 352 cases of puerperal infection have been treated, with a mortality of 29.74 per cent.; where streptococci were positively demonstrated, the mortality was 33 per cent. 2. Marmorek's claim, that his anti-streptococcal serum will cure streptococcal puerperal infection, does not appear to be substantiated by the results thus far reported. 3. Experimental work has cast grave doubts on the efficiency of antistreptococcal serum in clinical work, by showing that a serum which is obtained from a given streptococcus may protect an animal against that organism, but may be absolutely inefficient against another streptococcus, and that the number of serums which may be prepared is limited only by the number of varieties of streptococci which may exist. 4. Thus far the only definite result of Marmorek's work is the development of a method by which we can increase the virulence of certain streptococci to an almost inconceivable extent, so that one hundred billionths of a cubic centimeter of a culture will kill a rabbit. 5. Personal experience has shown that the mortality of streptococcal endometritis, if not interfered with, is something less than 5 per cent., and that such cases tend to recover if Nature's work is not undone by too energetic local treatment. 6. The committee unhesitatingly condemns curettage and total hysterectomy in streptococcal infection after full-term delivery, and attributes a large part of the excessive mortality in the literature to the former operation. 7. In puerperal infections a portion of the uterine lochia should be removed by Doderlein's tube, for bacteriologic examination, and an intrauterine douche of four or five liters of sterile salt solution given just afterward. If the infection be due to streptococci, the uterus should not be again touched, but the patient should be given very large doses of strychnia and alcohol if necessary. If the infection be due to other organisms, repeated douchings and even curettage may be advisable. 8. If the infection extends toward the peritoneal cavity, and in gravely septicemic cases, Pryor's method of isolating the uterus by packing the pelvis with iodoform gauze may be of service. 9. The experience of one of the members of the committee with antistreptococcal serum has shown that it has no deleterious effect on the patient, and, therefore, may be tried if desired. But nothing in the clinical or experimental literature or in the members' experience was found to indicate that its employment will materially improve the general results in the treatment of streptococcal puerperal infection.

The supplementary reports of the treatment of puerperal streptococcal infection by curettage, the cul-de-sac incision and the application of antiseptic dressings by Dr. Pryor show that all cocci are destroyed by this method and that the colon bacillus remains present. Dr. Fry adds a supplementary report of 8 cases of infection all treated by serum, in which 3 died and 5 recovered. In one of the fatal cases the injection was followed by apparent improvement, in another the treatment was begun only eighteen hours before death. In the other case the patient died from exhaustion, in spite of the treatment. Dr. Fry insists on the importance of preventing introduction of infection post-partum, and he holds that curetting is contraindicated in pure streptococcal infection.

16.—See title 145, p. 855.

17. **Vaginal Cystostomy.**—Knox reports two cases of irritable bladder, rebellious to treatment, in which operation by opening through the vagina between the cervix and mouth of the urethra was resorted to. In both cases great relief attended the operation, and subsequent closure of the fistula presented no difficulty. He thinks the more frequent adoption of this method would result in the cure of many thus far incurable cases.

19. **Parotid Gland Therapy in Ovarian Disease.**—Shober briefly reports nine cases of ovarian pain treated with parotid gland extract, with complete success. The cases are those usually spoken of as ovarian congestion and chronic oöphoritis unattended with excessive pelvic disease and without much exudate.

33. **Medical Treatment of Movable Kidney.**—The treatment of movable kidney, Stengel says, must be directed solely to its restoration to its normal position. It may be permanent if we can restore normal conditions, or it may be temporary. There are two plans, therefore, of medical treatment, the first intended to supply the perirenal fat which has become deficient, and the second to support the kidney by a proper abdominal

bandage and pad. The first of these is not applicable in cases where the loss of adipose tissue has played no considerable part in the production of the disease, but where this has been the case there is a distinct possibility of improvement or recovery. He cites one case in which this method of treatment was most satisfactory, though a relapse took place three years later, on account of loss of flesh from overwork and worry, and surgery was called in to rectify the condition. The use of an artificial support for the kidneys is necessary where other methods will not effect a cure. Sometimes a combination of both methods will secure temporary relief. While many authors are inclined to condemn the abdominal belt and pad in these cases, Stengel is convinced that if properly made they may be effective. A pad to be effective should be so shaped and applied as to make pressure upward, backward and toward the right, so as to push the kidney toward its normal position. It has had various pads made and applied and has had striking results in four cases, two of which are here reported. This paper was presented to the Section on Practice of Medicine at the recent meeting of the Association.

35. **Leucocyte Count in Appendicitis.**—Head calls attention to the value of the leucocyte count as an aid to diagnosis in appendicitis, as a means of determining the character of the inflammation, whether catarrhal or suppurative, and as a help in following the course of the disorder and determining whether or not it is extending or receding. Leucocyte count is almost diagnostic between appendicitis and typhoid, almost without exception showing increase in the former. The same is true to a great extent as regards the diagnosis of gall-stones and intestinal obstruction. Other conditions in which it has diagnostic value are stercoreal colitis and floating kidney, in each of which conditions the leucocytosis is a marked distinction. As regards the character of the inflammation, it is useful between suppurative and catarrhal cases. Cases of appendicitis with a white count over 14,000 are suppurative. This is of value in about 86 per cent. of all cases. The leucocyte count may, he shows by a table, be very high and yet the patient recover without operation. The whole blood count is also of great value in interpreting the course of the inflammation, an increase of the white globules indicating an advancing process, and a decrease the reverse. This is true when the counts can be made regularly from the beginning of the trouble. There is a small percentage of cases, suppurative or necrotic, in which the white count is low, and these may be misleading. He sums up by saying that the count may be of value: 1, where doubt existed as to the diagnosis between appendicitis and diseases which simulate its symptoms, but cause no leucocytosis; 2, where the diagnostician was uncertain whether pus was present, in or about the appendix; 3, where the clinical symptoms mystified the clinician and gave him no clue as to the course the inflammation was pursuing.

37. **Surgical Tuberculosis.**—Aside from general remarks on the subject, the most important point in Eitel's article is the importance of complete operations when dealing with surgical tuberculosis. Incomplete operations often aggravate the disease.

43. **Fibromyoma and Carcinoma.**—Remarking that the old notions of the malignant degeneration of myomata have been discarded and of late given place to a tendency to consider them as entirely distinct and independent of malignant growths, and that the co-existence of both forms in the same organ has a certain clinical interest, Babcock reports three cases in which both were found. After discussing the condition and the opinions in regard to it, as given by different authors, he concludes: 1. The frequency of association of fibromyoma with adenocarcinoma of the corpus uteri is greater than would be *a priori* expected, and relatively much greater than with the more common epithelioma of the cervix. 2. A coincidence of the two growths is favored by their individual proneness to affect the nulliparous; but the frequency of the association seems greater than is thus explained, or than is explained by the frequency of fibromyomas in all uteri after middle life. 3. The endometrial hyperplasia and the congestive and irritative influences produced by fibromyomas would seem to favor the development of the malignant tumor. 4. Further investigation is desirable before the old theory that fibroids predispose to cancers in the uterus is considered as disproved. 5. The occasional serious errors of diagnosis from this association render the routine

examination of the endometrium desirable in elderly women with fibroids, and imperative when there is excessive or odorous discharge, or abundance of scrapings.

48. **Pernicious Malaria.**—After noticing the symptoms of hemorrhagic malaria, or yellow disease, Dickinson asks how we will prevent its occurrence and spread. He notes that the negroes have been as a rule free, and suggests that their serum may possibly be of value. In treating the disease the chief importance is to avoid those remedies that are sure to kill. These are morphin, atropin, heroic purging and heroic emochizing. A gentle sarsaparilla is efficient and demanded, but too much only exhausts the already depressed vitality. He asks what are the conditions that must be relieved, and says that after arranging to get 15 grs. of quinin hydrochlorate every twelve hours into the circulation, two important conditions must be met, and these successfully combated and the patient tidled over twenty-four hours—then one may feel comfortable. These two conditions are nausea and anæmia. The former may almost always be relieved by avoiding morphin and giving 20 to 30 grs. of lithium bromid every two or three hours. These are all that is necessary for the restlessness. The circulation might be renewed by transfusion, but he has never done it. He has instead used large subcutaneous injection of normal salt solution, and large saline injections per rectum. Give no remedy for hæmaturia. If the kidneys act well, Nature is relieving herself of the decomposed blood. If fever is high, the skin hot and dry, or the liver at fault, he gives 2 grs. each of caffein citrate and acetanilid, and 4 grs. each of sodium salicylate and ammonium bromid, all in one powder or capsule, every two or three hours, with good effect. His mortality under this treatment was 33 1/3 per cent.

50. **Embryology of Middle Ear.**—It has long been known that the middle ear in children frequently contains fluid of a suppurative character, and the question whether this is due to suppurative inflammation has not yet been fully settled. It is discussed here at length, by Aschoff, who answers the question as to whether it is due to a bacterial process in the negative, supporting himself by the bacteriologic investigations of Gradenigo and Penzo. There is therefore no otitis media neonatorum. The older statements as to the intrauterine inflammatory diseases of the middle ear with functional paralysis and drum perforation no longer hold. It is found, however, that particles of the amnion and meconium reach the middle ear during intrauterine life, through intrauterine respiratory movements. It is this contamination, whether it occurs early or late, that produces the collection of leucocytes in the cavity tympani.

55. **Effects of Artillery Practice on the Ear.**—The effects on the ears of artillery firing is commonly known, and is here investigated by Müller of Berlin. He examined 51 men, mostly private soldiers, but some officers, both before and after firing. The results showed that violent detonations of heavy artillery did greater harm to ears with retracted membranes and middle ear catarrh than to healthy ones. Permanent injury to ears that are not exactly normal is more likely to occur as the result of prolonged exposure to detonations of heavy artillery.

56. **Complications Following Intra-nasal Operations.**—Wertheim, after noticing the natural protective arrangement of the nose, shows that different morbid processes may develop when this is defective, such as fibrinous rhinitis from the specific infection of Löffler's bacillus, and pseudo membranes from pyogenic germs. He illustrates the predisposing effect of such acute inflammatory processes in the nose at the time of operation, by a case in which there was high fever, and general prostration occurred after cauterizing for nose-bleed, and he states that local therapeutic measures, especially nasal plugging, may increase the disposition to infection. The galvanocautery is more liable to be followed by complications than are operations with the knife. He reports two cases of pulmonary and kidney infarction following operation for polyp. The use of peroxid of hydrogen entails the danger of gas embolism by the entrance of gas bubbles into the open blood-spaces. The general result of his observations is the absolute necessity of asepsis in nasal operations. Antiseptic operations are useless, as the microbes can not be reached. The chief care should be not to transfer the infective agents from without, since the microbes existing in the nose remain harmless under normal

conditions. Cauterization of the middle turbinals should be avoided on account of endocranial complications that have been observed to follow. Plugging should be done with antiseptic gauze, sterilized by steam, which should not be left in place over twenty-four hours. In all cases the direct treatment of the bleeding spot should be attempted, though plugging can not be spared during the first hours. After the cessation of the hemorrhage the parts should be covered by anti-septic iodol or iodoform or indifferent sterilizable—dermatol powders.

57. **Septic Pneumonia.**—Gray remarks that the literature of septic pneumonia is scant, and after noticing what he has found in this line, he reports an epidemic of a malignant type near Albia, Iowa. In these cases the possibility of direct contagion could not be excluded.

72.—This paper appeared in the *JOURNAL* of August 26.

77.—See abstract in *JOURNAL*, August 19, p. 482.

79.—*Ibid.*, August 12, p. 414.

84.—*Ibid.*, July 8, p. 101.

87. **Cholelithiasis.**—Means reports ten cases of gall-stones, and analyzes them and their symptoms. The conclusions at which he arrives are as follow: 1. There are no pathognomonic symptoms of the existence of gall-stones in the early stages of the disease. 2. While the symptoms of gall-stones are obscure in the early stages, those of disease of the gall-bladder and ducts are sufficiently pronounced to make a diagnosis of the latter with much certainty. 3. A patient complaining of recurrent stomach cramps, slight jaundice, tenderness of the liver, and digestive disturbances, should receive treatment for biliary trouble, and if the conditions do not improve, should have an exploratory operation. 4. A patient suffering from recurrent attacks of colic in the region of the stomach, followed by jaundice, rigors, fever, digestive disturbances, and light colored stools, is probably suffering from gall-stones and should be treated by an operation. 5. Early operations in cholelithiasis will reduce the mortality of the disease as certainly as early operations do in appendicitis. 6. A large percentage of patients suffering from gall-stones will not receive any benefit from medicinal treatment, therefore surgical interference is the rational method of treatment. 7. Cholecystostomy, where there are no complications, is a comparatively easy and safe operation. 8. Cholecystostomy should be completed in one operation, and the gall-bladder attached to the peritoneum and aponeurosis and drained. 9. Cholecholeostomy is a difficult and dangerous operation, and therefore should not be attempted by any one who is not experienced in abdominal surgery.

89. **The Lithemic Habit.**—Isaier's paper treats of the lithemic condition and its management, holding the uric acid theory in full. She believes that in treating the disease we must secure a restricted diet, not too generous in the nitrogenous element, or in sugar and starchy substances that impede proteid metabolism. There must be exercise, either active or passive, varied and increasing. There must be free use of water, both internally and externally. Electricity, of one form or another, is a valuable adjunct. Among medicines, such may be sparingly used as temporarily meet urgent symptoms. Sodium phosphate is the best to stimulate the liver and act as a laxative. Reliance for permanent relief must be placed on the lithia salts, bitartrate of lithium being one to be preferred.

91. **Pelvic Disorders and Nervous Diseases.**—According to Riggs, the neurologist and gynecologist have been approaching each other in their opinions in regard to the relation of pelvic and nervous or mental disorders, within the last few years. He holds that all sources of irritation, pelvic or otherwise, should be done away with in treating nervous and mental conditions, though it is his belief that no operative procedure can directly relieve the abnormal irritability of the nerve-cell, or the accompanying lack of inhibition. The benefit to be derived will be in the generally improved condition of the patient, not in any specific local action. As regards the suggestive action of operative procedures on the hysteric or the insane, he says that it is a two-edged sword, especially in hysteric cases. He gives the opinions of a number of authorities, alienists and others, advocating conservatism as regards active gynecologic work among the insane, and he states that the general results of such work are likely to be disappointing as regards the direct mental results, though valuable in building up the general

death. This, he thinks, will be found to be more and more accepted view among candid physicians.

93. **Throat and Nose Disinfection in Diphtheria.**—From study of cases, Adair concludes that while the diphtheria bacillus is undoubtedly present with other germs in every case of diphtheria, its mere presence is no guide as to the virulence or otherwise. This bacillus, or one morphologically identical with it, is present in nearly one-third of all children, and is found about as frequently in those who have never had diphtheria as in those who have had acute attacks, but is in the one or liable to be variant in type. It is found more frequently in the nose than in the throat, and is not dependent on abnormal conditions. The theory that the apparent non-virulence in these cases is due to toxin absorption and the consequent immunity is plausible but not proved. Efforts to permanently dislodge the bacillus from the tissues of the throat and nose, with our present means and knowledge, unavailing. These conclusions were obtained in part by bacteriologic findings in the laboratory of the State Board of Health of Minnesota.

96. **Cerebrospinal Meningitis.**—Speer reports an epidemic of tetanus occurring during the winter of 1898-99, at Manistee, Mich., giving full notes of two cases. As regards the treatment, he lays down four principal heads: relief of pain; cleansing out and keeping clean the alimentary tract; drawing the blood away from the nerve-centers, especially at the base of the brain and medulla; and causing the absorption of the inflammatory products as soon as they are found to be producing pressure on the nerve-centers. When a case is first seen, morphia is generally required. It should be given in quantities sufficient to make the patient comfortable. It can not, however, be continued as long as required in these cases, and he prescribes a mixture of chloral hydrate and potassium bromid, 2 drams of each with a grain each of cannabis indica and nuxvomycin in a one-ounce mixture. He gives 5 to 10 drops to a child 2½ years old, repeating every ten minutes until the full effect is secured, to be resumed again when restlessness appears. In one of his cases, a powerful adult, 30 drops of this mixture was given every half hour for three days, with good effect. To cleanse out the bowels, calomel is preferable, given in small doses frequently repeated. To draw away the blood from the nerve-centers he uses hot packs or hot poultices along the spinal column, replaced later by mustard plasters applied not only to the back but to the back of the thighs, calves, soles of the feet, removing before the danger of blistering. He has used ice to the head and has kept it on. When symptoms of pressure occur the iodids are indicated, a saturated solution of the potassium salt, which he has found well tolerated by a child. For fever he has given aconite in small doses frequently repeated or alternated with belladonna. Other aspects of the disease are treated symptomatically. He has found giving fruit to these patients in certain stages harmless and beneficial. The results of his treatment have been good, in six cases only one death, and similar success has attended other physicians in his epidemic.

97. **Traumatic Shock.**—Montgomery's paper is one presented in the Section of Surgery and Anatomy, at the recent meeting of the ASSOCIATION. He believes that the etiology depends on the amount of constitutional disturbance that has been produced by the "solution of continuity," or, as he says: "In a restricted sense, therefore, shock is the inhibitive action of the nervous system accompanied with paralysis of a more or less general character, of the reflexes, in which the circulatory *vis a tergo* force becomes seriously involved so as to preclude or temporarily suspend or prevent the supply of the vascular system from being properly or equally distributed throughout the tissues of the body, and that which tends to operate to check the functions of organic activity is necessarily followed by a degenerative tendency leading toward serious results." He also considers the symptoms, diagnosis, prophylaxis and management, and goes at length into the treatment.

101. **General Peritonitis.**—The argument of Stone's paper is that complete peritonitis involving the whole peritoneum is not relievable or curable. Cases like the one which he reports are apparently generalized and yet recover, but he does not believe the entire peritoneum was affected.

115. **Bacillus Icteroides.**—NAY'S paper is a reply to that of Dr. Sanarelli, which appeared in the *News* of August 12.

(See *JOURNAL*, August 19, p. 474; also September 16, p. 723, p. 725.)

116. **Yellow Fever and the Digestive Tract.**—This paper is a translation of one by Vitale, who was a student with Professor Sanarelli at the time the latter was carrying on his investigations concerning the bacillus ictericoides. Vitale discusses the question of the difficulty in inoculation through the digestive tract, and of the value of experimental results thus obtained. Concerning the microbes, which, either because of their immediate pathologic effects or their quality of resisting the action of the gastric juice, are able to gain a foothold in the gastro-intestinal tract, he points out that the cholera vibrio is able to traverse the acid stomach and preserve its vitality in the intestine for a longer or shorter period without producing cholera. The rabbit is the animal most susceptible to the bacillus ictericoides, succumbing to the minutest intravenous injections of a culture of the bacillus within forty-eight hours, and to a subcutaneous injection in four to five days. He has, however, in a number of instances fed large quantities of warm cultures to rabbits without their even becoming sick. He considers that the conclusion of Drs. Reed and Carroll, that the bacillus ictericoides is a variety of the hog cholera bacillus, is hardly established.

117. **Surgical Aspects of Syphilis.**—Hartley limits his remarks to a discussion of the manifestations of syphilis occurring in the muscles, sheaths and tendons, bursa, bones, joints, lymphatic glands and rectum. He says that the tongue is a favorite seat for the granuloma of syphilis. Lesions involving muscles generally occur in the late variety, and either as a circumscribed mass or as a diffuse connective tissue induration, with or without disseminated gummatous cocci. He also points out that syphiloma in the muscles has great surgical interest on account of the size it may attain, thus leading to a mistaken diagnosis of tumor. He presents two cases and considers differential diagnosis between syphilis, tuberculosis and actinomycosis. The paper will be concluded in a future issue.

118. **Treatment of Enlarged Prostate.**—Newman says that the treatment of prostatitis should first be directed toward allaying pain and irritation, before radical measures for cure can be commenced. He considers irrigation with hot water very important. He also employs anodyne suppositories, and local galvanization when the painful irritation has subsided, the galvanic current being from 3 to 5 milliamperes. Hypertrophy of the prostate differs from prostatitis in being a disease of advanced age and not painful. He describes the Bottini operation for this condition, but objects to it for the following reasons: 1. The instrument is clumsy, unhandy and heavy. 2. The platinum burner is so thick that it gets hot too slowly, and when hot loses its shape by bending, so that sometimes it will not move back into its beak. 3. The very large storage battery is too heavy for transportation and a smaller one does not generate enough heat. 4. The instrument is shaped like Heurleloup's lithotrite, the end having only a short condyle. Such an instrument is exceedingly difficult to introduce, and, in many cases of hypertrophy nonintroducible, the mechanical obstruction leaving no space for its passage. The intention is to push the instrument into the bladder over and beyond the enlargement of the prostate, then to reverse it so that the beak is turned downward. The galvanocautery knife is hidden inside the beak and moves outward when the dial is turned on the handle, as the battery heats it, thereby making a central cut in the obstructing prostate. 5. The result of this operation is very uncertain. 6. The patient has to remain in bed for weeks, and from some reports made by Bottini himself it has been shown that voluntary micturition occurred only after twenty-four days. 7. The operation is not free from danger. He has, therefore, constructed his own galvanocautery sound, which "is catheter-shaped, of smooth, polished metal with a short curve at one end. At this end is a fenestrum in which is placed the platinum wire, the burner to be heated. A serpentine form is best for this wire. Each end is firmly attached to one of the two copper rods inside the tube and represents respectively the positive and negative pole. The other end of the instrument is straight and forms the handle, in which extend the copper rods, each of which is fastened to one of the pins or heat conductors. These two pins are connected with electric cords by binding screws. The

other ends of the two electric cords are fastened respectively to the positive and negative pole of the battery. The current-breaker is movable, and when set straight and present, firmly down on the screw, electricity is evolved and the burner instantaneously heated. The improvements consist in: 1, the handle being in one light, convenient piece; 2, having the current-breaker under the immediate control of the index finger; 3, having the fenestrum filled up, by which means the instrument is more thoroughly insulated and less liable to become heated; 4, having the tube filled up, thus preventing it from getting wet or blocked with debris. A storage battery is used to heat the wire.

119. Fracture of Lower End of Radius.—This article is continued from the *Journal* of September 9. Beck says that the first requirement, accurate reduction, may be carried out with little difficulty by moderate extension, the flexed hand being grasped as in a firm hand-shaking, with downward pressure by the surgeon's thumb, while counterextension is used on the forearm, which is flexed rectangularly. If this procedure should fail, anesthesia must be employed. Fracture of the lower end of the radius combined with fracture or fissure of the lower end of the ulna is frequent, but in case of fissure of the ulna no displacement is present, the symptoms being the same as for complete fracture. The symptoms of lateral displacement are well pronounced in complete fracture of the ulna, which is a rarer accident, but this combination is the main cause of impairment of supination and pronation. The treatment is practically the same as that of complete fracture with lateral displacement, lateral pressure, by attaching an adhesive-plaster pad over the ulnar fragment after reduction, being well kept up. In case of displacement, a plaster-of-Paris dressing is preferable for the first ten days. Fracture of the lower end of the radius, combined with fracture of the styloid process of the ulna represented 42 per cent. of all the author's cases of fracture of the lower end of the radius. In this variety the radio-ulnar joint is always more or less involved. He here considers it advisable to apply a plaster-of-Paris dressing while traction is used, the hand being firmly grasped by an assistant and held in slight ulnar flexion. Since the discovery of the X-rays, he says there are no more fractures the presence of which can not be established beyond doubt, and he thinks the danger of using them is much less than the danger of not using them, and he now declines to treat any fracture until he has first been given the privilege of taking a skiagram thereof.

120. Guaiamar.—This preparation is a glycerol ether of guaiacol, a definite chemical prepared by the reaction taking place between pure guaiacol and anhydrous glycerin. It is a dry, white, crystalline powder, melting at 75 C., soluble in alcohol, chloroform, ether, glycerin and in 20 parts of water. It is neutral, non-hygroscopic, possesses a bitter, aromatic taste, is compatible and may be advantageously administered with quinin, cod-liver oil, malt, hypophosphites and pepsin. While it has antiseptic properties, its chief value lies in the liberation of nascent guaiacol, partly in the stomach but chiefly in the intestinal canal. During the past year Butler has employed this preparation in twenty cases of typhoid fever, exclusive of any other remedy, except the cold bath, each case running an unusually mild course. He is satisfied that those to whom guaiamar was given did not have so high a temperature and the general symptoms were less severe than in the other cases where no therapeutic measure was resorted to except the cold bath. He reports three cases in detail.

124.—See abstract in *JOURNAL*, July 29, p. 280.

127.—See abstract in *JOURNAL*, September 23, p. 757.

128. Carcinoma of Ovary and Sigmoid Flexure.—First noticing the communication of Warthin in the *JOURNAL*, May 26, Bourland reports a case in which death occurred from cancer of the sigmoid flexure six months after the removal of two large multilocular ovarian cysts. This caused a reexamination of the tumors, which had been preserved, and it was found that they also presented evidence of malignancy. The character of the two growths, however, was so different that Bourland concludes that no direct relation existed between them. He considers the tumors, therefore, as primary coincident carcinomata. He also remarks on the case as being another example of the development of malignant growths from adenoma.

129. X-Rays in Chest Disorders.—Williams reports an

illustration of pneumohydrothorax and two of hydrothorax, as shown by the X-ray. The figures are very striking as evidence of the value of these methods in diagnosis.

130.—See abstract in *JOURNAL*, September 23, p. 790.

131.—*Ibid*, March 26, p. 664.

132.—See *JOURNAL*, September 23, p. 784.

133. Appendicitis.—Hupp's paper gives the responses to a series of questions sent to various surgeons, in regard to the necessity of operation in appendicitis, its signs and causes, and the proportion of cases recovering without surgery. The majority of these answers, which are from such surgeons as Scam, McBurney, Morris, Hunter McGuire and others, agree pretty closely in the main, with only slight differences in regard to the necessity of operation and the symptoms of fulminating appendicitis. In only one answer is operation advised when diagnosis is certain in all cases of primary attacks. Forty-five cases are reported in brief, and the author expresses the opinion that balancing the lives that will be saved, and the suffering obviated on one side, and on the other the risk of modern surgical operations, the answer can be but one way, in regard to the propriety of operation in such cases. He concludes his paper with letters from medical directors of various insurance companies, giving the latest facts as to the attitude of these organizations to persons who have had appendicitis.

134. Prevention of Tuberculosis.—The article by Struch is a plea for conservative views in regard to tuberculosis, and the necessity of building up the system as a defense.

140. Lateral Curvature of the Spine.—The conditions of lateral curvature are stated by Bradford and Brackett as follows: 1. Faulty attitudes with absolute flexibility of the spine, and without structural changes of ligaments, cartilage or bone. 2. A curved position of the spine with flexibility, except to a limited degree in certain portions where the normal flexibility is checked by slight structural alterations of muscles, ligaments, or cartilage. 3. Curves with limited flexibility of the spine, and with structural changes of the ligaments and cartilages. 4. Stiffness of the spine, the curve being fixed by structural changes in the ligaments, cartilages and bone. The treatment of the first and second of these classes would necessarily be largely gymnastic, in the second supplemented by measures to increase the flexibility of the spine. In the third class, where firm structural changes exist, mechanical measures will be required and the difficulties have been such as to seriously tax the surgeon. The authors think, however, that in young children there is hope for relief with proper applications which should be fixed so as to apply, exert and maintain pressure as long as necessary. Their paper is illustrated by figures of cases and appliances which they have used. Three cases are reported.

141. Tuberculosis.—Otis maintains that with proper measures it is probable that tuberculosis can be largely eradicated, and quotes the history of leprosy in Europe as a corresponding illustration. He makes a plea for sanatoria for isolation and treatment, and outlines a plan for the management of the condition and prevention of tuberculosis in a city like Boston.

142. Astringents in Intestinal Catarrh.—Noticing the changes in practice as regards the treatment of diarrhea within the last twenty years, and the modern dependence on antiseptics in these disorders, Meier maintains that there is still a use for intestinal astringents in the treatment of these cases.

144.—See abstract in *JOURNAL*, August 26, p. 127, p. 537.

145. Urine in Pregnancy.—Stewart reviews the work of investigators on this subject. See title 16, p. 822.

146. Uterine Cancer.—The importance of early diagnosis of uterine cancer is insisted on by Ashby, who points out that its origin is often insidious, and that it may reach an advanced stage before alarming symptoms appear. The early symptoms simulate simple functional disturbances of the menstruation, but hemorrhage during or subsequent to the climacteric should always be promptly investigated, and all forms of uterine disease not responding to judicious local treatment should arouse suspicion and lead to a microscopic examination. Lesions about the cervix should be corrected, or at least examined at short intervals. When in doubt as to the cause of uterine disease, investigate for cancer.

147. Faddism.—McConaenie notices the medical superstitions of the day, and points out the methods of cure of disease

and its limitations. He believes that we should teach the public these facts and in this way correct the growing tendency to superstition and fads.

148. **Medical and Surgical Treatment.**—Platt notices the lack of details as to treatment in modern medical works, and deprecates the fact.

149. **Demonology in Medical Practice.**—Kiernan notices some modern medical superstitions, including "Christian Science," Dowicism, etc., and attributes them to the influence of commercial conditions, raising individuals of a low grade of culture to comparative affluence. Thus these superstitions ostensibly appear in the higher ranks of society.

FOREIGN.

British Medical Journal, September 2 and 9.

Bacillus Diphtheriae in Milk. J. W. H. EYRE.—The author reports on examination of the milk in an epidemic of diphtheria which occurred among the inmates of a large school, receiving its milk-supply from one source. He gives the details of his experiments, the results, staining reaction, and culture character of the germs found, and shows that the typical appearance of the diphtheria bacillus was clearly recognized.

Early Decay of Teeth in Britain. JAMES CANTLIE.—This author calls attention to a condition of things which we had not supposed was so prevalent in Great Britain as in this country, but it appears that the children's teeth in Her Majesty's dominion are suffering more at the present time than was formerly the case. He believes that the cause is to be found in deficient and artificial feeding in infants. This causes abnormal development of the jaws, which is the source of nasal abnormalities, and the arched jaw, which is coming to be so common, is produced within the first twelve months of infant life by abnormal feeding. The early decay of the teeth is one of the symptoms of want of care of the infant. He calls for a commission of the British Medical Association to investigate the subject, and to ask for the co-operation of the Americans, and probably also the Germans, French and Italians in this matter.

Frequency of Sick Room Infection in Typhoid Fever. HERBERT BECK.—The observations and deductions of this paper are derived from 206 cases of typhoid fever observed by the author during the 6½ years ending September, 1898. He investigated all the probable cases of typhoid among these patients and tabulates them. He finds that 12.5 per cent. of the cases investigated were certainly due to sick-room infection. Other cases were probably due to this, but he prefers to exclude them from his percentage as not being absolutely proved. His conclusions are that sick-room infection is more common than is ordinarily supposed, and that its dangers do not receive the attention they deserve. It is much more common in the small crowded houses of the poor than in the large dwellings of the well-to-do.

Prolonged Standing and Women's Diseases. STUART NAIRNE.—The author has here prepared tables showing the effects of prolonged standing in the production of gynecologic disorders, and concludes that 7 per cent. of unmarried shop girls only come for medical attendance, but 40 per cent. of married women who have been shop girls come under medical attention at a very early period in married life, namely, mostly under 30 years of age. Out of the 7 per cent. of single women, 3 per cent. come with diseases special to women, and out of the 40 per cent. of married 21 per cent. with the same class of disease, so that we have a clear 30 per cent. who are or have been shop girls, suffering from these special diseases. "Why should there be," he says, "comparatively such a small percentage of single girls in actual employment under treatment, and such a large percentage of married women? This looks very extraordinary at first sight, and seems to somewhat minimize the importance of the position I have maintained. A moment's consideration will, however, put this right. The girls in work are, as a rule, kept busy from morn till night: they are young and have not yet exhausted their energies; they have little time to rest and no time to complain. Parents and masters are alike frequently unobservant of the early symptoms of exhaustion and overwork. The girls themselves are anxious to work: they like to be considered strong, the world is before them, and much brighter if they look or pretend to be

healthy. They are much more likely to form a suitable 'match' if they are strong, and therefore they go on, and only the 3 per cent. come for advice and assistance who can go on no longer. Now, with regard to the 40 per cent., the alarmingly large proportion of 27 who suffer from special uterine and ovarian disease shows emphatically that it is no chance illness, but that it must be a regular and frequent consequence of some condition of their daily work. One of the conditions, and I have no hesitation in saying it, one of the most potent, is the long period of standing and hanging about on their feet."

Psilosis or Sprue; Its Relations to Other Forms of Tropical Diarrhea and Its Treatment. GEORGE THIN, EDWARD HENDERSON, JAMES WATSON, W. J. BUCHANAN and others.—Thin takes up the subject of psilosis or sprue, which includes, according to his view, a considerable range of tropical diarrheas. Following, Henderson takes up the classification of cases, pathology and treatment, and Watson reports a case and considers the treatment. Buchanan's views are as follows: 1. Primary or protopathic sprue is common among natives of India. 2. Secondary sprue following on a, dysentery; b, acute enterocolitis or enteritis, is common. 3. Incomplete or arrested sprue is probably very common. 4. The condition known as "famine diarrhæa" is essentially the same in its symptoms and ultimate results as sprue. 5. In many cases of chronic relapsing dysentery, a condition strongly resembling fully-developed psilosis is met with, and characteristic frothy pultaceous diarrhæa alternates with the dysentery. In the discussion following, Dr. Manson said that this condition is not to be regarded as one disease, but as a variety of diseases with a series of common symptoms. There was no exclusive treatment, and there would not be until its etiology was known. The general principles, however, were the same for all types, that is, physiologic rest, rest in bed, warmth and simple diet. Dr. Sambon does not agree with Dr. Thin in recognizing two separate varieties. He thinks much importance should be given to its geographic distribution, which separates it from dysentery and hill diarrhæa.

Insects, Arachnids, and Myriapods and the Propagation of Infective Diseases of Man and Animals. GEORGE H. F. NUTTALL.—The part played by insects in the dissemination of disease is summarized by Nuttall, who classifies them in two groups, the passive and active. Among the diseases passively carried by insects, we have anthrax, plague, typhoid fever, cholera, yaws, etc. In most of these cases flies have been the transporters, but ants and other insects may have their share. The active transmission of disease through the agency of insects that may act as intermediary hosts and convey the disorder by being passively eaten, or actively by their bites, are numerous, and he gives quite an extensive table of these forms. The animals that may act as definite hosts of the parasite include many of our domestic animals as well as the household pests, rats, mice, beetles, bugs, etc., and the intermediate hosts are equally numerous.

Hemoglobinuric Fever and Paludism. W. H. STALKART.—After reviewing the nature, distribution, symptoms and etiology of blackwater fever, the author says: As far as our knowledge at present goes, it would seem that: 1. Blackwater fever is only found associated with malaria. The circumstances under which it occurs, or which appear to be propagating factors, would indicate this. 2. Blackwater fever is not simply malaria, but a distinct disease, possibly malarial in nature, due probably to an organism having a specific action, or one of peculiar intensity, in giving rise to great blood destruction. 3. Quinin is not the cause of true blackwater fever, although in certain cases it may aggravate it. 4. Quinin has been distinctly beneficial in this malady; to what extent is uncertain, but with mixed malarial infection, or in warding off subsequent malaria, it should be given a foremost place. Few, indeed, would care to omit it from their medicinal equipment. In the main these conclusions were supported by those who took part in the discussion.

Thermic Fever (So Called Siriasis), With Special Reference to Its Alleged Microbic Causation. KENNETH MACLEOD, C. M. GILES, L. W. SAMBON, PATRICK MANSON and others.—In opening the discussion on thermic fever, Macleod questioned the parasitic action of microbes in this condition as had been suggested by Sambon. He criticizes his argument and

maintains it as reasonable that fatigue of the heat-regulating nerve-centers, as well as to the heat-dispersing agency, is an essential, or the essential, factor in the production of thermic fever. Sambon in reply repeated his argument, referring to the micro-organism of Cagical and Lapierre, though he has not been able himself to confirm it. He alludes to the geographic distribution of sunstroke, claiming that in some of the hottest parts of the world it does not occur, and holds that the theory attributing the disease to heat alone is purely hypothetical, and does not agree with post-mortem findings. The only theory that fully covers the natural history of siriasis is the parasitic. He quotes Van Gieson, that there is no other interpretation open, as to the significance of the acute parenchymatous degeneration of the ganglion cells of the nerve-centers, than the action of a toxic substance in these cells. Manson supports Sambon, while Wood, Watson and others take the opposite view.

Lancet, September 9.

Reerudescence of Plague in the East, and Its Relations to Europe. W. J. SIMPSON.—The author, after reviewing the history of European invasions of the plague, considers the present one rather a pandemic than an epidemic and possessing what other plague epidemics for the last 200 years have lacked, the quality of diffusiveness, which defies the precautions hitherto used against its progress. The present commercial conditions are favorable to its diffusion, but fortunately we are better prepared with preventives, especially the Haflkine serum.

Mediterranean or Malta Fever, with Special Reference to the Specific Agglutinating Substances Which Make Their Appearance in the Blood in the Course of That Disease. C. BIET and G. LAMB.—This paper is rather an extensive one. The authors describe the biologic character of the micrococci, the effect of specific serum on it, and the appearance, etiology and significance of the agglutinating substances in the blood as an aid to prognosis. They hold that an abundance of agglutinins seems to be a favorable indication, while their decrease justifies caution in prognosis. They also quote, as giving the same findings and results, the memoir of Courmont of Lyons.

Medical Press and Circular (London), September 6.

Albuminuric Retinitis. SAMUEL WEST.—West brings this communication to a conclusion by summing up the facts which he thinks justify the drawing of a sharp distinction between the two forms of albuminuric retinitis, the degenerative and the exudative. He says they stand in strong contrast with each other in the following respects: 1. Of the forms of disease with which they are usually associated; the degenerative with granular kidney, the exudative especially with parenchymatous nephritis. 2. Of their nature and cause; the exudative being inflammatory and probably toxic in origin, the degenerative consequent on vascular changes and more or less mechanical in origin. 3. Of sight; for the exudative, even in extreme forms, may recover, with little or no defect of sight, but with the degenerative, if there is any impairment of sight, it is usually progressive. 4. Of diagnostic value; the exudative being an interesting by-phenomenon of chronic parenchymatous nephritis, an affection the existence of which is obvious enough, while in granular kidney the degenerative often makes the diagnosis certain in cases which have been hitherto obscure. 5. Of risk of life; for while in both cases it indicates a grave form of renal disease which may of itself prove fatal, in granular kidney it indicates in addition all those dangers to which arterial disease exposes the patient. He thinks, therefore, that the distinction is not only justified by the facts, but explains many of the apparent contradictions which are made by different authors.

Alcoholism in Its Relation to Heredity. GEO. ARCHBALL REID.—The author reiterates here his well-known views as to the racial immunity produced by alcohol. He claims that races and nations crave for alcohol in inverse proportion to their past familiarity, and that the plan of abolishing drink will destroy the immunity and in time produce aggravation of intemperance and its effects.

Practitioner (London) September.

On Achondroplasia. WILLIAM TURNER.—Achondroplasia is the name here given to a condition having some of the pe-

culiarities both of fetal rickets and of cretinism. The title, however, is criticised, as it gives the idea of there being no growths of cartilage cells, while the reverse is the case, but it is not in such a direction as to increase the length of the bones. The essential change, according to those who have studied this condition, Shattock, Barlow, Ziegler and Kaufman, is located at the line of ossifying cartilage where the epiphysis joins the diaphysis. Here the cells are altered in size, shape and arrangement, becoming larger and more spherical, while the columnar arrangement is deficient or altogether lacking. There is, therefore, no attempt at the formation of primary bone areole, and consequently no increase in the length of the diaphysis. With this there is a fibrous ingrowth of the periosteum between the epiphyseal cartilage and the adjacent diaphysis, completely preventing the possibility of the cartilage cells developing into bone areole, and there is sometimes non-union of the diaphysis and epiphysis during life. Together with these changes there is a premature synostosis of the basi-occipital and basi-sphenoid, so that the growth of the base of the skull ceases and the depressed condition of the bridge of the nose, always present at birth, persists. The bones of the calvarium are not impeded in their growth, and the skull is comparatively larger than usual. With these changes there is also thickening of the long bones, and sometimes beading of the ribs. The pelvis is always deformed and small, and there invariably is lordosis. The cause of this change in the cartilage cells is absolutely unknown, and no real cause can be given for the disease. The paper is well illustrated with pictures of the patient described and skiagraphs of the deformity of the bones.

Occurrence of Rheumatic Fever Without Arthritis. C. O. HAWTHORN.—The question as to whether the rheumatic poison may produce pyrexia without the arthritic symptoms is here discussed, and the author reports a case which he considers illustrative. The diagnosis was not at all clear during the febrile state, but later, when the temperature was sub-normal, arthritic symptoms appeared. He quotes various authorities who support the view that rheumatism may occur without arthritic disturbances.

Australasian Medical Gazette (Sydney, N. S. W.), July 20.

The Epidemics of 1898. WALTER SPENCER.—The author reports his experience with two epidemics of measles and rubella, 231 cases of the former and 147 of the latter. Of his measles cases, 28 were adults, and 7 of these claimed to have had it before. In 29 instances, second attacks were claimed in children, and 13 of these he had attended at their first, in 1893. He has no notes of second attacks of rubella. From his limited experience, he would say: that the signs and symptoms ascribed to measles and rubella are common to both; that any of them may be absent or modified, and that in measles they are more prolonged and of more severity; that measles or rubella may be expected to confer immunity against itself, but does not invariably do so; that second attacks of measles in children are milder than the first; that Duke's law is consequently not absolute, being subject to limitations which are as yet imperfectly understood. Influenza has been endemic, and for seven years he has seen it every week. For diagnosis he has been led to place most reliance in the sign of Faisan, a sort of opaline film on the tongue, which can not be removed, though sometimes obscured by fur. A puzzling complication of the ordinary variety is the onset of hepatic congestion and severe gastro-enteritis twenty-four hours after apparent convalescence. He found his grippé not only predisposing to other diseases, but also to it self, and his patients suffer from severe successive attacks rapidly following each other.

Observations on Ether Anesthesia Preceded by Administration of Morphia and Atropin Hypodermically. W. C. McCLELLAND and L. H. L. HARRIS.—The experience of these authors, with the administration of morphin and atropin hypodermically, before ether anesthesia, in 100 cases taken as they came, rejecting only those that proved to have albuminuria, lead them to the following conclusions: 1. The patient's nervous system is quieted, being rendered more susceptible to the influence of ether. 2. The patient becomes anesthetized in a very short time, on an average in less than four minutes; only a small quantity of ether is required to produce and to maintain the anesthesia. 3. Salivation is the

exception and practically never occurs. 4. The patient breathes tranquilly and regularly. 5. The atropin exerts its action on the heart as a stimulant, and thus the patient is less liable to shock following the operation. 6. Should the patient inadvertently come out during the operation, or just before its termination, there is no straining or tendency to vomit. 7. The patient generally emerges from the anesthesia in a gradual and tranquil manner, and seldom complains of pain, sleeping quietly for several hours. 8. The tendency to nausea and vomiting after the operation is greatly diminished, and when present is very slight and does not cause much distress. 9. No deleterious after-effects appear to follow this method.

Intercolonial Medical Journal, Australasia (Melbourne), July 20.

Management of Injuries to Lower Epiphysis of Humerus. R. HAMILTON RUSSELL.—The principal features of Russell's article are his condemnation of the angular splint, which he considers a clumsy, uncomfortable and stupid appliance. His method to treat injuries of the lower humeral epiphysis is that of the late Mr. Szme of Edinburgh. The fragments are brought into good position, by gentle traction of the forearm, held at a right angle, with counter-pressure of the flexor surface of the humerus. A pad of lint is applied to the front of the humerus, and another small pad over the olecranon. A strip of strapping to keep the pads in position, and a figure-of-eight bandage over all completes the retentive apparatus. It is essential that the arm be retained altogether underneath the clothing. No splint is required. He claims that this arrangement, if applied with moderate dexterity, meets all the requirements. After four weeks the arm is released and gently put into the sleeves, and passive motion, which is another measure he strongly condemns, is never employed. The cases to which he refers appear to be mostly in children.

Journal de Medicine et de Chirurgie (Paris), txx, 15.

Syphilis Contracted After Sixty. LEBARD.—Untreated syphilis contracted after 60 years of age is almost always fatal. Thirteen observations, reported by Lebard, indicated that the incubation is longer, cicatrization extremely tardy, adenopathy very voluminous and diffuse, and extragenital chancre unusually frequent. Emaciation, asthenia and anorexia appear with the secondary period, with frequent nervous and psychic disturbances, iritis and cutaneous manifestations. The tertiary period follows closely, and gummata are not infrequently observed during the first year. Treatment should be exceptionally prompt and effective, sparing the stomach. Lebard endorses Gancher's subcutaneous injections of bichlorate of mercury, 1 to 2 eg. a day, potassium iodid given early and careful local treatment.

Presse Medicale (Paris), August 30 and September 6.

Tabetic Laryngeal Paroxysmal Attacks. TOUCHE.—Forty patients with tabes were examined in reference to the frequency of laryngeal attacks and their relation to visceral attacks or crises, as the French call them. It was found that more than one-fourth were affected with them. The intensity was variable, ranging from fatal suffocation in one to a few pertussis-like coughs. An isolated laryngeal crisis was rare. It was usually associated with a gastric, very rarely with an isolated diarrhetic, crisis; usually with a gastric crisis associated with a rectal and diarrhetic one.

Social Danger of Syphilis. FOUENIER.—In this address, presented to the International Prophylactic Conference at Brussels, Fournier paints the picture of the damage inflicted on individuals, families, children, children yet to be born and children's children, in the blackest colors and asserts the unquestionable right of society to protect itself against this scourge, to protect the innocent and those who do not care for protection, but who must be protected because of the contagion from them of others who do not expose themselves. "It is the right of society, it is the duty of society."

Social Danger of Gonorrhoea. NEISSER.—This address, similar to the above, urges the necessity of educating the public to the dangers and significance of venereal affections. "If physicians and the public only utilized what science has established in regard to them, individual protection would be more effective than all legal and administrative measures in preventing their propagation."

Progres Medicale (Paris), September 2.

Typhoid Fever at the Bicetre Hospital. BOURNEVILLE.—An epidemic of twenty-one cases, occurring among the idiot children at Bicetre, was noticeable on account of the mortality—six deaths—and the peculiar state of excitement which marked the disease instead of the usual stupor; the idiots seemed to acquire increased mental powers; also the predominance of pulmonary symptoms masking the gastrointestinal, and the difficulty of diagnosis where the first symptom to call attention was the lack of appetite, no details being obtainable from the subjects. Another feature of the epidemic was that seven patients were epileptics, and all seizures were suspended during the disease. This inhibiting effect has persisted since recovery, only one or two attacks having been noticed since in all.

Revue de Gynecologie (Paris), August.

Solid Tumors of the Ovary. L. DARTIGUES.—Among the general conclusions of this comparative study of these neoplasms, from the literature, classified as fibroma, sarcoma and their mixed forms, and cancer or "massive and medullary epithelioma" we note that the malignancy increases with the frequency and also with the age of the subject. Hereditary neoplastic antecedents seem to be rare; when encountered, there was no similitude between the nature and site. Bilaterality increases with the malignancy; fibroma is usually unilateral, while cancer is almost invariably bilateral. A knobby appearance usually coincides with malignancy, also a deep red or violet color. The hematic color of the ascitic fluid is another characteristic of malignancy. Fibroma is of a solid consistency; sarcoma more resistant. Cancer is hard, almost woody, although friable. The variety of tissues constituting the ovary explains the variety of neoplasms which develop from it, and the transformation of one kind into another. Generalization is rarer and less rapid with sarcoma, and does not follow the lymphatic route, like cancer, but occurs at a distance and more scattered. The grafts of cancerous tissue observed in wounds of laparotomies for extirpation of cancer plead for its inoculability, and impose extreme caution on the surgeon not to allow any of the cancerous matter to come in contact with any cut or denuded surface.

Mechanical Seismotherapy in Gynecology. F. JAYLE.—This new term is derived from the Greek word for earthquake, meaning to express treatment by rapid regular vibrations imparted to a part of or the whole body—an improved kind of massage, simpler and less fatiguing, and free from the disadvantages of manual massage of the vagina. Except in cases of tumors or suppurations of the uterus or adnexa, it will be found an excellent palliative treatment, reducing congestion and intestinal atony, favoring the circulation in the intestines and favorably affecting the local and general nervous system. Thirty-six observations and the small electric apparatus are described in detail.

Abdominal Migrations of Abscesses of the Liver. J. FONTAN.—An abscess on the point of migrating into the abdomen usually forms an arching protuberance along the lower margin of the liver, elongating down into the abdomen, while perihaptic friction has disappeared; edema of the wall extends over the abdomen; pus obtained by puncture is white or grayish instead of chocolate. As a general rule the incision must hug the lower limit of the thorax, corresponding to the normal position of the liver, as after operation it usually recedes to its normal position, and it is very important to maintain the parallelism between the wound and the organ, to promote drainage, etc. The migrating pus shows a tendency to follow the anterior abdominal wall, and in one autopsy the hepato-peritoneal abscess extended across the abdomen to the crural ring, like a vase, broad top and bottom, entirely in front of the intestines. If diagnosed in time, intervention would have been easy and effective. Another case had pain at the umbilicus; palpation of right side of the abdomen extremely painful but no marked "doughiness," bilious vomiting, slight fever, and a history of sudden pain two months before in the right iliac fossa. During tropical dysentery, two years before, there was pain in the liver, but hepatitis was not suspected. Appendicitis was diagnosed. The operation showed the peritoneal cavity, especially in the small pelvis, full of yellow pus which had emigrated along the colon from a focus in the in-

ferior aspect of the liver. When the abscess opens into the intestine the liver does not evacuate all its contents and still requires an operation, even if the intestine has healed over at the point of juxtaposition when the liver has retracted. In most cases the contents of the intestine back up into the liver and produce severe infection. In one of his observations he found both liver and intestine gangrened, requiring marsupialization, and an abscess in the hypocondrium. The recovery demonstrates that these cases can be successfully operated on even in *catenae*. Migration into the stomach is so grave that the mere menace of it requires operation, as when an abscess of the liver presses on the stomach and causes vomiting.

Value of Electro-Hemostasis. C. JACOBS.—This communication describes the use and results of Skene's electric forceps, —described in the *JOURNAL*, xxxii, March 4, 1899, p. 490—and "numerous tests which have brilliantly confirmed all and more than the American surgeon claims for this new method of hemostasis."

Centralblatt f. Chirurgie (Leipzig), September 2.

Improved Technic for Ensuring Good Weight-Bearing Stumps After Amputation of the Leg. A. BIER.—It is generally conceded that Bier's method—retaining a living bone flap for the base of the stump—insures the best stumps, but the double amputation required has deterred many surgeons from adopting it, although time and experience have confirmed its great value. He now describes a modification which obviates the necessity of the two amputations, the cutting of the bone flap and the amputation being all performed with one sweep of the saw. The cutaneous incision is the same as described in his original communication, in No. 31, 1897, starting very high on one side and brought down very low on the other, the flap thus formed turned up on the leg like a high collar on a woman's jacket. The bone flap is then cut out, using a strong, slightly modified Hehrlich bow saw, the span very wide and high, the blade not wider than 3 mm. from the tip of the teeth to the back, and inserted in the bow almost at a right angle to its plane. In making the first transverse incision—the depth corresponding to the desired thickness of the bone flap, and the distance below the turned up skin flap corresponding to the area of the base of the stump to be covered—the bow is held sloping to the left. When this is completed the blade is turned parallel to the surface and the bone flap is sewed up nearly to the base of the skin flap, with the soft parts left projecting on all three sides of the bone flap to afford a good hold for the stitches. A wedge is then inserted under the bone flap, and by slanting the bow to the right the upper end of the bone flap is cut across on a line with the first incision, approaching the surface and stopping just short of the periosteum, the final connection of the bone broken by prying up with the wedge. The end of the blade of the saw is then transferred to a hole just beyond, in the bow, which brings it into the same plane as the latter, and the entire leg is sawed across just above the bone flap and below the turned-up skin flap. The four-sided bone flap is then brought across the base of the stump and sutured to the soft parts, and the skin flap brought down over it from the other side and fitted over the end of the stump, the operation completed by a short transverse suture of this flap a little distance above the end of the stump.

Surgical Intervention in Hysteria. M. SANDER.—A man of 23 presented the clinical picture of intestinal occlusion, and a young woman, that of perforating peritonitis. Each was operated on and everything found normal, the first undergoing operation twice and the second four times, until it was suggested to tattoo "Beware" on their abdomens. Sanders thinks that such mistakes could be avoided by more careful search for hysterical antecedents. In the observations reported, the lack of proportion between the pulse and the fever, and also between the general appearance and the severe symptoms, the rapid changes in the symptoms, their severity in the presence of the physician and subsidence in his absence, combined with evidences of hysteria, should have warned against intervention. He also notes the "elective" character of the vomiting, and that meteorism can be caused by voluntary swallowing of air. He classifies hysteria as a form of degenerative psychosis with many points in common with the severer forms. Hospital treatment is directly injurious. The patient should be in a "closed

establishment" and all his complaints systematically ignored and attention diverted, with general tonic treatment, suggestion and faradization later.

Partial Substitution of the Cornea. KUHN.—An experience with nearly a thousand patients in the last fifteen years, with ulcerative processes, perforations after ulcerations, or after removal of fresh or old prolapse of the iris, fistulae, keratoceles, incipient partial staphylomata, injuries with or without an opening into the inner eye or after various operations, all treated by applying a flap of the bulbar conjunctiva with or without a stem, as the substituting plastic material, enables Kuhn to affirm the extreme benefits derived from this simple process. The shape of the eye is retained, and sometimes part of the vision, even after severe injuries or lesions. The flap is sometimes left attached at both ends, sometimes re-enforced with a second flap, freshening the edges of the wound before covering it. In case of an ulceration, after evacuation and cleansing, the flap is applied, and the success is surprising. Pain disappears and healing is complete in five to seven days, after which the flap gradually vanishes, finally leaving nothing but a kind of *pannus tenuis*.

Muenchener Medicinische Wochenschrift, September 2.

New Problems in the Pathology of the Cell. E. ARBRECHT.—Further investigation has confirmed Albrecht's announcement of the fluid character of the cell; that the nucleus as well as the nucleolus of the immature cell, also the mature nucleus of the ovum, the segmentation nucleus and the nuclei of the blastomeres, are all drops of fluid in a likewise fluid cell body. They all have the properties peculiar to fluids, and these properties alone. The conclusion follows that all physiologic alterations in the shape of the cell must be interpreted according to the laws of fluid bodies, processes of mixing and unmixing, etc., e. g., such as we might imagine if we were able to restore, to its original form, the drop of fat saponified and dissolved in an alkaline solution. It is evident that various causes will affect the different elements in the cell differently, and numerous experiments with cells from warm and cold-blooded animals, suddenly heated or exposed to the action of diluted acids, showed a production inside the cell of a moderate number of tiny granules. It is impossible to determine, however, whether this fractional precipitation of living substance corresponds to the albuminous substance or to more complex combinations in the cell, and whether these changes regress or not, that is, whether they are localized lesions or partial necrosis. The direct microscopic picture, as well as the microchemical reactions, establish that at least a large part of the contents of the cell in cases of fatty degeneration, "coagulation necrosis," and albuminous degeneration of cloudy swelling, are coagulated bodies in the physiologic chemistry sense. The question then arises: Is coagulation necrosis a necrosis of the cell from or with coagulation, or is it merely a necrosis with consecutive, post-mortal accidental coagulation? Whether we regard the cell as a living element or an agglomeration of chemical substances, its complete physical interpretation must proceed from the premises of our knowledge of nature. The first and foremost question is, therefore, the "aggregate condition" of the mass. To determine this by objective methods is the most important task of cytophysics for the future.

Wiener Klinische Rundschau, September 2.

Parenchymatous Keratitis in Acquired Syphilis. E. ROUBICEK.—While specific treatment is unmistakably effective in this affection with acquired syphilis, mercurial inunctions have no effect on congenital cases, and hence inunctions are not applied to children in Deyl's clinic. Roubicek reports several observations which differ in several points from the schema established by Valude; he claims that in case of acquired syphilis the keratitis is unilateral, disproved by two of the observations; also that the pain is less than in congenital cases, with no lachrymation or shrinking from light, which was the reverse of what was observed in another case. But the observations confirmed his other points: the lesser vascularization with acquired syphilis, and the fact that the cloudiness of the cornea commences at the edge with distinct cloudy patches which slowly merge together. With congenital syphilis the tongue-shaped patches of cloudiness soon spread over the entire area of the cornea. Many cases of the affection with ac-

quired syphilis have probably been included with the congenital, especially in children, as we are apt to forget that children can acquire syphilis. Roubicek considers it almost impossible to distinguish between interstitial keratitis from acquired or congenital syphilis, as experience has shown that Hutchinson's stigmata can occur with acquired syphilis. Fournier advises the following questions: syphilis in the family; do the parents acknowledge it; syphilitic stigmata on them; occurrence of abortions, premature births, eclampsia and convulsions, bearing in mind the possibility of lead and tobacco intoxication, as women in tobacco factories abort regularly.

Zeitschrift f. Hygiene u. Inf. (Leipzig), xxxvi, 2.

Blackwater Fever (Hemoglobinuria). R. KOCH.—A large number of observations (41) are reported, which sustain Koch's previous assertions that blackwater fever is an acute intoxication with quinin, in persons who are naturally peculiarly susceptible to this drug or have acquired this idiosyncrasy from malarial infection or the continued use of it. One observation is particularly interesting: a person who had always taken a gram of quinin without inconvenience, became so sensitive that finally a half, a quarter or a tenth of a gram induced the typical attack of blackwater fever—chill, hemoglobinuria. He does not attempt to explain why this fever is frequent in some localities and rare in others, and adds that hemoglobinuria has also been observed in connection with the administration of phenacetin, sodium salicylate, antipyrin and phenol.

Gazzetta degli Ospedali e delle Cliniche (Milan), August 27.

Prognosis of Hydrophobia Complicated with Albuminuria. G. GRAZIANI.—A number of experiments on rabbits, and personal observations, have shown that the congestion of the kidneys with the other organs leads to albuminuria by the action of the virus on the renal lesion, and when this has occurred the antirabic treatment is powerless to arrest the disease at this stage, and the prognosis is exceedingly grave.

Injections of Phenic Acid in Tetanus and Erysipelas. S. PASCOLETTI AND S. TERESI.—The first writer describes two cases of tetanus cured with Bacelli's subcutaneous injections of 1 to 2 per cent. solution of phenic acid. The other describes his successful treatment of four cases of generalized erysipelas with similar injections at a distance from the localized lesions. Both comment on the tolerance of subjects with tetanus and erysipelas for large doses of phenic acid, and its prompt influence on the pathogenic agents and their toxins, which they ascribe chiefly to a modification of the soil.

Nord Medicale (Lille), September 1.

Vulvar Edema and Gangrene in the Puerperium. V. BUE.—In one of the observations described, the enormous edema was the classic albuminuric type; in the other, its early appearance, the coexistence of twin pregnancy, and the absence of albuminuria indicated that it was due to compression. Both cases were scarified and gangrene ensued. The first died, the other recovered. Bue adds that rest and milk diet may relieve the albuminuric type, but not the other, and warns that scarification should only be done in case of extreme necessity and the resulting wounds closely supervised.

Societies.

COMING MEETINGS.

Mississippi Valley Medical Association, Chicago, October 3-6.
Idaho State Medical Society, Lewiston, October 5-6.
Utah State Medical Society, Salt Lake City, October 6-7.
Wyoming State Medical Society, Laramie City, October 10.
American Academy of Railway Surgeons, Omaha, Neb., October 12-13.
Vermont State Medical Society, Burlington, October 12-13.
Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, October 24-26.
New York State Medical Association, New York City, October 24-26.
Medical Society of Virginia, Richmond, October 24-26.
American Public Health Association, Minneapolis, Minn., October 31.

New York State Medical Association.—The preliminary program of this Association, which holds its sixteenth annual meeting October 24 to 26, in the New York Academy of Medicine, New York City, has been received. There will be a discussion on typhoid fever, participated in by Drs. Herman M. Biggs, William Osler, Reginald Fitz, A. Jacobi, W. W. Keen

and others, with a medicolegal symposium on expert testimony. In addition the program announces a large number of miscellaneous papers by leading practitioners, and a reception on the evening of October 25, to Dr. W. W. Keen, president of the AMERICAN MEDICAL ASSOCIATION.

Executive Health Officers of Ontario.—The fourteenth annual session of this association met in London, Ont., September 13 and 14, Dr. M. Rae of Guelph, the chairman, presiding, and Dr. J. J. McKenzie, Toronto, acting as secretary. A large number of the health officers from all over the province were present. Dr. J. J. McKenzie, bacteriologist of the Provincial Board of Health, read a paper on the "Odors of Water Supplies," and after that had been fully discussed, read another prepared by Dr. McDonald of Hamilton, on "Tuberculosis in Cattle." This paper elicited a very interesting and animated discussion, several of the members differing as to the amount and also the causes of this disease in Canada. On the morning of the second day, the delegates visited the asylum for insane, and inspected the sewage farm in operation there: afterward papers were read on "School Ventilation," by Mr. A. B. Shantz of Caledonia; "Anthrax," by Dr. W. T. Connell, Kingston, and one, "Sewage Disposal," provoked a long discussion which occupied the major part of the afternoon session.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Abstract of Proceedings of Twelfth Annual Meeting, Held at Indianapolis, Ind., Sept. 19, 20 and 21, 1899.

FIRST DAY—MORNING SESSION.

The Association convened in the Century Club Rooms of the Denison House, under the presidency of Dr. Edward J. III, of Newark, N. J.

An address of welcome was delivered by Mayor Taggart, which was responded to by the President.

After the transaction of routine business in executive session, the reading of papers was proceeded with.

THREE RARE CASES OF KIDNEY CYSTS.

DR. JAMES F. BALDWIN, Columbus, Ohio, reported these cases:

CASE 1.—*Enormous Hydronephrosis Simulating Ovarian Cystoma.* The tumor in this case filled the entire abdomen and entered the true pelvis, pushing the uterus to the left. The patient was unaware of the existence of any tumor, but thought that she had been getting stout for two years. There was no history whatever of any disturbance about the kidney. The enlargement was much more marked on the left side of the abdomen. At the operation the tumor was found to be hydronephrotic, of the right side, and with entire destruction of all kidney tissue. The blood-vessels had so far disappeared that the only pedicle was an enormously distended ureter resembling a piece of small intestine. The cyst, which was retrocolic, was enucleated without special difficulty, and recovery was uninterrupted.

CASE 2.—This was a large paranephric cyst containing about one and a half pints of straw-colored fluid resembling urine. The cyst wall was exceedingly thin, but was successfully enucleated and the cavity closed with temporary drainage. Healing occurred by first intention.

CASE 3.—*Hydronephrosis of a Retrorectal Congenitally Misplaced and Sarcomatous Kidney.* This tumor filled the pelvis, pushing the uterus up and pressing so firmly on the urethra as to necessitate the use of a catheter. The rectum was so pressed on as to render defecation almost impossible. After separating the tissues the cyst was tapped through the vagina and about one quart of urinous fluid drawn off. The completion of the enucleation had to be made through the abdomen. The specimen proved to be a sarcomatous kidney congenitally misplaced in the pelvis. During the development of the disease, hydronephrosis resulted, giving rise to the cyst which obstructed the pelvis. The patient recovered without difficulty and continued well at the time of the report.

While hydronephrosis simulating ovarian cystoma is not excessively rare, paranephric cysts, of any considerable size at least, have been very seldom reported. The case of hydronephrosis of a pelvic kidney is, so far as the reporter could ascertain, after a somewhat extended correspondence, entirely unique.

DR. JAMES F. W. ROSS, Toronto, Ont., called attention to a point in connection with the diagnosis of cystic tumors of the kidney, and it was this: Given a tumor that is unilocular by fluctuation, but looks like a multilocular tumor, in consequence of the stric it is always a tumor of the kidney, and not of the ovary. He also drew attention to one other point, relative to the treatment of the ureter. He believes that if the end of the ureter is tied with catgut, it can be left in the course of nephrectomy, and he does not think it is necessary to follow the ureter down to the bladder.

DR. LEWIS S. McMURTRY, Louisville, Ky., concurred in the remarks of Dr. Ross in regard to dealing with the ureter. In a number of cases of nephrectomy that he had done the ureter was not dilated as much as in the case described by the essayist. In one case particularly he did not attempt to trace the ureter up to the bladder and remove it, but left it, and it did not give any trouble.

DR. L. H. DUNNING, Indianapolis, Ind., directed attention to an important diagnostic point in dealing with cysts of the kidney, namely, the presence of the colon in front of the tumor. He has been able to demonstrate this in large sarcomatous tumors of the kidney, and by pumping the colon with air, the distended colon can be seen running over the outer border or center of the tumor. He has removed three kidneys for tuberculosis. In one instance he did not tie the ureter; he did not dissect and remove it far down toward the bladder, and he had considerable trouble in that case, following it for some time. He thinks it is unsafe, in tuberculosis of the kidney, to leave the ureter, and believes it ought to be removed low down in the pelvis and tied wherever it is left, and not followed down clear to the bladder.

DR. J. HENRY CARSTENS, Detroit, Mich., said that surgeons always had more or less difficulty in making the diagnosis in the cases under discussion, and while the point brought out by Dr. Dunning was a good one, it did not always hold good. He recalled one case in which he supposed he had an ovarian tumor, but found a hydronephrotic kidney as large as that of the first case reported by the essayist. The kidney was very loose, and afterward a stone was found in it. The stone was quite large. He believes that when we have a loose kidney which flops around, it may grow over the colon, and the colon in some of these cases is behind instead of in front of the tumor.

DR. JOSEPH EASTMAN, Indianapolis, Ind.—by invitation—stated that he had recently had a case of pancreatic cyst as large as a good-sized head or larger, and it was very satisfactory to notice the ascent and descent of this tumor during inspiration and expiration, a thing not possible if the tumor had been post-peritoneal or connected with the kidney. The pancreatic cyst had distended the mesocolon to such an extent that the transverse colon was very perceptible, lying across in front of the enormous pancreatic cyst; so the diagnostic point mentioned by Dr. Dunning, he thinks, is applicable to pancreatic cysts.

DR. JOHN M. DUFF, Pittsburg, Pa., narrated an instructive case in which a diagnosis of abscess of the spleen had been made, but a more careful subsequent examination revealed the fact that the tumor was connected with the kidney, as he had suspected. A median incision was made; the tumor had pushed up the mesocolon; the colon was adherent to the tumor around at the side, and the mesocolon was almost ulcerated through. The kidney was removed through the mesocolon. There was no secretion of urine from the kidney, an examination not having been made with the Harris instrument for the purpose of ascertaining the condition of the urine from both kidneys.

DR. DUNNING asked as to the reliability of the Harris instrument, to which Dr. Baldwin replied that it was a very satisfactory one. He had used it several times in the female. It can be used more quickly and with less trouble than ureteral catheterization.

ECTOPIC GESTATION: SHALL THE CASE BE OPERATED ON AT OR NEAR THE FULL TERM, THE CHILD BEING ALIVE?

DR. L. H. DUNNING, Indianapolis, Ind., read a paper on this subject. As preliminary to a discussion of this theme, he reported the history of a case of ectopic gestation of eight months' duration, and operated on five weeks after the death of the fetus. He said that the proper treatment of ectopic pregnancy

after the sixth month, when the child is still living, is yet under discussion. He wrote his paper for the purpose of considering only one phase of the subject, namely, shall operative intervention be instituted during the period of viability of the child, or shall we await the death of the child and the cessation of the active circulation of the placenta, and then operate? The settlement of this question, he said, must hinge on the relative mortality of the different procedures to the mother. The ectopic infant is of such low vitality and so frequently deformed that if to resuscitate it greatly jeopardizes the life of the mother, then ethically one must withhold the hand and permit it to die that the greater life may be saved. Such have been the sentiments of the writer for many years. He has had three cases of ectopic gestation at or near full term. In the first, the operation was done during spurious labor at full term. In this case, although fetal movements were detected one hour before operation, the child never breathed after removal by abdominal incision. The mother died the eighth day after operation, of hemorrhage resulting from the removal of the placenta, which was left at the time of the initial operation. The placenta was removed thus early in consequence of impending death from septicemia. The other two cases were briefly narrated. A statistical table accompanied the paper. He stated that if the tables given by him approximately show the percentage of recoveries to mothers, then there was an answer to the perplexing and heretofore mooted question, "Shall operative intervention be instituted during the life of the child or only after its death?" We are not compelled to longer consider and weigh the probability of the length of life in days of the child, the safety of the mother alone demands intervention. Undoubtedly other questions will urge themselves on us, such, for instance, as, "Is it less dangerous to operate at six months or at nine months, and what treatment of the placenta yields the least mortality?" These are still under discussion, but it was aside from the writer's purpose to discuss them. His only endeavor is to strive to arrive at a correct and fruitful answer of the question, "Is it safer for the mother to be operated upon in a case of ectopic gestation during the viability of the fetus?" He believes that the statistics collected and compiled by him are so nearly complete and correct that the answer may now be given unqualifiedly in the affirmative. There will undoubtedly be individual cases in which the good judgment of the surgeon will direct him to await the death of the fetus. These will be exceptional ones. The rule will be to operate at or near term during the life of the child.

DR. J. HENRY CARSTENS agreed with the essayist that the proper way, other things being equal, is to operate at once when the child is living and viable. The placenta is not always attached to the broad ligament. Often rupture takes place, and the placenta is attached to the intestines, the colon, the rectum, or the sigmoid, and in cases of that kind it is utterly impossible to remove the placenta when an operation is performed when the child is alive. He had seen such operations performed by other surgeons, and the patients invariably died from hemorrhage.

DR. LEWIS S. McMURTRY endorsed what Dr. Carstens said, with one slight qualification. He thought Dr. Carstens struck the keynote in determining the course to pursue in these cases. By referring to one of the earlier volumes of Transactions of the Association, the report of a case may be found where the fetus went to full term, was dead, and some weeks after a spurious labor, when there were beginning septic symptoms, he operated. No fetal movements had been observed for nearly three weeks. The placenta was very large; there was no sign of any atrophic changes in it in consequence of the death of the fetus; it was spread out over one side of the uterus, over the colon and ileum, and there was such a profuse hemorrhage as will obtain from an attempt to enucleate the placenta as never will be seen at the operating-table under any other circumstances. It was perfectly dreadful, the woman being exsanguinated within a minute, the pelvis being full of blood. When the placenta is disposed toward the broad ligament and uterus, as in the case described by Dr. Dunning, he believes there is a good opportunity for complete enucleation of it.

DR. X. O. WERDER, Pittsburg, Pa., said he had reported, in the Transactions of the Association, a case in which he did a celiotomy for ectopic gestation at full term, or within two weeks of full term, in which he succeeded in enucleating the

placenta and removing at least two-thirds of the sac. The rest of the sac was adherent to the intestines, and he found it advisable to stitch it to the abdominal wall. Hemorrhage during the removal of the placenta was very profuse, but he succeeded in controlling it promptly by clamping the uterine and ovarian arteries. The woman recovered, and the child lived four days.

Dr. JOSEPH EASTMAN fully concurred in the conclusions of the essayist, and narrated an interesting case of ectopic gestation that had come under his observation ten years ago.

Dr. JOHN M. DUFF believes that in every case of extrauterine pregnancy, as soon as the diagnosis is made, arrangements should be perfected for an operation as soon as possible.

The paper was further discussed by Drs. Gilliam, Ricketts, Ross, all of whom agreed with the essayist with slight differences of opinion.

WHAT SHALL WE DO WITH THE POST-OPERATIVE HEMORRHAGE OF CELIOTOMY?

Dr. D. TOP GILLIAM, Columbus, Ohio, presented this paper. Cases of post-operative hemorrhage were cited, and he said he had very little to offer in the way of suggestion. As a burnt child dreads the fire, so his most painful experience in the tragic cases he had cited had imbued him with a wholesome dread of delayed interference after celiotomy. He has on several occasions opened the abdominal incision down to the peritoneum, for hemorrhage from the walls, without untoward result. This class of cases can usually be easily distinguished from intraperitoneal bleeding by the puffed and discolored appearance of the tissues along the line of incision. If he was satisfied that a large vessel had let go, as indicated by the rapid development of symptoms indicative of hemorrhage, he would open the abdomen with the utmost celerity. But the author's paper was not inspired by any hope or expectation of being able to suggest any line of action, his sole object being to elicit an expression of the prevailing views of his fellows. Still he would like to make one suggestion with reference to the medical treatment of such cases, and that is the use of atropin. Some time since he had in charge a young woman who was subject to the most violent and persistent uterine hemorrhage of unaccountable origin. She had passed through many hands before coming to him, and he had tried many of the vaunted remedies without avail, as she could not make up her mind to have a curettage, and during one of her spells she fell into the hands of his brother, Dr. Charles F. Gilliam. He placed her on atropin, with the result that, after the physiologic effects of the atropin became manifest, the bleeding ceased. Since then her attacks have been less frequent and always promptly amenable to the atropin treatment. Other cases followed in the practice of Dr. Gilliam and his brother, among which were some intractable cases that had been curetted, and in every instance so far the hemorrhage had been controlled by the atropin. The results had been so convincing in these cases that had fallen under his observation as to force conviction.

As to the *modus operandi* of atropin, he could only speculate. It is known that it increases the cutaneous circulation, producing a general and marked hyperemia of the surface, and that the cutaneous vessels are capable of containing nearly one-half of the blood of the body, hence by derivation it diminishes the amount of blood circulating in the internal organs. The author thinks it quite likely that the vasomotor action which dilates the cutaneous vessels coincidentally and by way of equation constricts the visceral vessels. The duodenal ulcers resulting from extensive burns of the skin would argue in favor of compensatory vasculature. It is not expected that this or any other medicinal agent will arrest the torrential hemorrhage of the larger vessels, such as the uterine or ovarian arteries, but is especially applicable to that troublesome form of hemorrhage which emanates from numerous vessels of smaller caliber.

As to the vital question, when to interfere surgically, and when to refrain, the paper ended where it began—in an interrogation point.

Dr. CHARLES A. L. REED, Cincinnati, Ohio, said that when he observes symptoms unmistakably indicative of internal hemorrhage, he wants to get at the bleeding point as quickly as possible. He cited some cases in which he had had to deal with post-operative hemorrhage following celiotomy.

Dr. H. W. LONGYEAR, Detroit, Mich., said there was nothing

more puzzling than to know just what to do in cases which showed the condition of collapse described by the essayist, indicative of internal hemorrhage. And yet there were other conditions which produced the same symptoms, and the surgeon must use fine discrimination. If he knows a vessel is bleeding, he considers it his duty to cut down and search for the bleeding point, no matter what the condition of the patient may be. In a case of ruptured tubal pregnancy, where there is internal hemorrhage going on, it is the duty of the surgeon to reopen and do the best he can. It is not always easy to find the bleeding vessel. Dr. Longyear cited two cases that had come under his observation in the last two years, that brought this forcibly to his mind.

Dr. RUFUS B. HALL, Cincinnati, Ohio, stated that hemorrhage or shock could be determined largely by the operator himself. When a patient is put to bed after an operation, the surgeon is rather well aware whether there is great danger of secondary hemorrhage or not. If the operation has been a complicated one, and a condition is left which adds to the risk of hemorrhage, this materially aids the surgeon in determining whether or not the patient is bleeding or suffering from shock. He would not hesitate a moment to take out a stitch, after the abdomen is closed without drainage, and he believes that without very extensive exploration he could readily and certainly determine whether hemorrhage was taking place or not.

Dr. LEWIS S. McMURTRY called attention to the fact that post-operative hemorrhage was very much less frequent now than formerly. In the early days, before operative technic was improved as it is now, and the drainage-tube was more universally used, it was common twenty-four or forty-eight hours after an operation to see great quantities of blood pumped out of the drainage-tube. Hemostasis was not as thorough then as it is now. To-day the small vessels are carefully ligated. He has pursued the course of securing the ends of vessels with a small ligature, which gives additional security.

Dr. J. HENRY CARSTENS dwelt on the differential diagnosis between hemorrhage and shock. He believes in the efficacy of medication for the control of hemorrhage, and thinks that atropin or belladonna is a good thing. He uses them in preference to strychnia.

Dr. JAMES F. W. ROSS said that in cases of thick pus-tubes with a very edematous pedicle, the surgeon was liable to have such a hemorrhage, particularly from the edematous pedicle and rotten condition of the tissues afterward. He would not hesitate to remove a stitch, after the abdomen had been closed, and search for the bleeding vessel.

Dr. L. H. DEXNER called attention to what he considered a valuable diagnostic sign in differentiating between shock and hemorrhage. He has seen shock occur in twelve, twenty-four, and thirty-six hours after operations. He has also seen patients recover from shock, who could not have recovered from hemorrhage. This differential diagnostic sign is that of irregular capillary circulation or congestions here and there. He recalled three or four cases in which he spent hours at the bedside of patients, hesitating between shock and hemorrhage, and on the appearance of localized spots, as a purple ear or purple lip, or a spot on the face, he decided it was shock.

Dr. X. O. WEBER stated that it is his rule, as soon as he suspects a hemorrhage, after an operation, to take out a stitch, after the abdomen has been closed, and insert his finger for the purpose of making a diagnosis of hemorrhage, and if it is confirmed he reopens the abdominal wound and ties the bleeding vessel without putting the patient under the influence of an anesthetic.

Dr. EDWIN RICKETTS, Cincinnati, Ohio, said that whenever ligatures are used, there is one procedure that he wished to refer to, one always resorted to by Bantock, that is, crushing the tissues for one-half or one-quarter of a minute by the heavy jaw clamp, and after removal of the clamp the ligature is applied. The angiotribe, which is being advocated by some operators, in which the ligature is not used at all, is applied and permitted to remain for two and a half minutes, and then removed, and it is claimed no hemorrhage follows its application. The plan, however, suggested by Bantock, is one that should not be lost sight of in applying the ligature.

Dr. WILLIAM H. HURSTON, Cleveland, Ohio, stated that if each vessel was caught separately, and tied with fine catgut or silk, reinforced by seizing the ovarian artery as it comes off the pelvic wall and inserting one stitch and one near the cornu of the uterus, one need not have hemorrhage. He thinks it is unnecessary to crush the tissues after the method mentioned by Dr. Ricketts.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

No. 61 Market Street, Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, 100 Washington St., Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

These new members of the Association should send their annual subscription direct to the Treasurer, Dr. Henry P. Newman.

All communications and manuscripts of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof-sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street Chicago.

Original communications are accepted with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, SEPTEMBER 30, 1899.

ADENOMYOMATA OF THE FEMALE SEXUAL APPARATUS.

In his studies of the origin, nature and destiny of the adenomyomata of the female sexual apparatus, Leopold Landau, Berlin, has developed some new knowledge of an old subject. The new matter has for the most part been accumulated within the last five years, and is so complete that the story of the origin, construction and treatment of these neoplasms may now be told in a purely pragmatic and sequential way.

As early as 1896 Von Recklinghausen observed, in addition to the ordinary fibromata, myomata and fibromyomata of the uterus, certain muscle tumors in which glands and cysts were present. The epithelium of the glands and cysts of these neoplasms, which he denominated "organoid myomata," he believed to be derived, either from prenatal inclusion within the tissues of the coalescing tubes of Mueller, of fragments of the Wolffian bodies, or from cut off post-fetal out-shoots of epithelium, growing from the uterine mucosa deeply into the muscularis.

Landau recalls that the tubes of Mueller, which in the female become the Fallopian tubes, and by the blending of their lower extremities form the uterus and vagina, are so situated in the embryo that the upper segment of each tube lies laterally to the Wolffian body of the same side; also that at a lower point which corresponds to the tubo-uterine junction of post-fetal life, the tube of Mueller crosses the Wolffian duct, coursing in a median-ventral direction, and that the lowest or vaginal segment lies median to the duct of the Wolffian body. With these relations in mind it is not difficult to

understand how, as Recklinghausen has shown, fetal inclusion of epithelium from the Wolffian ducts within the substance of the uterine extremity of the Fallopian tube, or the muscularis uteri, could come to pass.

The first substantial proof of Von Recklinghausen's theory is to be found in the fact that these tumors occur with overwhelming frequency in the peripheral layers of the uterine muscularis near the tubo-uterine junction, and are very often bilaterally symmetric.

The second and most remarkable proof consists in the fact that the gland tubules of the adenomyomata under discussion, both in systematic anastomosis and character of epithelium, are strikingly similar to the Wolffian canals. In these tumors there may be traced out the systems of winding, secreting tubules with dilated extremities emptying into a straight connecting tubule or main canal, comb fashion, like miniature parovaria. In other words, we see in a neoplasm of adult life, the complicated anatomic structure of an elaborate embryonic organ.

Landau has always sought for epithelial inclusions whenever a myoma presented which had entangled itself in uterine muscularis, displaying no distinct line of demarcation, and each time with a positive result. Contrary to V. Recklinghausen, he states that adenomata which grow out from the uterine mucosa after birth may arise from the entire mucosa corporis or from a small circumscribed area, and may grow centrifugally through the uterine wall to the serosa and even into the pars uterina tube and ligamentum latum. He has shown, moreover, on the basis of L. Pick's observation, that not all of these included epithelial outshoots from the mucous membrane represent post-fetal inclusions, but that some are developed from epithelium and connective tissue which grows deeply into the muscularis—peripheral layers—in fetal life. Pick has found glands of the fetal endometrium corporis occupying the subserous layer of the myometrium in adults, and has demonstrated that myomatous proliferation may take place about such displaced fragments of mucous membrane and remains of the tubes of Mueller. He has shown that mucous membrane adenomata exist, which are primarily of fetal origin.

It is well known that the stroma of the normal mucosa corporis uteri is made up of the so-called cytogenic tissue. In other words, it is a connective tissue composed of abundant round and spindle cells and intercellular substance containing fine reticulating fibers. This tissue is not found in the Wolffian body nor in its post-fetal remains, neither in the epi-ovarium nor parovarium. It is likewise absent in parovarian adenomata showing the scattered arrangement and which have not attained considerable growth. If, however, the Wolffian tubules proliferate extensively, developing many adenomatous systems—closed arrangement—there then appears an accompanying growth of cytogenic connective tissue. The appearance, therefore, of cytogenic tissue in adenomyomata as the stroma of Wolffian body epithelium

is not dependent on the localization of the neoplasm, but on the extent and intensity of the growth, but if epithelium lined tubules are found anywhere in the female genital apparatus where such structures do not histologically belong, the presence of cytogenic connective tissue as their supporting substance gives evidence of their origin from the tube of Mueller or from the mucosa corporis uteri.

Landau very appropriately calls attention to the great practical importance of knowledge of the origin of these neoplasms. He believes that juxta-uterine adenomata, and even voluminous subserous uterine adenomata, despite the diffuse transition of their bases into the normal muscularis, may often be treated successfully by conservative myomectomy.

Pick and Landau have, moreover, encountered adenomata in the round ligament and in the posterior fornix of the vagina. Adenomata of the round ligament are hard, varying in bulk from the size of a walnut to that of a plum. They are not sharply defined from the surrounding tissues. In all cases of adenomyomata of the vagina the neoplasms are situated in the muscularis of the posterior fornix. They project as knotty masses into the perivaginal cellular tissue or protrude, polypus-like, into the vagina. In macroscopic section the fiber bundles are distinct, as in ordinary fibroids. Here and there are scattered yellowish and brown spots of pigment and irregular splits and cracks. On microscopic examination the supporting structure is seen to be composed of atypical fibromyomatous tissue. The little pigmented spots are seen to be gland and cyst formations presenting cylindrical and ciliated epithelium.

The adenomyomata of the ligamentum rotundum and posterior fornix offer valuable evidence in substantiation of Von Recklinghausen's theory of the origin of such neoplasms from displaced tubules of the Wolffian bodies. As in the male, the epididymis is transported during the "descensus testicularum" through the gubernaculum Hunteri, so in the female the cord of the primordial kidney in descending may draw a portion of this embryonic organ down with it into the inguinal canal. The Wolffian tubes, particularly of the distal parovarian segment, may thus descend into the canal of Nuck or into the labia majora.

The transport of epithelium from the primordial kidney through the ligamentum teres uteri to the inguinal region may be assumed without misgivings. Even Kossman, who denies the parovarian origin of uterine and tubal adenomyomata, concedes that the epithelium of adenomyomata of the round ligament comes to this region along the route indicated.

If the Wolffian body is abnormally long and extends down over the dorsum of the sinus urogenitalis, or the canals at its lower pole persist until the tubes of Mueller blend at the sinus, the parovarian segment of the Wolffian body could easily be swallowed up in the dorsum of the uterus or vaginal fornix. The adenomyomata of the posterior fornix present further evidence of their prim-

ordial kidney source in the dichotomous branching of their tubules. In the case of those adenomata originating from the epöoöphoron we have to deal not with hypothetical Wolffian canals, but with physiologically preserved masses of primordial kidney.

To the adenomyomata derived from the Wolffian body, L. Pick has given the name "meso-nephritic adenomyomata" and to those derived from the mucous membrane the name of "mucous membrane adenomata." The adenomyomata of the female sexual apparatus, therefore, belong to one or the other of these groups, and must not be confused with the ordinary histoid myomata which represent simple circumscribed outgrowths from the muscularis uteri, and which, according to Virchow, are the result of irritative or inflammatory processes and are not developed in any way from displaced epithelium.

THE ORIGIN AND OCCURRENCE OF EOSINOPHILOUS CELLS IN THE SPUTUM.

One of the most conspicuous elements in the richly-colored blood preparation, made according to Ehrlich's method, is the eosinophilous cell. The brilliantly stained granules in its protoplasm make this cell a marked object. Nevertheless, but very little is known concerning the place and the mode of its origin; the opinions of the investigators on these points vary greatly. The occurrence of eosinophilous cells in the sputum, under various conditions, has also attracted considerable attention. Their presence in the sputum is explained in two directly contradictory ways: Ehrlich and others derive them from the blood; but their presence in the sputum in enormous numbers in bronchitis and bronchial asthma without a corresponding eosinophilia in the blood has given rise to the opinion that they are formed in the respiratory tract. Fuchs¹ recently called attention to the possibility that eosinophile cells and free granules in the sputum might in some cases stand in relation to disintegrating red blood-corpuscles. In a case of hemorrhagic pleuritis, undergoing absorption, Klein² observed the development of an increasing eosinophilia in the exudate followed by an increased eosinophilia of the blood. It does seem quite natural that red blood-discs should furnish the material for eosinophilous granules, both in bloody exudates and in sputum. These granules are, like the red corpuscles, albuminous, and contain hemoglobin as well as iron. Fuchs found eosinophile cells in large numbers in sputum which was hemorrhagic on account of various processes in the lungs.

Eosinophile cells are, according to Fuchs, also frequently present in large numbers in the sputum in bronchial asthma, in catarrhal bronchitis, passive congestion of the lungs, bronchiectasia, pulmonary infarct, carcinoma and syphilis of the lungs, and also in coryza and pharyngeal catarrh. Teichmüller found these cells in the sputum in 73 per cent. of 167 tuberculous patients, and Fuchs in 66 per cent. of 38 cases. Teichmüller attributes to the eosinophile cell a pronounced protective influ-

¹ Deutsche Arch. f. Klin. Med., 1899, 63, 427.

² Chl. f. Innere Med., 1899, 20, 97.

ence against tuberculosis, and he would in a measure estimate the resistance of the patient on the basis of the sputum eosinophilia. Fuchs does not fully agree in this; he believes that the absence from the sputum of the cells stands in some relation to the presence of fever in tuberculous cases, because the number of eosinophile cells is generally small in fever; eosinophile cells occur in varying numbers in the sputum in all diseases of the respiratory tract not immediately accompanied with fever. These cells are not all of the same origin; some are probably derived from leucocytes with neutrophile granules, others develop by phagocytosis of changed red blood-corpuscles. Neither do they originate in any single definite place, but may develop in practically all organs and tissues. Their general significance may be interpreted as a manifestation of the protective and reparative powers of the organism.

MENTAL ABERRATION AND LABOR DISTURBANCES.

The observation that would-be leaders of men are not infrequently representatives of degenerate and unsound types of mind, is by no means novel. History, modern and ancient, furnishes an overabundance of illustrations of this tendency of the mentally deficient to attempt to dominate the sober but less active minds of the toiling classes. Those of the degenerate type hold atavistic views and wish society to be recognized on the basis of the primordial communal system when the community held all things in common, including wives, and when individual property, with its incentive to the energetic, was not permitted. It may be noted as a historic fact that civilization consisted largely in the emergence of society from this chrysalis stage. The otherwise unsound type of leader may be known by his advocacy of dreamy, supposed reforms, and his expressed desire to tear down every institution of modern social organization. No one of sense, of course, maintains that the present organization of society is perfect, and so all these "cranks," as we call them, get a hearing. A recent uncontradicted published report of an address delivered by an "agitator," well known in his own community for his anarchistic beliefs, on the subject of one of the late labor demonstrations, discloses a marked example of this mental twist.

Referring to the action of a riotous mob, he said: "This wholesale gathering of people opposed to constituted authority was a grand thing. This gathering of mobs will continue. The opposition against constituted authority will grow, and some day the mob will act." "There has been little violence done but there will be some time." "The people will rise up, and mobs will gather to put down constituted authority." To this type of insanity—for who will maintain it is not really insanity?—the rising of the people, to put down by violence authority peaceably erected by themselves for their own protection, is not absurd. Had he but an opportunity, the alienist would here surely find a paranoiac. The true reformer proposes a peaceful remedy for social

ills, the insane reformer merely wishes to destroy all restraint on license. The physician, as the only ubiquitous physiologic student of human psychology, has herein a manifest duty to society in pointing out to the untrained the patent earmarks of mental strabismus. In the past the degenerate and the paranoiac have at times accomplished tremendous harm, because the world lacked the data for discriminating between honest solicitude and insane plausibility. To-day the medical profession, with its well-founded psychiatry, must stand between the public welfare and those aberrant minds that seek to upset social order. The paranoiac and the degenerate are abroad in the land, not, it is true, accomplishing as much harm as in former more ignorant ages, but yet doing much to make mankind uselessly unhappy and to hinder true social progress. To the medical profession is committed the great trust of studying and analyzing these mild but infinitely dangerous types of warped mentality. On the profession must rest some at least of the responsibility of continually restricting the influence on the public of these diseased minds.

NO COMMERCIALISM IN SWEDEN.

The medical profession in Sweden enjoys a most enviable existence, if we are to believe a writer in the *British Medical Journal*. This gentleman writes to call attention to the commercialism which he thinks is too prevalent in England, especially objecting to the habit of putting up one's own prescriptions, selling and buying practices, etc. As a contrast, he calls attention to the professional sensitiveness of the Swedish doctors, who do not even send bills for their attendance. "Most Swedish families send their doctor a check once a year; the amount varies according to their means. The doctor does not send a receipt but simply his card, 'with many thanks and wishes for a happy New Year.'" This, we repeat, indicates a very enviable condition for the Swedish doctor, but we are afraid it would not "go" here. We opine the butter would be very thin on the bread of the average practitioner, if the bread itself did not finally come up missing, were the Swedish method adopted in this country. However, the idea is a beautiful, yes, an ideal one, and if some of our readers will adopt it for a few years and report, we shall be delighted to publish their experiences.

"FORCED" EDUCATION.

The damage to the nervous organization of the child, and the generally disastrous effects of forcing in the school curriculum, have been often remarked, but the evil still continues. The *N. Y. Medical Journal* (September 16) notices with approval an address made before a provincial Canadian medical society last summer, in which this subject was taken up. The special point made was that the course of study should be carefully adapted to the average, or rather, the under-average child, and this both as regards mental and physical development. "Fundimentary education is all that the community should set peremptorily before the mass of children; those who have the capacity for more ad-

vanced education are few in number, and their aspirations may well be met by a few high schools." These are truths, we might better say truisms, but our educational authorities do not always seem to regard them, and their repetition can not well be too emphatic. With all our boasted intelligence, we might as well recognize the fact that mediocrity is the rule and talent and genius are the exceptions. We can not follow the *Journal*, however, if we understand it correctly, in its view that the same evil exists to a flagrant extent in our medical schools. The errors of the medical curricula—and they may be numerous enough in the present transition state of medical education—are not that they are too thorough and advanced. Up to date they have not been advanced enough. Nor do we want a low average in our profession, something above mediocrity should be the aim. The foolishness of "forcing" has not yet revealed itself in American medical education.

AN ENVIABLE PRINCIPALITY.

We are not accustomed to think of an Indian prince, ruling some tributary state in British India, as a man of advanced ideas. In the *Indian Medical Record*, however, we read that the Thakore Sahib of Gondal, the ruler of a principality of some thousand square miles, is a medical graduate of Edinburgh University and the author of a medical work; that in his dominions sanitary regulations are thoroughly carried out, vaccination enforced, hospitals and dispensaries maintained, and an efficient health organization that enforces local sanitation and reports reliable statistics exists. Inquests are made over every accidental, violent or suspicious case of death, food and water infection, etc., in short, everything apparently that we expect to find in all these particulars in a highly civilized Caucasian community. The only Oriental feature in the report is the order to remove a village bodily from an unhealthy locality to a better one, which was carried out and "hailed with delight by the villagers concerned," who received "every facility, pecuniary or otherwise," in the removal. Notwithstanding the fact that the principality appears to be within the plague-stricken section of India, it has escaped the pest, owing to the extreme precautions taken. It has an increasing birth-rate, with a decreasing death-rate to top off its sanitary prosperity. Agriculture is aided by the government, which maintains public gardens and an experimental farm, and there is an "agricultural association" under its direct patronage. The exports are increasing and the imports decreasing, while the gross public revenue exceeds expenditures nearly 50 per cent. If all the minor states in British India were like the one here described, that section of the world would be a most enviable one in many, if not all, respects.

VENEREAL DISEASE AND THE BRUSSELS CONFERENCE.

The discussion of regulation of venereal diseases at the Brussels conference of social hygiene, September 4 and 5, was notable for the number of participants and the very widely differing views expressed. As the report in the *British Medical Journal* states it, no decision of any kind was arrived at in the two days' discussions, it

having revealed the greatest differences of opinion and the utter absence of any trustworthy data for the formation of sound conclusions. Statistics were handled freely on both sides; there was no lack of authority in favor of either of the combated views. The zeal of the speakers is evidenced by the fact that calls to order by the president appeared to be frequent. It is perhaps to be regretted that the expression of opinions was not confined to medical men, as the participation of lay advocates of abolition of supervision detracted somewhat from the purely scientific character of the discussion. The differences of opinion, however, among high medical authorities, were great enough to demonstrate that the question is still an unsettled one, and to leave it open for further study. The main point seemed to be confined to the spread of syphilis, and it was admitted that some statistics showed that regulations had not affected the frequency of chancroid and gonorrhoea. Since, according to modern medical theories, gonorrhoea is hardly, if at all, behind syphilis as a danger to public health, this is a serious fact—if it is a fact. Regulation that only suppresses syphilis does only half or less than half its work. Considering all things, any system that supervises only one sex is inefficient; an infected man is as much a source of danger as an infected woman and, as an active rather than a passive agent, even a greater peril to public health. We are not much surprised, therefore, at the character and outcome of the discussion. We shall await the publication of the final conclusions of the conference with some interest.

DR. OGSTON'S CRITICISMS.

The English people, while comparatively pacha, dermatous as regards criticism from without, do not take kindly to public acknowledgements of their faults from home sources, even in a modified and comparatively harmless way. Dr. Ogston's recent address on the faults of the British army and navy medical services has therefore stirred up something of a wasp's nest sort of turmoil. Army and navy surgeons are inclined to resent some of his criticisms, and medical men in civil life have found some features of his address unacceptable. We wonder what the British public would have to say to such rampant criticism of all kinds as everything in our late unpleasantness with Spain received from responsible and irresponsible writers last year. It would be a new experience to them, but we can dismiss it from our imaginations as an impossibility in any country but our own. The saving fact is that we know how to take it, though we are altogether too negligent as to the reputation it gives us abroad. Apropos to the above, a recent letter to the *London Times* has again stirred up our British confrères on the subject of secret commissions. Public charges have been made, not too well supported, it is true, but such as are likely to impress the lay mind, and the profession therefore naturally resents them. There are mercenary individuals in every profession, and some of these are beyond doubt to be found among British physicians, but they are there, as here, the exceptions and not the rule. Wholesale accusations fall of their own weight; they are incapable of proof and their effect is only temporary. It does not seem to us that the charges of Sir Edward Fry need cause

our British professional brethren any serious anxiety, but should only quicken their ethical instincts to avoid even the most innocent contaminations with the prevalent commercialism of the day. We in this country have abundant evidence of this necessity.

RHEUMATIC FEVER WITHOUT ARTHRITIS.

The symptoms of disease may be looked on as an expression of the reaction between the causative irritants and the invaded body. In most cases the irritants are micro-organisms, which sometimes cause local lesions at the site of entrance into the body, and almost invariably give rise to the generation of poisons, to the activity of which often the most pronounced phenomena of the disease are due. Febrile multiple arthritis may result from numerous causes, and it is possible that what is clinically designated acute rheumatism may have a like diversity of origin. Such evidence as exists indicates that acute rheumatism is an infectious disease, but, although a number of micro-organisms have been found in the articular and complicating lesions, there is as yet no agreement as to a specific etiologic factor. While the arthritis is generally considered the most characteristic manifestation of acute rheumatism, it can be conceived that the disease may exist without articular manifestations. These must be viewed as dependent on the activity of the causative micro-organisms or their toxins, and it requires no stretch of the imagination to believe that for some unexplained reason the joints may resist the invasion of the irritants, although pain, fever, and sweats may be present. Of the possibility of such an occurrence, evidence is afforded by a case reported by Hawthorne¹: A woman, 18 years old, had for several days been complaining of headache and aching in the back, with thirst and want of appetite. Her throat was sore and the temperature was 103.6 F., and the fauces were congested. The knees and shins were tender on pressure, and the skin was moist. The febrile temperature continued for a week, when it became subnormal. Two weeks later the patient complained of acute pain in the right knee, and the joint soon became distended with fluid. This condition improved under rest, and the patient was shortly dismissed quite well. It is known that acute rheumatism may attack a single joint, and it has also been pointed out that the tonsils probably constitute a common portal of entry for the hypothetic micro-organism of the disease, so that, in the case reported, there is no sufficient reason for excluding the diagnosis of acute rheumatism, although the attack proper was unattended with articular symptoms.

Medical News.

FIRE destroyed St. Vincent's Hospital, Norfolk, Va., recently, and five patients lost their lives.

THE ONTARIO Medical Council building, Toronto, is for sale; the price being asked is \$100,000.

OUR RUSSIAN exchanges announce that the small epidemic of supposed plague in the Astrachan district has died out.

DR. GEORGE W. GROVE, Kansas City, Mo., has gone,

and Dr. J. H. Austin, of the same city, will now go, to New Mexico.

AMONG the charitable bequests of the late E. Ray Thompson, Troy, N. Y., is a gift of \$5,000 to the Child's Hospital at Albany.

GRACE CHURCH, Winnipeg, at the sacramental service on the evening of September 17, adopted the system of individual communion cups.

DR. G. FRANK LYSTON, Chicago, was recently operated on in New York City, for appendicitis. He has gone to Florida to recuperate.

BY THE will of William J. Pinkerton, who recently died in Mt. Joy, Pa., \$1000 has been left the Presbyterian Hospital of Philadelphia.

DR. PEARCE KINTZING, B. Sc., has been elected professor of anatomy and clinical surgery at the Woman's Medical College, Baltimore, Md.

DR. J. CLARENCE WEBSTER has returned from abroad, to enter on the duties of his recent appointment to the chair of obstetrics and gynecology in Rush Medical College, Chicago.

THE LAYING of the corner-stone of the Lucien Moss Home for Incurables, Philadelphia, took place September 22. Many prominent physicians took part in the opening exercises.

W. W. FORD, B.A., Adelbert College, M.D., Johns Hopkins, is associated with Dr. McCrae as being one of the first holders of the newly founded research fellowships in pathology, of McGill University, Montreal.

A COMMITTEE has been appointed by the Philadelphia County Medical Society, to confer with the mayor of Philadelphia, relative to the growing practice of blocking the public streets to physicians on their round of duty, by parades, etc.

IN A RECENT ruling made by Judge Buffington of Philadelphia, in the case of Howard Butler and Joseph Wilkins for alleged violations of the oleomargarin laws, the decision is in favor of the Federal Government, and a penalty has been assessed.

DR. WILLIAM A. DAVIS, Baltimore, Md., has been appointed assistant instructor in histology and biology at the Baltimore Medical College. Dr. Davis has been assistant demonstrator of anatomy there for several seasons, being also engaged in practice.

DR. PROCTOR, Kamloops, B. C., is stirring up that town to a better and more efficient sewerage system. A system of cesspools is being constructed there, and he advocates some system of inspection as to where these are to be placed and how they are to be built.

THE AMSTERDAM Congress appointed an international committee on obstetric nomenclature, including Trub, Bar, La Torre, Rapin, Queirel, De Rein, Davis, Edwards, Simpson and Freund. Bar is to report to the obstetric section at the International Congress of 1900.

A NEW departure has been made in the Baltimore Medical College, in the adoption of physical instruction and athletics. Dietrich Stolte, formerly of the Bangor (Me.) Training School, has been elected physical instructor, and a gymnasium will be secured, and football and other teams organized.

ACCORDING to the *Argonaut*, a wealthy Russian named Astroff, who recently died, left (1,000,000 roubles) \$500,000 toward the foundation of a university for women in Moscow, to comprise a mathematic, scientific, and medical faculty. The Municipal Council of Moscow

¹ Practitioner, September, 1899, p. 278.

has voted an annual grant of (3000 roubles) \$1500 to the institution.

COUNT K. BRANICKI, Warsaw, has donated an estate and over two hundred thousand roubles in money to found an establishment for the shelter of incurable and cancer patients, with a further endowment of twelve thousand roubles a year, according to *St. Petersburg Med. Week.*, September 9.

IT WILL BE a year October 23 since young Dr. Mueller lost his life in the "laboratory plague epidemic in Vienna." An imposing memorial to him will be unveiled on that date, in the grounds of the General Hospital opposite Nothnagel's clinic, the expenses defrayed by subscriptions from the profession.

AT THE FIFTIETH anniversary of the Woman's Medical College, Philadelphia, to be held next spring, an interesting feature will be the presentation of a portrait of the late Dr. Ann Preston, who was a member of the first graduating class, and subsequently of the college faculty, and the first woman to hold the office of Dean.

A RECENTLY graduated French M.D. is the Reverend Dr. Migot, pastor of a large protestant parish in the Faubourg Saint-Antoine, Paris. He replied to the question whether he were going to give up the cure of souls for the cure of the body, that there is no antagonism between them, and that he intends to practice both.

ST. JOHN, N. B., has received word from the Minister of Marine and Fisheries, that the marine hospital of that city will be handed over to the civic authorities, immediately, for the purpose of a home for incurables. In connection with this, Mr. Ellis, M. P., and Dr. Walker, have been sent to Toronto to investigate the working of a similar institution in that city.

THE FOLLOWING changes in the faculty of the Maryland Medical College, Baltimore, are announced: Richard L. McNear, associate professor of histology, pathology and bacteriology; S. Griffith Davis, associate professor of anatomy and clinical surgery; J. T. Burkhalter, associate demonstrator of anatomy; Alex. McKee, demonstrator of histology and pathology.

EVER SINCE the microbe of bubonic plague was discovered, the Paris Institut Pasteur has been studying and producing the antipneumonic serum in readiness for an emergency, and Metchnikoff informally states that sufficient is on hand to supply the needs of Europe for the moment, without encroaching on the reserve for home use. Its efficacy is well established.

AT A meeting of the New York State Board of Health, held in New York City, September 22, resolutions were adopted approving of the establishment of special hospitals for tuberculosis, in connection with large cities, and urging the state legislature to enact the necessary legal measures for the organization and maintenance of such institutions under municipal control.

THE NEW Institut de Biologie, at Paris, will be in operation by the end of the year, another memorial to Baroness Hirsch, who presented nearly a half million for the purpose, says *Gaz. Med. de Paris*. It is built in the same style as the adjoining Institut Pasteur, but is much more extensive, reaching from the rue Dutot to the rue de Vaugirard, and containing a large amphitheater and a series of vast laboratories.

PHILADELPHIA begins to take hope in its conquest of bribed aldermen, ignominious politics, and foul water, with which it has been afflicted for so many years. After long months of waiting, the mayor has been furnished with the report of the experts, recommending that sand

filtration be instituted. It is hoped Councils will recommend the passage of an ordinance providing for a loan of \$12,000,000 necessary for sand filtration.

THE COLLEGE OF PHYSICIANS AND SURGEONS, Baltimore, will reopen October 2, with the extensive improvements costing \$100,000 nearly completed. The old college building has given place to a modern one, and there will be a house-warming at the opening of the course. The two new members of the faculty are Dr. Wm. F. Lockwood, chair of therapeutics, and Dr. L. R. Trimble, anatomy.

FOR SOME time past rabies has been very prevalent in Erie County, N. Y., and on September 19 the State Commissioner of Agriculture placed the entire county under quarantine. In the notice promulgated, he warns all persons to seclude, for a period of sixty days, in or on the premises where they are kept, all dogs and other domestic animals which are susceptible to the disease, and which may in any way have been exposed to it.

JOHN McCRAE, B.A., M.B., late fellow in biology at Toronto University, and sometime resident physician on the staff of the general hospital of the same city, has been appointed to the research and teaching fellowship in pathology at McGill University, Montreal. He was graduated in 1896 as gold medalist from Toronto University, and immediately became resident physician at the Garrett Hospital for Sick Children, Mount Airy, Md.

ACCORDING to the *Medical News*, September 23, there is a likelihood of a breaking down of the quinin trust organized by German manufacturers. This trust had its culmination through a movement said to have been started recently by leading cinchona planters of Java for the purpose of keeping the raw material out of the hands of the syndicate of manufacturers. There seems moreover to be no good reason why the United States should not get both the cinchona bark and the sulphate of quinin direct from Java, and thus avoid the trust.

IT IS stated that two druggists of York, Pa., recently entered into a lively competition regarding the sale of morphin, and one of them offered the drug as low as 15 grains for 10 cents. As a result of the increased consumption, at the low price, many young men have become addicted to the habit. The local press states that there are 100 habitués. A crusade has been made against the sale of the drug, owing to the death of one of the prominent young men of the town, which followed a hypodermic injection administered by a friend.

THE PROSPECT of San Francisco at last getting a new City and County Hospital seems good. The Board of Supervisors has signified its willingness to grant an initial appropriation of \$50,000, and the Board of Health is considering the question of plans. Judge Hunt, of the superior court, has decided that under the existing statutes the Board of Health may appoint as many assistants as in its judgment are necessary, and that the auditor will have to audit the bills. Consequently we may expect to see the merry quarantine war once more on the carpet, on the first good opportunity.

ACCORDING to the *Gazzetta degli Ospedale* (Milan, September 12), a number of cases of the plague have occurred in France, at Marseilles, Havre, Bordeaux and even at Paris, and refugees constantly arriving from Egypt and India are a constant menace, especially traveling variety shows, etc., which, finding no audiences in the infected regions, are all flocking to Paris. It concludes: "The efforts to keep the secret have been enormous and

have been crowned with success to date, the French Government proclaiming that the public health is excellent, but the army maneuvers in the West have been suspended and tourists are rapidly leaving Paris."

THE ONE HUNDRED AND FORTY-EIGHTH annual report of the Board of Managers of the Pennsylvania Hospital, Philadelphia, issued during the week just passed, reviews the part taken by this institution in the relief of soldiers treated during the late war, the total number treated being 326. To meet the increased attendance required in the additional wards, all of the medical staff offered their services. The number of resident physicians, only four four years ago, has now been increased to eight. Since the foundation, in 1751, there have been 143,788 patients admitted to the wards, of whom 99,887 were supported at the expense of the Hospital. Since the reorganization of the out-patient department, in 1872, 187,112 out-patients have been treated, making 713,874 visits.

THE LIBRARY of the medical department of the University of California is now properly housed, properly cared for, and is being rapidly catalogued and extensively indexed. It already contains some 2000 bound volumes, including complete files of many journals, such as *Virehow's Archiv*, *Schmidt's Jahrbuch*, the *Lancet*, etc., and a large and valuable collection of pamphlets, over 6000 in number. The librarian, Dr. Philip Mills Jones, respectfully requests that books, pamphlets, journals, etc., may be sent to the library; proper recognition will be made at once and the material will be well looked after. If necessary, and where no provision is made for transportation, parcels may be sent collect. Address the library of the medical department, University of California, San Francisco.

AGNEW'S INSANE ASYLUM, California, is having a sort of two-ring circus. Dr. Sponogle, who was dismissed from the position of superintendent, as previously noted in the JOURNAL, now refuses to give up the command to his regularly, or as he claims, "irregularly appointed" successor. There are, therefore, now "two superintendents" at the asylum, both giving orders, both signing papers, and both, quite amicably, carrying on the business of the institution. The courts are being kept busy with the legal difficulties of the superintendent, or the ex-superintendent, and the Board of Trustees; an injunction was issued, has been argued and dismissed, but Dr. Sponogle still refuses to be dispossessed and will not give up the keys. As soon as the present crisis no longer demands his attention, he says, he intends to file the \$100,000 damage suit against the governor.

CALMETTE and Salimbeni, officially delegated by the Paris authorities to study the plague at Oporto, confirm Jorge's diagnosis and the extreme virulence of the germs. They were inoculated with preventive injections of anti-plague serum before starting, and report that the three cases they have treated with the serum are all convalescing. In a communication to the Paris lay press (*Figaro*, September 11), they state that the epidemic may last months, or even years, at Oporto, without increasing in intensity. They claim that the plague should be regarded as an infectious disease propagated by certain conditions of poverty and filth, the same as typhoid fever by contaminated water. There have been sixty-four cases in Oporto, all among the working classes, with twenty-six deaths, to September 9. The unsanitary conditions, lack of sewers, etc., invite almost any disease. All the members of the profession, local and foreign, denounce the sanitary cordon around the city as ineffectual and ill-advised, a barbarous measure resulting only in

increasing the financial distress and famine in the city and thus fanning the flame of infection.

Correspondence.

The Government Hospital for the Insane.

BRIDGEWATER, MASS., Sept. 19, 1899.

To the Editor:—In the JOURNAL of September 2, an unsigned letter was published, under the above heading, which, for fairness' sake, I wish to review. The ostensible object of the letter was to express condemnation of a "vicious" system of appointment, which, according to the writer, secures incompetent men as chief executives of insane asylums.

If the writer's premises were correct, if it were a fact, that "few of them (superintendents) before appointment, have had either practical or theoretic experiences in the treatment of mental or nervous disease," he would deserve the thanks of the profession generally, and particularly of those assistant physicians who are doing painstaking medical work in the hospitals for the insane, for his so-called "arraignment" of their chiefs. But because his premises are only true in exceptional cases, his conclusions are invalid.

A brief letter is sufficient to formulate a long list of aspersive propositions reflecting on other physicians, if no attempt to produce proof is made. If it is counted ethical and honorable, among specialists, to publish unsigned letters extolling their own class and deprecating others, it may harmonize with the same sense of "judicial fairness" to leave the burden of proof on the "arraigned."

It is fair to assume that every physician giving his energy and his best days to the care of the insane has a natural regard for the respect and good-will of his brother physicians. It ought to be remembered that the young man who begins his professional life as a junior assistant in a hospital for the insane is as well qualified as he who enters on any other line of medical work. In New York, and some other states, he has been the successful candidate in a rigid competitive examination. In other states he is chosen from the best available material, and is promoted according to experience and competency, as vacancies occur. His duties are more nearly akin to that of the general practitioner than to that of any specialist, because of the fact that the symptom-complex we call insanity is as often dependent on, or aggravated by, disease of the digestive, respiratory or reproductive system, that to treat mental alienation successfully, means to intelligently treat all the diseases to which human flesh is heir.

The asylum physician, as a rule, is well acquainted with such standard authors as Gowers, Dana, Starr, Spitzka and Clouston, and is seen fairly well posted in general medicine. He depends for his reputation, limited as it may be, on devoting himself to the many unfortunates who look to him for daily cheer, as well as relief from bodily ills.

Experience has proved that the natural rule has been most successful, that the best superintendents have been those who have served from junior assistant physicians to assistant superintendents. Departures from this common rule are becoming less frequent. When your correspondent asserts that "no one ever connected with an insane asylum has made any important discovery regarding the brain and nervous system, he echoes the personal opinions of a prominent neurologist, from whose public address, a few years ago, he presumably gets his cue. As "important discovery" is a relative phrase, the ungracious allegation can not be met in positive terms.

When he seeks to make the general profession believe, by insinuation, that the representative superintendent is capable of telling the court, that "there is no such thing as nocturnal epilepsy; that quinia has no effect on the brain; that heredity is not a factor in insanity, etc.," we wonder what considerations could induce an honorable physician to adopt such methods. If he ever knew a superintendent to so testify, would not every impulse of fairness and honor suggest that it be pointed out as an anomaly, rather than representative of the medical knowledge of the asylum physician?

Does he not know that nearly every insane hospital report emphasizes the importance of heredity as a factor in insanity,

and that "hysterical insanity" will be found in the classified list of forms of mental alienation in almost every case?

The truth is, psychiatry, as an art must include the science of economics, as well as the science of neuropathology. It has advanced by a process of evolution, rather than by startling discoveries. It is no dishonor to psychiatry that it must utilize, to the best advantage, the fruits of the field, water, fresh air and sunlight, nor does it reflect to the disadvantage of the asylum superintendent that, after serving several years as assistant physician, he delegates the bedside attendance, the prescribing of drugs, the examination of urine, blood and sputum to the younger men; to assume the duties of executive director and consultant.

To maintain a healthy discipline, to wisely select department heads, to protect the tax-payers from wasteful extravagance; to encourage the scientific efforts of the younger medical men; to follow the varying mental condition of the acute cases admitted, and to defend the interests of the insane against ward politicians, are not all purely medical functions, it is true, yet hygiene and preventive medicine are such important elements of the whole, that one is not the less a physician if he performs these manifold duties well.

C. A. DREW, M.D.

"A Possible Check to Quackery."

WASHINGTON, D.C., Sept. 19, 1899.

To the Editor:—I have the honor to acknowledge the receipt of your letter of the 31st ult., inclosing a newspaper slip relative to the liability to the internal revenue stamp tax of remedies furnished to patients, by physicians and companies who advertise in the public prints their ability to cure the various diseases incident to the human body, and requesting to be fully informed as to the rulings of this office on the subject.

In reply I inclose you a copy of Circular 501 Revised, dated Jan. 24, 1899, containing the regulations of this office as to the liability of medicinal preparations to the stamp tax under Schedule B, Act of June 13, 1898. On page 5 of said regulations will be found a ruling that the tax is also imposed on the following:

All mixtures or prescriptions by whomsoever sold, the demand for which is created by circulars, circular letters, or public advertisements, and which by reason of such solicitation pass through the mails or express office to the consumer. This includes preparations made by physicians or other persons who seek patronage by post-office or by printed circulars or advertisement, or who solicit the afflicted by means of classified lists of afflicted persons.

This office having been reliably informed that the method indicated above, of soliciting the patronage of the sick and afflicted, was being extensively employed throughout the country by physicians who failed to stamp the remedies furnished, the attention of collectors and revenue agents was recently called to the matter with a view to a more thorough enforcement of the law.

The only difficulty in enforcing the law in this respect has arisen from the difference in the manner employed by the advertising physicians in collecting the amount charged for medicines.

In the first place, it must be stated that this office does not assume to tax in any manner the sum received for professional services by any physician.

Among the physicians advertising as above indicated, there appear to be three methods of making charges, as follows: 1. A specific charge is made for services and a specific charge is made for the medicines. The case presents no difficulties, as the medicines must be stamped according to the amount charged for them—unless manifestly and intentionally inadequate—and no account made of the services. 2. Where nothing is charged for the services, and the only charge is made for the medicines. In this case the medicines are to be stamped according to the price fixed by the physicians. 3. Where the advertising physicians profess to furnish medicines free to patients and only charge for advice. In such a case this office rules that payment for the value of the medicines is included in the sum charged for advice. The amount charged for the medicines can be segregated from the amount charged for advice by the physician making the charges, if he so desires, but if in any case the advertising physician refuses to separate the

charges, the whole amount charged will be estimated as the price of the medicines, and the tax will be computed accordingly, under the authority conferred on the Commissioner of Internal Revenue by the provisions of Sec. 3437, Revised Statutes of the United States.

In conclusion I will state that where an advertising physician professes only to give advice in regard to the treatment of diseases and furnishes no medicines or remedies, either directly or indirectly, no tax accrues under the Internal Revenue Laws.

Respectfully,
G. W. WILSON,
Commissioner.

See JOURNAL, September 16, p. 738.

Gall-Stones.

NEW YORK CITY, Sept. 15, 1899.

To the Editor:—The enclosed tabular statement of my operations on the common-bile duct has been omitted from my article on "Gall-stones," published in the JOURNAL of September 16.

Age.	Date.	Gall-Bladder.	Calculi.	Duct Sutured.	Leakage.	Result.
1. Mrs. J. M. 42	Feb. 19, 1885.	Thickened, Size 1 large and 2 small.	Size 1 large and 2 small.	Yes.	None.	Recovery.
2. Mrs. B. B. 37	May 1, 1885.	Thickened and shrunken.	1 large.	Yes.	Yes.	Died fourth day. Pneumonia.
3. Mrs. E. H. S. 37	Oct. 27, 1895.	Distended.	1 large.	Yes.	None.	Recovery. At time of operation patient was very weak.
4. Mrs. T. L. 41	Feb. 18, 1897.	Distended.	1 large.	Yes.	For 18 days.	Recovery. Patient died of an abscess of the neck. She did not abort.
5. Mrs. R. H. 50	May 29, 1897.	Thickened and shrunken.	2 large.	Yes.	Slight for 31 days.	Recovery.
6. Mrs. E. D. 60	Jan. 18, 1898.	Thickened and shrunken.	3 large.	Yes.	Slight for 45 days.	Recovery.
7. Mr. P. D. 60	Jan. 18, 1898.	Thickened and shrunken.	2 large.	Yes.	For 22 days.	Died on second day of pneumonia.
8. Mrs. E. J. 32	May 19, 1898.	Thickened and shrunken.	Size 1 very large.	Yes.	For 15 days.	Recovery.
9. Mrs. N. 59	Aug. 10, 1898.	Thickened and shrunken.	3 large.	Yes.	For 15 days.	Recovery.

CHOLEDOCHOTOMIES.

This omission occurred because of failure to correct the proof, owing to my absence. Will you kindly publish the table and oblige.
Yours, very truly,
A. J. McCOSH, M.D.

Canada.

(From Our Regular Correspondent.)

TORONTO, Sept. 23, 1899.

ONTARIO'S HEALTH IS BAD.

The Provincial Health Board has just issued its regular monthly bulletin, which shows that there were in the Province no less than 2069 deaths recorded in the month of August, the returns being derived from over 75 per cent. of the total population. This shows an increase of 426 over the preceding month of July. Deaths from typhoid fever and whooping-cough are more than for any month during the last four years. In Aug-

ust, 54 persons died from typhoid fever, while in 1896, for the same month, the deaths were 46; in 1897, 22; in 1898, 34. Fifteen deaths are reported from whooping-cough, 3 more than for the corresponding month of last year. The total number from contagious diseases is 269, 59 more than in July; of these, 171 were due to tuberculosis. The drouth of last month has had a direct effect in the production of the typhoid cases, the wells having become dried up, and the drinking water as a consequence rendered impure. The recent rains have exercised beneficial effects noticeable in a reduction of the disease.

JUBILEE HOSPITAL, VICTORIA, B. C.

The Board of Directors of this institution met on the 11th inst. On January 14, last, a committee was appointed to devise ways and means for the erection and maintenance of a children's ward, a maternity ward, a residence for the medical officer, increased accommodation for the nurses, the completion of a sewerage system, the draining and beautifying of the hospital grounds and the promoting of such other necessary adjuncts, with the adoption of modern appliances, as would place this institution in the van of similar hospitals. This committee reported at length at the aforesaid meeting; and the report was handed over to the printing committee, to be combined with the annual report of the Board. It further suggested that the government grant should be doubled, and this was strongly supported by many of the members of the Board, as they considered that the hospital was more provincial in its character and work than a mere local civic institution. The medical health officer, Dr. Hasell, reported that the daily average of patients was 42.35, the total days' stay was 1373, and the average cost \$1.28. His Excellency, G. Digby Barker, C. B., commander-in-chief and governor of the Bermudas, wrote thanking the authorities for the excellent treatment Mrs. Barker had received there; and enclosed his check for \$100, to be applied to the women's auxiliary fund.

MORTALITY FROM INFANTILE DIARRHEA.

Winnipeg is congratulating herself on the fact that the mortality this past summer has not been so great as in previous years. Last winter the question of a pure milk-supply was agitated, with the result that the Copenhagen system was adopted to a considerable extent, and the resulting decrease in infant mortality has proven the wisdom of the agitation. The city further calls on the authorities to enforce the by-laws with regard to milk inspection, etc.

As regards Toronto, in 1897, for example, 31.23 per cent. of all deaths were under 1 year, and 5.15 per cent. of all occurred from diarrheas, under 1 year. The total number of deaths from diarrheas under 1 year was 161, out of 977 deaths all told, i. e., 16.48 per cent. These figures compare very favorably with those of the large American cities. A perusal of a table of figures prepared by the registrar-general's department shows that July, August and September are notoriously bad months, mostly for those in the first year of their existence. From 1894 to 1898, inclusive, the total number of deaths in these three months was as follows: July, 278; August, 273; September, 156. The totals in the other months were as follows: January, 1; February, 8; March, 4; April, 8; May, 11; June, 45; October, 61; November, 13; December, 15. Inspection of the table as regards age is equally interesting: First year, in 1897, 173; in 1897, 161; in 1896, 150; in 1895, 178; in 1894, 136; second year, in 1898, 9; in 1897, 10; in 1896, 0; in 1895, 0; in 1894, 0; third year, in 1898, 1; in 1897, 1; in 1896, 9; in 1895, 18; in 1894, 26.

As regards the whole province of Ontario, the total number of deaths from all causes—still keeping to the same year, 1897—was 25,307; and of these, 1082 were due to cholera infantum and infant diarrheas, i. e., 1 in every 25 deaths in Ontario was due to this disease. Commencing with January, consecutively, these are the numbers: 13, 18, 14, 13, 12, 52, 166, 338, 293, 103, 25, 18. By ages: first year, 925; second year, 121; third year, 11; fourth year, 25. Since 1897, the Health Department of Ontario has had the Bertillon system in use, and it has proved eminently satisfactory.

THE MEDICAL ALLIANCE OF CANADA.

This "association," "institution" or "concern" has been and is at the present time exploiting the profession and the general public in Montreal, soliciting on all sides for the people to enroll themselves in its membership. It claims to be "a con-

clave of physicians and surgeons organized for the purpose of supplying medical attendance and medicines in sickness or accidents for a small weekly investment." Certain inducements are held out to the physician if he will only become a member of the society: 1. The physician shall receive at least one dollar for every visit paid to every member of the alliance. 2. He will still have the privilege of attending his own private patients—provided they, too, are willing to become members of the society—the members being allowed to select any doctor connected with the society, to attend them. 3. As there are many persons joining, who have no regular physician, these individuals will become patients of the various doctors connected with the alliance. 4. The principle on which the physician is paid for his services is completely the opposite to the ordinary benefit society and free from the objections arising from that system. Now, what do these people offer the public to join? "For the small sum of 10 cents, weekly, they will be entitled to call in any of the physicians or surgeons of the alliance at any time for the slightest cause," and the doctor "will supply the necessary medicines free of charge." When ten years have elapsed each member will receive back \$52, thus getting medical attendance and medicine all that time for nothing. Here is a paragraph, taken from the agreement between the society and the doctor, who is to become a member: "For and in consideration of such services the first party (the alliance) agrees to compensate the said second party (the doctor) as follows: To place in a fund to be known as the "Medical Expense Fund" the sum of 12 cents, monthly, for each and every member entitled to the above mentioned attendance and medicines as shown by the books of the alliance, and to divide the sum total (monthly) by the total number of visits made and reported by the physicians of the district, which division will show the actual amount due each physician for each call made; but in no case shall any physician receive an amount in excess of two dollars for each house-visit and one dollar for each office call (which amount will include the cost of medicines furnished), and the excess, if any, will be carried over to the succeeding month; and if, on the first day of January of each year there still remains a surplus, the same will be divided equally among all the physicians employed by the alliance *pro rata* to the number of calls reported during the preceding year." The following is a paragraph relating to an ordinary member: "In consideration of the prompt payment of 10 cents weekly, John Smith shall be entitled to medical attendance and medicines from any of the physicians of the alliance, in case of sickness or accident of any kind except chronic or venereal diseases or diseases not common to both sexes. And in further consideration of the prompt payment of the amount above mentioned for a period of or exceeding ten years, the said member will upon surrender of this book at the office of the company be entitled to a sum in cash not exceeding the amount stated in the following 'table of values' (\$52 at the end of ten years) as his or her proportion of the profits of the alliance." When any member of the profession in Canada is approached by the agents of this alliance, they should be careful to read the following on the reverse side of the contract: "Failure to make payments for thirty days will cause the agreement to be lapsed, void and of no effect." If on joining, the physician gets dissatisfied with the affair, he can terminate his connection at any time under the following ambiguous rule: "This agreement will terminate January 1, —, or may at any time be terminated by the mutual consent of the parties thereto." It will behoove the profession in Canada to make a careful examination of the whole subject before they allow themselves to be duped into becoming connected with any such undertaking. The *Montreal Medical Journal* for September gives a clear and clever criticism of the whole affair.

New Instrument.

INFLATING RECTAL SPECULA.

BY J. RAWSON PENNINGTON, M.D.
CHICAGO.

The various rectal specula at my command, together with the advantages of atmospheric pressure not being adequate in many cases to inflate the bowel sufficiently to obtain a

satisfactory inspection, I have devised a set of inflating rectal instruments, and have demonstrated their superiority in investigating the lower intestinal tract. All of the specula in the practical set have a common diameter of 21 mm., except the anoscope, which is conical, being 30 mm. in diameter at the junction of the flange and cylinder. Its cylinder is 5 cm. long, that of the proctoscope 12 cm. The distinctive features are the cap (C) and the tube (T) for connecting the insufflator (I).

Technique.—The obturator (O), being placed in the speculum (S), is warmed and well coated with vaselin. When introduced into the bowel, the obturator is withdrawn and the cap (C) thoroughly screwed on the flange. The nozzle of the insufflator (I) is then pushed firmly into the tube (T). By compressing the bulb and, at the same time, with the aid of reflected light, looking through the glass window in the cap, you will notice the bowel becoming distended, when it can be thoroughly inspected and examined. The entire colon may be inflated for diagnostic purposes if desired. A part, only, of the air escapes on removal of the cap, the bowel remaining more or less distended. These instruments were manufactured for me by Sharp & Smith, Chicago.

Deaths and Obituaries.

G. A. HENDRICKS, M.D., professor of anatomy in the University of Minnesota, died of acute Bright's disease, September 24, in Minneapolis. The Doctor went to Minneapolis in 1889, from the University of Michigan, where he had been an assistant in the department of anatomy.

WILLIAM HEMBEL TAGGART, M.D., Reading, Pa., died September 20, aged 70 years. Dr. Taggart was born in Winchester, Va., July 15, 1830, and graduated from the University of Pennsylvania in 1849, when he became resident physician to the Philadelphia Hospital, where he remained one year, subsequently finishing in the hospitals of Paris. In 1857 he was elected to the chair of materia medica and therapeutics in the Philadelphia College of Medicine, and in 1859 was appointed to the same chair in the Pennsylvania Medical College. At the outbreak of the Civil War, Dr. Taggart was appointed surgeon of the Tenth Regiment, Penn. infantry, and later surgeon of the Second Regiment, Penn. cavalry. Ill health compelled his resignation. For ten years he was surgeon of the Philadelphia City Troop, and for many years he was a member of the Philadelphia College of Physicians and of the Academy of Natural Sciences of Philadelphia.

W. H. BALTZELL, M.D., Frederick City, Md., died of heart disease on September 12, at the age of 67 years. The Doctor was a graduate of the University of Pennsylvania, class of

1854, and in 1855 practiced in Chicago, but returned to Maryland on the breaking out of the Civil War.

L. L. BENNETT, M.D., Harpersfield, Ohio, died September 17. . . . GEORGE M. BUTLER, M.D., Wellsburg, Va., September 12, aged 77 years. . . . E. P. CARTER, M.D., Orangeville, Ind., September 17. . . . RUDOLPH HANSEN, M.D., Woodstock, Ill., September 15. . . . C. K. HARRIS, M.D., Iager, W. Va., September 19. . . . E. P. HENDERSON, M.D., Zanesville, Ohio, September 12, aged 42 years. . . . H. C. HUBBARD, M.D., Bloomington, Ill., September 24, aged 53 years. . . . JOHN M. McNULTY, M.D., Fort Dodge, Iowa, September 14, aged 75 years. . . . HENRY NORTON PORTER, M.D., Washington, D. C., September 12. . . . EDWARD L. REEVES, M.D., Paulsboro, N. J., September 21, aged 68 years. . . . J. C. ROBERTSON, M.D., Council Bluffs, Iowa, September 12, aged 54 years. . . . GEORGE WOODWARD, M.D., Springfield, Ill., September 18, aged 25 years.

DEATHS ABROAD.

K. B. BRUHL, Graz, died recently in his 80th year. He had been professor at Craeow and Vienna, and leaves several important works on comparative anatomy. . . . Professor Binaud of Bordeaux is dead at the age of 39 years.

Miscellany.

Cemetery for Pets.—A cemetery for domestic pets has been established in Paris, on a small island in the Seine. A young man appears at the door, in response to a telephone call, with a suitable casket for the defunct pet and transports it to the cemetery.

Portrait Busts From the Stone Age.—An interesting experiment is reported by Professor Kollmann of Basle, who took a cast of a female skull dating from the stone age, and had a sculptor model the soft parts over it. The bust thus produced scarcely differs from the young women of Switzerland of the present day. Professor Merkel of Göttingen also reports similar experiments with skulls of a later age. The resemblance to modern types is most striking.

Hemorrhage After Operations on Biliary Passages.—Weiss reports a couple of cases of sheet hemorrhage or hemothosis after cholecystostomy, in which no wound nor rupture of a vessel could be found to explain the hemorrhage. From his experience he concludes that the surgeon must examine the urine, etc., to determine the condition of the liver function, and not interfere in case it is entirely compromised.—*Semaine Med.*, September 6.

Temporary Elastic Ligature of Abdominal Aorta.—Faure highly recommends this measure as a means of provisional hemostasis in the course of abdominal operations threatening excessive hemorrhage from extremely vascular tumors, etc., says the *Revue d'Gen.*, August. It is especially simple and effective when the pelvis is elevated. He cites several instances in which death would certainly have occurred on the table if he had not at once sought and applied the temporary ligature on the aorta.

Mercury Bath for Massage of the Hand.—Massage can not usually be borne in gouty arthritis, although it would prove as useful in this as in all other chronic arthropathies. Professor Rindfleisch of Würzburg (*S. u. Med.*, September 6) found by experience with himself, that plunging the hand or part affected in a vessel filled with mercury produced a gentle, even pressure to a certain degree resembling massage, which caused the rapid disappearance of the tumefaction of the joints, especially in chiroagra. Moving the hand to and fro augments the massage action of the mercury.

Goethe as an Anatomist.—Galen noted an intermaxillary bone in animals, and also ascribed them to man, but centuries later Camper claimed that the lack of these bones is an es-

sentinal mark of distinction between man and animals, especially the monkey. Goethe revived the discussion and after considerable research compelled the recognition of the site of the incisors as rudimentary intermaxillary bones. He also tried to prove that the skull is but a higher developed vertebra, and urged that the three portions of the temporal bone should be considered distinct.

Benefit of Rest After Operations on the Eye.—E. Clarke recently exhibited a set of rabbits' eyes on which operations had been performed, showing that when the animals were kept under the influence of an anesthetic for ten minutes to half an hour afterward, the wound closed and the anterior chamber re-formed very rapidly, until it was scarcely possible to distinguish the operated from the sound eye. Animals allowed to recover from the anesthetic and not killed for half to two and three-quarters hours afterward, showed evidences of irritation in the eye, turbid aqueous, etc. His experiments confirm the extreme rapidity with which the aqueous is resected under favorable conditions and the value of rigid rest.—*Clinical Journal*, August 30.

Roentgen Rays Data Wanted.—The editors of the *Fort-schritte a. d. Geb. der Roentgen-Strahlen* are collecting material for a comprehensive report on the application of the Roentgen rays, and appeal to physicians to assist them in their task, by replying to the following questions: 1. Kind of affection of skin, hair, nails, etc., and of other parts of the body, induced by the rays. 2. General constitution of patient—whether anemic, tuberculous, syphilitic, etc. 3. Severity of affection induced. 4. Termination, whether in recovery, and method of treatment followed. 5. Subjective sensations of patient. 6. Number and length of sésances. 7. After how many sésances did the first symptoms appear—redness, etc.? 8. What measures were taken to protect parts not to be exposed to the rays? 9. Which tubes were most effective, soft (low), or hard (high)? 10. Distance between tube and part to be treated. 11. Was the tube perpendicular to the part treated? 12. Length of sparks. 13. Voltage and amprage. 14. Number of interruptions per minute. 15. For what pathologic conditions were the rays employ'd? 16. Remarks.

"Ten Per Cent." Doctors.—One of the latest stories about doctors is worth repeating, even though it is not true: Some college students—not medical of course—of expensive tastes find it necessary to resort to subterfuges that often tax human ingenuity. One of these is the "10 per cent. doctor." This member of the medical fraternity is a played-out practitioner residing in the vicinity of the college, who makes a goodly sum out of students who have "blown in" their allowances long before their next is due. The student whose pocket-book has suddenly become depleted goes to this "medic," and for the consideration of 10 per cent. of the amount gets a receipt for "professional" services. This receipt is sent home and usually a remittance for that amount is received in return. One student last year had two expensive "operations," thus realizing a neat sum.

Formaldehyde in Disinfection.—The Secretary of the Illinois State Board of Health advises us concerning a series of experiments in aerial disinfection by the use of formaldehyde, carried on under the direction of Prof. T. J. Burrill, mostly at the state laboratory, the tests being made on the various lamps and generators producing formaldehyde from methyl alcohol, also on different apparatus regenerating the gas by the heating or boiling of the 40 per cent. aqueous solution. There were also experiments with the method of spraying suspended sheets with the 40 per cent. solution, this having been recommended by various state and other health departments, and being in use exclusively by some railroad companies as their means of disinfection. The results showed that all portable generators producing formaldehyde by the oxidation

of methyl alcohol were unreliable and in many instances worthless. As to surface disinfection, it was seldom accomplished, and the gas apparently possessed no penetrating power whatever, probably due to the fact that by this manner of generation but a small quantity of the alcohol is converted into formaldehyde. With the machines evolving the gas from the solution, the investigators had better success, but even here the effect on cultures was not constant, the action of the gas seemingly being entirely dependent on atmospheric and other conditions which prevailed. While sometimes complete surface disinfection was frequently not obtained, even in instances where the organisms were themselves the least tenacious of life, as with the generators using methyl alcohol, the penetrating power of the resulting gas was almost nothing.

In experiments where the vapor of formaldehyde was exposed in the room with sprayed sheets hung across it, 40 per cent. solution being used, commercially known as formalin, little better results were secured, although the tests were made in the most painstaking manner, and repeatedly during a period of three months, and were conducted in living rooms, railroad cars, and stores. Practical surface disinfection by the use of 150 c.c. of formaldehyde per 1000 cubic feet, commonly recommended and used, also gave unsatisfactory results, but where the amount of the material was considerably increased in proportion to space, where freely exposed bacteria were concerned, disinfection was possible. It was, however, necessary to use 250 to 300 c.c. per 1000 cubic feet to insure success in these experiments, 250 c.c. being the smallest amount that could be relied on to destroy dry bacteria.

The temperature of the room greatly influenced this method of disinfection, as did the relative humidity of the atmosphere and the character of the room's contents. Satisfactory results were seldom obtained with the thermometer 50 F. or below, with the gas produced by the oxidation of wood alcohol or liberated by the action of heat on the solution.

The Board has concluded that formaldehyde as employed in the tests conducted can not be relied on as an efficient germicide, as the destruction of pathogenic organisms is only accomplished under certain conditions which are not always at hand. Further investigations will be carried on, but in the meantime the Board advises physicians and local health authorities to use and recommend sulphur dioxide, 4 pounds to each 1000 cubic feet of air space, preferably burned in the presence of moisture, the time of exposure being twelve hours, longer if possible. The Board also recommends that the use of this be followed by a thorough washing with a 1/1000 solution of bichlorid, and in all cases by a liberal application of fresh air and sun-line if procurable.

Appropos to this investigation of the Board, the following from the press dispatches of September 25 is of interest, as appearing in the report of the Surgeon-General of the Marine-Hospital Service: "Passed Assistant Surgeon E. K. Sprague desires it to be distinctly understood that he does not recommend formaldehyde as a disinfectant agent on which reliance can always be placed for the treatment of articles requiring much penetration. His conclusions are as follows:

"A review of the experiments will show," he says, "that in twelve series in which the quantity of formalin mixture varied from 300 c.c. to 1000 c.c., or, taking the ratio given from one to five, and one to two, mattresses and pillows were sterilized; but in two series in which the proportion of the mixture was as one to five the mattresses and pillows were not penetrated. A critical examination of nearly all the published experiments with this agent also reveals instances in which organisms that there was every reason to expect would be killed have survived, and vice versa. It is that occasional unaccountable uncertainty of action that calls forth the warning not to attempt disinfection with formaldehyde in a case in which there is any doubt as to the results."

Queries and Minor Notes.

ARTIFICIAL GUANOS.

VANCOUVER, B. C., Sept. 18, 1899.

To the Editor:—Will you kindly inform me where I can obtain a book containing the method for analyzing artificial guanos, with special regard to fish guanos. I believe there is one generally used by the U. S. Agricultural Society, but of this I am not quite certain. F. T. U.

ANSWER:—The only recent work meeting our correspondent's needs, that occurs to us, is "Willey's Principles and Practices of Agricultural Analysis," published by the Chemical Publishing Co., Washington, Pa., 1895, the second volume of which is devoted to fertilizers. Dr. Willey is chemist of the agricultural department at Washington. There are other works on agricultural chemistry, such as Johnston's, Adie's, and Storer's, and others, but how far they contain what he wishes to know we can not say. If references to analyses and reports on the special subject of inquiry are required, we should think that they might be obtained by correspondence with the agricultural departments at Washington, D. C., or Ottawa, Canada. The agricultural department of the JOURNAL has not yet been organized, and the above reference is therefore the best we can supply.

"CLUB PRACTICE" IN EARNEST.

We have just received a letter from a physician in Canton, Ohio, which is as follows: "I enclose you a circular which is self-explanatory, and desire your opinion as to the course to be pursued by reputable physicians toward such an organization. Also, can promoters of such an organization be permitted membership in the AMERICAN MEDICAL ASSOCIATION, or in any medical society?"

The circular is a six page folder, printed in red and black, and calls attention to the great benefits to be derived from joining the "Red Cross Medical Association," which agrees to furnish physicians and medicine to its members, membership being divided into three classes, as follows: "Class A—Members of class 'A' will receive a family certificate, which calls for both surgical and medical treatment at the office of any physician on the medical staff, together with visits, when necessary at the house, both day and night in the event of sickness or accident. This includes all members of the immediate family, when not exceeding twelve in number. Cost \$1.25 per month."

We are glad to see there is to be some limit, even though that limit be not even dozen.

"Class B—Members of class 'B' will receive an individual certificate, providing for the same attention for the individual as Class 'A.' One dollar for the first month and fifty cents per month thereafter."

This will be a money-making "class" for the promoters, for \$6 a year is big pay for the ordinary individual.

"Class C." is about the same as the others except that hospital fees are paid.

From one of the "Ten Reasons Why" everybody should join this organization, we learn that "this plan has been in successful operation in other cities for years, and in case you visit or remove to such cities you will be taken care of." While the statement that "this plan has been in operation for years" is untrue, there is evidently a general movement on the part of the "promoters" to introduce it everywhere.

To our correspondent's question as to the course to be pursued by reputable physicians toward such an organization, there can be but one answer: "Unite together and stamp it out!" And now is the time to do it. There is no need for us to say why. The experience of the old world is sufficient reason if there were no other. It should be done now while it is beginning, and we should not wait to see how big and how disastrous it will be before a movement is made. And the physicians of Canton are its members of the AMERICAN MEDICAL ASSOCIATION. Surely he can not realize the evil results of the action he is taking. The temporary financial gain for those who go into such an organization, if there is even a temporary gain, will soon be lost, and with it will also be lost the respect of their fellow practitioners. We appeal to the physicians of Canton to unite and put down this worst phase of "club practice" in its incipency.

COMMERCIALISM

Our exposé in this department last week, of the woman who "cures cancer" by circular letters, trying to bribe physicians to send her patients, has resulted in an investigation being made as to her right to practice. As we expected, she holds no registrable diploma, and the Illinois State Board of Health has commenced proceedings against her for practicing illegally.

The Public Service.

Movements of Navy Medical Officers.—Changes in the medical corps of the U. S. Navy for the week ended Sept. 23, 1899:

P. A. Surgeon George H. Barber, detached from the *Monowahoko* on arrival at Newport, ordered to duty at the *Albatross*, September 30.

P. A. Surgeon George Rothgauer, ordered to duty at the United States naval hospital, New York.

Asst.-Surgeon M. V. Stone, detached from the *Brutus* and ordered to the Asiatic station.

Surgeon L. B. Baldwin placed on the retired list.

Asst.-Surgeon R. S. Blakeman, ordered to the naval hospital, Newport, R. I., on completion of preliminary examination for promotion.

Asst.-Surgeon J. J. Snyder, detached from the naval hospital, Newport, R. I., and ordered home to be ready for further orders.

Surgeon P. A. Lovering, detached from the recruiting rendezvous, Buffalo, N. Y., and ordered to proceed home as directed in orders of 12th.

Surgeon H. H. Marsteller, detached from the recruiting rendezvous, Buffalo, N. Y., and ordered to duty at the *Albatross*.

Surgeon G. P. Lumsden, detached from the *Richmond* and ordered to the recruiting rendezvous, Buffalo, N. Y.

Marine-Hospital Changes.—Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine-Hospital Service, for the seven days ended Sept. 21, 1899.

Surgeon C. E. Banks, granted leave of absence for one day.

Surgeon C. T. Peckham, to proceed to Eagle Pass and Laredo, Texas, as inspector.

Surgeon W. P. McLaughlin, to proceed immediately to Meridian, Miss., and report by wire to Surgeon H. R. Carter at New Orleans, for special temporary duty.

P. A. Surgeon Werthebaker, leave of absence extended sixteen days on account of sickness.

Asst.-Surgeon L. D. Fries, directed to assume temporary charge of the service at Key West, Fla., relieving Asst.-Surgeon McAdam.

Asst.-Surgeon W. R. McAdam, relieved temporarily from the hospital at Key West and detailed for special duty in connection with the yellow fever epidemic at Key West.

Acting Asst.-Surgeon E. B. Hallett, granted leave of absence for one day.

Hospital Steward H. E. Davis, upon the arrival of Steward Warhank, to report at Boston, Mass.

Hospital Steward C. T. Warhank, relieved from duty at Chicago, Ill., and directed to proceed immediately to Baltimore, Md., for temporary duty and assignment to quarters.

APPOINTMENT

W. J. W. Woolgar of Ohio, to be acting assistant-surgeon for duty at Cleveland, Ohio.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended Sept. 23, 1899:

SMALLPOX—UNITED STATES.

Massachusetts: Fall River, September 2 to 3, 1 case.

Michigan: Battle Creek, September 3 to 16, present; Maple Grove, September 8 to 16, present.

Ohio: Cincinnati, September 2 to 3, 5 cases.

Pennsylvania: Allegheny, August 19 to September 2, 2 cases.

SMALLPOX—FOREIGN.

Belgium: Antwerp, August 19 to 26, 3 cases.

Brazil: Rio de Janeiro, July 1 to 28, 54 cases, 34 deaths.

Cuba: Manzanillo, September 5, several cases.

Egypt: Cairo, August 11 to 19, 4 cases.

Greece: Athens, August 22 to September 2, 14 cases, 3 deaths.

India: Bombay, August 8 to 15, 11 cases.

Mexico: Chihuahua, August 28 to September 9, 11 deaths; Mexico, August 27 to 29, 2 cases, 6 deaths.

Russia: Moscow, August 12 to 26, 4 cases, 1 death; Odessa, August 19 to 26, 1 case, 3 deaths; St. Petersburg, August 19 to September 2, 11 cases, 4 deaths; Warsaw, August 12 to 26, 3 deaths.

Straits Settlements: Singapore, July 29 to August 5, 1 death.

YELLOW FEVER—UNITED STATES.

Florida: Key West, September 11 to 19, 164 cases, 7 deaths.

Louisiana: New Orleans, September 2 to 19, 18 cases, 2 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Bahia, August 20 to September 3, 10 cases, 8 deaths.

Colombia: Barranquilla, August 12 to 26, 1 case, 1 death; Colon, August 23 to September 3, 1 case, 1 death; Panama, September 5 to 12, 8 cases, 3 deaths.

Cuba: Havana, September 3 to 10, 21 cases, 3 deaths; Nuevitas, September 2, 1 case; Santiago, August 29 to September 5, 3 cases.

Guatemala: Guatemala, September 8 to 16, 5 cases, 1 death; Tuxpan, August 29 to September 4, 2 deaths; Vera Cruz, September 1 to 14, 21 deaths.

CHOLERA.

India: Bombay, August 8 to 15, 1 death; Calcutta, July 30 to August 5, 27 deaths.

PLAGUE.

China: Hongkong, July 29 to August 5, 29 cases, 29 deaths.

Egypt: Alexandria, August 13 to 27, 5 cases, 3 deaths.

India: Bombay, August 8 to 15, 71 deaths; Calcutta, July 30 to August 5, 52 deaths.

CHANGE OF ADDRESS.

Adams, S. S., from West Springfield, N. H., to 1 Dupont Circle, Washington, D. C.

Crockett, L. A., from Bloomington to 249 N. Pennsylvania St., Indianapolis, Ind.

Cox, G. W., from Chicago, Ill., to 774 E. Congress St., Detroit, Mich.

Cooley, N. P., 757 W. Monroe St., Chicago.

Coates, W. E., from 635 W. 12th St. to W. Congress St., Chicago.

Durkin, A. C., from Joliet to 218 W. Congress St., Chicago.

Felt, R. W., from Knoxville, Ill., to Oconomowoc, Wis.

Griffin, R. A., from Rutherford to Martin, Tenn.

Harris, H. A., from 108 W. 3rd St. to 74th St., New York City.

Harris, J. E., from 918 S. 12th to 624 Catharine St., Philadelphia, Pa.

Hambley, E. C., from Maquoketa, Ia., to 238 S. Winchester Ave., Chicago.

Homer, C. P., from Chicago to Washburn, R. R. Hosp., Springfield, Ill.

Keath, J. V., from Philadelphia to Shiloh, Pa.

Leavell, H. N., from Louisville, Ky., to Amissville, Va.

LeMoyne, F., from Atlantic City, N. J., to 503 Castlemar St., Pittsburg, Pa.

Lucas, F. B., from 314 W. Madison to 700 Knox St., Peoria, Ill.

Meek, J. M., from Morgan to Falmouth, Ky.

O'Brien, M. C., from Lewiston, Me., to 161 W. 122d St., New York City.

Perry, T. M., from San Francisco, Cal., to U. S. Marine Hospital, Stapleton, N. Y.

Pfouts, I. M., from Massillon to Beach City, Ohio.

Porter, W. O., from Morton to Caldwell, Miss.

Rees, H., from Hutton N. D. to Highlandville, Mo.

Rieman, W. H., from Cape to St. Clair, Mich.

Rodenhaus, E., from Quincy to Main and 5th Sts., Lafayette, Ind.

Webb, J. A. H., from Stafford to Steward, Kan.

Woodard, B. C., from Cecil to Adel, Ga.
