

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE: S. NEWCOMB, Mathematics ; R. S. WOODWARD, Mechanics ; E. C. PICKERING, Astronomy ; T. C. MENDENHALL, Physics ; R. H. THURSTON, Engineering ; IRA REMSEN, Chemistry ; CHARLES D. WALCOTT, Geology ; W. M. DAVIS, Physiography ; HENRY F. OSBORN, Paleontology ; W. K. BROOKS, C. HART MERRIAM, Zoology ; S. H. SCUDDER, Entomology ; C. E. BESSEY, N. L. BRITTON, Botany ; C. S. MINOT, Embryology, Histology ; H. P. BOWDITCH, Physiology ; J. S. BILLINGS, Hygiene ; WILLIAM H. WELCH, Pathology ; J. MCKEEN CATTELL, Psychology ; J. W. POWELL, Anthropology.

NEW SERIES. VOLUME XIV.

JULY-DECEMBER, 1901.

NEW YORK
THE MACMILLAN COMPANY
1901

170.

THE NEW ERA PRINTING COMPANY,
41 NORTH QUEEN STREET,
LANCASTER, PA.

CONTENTS AND INDEX.

N. S. VOL. XIV.—JULY TO DECEMBER, 1901.

The Names of Contributors are Printed in Small Capitals.

- ABBE, C., Cannonade against Hail Storms, 738
Acoustics, Progress in, JAMES LOUDON, 987
Agricultural, Colleges, American, Assoc. of, A. C. TRUE, 883; Chemists, Official, H. W. WILEY, 997
Agriculture, Secretary's Annual Report, 954
Alaska, W. J. M., 807
'Albatross,' Work of the, F. A. L., 899
ALLEN, E. W., Agricultural Bacteriology, H. W. Conn, 1001; The Feeding of Animals, W. H. Jordan, 1002
ALLEN, G. M., Boston Soc. of Nat. Hist, 1010
American Association for the Advancement of Science, 59, 74, 108, 156, 185, 188, 233, 255, 297, 305, 315, 345, 348, 357, 360, 375, 385, 393, 444, 474, 482, 492, 527, 545, 585, 596, 602, 625, 658, 705, 717, 745, 785, 794, 800, 801, 912, 965, 970, 984
AMI, H. M., Royal Society of Canada, 111
Anopheles Punctipennis and Culex Pipiens, G. W. HERRICK, 329
Antarctic Expedition, British, National, 94
Anthropological Society of Washington, W. HOUGH, 936, 1005
Anthropology, at the American Association, 297; G. G. MACCURDY, 717; at University of California, 619; and Psychology at the N. Y. Acad. Sci., R. S. Woodworth, 934, 971; Current Questions in, W. J. M., 996
Archeological Publication, New, H. I. SMITH, 300
Astigmatic Images of the Bottom of Pool, F. E. NIPHER, 855
Astronomical Science, Advances in, C. L. DOOLITTLE, 1
Astrophysical Observatory of the Smithsonian Institution, C. E. MENDENHALL, 407
Atkinson, E., Ganot's Natural Philosophy, W. LE C. STEVENS, 257
B., F. A., Patagonian Personalities, 693
B., G. F., Centroid of a Quadrangle, 696
B., H. C., Smithsonian Institution Documents, W. J. Rhees, 931
BAIN, S. M., Fungicides and Peach Foliage, 221
BANKS, N., Notes on Entomology, 977
BARUS, C., Stability of Vibrations, 403; The Hittorf Jubilee, 897
BASKERVILLE, C., A Basis of Scientific Thought, 165; Elisha Mitchell Scientific Society, 615, 813
BATHER, F. A., Geologic Distribution of Pollicipes and Scalpellum, 112
Bather, F. A., on Echinoderma, C. E. BEECHER, 844
BEAL, W. H., Physics of Agriculture, F. H. King, 1002
BEATTIE, W. R., Hydrocyanic Acid Gas in Extermination of Household Insects, 285
Beaufort Laboratory, H. V. WILSON, 739
BEECHER, C. E., Bather on Echinoderma, 844
Bergey, D. H., Hygiene, G. M. KOBER, 727
Bernadou, J. B., Smokeless Powder, C. E. MUNROE, 767
BESSEY, C. E., Botanical Notes, 72, 331, 938; A Botanist's Journey to the Denver Meeting of the A. A. S., 185; Coulter and Chamberlain's Morphology of Spermatophytes; Chamberlain's Methods in Plant Histology, 260; Ganong and MacDougall on Plant Physiology, 494; Early Winter Colors of Plant Formations, 721; Britton's Flora of the Northern States and Canada, 732
BESSEY, JR., C. E., Botany at the American Association, 596
Bibliographical Research, A. G. S. JOSEPHSON, 615
Bibliography, A. G. S. JOSEPHSON, 535
BIGGS, H. M., Malarial Fever, 266
Bigourdan's Système métrique, T. C. MENDENHALL, 143
Biological, Society of Washington, T. W. STANTON, 849; F. A. LUCAS, 895, 1007; Survey of Great Lakes, J. REIGHARD, 34
Birds, Song in, W. E. D. SCOTT, 522
BUGERT, M. T., Les plantes tinctoriales, Les matières colorantes naturelles, V. Thomas, 278, 846
BOLTON, H. C., Christian Friederich Schönbein, 689; Del Mar's History of the Precious Metals, 893
Bornstein, R., Leitfaden der Wetterkunde, H. H. CLAYTON, 651
Boston Soc. Nat. Hist., G. M. ALLEN, 1010
Botanical, Notes, C. E. BESSEY, 72, 331, 938; Work Committee, 136; Society in America, D. T. MACDOUGAL, 526; Seminar, Univ. of Nebraska, 775
Botanists' Journey to the Denver Meeting of the A. A. S., C. E. BESSEY, 185
Botany, Systematic, Problems and Possibilities of, B. L. ROBINSON, 465; at the American Association, C. E. BESSEY, JR., 596
BRANNER, J. C., Travertine Falls and Reefs, 184
BRASHEAR, J. A., Carnegie Technical School, 385
BRITCHER, H. W., Onondaga Academy of Sci., 149
British Association for the Advancement of Science, Approaching Meeting of, 376; Address of the President, A. W. RÜCKER, 425; Address of President of Physiological Section, J. G. MCKENDRICK, 517, 539; and President McKinley, 580; Address of President of Anthropological Section, J. D. CUNNINGHAM, 603, 640; Glasgow Meeting, J. P. McMURRICH, 633, 682; A. L. ROTCH, 757
Britton, N. L., Flora of Northern States and Canada, C. E. BESSEY, 732
Brontosaurus, H. B. HATCHER, 1015
Bumpus, H. C., Lobster Culture, 1013
BURGESS, E. S., The Torrey Botanical Club, 69, 850, 935, 971
BUTLER, A. W., Notable Factor in Social Degeneration, 444

- C., E. F., Packard's History of Medicine, 769
C., T. D. A., Las Vegas Science Club, 1009
CAJORI, F., Deviation of Falling Bodies, 853
Calendar of Societies and Academies, 894, 933
Calkins, G. N., The Protozoa, W. M. WHEELER, 808
Carnegie Technical School, 41, 656; J. A. BRASHEAR, 385
Catalase, A New Enzyme, D. W. MAY, 815
Catalogue, International, of Scientific Literature, T. WILLIAMS, 328
CATELL, J. MCK., Visual Perception of Space, 263; Washington Memorial Institution and a National University, 574
Centroid of a Quadrangle, G. F. B., 696
Chamberlain, on the Functions of a University, 226
Chamberlain's Methods in Plant Histology, C. E. BESSEY, 260
CHAMBERLAIN, A. F., Ameliorations of English Grammar, 814
Chemical, Society, American, N. Y. Section, D. WOODMAN, 30; J. A. MATHEWS, 692, 1007; Northeastern Section, H. FAY, 1008; Denver, Meeting, A. C. HALE, 154; Laboratory, Harvard, 36
Chemistry, Teaching, in Schools, R. P. WILLIAMS, 100; In Medical Schools of the U. S., J. H. LONG, 360; at the American Association, W. MCPHERSON, 482; Inorganic, Notes on, J. L. H., 536, 696, 855
Chester's Bacteriology, H. W. CONN, 967
Chicago University, Conferring Degrees, 73; Field Work in Botany, Geology and Zoology, 459
CHILD, C. M., Zoological Club, University of Chicago, 28
Clark, W. B., Allegany County, Maryland, G. W. STOSE, 181
CLARKE, J. M., Maryland Eocene Book, 27
CLAYTON, H. H., Leitfaden der Wetterkunde, R. Bornstein, 651; Air Pressure and the Pulse, 6; 6 Cliff Dwellings, Colorado, H. I. SMITH, 333
COCKERELL, T. D. A., Horned Lizard, 111
COLE, F. N., American Mathematical Society, 375, 772
Color, Vision, Ebbinghaus's Theory of, C. L. FRANKLIN, 30; of Plant Formations, C. E. BESSEY, 721
Columbia University, Resignation of the President, 656
COMSTOCK, G. C., Astronomischer Jahresbericht, W. F. Wislicenus, 216
Comstock, G. C., Astronomy, S. D. TOWNLEY, 612
CONN, H. W., Chester's Determinative Bacteriology, 967
Conn, H. W., Agricultural Bacteriology, E. W. ALLEN, 1001
Connecticut Rivers, W. H. HOBBS, 1011
CONRADI, A. F., Toads killed by Squash-bugs, 816
Convocation Week, Report of the Committee on, C. S. MINOT, R. S. WOODWARD, E. L. NICHOLS, L. O. HOWARD, J. MCK. CATELL, 984
Corals, Bahaman, T. W. VAUGHAN, 491
Coulter and Chamberlain's Morphology of Spermato-phytes, C. E. BESSEY, 260
COULTER, J. M., Proceedings of American Association, 348
CRAMPTON, H. E., Biology at the N. Y. Academy of Sciences, 109
CROES, J. J. R., A Century of Civil Engineering, 83
CUNNINGHAM, J. D., Address of President of Anthropological Section of British Association, 603, 640
DAVENPORT, C. B., Zoology of the Twentieth Century, 315
DAVIS, W. M., Current Notes on Physiography, 70, 152, 222, 299, 457, 537, 617, 698, 778, 856, 975
DEARBORN, G. V. N., Psychology and the Medical School, 129
Degeneration, Social, A. W. BUTLER, 444
Del Mar's History of the Precious Metals, H. C. BOLTON, 893
Deviation of Falling Bodies, F. CAJORI, 853
DEXTER, E. G., Success at School, 248
Discord, M. MEYER, 328, 616; W. LE C. STEVENS, 455, 654
Discussion and Correspondence, 30, 111, 150, 183, 220, 263, 326, 412, 455, 496, 534, 573, 615, 654, 693, 735, 775, 814, 852, 896, 936, 973, 1011
Doctorates, conferred by American Universities, 161; at the University of Pennsylvania, 333
DODGE, R. E., Geology and Mineralogy at the N. Y. Academy of Science, 773

SOME ADVANCES MADE IN ASTRONOMICAL SCIENCE DURING THE NINETEENTH CENTURY.*

IN glancing over the field of astronomical achievement during the century recently closed, the most striking feature is undoubtedly the rise and growth during the past fifty years of an entirely new department, one totally unknown and almost undreamed of before the first half of the century had passed, that called by Professor Langley the new astronomy, more technically known as astrophysics. In considering the restrictions which must be regarded in case this address is to be kept within manageable limit, perhaps it would be well to confine my remarks to this new branch of the science. I shall, however, give the chief place to the older astronomy, touching briefly upon the newer phase.

Near the close of the seventeenth century appeared Newton's immortal work called by him 'The Mathematical Principles of Natural Philosophy.' In this treatise the law of universal gravitation as the controlling and governing principle of the planetary system was established by a rigorous course of mathematical reasoning. It was many years, however, before these conclusions were universally accepted. On the continent of Europe particularly, the

* Annual address delivered before the University of Pennsylvania Chapters of the Society of Sigma Xi, June 13, 1901, by C. L. Doolittle.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

field was already occupied by the philosophy of Descartes. The glittering generalities found here in place of the severe mathematical reasoning of Newton proved too attractive to be at once overthrown.

Fifty years elapsed before anything material was added to the science of Newton, then came a galaxy of distinguished men, including Euler, Clairaut, D'Alembert, Lagrange and Laplace, who, by a series of most brilliant and exhaustive researches, made possible by the development of much more powerful mathematical instruments than those possessed by Newton, practically disposed of every objection which the opponents of Newton's theory could discover.

Their last stronghold and one which proved extremely difficult to carry was the explanation of the secular acceleration of the moon's motion. Halley, one of Newton's disciples, had found by a comparison of ancient and medieval eclipses with those of modern times, that the lunar month is now shorter than was the case 2,000 years ago. How this could be if the motion of this body were governed by the law of gravity only proved an extremely difficult question. It was finally shown by Laplace to be one of the consequences of this law, that what is now an acceleration will in the future become a retardation, thus preserving the system essentially as we see it to-day. This took place near the beginning of the nineteenth century. We may, therefore, say that this century began its course with the law of universal gravitation firmly established. In fact no one was hereafter found to seriously call it in question whose opinion was worthy of notice.

It is not to be supposed, however, that the science of celestial mechanics was now finished. In fact we can hardly say that any branch of physical science ever has been or ever will be finished. Results depending for their value upon observations of any kind must share the inevitable imper-

fections of the observer and of his instrument.

The problems of celestial mechanics have accordingly occupied the attention of a large number of distinguished men during the century past. With the discovery of new planets and comets and stellar systems, new applications are constantly appearing calling for the most refined skill and active perseverance of its votaries. Refinements in observation and improvements in method also call for frequent revision of the old investigations. This is particularly true of the lunar theory.

The study of the moon's motions was one of the first problems to attract the attention of the ancient astronomers. Since their day we are probably safe in saying that no problem in the entire range of science has called out anything approaching the labor and ingenuity bestowed upon this one. Yet the theory is hardly in a satisfactory condition to-day. Such a statement may seem to those who have never looked into the intricacies of the problem like a confession of failure.

So far as it concerns a purely mathematical statement of the conditions the problem offers no difficulties. The relations between the coordinates of a body like the moon, acted on by any system of forces, are very readily expressed by a series of three differential equations of the second order. The forces here are the mutual attractions exerted by the sun, moon and planets. If only two bodies are present the solution offers no difficulty. If there is a third, we have the famous problem of the three bodies. In spite of all that has been done during the century in the way of mathematical advancement this problem still defies its most powerful resources. Recourse must be had to methods of approximation, expansion in the form of series being one of the most obvious. No one can form an idea of the intricacy and

complexity of the resulting expressions who has not himself looked into the problem. Delaunay, at one time director of the Paris Observatory, carried this investigation farther than any of his predecessors had done, but though it had occupied his almost undivided attention for twenty years, it was still unfinished at the time of his death. (He was unfortunately drowned at Cherbourg in 1872 by the capsizing of a pleasure boat.) We have in this country to-day three investigators who are perhaps the greatest living authorities on this subject—Professors Newcomb, Hill of New York, and Brown of Haverford.

The general problem of three bodies has proved a very fascinating one. If, for instance, Mars and Jupiter were of approximately the same dimensions as the sun, the determination of their respective motions would be vastly more complex than it now is. Mr. G. H. Darwin has been giving much attention to this class of problems bringing out some interesting results. Although the problem does not confront us in this unmanageable form in our own system it will eventually find practical application in unraveling the intricacies of the stellar motions.

Probably no achievement in the domain of science ever produced so profound an impression upon the unprofessional public as the discovery of Neptune by a purely theoretical investigation undertaken independently by Leverier and Adams, predicting its place in the heavens before it had ever been seen, or at least recognized as a planet. It is unnecessary now to rehearse the familiar story of that brilliant discovery. It was somewhat like the egg of Columbus, but up to the present time the attempts to apply the process in other regions of the planetary system have not been attended with success. The first such attempt was by Leverier himself, followed in 1859 by his confident announcement of a

planet between Mercury and the Sun. The prestige of Leverier's name, accompanied by a supposed view of the planet by Dr. Lescarbault, an amateur astronomer, proved sufficient to carry conviction generally; and Vulcan found a place with the other planets in many books written thirty or forty years ago. No one else, however, whose authority was worth much claimed to have seen the planet until the occurrence of the total eclipse of the sun July 29, 1878. At this time Professor Watson, of Ann Arbor, and Lewis Swift, of Rochester, believed they had each seen one and perhaps two planets near the sun. The reputation of both as skilled observers naturally gave great weight to their authority, but the planets were never seen again and a critical examination of the places assigned renders it practically certain that fixed stars were mistaken for planets. Vulcan as a single large planet within the orbit of Mercury is now by the unanimous verdict of the astronomical profession relegated to the realm of myths. It was very natural to attempt to apply the process to the discovery of planets beyond Neptune, but although some indications of one and possibly two such have been suspected, nothing of the kind has yet been seen.

The eighteenth century ended with a list of known planets numbering 7 not including satellites. The nineteenth began with eight, the first day of January, 1801, being distinguished by the addition to the list of Ceres, the first of the long line of asteroids to be detected. The fortunate discoverer was Giuseppe Piazzi. The scene of Piazzi's activities was the University of Palermo, where he had been diligently engaged for nine years with the most perfect instrument which the skill of that day could produce in accumulating materials for a great stellar catalogue. At the time of which we are speaking his attention was directed to a place in the constellation Taurus on account

of an error of Wollaston, one of his contemporaries, in assigning a place to a star where none existed. Piazzi found, however, an eighth magnitude star not before noted, and upon repeating the observation the following evening, it was found to be in motion. Piazzi carefully followed the planet until February 11, when he fell ill, and his activities were for some time suspended. Meanwhile letters had been sent to Oriani, at Milan, and Bode, at Berlin. About this time, however, it may be remembered that another individual, not wholly unknown to fame, was actively employed in this part of the world in the practical applications of military science. We refer to one Napoleon Bonaparte. This may explain the fact that Oriani's letter arrived at Milan two and one-half months after it was written. Olbers, however, received that directed to him at the end of two months. The planet was now lost in the sun's rays and it was greatly feared that it would not be recovered, for, with a body so minute, unless its position could be given with some approach to accuracy the attempt to find it was an almost hopeless task. This emergency brought to the front the great mathematician Gauss. At that time a young man unknown to fame, he attacked the problem, and as a result produced a method for determining an orbit from three observed positions which completely overcame the difficulty, at the same time showing its author's title to a place in the front rank of mathematicians.

The discovery of three more planets belonging to the asteroid group soon followed, Juno, Vesta and Pallas, then, after a long interval came Astræa in 1845. The discoverer was Hencke, an amateur astronomer, who had been watching the heavens during fifteen years in the hope of this reward. The number now known to exist is near five hundred, with no indication that the supply approaches exhaustion. About ten years ago the application of photography

to this purpose by Wolf, of Heidelberg, made possible what may be called a wholesale process. One plate, taken October 22, 1900, showed no less than five of these bodies. This is at present believed to be the maximum record. What is to become of this numerous family is one of the serious questions of this day. The complete investigation of the theory of one is almost the work of a lifetime.

Of satellites, or secondary planets, seven have been added to the list during the century, one of Saturn, by Bond of Cambridge, September, 1848; one of Neptune, by Lassell, soon after the discovery of the planet itself; two of Uranus, also by Lassell, 1851; two of Mars, by Hall, of Washington, August, 1877; one of Jupiter, by Barnard, of the Lick Observatory, September, 1892. We should perhaps include an eighth in this category, an additional satellite of Saturn having been announced by W. H. Pickering two years ago, but as it has not yet been confirmed, judgment must be suspended for the present.

The periods of rotation of Mercury and Venus were investigated by the German astronomer Schroeter, sometimes called the Herschel of Germany, near the beginning of the century. His conclusion was that the length of the day on both these planets differs but little from our own. These results kept their places in the text-books almost unchallenged until near the close of the century. The multiplicity of observers equipped with instruments greatly superior to those of Schroeter were apparently unable either to confirm or disprove his conclusions. In 1889, however, Schiaparelli found what he considered decisive evidence showing that the planet Mercury rotates on its axis in the same time required to complete a revolution about the sun, thus like our moon always keeping the same hemisphere presented to the primary body. Later Schiaparelli came to

the same conclusion with regard to Venus. The results obtained at Flagstaff, Arizona, by Messrs. Lowell and Douglas are in perfect agreement with these conclusions. Although probably correct, the question is still regarded by many as an open one. The spectroscope will give the final verdict. Attempts in this direction have already been made by two experienced spectroscopists, Keeler, at the Lick Observatory, and Belopalski, at Pulkowa. Keeler's career was closed by death, leaving this and many other important researches unfinished. Such references to Belopalski's results as have come to our notice seem to throw but little additional light on the question. It may be that the instrument has not yet reached that degree of mechanical perfection which an investigation of such delicacy demands; but we may confidently predict its ultimate success.

With regard to the rotation periods of Uranus and Neptune, we know next to nothing. Such scanty bits of information as have been obtained, however, point to short periods in both cases, 8 to 12 hours; here again we may look to the spectroscope to give us a final answer.

As to the physical condition of the planets themselves, their adaptability to the support of animal and vegetable life, we certainly know a little more now than was known during the early part of the century. The author of the 'Positive Philosophy' expresses what seems to have been the prevailing sentiment regarding the orthodox science of that day as follows: "With regard to the heavenly bodies, we may obtain practical knowledge of their geometrical and mechanical phenomena, but all physical, chemical, physiological and social researches for which our powers fit us on our own earth are out of the question in regard to the planets. The only case in which this rule may be too severe is in that of the temperature."

There was, however, no dearth of philosophers whose speculations disregarded these modest limitations. To such the planets, like our own earth, were the abode of vegetable and animal life with, of course, intelligent beings, perhaps greatly superior to ourselves at the head. As no other use in the economy of the universe could be suggested for these neighboring worlds, and as God could not be supposed to create anything in vain, the conclusion was obvious. More exact knowledge has, however, dissipated most of these plausible theories. It seems at present unlikely that a single one of the other planets, with the possible exception of Venus can now be in a condition to support the higher forms of life.

It is not now proposed to enter into a discussion as to the indications of the existence of intelligent beings on the planet Mars. Though there are some who assert with great confidence that such is without doubt the case, there are others whose opinion is of equal value who are certain that the last Eskimo was frozen to death on the planet's equator many thousands of years ago. As to the large planets, Jupiter, Saturn, Uranus and Neptune, on account of their great size and consequently slower development, it is certain that they have not yet reached a condition adapted to the support of life, unless it be in its lowest forms. There is every indication that a very high temperature exists in the case of all four of these planets, that they are largely gaseous, consisting to a great extent of vapors floating in atmospheres whose depth must be reckoned in thousands of miles, and that certainly no part of the solid nucleus is ever seen by us.

We have every reason for believing that the sun with the attendant planets, our earth included, had a common origin, that they are composed of the same materials, that the same chemical and physical laws pre-

vail throughout the system. We may feel very confident also that the same combinations of physical and chemical conditions which on this earth are associated with organic life will be similarly associated on other planets, that those conditions which prevent this development except in its lower forms above the line of perpetual snow will act in the same manner on Mars or Venus.

At the beginning of the century one comet was known to be a member of our system, more than one appearance having certainly been observed, viz., that of Halley. This comet is famous historically as the first whose return was successfully predicted, thus completely demolishing the vague and absurd notions which had been held regarding these bodies. At the close of the century something like a score have been observed at more than one appearance, one of which, that of Biele, has certainly gone to pieces, with many indications that a like fate is in store for all. Closely associated with the subject of comets is that of meteors, a subject to which the attention of all of us has been more or less directed within the past two years by the amount of space which the journals have given to the expected appearance of the November displays. This department of astronomy was quite unknown to science a hundred years ago. In the early part of the century writers who condescended to mention meteors at all spoke of them as atmospheric phenomena. As for meteoric stones, specimens of which are seen in all mineralogical collections, scientists would have none of them. Learned academicians ridiculed the idea that any one should be so absurdly credulous as to admit the possibility of a ponderous stone falling from heaven. When in 1790 an official statement signed by 300 eye witnesses of such an event was sent to the French Academy one of the distinguished physicists of that body wrote concerning it

“How sad it is to see an entire municipality certifying in a formal official document to the truth of a fable which can only be regarded with pity.” Finally in 1803 occurred a fall in France of so conspicuous a character and attested by such a host of credible witnesses that it could no longer be treated as a childish fable. The matter was investigated by the Academy with naturally only one possible verdict. Since then much attention has been given to this subject, but it does not appear that any part of it was shared by the minute shooting stars, with the appearance of which every one was so familiar, until the great display of 1833 had drawn attention to them. It soon began to be discovered that records of similar occurrences at various past times were to be found, and finally Professor Newton, of Yale, in 1864 brought together a series of such historic notices extending back to the year 902, October 15. It was found that these could be represented as successive recurrences of the same phenomenon at intervals of 33 years. Professor Newton, therefore, predicted with much confidence a repetition in 1866. This prediction was fully verified.

The details of the investigation, by which this was shown to be due to a swarm of meteoric bodies, of average dimensions, probably not much exceeding a grain of sand, moving in a long procession about the sun with a period of $33\frac{1}{2}$ years, we cannot enter into now. The length of the stream was found to be such that about three years were required to pass the point of intersection with the earth's orbit. In fact the particles are scattered—very thinly for the most part—over nearly the entire path.

Precisely how it came about that the display was so meager in 1899 is uncertain. Perhaps it was caused by the particles being very unequally distributed along the line and that the earth on that occa-

sion passed through a comparatively thin region. Perhaps the perturbations of the planets have changed the course of the stream to such an extent that the earth no longer encounters it. The question will doubtless receive an answer in due time.

A large number of these meteoric streams have been recognized. A list of 695 radiants, as they are called, is to be found in the *Monthly Notices*, R. A. S., for 1875. Probably, however, a considerable number of these are fictitious.

One of the most remarkable discoveries connected with this subject was announced in 1866 by Schiaparelli, viz., that the well-known August swarm of meteors moves in practically the same orbit as a bright comet seen in 1862, known as Tuttle's comet. Shortly afterwards the orbit of the November swarm was identified with that of Temple's comet of 1866. A number of other such coincidences have been found, the most remarkable being that of a swarm known as Andromedes, which appears to have taken the place formerly occupied by Biele's Comet, in short to be nothing more or less than the shattered fragments of that body. Whether, on the one hand, those streams which have not been identified with any known comet are also the remnants of such a body long since disintegrated, and, on the other, whether those comets permanently attached to our system are undergoing a like process of dissolution, we can not say with certainty, but the theory looks very plausible. One such catastrophe has been carried to completion within the memory of many now living.

Another case in which this process was rapidly developing was that of the great comet of 1882, which many of us will remember. As this body receded from the sun its nucleus was broken into seven distinct fragments which gradually separated farther and farther from each other, until the body disappeared from view.

According to the best determination of its period, this comet should return in seven or eight hundred years. When it does return, if this ever happens, undoubtedly it will be in the form of at least seven distinct comets, following each other at intervals of perhaps several years. Each of these will very likely be again subdivided, the operation continuing until nothing remains but minute fragments.

We may follow the process backward as regards this body. In 1843 appeared a splendid comet whose orbit was remarkable on account of the nearness of its approach to the sun. Again in 1880 a large body of this kind appeared whose path so closely resembled that of 1843 that it was generally believed to be the same body, though how such a conspicuous object could return to our neighborhood every thirty-seven years and never have been seen before 1843 was a puzzling question. Greatly to the surprise of astronomers, the great comet of 1882 was found to follow almost precisely the same path. The theory was at once advanced that on account of the close approach of this body to the sun, passing as it did through millions of miles of the solar corona, the resistance encountered was rapidly bringing it into the sun. A few years, possibly a few months, would suffice for completing the work. What effect this collision would produce upon the sun could only be conjectured. Would it bring disaster to our earth or not?

The comet, however, pursued its way after passing the sun, with no appreciable change in the character of its orbit. It was followed from September 3, the date of its discovery, until the following June, when its distance from the sun was 470,000,000 of miles. Abundant material therefore existed for investigating its movements. The result was that at least 650 years must elapse before its return, the time being more likely to be 800 years. It

seems almost certain, therefore, that the three comets which appeared respectively in 1843, 1880 and 1882 originally constituted one gigantic body, which, on the occasion of a previous visit, perhaps about the time of the Norman conquest of England, had been torn in pieces by the sun's action precisely as was the case with the fragment which returned in 1882.

Whether the meteoric stones of which mention has been made are in any way related to the minute shooting stars, and whether or not they also at one time formed constituent parts of comets, we cannot say with certainty, but there seems to be no clear line of demarkation between the two classes of bodies. It appears to be simply a difference of dimension. A few of the fragments are massive enough to make their way through the air, and are known as meteoric stones. The great majority are so small that they are dissipated in the upper regions of the atmosphere.

On July 8, 1842, occurred a total eclipse of the sun, the line of totality passing over central and northern Europe. Great interest in this event had been aroused, largely due to the enthusiasm of the English astronomer Francis Baily. What we may call the first of the series of eclipse expeditions, since become such a conspicuous feature, were sent out at this time. Among those who made the long journey—long for those days—were the Astronomer Royal, Baily, Struve from Poulkova, Schumacher from Altona, and Arago from Paris. Though the corona and solar prominences had been frequently seen and described in a casual manner by previous witnesses of similar phenomena, such accounts had attracted little attention. Apparently most of the observers on the present occasion were totally unprepared for the spectacle which confronted them. So far as it concerns the cause of science, these now familiar appendages of the sun may be said to date their

discovery from this occasion. Baily is particularly eloquent in his account of the corona, closing as follows: "Splendid and astonishing, however, as this remarkable phenomenon really was, and although it could not fail to call forth the admiration and applause of every beholder, yet I must confess that there was at the same time something in its singular and wonderful appearance that was appalling; and I can readily imagine that uncivilized nations may occasionally have become alarmed and terrified at such an object, more especially at times when the true cause of the occurrence may have been but faintly understood, and the phenomenon itself wholly unexpected.

"But the most remarkable circumstance attending the phenomenon was the appearance of three large protuberances, apparently emanating from the circumference of the moon, but evidently forming a portion of the corona. I never lost sight of them when looking in that direction, and when the first ray of light was admitted from the sun, they vanished with the corona altogether and daylight was instantaneously restored."

The importance of these phenomena was now for the first time brought home to astronomers, and the desirability of investigating their true character. A variety of theories were advanced, some old and some new, some not far from the truth and others very much so. Professor von Felitsch, of Griefwald, published a treatise in which he proved to his own satisfaction that corona, prominences and chromosphere were purely optical appearances.

Some of the mists and haze enveloping the subject were cleared away by the eclipse of 1851, which was successfully observed in Norway and Sweden, but it was not until 1860 that the true character of these phenomena, that of solar appendages, was firmly established. This occasion marked an im-

portant epoch in this class of investigations from the fact that photography was now for the first time generally applied. The photographs possessed the great advantage of freedom from personal bias and of forming a permanent record which could be studied at leisure. Although nothing was previously known of the character of the rays with which the impression must be taken, as it happened the results were eminently satisfactory. The comparison of plates taken hundreds of miles apart showed identically the same forms, thus disposing of the notion that they were due to personal or atmospheric causes, while those taken at the same place, in close succession, showed the moon to pass over them, gradually covering or uncovering them as the case might be.

The eclipse of 1868 was distinguished by another great advance in the practical application of the spectroscope. Now for the first time the true character of the so-called prominences was demonstrated, viz., that of glowing gases or vapors shooting up to heights of fifty or a hundred thousand miles above the sun's surface, and composed in great part of hydrogen. A conspicuous line was also seen near the D line of sodium. As this corresponded to no chemical element then known, it was called the helium line. In 1895 helium was discovered in a gas obtained from the mineral cleveite, an interesting case of a chemical element first discovered in the sun.

In connection with this eclipse it was found that these prominences could be observed at any time when the sun was visible by a proper use of the spectroscope. This important discovery was hit upon independently by M. Janssen and Mr. Norman Lockyer. Both discoverers communicated their methods to the French Academy, the letters reaching the Secretary within a few minutes of each other. In commemoration of this event a medal was

prepared bearing the effigies of both Janssen and Lockyer.

The principle employed in obtaining the images of the prominences is as follows: The light of these objects is largely monochromatic. If such a ray is passed through a prism it is bent out of its course, losing a little of its brightness by the absorption of the glass but not otherwise. The light due to the glare of the atmosphere, however, which is the cause of our inability to see these features whenever the sun is visible, being composed of all the colors of the spectrum, is dispersed and rendered so faint as not to interfere with the image of the prominence. The higher the dispersion, the darker is the background against which this image is seen. It was at first thought necessary to employ a narrow slit, thus gradually building up the prominence by taking narrow slices in succession. It was soon found that the slit could be opened wide enough to show the entire image at once. This discovery made possible the careful and deliberate study of this feature of the sun, with the result that more is probably known of it than could ever have been ascertained, had it been necessary as at first to employ only the few moments during total eclipse.

The next step in advance would seem to be in the direction of accomplishing for the corona what had been done for the prominences and thus make possible the study of this feature of the sun's environment under the same leisurely and deliberate conditions. This problem has received a great amount of attention during the past twenty years. Various methods of attack have been suggested and tried, but so far without success.

In 1882 Professor Huggins believed that he had solved the problem. By the use of plates sensitive only to the most prominent rays of the corona, he obtained photographs which had every appearance of being genu-

ine pictures of the solar appendage. The results were regarded by many as genuine, while others doubted. Much discussion followed, some of it slightly fervid in temperature.

However, the test was simple as soon as an opportunity could be had for applying it. The eclipse of 1886 gave the wished-for opportunity. Photographs taken during totality were compared with those taken by Huggins's process, but alas! the results were far from identical. The supposed coronal forms were therefore fictitious.

Though much in the way of detail has been learned of the corona in connection with recent eclipses, it still remains very much of an enigma. Unless some new method may be found for attacking the problems which it presents, apparently their complete solution will be long delayed. Here too, as in other cases, the solution of one problem is likely to suggest a score of new ones, so that eclipse expeditions seem unlikely soon to be exclusively things of the past.

At the opening of the century, it can hardly be said that astronomers were in possession of more than two or three catalogues of stars which would be of any use whatever for the exact astronomy of today. Even these were of quite limited extent as regards the number of stars contained. There were, it is true, a number of such catalogues based upon the imperfect methods of the previous century, and a considerable amount of valuable material in the form of unreduced observations existed, but the latter was of little practical service so long as it remained in this form. Even if accessible, which was not always the case, very few could undertake the drudgery of searching through the records for the wished-for material, and when found, if found at all, to apply the reductions necessary to prepare it for practical use. It is to George Biddel Airy, who became Astron-

omer Royal in 1835, that astronomers owe the introduction of the present practice of reducing and publishing observations promptly, thus making them accessible to all.

The most valuable series thus buried out of sight at the beginning of the century was that of Bradley. The observations were made at Greenwich between the years 1750 and 1762. These were first rendered accessible by Bessel, who in 1818 published under the title 'Fundamenta Astronomiæ,' a catalogue of 3112 stars constructed from all Bradley's observations. More recently a re-reduction has been published by Auwers, in which every refinement which the present state of science could suggest has been employed, in order to obtain from them the best possible results. This catalogue is of special value in such investigations as involve the stellar motions, the remoteness of the time of observation—140–150 years—being a great advantage in this respect. There was also a great mass of observed star places, the result of the untiring industry of LaCaille, D'Agelet and Lefrançais Lalande, nephew of the more widely celebrated astronomer. Most of this material was only placed in an accessible form after the nineteenth century was far advanced, the last contribution being the publication by our own Dr. Gould, in 1864, of the final reduction made under his direction of the observations of D'Agelet, all reduced to the epoch 1800.

The beginning of the century found Piazzi busily engaged at his observatory in Palermo accumulating material for his famous catalogue of 7646 stars, which finally appeared in 1814. As he possessed for this purpose an instrument superior to anything previously constructed, and was himself a careful and most industrious observer, this catalogue has been of very great value. A re-reduction of the observations is now in progress, based upon the more accurate

values of the constants which we now possess, and with improvements in method unknown one hundred years ago, which cannot fail to add greatly to its usefulness.

As time went on observations were conducted with more or less regularity at various places, each observer or institution acting independently of what was done elsewhere. As a result, many stars were observed over and over again, and others, equally important, not at all. In 1866, however, the *Astronomische Gesellschaft* of Germany organized a systematic campaign, having for its object the accurate cataloguing of all stars of the northern heavens not fainter than the 9th or 9.5th magnitude. For this purpose the entire northern heavens were divided into zones of about 5° in width, and thirteen different observatories each undertook to observe one, or in some cases two, of these zones, the work all being done on a strictly uniform plan, so that the results shall be homogeneous throughout. This work has been in progress for more than thirty years—somewhat deliberately at some places, it must be said, but is now nearly completed. The plan has since been extended to include southern stars as far as the tropic of cancer. Meanwhile our own distinguished countryman, Dr. B. A. Gould, as the result of fifteen years' labor at Cordoba, Argentina, has given us a similar catalogue of 73,160 stars between the tropic of cancer and the south pole.

The great work, instituted by the *Astronomische Gesellschaft* in 1865, is still unfinished, yet an even more ambitious undertaking was inaugurated fourteen years ago by an international congress assembled at Paris for that purpose. This calls for a photographic survey of the heavens to be participated in by a number of observatories—eighteen have joined in the undertaking—two sets of plates being taken.

The first set are to have sufficient length of exposure to give positions of all stars not fainter than the eleventh magnitude. These are to be measured and the resulting positions catalogued. When completed, this catalogue will include between two and three million stars. The second series of plates is to have a longer exposure, sufficient to show stars of the fourteenth magnitude and will furnish charts of the heavens. 22,154 plates are called for and many years will be required for its completion. The results already obtained show that star positions may be obtained in this way with an accuracy little if anything inferior to the results of meridian observation.

The problem of the past history and future destiny of the solar system has occupied much attention during the century. Near its beginning Laplace had announced his famous nebular hypothesis. For many years it seems to have been taken for granted that little if anything could be added to this theory. In a general way it may be said that it forms the foundation of whatever has been developed in this direction. Laplace began with the sun already existing, surrounded with an atmosphere of heated vapor extending beyond the farthest planet. This body revolved on its axis and gradually shrunk as its heat was radiated into space. The linear velocity of the outer parts remaining constant, the angular velocity would constantly increase until in time the centrifugal force became equal to the centripetal when the central part separated, leaving the equatorial part in the form of a ring. This ring contained the material out of which the outermost planet was formed. Successive repetitions of the process produced the different planets, and these in turn produced satellites in the same manner. The rings of Saturn were held to be almost an unanswerable piece of evidence in favor of the theory. Though, without doubt, the

system was evolved in some way from a primitive nebula, we may say with certainty that it did not follow the orderly course marked out for it by Laplace. The subsequent discovery of the great principle of the conservation of energy dispensed with the original hypothesis which started with the mass in a heated condition, at the same time that it associated with it the important question as to the supply of heat and other forms of energy which are constantly being poured out with such prodigality by the sun. If we suppose the matter composing our system to have been at one time a nebulous mass, filling the present orbit of Neptune, the temperature may then have corresponded to the absolute zero so far as our purposes are concerned. The process of shrinking and condensation to the present condition would have evolved an amount of heat quite equal to that which the problem calls for, but, unless a constant supply is furnished from some source, the present process of radiation will soon come to an end. The explanation of this supply which is generally accepted was first announced by Helmholtz in 1854. He ascribed it to the shrinkage of the sun now going on. It is capable of mathematical proof that a body consisting of matter in the form of a gas, which is the case with the sun, by the process of condensation due to the pressure produced by its own attraction, will constantly grow hotter so long as it remains a gas. This operation must end when a considerable portion of its matter is reduced to a liquid or solid form. The system, then, had a beginning, and as a consequence it must come to an end. Or more properly speaking the present condition of things can not last forever. Thus Helmholtz concludes that if the intensity of radiation has been uniform from the beginning, the present order can not have existed longer than 22,000,000 years. Others make the period less. Look-

ing into the future, at the end of 5,000,000 years, the sun will have contracted to half its present volume, and at the end of another 5,000,000 years it will be mainly if not entirely solid, and must have ceased to be self-luminous much earlier. An interesting corollary to this subject is the principle of tidal evolution developed by Mr. G. H. Darwin. Supposing the moon to have been separated from the earth by some process at a time when the matter composing them was in a liquid condition, each body would produce enormous tides in the other. Consider those produced on the earth by the action of the moon: the effect would be on the one hand to retard the earth in its rate of rotation, and on the other to drive the moon farther from the earth. Without going further into detail, we may say that Mr. Darwin finds that if no other causes were at work not less than 50,000,000 years would be required for the evolution of the system of the earth and moon as it now exists.

It was not far from the beginning of the century that Herschel attempted the solution of the greatest of all problems—that of the structure of the universe. The problem proved, as may be supposed, quite impossible of solution by methods then available. Much has been learned during the century which was unknown to Herschel, but we seem to be as far as ever from the final solution. Instead of an orderly distribution of stars, clusters and systems, we find all apparently intermingled with vast cosmic clouds and huge dark bodies, possibly burned-out suns. For anything we know these latter may be as numerous or more so than the brilliant ones. Will the labor of another century bring order out of this seeming confusion or will it only disclose still greater complexities unknown to us? Time alone can tell.

C. L. DOOLITTLE.

UNIVERSITY OF PENNSYLVANIA.

SOME UNSCIENTIFIC REFLECTIONS UPON
SCIENCE.*

SCIENCE has its limitations and often confesses to them more or less directly, so that there must be some justification even from science for the heretical standpoint that I am now taking. Like all limitations, too, those of science are as much a source of danger as of opportunity to science itself. And also as for my being unscientific, it may be well to reflect that in these days any negative term can be looked upon as only an extreme or limiting degree—in one direction or the other—of that which it denies, so that I have at least an even chance of saying something scientifically worth while.

With regard to the limitations of science, it is a commonplace of the day that for accuracy and genuineness or purity science must be (1) independent of life, the subjective interests, whether personal or social, being perhaps science's most unsettling influences, (2) specialistic, the 'Jack of all trades' in science being anything but *persona grata* among scientific men, and (3) positivistic, all conceits about what is beyond actual experience and even all dogma about what seems really present to experience being most arrant heresy. But in every one of these requirements or conditions, that do indeed make science possible, there lurk serious dangers, which I wish to point out and emphasize. Not that they have never been seen or heard of before, but rather that certain things are sometimes so commonplace, so well known, as to be unappreciated, if not forgotten altogether.

So, in the first place, the ideal of objectivism for science tends, just in proportion as it is realized, to bury science in the deep

* This paper was read in part at the Baltimore meeting of the American Psychological Association, December, 1900, and *in toto* before the Research Club of the University of Michigan, in May, 1901.

grave of technique. Of course, if one believes in a resurrection, all may yet be well, but many do not or at least would blush to admit any such belief. And just what do I mean by technique? I mean everything that makes scientific work purely mechanical, for pure mechanicalism is the inevitable method of pure objectivism. Scientists have their etiquette about preempted problems or fields of research, their notions about originality as dependent on working in a new field—hence the preemption to prevent transgression or theft of originality, their conceits about bibliographical information, linguistic proficiency and technical phraseology, their satisfaction over 'publication,' 'contribution,' 'production,' and even 'research,' and a very humble deference of each to each among the different branches of scientific enquiry; and under technique I would include all these things as well as the more familiar matters of method and apparatus and material. Physicians, we are told, and not infrequently their patients, suffer from a professional ritual and etiquette, but they are far from being alone in their misery. Scientists are a close second. Of course to deny that technique has its uses would be absurd. The danger, however, not the use of it, is what now concerns us. Technique is one of the enabling conditions of science, but science that gets no further, that is only 'pure' and 'objective' and 'inductive,' is not true science; its much-vaunted observation and experiment may fill a good many pages and a good many volumes, but material, even material in books, and experiments, even carefully reported experiments, are not science necessarily.

True science, as I conceive it, and I think as all are conceiving it to-day with growing clearness, is synthetic as well as analytic, being interested in something more than a decomposable object. It is activity, not

mere passive receptivity; it is invention, not mere discovery; and what so many are pleased to call the real life, subjective as this is, the real life of a person, a society, or a race, is as important to it, as much a warrant of its conclusions, as any object, however mathematically describable, with which science was ever concerned. True science, I say, is no mere knowledge of an outer world; it is invention, the invention of a tool, the making of a great machine, with use of which human life is to become more vital or more effective, more nearly adequate to the world in which man finds himself; it is what a biologist might call an instrument of adaptation to environment. Sometimes this instrument takes visible, wholly material form; sometimes it appears as method in the practical arts; sometimes it is only an atmosphere or point of view, a habit of mind; but, whatever it is, it is useful, incalculably useful, and its invention is science's chief justification.

This, objects somebody, is sentiment, and sentiment of the sort that destroys science, making serious accurate science impossible. I can not possibly agree. Is a man less interested in having a proper edge on his razor because eventually he must use it on himself? Nothing but the truth can ever set anybody free. But, all question of sentiment or of sharp razors or of a truth that liberates aside, the consistent evolutionist is obliged to take the view of science that is here asserted, just as in general he is obliged to think of consciousness as one of the positive conditions of organic development. To be an evolutionist and at the same time to think of consciousness as only an external ornament of life, perhaps a result without being a condition of development, or of science as solely for its own sake, would be nothing more nor less than to stultify one's self completely. For the historian, too, whether evolutionist or

not, whose chief business is to remind us that the present is not all, the prevailing devotion to science for its own sake, which also in other times has possessed the minds and hearts of men, can be at best only a passing phenomenon. And then, apart from the standpoints of evolution and history, human society is sure sooner or later to resent what I venture to call the aristocratic temper that pure objective science is all too likely to acquire from the exclusiveness of its ritual or technique or say from its academic dress. Aristocratic temper, whatever its direction, is unquestionably as desirable in social life as it is inevitable; it is incident to the development of all institutions, political, ecclesiastical, industrial or educational; but the resentment which it is sure to awaken is not one whit less serviceable to society, insuring, as it does, among other things the 'extension' of science, the translation of science into life.

So for a time pure science may lord it over applied science, the perfecting of science as a tool being the absorbing interest, and inferior men or at least so-called inferior men may be the unfortunate representatives of science in industry and the arts generally, but in our own day applied science has begun to assume its proper place of honor, and those engaged in it are even often recognized as 'research men,' and in general the use of any tool, which men devise, with never mind how much cloistered seclusion and esthetic fervor, is as necessary as the making. The true scientist, accordingly, can only welcome enthusiastically the many indications in recent times of an offensive and defensive alliance between science and industry, seeing in these a conclusive answer to those who have raised the cry of science's bankruptcy. Furthermore, the conflict between pure science, science as technique and applied science is one in nature, and I think also in time, with that between ecclesias-

ticism and theology on the one hand and practical religion on the other and the close analogy between the two must help to emphasize the danger of the purism, which is the objectivism and technique of science, without seriously reflecting on its usefulness.

But besides burying science in technique, objectivism involves a most interesting expression of conservatism. I am not now thinking of the double truth or the double life which it sanctions so cordially that men can entertain advanced scientific doctrines without feeling them in any serious conflict with the traditional teachings of religion and morality, but something else, perhaps not wholly unrelated to this, is in my mind. Thus, while science is commonly supposed to be advanced and 'up to date,' if anything is, it is so only in a way that needs to be very carefully qualified, for it manages to perpetuate not indeed the letter, but still the spirit of old views. Certainly a purely objective science can at best only give a new material content to existing and time-worn forms of thought; it cannot do that in which progress must always consist, namely, develop and adopt new forms of thought, new categories; it cannot do this without betraying its objectivism. Objective science, for example, has said, relatively to a certain doctrine of creation, that spirit did not precede matter in time, but instead matter preceded spirit, and, except for the excitement of the drawn battle which this startling assertion has precipitated, it can hardly be said to have involved any great advance. Also, while deposing the First Cause, an objective science has made all things causes after the same plan, individual, arbitrary, antecedent causes, and this is only to multiply indefinitely, perhaps infinitely, the offensive creationism. Not so, some one objects, since it involves a great deal more than mere multiplication, for by making all things causes it brings into science the

important principle of the equation of action and reaction, a principle which, turning creationism fatally against itself, yields the new standpoint of mechanicalism. Readily I grant this, but a purely objective science has no right to any such development; a purely objective science has no right ever to change its standpoint.

Perhaps this does not mean very much. Then let us approach the matter in another way, risking a reference to one of science's pet conceits, the familiar 'question of fact.' It has been for science a 'question of fact' whether matter made mind or mind made matter, whether this or that thing is or is not a cause of some other thing, whether certain very low, mayhap unicellular organisms, show purpose in their activities or do not, are gifted with a natural tendency to social life, a real interest in their kind, or are not so gifted, or—to take one more case—whether the changes in the brain that precede bodily movements are or are not directed by consciousness, consciousness being in the one case in causal relation with the brain and in the other only an idle external accompaniment, an 'epiphenomenon'—but in each one of these questions of fact we can see how the scientist is given to standing in his own light, obscuring the view of what he above all others ought to see. Are mind and matter, cause and effect, purpose, society, brain-process and consciousness such well-established conceptions, as if independent constants in the scientist's formulæ, that mere external questions of fact can be asked about them? Why, when one really thinks about it, to assume, as questions of fact are usually made to assume, such is their natural objectivism, that anything either is or is not something else, is about as blinding and as ill-advised as could well be. It keeps the scientist busy no doubt, eternally busy, as busy as the sportive cat that so hotly pursues her own caudal extremity, but it does

not contribute much that is positive and progressive. To the question, for example, about lower organisms showing purpose or social feeling in their activity the scientist may answer no and be quite emphatic in his answer too, but almost at once he will appreciate that mankind, when scrutinized in the same way, is similarly deficient; and then somehow the wind is taken out of his sails, since purpose and social feeling are not to be so easily disposed of, and the question of fact simply returns for another reckoning, with Shelley's cloud, silently laughing at its own cenotaph. And what is the difficulty? The difficulty is in the assumption that purpose or social feeling is a fixed conception, so fixed and so well known that its presence or absence can be established by an experiment or two on strictly objective principles. No conception is fixed, and a science that entertains a question of fact with its 'either this or not this,' 'either that or not that,' simply needs to betray its objectivism sufficiently to *recognize* that no conception is fixed, and to recognize at the same time—for this is directly implied—that any division of the things of the world into *a* and not-*a* or *b* and not-*b* is necessarily artificial. In a real universe everything must be true of everything, nothing can be what anything else is not. Let science recognize these things and it will promptly exchange its external objective question of fact for direct internal questions of meaning. Thus, for one of the cases in hand, not Are low organisms social or purposive, but What do they testify as to the real nature of society or of purpose? Being subject to the principle, which I but just now referred to and which I think is not to be gainsaid, that in a real universe everything must be true of everything, that a real universe is really indivisible, the things of man's experience, whatever they be, must always be means to man's understanding of himself, not the

affairs of an wholly objective science. What they are not, he is not; what they are, he is. So, instead of denying purpose or social feeling, or even of assuming the possibility of their denial to lower organisms, science should simply seize the opportunity which its experiments afford of a clearer definition of purpose or society. Thus the experiments seem to show, not that there is no purposive activity or social life in low organisms, but that purpose itself, wherever exhibited, is only the urgency of expressing an existing adaptation, an adaptation that is at once realized and even consciously appreciated. A purely objective science could never assume the standpoint here illustrated, but a progressive science, a science for which let us say knowledge is as much a reaction as an action, a reflection as an observation, can take no other.

The conservatism of objective science or the viewpoint in its questions of fact, which the conservatism determines, is the chief reason for the negative attitude of science, so often an object of *just* complaint. Thus, to use still another illustration, for science to assume that God either is or is not, because He must either be or not be what men have thought Him, is simply to beg the theological question altogether, and true science, or at least true thinking, cannot be and should not be identified with such question-begging. Thus, for science's question of fact, a negative answer is a foregone conclusion, inasmuch as the very fact of the question is evidence that a new idea of God is only just below, if not already on the horizon of man's consciousness. What, therefore, we should ask is, not *Is God?* but simply and candidly, *What is He?* The business of science is to accept and interpret experience, not to question its very reality.

But, secondly, there is scientific specialism, a natural concomitant of objectivism, since the objective as innocent of all

subjective relations is necessarily manifold and discrete, and so turns scientific study into many separate ways. The peculiar danger of specialism is that it is almost certain to make vision dim, if not to induce complete blindness, or, as virtually the same thing, to create in consciousness curious fancies, strange distortions of reality, seen not with the eye at all, but with the mind, which is always so ingeniously constructive, so original, so imaginative, and one might even say so hypnotic in its power of suggestion over the senses. Specialism closes one's eyes and makes one dream. It makes the specialist among physicians see his special ailment in every disorder, and every disorder in his special ailment, and this so truly that merely to consult him is to fall his victim. Of course, he can never be wholly wrong, and his unwitting transgressions help discovery, but, nevertheless, his situation is full of humor. And in science generally, the specialist dreams, transgressing his own proper bounds without clearly knowing that he has transgressed. Why? Because thought, which although often apparently suppressed and abused never actually deserts experiment and observation, is so much greater than vision, than mere sensuous perception. In spite of the specialist being all eyes for his own peculiar interest, the thought that is within him, being bound to conserve an indivisible universe in every particular thing, leads him, thoughtless devotee that he is, patiently repeating his sacred syllable, into most wonderful visions, projecting his consciousness to regions of such logical subtlety and marvellous construction as was certainly never known before, unless, perhaps, among those Eastern sages who fed their minds on 'om.' A specialist, he sees the universe, not knowing in his blindness or in his dreaming that it is the universe; and his danger, the danger of all specialism, is that he may never awake.

Thus mathematics and physics and chemistry and biology and psychology, not to say also the social sciences, are dependent upon the visions of specialism. Each of them may indeed be special, but thought insists upon making its object conform to reality, which is never special, so that in each there do and must arise abstractions, logical constructions, for the others. When, for example, a physical scientist insists on seeing his world of material phenomena only physically, while in reality it is and must be a world of chemical process also, and even of vital and mental character, he is bound to admit to his thinking what he will call working hypotheses, formally true to his physical standpoint, but what any outsider, in order to explain why they are hypotheses that work, must call compensating conceptions, in short logical constructions that are substitutes for the neglected points of view. A science's working hypotheses are thus as if doors in the paneling by which the other sciences are secretly admitted to a room that seems tightly closed to all comers. Every science, in short, and this the more as the science is special and objective and exact, entertains the others unawares. Tennyson's 'flower in the crannied wall' is nothing in its all-inclusiveness when compared with a well-developed special science. In a sense that is indeed coming to be widely appreciated, no science ever does or ever can live unto itself alone. It may will to, but it does not and cannot.

But what are these 'working hypotheses' that work because they are 'compensating conceptions' or 'doors in the paneling'? Some illustration of the foregoing is now imperative. Illustration, however, is difficult, very difficult, for a reason which the scientists will allow me to mention. They know too much about the sciences, while I know too little. Still, as too much knowledge is often blinding and so is only a form

of ignorance, the situation is not altogether hopeless. Thus, while it is true that scientists are likely to insist, even in the face of the principle of thought preserving the unity of an indivisible universe in all the varied studies and conclusions of science, that physics is nevertheless only physics and chemistry only chemistry and biology only biology and psychology only psychology, and while also my illustrations must all come from the field of their special sciences and may therefore only set them more firmly in the willful blindness of specialism, still the principle itself, the principle of a conserving thought, is a disturbing influence which they cannot escape, and then besides I am for the moment forgetting and asking them to forget a very important fact of scientific study today. In these times the running together, or merging, of different sciences, as if through something of the nature of a chemical reaction, is a very familiar phenomenon, and it has been taking place with such persistence and confidence as actually to suggest a natural affinity, each of the sciences involved having the rich experience of discovering itself in the others. This fact, then, must make illustration at least less difficult, since in a way that is certain to appeal to science as no mere theory ever can, it proves or goes far towards proving what is to be illustrated. Moreover, specific illustration is hardly necessary in the sphere of the physical sciences or again in that of the social or of the psychological sciences, for within each one of these groups the affinity but just now referred to has been clearly exemplified, as in the interesting case of physics, chemistry and mathematics. Illustration, then, is needed only for the physical in relation to the social and psychological, and to this I now turn.

In articles already published under the titles 'Epistemology and Physical Science

—A Fatal Parallelism,'* and 'Physical Psychology,'† I have undertaken to show, and I believe I have at least made a beginning of showing, that the dualism of mind and matter, which separates the physical and psychical sciences, is logically reproduced, as if by a sort of projection, within the special spheres of each. Physical psychology is 'concerned with the substitutes or indirections for mind [for the sort of unity, intensive instead of extensive or qualitative instead of quantitative or vital and spiritual instead of physical, which is always associated with mind] that appear in all the so-called physical sciences,' and corresponding to physical psychology there is a psychological or epistemological physics, in its turn concerned with the substitutes for quantity and matter that are present in all the psychical sciences. The sensuous self, for example, with the atomism that it has always involved psychology and epistemology in, is only as if a projection of the physical on the psychical. Sensationalism, as we all know, has ever been closely associated in history with materialism. And, on the other side, in conservation,‡ in plentitude, in motion as relative, that is to say, as always under a principle of uniformity or constancy, and also as inclining to something like vibration or rotation, in which it is an expression of rest as well as motion, and finally, not to continue what might be a long catalogue, in the infinity of space and time or—as the same thing—of quan-

* See *Philosophical Review*, July, 1898.

† See *Psychological Review*, March, 1900.

‡ The case of conservation, in addition to what is to be said here and to what has been said in the two articles referred to above, may be put in this way. This is not the 'constant quantity,' not a mere quantity, but a ratio? As a ratio, even if finite, it is, like all ratios, more than merely quantitative, its constancy testifying, not to mere quantitative unity, but to a unity that quite transcends any purely quantitative differences. As ratios all quantities are both finite and infinite.

tity, the physical sciences have 'doors in their paneling' for the silent entrance of psychical. Do you fail to see this? Then, I can now only suggest, and probably I need only to suggest, that every one of these physical notions, either implicitly or explicitly, is paradoxical, and the paradox, whenever it arises, shows the thinker become a traitor to his chosen standpoint, to his accepted forms—in the case in hand, of course, to the forms and standpoint of physical science.* Moreover, such conceptions as conservation and plenitude and vibration and rotation and infinity, dependent as so largely they are upon what is agreeably known as the scientific imagination, are usually recognized as the physical basis of the very possibility of science, which I would now venture to define, not as mind's knowledge of matter, or in general of objective reality, but as mind's knowledge of itself in matter or in objective reality. Science, in other words, even special science, even objective science, is self-consciousness; say a very realistic self-consciousness, the self seen through the mirror of not-self; which, although metaphysical and almost offensive, reminds me and perhaps others of Burns:

"O wad some power the giftie gie us,
To see ourself as others see us!
It wad frae monie a blunder free us,
And foolish notion."

The bonnie Robert was too much of a specialist in poetry to see that science was the very thing he prayed for.

But now for further illustration of the way in which thought defies specialism and

* Thus conservation as quantitative is a paradox since the constant quantity cannot be finite and infinity is not a mere quantity. The plenal medium can be material only if displaced by material things and plenal only if not material and it is used, too, as an immobile, albeit elastic to an infinitesimal sensitivity, basis of motion. Motion itself is also rest. And infinity, as already implied, is a quantitative paradox, which means a 'door' for quality, for the intensive unity of mind.

conserves its universe I would mention several important facts, that are certainly not unfamiliar, as follows: Thus the social sciences imply affinity for the physical sciences, in that, besides their more special divisions, they are constantly making appeal to science in all its branches from physics to psychology; and the biological sciences, in addition to their more conventional forms, are becoming most hospitable to psychology, chemistry, and even to mechanics. Again, all the different sciences, however special, are wont to adopt the same general method, as, for example, the historical method, the consequences of which to the cause of pure specialism may easily be inferred. And, lastly, striking analogies, other than that of method, are always easily traceable among the sciences of any particular time. Atomism in physics is contemporary with individualism—consider Democritus and the Sophists—in politics; a monarchical politics with an anthropomorphic creationistic theology and a heliocentric astronomy; and a Newtonian astronomy, which makes a law or force instead of an individual body the real center of the solar system, with democracy or constitutionalism and inductive instead of deductive logic and naturalistic theology; so that at no time, whatever a scientist's interest, can he fail to have at least a formal sympathy with other sciences. Analogies among the sciences, so often recognized in these times, are not exactly 'doors in the paneling,' but they may be said to make the paneled partitions all but unsubstantial and transparent.

Specialism, then, is more formal than real. The special science needs only to develop to become, and to find itself, universal. The barriers with which it surrounds itself gradually vanish into mere imaginary lines, which only long usage can possibly make seem substantial and opaque, so that specialism by a logic of its own or by

the logic of a thought that conserves its universe even in the varied studies and conclusions of the many sciences, is destined to end in the unification of the sciences. To say the very least it is the natural fate of the special science to develop into methods of each other.

Unification of the sciences, however, implying as it does the decline of specialism and so also the decline of objectivism, brings with it the translation of science into life, in short the application of science, of which, in addition to what was said before, I would now speak again, but briefly and concisely, for the positivism of science is still to be considered.

The decline of specialism, which we have found to be natural to specialism, by making the dividing partitions unreal is bound in the first place to free the sciences from that bondage of technique, just as, for example, the decline of religious—or irreligious?—sectarianism, a form of specialism certainly, is bound to free religion from the bondage of ritual. Secondly, it must make the distinction between self and not-self, subject and object, man and nature, only a formal one, formal in the way in which the special sciences themselves are distinguished, since the unity of the objective world is one and the same with the self or subject. This we but just now saw, when we were able to define science as not mere knowledge of an outer world, but self-consciousness, realistic self-consciousness, to understand which only reflect further upon the art and literature so natural to an age of science. Art and literature are self-consciousness. But, thirdly, whether because of the freedom from technique or because the scientist does come to discover his own image in the clearing and quieting waters of science, the decline of specialism, again like the decline of sectarianism, brings what some are pleased to style the liberation of the human spirit, a libera-

tion that means freedom in, not freedom from, the natural world, and what a psychologist would call the development of knowledge into will, in short the application of science. Of course applied science must be not special, but general, because life is general; not ritualistic, but spiritual, because life is not ritualistic, making no fast distinctions between part and part or part and whole; and practically or even intuitively wise or skilled, as well as confidently volitional, not technically learned and esthetically satisfied, because life is not learned, but wise. Yes, the natural decline of specialism means the unification which is also the application of science, and, to bring the matter home, any scientific association, through which the sciences find each other out is really dangerous to the cause of pure, of objective and special science, since it can only forerun the movement of science into life.

But now as to positivism, at once the third condition and third danger of science. It can hardly be necessary to show that this is involved alike in objectivism and in specialism. Positivism confines knowledge to actual experience and to only a tentative confidence in actual experience. Scientific knowledge is positivistic, because it is obscured or refracted by the aloofness of the scientific point of view. Science is aloof from life and—in its specialism—also from itself. Then, when men who would be scientists withdraw, as we say, from affairs, it is as if they had put on distorting and discoloring glasses, through which they would see the world, the 'objective' world. The space and the time, for example, in which they see things are widely different from the space and time in which things are doing, from the space and the time of will and action. The difference is felt by us even in ordinary life, but the extreme attitude of science greatly exaggerates it. For science space and time are quantitative, divisible,

formal, independent of what is in them; for will and action they are qualitative, indivisible, inseparable from their content. Again, the scientists reduce causation to mere uniformity of coexistences or sequences, which is no real causation at all, being only so much passive existence or fatal process; while will or action is causation, the positive interaction of things that are, the active relation and conservation of what was and is and will be. And, once more, science needs elements, while will or life is the eternal denial of elements or anything like them. Says a recent writer: * "It is one of the greatest dangers of our time that the naturalistic (or scientific) point of view, which decomposes the world into elements for the purpose of causal connection, interferes with the volitional point of view of the real life, which can deal only with values and not with elements." Of the danger involved I shall speak in a moment, † but the bondage of science to elements, to thoroughly decomposed reality, is indubitable. And then, in addition to the formal space and time, the empty causality and the unreal elements, that are peculiar to the aloofness of science from life, there are in the special sciences the different 'working hypotheses,' which we found to serve the purposes of protecting conservation against specialism, but which, nevertheless, so long as retaining their projected forms, make science artificial. Science, accordingly, has no choice; it is condemned to positivism. Even the much-vaunted experience of observation and experiment, although our only possible source of knowledge, can never lead to direct knowledge of reality, can never put us face to face with that which is. Even in science we know appearances, not things.

* See Münsterberg's 'Psychology and Life,' p. 267. Houghton, Mifflin & Co. 1899.

† See also Münsterberg's 'Grundzüge der Psychologie' in the *Psychological Review*, May, 1901.

But what now is the danger? The writer quoted above says it is the interference of the scientific with the volitional point of view. With not less truth, however, it is that the two points of view will not interfere, that both science and life will fail to appreciate, as that writer has failed to appreciate, the true import of their incongruity, and so will forever stay apart, the one losing itself in a morbid intellectualism, the other in a dead monotony of mere existence. Whatever be true about their incongruity, life without science is certainly lifeless; science without life, meaningless—as meaningless, as empty, as the proverbial Greek. We know men who lead what we often abusively call the double life. They have their science, perhaps their laboratories and their books and their own pet doctrines, and they have also their social affiliations in business, in politics and in religion; and their life seems double, because their sociology and their business, or their political theory and their party ties, or their biology and their religion, simply will not mix. But is their duplicity as real as it seems? To them, as well as for us looking on, the opposition needs only to grow to make all the science meaningless and all the life dead; certainly a strange, ineffectual opposition; a double life, that can be double only in form, only numerically and that must be tedious and unhappy even in its peacefulness. And what more can be said? This. Such duplicity, the duplicity of science and life as never interfering, is not even possible. *Of course* scientific technique, with its aloofness and its logical constructions, and life that in its special affairs is only conventional and ritualistic, or say, routine in the study or the laboratory and routine in the church or the market place, can never conflict, but routine is never either real science or real life. Witness the avowed, although sometimes forgotten, positivism of technical

science and the unrest, the bravado that is so ill-disguised, of what some call 'life.' Science knows that it does not know, that it can not know, that even conscious man has always moving within him another relation to his world than that of knowledge; and life, as apart from knowledge, shows that it does not live. So again I say that the real danger of positivism, of a blind or forgetful positivism, is that the naturalistic or scientific point of view and the volitional point of view will not interfere with each other. Certainly within the laboratory and the study to keep them apart, to separate theory and experiment, would be fatal to both; the life that we call science needs their constant interference, and with every one of its experiments shows that they are not as incongruous as they seem; but what is the world, if not a great laboratory that is related to the smaller as real life to the theater, as nature to the conservatory, as an unaided vision to the microscope?

Agnosticism is another name for positivism. The positivist, the devotee of pure, objective, special science, cannot but believe in an unknowable, and this belief, in its turn often forgotten, needs always to be recognized as a part, a very important part, of the scientific consciousness, for it is only one other way in which thought conserves its universe. Thus the unknowable, whether seen as compensating for science's aloofness from life or for the dreaming that specialism induces, is a constant safeguard against the abuse of knowledge.

The unknowable is a negative that bears constant witness, not to another sphere which some mind quite different from our own might consciously comprehend, and which we, being intellectually outside, and so only creatures of faith, can merely blindly will, but to another relation than that of mere knowledge, which we *as knowing creatures* have to reality. There is, in short, an unknowable for the single reason

that to know is also to will. Or, again, the unknowable is not for knowledge, but for action.

Let us be blindly scientific, insisting on science being only for science's sake, recognizing nothing as worth while but great learning about a Greek particle or a minute insect or a mysterious element, and like a dark cloud there arises and spreads over our view the unknowable, and from this cloud a voice comes: "Only the All is and the All is One and the One is not for knowledge." But as we apply our science, breaking through the walls of specialism, and liberating the will that was for the time their not unwilling prisoner, the sky clears. The one is not for knowledge, but for life; knowledge is not for knowledge, but for will, its natural fulfillment. "The end of man is action, not thought, though it were the noblest."

ALFRED H. LLOYD.

TRUMAN HENRY SAFFORD.

A LONG, active, busy life, devoted without reserve to teaching, to research, to cares of family—such a life of science as that which closed on June 12, in Newark, cannot receive adequate appreciation in the brief space available here. But the friendship of years crowding one upon another will not let pass in silence the death of Truman Henry Safford. A few words of personal sorrow demand immediate expression; leaving a more complete summary of his life's tribute to astronomy to await dignified publication in the annals of those learned societies of which he was a distinguished member.

The friendship of years is no light thing. It was in the latter part of 1884 that Safford paid his first visit to the modest observatory of Columbia College, then situated in 49th Street, N. Y. He found there a stripling engaged in testing a level. The

youngster noticed a kindly face appearing in the doorway; conversation began about the level—and from that day on, no year has passed without the interchange of friendly visits between Safford and the writer of these words. Often and often have we sat far into the night in his 'den' at Williamstown, our talk always of astronomy and its masters. And well he knew the masters, ever recommending and emphasizing that they be studied at first-hand, not through editorially emasculated translations and editions. Gauss was an especial favorite; for Safford was first of all a teacher, and believed that mathematical instruction should always include concrete examples, especially numerical ones. The 'Theoria Motus,' with its endless ramifications of trigonometrical applications and its orbit computations, was beloved by him both for personal reading and as a text for his students. Bessel's works, even those less frequently read, like the 'Tabulæ Regiomontanæ,' he had at his fingers' ends. Text-books attracted him less. He did not use Chauvenet's astronomy, that *vade mecum* of the younger generation; it is doubtful if he owned a copy.

Indeed, a rich fund of anecdote might be collected to illustrate Safford's lovable quaintness of character. One of the cherished dreams of his life was his plan of an extended visit to Europe, its astronomers, observatories and places of historic or scenic interest. Circumstances always prevented this voyage; yet, though he was never abroad, he possessed a most intimate acquaintance with foreign countries. Few Londoners could equal his knowledge of the geography of their city. The interminable intricacies of its streets he had studied from maps until, as his friends said, he could have found his way anywhere without a guide. 'Bradshaw,' the incomprehensible British railway time-table, was an

unsealed book to him. A copy was always close at hand in his library at Williamstown, and he was never tired of extracting from it new and difficult railway problems with their solutions, to the huge amusement of his family and friends.

This ungratified longing for foreign travel showed itself in still another amusing way. On the occasions of his visits to New York, he would often go to parts of the city frequented by foreigners, and afterwards entertain his friends with odd experiences, especially in the foreign restaurants. On one occasion, in the year of the Chicago Exposition, it fell to Safford to act for a day as *cicerone* in New York to two distinguished Englishmen, one a professor, the other an admiral. All three returned from their day delighted; it had been passed at an island much liked by excursionists. Here Safford had discovered, to his great glee, a place called *Klein Deutschland*, and could imagine himself for the moment in Germany. Afterwards, it always gave him indescribable enjoyment to talk of this trip, and especially how acquaintance had been made with a man who insisted on explaining the men-of-war lying in the Brooklyn Navy Yard, and was even led on to go a little into astronomy. Neither the two professors nor the admiral made known to their informant that they had even so much as heard of stars or ships before. Safford had an inexhaustible love for the humorous and the quaint; to those who knew how to understand him, he could be most entertaining. He was passionately fond of music, and could appreciate the best.

But we must not give too much space to those characteristics which attracted his friends so strongly, to the neglect of that which the world of science owes him. Born January 6, 1836, at Royalton, Vt., he showed already in his early boyhood the extraordinary arithmetical powers which distinguished him through life; for he could

at all times multiply mentally very large numbers, knew off-hand the multiplication table to 1,000, and most of the logarithmic tables to three figures. At fourteen he is said to have calculated a cometary orbit, and he graduated from Harvard at eighteen. For some years he was observer at that university under Bond, and for a short time was acting director. In 1865 he took charge of the Chicago Observatory, where he began as his serious work the observation of one of the *Astronomische Gesellschaft* zones. But his work was cut short and his position lost through the great Chicago fire. He then entered Wheeler's astronomical survey in the far West, and worked during several years for the government scientific bureaus of Washington. It was not until 1876 that he finally settled down for life as professor of astronomy in Williams College, Williamstown, Mass.

Here was done his principal work, which related especially to star positions and star catalogues. He made an elaborate discussion of all existing observations of the stars most suitable for determining geographical latitudes in the United States. This resulted in a catalogue of 2018 stars, which was published by the Engineer's Department, U. S. Army. Later, he made a similar catalogue of 612 stars, and upon it has been based the new boundary between the United States and Mexico. This was published in the report of the Mexican Boundary Commission, Washington, 1898. Safford built at Williamstown a meridian observatory which is a model of its class. In it he installed a Repsold circle, with which he made extensive observations of the close polar stars. He liked these stars especially, and the unusually lengthy numerical calculations connected with them did not frighten him. He needed no observing list, as his memory never failed to give him the instrumental setting for each of his beloved polars in every possible posi-

tion of his instrument. These polar observations were collected and published by him in the 'Williams College Catalogue of North Polar Stars.'

But all this work belongs to a class important to pure science, though comparatively uninteresting to the general public; for Safford possessed especially that kind of devotion which can give generously to science without hope of public notice. More striking, perhaps, was his confident prediction in 1861 of the minute unseen companion of the bright star Sirius. Basing laborious calculations on the tiny irregularities in existing observations, he was able to show just where the little *comes* must be. And there it was found in January, 1862, by Alvan Clark, of Cambridgeport, Mass., while he was testing the 18-inch glass now mounted at Evanston, Ill.

Safford was a frequent contributor to astronomical and educational publications, and a member of many learned bodies. The Royal Astronomical Society, of London, honored him with an election as associate in 1866, when he was but thirty years of age. Great as were his abilities in astronomy, he was yet at his best as a teacher. Those who came under his influence at Williamstown can bear witness to this; his ablest pupils profited most from his stored learning, and some from among them are laboring for astronomy today. He was a loving and dearly loved husband and father. To him were granted these priceless blessings: a devoted wife, a united family, a few time-tested friends. A man of genuine piety, the conflict of science and religion had no terrors for him. He knew that no such conflict exists; that the foundations of belief rest not upon ponderous tomes of logic, but on simple faith. Such faith he had, as of a little child; and, like a child asleep, so shall God's acre rest him.

HAROLD JACOBY.

SCIENTIFIC BOOKS.

X *Ind.*
A Synopsis of the Mammals of North America and the Adjacent Seas. By DANIEL GIRAUD ELIOT. Publications of the Field Columbian Museum, Zoological Series, Vol. II. Chicago, Field Columbian Museum; New York City, F. P. Harper; London, R. H. Porter; Berlin, R. Friedländer & Son; Paris, J. B. Bailliere & Son. March, 1901. Pp. xv + 471. Pls. XLIX. Text figs. 94. Price, \$3.00.

Until the appearance of Mr. Elliot's synopsis, no general work on the mammals of North America had been written since 1857, the date of publication by Baird of the eighth volume of the Pacific Railroad Survey reports. The need for a work of this kind may be appreciated from the fact that the number of mammals known to inhabit America north of Mexico has increased, during the past forty-four years, from about 300 to over 1,000.

"This Synopsis," the author writes, "is an attempt to bring together all the forms of North American * mammals that have been described, and which are generally considered as entitled to some kind of recognition. * * * The present time cannot be supposed as opportune for a final and satisfactory revision of the various groups * * *. That must be the work of some future Mammalogist, who can bring to the task not only a thoroughly unprejudiced mind, but who may have acquired a more intimate acquaintance with the quadrupeds of those sections of our country, as yet little known, and whose knowledge of geographical distribution of mammals, the extent of the individual variation of crania, the relationships that apparently different forms have for each other, and the changes in color assumed by the pelage throughout the year, and in some cases adopted by the sexes, has been gained from extensive series of specimens, much greater and more complete than those possessed by any naturalist at the present day. * * * This Synopsis, therefore, may only be regarded as a starting-point upon which such a final list may be founded, and does not purport to indicate how many species of mammals there are in North America, but merely to

* Or, more correctly, species inhabiting the United States and Canada, since those confined to other parts of the continent are omitted.

show how many forms are given some kind of distinctive rank at the present time * * *." Obviously the work is intended as a reflection of current opinion, and not as a critical treatment of the subject. Therefore it will be necessary, in order to appreciate the book, to gain some understanding of the tendencies of the more recent work on North American mammals, and also of Mr. Elliot's attitude toward the conclusions that he wishes to summarize.

The object of systematic biology was defined by Cope as the accurate statement of the results of organic evolution. Convenience in naming and labeling individual specimens is no longer to be regarded as of more than secondary importance. During the past fifteen years, the period of greatest activity in the study of North American mammals, series of specimens aggregating many thousands of individuals have been collected with the special object of showing the results attained by the process of evolution at the present time. These results, though not yet thoroughly understood, have been found much more complex than had been supposed. Species and subspecies, to use for the present these obsolete terms in the absence of the single word needed to replace them, are not invariably separated from their allies by characters easy to describe. They are interrelated with every degree of intricacy, and it is through the study of the more closely allied forms that the most significant facts are to be discovered. Sharply defined species have lost their history and with it their chief interest. No systematic work, therefore, is more important than the record of minute differences; and such difficulties as are met arise from the nature of the results which the process of evolution has reached, and from the inadequacy of language to express all that can be detected by the eye. That these difficulties are not averted when ignored is the standpoint of those with whose work Mr. Elliot deals. His attitude toward it may be learned from the second paragraph of the preface:

"It is very manifest to many Naturalists that too many forms have been given distinctive rank, and without doubt a considerable number of the so-called species and subspecies contained in this volume will eventually swell the

list of synonyms, already sufficiently formidable. In late years there has been an evident inclination among some Mammalogists to unduly magnify, as it would seem, trivial dissimilarities observed among their specimens, and thus greatly increase the number of slightly differentiated individuals elevated to a separate rank, at the risk of reducing the science to one founded on labels and localities, instead of distinctive and prominent characters, and thus a knowledge of the place where an example was obtained becomes at times of more importance for its identification than are the differences that may separate it from its allies. The lack of resemblances often observed among crania is frequently but the individual variations of a type, and taking these for characters upon which to establish a new species is apt to lead to error, and in not a few instances too much reliance has been placed on such slight differences. The same may be said of shades of color, and not a few names in this Synopsis have been given to specimens so closely alike, that one author, in speaking of his key, which was intended to be the means for distinguishing the species, has been obliged to say: It will be necessary to have both skins and skulls in hand, and even then *it will be impossible to identify some of the forms without actual comparison with their nearest allies*. The scientific value of such species (?) can only be very questionable at the best, and the elevation to a separate distinctive rank of such intimately related creatures cannot be considered as helpful or beneficial to Mammalogical Science. It can be safely asserted that there is hardly a genus of North American Mammals that does not contain too many named forms, and that the science would be benefited if a considerable number were relegated to their proper place among the synonyms."

No more would be required to show that the author is not in sympathy with the tendency toward minute accuracy characteristic of the work of to-day; but this hostile attitude is so insistently brought before the reader that one more allusion to it may be made. At the end of the account of the prairie wolves, rendered exceedingly obscure by the omission of details concerning skulls and teeth (pp. 301-303) occurs the following footnote: "It is difficult to dis-

tinguish these varieties of the coyote by any description, and still more so by the skins or skulls."

It is to be regretted that an author who is admittedly unable to present his own views throughout, and who is so obviously at variance with the opinions of others, should not have been content with bringing together as impersonally as possible the multitudinous scattered papers that now make the literature of the subject a maze. In the work as it stands, personal opinion, confessedly defective, and compilation, often not free from bias, are so blended that neither is convincing; and considerable knowledge on the part of the reader is required to avoid misunderstanding.

The book is well printed, though on glazed paper that is probably ill adapted to withstand constant use. This, however, was rendered necessary by the profuse half-tone figures with which the text is illustrated. Throughout the work a tendency to abbreviation is manifested, which, while it may have curtailed the length of the volume by a few dozen pages, has not increased the usefulness of the book. The time saved to author and printer by the use of such references as Schleg. Abte. Geb., or S. S. S. does not compensate the reader for that lost in search for the meaning so effectually concealed. Probably the feature of the work which will most forcibly impress those by whom it is most needed, and that which may be said to be its great defect, is the absence of keys. Of these there are none, either to species, genera or higher groups. The diagnoses of the 10 orders, 34 families, 115 genera and 998 species and subspecies occupy about one-third of a page each. In those relating to species and subspecies there is a noticeable lack of detail concerning skulls and teeth; while the characters given are often compiled in such a manner as to be misleading. The classification is essentially that of Trouessart, with the order reversed to begin with the marsupials. Species and subspecies are arranged in accordance with their supposed affinities, and, as might have been anticipated, the result is frequently less satisfactory than a purely alphabetic sequence would have been. No allusion is made to habits or life histories, and no English names are used except in the table

of contents. The technical nomenclature departs little from accepted usage, though it may be noted that the name *Cubassous* McMurtrie, 1831, is substituted for *Tatu* Blumenbach, 1799, *Manatus* Storr, 1780, for *Trichechus* Linnæus, 1758 (as applied to the manatee), and *Dicotyles* Cuvier, 1817, for *Tayassu* Fischer, 1814. The name *Trichechus*, though based on the manatee alone, is applied to the walrus. *Aplodontia* is altered to *Haplodontia* to conform with rules irrelevant to nomenclature, but *Reithrodontomys*, *Cynomys*, *tridecemlineatus* and doubtless many others, which on the same ground might be changed, are left in their correct original form. A single new name is proposed, *Balænoptera velifera copei* (page 13). As if to compensate for the brevity of the text, the book is illustrated with a profuseness hitherto unknown in similar works. The plates and text figures contain half-tone reproductions of photographs of the skull and teeth of at least one representative of nearly every genus and subgenus. The standard of excellence of these figures is very high, and no equally successful application of photography to zoological illustration on so extensive a scale has hitherto been made.

GERRIT S. MILLER, JR.

THE MARYLAND EOCENE BOOK.

THOSE who have had to deal with official geologic surveys know how frequently it is argued that publications of a character so purely scientific as paleontology appeal to a very limited audience, too limited, it is often urged, to justify the expenditure necessary for their proper production. The counter-argument, however, gets at the facts. Toward the close of the Second Geological Survey of Pennsylvania, after a cloud of volumes upon tectonics, economics and devitalized stratigraphy had been issued, Dr. Lesley prepared a 'Dictionary of Fossils,' profusely illustrated, suffused with important facts, amusing fancies and pages of errata, but a work of great usefulness. The demand created by the appearance of this book was so much greater than the supply that the edition was gone while its reportorial predecessors were resting on the shelves waiting for inquirers. In New York, Ohio and Illinois the experience has been very much the same.

'Maryland Geological Survey: Eocene' is the title of the first of a series of monographs upon the historical geology of Maryland, that is to say, its stratigraphy and fossils, in other words its paleontology. It seems eminently appropriate that the Eocene is chosen as the subject for the initial volume of this series in view of Professor Clark's exhaustive acquaintance with this formation. The state geologist, though taking a leading part in the composition and execution of the work has brought into cooperation with himself a number of experts in various special lines of research. Thus the leading chapter on Eocene stratigraphy and sequence, 'The Eocene Deposits of Maryland,' is by W. B. Clark and G. C. Martin. Under the part assigned to descriptive paleontology the chapters are as follows: Reptilia, by Case; Pisces, by Eastman; Arthropoda, and Bryozoa, by Ulrich; Mollusca, Brachiopoda and Echinodermata, by Clark and Martin; Coelenterata, by Vaughan; Protozoa, by Bagg, and Plantæ, by Hollick. Ten plates of maps and half-tones illustrate the first part of the work, and fifty-four process plates, largely of McConnell's fine pen-and-ink drawings, are devoted to the fossils. Like the other volumes of Professor Clark's survey this is exquisitely constructed on finished lines and commends itself to lovers of well-made books, who will all pray that the supercalendered wood-paper used for the plates may last until the world has no further need of the facts registered upon them.

It is an admirable achievement, bringing together in one place all that is now known of the Eocene stratigraphy and fauna in an important political division, and long after the present quarry workings, coal mines and clay pits of Maryland shall have been exhausted and abandoned, and all the economic products of the State shall have been converted into cash, the facts here brought together will endure, with a never-lessening value to the sum of human knowledge. The book will receive a welcome from paleontologists and merits the cordial appreciation of the citizens and students of the State for whom it has been specially prepared.

SOCIETIES AND ACADEMIES.

ZOOLOGICAL CLUB, UNIVERSITY OF CHICAGO,
WINTER QUARTER, 1901.

II.

At the meeting of February 6 the program consisted of a paper by Mr. C. M. Child, entitled 'Regulation in *Stenostomum*.'

This paper dealt chiefly with some of the phenomena of regulation following the cutting of an asexual chain of *Stenostomum*-zooids at various points. Some of the more important points are as follows:

The changes which occur after cutting a chain of *Stenostomum*-zooids differ greatly according to the position of the cut with respect to the zones of fission and according to the stage of development of the latter.

Pieces above a certain relative size, cut within the limits of a single zooid, regenerate the anterior and posterior ends without the formation of a distinct bud of new tissue, although proliferation occurs at the cut surfaces. A very rapid change of form occurs, the piece becoming longer and more slender and acquiring the 'normal' form of a *Stenostomum* individual. The time required for the completion of the regulation varies with the temperature, but is in all cases very short. At a temperature of 75° F. it is only three or four days.

If the piece consists of parts of two or more zooids, *i. e.*, if it contains one or more zones of fission, the processes of regulation are more complex. In pieces consisting of the posterior portion of one zooid and the anterior portion of the succeeding zooid the changes depend upon the stage of development of the organs about the zone of fission. If the zone of fission be at a very early stage it may disappear entirely, the whole piece becoming a single individual with head and tail at the two ends. In this case the part which was destined to become the posterior half of an individual becomes, in consequence of its separation from the chain, the anterior half, while the portion behind the zone of fission, which was destined to become the anterior half of an individual, now becomes the posterior half.

If the zone of fission is older, *i. e.*, if the new brain behind it is well established, all that por-

tion of the piece which lies in front of the zones of fission is absorbed by the part posterior to it, *i. e.*, the part which possesses the brain. This occurs even though the anterior piece is much the larger. As the anterior piece is absorbed it is reduced in size, and the zone of fission and the brain appear to migrate in the anterior direction until finally they reach the anterior end of the whole piece, *i. e.*, until the anterior part is completely absorbed. In a recent paper (*Proc. Cal. Acad. of Sciences*, Ser. III., Zoology, Vol. I., No. 6, 1901) Ritter and Congdon have asserted that the brain actually does migrate in pieces of this kind. This seems to be an error of interpretation. Continuous observation of the pieces shows that the facts are as stated above. Indeed, the migration of the intestine out of the anterior piece can be observed.

If the zone of fission has reached a late stage of development, so that the brain of the posterior zooid is well formed and the pieces are more nearly ready to separate, little or no absorption of the anterior piece occurs and the two pieces separate as they would under normal conditions, the anterior pieces developing a new head and the posterior piece a new tail at the respective cut surfaces.

The absorption, when it occurs, is always in the posterior direction, *i. e.*, the part deprived of a brain is absorbed by the part which still retains the brain. The actual disappearance of the zone of fission occurs only in the early stage when the brain posterior to it is not developed or is at a very early stage of development. In general the results depend upon the presence or absence, or the relative development, of the brains in the parts of zooids which make up the pieces.

In sexual individuals of *Stenostomum* asexual multiplication ceases, though the single individual may attain a length as great as a chain of eight or more sexual zooids. The power of regeneration in sexual individuals is not as great as in the asexual chains. The energy of the body appears to be directed in large part toward the elaboration of the sexual products, the consequence of this condition being the cessation of asexual multiplication and the reduction of the power of regeneration.

The session of the Club held on February

20 was devoted to an account by Mr. E. H. Harper of 'Regeneration in *Nais lacustris*.' The paper comprised the results of experiments on both sexual and asexual individuals of this species. The following is a brief abstract:

In the asexual forms where from one to five anterior segments are removed the same number is regenerated as was cut off. In this region in the sexual forms the head segment alone is regenerated, or frequently the surface heals over without regenerating.

When more than five segments are removed in the asexual forms a pharyngeal region of five segments is regenerated. In the sexual animals the process is much slower and in an advanced sexual stage a dwarfed region of five very short segments is produced. The clitellum and sexual organs may be regenerated. This has been seen to occur after a considerable time.

So far as could be determined mutilation never causes the disappearance of the sexual organs, but the formation of a regenerating region will under certain conditions inhibit the process of asexual multiplication and cause the disappearance of the zone of fission. This effect may be produced by a cut anterior to the zone of fission, less often by a cut posterior to it, and occurs only when the zone is embryonic. The zone is also more likely to disappear if the cut is near to it. The band of transparent embryonic tissue redifferentiates and the energy of growth is transferred to the regenerating region.

In the asexual individuals the power of regeneration is less in the anterior specialized region and also in the posterior budding region than in the middle of the body. Short posterior pieces may live a considerable time, but do not regenerate. Anterior pieces of eight or nine segments may survive a short time without regenerating, but pieces of the same length from the middle of the body regenerate freely.

Internal conditions favorable to proliferation, such as the exposure of cut surfaces of intestine and blood vessels, are present in nearly all possible experiments. But if a corner of the head segment be removed, including the prostomium, without injuring the pharynx,

the ectoderm will close over the surface and regeneration will not take place. In the sexual forms failure to regenerate may occur when the pharynx is cut through. Here the tendency to proliferate is slight and it may be that the epithelium differentiates completely over the cut surface before any appreciable amount of regeneration has occurred. And it is probable that after the epithelium is formed there is no further tendency to regenerate.

Growth takes place at right angles to a cut surface; and if the cut is oblique the bud will grow out at an angle to the axis of the body. Straightening is effected after the penetration of the lumen of the intestine into the region under the influence of its peristaltic motions.

Many of the internal phenomena of regeneration may be observed in the living animal on account of the transparency of the body wall. Migration of pigmented cells from the intestine toward a regenerating region can be seen. If a corner of the head segment be cut off, including one eye, the pigmented portion of the other eye is usually fragmented and pigment migrates in various directions.

It has been stated that the regenerative power of these animals varies with the season of the year, being less in autumn and winter. No evidence of this has been observed, but the evidence points rather, as we have seen, to an inverse correlation between regenerative power and sexual activity. Budding, *i. e.*, asexual, individuals regenerate freely and completely in December. The sexual forms are found from October to December.

The program for the meeting of March 6 consisted of two papers, 'The Excretory System of the Bryozoa,' by Miss A. W. Wilcox, and 'Montgomery on the Spermatogenesis of *Peripatopsis*,' by Mr. E. R. Downing.

Miss Wilcox reviewed the literature upon the excretory organs of the Bryozoa and gave the results of some work of her own on the Phylactolæmata. Her paper will appear in full elsewhere.

Mr. Downing's paper consisted of a review and discussion of Montgomery's recent study of the spermatogenesis of *Peripatopsis*.

C. M. CHILD.

THE NEW YORK SECTION OF THE AMERICAN
CHEMICAL SOCIETY.

THE last meeting of the season of the New York Section of the American Chemical Society was held on Friday evening, June 7, at the Chemists' Club, 108 West 55th Street. Dr. Charles A. Doremus occupied the chair.

The chairman delivered his annual address on 'The Development of an American School of Chemistry,' in which he urged the advancement of chemical engineering by the development of originality and the assumption of greater responsibilities by chemists.

The secretary's report showed a net gain in membership of sixty during the year, and that twenty-nine papers had been read at the nine meetings which were held.

The election of officers for 1901-1902 resulted as follows:

Chairman—Professor Marston T. Bogert (Columbia University).

Vice-chairman—Durand Woodman (127 Pearl Street, N. Y.).

Secretary-treasurer—Professor J. A. Mathews (Columbia University).

Executive Committee—P. C. McIlhiney (Columbia), Professor E. H. Miller (Columbia), T. C. Stearns (Jersey City).

Delegates to the Scientific Alliance: Wm. McMurtrie, Professor Marston T. Bogert, H. C. Sherman (Columbia University).

Papers were read as follows:

M. T. Bogert and L. Boroschek—'Some Experiments with the Mono-nitro-orthophthalic Acids.'

H. C. Sherman, J. L. Danziger, L. Kohnstamm—'On the Maumené Tests for Oils.'

E. F. Kern—'On the Separation and Determination of Uranium.'

The paper on the 'Maumené Test for Oils' was a brief account of the principal results obtained in a series of experiments on several varieties of oils, with different modifications of the Maumené test. The common practice of diluting oils with petroleum to prevent too violent a reaction was found to give unsatisfactory results, the figures obtained from such mixtures being too high; as was also the case when the oil was dissolved in an equal weight of carbon bisulphide or chloroform. The necessity of

taking account of the specific heats of the oils and diluents was noted. In order to avoid the necessity of diluting the oil and the resulting uncertainty in the interpretation of results, the use of a weaker acid was proposed. Sulphuric acid of about 87 per cent. can be added directly to all the common oils and the test can be carried out in exactly the same way for the drying as for the non-drying oils. Even when calculated as 'specific temperature reaction' the results are somewhat influenced by the strength of the acid used, higher figures being obtained with the more concentrated acids. It was, therefore, recommended that the test be always made with acid of such strength as will give with water a rise of 33° to 34° C.

It was announced that the courtesies of the society had been extended to Professor Van't Hoff, and a motion was made and unanimously carried authorizing the chairman and executive committee to take such measures and make such preparations as might be required for entertaining Professor Van't Hoff.

The meeting then adjourned until October.

DURAND WOODMAN,
Secretary.

DISCUSSION AND CORRESPONDENCE.

EBBINGHAUS'S THEORY OF COLOR-VISION.

IN proposing his specialization of Hering's theory of color-vision, Ebbinghaus had for an object to give it a basis in fact by showing a connection between the kind of light which must be absorbed by the colored substances in the retina and the subjection distribution of color throughout the spectrum as revealed by color-equations—especially those of the partially color-blind. The connection was a very forced one from the beginning: the visual yellow could stand very well as the absorbent of the light necessary to the production of the sensation blue, but the visual purple ought to have been *blue* in color to fulfill its function of absorbent of the light that causes the sensation *yellow*, while in reality it is not even purple (in the English sense of the word), but magenta; and the existence of a visual green and a visual red was purely hypothetical. Thus of the four colored absorbent substances to which so

fundamental a rôle was assigned, two (the red and the green) did not exist at all so far as known, and one existed only in a wholly erroneous color, and, moreover, in the fovea where vision is most acute, not even the visual yellow, the sole carrier of so large an assumption, has ever, by the most careful methods, been detected; it would seem to be far simpler to suppose that the objective color of the absorbent medium has nothing to do with the case.

The proof which was furnished by König immediately after the Ebbinghaus theory was proposed that the absorption of the visual purple is exactly what is needed to account for that increment in vision which is gradually acquired upon the oncoming of darkness, rendered the theory, of course, far more untenable still, and in fact Professor Ebbinghaus himself seems to be no longer inclined to insist upon it. He says (*Grundzüge der Psychologie*, I., 261, 262): "Ich habe vor einiger Zeit einen Versuch in dieser Hinsicht gemacht und darauf hingewiesen, dass zwischen der Art, wie die Farbenblinden Gelb und Blau im Spectrum verteilt sehen, und der Lichtabsorption des Sehpurpurs und des Sehgelb (nach der Untersuchungen Kühnes) eine auffellende Aehnlichkeit bestehe. Da nun offenbar die Bewusstseinswirkung der optischen Reize durch eine den Eindrücken entsprechende Absorption der verschiedenen Lichtstrahlen vermittelt werden muss, so nahm ich an, dass eben in dem Sehpurpur die Heringsche Blaugelbsubstanz zu erblicken sei.

"Ich sehe jedoch davon ab, die an diesen Ausgangspunkt angeschlossenen und zum Teil davon gang unabhängigen Gedanken hier zu wiederholen, weil sich bei genauerer Untersuchung des Sehpurpurs durch A. König meine ihn betreffende Annahme nur teilweise bestätigt fand. Das Sehgelb allerdings zeigte in dem einzigen Falle, in dem es erhalten werden konnte, eine mit der Blauempfindung der Farbenblinden annähernd übereinstimmende Lichtabsorption. Die Lichtabsorption des Sehpurpurs selbst dagegen entsprach vielmehr der Verteilung der Helligkeiten in dem Dunkelspectrum des normalen Auges, d. h. also auch in dem Spectrum der total Farbenblinden."

To refrain from reproducing the theory in

its author's own text-book of psychology is probably to be regarded as tantamount to withdrawing it.

C. L. FRANKLIN.

SHORTER ARTICLES.

NOVA PERSEI, NO. 2.

AN examination of the Draper photographs of the spectra of Nova Persei, No. 2, by Mrs. Fleming, shows that, like other novæ, it has been gradually changing into a gaseous nebula. The resemblance to the nebula N. G. C. 3918 is now so close that in a photograph taken on June 19, 1901, no marked difference was noted, except that the nebular line, 5007, is about eight times as bright as $H\alpha$ in the nebula, and only equal to it in the nova. The lines 3869, 3970 ($H\gamma$), 4102 ($H\delta$), 4341 ($H\gamma$), 4688, 4862 ($H\beta$), 4950, and 5007, are common to both and, except the last, have nearly the same relative intensities. Four bright lines between $H\gamma$ and $H\beta$ appear faintly in the nova and are not present in the nebula, while one, 4364, is seen in the nebula but not in the nova, perhaps owing to the proximity of $H\gamma$.

HARVARD COLLEGE OBSERVATORY,
CAMBRIDGE, MASS., June 25, 1901.

LIME AND MAGNESIA IN PLANT PRODUCTION.

SINCE 1899, the writer, with Dr. O. Loew, of the Division of Vegetable Physiology and Pathology of the U. S. Department of Agriculture, has been carrying on a series of experiments on the relation of lime to magnesia in the growth of plants. Some very interesting results have been attained which are to be published in a Bulletin of the Division to be issued at an early date. It may be of interest to here set forth a few of those results.

It is well known that magnesium salts form some of the more noxious alkali soils of the arid regions. In other sections it has been noticed that the soils well fertilized, especially with certain crude potash salts, after a time fail to respond to the fertilizers applied and either become sterile or their productive capacity is greatly reduced. This is apparently due to the accumulation of magnesia in the soil, it being present in some potash salts to a great

extent. One examined by the writer contained 9.37 per cent. of this element.

In our experiments in water, sand and soil cultures covering a great many trials we found that magnesia in a soluble form in very small amounts was, in the absence of lime, very toxic to plants. By the addition of lime in a soluble form in amount equal to or in slight excess of the magnesia the poisonous effect of the latter was eliminated. The plant was even enabled to withstand any bad effects from a greatly increased amount of magnesia, provided the lime was also increased in an equal or greater degree.

While the addition of other salts to the magnesia in the culture solutions variously affected the toxicity, in no case as far as tested did it have any degree of action comparable with that of the lime salts.

In sand cultures in which the lime and magnesium salts were applied as nitrates the plants made the better growth where the lime was slightly in excess of the magnesia. With lime greatly in excess there was apparently a starvation of the plant, it making a straggling growth for awhile. With the magnesium in excess the plant soon succumbed, and in moderate excess made a slow and unwholesome growth.

In soil cultures in which magnesium carbonate had been added, calcium carbonate was not efficient in overcoming the noxious influence of the magnesia. This was undoubtedly due to the less solubility of the calcium carbonate in comparison with the magnesium carbonate. By the addition of calcium sulphate the toxicity of the magnesia was readily overcome.

In the practical application of lime for its physiological effect the process could be more intelligently carried on where the amount of soluble magnesia and lime already present, *i. e.*, the portion immediately available to plants, is known. However, the danger lies in under- rather than in over-liming. In a soil containing CaO 0.144 per cent. and MgO 0.144 per cent. soluble in 1.115 per cent. of hydrochloric acid the addition of 0.8 per cent. of gypsum, and again of 0.8 per cent. of gypsum and 0.2 per cent. of magnesium carbonate, produced plants similar to those in the natural

soil. With the addition of gypsum 0.2 per cent. and magnesium carbonate 0.68 per cent. the plants made a very slow and spindling growth, too much so for profitable crops.

In liming soils for the physiological effect the sulphate is, among the more soluble forms, the best available. Where a large amount is to be added on account of a high magnesia content of the soil it is better to add small portions yearly, as has been pointed out. However, the process should be repeated until the lime content of the soil is made to equal the total magnesia content.

As stated by Wheeler in his work on Rhode Island soils, calcium carbonate is the best form of lime for overcoming an acid reaction. In applying it for this or any other purpose care should be taken that magnesian limestone be not used unless the soil is also deficient in magnesia. Again in the continued application of crude potash salts the lime and magnesian content of the soil should be known. In case there is a deficiency of lime in the soil the addition of gypsum should also be made in some excess of the magnesia contained in the fertilizers.

AGRICULTURE.

QUOTATIONS.

INDUSTRY AND RESEARCH.

LORD GEORGE HAMILTON has written to Sir Alfred Hickman, M.P., ex-president of the British Iron Trade Association, explaining why certain contracts were placed by Indian railway companies with American firms. In the course of his remarks he says: "You seem to think that orders have only gone abroad because those who gave them did not understand their business. I wish that it were so. The competition we have to face is founded on something much more formidable and substantial. Chemical research, concentration of capital, thorough technical education, improved industrial organization have made in recent years greater advance in America than here; it is with the product of these combinations and not with the assumed stupidity of Indian officials that the British engineer has to contend." Sir Alfred

Hickman replies in a long letter, which appeared in the *Times*, but his remarks refer more to alleged imperfections in American work and the value of protection than to the cause of competition. He asks what evidence exists of 'superior chemical research, technical education, etc.,' and says, "I deny the 'chemical research'" mentioned by Lord George Hamilton. Apparently Sir Alfred Hickman attaches no importance to such reports as those prepared for the University of Birmingham and the Manchester Technical Education Committee as to the position of technical education in the United States; and he can scarcely be familiar with American scientific and technical publications or he would not 'deny the chemical research' with so free a mind. It seems pretty clear, however, that the India Office official who wrote Lord George Hamilton's letter to Sir Alfred Hickman was not the one who expressed views about the chemistry at Coopers Hill and aided the efforts which have strangled the technical education of the officers of the Indian Public Works Department.—*Nature*.

CURRENT NOTES ON METEOROLOGY.

CANNON-FIRING TO PREVENT DAMAGE BY HAIL.

A MOST unfortunate report was recently made to the State Department by the United States Consul at Lyons, France. According to the summary of the report published in the daily papers, the consul states that great success has attended the experiment of firing cannon as a means of protecting orchards and vineyards from damage by hail, and goes on to say that cannon firing is now to be used in order to prevent or to lessen injury by frost. As Consular Reports are official documents, and are looked upon by most persons as authoritative, many inquiries naturally came in to the Department of Agriculture, in Washington, as to when the United States Government intended to adopt, or to experiment with, some such method of protection. It therefore became necessary that some official answer should be made to these inquiries, and by direction of the Secretary of Agriculture, the Chief of the Weather Bureau recently issued a statement to the press in

which he says that it is his conviction that "we have here to do with a popular delusion as remarkable as the belief in the effect of the moon on the weather. * * * The great processes going on in the atmosphere are conducted on too large a scale to warrant any man or nation in attempting to control them. * * * After the experience that this country has had during the past ten years with rain-makers, I am loth to believe that the bombardment of hailstorms will ever be practiced, or even attempted, in the United States, much less encouraged by the intelligent portion of the community. Every effort should be made to counteract the spread of the Italian delusion which has been imported into this country."

On this recently much-debated question as to the possibility of preventing hail by means of cannonading, Van der Linden, in *Ciel et Terre* for May 16 sums up the discussion about as follows: "We see, on the one side, many who believe in the new method; on the other side, sceptics and those who are opposed to the method are calling for clearly established facts before they commit themselves, one way or the other. Under the circumstances, it seems wisest to await further developments before forming an opinion."

CLIMATE OF MANILA.

METEOROLOGICAL data lately published by the Jesuit Observatory, at Manila, are based on pressure, temperature and humidity observations made during the years 1883-1898, and rainfall observations during 1865-1898. The normal temperatures, relative humidities and rainfall for each month follow:

	Temperature. Fahr.	Relative Humidity. Per cent.	Rainfall. Inches.
Jan.	77.0	77.7	1.193
Feb.	77.7	74.1	0.413
March	80.4	71.7	0.736
April	82.9	70.9	1.142
May	83.3	76.9	4.197
June	82.0	81.5	9.622
July	80.8	84.9	14.567
Aug.	80.8	84.4	13.866
Sept.	80.4	85.6	14.925
Oct.	80.4	82.6	7.536
Nov.	79.0	81.6	5.126
Dec.	77.4	80.7	2.134

EQUINOXES AND STORM WINDS.

At the May meeting of the Royal Meteorological Society (London) Mr. Rupert T. Smith read a paper on 'The Periodicity of Cyclonic Winds,' which was a discussion of his own observations made in the neighborhood of Birmingham during the years 1874-1890. The equinoxes do not appear to be very stormy periods, but the greatest frequency and force of cyclonic winds occurs some two weeks before the spring equinox and some three weeks after the autumn equinox.

R. DEC. WARD.

*BIOLOGICAL SURVEY OF THE GREAT LAKES
BY THE UNITED STATES FISH
COMMISSION.*

THE United States Fish Commission will continue during the present summer the Biological Survey of the Great Lakes, inaugurated in 1898. The writer withdraws temporarily from the active management of the enterprise, and the Survey has been placed for the summer under the direction of Professor H. S. Jennings of the University of Michigan, and Professor Henry B. Ward of the University of Nebraska. Active work begins June 15.

Professor Ward, with an assistant, will continue the investigations on the plankton and plankton methods carried on during previous summers.

The remainder of the work, under the immediate charge of Dr. Jennings, will have headquarters at Put-in-Bay, Ohio, on Lake Erie, although the different investigations will be carried on at such points on the lakes as are most favorable. The following is a list of the investigators who will be at work, together with the lines of research which will be carried on:

Professor H. S. Jennings, of the University of Michigan: the movements and reactions of the plankton organisms.

Professor F. C. Newcombe, of the University of Michigan, in general charge of the botanical work: physiological investigations into the relations of the lake plants to the water and substratum.

Professor R. H. Pond, of the Maryland Agricultural College: the distribution of plants and soils at the west end of Lake Erie.

Professor Julia Snow, of Rockford College: the lake Alge.

Professor S. O. Mast, of Hope College: the breeding habits of the sturgeon.

Mr. Raymond Pearl, of the University of Michigan: a statistical study of the races of whitefish and wall-eyed pike.

Mr. Leon J. Cole, of the University of Michigan: a study of the biology and feeding habits of the introduced carp, with especial reference to their supposed destruction of the eggs of other fish.

Professor Chas. Fordyce: systematic work on the Cladocera.

Mr. H. W. Graybill, of the University of Nebraska: the Echinorhynchi of the lake fish.

The University of Michigan cooperates with the Survey by allowing the use of its extensive library of the fresh-water fauna and of certain apparatus. The U. S. Fish Hatchery at Put-in-Bay will be fitted up as a working laboratory, and the steamer *Shearwater*, belonging to the Put-in-Bay station, will be employed in some of the investigations undertaken.

JACOB REIGHARD.

ANN ARBOR, MICH., June, 1901.

*THE JUBILEE OF THE UNIVERSITY OF
GLASGOW.*

ONE of the most interesting events in connection with the recent celebration at Glasgow was Lord Kelvin's oration on James Watt and Sir Joseph Hooker's address in connection with the opening of the new botanical department.

As reported in the London *Times*, Lord Kelvin said:

"The name of James Watt was famous throughout the whole world, in every part of which his great work had conferred benefits on mankind in continually increasing volume up to the present day. It was fitting that the University of Glasgow, in this celebration of its ninth jubilee, should recollect with pride the privilege it happily exercised 145 years ago of lending a helping hand and giving a workshop within its walls to a young man of no University education, struggling to begin earning a livelihood as a mathematical instrument-maker, in whom was then discovered something of the genius destined for such great things in the future. In a note by Watt appended to Professor Robison's dissertation on steam engines, he said that his attention was first directed in

the year 1759 to the subject of steam engines by the late Dr. Robison, then a student in the University of Glasgow and nearly of his own age. He at that time threw out an idea of applying the power of the steam engine to the moving of wheel carriages and to other purposes, but the scheme was not matured, and was soon abandoned. On his going abroad about the year 1761 or 1762, Watt tried some experiments on the force of steam in a Papin's digester, and formed a species of steam engine by fixing upon it a syringe one-third of an inch in diameter with a solid piston, and furnished also with a cock to admit the steam from the digester or shut it off at pleasure, as well as to open a communication from the inside of the syringe to the open air, by which the steam contained in the syringe might escape. That single-acting, high-pressure syringe engine, made and experimented on by James Watt 140 years ago in his Glasgow College workshop, now in 1901, with the addition of a surface condenser cooled by air to receive the waste steam and a pump to return the water thence to the boiler, constituted the common road motor, which, in the opinion of many good judges, was the most successful of all the different forms tried within the last few years. Watt left Glasgow in 1774 to live in the neighborhood of Dr. Erasmus Darwin, grandfather of Charles Darwin. But Greenock and the University and city of Glasgow never lost James Watt. The University conferred the honorary degree of LL.D. upon him in 1806. In 1808 he founded the Watt Prize in Glasgow College. He became Fellow of the Royal Society of Edinburgh in 1784, Fellow of the Royal Society of London in 1785, correspondent of the French Academy of Sciences in 1808, one of the eight 'Associés Etrangers' of the French Academy of Sciences in 1814. He did not know if any university in the world ever had a tradesman's workshop and saleshop within its walls, even for the making and selling of mathematical instruments prior to 1757. But whether the University of Glasgow was or was not unique in its beneficent infraction of usage in this respect, it was certainly unique in being the first British University—perhaps the first university in the world—to have an engi-

neering school and professorship of engineering. This began under Professor Lewis Gordon about 1843. Glasgow was certainly the first university to have a chemical teaching laboratory for students started by its first professor of chemistry, Thomas Thomson, some time between 1818 and 1830. Glasgow was also certainly the first university to have a physical laboratory for the exercise and instruction of students' experimental work, which grew up with very imperfect appliances between 1846 and 1856. Pioneer though it was in those three departments, it had been outstripped within the last ten or fifteen years by other universities and colleges in the elaborate buildings and instruments now needed to work effectively for the increase of knowledge by experimental research and the practical instruction of students. But there was no lagging to-day in the resolution to improve to the utmost in all affairs of practical importance, and they almost saw attainment of the further aspirations to excel over all others in the magnificent James Watt Engineering Laboratory of the University of Glasgow to be ready for work before the expected meeting of the Engineering Congress next September. Now, through the magnificently generous kindness of Mr. Andrew Carnegie to the people among whom he has made for himself a summer home in the land of his birth, all the four Scottish universities could look forward to a largely increased power of benefiting the world by scientific research and by extending their teaching to young people chosen from every class of society as likely to be made better and happier and more useful to our country by university education."

In the course of his address Sir Joseph Hooker said :

"The audience might imagine themselves carried back to the first quarter of the last century when his father was professor of botany. He had not been educated for the medical, or, indeed, any other learned profession. Having inherited ample means and having been from childhood devoted to the study and collection of objects of natural history, he determined to devote his life and his fortune to travel and scientific pursuits. Early in 1820, reduced circumstances requiring him to turn

his botanical attainments to material account, he obtained, through the influence of his friend, Sir Joseph Banks, with George III., the chair of regius professor of botany in this university. It was a bold venture for him to undertake so responsible an office, for he had never lectured, or even attended a course of lectures, and in Glasgow, as in all other universities in the kingdom, the botanical chair was, and had always been, held by a graduate in medicine. Owing to these disqualifications his appointment was naturally unfavorably viewed by the medical faculty of the University. But he had resources that enabled him to overcome all obstacles—familiarity with his subject, devotion to its study, energy, eloquence, a commanding presence, with urbanity of manners, and, above all, the art of making the student love the science he taught. After 20 years of the professorship his father retired and undertook the directorship of the Royal Gardens, Kew. Since that period great changes had been introduced in the method of botanical teaching in all our universities, due, on the one hand, to a vastly advanced comprehension of the structure of plants and of the functions of their organs, and, on the other, to a recognition of the fact that the study of the animal and vegetable kingdoms could not be considered apart. Furthermore, chemistry, physics, and greatly improved microscopes were now necessary for the elucidation of the elementary problems of plant life. The addition of the building in which they were assembled was evidence of the resolve that botany should not fall from its well-earned position. The botanical laboratory would prove an invaluable aid to research under the ægis of its distinguished director, and in that belief he now declared it open.

THE HARVARD CHEMICAL LABORATORY.

PROFESSOR T. W. RICHARDS writes in the last number of the *Harvard Graduate Magazine* in regard to research work, as follows:

“Original investigation, which has added so much to the intellectual life of the Laboratory, continues with unabated vigor. In the last five years about seventy papers have been published by the officers and students in Boylston Hall. These covered a wide range of subjects,

about half of them concerning organic chemistry, and the other half physical and inorganic chemistry. Professor Jackson’s extended researches upon the structure of aromatic substances have yielded in the hands of many students a large number of interesting new compounds and the basis for further generalization upon the mechanism of chemical action. Professor Hill’s precise and detailed study of pyromucic acid has now in part given place to an extremely interesting series of syntheses of the benzol ring. In physical chemistry several comprehensive papers on chemical thermodynamics have appeared, and various phenomena were studied in the Laboratory by both instructors and students. For example, the passage of electricity through gases received attention; modern theory of dissociation was studied in its relation to the sense of taste; a new basis for thermometric standardization has been found; and the fundamental Law of Faraday has been subjected to a verification more rigorous than ever before. The study of the law of definite proportions, the one other chemical law which seems to rank with Faraday’s in unflinching precision, has been steadily continued. In the last ten years the atomic weights of copper, barium, strontium, calcium, zinc, magnesium, cobalt, nickel, uranium and cesium have all been studied with a care which seems to carry conviction with it. This work has all been handicapped by the inadequate quarters in which it had to be performed, and we now have to face the bitter alternative of being obliged either to turn away graduate students, or else so to crowd them together as to make accurate investigation almost impossible.”

SCIENTIFIC NOTES AND NEWS.

HARVARD UNIVERSITY has conferred the LL D. degree on Dr. H. S. Pritchett, president of the Massachusetts Institute of Technology; on Professor J. H. Van’t Hoff, professor of physical chemistry at the University of Berlin, and on Professor C. S. Sargent, director of the Arnold Arboretum. The honorary M. A. was conferred on Dr. Hugo Münsterberg, professor of psychology, and on Dr. Theobald Smith, professor of comparative pathology. In conferring these last degrees, President Eliot referred to the

recipients as follows: "Professors in this University, not of Harvard nurture, distinguished for productive research—to make them children of the house."

YALE UNIVERSITY, at its commencement exercises last week, conferred the LL.D. on Dr. E. B. Wilson, professor of zoology in Columbia University. It will be remembered that the same degree was given to Professor Wilson by the University of Chicago the previous week. The honorary M.A. was conferred on Mr. Gifford Pinchot, B.A. (Yale, '89), chief of the Bureau of Forestry, U. S. Department of Agriculture.

TRINITY COLLEGE has conferred the LL.D. degree on Professor W. H. Howell, professor of physiology in the Johns Hopkins University, and on Professor F. H. Osborn, professor of zoology in Columbia University and curator in the American Museum of Natural History. It will be remembered that Professors Howell and Osborn gave the chief addresses on the occasion of the dedication of the Hall of Natural History last winter.

BOWDOIN COLLEGE has conferred its LL.D. on Dr. Alpheus S. Packard, professor of zoology and geology at Brown University.

AT the recent celebration of its ninth jubilee, the University of Glasgow conferred its LL.D. degree on 120 delegates from various universities and institutions. These included J. Mark Baldwin, professor of psychology at Princeton University; William G. Farlow, professor of cryptogamic botany at Harvard University; Dr. Adolph Meyer, lecturer on psychiatry at Clark University, and R. Mark Wenley, professor of philosophy at the University of Michigan. The foreign men of science on whom the degree was conferred are: Professor Karl Bezold, University of Heidelberg; Professor W. C. Brogger, University of Christiania; Professor Daniel J. Cunningham, Trinity College, Dublin; Professor Nicolas Egoroff, Imperial Military Academy of Medicine, St. Petersburg; Principal George Carey Foster, University College, London; Sir Archibald Geikie; Professor A. A. W. Hubrecht; Professor Kronecker, University of Berne; Dr. Joseph Larmor, St. John's

College, Cambridge; Principal Oliver J. Lodge, University of Birmingham; President James Loudon, University of Toronto; Sir William MacCormac; Professor James G. MacGregor, Nova Scotia; Professor John Perry, Royal College of Science, London; Professor F. York Powell, Oriel College, Oxford; Sir Henry S. Roscoe, Vice-Chancellor of the University of London; Professor Joseph J. Thomson, University of Cambridge; John Isaac Thornycroft, naval architect and engineer.

SURGEON-GENERAL GEORGE M. STERNBERG has left for the Philippine Islands on a tour of inspection.

DR. CH. WARDELL STILES, of the Bureau of Animal Industry, has been appointed a delegate from the U. S. Government to the International Congress of Zoologists which meets at Berlin next August.

PROFESSORS NICHOLAS SENN and D. R. Brower, of the Rush Medical College, University of Chicago, and Professor Jacob Frank, of the Chicago Polyclinic, have left New York for a trip round the world by the way of Siberia. It is expected that only fifty-nine days will be required for the traveling and one month will be spent at stopping places. They have been invited to hold surgical clinics in Moscow and Japan.

MAJOR ROSS, of the Liverpool School of Tropical Medicine, and Dr. Logan Taylor, assistant professor of pathology at Glasgow University, sailed on June 15 from Liverpool for West Africa to continue researches on malaria.

A PARTY from the U. S. Geological Survey, including Mr. W. C. Meudenhall, geologist, and L. E. Reaburn, topographer, have left Dawson for explorations in northern Alaska.

DR. S. WEIR MITCHELL, of Philadelphia, has arrived in California after a trip round the world.

DR. OSCAR UHLWORM, of Cassel, editor of the *Botanisches Centralblatt*, has been appointed director of the German Bureau for the International Catalogue of Scientific Literature.

A WALKER PRIZE, of the Boston Society of Natural History, has been awarded to Mr.

Edward W. Berry, of New York, for a memoir on *Liriodendron*.

PROFESSOR St. JOHN, of Oberlin College, and Professor Nichols, of Dartmouth College, will spend the summer working at Yerkes Observatory.

THE professors of chemistry at Harvard University, Professors Jackson, Hill, Sanger and Richards, gave a dinner to Professor van't Hoff, of the University of Berlin, on June 27. Among the invited guests from a distance were Professor Michael, of Tufts College, and Professor Bancroft, of Cornell University.

THE Rev. Joseph Cook died at Ticonderoga, New York, on June 24. Some years ago Mr. Cook attracted much attention by his Boston Monday lectures on religion and science, published under titles such as 'heredity,' 'biology,' etc.

DR. SVEN HEDIN has returned to Chaklik after a successful journey through the Desert of Gobi. He is now continuing his travels across Thibet.

THE members of the French commission entrusted with the measurement of an arc in Peru arrived at Guayaquil on June 1, and will commence their observations during the present month. They will be joined by M. Gonnessiat, who, a year ago, took charge of the observatory at Quito.

ACCORDING to the N. Y. *Evening Post* E. A. Martel, the French explorer of caverns, whose discoveries underground have attracted much attention, reports that he has found in the department of Hautes Alps a cavity in the form of a 'natural well,' whose depth exceeds that of any other known. He has sounded it to the depth of about 1,027 feet, but the actual bottom has not been reached.

KING CHARLES of Portugal and the members of the Portuguese Cabinet opened at Horta, in the Azore Islands, on June 29, the meteorological observatory in connection with the Weather Bureau at Washington.

IN the fire at Jacksonville, Fla., the herbarium of Mr. A. H. Curtis, containing about 16,000 sheets, was destroyed.

A SECOND Livingstone Exhibition was opened in London, on June 18. In addition to a collection of relics of the great explorer, lent by the Geographical Society and other contributors, there is a display of all kinds of articles conducing to the health or comfort of travelers in uncivilized regions. Not only are the special requirements of travelers represented, such as camp equipment, portable foods, clothing and general outfit, but other sections are devoted to sanitation, house-building and various matters of interest to residents in such regions. In connection with the Exposition a reception was given by the Royal Geographical Society on the eighteenth. During the evening, lectures were given in the council chamber, with the aid of the lantern, by Dr. Cornish, on 'Waves in Air, Water, Sand and Snow'; Dr. Francisco Moreno, on the 'Scenery of Argentina'; Dr. Manson, on 'Recent Malarial Discoveries'; Captain Barker, on the 'Antarctic Ship Discovery'; and Dr. Mills, who exhibited some recent geographical photographs.

AT the last International Congress of Librarians, held at Paris, Mlle. Marie Pellechet established two prizes, of the value respectively of 1,000 and 500 fr. for the best memoirs relating to the insects that destroy books. The memoirs should be sent to M. Henry Martin, secretary of the congress, rue de Sully I, Paris.

THE Rev. W. M. Beauchamp, Syracuse, N. Y., is continuing his series of archeological bulletins, published by the New York State Museum. The sixth bulletin on 'Bone and Horn Articles' is in press, and Mr. Beauchamp is now at work on metallic implements and ornaments. There will be figures of most of the native copper articles known in New York, and Mr. Beauchamp requests collectors of such articles to communicate with him.

THE census returns show the population of France to be about 38,600,000, an increase of 330,000 since 1896. To this small increase Paris and its suburbs contribute 292,000, the greater part of which number is due to foreign immigrants, so that the rest of France gives an increase of only 38,000. Since 1850 the population of France, allowing for alterations of boundaries, has only increased from 35,000,000

to 38,000,000, whereas that of the United Kingdom has risen from 27,000,000 to 41,000,000, Germany from 35,000,000 to 56,000,000, Austria from 30,000,000 to 45,000,000, and Italy from 23,000,000 to 32,000,000.

MAJOR-SURGEON W. C. GORGAS, chief sanitary officer of Havana, has presented his report for May, showing a very gratifying state of affairs in Havana. For the first time in its history, there was not a single case of yellow fever in Havana on June 1, and there was only one death from this disease in the preceding three months. Regarding the two slight outbreaks of yellow fever, Major Gorgas writes: Since March 8 outbreaks of yellow fever have occurred twice. The first time, April 21 and 22, we had two cases; and again, on May 6 and 7, four cases. Each time the infected houses and three or four contiguous houses on every side of the infected house were carefully gone over. Every room in each of these houses was closed and sealed, and insect powder burned in them at the rate of one pound to 1,000 cubic feet. All standing water was drained away where possible, and oiled where it could not be drained. The results look as if the focus of infection at that particular point had been eradicated. In the case of the patient taken sick March 8, after our disinfection, we went forty-two days till the next case. Then an outbreak occurred, April 21 and 22. We again disinfected, and went fifteen days till the next cases, May 6 and 7. We again disinfected, and have gone twenty-four days without a case. I am more particularly impressed by these figures, as we commenced our systematic destruction about the middle of February. Formerly we paid no particular attention to the mosquito, merely disinfecting for yellow fever, as we do for other infectious diseases. The only part of the process that killed the mosquito was the formaline used in one or two infected rooms.

THE Medical Society of the State of California has passed the following resolution:

Whereas, It has been shown by our local bacteriologists, and by the Commission sent by the United States Government, that the bubonic plague has existed in San Francisco, and probably does at the present time; therefore, be it

Resolved, That the Medical Society of the State of California express its confidence that the San Francisco Board of Health, the State Board of Health, and the United States Commission will be able to watch the disease, and to take proper measures for its suppression.

THE Imperial Russian Association of Fisheries will hold an international exposition in February and March, 1902, at St. Petersburg, for the purpose of showing the condition of the fresh and salt water fisheries of the world. The expense of the exposition will be defrayed by the association, the crown, the municipal government, private contributions, and by charges for exhibition space and for the admission of visitors. Premiums will be awarded in the form of gold, silver and bronze medals, diplomas of honor and money prizes. The exposition will have nine departments, as follows: (1) Fisheries in general; (2) salt and fresh water fisheries; (3) implements used in the fisheries industry; (4) products of the fisheries; (5) manner and means for preserving fish; (6) arrangement of fish hatcheries; (7) fishing sport; (8) aquariums and their inmates; (9) scientific researches concerning the lives of fishes, etc.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. J. PIERPONT MORGAN has undertaken to erect for the Harvard Medical School three new buildings at an estimated cost of \$1,000,000. They are to be a memorial to his father, Mr. J. S. Morgan, who began his business career in Boston. This great gift was the result of an interview with Professors H. P. Bowditch and J. C. Warren last winter, but was communicated by cable from England at the recent commencement exercises. The Harvard Medical School can now be removed from its present site in Boston to Brookline, where twenty-one acres of land have been secured. The three buildings to be erected are for administration, for anatomy, histology and embryology, and for physiology and physiological chemistry.

It was announced at the recent commencement exercises of Yale University that it was expected that the bicentennial fund of \$21,000,000 would be collected by next autumn. The

sum required for land and buildings, \$1,185,000, has been entirely secured. The subscribers to the fund number about seventeen hundred.

MR. EZRA J. WARNER, of Chicago, has given \$12,500 to Middlebury College for the furnishing of Warner Science Hall, erected last year at a cost of over \$80,000. The college has also received a gift of \$5,000 from Dr. M. Allen Starr, of New York, to purchase books for the library.

THE cornerstone of the new science building at Drury College, Missouri, was laid on June 13. Toward the cost of this building Dr. D. K. Pearsons contributed \$25,000, and an equal amount has been made up by general subscription.

SENATOR HANNA has given \$50,000 to Kenyon College, Gambier, O., for a dormitory.

JOHN D. ROCKEFELER has promised \$25,000 to Des Moines College, Iowa, on condition that friends of the institution raise \$55,000 more.

THE College of Physicians and Surgeons, Chicago, which is the medical department of the University of Illinois, has been destroyed by fire resulting from lightning. The loss on the building and equipment is said to be \$200,000.

THE commission selected to draft plans for the Carnegie Technical School at Pittsburg has presented its report. The commission proposes three divisions, the Carnegie Technical College, the Carnegie Technical High School and the Carnegie Artisan Day and Evening Classes. It advises that experimental shops and laboratories be built, that the college support one or more publications, to give the fruits of its research to the world; that English, French, and German and Spanish be studied. It also recommends courses of study for the three divisions. The commission consists of Professors V. C. Alderson, of Chicago, Robert H. Thurston, of Cornell University, Thomas Gray, of Terre Haute, Ind., and J. B. Johnson, of Wisconsin University.

DR. F. W. SANDERS has been compelled to resign the presidency of the New Mexico College of Agriculture and Mechanic Arts (Mesilla

Park, N. M.). The following abstract from his letter of resignation has been published in the *New Mexico Collegian* for June, 1901: "I have declined to serve you longer unless you would abandon the pernicious system of annual elections, and have urged you to give this system up for a number of reasons; because, among other things, it almost inevitably lends itself to the control of the pettiest of personal and local and political influence, and makes a permanent policy impossible; but especially because it makes possible the removal of able and faithful employes for reasons that will not bear the light." The new president has not yet been elected.

THE University of New Mexico, at Albuquerque, N. M., has been unfortunate in losing its president, Dr. C. L. Herrick, who resigned on account of ill health. Dr. Herrick is at present in the field, continuing his important researches in the geology of New Mexico.

DR. TALIAFERRO, an instructor in the Pennsylvania State College, has been made President of the Florida Agricultural College.

AT the University of Colorado, a chair of geology has been established which will be filled by Dr. N. M. Fenniman. The chair of philosophy, vacant by the death of Dr. Francis Kennedy has been filled by the appointment of Dr. M. F. Libby.

KARL E. GUTHE has been promoted to an assistant professorship of physics at the University of Michigan.

DR. A. P. SAUNDERS has been promoted to a professorship of chemistry at Hamilton College.

S. P. ORTH has been promoted to a professorship of natural science at Buchtel College.

ARTHUR L. CLARK has been appointed professor of physics at Bates College.

DR. MARGARET K. SMITH has been appointed professor of psychology at the State Normal School, New Platz, New York.

DR. W. PALLADIN has been made professor of plant anatomy and physiology in the University of St. Petersburg.

THE CARNEGIE TECHNICAL UNIVERSITY.

It was some weeks ago announced by the daily press as definitely settled that Pittsburg is to have a great technical institution, especially adapted to its peculiar needs and to be made, in its industrial field, as complete and admirable as the Carnegie Institute of that city has become in art and æsthetics. Mr. Carnegie, who has now placed the Scotch universities in a comparatively comfortable position by an endowment of ten millions of dollars, and has thus contributed to the cause of liberal education more than has ever been before given by any individual in a single gift, has now determined to do something on a liberal scale for that department which most naturally appeals to his personal sympathies—education in applied sciences—and he has agreed to supply the funds for the new foundation. The organization of the institution has been entrusted to the local Board of Trustees, already having charge of the Carnegie Institute and the Carnegie Library at Pittsburg. This body has appointed a committee 'On Plan and Scope' and this committee, in turn, has called in experienced and expert advisers to aid them

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

in determining upon the very best plan and the most suitable scope of the institution, and of its curriculum.

These expert advisers were Dr. R. H. Thurston, Director of Sibley College, Cornell University, Professor J. B. Johnson, Dean of the College of Engineering, University of Wisconsin, Professor Thomas Gray of the Rose Polytechnic School and Professor V. C. Alderson of the Armour Institute. After their several reports had been made, they were organized into a committee to consider and report upon the schemes of the individual reports and to present a final and condensed statement of the plan upon which all could agree. This is the report which we present herewith to the readers of SCIENCE. It includes, as is seen, three different and distinct forms of school which may be combined as parts of one complete technical university that might satisfy the ambition of John Scott Russell, were that greatest of promoters of industrial education living; or they may be adopted, singly or together, on any scale which the needs of the city, the opportunities of the founder and the ambition of Mr. Carnegie and his coadjutors may seem to justify.

It is understood that this is simply a recommendation of his committees and that Mr. Carnegie is in no way bound to accept either the plan, the scope or the estimated endowment as binding upon him. It is understood that the committees will report to him the plan and scope proposed for these schools, leaving him free to found a school for artisans, a technical high school or a technical college, or, if his ambition mounts so high, a true *technical university*,

including them all, and more complete and universally fruitful of good to all sorts and conditions of men and women—it is understood that both sexes are to be provided for—than has been any institution for technical, industrial and scientific education, ever before conceived. Even this latter is entirely within the means of Mr. Carnegie, as limited by his publicly declared plans of distribution of funds for educational purposes, and it would be a glorious thing for the world, as well as for Pittsburg and our country, could the ideal technical university be thus made a reality by our greatest philanthropist.

REPORT OF THE ADVISORY COMMITTEE ON THE
CARNEGIE TECHNICAL SCHOOLS OF
PITTSBURG.

PITTSBURG, PA., June 25, 1901.

Mr. William McConway, Chairman Committee on Plan and Scope.

DEAR SIR.—Your Advisory Committee begs leave to submit the following report upon the scope of the proposed Carnegie Schools of Technology.

INTRODUCTION.

It has become clear, both to educators and to business men, that the new century demands a wide dissemination of a *new type of school training*. The new methods of concentrated capital and of wholesale production; the ready means of transport by which our antipodes have become both our customers and our sources of supply; the practical abandonment of both the apprenticeship system and of the individual manufacturer; the world-wide field of operations in all lines of trade; the infinite number of applications of scientific knowledge in all fields of modern industry; the whole-world competition which confines success to the most economic production;

and the constant supplanting of manual labor and man power by automatic machinery and by steam or electric power; these are some of the signs of the times by which it is clear that some new kind of preparation for the work of life must be introduced into the school training of both boys and girls. This, too, not only for their individual success, but for the maintenance of American leadership in manufacturing and commerce. What this new education should be for America may be exemplified by the proposed Carnegie Technical Schools of Pittsburg. Nothing short of such a complete system should be planned.

The scheme which your committee proposes may be divided as follows:

- I. The Carnegie Technical College.
- II. The Carnegie Technical High School.
- III. The Carnegie Artisan Day and Evening Classes.

I. THE CARNEGIE TECHNICAL COLLEGE.

This should be a first-grade technical college, superposed upon a high-school curriculum, with entrance requirements equal to those demanded by the best grade of existing colleges of engineering. It should be a school of both pure and applied science, and should prepare young men for leadership in the commercial as well as in the industrial pursuits. Both our manufacturing industries and our foreign commerce are now demanding the highest technical training it is possible to bestow, but this training must be fitted to particular vocations.

This college should be made attractive to the greatest scholars in the fields of physical and chemical science. To obtain and hold such men they must be given ample opportunities for research. This college must be supplied, therefore, not only with great experimental shops and laboratories for students' use, but in all departments there should be splendidly equipped laboratories of investigation and research, under the direction of the head of such depart-

ment, and with a full corps of assistants for the carrying on of lines of investigation which are now partly or wholly unprovided for in America. These well-equipped workshops and these experimental and research laboratories would form the chief distinction of this technical college, and they would also be the chief item of expense. This college would support one or more publications in which the fruits of this research department would be given freely to the world. While the number of students in this college would be small, as compared with the number in the technical high school, the work done here would be of far more benefit to the world, and it would form the chief, if not the only, feature of the whole scheme to attract attention and to extend its beneficent influences beyond the immediate vicinity of Pittsburg.

Instruction in the Technical College should include:

1. Technical courses in—
 - a. Mechanical engineering.
 - b. Electrical engineering.
 - c. Civil engineering.
 - d. Chemical engineering.
 - e. Electro-chemical engineering.
 - f. Marine engineering.
 - g. Railway engineering.
 - h. Sanitary engineering.
 - i. Mining engineering and metallurgy.
 - j. Architecture.
 - k. Commerce and transportation.
2. Courses in pure and applied sciences.
 - a. Mathematics.
 - b. Physics.
 - c. Chemistry.
 - d. Biology.
 - e. Geology.
 - f. Mineralogy.
 - g. Astronomy.
 - h. Economics.
 - i. Commercial geography.
3. Courses in modern languages.
 - a. English.

- b. German.
- c. Spanish.
- d. French.

II.—THE CARNEGIE TECHNICAL HIGH SCHOOL.

The work of this school should be superposed upon the work of the public grammar schools of Pittsburg and Allegheny. Its scope should be broad and comprehensive. The elective principle should be recognized, and graduation would depend not upon completing a prescribed curriculum, but upon completing a required number of courses, to be selected by the student under the direction of the director of the school.

In this school, the boy who wished to fit himself for industrial pursuits would find equal advantages with the boy who desired to prepare himself for professional engineering, or the girl who wished a general high school education supplemented by instruction in the home-making arts.

To make this instruction practical and fruitful of results it would be necessary to have well-equipped shops and experimental laboratories in all the courses leading toward specific employments, and these require a liberal housing, an expensive equipment and an expert direction by accomplished artisans. Such a complete school as is here proposed does not now exist in this country, but it would prove a pattern to be copied in every large city and such as the new century and the new industrial conditions demand.

Instructions should include:

1. The ordinary English high-school studies.
2. Physics, chemistry and biology, with students' laboratory practice.
3. The elements of the calculus and applied mechanics.
4. French, German and Spanish.
5. Commercial studies.
6. Domestic arts and sciences.
7. Freehand and mechanical drawing.

8. Technical studies, fitting for the industries of the locality, such as:

- a. Blast furnace and foundry practice.
- b. Glass-making.
- c. Brass-founding and finishing.
- d. Pattern-making and joinery.
- e. Metal-working.
- f. Stationary, locomotive and marine engine and boiler management.
- g. Light and power station management.
- h. Gas manufacture.
- i. Railroad transportation.
- j. Plumbing and domestic sanitation.
- k. Surveying.
- l. Clay working and ceramics.
- m. Industrial art.

III.—THE CARNEGIE DAY AND EVENING CLASSES.

These classes are proposed for the benefit of those who are unable to take advantage of the more complete courses in the Technical High School. They should be available to both sexes. Instructions should include:

- a. Elementary mathematics.
- b. Elementary physics.
- c. Elementary mechanics.
- d. Elementary chemistry.
- e. Freehand and mechanical drawing.
- f. Modern languages and elementary instruction in such technical subjects as are taught in the Technical High School.
- g. Courses of special lectures on subjects of interest to artisan classes.

In conclusion your committee desires to state that in its judgment a large tract of land, not less than 50 or 60 acres in extent, should be provided, in order that the buildings may be grouped about an attractive campus.

Furthermore, the best educational experience leads us to believe that the highest interests of these schools will be conserved by being maintained as independent insti-

tutions unhampered by public or private control.

Respectfully submitted,
(Signed) ROBERT H. THURSTON,
VICTOR C. ALDERSON,
THOMAS GRAY,
J. B. JOHNSON.

A NATIONAL UNIVERSITY.*

To the National Council of Education:

The undersigned members of the committee to investigate the entire subject of a national university and to report to the Council do now report, as follows:

The appointment of the committee was authorized by the Council at their meeting at Washington, D. C., on July 11, 1898, in the passage of the following resolution, offered by Mr. Dougherty, of Illinois:

Resolved, That the chair appoint a committee of fifteen, the majority of whom shall be members of the Council, who shall investigate the entire subject of the establishment of a national university and report to the Council.

MEMBERSHIP.

The president of the Council subsequently appointed the committee, as follows:

WILLIAM R. HARPER (*chairman*), president of the University of Chicago.

EDWIN A. ALDERMAN, president of the University of North Carolina (now president of Tulane University of Louisiana).

JAMES B. ANGELL, president of the University of Michigan.

NICHOLAS MURRAY BUTLER, professor of philosophy and education in Columbia University.

JAMES H. CANFIELD, president of Ohio State University (now librarian of Columbia University).

J. L. M. CURREY, agent of the Peabody and Slater educational funds.

NEWTON C. DOUGHERTY, superintendent of schools, Peoria, Ill.

ANDREW S. DRAPER, president of the University of Illinois.

CHARLES W. ELIOT, president of Harvard University.

EDMUND J. JAMES, professor of public administration in the University of Chicago.

*Report of the Committee of the National Educational Association.

WILLIAM H. MAXWELL, superintendent of schools, New York, N. Y.

BERNARD J. MOSES, professor of history and political economy in the University of California.

J. G. SCHURMAN, president of Cornell University.

F. LOUIS SOLDAN, superintendent of schools, St. Louis, Mo.

WILLIAM L. WILSON, president of Washington and Lee University.

MEETINGS.

The committee have held three protracted meetings: at Washington, D. C., on November 2, 3 and 4, 1899; at Chicago, Ill., on February 26, 27 and 28, 1900; and at New York, N. Y., on May 23 and 24, 1901. The first meeting of the committee was attended by all the members except Messrs. Angell, James (absent in Europe), and Moses. The second meeting was attended by Messrs. Harper, Alderman, Butler, Dougherty, Draper, Eliot and Soldan. The third meeting was attended by Messrs. Harper, Butler, Canfield, Dougherty, Draper, Eliot and Maxwell.

Mr. Moses has been absent from the country on public business, and so has been prevented from sharing in any of the deliberations of the committee. Mr. Wilson's untimely death in 1900 deprived the committee of the benefit of his cooperation in the preparation of this report.

PRELIMINARY INQUIRIES.

Before the committee came together for the first time, individual members had, at the request of the chairman, undertaken to prepare reports upon special phases of the subject referred to the committee, with a view to preparing the way for their more intelligent consideration and discussion. The reports so prepared included one by Mr. James, on the constitutionality of a national university (printed in the *Educational Review*, Vol. XVIII., pp. 451-66, December, 1899); one by Mr. Canfield, on past efforts to establish a national university and the reasons for their failure; two

by Mr. Butler, to establish a national university; one by Mr. Eliot, before the Congress, and on the disposal of any funds and requests toward the establishment of a national university, respectively; one by Mr. Harper, the steps taken by the Association of Agricultural Colleges and Experiment Stations to secure provision for further study in the government departments at Washington by graduates of those institutions; two by Mr. Eliot, on the existing educational agencies at Washington which might be affected by any scheme for a national university, and on the number, variety, extent and character of the scientific or technical departments of governmental work which might properly be included in any scheme for a national university, respectively; one by Mr. Angell, on the probable attitude of the principal universities of the country toward the project to establish a national university; and one by Mr. Maxwell, on existing organizations which are interested in the establishment of a national university.

QUESTIONS STATED.

With the information contained in these reports before them, the committee proceeded to the consideration of the following questions:

1. Should there be established a statutory university of the United States?

2. (a) If the first question be answered in the affirmative, how should such university be established and governed, and what should be its scope and functions?

(b) If the first question be answered in the negative, should the Congress be asked to place the educational facilities of the government departments at the disposal of a non-governmental institution?

3. If the question 2 (b) be answered in the affirmative, should a plan be devised by which, through the cooperation of several institutions, such a non-governmental in-

stitution might be established and maintained at Washington, this to involve its incorporation and governmental aid?

ARGUMENT FOR A NATIONAL UNIVERSITY.

In considering the first question, the committee took into careful consideration the argument advanced in favor of a statutory university of the United States, which is usually presented in the following form:

1. Such a university is needed to complete and to crown the educational system of the United States.

2. Such a university is needed to supplement the resources of existing institutions and to offer opportunities for more advanced investigation and research than are now offered by the universities of the country.

3. Such a university was urged by Washington, and has been urged by many eminent statesmen since the foundation of the government, as desirable and necessary.

4. Such a university is needed in order to coordinate the scientific work now being carried on in the several government departments at Washington, and to put that work at the disposal of advanced and adequately trained students.

CRITICISM OF THIS ARGUMENT.

Waiving all questions of the constitutional power of the Congress to provide for a university of the United States, which power is held by Mr. James, in the report above referred to, to be fully established, the fourfold argument in favor of a national university suggests the following considerations and comments:

1. There is no educational system of the United States in the formal and legal sense in which there is an educational system of each of the several States, and therefore the contention that there should be a national university to serve the nation, as each of the State universities serves its

State and the State educational system, rests upon a false analogy. In a general and popular sense there is undoubtedly an American educational system, but it consists of institutions of three different types :

A. Those which the State establishes and maintains, such as the public schools and the state universities.

B. Those which the State authorizes, such as school and university corporations, private or semi-public in character, which gain their powers and privileges by charter, and which are often exempt in whole or in part from taxation.

C. Those which the State permits, such as private-venture (unincorporated) educational undertakings of various kinds.

Each of these classes is in a true sense national, in that it reflects and represents in part the way which the American people have followed in providing general education. No inventory of the nation's educational activity is complete that does not include them all. There are in existence at the present time a group of truly national universities, some of them of the State-authorized and some of the State-supported type, and in them the national ideals and the national temper are as truly revealed and realized as are those of Germany in Berlin and in Leipzig, those of England in Oxford and in Cambridge, and those of France in Paris and in Montpellier. The argument for a statutory national university based upon the hypothesis that there is now no national university in existence is only formally true; in fact, it is without foundation.

2. The argument that a statutory national university is needed to supplement the resources of existing institutions is based upon a misunderstanding of the facts. No one of the world's universities can possibly be supreme in all departments of intellectual activity; a statutory university of the United States could not be so.

Conditions of time, place, special equipment and of individual scholarship all tend to make one university stronger in some one field of investigation than in others and to render it as unwise as it is impracticable for any one university to set before itself the hope of excelling in every branch of scholarship. The universities of the United States now offer ample opportunities for the most advanced research, and these opportunities in many departments are far in excess of the number of students wishing to avail of them. On the other hand, a university which should aim to hold mature and highly trained men indefinitely in the stage of learning without either producing or teaching would be a positive injury to the national life and character. The period of preparation for the active duties of life is already unduly prolonged.

3. An examination of the several passages in the speeches and writings of Washington that relate to a national university discloses the facts that the evil against which he wished a national university to guard has long since ceased to be possible, and that his plans and hopes have been realized with a completeness of which he never dreamed by the universities which have grown up in the United States. Washington's fear was that the youth of America, being forced to obtain their higher education in Europe, would not 'escape the danger of contracting principles unfavorable to republican government.' Obviously this fear has been utterly dispelled, and the universities that exist are far more complete and far more advanced than anything that could have been foreseen a century ago. There appears, therefore, to be no force in this phase of the argument for a statutory university at Washington.

4. That there are important opportunities for research of various kinds in connection with the government laboratories and collections at Washington is certain, and that

full advantage should be taken of these opportunities is greatly to be desired. This desire is confessed by the Congress itself in the joint resolution of April 12, 1892, to be referred to more fully hereafter, and is frequently expressed by the directors of the scientific work of the government. But it by no means follows that the only way, or indeed the best way, to make use of these opportunities is through the creation of a statutory, degree-conferring university. The objections to such an institution far outweigh any possible advantages which might follow from its establishment for the sole purpose of making fully effective the existing opportunities for higher instruction and research in connection with the government service, especially as it is possible to make these opportunities fully effective in what is in our judgment a simpler and a better way.

DECLARATION OF THE COMMITTEE.

The committee, therefore, by unanimous vote—twelve members being present and voting—adopted the following declaration on November 3, 1899 :

1. *It has been and is one of the recognized functions of the federal government to encourage and aid, but not to control, the educational instrumentalities of the country.*

2. *No one of the bills heretofore brought before Congress to provide for the incorporation of a national university at Washington commends itself to the judgment of this committee as a practicable measure.*

3. *The government is not called upon to maintain at the capital, a university in the ordinary sense of the term.*

ALTERNATIVE PLANS.

In this declaration the committee answered in the negative the first question under consideration, namely: Should there be established a statutory university of the United States?

The second question before the committee

was: Should the Congress be asked to place the educational facilities of the government departments at the disposal of a non-governmental institution?

It appears from the public record that the Congress has already done this. There are two expressions of the will and the purpose of the Congress in this matter.

The first is contained in the joint resolution, approved April 12, 1892, which is as follows :

Joint resolution to encourage the establishment and endowment of institutions of learning at the national capital by defining the policy of the government with reference to the use of its literary and scientific collections by students :

WHEREAS, Large collections illustrative of the various arts and sciences, and facilitating literary and scientific research, have been accumulated by the action of Congress through a series of years at the national capital ; and

WHEREAS, It was the original purpose of the government thereby to promote research and the diffusion of knowledge, and is now the settled policy and present practice of those charged with the care of these collections specially to encourage students who devote their time to the investigation and study of any branch of knowledge by allowing to them all proper use thereof ; and

WHEREAS, It is represented that the enumeration of these facilities and the formal statement of this policy will encourage the establishment and endowment of institutions of learning at the seat of government, and promote the work of education by attracting students to avail themselves of the advantages aforesaid under the direction of competent instructors ; therefore,

Resolved by the Senate and House of Representatives of the United States of America, in Congress assembled, That the facilities for research and illustration in the following and any other governmental collections now existing or hereafter to be established in the city of Washington for the promotion of knowledge shall be accessible, under such rules and restrictions as the officers in charge of each collection may prescribe, subject to such authority as is now or may hereafter be permitted by law, to the scientific investigators and to students of any institution of higher education now incorporated or hereafter to be incorporated under the laws of Congress or of the District of Columbia, to wit :

One. Of the Library of Congress.

Two. Of the National Museum.

- Three. Of the Patent Office.
 - Four. Of the Bureau of Education.
 - Five. Of the Bureau of Ethnology.
 - Six. Of the Army Medical Museum.
 - Seven. Of the Department of Agriculture.
 - Eight. Of the Fish Commission.
 - Nine. Of the Botanic Gardens.
 - Ten. Of the Coast and Geodetic Survey.
 - Eleven. Of the Geological Survey.
 - Twelve. Of the Naval Observatory.
- Approved, April 12, 1892.

The second is contained in the following paragraph in the general deficiency appropriation bill passed at the second session of the Fifty-sixth Congress, and approved March 3, 1901 :

That facilities for study and research in the government departments, the Library of Congress, the National Museum, the Zoological Park, the Bureau of Ethnology, the Fish Commission, the Botanic Gardens, and similar institutions hereafter established shall be afforded to scientific investigators and to duly qualified individuals, students and graduates of institutions of learning in the several states and territories, as well as in the District of Columbia, under such rules and restrictions as the heads of the departments and bureaus mentioned may prescribe.

The joint resolution of April 12, 1892, placed the governmental facilities for research at the disposal of duly qualified students of institutions of learning at Washington, D. C. The law of March 3, 1901, extends the same privilege to duly qualified students or graduates of institutions of learning wherever they may be situated throughout the United States.

It appears, therefore, that the Congress has already taken the necessary steps to make possible all that is desired in this connection, and it only remains to devise a plan by which the advanced students who wish to avail of the opportunities offered may be given such systematic information, direction and oversight as they may need in order to carry on their studies to the best advantage, and in order that such official records of their work at Washington may be kept, as will justify the several uni-

versities of the country in recognizing the period spent in study and investigation at Washington in passing upon their qualifications as candidates for the higher academic degrees.

A NON-GOVERNMENTAL INSTITUTION AT
WASHINGTON.

The remaining question before the committee for consideration was, then, this: Should a plan be devised by which, through the cooperation of several institutions, such a non-governmental institution should be established and maintained at Washington, this to involve its incorporation and governmental aid.

The subject of the best form of organization for such an institution and of its precise relations to the government has been given prolonged consideration. Advice and suggestion have been sought from the heads of the several scientific bureaus at Washington, from the representatives of the Association of Agricultural Colleges and Experiment Stations, from the presidents of the State universities and land-grant colleges, and from many others believed or supposed to be interested in the question. It seemed at first as if a solution might be found through the Smithsonian Institution, and that it might most wisely undertake the advisory and supervisory functions for which provision was to be made. The authorities of the Smithsonian Institution, however, did not view the suggestion with favor, and, in addition, they were doubtful of their legal capacity to perform such functions. Another objection was found in the fact that the Smithsonian Institution restricts itself to the field of the natural sciences, whereas students of history, political economy, and philology are also to be provided for.

An alternative suggestion was that the Bureau of Education should be asked to assume executive control of the proposed

student body. On reflection, however, it appeared that this would require far-reaching amendments to the law governing the bureau, that these might be difficult or impossible to obtain, and that the matter might become complicated with wholly extraneous considerations relating to the status of the Bureau of Education and the extension of its authority in other directions.

It has, therefore, seemed best to the committee not to propose either of the plans above mentioned.

The committee have been advised, however, of a plan for a non-governmental institution at Washington, which may be able to supply all that is desired. This plan is the outcome of action taken by the Washington Academy of Sciences and by the George Washington Memorial Association.

WASHINGTON ACADEMY OF SCIENCES.

The Washington Academy of Sciences includes in its membership all, or nearly all, the directors and officers of the scientific bureaus of the government. It was organized in 1898 and grew out of the affiliation which had previously existed between the local scientific societies. It is an incorporated body having for its main object to bring within a single organization the representatives of the varied scientific work being carried on at the capital. The academy has power to acquire and to hold real estate, to publish, to conduct or to assist investigation in any department of science, to maintain a library, and in general to transact any business pertinent to an academy of sciences. The list of members, resident and non-resident, of the Washington Academy of Sciences shows that it is national in its scope and influence, and that representatives of philosophy, history, education and political economy are included.

GEORGE WASHINGTON MEMORIAL ASSOCIATION.

The George Washington Memorial Association is an organization of women, incorporated in the District of Columbia in 1898, "to advance and secure the establishment in the city of Washington, D. C., of a university, for the purposes, and with the objects, substantially as contemplated and set forth in, and by, the last will of George Washington, the first President of the United States of America, and to increase the opportunities for the higher education of the youth of the said United States, and to this end to collect, take and hold moneys, gifts and endowments, to take and to hold by purchase, donations, or devise, real estate, to erect and furnish buildings to be used by said university, when legally established," and so forth.

In the year 1901 the certificate of incorporation of the George Washington Memorial Association was amended in due legal form, and all mention of a university was omitted from the statement of its purposes. The object of the Association is now declared to be "to aid in securing in the city of Washington, D. C., the increase of opportunities for higher education, as recommended by George Washington, the first President of the United States of America, in his various messages to Congress, notably in the first, in favor of 'the promotion of science and literature,' and substantially as contemplated and set forth in the last will of George Washington, and by and through such other plans and methods as may be necessary and suitable for the objects and purposes herein set forth, and to this end to collect, take and hold moneys, gifts and endowments, to take by purchase, donation, or devise, real estate, and hold the same, to erect and furnish buildings to be used for the purposes herein set forth, and, when necessary for the said purposes, to sell, convey, mortgage and exchange any real and personal estate which the As-

sociation may hold, and to do any and all things which may lawfully be done in carrying out the objects and purposes of this corporation."

ACTION OF THESE ORGANIZATIONS.

It appears that action has been taken by these organizations—by the Board of Managers of the former on February 26, 1901, and by the Board of Trustees of the latter on March 13, 1901—which brings the support of each to a plan for an institution of the type which has been discussed above. Both organizations have agreed to cooperate to found an institution in the city of Washington, as a memorial to George Washington, which shall be maintained to promote the advanced study of the sciences and the liberal arts, and which shall assist in carrying out the purposes and the intent of the joint resolution of April 12, 1892, and of the law of March 3, 1901.

WASHINGTON MEMORIAL INSTITUTION.

On May 17, 1901, articles of incorporation were filed at Washington, D. C., signed by Daniel C. Gilman, president of the Johns Hopkins University; Charlotte Everett Hopkins, president of the George Washington Memorial Association; C. Hart Merriam, chief of the United States Biological Survey; George M. Sternberg, surgeon-general, United States army; Charles D. Wolcott, director of the United States Geological Survey; and Carroll D. Wright, United States Commissioner of Labor, as follows:

ARTICLES OF INCORPORATION.

WE, the undersigned, persons of full age, and citizens of the United States, and a majority of whom are citizens of the District of Columbia, being desirous to establish and maintain, in the city of Washington, an institution in memory of George Washington for promoting science and literature, do hereby associate ourselves as a body corporate, for said purpose, under the general incorporation acts of the Congress of the United States enacted for the District of Columbia; and we do hereby certify in pursuance of said acts as follows:

1. The name or title by which such institution shall

be known in law is the Washington Memorial Institution.

2. The term for which said institution is organized is nine hundred and ninety-nine years.

3. The particular business and objects of the institution are: to create a memorial to George Washington; to promote science and literature; to provide opportunities and facilities for higher learning; and to facilitate the utilization of the scientific and other resources of the government for purposes of research and higher education.

4. The number of its trustees for the first year of its existence shall be fifteen.

Steps are to be taken at once by these incorporators to organize the institution, as described, and to select a body of trustees which shall be efficient and, so far as may be, representative of a variety of scientific and educational interests.

CHARACTERISTICS OF THE INSTITUTION PROPOSED.

Concerning the proposed institution, we assume:

1. That it will be independent of government support or control, as it will also be independent of the support or control of existing educational institutions. It might well appeal with peculiar force to the generosity of those men and women who are willing to increase, and who are desirous of increasing, the endowment of higher education in the United States.

2. That its objects will be:

a. To facilitate the use of the scientific and other resources of the government for research.

b. To cooperate with universities, colleges and individuals in securing to properly qualified persons opportunities for advanced study and research now obtainable only to a limited extent in Washington and not at all elsewhere.

3. That its oversight and control will be in the hands of trustees and officers representing the educational experience and ideals of the existing institutions for higher education.

4. That the arrangements between the student body and the several governmental bureaus will be made, subject to the by-laws of the trustees, in such a way as to carry out to the fullest possible extent the declared policy of the Congress. It is expected that the government officials will advise rather than instruct the students assigned to them.

5. That the sole test of admission to the privileges which the institution offers will be merit and proficiency, to be ascertained in such way as the trustees shall provide.

6. That students coming from universities and colleges for a period of study or investigation at Washington will, upon request, be given appropriate credentials, on completing their work, for presentation to the institution from which they seek a degree.

7. That students working in government laboratories or collections will be subject to the rules and regulations there prevailing.

8. That, if successfully carried out, this plan will provide a body of trained students, ready for expert work, many of whom might enter the government service, while others would become instructors in institutions of learning or be engaged as experts in a private capacity.

The departments or subjects in which graduate students could be received and the provision that could be made for them at present are unofficially estimated to be as in previous table.

ACTION OF COMMITTEE.

The committee have adopted the following resolution :

Resolved, That we approve the plan for a non-governmental institution, known as the Washington Memorial Institution, to be established and maintained at Washington, D. C., for the purposes of promoting the study of science and the liberal arts at the national capital, and of exercising systematic oversight of the advanced study and investigation to be carried on by duly qualified students in the governmental laboratories and collections, in accordance with the terms of the joint resolution of Congress approved April 12, 1892, and those of the act of March 3, 1901.

We recommend that the National Council of Education adopt the following resolution :

Resolved, That the report of the committee authorized by resolution of July 11, 1898, to investigate the entire subject of a national university be received, and the committee discharged.

*RADIO-ACTIVE SUBSTANCES AND THEIR
RADIATIONS.*

DURING the past five years many physicists, attracted by the freshness of the field and the promise of important discoveries, have turned their attention to the study of the newly discovered radio-active substances. The result has been a rapid increase in knowledge of and interest in the phenomena, until now the main facts are known to all scientists, but, since the knowledge of the subject is increasing so fast, a short review is now and then acceptable and necessary, especially to those whose chief interests lie along other lines. In this article an attempt is made to point out the more interesting features of the subject.

The real discovery of the persistent radiations from the uranium compounds was made by M. Henri Becquerel in 1896. It had been stated by M. Niewenglowski that under the action of sunlight certain phosphorescent salts emit radiations which can penetrate black paper. In testing whether this applies to uranium salts, M. Becquerel discovered to his surprise that with uranium salts exposure to sunlight is unnecessary; uranium compounds are all the time giving off radiations which can pass through opaque bodies and affect a photographic plate on the other side. It was soon found that the uranium radiations discharge electrified bodies in the neighborhood by ionizing the surrounding air after the manner of kathode and X-rays. Naturally, about

the first hypothesis was that the radiations are ether vibrations, perhaps of very short wave-length, and many attempts were made to find evidence of reflection, refraction or polarization, with the result that none of these properties nor any of the properties peculiar to wave motion has yet been shown to belong to these radiations.

A few months after the discovery of the uranium radiations Professor Schmidt and Mme. Curie, a Polish physicist working in Paris, independently discovered the radio-activity of thorium compounds. An elaborate study of thorium radiations has since been made at McGill University by Professors Rutherford and Owens.

A greater discovery, however, was in store for Mme. Curie; for observing that many specimens of pitchblende, the principal ore of uranium, were more strongly radio-active than the pure uranium salts, she and her husband attempted a chemical separation of the suspected more active element. The result is well known; they succeeded in isolating two substances having at least 100,000 times the radio-activity of uranium. The first of these substances, which they named polonium, follows the bismuth in the separation from pitchblende. The separation from the bismuth is effected by taking advantage of the fact that polonium sulphide is more volatile than bismuth sulphide. The second substance they named radium. It follows the barium in its chemical reactions, but its chloride is less soluble in water than barium chloride, which affords a means of separation from the barium. Another very active substance has been obtained from pitchblende by M. Debierne. He has named it actinium. Chemically it is closely allied to titanium.

No one of these three substances has been obtained free from impurity, and the amounts obtained are exceedingly small, only a few centigrams from a thousand kilograms of pitchblende.

The spectrum of radium has been carefully examined by M. Demarcay, who assigns to it several new lines, the strongest having wave-lengths 4,683 and 3,814.7, and two bands. No characteristic spectrum has yet been found for polonium or actinium. On account of the small quantities of these substances available, no accurate atomic weight determinations have yet been made, but from what has been done it appears that radium has a higher atomic weight than barium.

At first it was supposed that the uranium itself was the source of the radio-activity of the uranium salts, since often the activity of the compounds seemed to depend on the amount of uranium present, but after the discovery of radium and polonium the radio-active power of uranium began to come under suspicion. Professor Crookes found that often different specimens of the same uranium salt would have very different radio-active strength, which difference in strength could be very little changed by changes in chemical or physical conditions, the strongly active salt remaining so and the less active salt never gaining strength. Suspecting that the radio-activity was due to something other than the uranium, Professor Crookes set about separating this irrepressible element. Such was his success that, starting with active uranium nitrate, he was able to obtain from it uranium nitrate which had no effect on a photographic plate even with an exposure of seven days. At the other end of the separation he had a substance many times as active as the original salt. The best and simplest of several methods of separation makes use of ether as a solvent. The ether dissolves the uranium nitrate and leaves undissolved most of the radio-active substance. This substance Professor Crookes calls UrX , the X testifying to our present ignorance of its real nature. Professor Crookes has also tried to separate

the active material from the thorium compounds, but has so far met with only partial success. It seems not unlikely, though, that it may yet be done as completely as in the case of uranium. Meanwhile it is convenient still to speak of uranium and thorium radiations.

PHOTOGRAPHIC AND CHEMICAL EFFECTS OF THE RADIATIONS.

The photographic effect was the one first discovered and it remains the most delicate test for radio-activity, for the effect is cumulative, and the exposure may be made as long as desired. Any one can obtain very good radiographs from any of the ordinary uranium salts by using rapid dry-plates and an exposure of two days, while visible effects can be obtained with a much shorter exposure. Polonium and radium affect a photographic plate in a few minutes if sufficiently close to it. Even with a distance of a meter between the radium and the plate, radiographs have been obtained after a few days' exposure. These are very sharp, showing thus the rectilinear propagation of the radiations. Polonium radiations are so rapidly absorbed by the air that no effect is produced with a greater distance than a few centimeters.

Under the action of the radium radiations glass takes a permanent brown or violet tint. The haloid salts of the alkali metals become colored just as under the action of the X-rays. Paper is sometimes discolored and under certain conditions ozone may be formed in the neighborhood of the very active substances. Barium platino-cyanide is colored brown.

The action of the radium rays on the skin is the same as that of the X-rays. At first there is a slight reddening of the skin, but after three or four weeks' exposure severe inflammation sets in.

FLUORESCENCE.

Most of the substances that show fluorescence under the action of ultra-violet light or the X-rays also fluoresce under the action of the radium radiations, while those that fluoresce under ordinary light do not fluoresce under the radium radiations; but there are numerous exceptions to these rules.

It is a very interesting fact that when freshly prepared the radium salts are faintly self-luminous, and this property seems to be retained as long as the salt does not absorb moisture. It is this property that has excited much of the popular interest in the radium salts, for it is a case of the longed-for light without heat. In fact, it is light with no apparent source of energy whatever. If radium chloride ever becomes cheap we may be given an opportunity to court fortune by investing in preferred stock of some 'International Radium Illuminating Company.' Just at present gold is dirt cheap in comparison with these radium salts. The self-luminescence is due to the fact that under the action of its own rays either the salt itself, or some of the unavoidable impurities, fluoresces.

Some of the tissues of the eye fluoresce under the radium rays, so a sensation of light is felt when some of the salt is brought before the closed eyelids or placed on the temple.

IONIZATION OF GASES.

Any gas traversed by the Becquerel rays, as Mme. Curie has named the new radiations, is made capable of conducting electricity. This conductivity is of the same nature as that produced in gases by the cathode and X-rays. According to the accepted hypothesis, the positive and negative particles or ions of the gas are knocked apart by the radiations, and the motion of these free charged ions when directed by an electric field constitutes the electric current.

If an ionized gas is left to itself the positive and negative particles soon reunite, and, in fact, the reuniting process goes on all the time in proportion to the number of free ions in the gas, so that under any given intensity of ionizing radiation a condition of equilibrium is soon reached in which the reuniting goes on as fast as the ionizing. Since the amount of ionization may be measured by measuring the electrical conductivity of the gas, this affords a convenient means of comparing the relative strengths of radio-active substances, and one which is much more rapid and accurate than the photographic one. It is by no means certain, however, that the radiations most effective for ionization will therefore produce most effect on a photographic plate. Ionization is proportional to the absorption of the radiations by the gas, so that if a bit of radio-active substance be placed between two metal plates a greater current may be sent between them when they are two centimeters apart than when they are only one, the greater thickness of the air in the first case absorbing more of the radiations.

An ionized gas is in many respects similar to an ordinary liquid electrolyte, and Lord Kelvin has shown that when a plate of copper and a plate of zinc are connected by a wire and the air between the plates exposed to radiations from uranium compounds, a current flows through the connecting wire just as if the plates were immersed in a liquid electrolyte. It has recently been shown that the Becquerel rays decrease the resistance of selenium, just as light and the X-rays do.

PENETRATING POWER.

The radiations from the various substances are not at all homogeneous, some being very penetrative, others being easily stopped by any substance. Polonium radiations, while intense, are of the non-penetrating kind, being stopped by even the

thinnest metal foil. Uranium radiations, and therefore Crookes' UrX radiations, are much more penetrating, passing through metals, glass and in fact all substances, but with considerable loss of intensity. Thorium compounds emit radiations of at least two very different penetrating powers, one part only feebly penetrating, another as penetrating as the UrX radiations. Radium and actinium also emit both penetrating and non-penetrating rays, some of the radium rays being the most penetrating of all. Screens of sheet metal act as sieves for the rays, soon cutting off the less penetrating rays and allowing the more penetrating kind to go through with but little diminution in intensity. One sheet of tin, 0.0025 mm. thick, transmitted 44% of the radiations from one radium specimen, two sheets of the same thickness transmitted 31%, and 15 sheets 15%. A sheet of glass 0.16 mm. thick transmitted 26%, and ten plates 16%. Aluminum 0.16 mm. thick transmitted 28%, six sheets 16%. On account of the non-homogeneity of the radiations it has been very difficult to determine the law of absorption, but it appears that for the rays of the most penetrating type, at least, the absorption is proportional only to the density and thickness of the absorbing screen, the kind of material, whether platinum, paper, glass, air or other substance, making but little difference. Because some of the less penetrating rays are absorbed by the salt itself, there is a larger proportion of the very penetrating rays in the radiations from a thick layer of the salt than in those from a thin layer.

DEFLECTION IN A MAGNETIC FIELD.

Several experimenters discovered about the same time that some of the Becquerel rays are affected by a magnetic field. This brought out strongly their resemblance to the cathode rays, and further experiment-

ing proved that if a beam of radium radiations is made to pass through a magnetic field which is perpendicular to the direction of the beam, then the beam is deflected just as a beam of cathode rays would be, that is, just as a stream of negatively charged atomic projectiles would be deflected. This fact furnished the basis for the present accepted hypothesis, namely, that the deviable rays consist of a stream of rapidly moving particles, charged with negative electricity. The deflection in a magnetic field gives further proof of the non-homogeneity of the radiations. The experiment is as follows: A vertical beam is obtained by placing the radio-active salt at the bottom of a narrow hole in a block of lead, which is then placed on a horizontal photographic dry-plate or a fluorescent screen, in the horizontal field of a large electro-magnet. When the magnet is energized the vertical beam of rays is deflected in a direction always perpendicular to its direction of propagation, and also perpendicular to the magnetic lines of force, so that it is finally bent over until it falls upon the plate or screen. The impression produced is not a spot, but a band or magnetic spectrum, which could not be the case if the beam were composed of homogeneous radiations. According to the electrified-projectile hypothesis this can be explained by saying that the particles do not all have the same velocity, in which case those having the highest velocity would be the least deflected. This view has support in the fact that of the deviable rays, the least deviable are the most penetrating, as we should expect from the higher velocity of the particles. Becquerel found that for the rays from a sample of radium the product of the strength of the field into the radius of curvature of the path varied from 350 to 3,000.

There are, however, certain rays that are not deflectable in a magnetic field, and

these are of the least penetrating kind, which, according to the charged-particle hypothesis, should, on the contrary, be most deflected by the field. A satisfactory hypothesis as to the nature of these non-deflectable, non-penetrating radiations has not yet been put forth. Perhaps they consist of particles of much larger mass than those of the deflectable rays. M. Villard finds also in the radium radiations a small proportion of very penetrating, non-deflectable rays, quite similar to the X-rays.

ELECTROSTATIC EFFECTS.

Now a stream of charged particles deflectable by a magnetic field should also be deflected by an electrostatic field. This is found to be the case. Furthermore, a shower of negatively charged particles ought to impart a negative charge to an insulated conductor. Of course in this case air would not act as an insulator, for it becomes a conductor under the action of the rays. M. and Mme. Curie got around this difficulty by insulating a conductor with a thin layer of wax over its surface, then exposed it to radium radiations and found that it became highly charged negatively. Insulating some of the radium salt in the same manner with wax, they found that it became highly charged positively, a beautiful corroboration of the theory that there is a separation of the atomic particles with their charges. If, as now seems almost certain, the negatively charged part of the atom has a mass only a small fraction, a thousandth perhaps, of that of the positive part, it is very reasonable that the negative particles would be the ones to be shot out in case of interatomic commotions. The rate of charging in the experiment was about 4×10^{-12} amperes per sq. cm. of the radium salt.

VELOCITY, MASS AND ENERGY OF THE RADIATIONS.

The velocity of a charged particle and the ratio of the charge to the mass may be

found by comparing its path in a magnetic field with its path in an electrostatic field. Then assuming the charged-particle hypothesis it should be possible to calculate the velocity of the particles in the deflectable rays from the radio-active substances. This has been done by M. Becquerel. The curvature of the path in the magnetic field can be measured without much difficulty, but the deflection in the electrostatic field is very small. The difficulty of the experiment is also increased by the complex character of the radiations, making it uncertain if rays of just the same kind are being observed in the two fields. Some confidence, however, must be placed in the results, though they give for the velocity of the particles an astounding figure, about half the velocity of light. How from a quiet, peaceful bit of white salt particles can be shot off with such a velocity as this remains for explanation. The ratio of the charge to the mass of the particles is of the same order as in the case of the cathode rays, another evidence that the atomic charges are invariable and inseparably connected with the particles.

By measuring the rate at which a charge is imparted to a conductor, and then using the values of the velocity and of the ratio of the charge to the mass determined as above, the kinetic energy per second of the particles emitted may be calculated. For a sq. cm. surface of a very active radium preparation it has been found to be 5.1 ergs per second, or five ten-millionths of a watt. The mass of the particles, calculated from the same data, is exceedingly small, the loss from a sq. cm. of surface being something like a milligram in a thousand million years. M. Becquerel observes that it is of the same order as the evaporation of certain odorous bodies.

Professor Rutherford and Mr. McClung made last year some interesting experiments on the energy required to produce ionization

of gases by kathode and X-rays. Assuming that the same energy is required to produce ionization by the Becquerel rays, they estimate that a sq. cm. surface of a thick layer of uranium oxide gives off energy at a rate not less than 10^{-11} calorie per second, which is sufficient to raise the temperature of 1 gram of water 1° C. in 3,000 years. In the case of radium, 100,000 times as active as uranium oxide, the energy given off is not less than 3,000 calories per year for a gram of substance. This value for the energy is 40 or 50 times as large as the value mentioned above, obtained by the other method. That the amount of energy concerned is so small emphasizes the extreme delicacy of the photographic and ionization tests.

SECONDARY RADIATIONS.

X-rays impinging on some substances induce secondary radiations, and it was soon found that the Becquerel rays also possess this power, with the important difference that the secondary radiations induced by the Becquerel rays continue after the action of the primary rays has ceased, which is not the case with those induced by the X-rays. These secondary radiations affect photographic plates and ionize gases. The radium preparations are the most active in producing secondary radiations, and the effect is produced equally well in the case of such different substances as platinum, zinc, bismuth and even paper. Up to a certain limit the intensity of the secondary rays increases with the time of exposure to the radium; after the removal of the radium the intensity gradually weakens, disappearing altogether after some hours. The source of the secondary rays was thought to be a fine dust which escapes from the radium and settles on neighboring bodies, but it cannot be removed by washing, and the radium rays have the power of imparting it even after passing through metal screens. It seems too that this power of emitting

radiations may even be imparted to gases. A number of substances may be made strongly radio-active by precipitation from solutions containing small amounts of the most active substances, and several times these temporarily active substances have been mistaken for compounds of new elements. It is not yet known to what extent the secondary radiations are like the primary, for their intensity is so small that a comparison is difficult.

Thorium oxide gives off a remarkable vapor or 'emanation' which causes a strong secondary radio-activity. This emanation can pass through paper and even very thin metal. It gradually diffuses itself throughout the air and is carried about by air currents. Air containing the emanation retains its electrical conductivity for as long as ten minutes after the thorium oxide is removed, though ordinary ionized air loses its conductivity in a few seconds. The emanation is not removed from the air by drawing it through wool or bubbling it through water or sulphuric acid. Any substance charged with negative electricity collects and concentrates the emanation, becoming very radio-active after a few hours in the presence of thorium oxide. Sand-papering or treatment with sulphuric acid removes the emanation from a platinum wire on which it has been concentrated. On afterwards evaporating the acid a radio-active residue may be obtained. The thorium emanation much resembles a fine radio-active dust.

NATURE OF THE RADIATIONS AND SOURCE OF THEIR ENERGY.

We may say then that for one component of these complex radiations a satisfactory explanation is offered. This component is of the same nature as the kathode rays, and consists of a rapidly moving stream of minute material particles each having its charge of negative electricity.

Another component is similar to the X-rays, and is probably a phenomenon of the ether rather than of ordinary matter. Perhaps this component is produced by the action of the first component, as the X-rays are produced by the action of the cathode rays. For the rest no satisfactory explanation has been given. Many of the secondary effects seem to result from a fine dust emitted from the radio-active substance. Possibly there is only a single primary radiation, the rest being secondary effects, as the cathode rays generate the X-rays and these in turn generate their complex secondary radiations.

The chemical nature of the radio-active substances or elements is still little understood, nor is it surprising when one considers the difficulty of working with substances occurring in such minute quantities as these. Only one new element, radium, is definitely established. Hofmann and Strauss thought they had isolated another new radio-active element, but while still claiming the new element, they now admit that it is not radio-active.

The question of the source of energy in these radiations is yet unanswered. Is the energy potential in an unstable molecular or atomic structure, or is it supplied continuously by outside sources? In the first case, how long will the energy last? In either case, is it a property that matter in general may under proper conditions assume, or is it, as it seems, restricted to a very few peculiar elements? Heat or cold, high or low pressure, has little influence on the emission of the rays. Mme. Curie once put forth the hypothesis that perhaps the radiation is induced in the radio-active elements by a sort of transcendental radiation more penetrating than the X-rays and pervading all our space. Professor Geitel found that if so the exciting radiations penetrate easily hundreds of yards of rock, for radium was still active at the bottom of

the deepest mine to which he had access. Finally, the study of the radio-active substances will surely lead to a better knowledge of that which is the subject of much of the physical research of to-day, the intimate structure of matter.

GEO. B. PEGRAM,

COLUMBIA UNIVERSITY,

June 21, 1901.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE following have completed their membership in the American Association for the Advancement of Science during the month of June.

Dr. Francis E. Abbot, Author, 43 Larch Road, Cambridge, Mass.

Ernest Kempton Adams, Scientific Investigator, 455 Madison Ave., New York, N. Y.

Harry Alexander, Elec. and Mech. Engineer, 18 and 20 West 34th Street, New York, N. Y.

E. B. Alsop, Metallurgy and Engineering, 541 Wood Street, Pittsburg, Pa.

James I. Ayer, Electrician, 5 Main Street Park, Malden, Mass.

Ralph Baggaley, engineer, Pittsburg, Pa.

Daniel Moreau Barringer, Geologist and Mining Engineer, 460 Bullitt Building, Philadelphia, Pa.

Professor Walter B. Barrows, Prof. of Zoology, Agricultural College, Michigan.

Francis Bartlett, 40 State Street, Boston, Mass.

James Newton Baskett, Author-Zoologist, Mexico, Mo.

Rev. John Mallery Bates, Botany, Callaway, Neb.

Dr. Henry Harris Aubrey Beach, Physician, 28 Commonwealth Avenue, Boston, Mass.

Professor Arthur E. Beardsley, Prof. of Biology, State Normal School, Greeley, Colo.

Bernhard Arthur Behrend, Civil and Elec. Engineer, Station H, Cincinnati, Ohio.

August Belmont, 23 Nassau Street, New York City.

Charles W. Bennett, Geologist, Coldwater, Mich.

Dr. Augustus C. Bernays, Specialist in Embryology, Anatomy and Surgery, 3623 Laeclde Avenue, St. Louis, Mo.

Solomon H. Bethea, United States Attorney, Chicago Club, Chicago, Ill.

Dr. Leslie D. Bissell, Physics, Hotchkiss School, Lakeville, Conn.

Dr. John B. Blake, Physician, 302 Beacon Street, Boston, Mass.

Lemuel Stearns Boggs, care Sargent & Lundy, 1,000 Isabella Building, Chicago, Ill.

Henry Martin Boies, President Moosic Powder Co., 530 Clay Avenue, Scranton, Pa.

Dr. Arnold L. Bossi, Chemist and Colorist, Manchester Mills, 1962 Elm St., Manchester, N. H.

Louis F. G. Bousearen, Chief Engineer, Water Works Commis., City Hall, Cincinnati, Ohio.

Albert A. Brooks, Teacher of Botany and Zoology, High School, Kansas City, Kans.

Frederick Burbidge, Mgr. Bunker Hill and Sullivan Mining and Concentrating Co., Kellogg, Idaho.

M. D. Burke, Civil Engineer, 404 Pike Building, Cincinnati, Ohio.

Robert E. Burke, Chemist, Mechanic Arts High School, 156 M Street, S. Boston, Mass.

Samuel Cabot, Chemist, 70 Kilby Street, Boston, Mass.

Professor Florian Cajori, Prof. of Mathematics, Colorado, Col., 1119 Wood Avenue, Colorado Springs, Col.

Frederic J. Carnell, Physics, 58 North Sheffield Hall, New Haven, Conn.

Arthur E. Childs, Mechanical and Electrical Engineer, 23 Central Street, Boston, Mass.

Isaac M. Cline, M.D., Section Director, U. S. Weather Bur., Weather Bur., Galveston, Texas.

Mendes Cohen, Civil Engineer, 825 N. Charles Street, Baltimore, Md.

Vernon G. Converse, Mechanical Engineer, 15th Street and Liberty Avenue, Pittsburgh, Pa.

Robert E. Cranston, Mining Engineer, Folsom, Cal.

David F. Crawford, Supt. Motive Power, Penn. R. R. Co., Fort Wayne, Ind.

Albert C. Crehore, Vice-President Crehore-Squier Intelligence Transmission Co., Brookside Park, Tarrytown, N. Y.

Frank H. Cockard, Civil and Mining Engineer, L. B. 34, Wheeling, W. Va.

Geo. W. Curtiss, Weatherford, Texas.

Irving S. Cutter, Botanist and Zoologist, Box 732 Lincoln, Nebr.

Dr. W. H. Dalrymple, Prof. Veterinary Science, La. State University, Baton Rouge, La.

Charles F. Davis, Chemist, Fort Collins, Colo.

William H. Davis, Assistant in Psychology, Columbia University, New York, N. Y.

William W. Davis, Chemist, Virginia Iron, Coal and Coke Co., Bristol, Tenn.

William H. Dean, Chemist, 167 West River Street, Wilkesbarre, Pa.

Frederic A. Delano, Supt. Motive Power, C. B. and Q. R. R. Co., 209 Adams Street, Chicago, Ill.

Alva C. Dinkey, General Supt. Steel Works, Homestead Steel Works, Munhall, Pa.

Rev. Charles F. Dole, Jamaica Plain, Mass.

Alexander Dow, Mech. and Elec. Engineer, 844 Cass Avenue., Detroit, Mich.

Dr. H. R. Dudgeon, Physician and Surgeon, Sealy Hospital, Galveston, Texas.

S. W. Dudley, Mech. Engineer, 15 Austin Street, Westville, Conn.

Robert B. Dunlevy, Geologist and Chemist, Winfield, Kans.

Dr. Robert T. Edes, Physician, 15 Greenough Avenue, Jamaica Plain, Mass.

August Eimer, 220 East 19th Street, New York City.

Robert W. Ellis, Tabor, Iowa.

Morton J. Elrod, Prof. of Biology, Univ. of Montana, Missoula, Mont.

Arthur B. Emmons, Newport, R. I.

Frederic J. Falding, Consulting Chemical Engineer, 52 Broadway, New York City.

SCIENTIFIC BOOKS.

Les problèmes de la vie. 1^{re} Partie. La Substance vivante et la cytodièrese. Par DR. ERMANNO GIGLIO-TOS. Turin. 1900.

A title, such as the author of the present volume has selected, is apt to excite suspicion by suggesting a discussion of phenomena for the explanation of which the data at our disposal seem at present hardly sufficient. The time when the biologist was content with an *ignoramus* or with the endeavor to conceal his ignorance under cover of vital force has passed away, and a school has arisen which pins its faith on the investigation of *Entwicklungsmechanik*, but which, it must be confessed, still subsists on the substance of things hoped for. The pendulum has swung from the predication of a special force to the application of the fundamental principles of physics and mechanics, but without as yet yielding the desired explanation of protoplasmic activity, possibly because the new position has not yet been sufficiently exploited.

Professor Giglio-Tos, however, believes that the lack of conclusive results is due to the pendulum having swung too far; the basis of an explanation of the phenomena of life is to be sought, in his opinion, not so much in the physical as in the chemical principles involved. The most fundamental of all the vital functions is assimilation and this he believes is exclusively a chemical phenomenon, perfectly analogous to the changes which organic chemical compounds may be made to undergo in our laboratories, acetic acid, for instance, if supplied with the proper food in the way of reagents, assimilating these and producing with their aid additional molecules of acetic acid. The example which he gives in illustration of the chemical nature of assimilation is so suggestive that it may be repeated here.

Thus *two* molecules of acetic acid supplied with the proper food (phosphorus pentachloride zinc ethyl and oxygen) have been able to assimilate additional atoms of CH.O, the result being the formation of *four* molecules of acetic acid (growth), together with certain excreta (phosphorus pentachloride, hydrochloric acid and zinc chloride). Arguing for this case, Professor Giglio-Tos lays down the following conditions as necessary in order that a molecule may exhibit the phenomena of assimilation :

1. It must be able, with the aid of assimilation, to divide into molecules similar to itself.

2. The necessary nutritive substance must be always present.

3. The nutritive and secondary (excreta) products must not act destructively upon each other.

4. The various processes of assimilation must follow one another in a definite order.

5. The physical conditions (heat, light, etc.) must be suitable.

The molecules of protoplasm, which are termed *biomolecules*, possess or exist under these necessary conditions and hence exhibit assimilation.

Having established this point, the author then proceeds to discuss differentiation. If we represent the primary molecule by *a* and the various compounds formed during the assimilative process by *b*, *c*, *d*, and *M*, the process indicated above may be graphically composed as

$$a \dots b \dots c \dots d \dots M = a + a$$

It is not necessary, however, that the resulting molecules should be identical in composition with that from which they arose, and the series may run thus :

$$a' \dots b' \dots c' \dots d' \dots M' = e' + e'$$

and finally it is possible that the two resulting molecules may differ from one another, thus

$$a'' \dots b'' \dots c'' \dots d'' \dots M'' = e'' + i''$$

As a combination of these various results of assimilation, which the author terms respectively autogenetic, homogenetic and heterogenetic, the differentiation of the biomolecules is produced. The biomolecules represent for Professor Giglio-Tos the fundamental constituents of protoplasm, but they are chemical constituents, and like many of his predecessors

he finds it necessary to postulate the existence of living particles composed of an aggregation of biomolecules and which he terms *biomores*. These he likens to a double salt and, since each biomore is composed of living molecules, it too is a living compound, and from the biological standpoint may be regarded as a symbiosis of molecules, since for the preservation of the biomore the component biomolecules must react favorably upon one another. The biomores are aggregated symbiotically to form a *bioplasma* and a symbiotic system of biomores which performs all the functions of life and constitutes a living unit, is termed a *biomonad*, while, finally, a *cell* is a biomonad 'characterized by the chemical nature of certain biomores which form its nucleus' or in other words is a differentiated biomonad.

Such in brief is the fundamental idea which the author expounds in the first five chapters of his book, and in the succeeding pages he proceeds to discuss the phenomena of cell division in the light of this idea. Reproduction is after all merely discontinuous growth and the causes which determine the growth or division of a molecule will be the same in the case of a biomore, or biomonad, or a cell. The division of a molecule depends upon the orientation of its constituent molecules, and the division of a biomonad, accordingly, is due to the orientation of its constituent biomores. It would lead us too far to attempt to follow the author in his minute analysis of the phenomena of karyokinesis, and it must suffice to quote from the concluding paragraphs of the book : "The property of division, which characterizes living substances, is not due to a special force. It is only the necessary, inevitable consequence of the constitution of this substance and of assimilation." "The force which unites the particles of living matter is the same as that which unites the particles of dead matter and is sufficient for the explanation of the phenomena of division. Division always occurs under the action of this force, whatever may be the constitution of the living substance, and the various figures which appear during division and which characterize cytodieresis are only the morphological consequences of that constitution."

In conclusion, it must be stated that notwithstanding the complexity of the problems discussed and the minute analysis to which they are subjected, the book is written with a rare degree of conciseness and lucidity. Professor Giglio Tos has certainly presented a somewhat abstruse subject in a most interesting manner and has given a new point of view, a working hypothesis which cannot fail to influence future cytological work. The book is suggestive from cover to cover, and the second volume, which is to treat of 'Ontogenesis and its Problems,' will be awaited with interest.

J. P. MCM.

A. de Bary's Vorlesungen über Bakterien. Dritte Auflage. Durchgesehen und teilweise neu bearbeitet. Von W. MIGULA. Leipzig, Wilhelm Engelmann. 1901. Mk. 3.60.

The name of DeBary's 'Lectures on Bacteria' still has power to conjure up pleasant memories in those persons who remember when this classic brochure was the only worthy book devoted exclusively to the young science of bacteriology. The ponderous tomes, too often filled with unassimilated facts, that have since appeared in abundance sometimes force us to recall with regret the days when selection of material and skilled exposition were not incompatible with completeness.

The attempt to put new wine into old bottles has always encountered certain experimental difficulties, and it cannot be said that these difficulties have been altogether overcome by Dr. Migula, although something of the charm of the original lectures has been retained. The general arrangement of the sections is the same as in the original edition, while the insertion of new facts and the dropping of outworn creeds is perhaps as skilfully carried out as could be expected. In spite of the defects to be anticipated in a rewritten work of this sort, the lectures will readily command interested readers. It will always be questioned, however, whether the successive changes in the viewpoint of a rapidly growing science do not continuously demand new methods of exposition, and whether it is quite fair to a book that has served well its day and generation to bring it again upon the stage.

E. O. J.

A Laboratory Guide in Elementary Bacteriology. By WILLIAM DODGE FROST, Instructor in Bacteriology, University of Wisconsin. Published by the Author, Madison, Wisconsin, 1901.

The development of bacteriology as a subject of general scientific importance has led in several American universities to the introduction of courses in bacteriology into the regular undergraduate curriculum, and has created a demand for a kind of laboratory training adapted to the requirements both of the college student and of the student of medicine. The book before us outlines a course of this character, elaborated during several years of experience at the University of Wisconsin. The arrangement and choice of matter will be generally commended. The ordinary technical procedures are lucidly described with the aid of many diagrams, and are in thorough accord with the latest and best practice. The book is not distorted by being wrested to special utilitarian ends, but is rather designed to lay a broad foundation for subsequent specialization in any branch of bacteriology. It is admirably fitted for this purpose.

E. O. J.

Elements of Quaternions. By the late SIR W. R. HAMILTON. Second edition. Edited by PROFESSOR C. J. JOLY. London, Longmans & Co. Vol. I., pp. xxxiii + 583; Vol. II., pp. liv + 502; quarto.

The first edition of the 'Elements of Quaternions' consisted of 500 copies; and as many of these were presented to men of science, the book soon became scarce on the market. The published price was one pound; five times that amount has been paid for a single copy. In fact it frequently happened that a student could not obtain a copy of the English edition, and was obliged to content himself with Glan's German translation. Therefore we hail with pleasure a second edition of this classic of the mathematics, especially as it is printed in two handsome quarto volumes, and can be purchased at a moderate price.

Hamilton spent the last seven years of his life in the preparation of the 'Elements,' which he designed to be the *Principia* of space-analysis. He did not live to see them published.

The successive sheets were revised by him and printed off under his direction; but at his death some intended articles remained unwritten, although everything up to them had been revised and printed off. Professor Joly testifies in his preface that he has found extraordinary accuracy both of matter and of printing in the first edition. To the new edition he has added a preface, an index, an analysis of each article in the table of contents, footnotes and an appendix containing more lengthy notes on the following subjects: 'Quaternion Determinants,' 'Miscellaneous Properties of Two Linear Vector Functions,' 'The Strain Function,' 'On the Specification of Linear Vector Functions,' 'On the General Linear Transformation in Space,' 'On the Theory of Screws,' 'On Finite Displacements,' 'On the Kinematical Treatment of Surfaces,' 'On Systems of Rays,' 'On Hamilton's Operator ∇ .'

It was Abel who said that if one wished to make progress in mathematical science he ought to study the original work of the master rather than the presentations of his pupils. This maxim applies especially to quaternions; and for facilitating the study of Hamilton's great work the Printing Board of Trinity College, Dublin, and the editor, Professor Joly, deserve the thanks of the mathematical world.

ALEXANDER MACFARLANE.

SOCIETIES AND ACADEMIES.

THE RESEARCH CLUB OF THE UNIVERSITY OF MICHIGAN.

THE Research Club of the University of Michigan was organized two years ago, its membership being made up from the University Faculties, and its aim being the promotion of research. During the year just closed, the Club has met six times, and its proceedings may be briefly summarized as follows:

At the first meeting, held in October, 1900, the theme for discussion was 'The Promotion of Research at the University of Michigan.' Dr. Vaughan, President of the Club, addressed the members on the organization and objects of the Club, and closed with remarks on the topic of the evening. Professors Wenley, Ziwet,

Adams and Reighard spoke by appointment, and they were followed *ex tempore* by Dr. Hulett, Dr. Bigelow and Dr. Dock.

At the second meeting, November, 1900, the speakers were Professors Hempl and Newcombe. Professor Hempl spoke on the formation of dialect districts in the United States, showing with the help of charts the boundaries of various dialectic differences. The speaker gave concrete examples of variation in the use and pronunciation of words and phrases, and made some attempt to trace the historical development of these variations.

Professor Newcombe narrated his experiments on the sensitive curves made by roots in response to the streaming of water, and in response to contact with a foreign body. It was shown that about one-half of the thirty-three species of plants tested are sensitive to the water-current, and that of the four water-plants used, none is sensitive. So far as tested, all those plants responding to the water-current responded to the contact of a foreign body, and those not responding to one did not respond to the other. Hence it is supposed, though not demonstrated, that the response in both cases is response to one-sided pressure. A summary of these results may be found in SCIENCE, XIII. (1901), p. 250.

The third meeting came in January, 1901. Professor Gomberg detailed the experiments which led to his discovery of the trivalency of carbon. Accounts of this work may be found in *Jour. Amer. Chem. Soc.*, 22, 757; *Ber. d. d. Chem. Gesellsch.*, 33, 3150; *Amer. Chem. Jour.*, 25, 317. Dr. H. S. Jennings stated his results in studying the reactions of infusoria to external stimuli, illustrating his summary with experiments, made visible to all present by projection with a lantern. The researches of which Dr. Jennings gave an account have been published in full in various journals, and an abstract appeared in SCIENCE for January 11, 1901 (XIII., 74), in the report of the Zoological Journal Club of the University of Michigan.

The February meeting listened to papers by Dr. George Dock and Professor W. B. Pillsbury. Dr. Dock described the method of teaching internal medicine in the University. The limited time in the medical course makes it

difficult for undergraduates to do more in the way of research than to work out some original detail. In this work, they make extensive use of the laboratory method, and the effort is made to require students to think for themselves. The paper closed with the citation of subjects of investigation followed in the medical clinic. Professor Pillsbury presented a summary of a paper entitled 'Do the Sensations of Movement Originate in the Joints?' The narration of his experiments showed that a current through the ankle or elbow was as effective in reducing the sensitiveness of knee or elbow as currents through the joints in question. This fact, he stated, can only be explained if the sensory endings in the tendon or muscle are the seat of the sensation, and not the joints as is usually claimed.

In the March meeting Dr. Warthin and Dr. Hulett presented papers. Dr. Warthin spoke on 'A Contribution to the Normal Histology and Pathology of the Hemolymph Glands' (preliminary report). In this paper the occurrence of glands containing blood-sinuses instead of lymph-sinuses is for the first time shown to be constant in the human body. The distribution of these glands, their minute structure, their hemolytic function under normal conditions, etc., are described. Two types of these glands—splenolymph and marrowlymph glands—are found to occur. In a number of cases of fatal anemia, pathological changes were found in these glands, showing conclusively that they may become centers of red blood-cell formation.

Dr. Hulett presented a report of his measurements of 'The Relation Between Surface Energy and Solubility.' The theoretical relation between surface tension and solubility was discussed, and experimental data given to show that the solubility of a substance depends upon the curvature of the surface—*i. e.*, the finer the state of division the more soluble (*t* constant). The solubility of gypsum was increased 19 % by decreasing the size of the particles from 2μ to 0.3μ ; barium sulphate showed an increase of 100 % in solubility, and mercury oxide 300 % over that of the normally saturated solutions.

At the last meeting, held the 29th of May, Professor Lloyd read a paper bearing the title

'Some Unscientific Reflections upon Science.' The paper was vigorously discussed, some of those present thinking that the attitude of scientific men had been unfairly portrayed, while others supported Professor Lloyd. This paper is soon to appear in full in SCIENCE. At this meeting also, Professor E. D. Campbell detailed in a highly interesting manner his researches on the microscopical and chemical composition of steel. His paper gave a comparison of the heat of formation, and the action of nitric acid and of iodine on cementite, one of the constituents of high carbon steel, and on the pure carbide of iron isolated from pearlite. From these comparisons the author concludes that free cementite is not only not identical with the carbide of pearlite, as is usually assumed, but is probably not a carbide at all, but a solid solution of carbon in iron.

FREDERICK C. NEWCOMBE,
Secretary.

THE TEXAS ACADEMY OF SCIENCE.

DURING the half year ending with June, this organization held four meetings in the Chemical Lecture Room of the University of Texas. On January 18, Dr. William Morton Wheeler, professor of zoology in the University, lectured upon 'The Relation of Ants to other Living Organisms'; on March 23, Dr. William L. Bray, professor of botany, lectured on 'Texas Forests: their Present Condition and their Future Management'; and on April 5, Dr. William B. Phillips, the lately appointed director of University Mineral Survey, lectured on 'Texas Petroleum.' The lectures of Messrs. Wheeler and Bray were illustrated by a liberal use of lantern slides.

The program of the annual meeting, held on June 10, was as follows: 'Contributions of the Nineteenth Century to Education,' William S. Sutton, M.A., professor of the science and art of education in the University of Texas.

'Rice Irrigation in Texas,' Thos. U. Taylor, M.C.E., professor of applied mathematics in the University of Texas.

'Texas Railway Stock and Bond Law,' R. A. Thompson, C.E., expert engineer to the Texas Railroad Commission.

'Texas Minerals and Mineral Localities' (by

title), Frederic W. Simonds, Ph.D., professor of geology in the University of Texas.

'Notes on the Yellow Oxide of Mercury,' E. P. Schoch, M.A., and O. W. Wilcox, school of chemistry, University of Texas.

Professor Sutton's paper was a thoughtful exposition of the subject—'Contributions of the Nineteenth Century to Education'—though necessarily brief. The closing paragraph, in the form of a summary, was as follows: "In conclusion, let us consider for a moment the question, What is the significance of all these contributions which the last one hundred years have made to education? Upon what principle can be explained the accomplishment of a task so stupendous as to involve, first, the most radical changes with respect to the aim in education; second, the vast expansion of the culture-material to accomplish this aim; third, the discovery of scientific method in instruction; fourth, the provision for the professional training of teachers; fifth, the organization and partial development of gigantic systems of public instruction at public expense; sixth, the increase of number of the learned professions by recognizing the dignity of applied sciences; and lastly, the extension of the privileges of education to the child in the kindergarten, and to the parent in the home? There can be but one answer to this question—it is the spirit of real humanism, which is the distinctive characteristic of the nineteenth century, a spirit which through the reign of reason seeks to bring all men to a knowledge of the truth, and which has for its ultimate purpose the complete physical and spiritual enfranchisement of the human race."

Mr. Thompson in discussing 'The Texas Railway Stock and Bond Law,' called attention to the fact that Texas is the only State in which the issuance of railway stocks and bonds is controlled by the government, and also that it is the only one which has prescribed an absolute basis for the valuation of railway properties.

The Stock and Bond Law declares that the issuance and execution of all railway securities are 'special privileges' subject to the absolute control of the State; and that no indebtedness shall be authorized beyond the 'reasonable value of property' to be fixed by the Railroad Commission in accordance with actual cost.

Railways existing at the time of passage of the law were valued at the estimated cost of reproduction.

The causes that led up to the enactment of the law were discussed, and it was shown that the contention by investors in railway stocks and bonds, that they should be entitled to charge freight and passenger rates sufficient to earn a fair rate of interest on their holdings, and the support of the Courts in the matter, led the State to limit the issuance of such securities, and to absolutely prohibit the current practice of 'watering' stocks and bonds.

It was shown from the reports of the Railroad Commission that the average amount of stocks and bonds outstanding against the railways of Texas, under the effect of this and other laws, had been reduced from \$43,961 per mile in 1894 to \$36,926 per mile in 1900. As the Stock and Bond Law continues in effect this will be further reduced, thus permitting a larger per cent. of the net earnings to be used in the upbuilding of the roads and guaranteeing safer investments to the purchasers of railway securities. Notwithstanding the restrictions of the law, railway building in Texas is progressing at a rapid rate—building for purely speculative purposes is checked and legitimate construction promoted. In 1901 it is thought that Texas will easily lead the States of the Union in miles of new railway.

The following notes on the red oxide of mercury were presented by Messrs. Schoch and Wilcox:

"The yellow oxide of mercury has been carefully examined in the laboratory of the school of chemistry of the University of Texas, with a view to clearing up disputed points. By heating up to 200°C. and weighing the water evolved only 0.6% was obtained, which invalidates the statements of Walker and Schaffner that the substance is mercuric hydroxide—a statement made on the basis of results obtained by heating the substance in the open air and reporting the loss as water, and corroborates the work of Siewert. The substance is distinctly crystalline; its specific gravity is 10.6 as determined by Mr. J. M. Kühne, while that of the red oxide is 11."

Upon the report of Messrs. A. M. Ferguson

and John K. Prather, tellers, President Harper announced that the following persons had been duly elected officers of the Academy for the year 1901-1902: President, Professor James C. Nagle of the Agricultural and Mechanical College of Texas, College Station; Vice-President, Dr. Henry Winston Harper, of the University of Texas; Treasurer, Mr. R. A. Thompson, Engineer to the State Railroad Commission; Secretary, Dr. Frederic W. Simonds, of the University of Texas; Librarian, Dr. William L. Bray, of the University of Texas; Other Members of the Council, Hon. Arthur Lefevre, State Superintendent of Public Instruction, and Professors Taylor and Wheeler, of the University.

FREDERIC W. SIMONDS,
Secretary.

THE TORREY BOTANICAL CLUB.

At the meeting of the Club on May 24, 1901, the scientific program consisted of a paper by Dr. H. M. Richards on 'The Botanical Establishments at Buitenzorg and Tjibodas in Java,' illustrated by numerous photographs, including views of the entrance to the botanic garden and of species growing within, of large lianas a foot in diameter, of the nutmeg, jackfruit, etc., of a tapioca plantation, beautiful treefern groves with alsephilas 40 feet high, etc. Dr. Richards described his journey by train from Batavia 40 miles to Buitenzorg among the foothills of the western mountains. The Botanical Garden of Buitenzorg is at an elevation of over 900 feet, and therefore much cooler than the coast lowlands, the thermometer rarely going below 80° or above 90° F.; rain falls almost every day and almost uniformly through the year; the forenoon is bright and clear; the conditions for plant growth are very much as in a hothouse. A smoldering volcano rises on one side and an extinct one on the other, with a very variable river between.

The history of the Garden dates from Sir Stamford Raffles, British governor, who made a picturesque park about 1811 about his palace, of which the Garden shows some remnants. The *Rafflesia*, which perpetuates his name, is but occasionally to be seen, and although the Garden endeavors to maintain examples of

growth, none were to be had at the time of Dr. Richards' visit. Since the present directorship, about 1880, the Garden has been greatly stimulated. Dr. Lotze, formerly at the Johns Hopkins University, is now one of the staff there. The eight laboratory tables for foreign workers were well filled. Much valuable work has been done of immediate agricultural utility; it is here that the *Cinchona* was acclimated from South America to replace the coffee industry, the coffee plants having been destroyed by a fungus. Experiments toward finding a new rubber supply are in progress, and others to improve vanilla and cocaine production. The Malay workmen who fertilize the vanilla plant by hand prove very skilful. About 30 Europeans and 200 natives form the garden force. In the Botanical Garden proper the orders are not grown in exact sequence, but are grouped and marked off by letters; two specimens of each species are grown; one at least of these is labeled; if grown away from its congeners that fact is indicated by use of a red label. Many screw-pines which belong to the salt or brackish water of the coast grow well here in the garden soil. The palm collection is one of the largest in the world; notable features are its specimens of *Areca* and of *Livistona*. Down by a brook is a fine *Casuarina* collection, the Javanese species of which forms large forests on the upper hills resembling northern larch forests. The *Ficus* group is abundant and supplies the favorite shade tree for Javanese streets. Orchids hang especially from trees of the leguminous type, as *Amherstia*, *Cæsalpinia*, etc. These trees are very like candelabra in direction and so expose a reduced surface to the excess of light.

The mountain-garden at Tjibodas, at an elevation of about 4,500 feet, affords the necessary complement to the botanical garden proper. Dr. Richards found it cool enough after the afternoon rain to make a fire very welcome. Good potatoes are raised there, and on the journey up one passes paddy-fields and tea-plantations, including that from which came the Javanese villagers at the Chicago fair. A great jungle of 700 acres extends up to the mountain-top, through which the ascent was taken at 3 A. M. by torchlight, to get the sunrise view. Here tropical oaks develop

into dense balls, epiphyte ferns are in abundance, fallen trunks are covered with moss, and the path through the jungle chokes up so quickly that it has to be cut open often. The jungle is said to contain 1,500 species of trees. The Malays are very keen in perceiving distinctions, and recognize two species of oaks there which the botanists have not yet discriminated. On the heights the aspect becomes more European, *Viola*, *Ranunculus*, *Primula*, *Lonicera*, *Lobelia*, *Oxalis*, etc., appear, and Wallace explained this by supposing these northern forms were pushed south by a glacial climate and on the retreat of the ice they themselves retreated to the mountains.

EDWARD S. BURGESS,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis, on the evening of June 3, 22 persons present, the following subjects were presented:

A paper by Dr. Gellert Alleman, on 'The Action of Alcohol on Certain Isomeric Diazo Compounds,' and one by Dr. G. Hambach, entitled 'A Revision of the Blastoidæ,' were presented by title.

Mr. Wm. H. Roever, of Washington University, read a paper on 'The Effect of the Earth's Rotation upon Falling Bodies,' in which he showed that a body falling from a great height has a southward deviation in the northern hemisphere and a northward deviation in the southern hemisphere. The deviation is given by the formula—

$$\Delta = h \left[\frac{\left(1 + \frac{h}{R}\right)^3 K \sin \phi \cos \phi}{1 - \left(1 + \frac{h}{R}\right)^3 K \cos^2 \phi} - \frac{1}{\left(1 + \frac{h}{R}\right)} \cdot \frac{K \sin \phi \cos \phi}{1 - K \cos^2 \phi} \right],$$

in which h is the height through which the body falls, R the radius of the earth (assumed spherical), ϕ the latitude of the place of observation, K the numerical fraction $\frac{1}{289}$ and Δ the deviation. If h and R are given in feet, Δ is in feet.

For $h = 578$ feet and $\phi = 45^\circ$, $\Delta = .00133$ inch.

Mr. G. Pauls presented a number of specimens collected at Eureka, Mo. He exhibited a large number of galls on hickory, maple and oak leaves, commenting on the remarkable variety of the forms of galls made by the minute insects. He had bred a good many of these insects, and found that in successive years a good many different forms came from these galls.

WILLIAM TRELEASE,
Recording Secretary.

CURRENT NOTES ON PHYSIOGEOGRAPHY.

NEW MAP OF THE MISSISSIPPI.

THE 'Preliminary Map of the Mississippi River from the mouth of the Ohio River to the head of the Passes,' published by the Mississippi River Commission (1881-1885, 32 sheets, one inch to a mile), is now to be supplemented by a new edition, of which 13 sheets are issued, bearing in red overprint the changes wrought by the river in about fifteen years. These new sheets are without question the most instructive exhibition of river work, quantitatively determined, yet published in this country; for a river of the first magnitude they have no rival in the world. They deserve to be widely known not only among engineers for whom they were primarily constructed, but among geographers and teachers to whom they convey much information. The general behavior of the meandering river may be inferred from the maps of the earlier edition, from which it appears that the meander system slowly moves down the valley, because the thread of fastest current, thrown toward the outer side of every curve, is therefore delivered to the down-valley side of every tangent or 'crossing' (so called because river boats must there cross the river obliquely in following the channel of greatest depth); and that the meander belt included between tangents drawn outside of the curves slowly widens as the curves increase in radius and arc until it here and there suddenly collapses when a curve is cut off. It may be noted in passing that it is for this reason that the abandoned curves—the ox-bow lakes—are frequently of larger radius than the average of the existing curves. The

down-valley shifting and the broadening of the meander belt are well shown by the pattern of the toe-taps of alluvium that are added, right and left, to the flood plain lobes as the meanders grow and shift, as in the accompanying figure.

All these systematic changes are directly shown by a comparison of the river banks in black and red on the new edition of the map; the wasting banks being systematically located on the outer and down-valley side of the channel, as indicated by heavy lines in the above diagram. Sheet 14 includes the remarkable serpentine meanders near Greenville, where the increase of radius and arc and the down-valley shifting are beautifully shown. Sheets 17, 18 and 19 include a number of curves in the neighborhood of Vicksburg, where the river has destroyed the old levees, thus necessitating the construction of new ones further back from the bank. The bends below Baton Rouge (sheet 25) exhibit relatively small change of position.

THE RIVER SPEY.

THE physiography of the Spey, a river flowing eastward from the Highlands of central Scotland to the North sea, is considered by Hinxman ('The River Spey,' *Scot. Geogr. Mag.*, XVII., 1901, 185-193). A number of the items presented are of interest, but the plan of the article does not imply a comprehensive view of the natural history of rivers. "The Spey valley for the greater part of its extent may * * * be regarded as the result of the slow erosion of the river, continued since early Paleozoic times"; this suggests altogether too great an antiquity; the incision of the Spey valley, and of all the existing valleys, glens and straths of Scotland, beneath the general level of the

Highland summits, is probably not older than Tertiary, and certainly not older than middle Mesozoic time. The valleys of "the river and its principal tributaries * * * belong to a very early period in the history of the earth. That they existed before the Old Red sandstone age" is known, because patches of that formation still remain in them here and there; a safer statement would be that an uneven land surface, presumably a region of hills and valleys, was buried by the Old Red, and that some of these ancient valleys have been re-excavated; but it is very improbable that the main and branch valleys of the Spey system are in any close degree coincident with any single ancient valley system. Indeed, much may be said in favor of the initiation of these and certain other Highland valleys on a land surface that was deformed by the tilting and faulting which disturbed the Old Red itself. No special consideration is given to the stage of development of the Spey in pre-glacial time, or to the amount of change produced by glacial action, destructive or constructive; but certain features of the existing river are presented. One is the diversion of a small upper part of river Feshie from the Dee system to the Spey; the diversion is ascribed to normal retrogressive erosion, but it is not shown that the capturing stream had any special advantage over the captured, and no account is taken of glacial action.* Reference is made to the temporary enlargement of the Spey by waters from Glen Spean, on the west, when the lower course of the Spean was obstructed by ice in the Glen Roy district; but that the Pattack and several other barbed headwaters of the present Spean were preglacial members of the Spey system is not considered. Special emphasis is given to the abnormal slope of the Spey; the upper course falls 327 feet in 14 miles, the middle course falls 215 feet in 40 miles; and the lower

* According to the Ordnance map, a gorge on the Feshie two miles southeast of Ruigh-fionntaigh would seem to mark the site of the divide between Spey and Dee before the diversion; and the diversion appears to have been associated with some glacial control. The gorge is not situated where it should be if the upper Feshie had been diverted by retrogressive erosion.

course falls 600 feet in 43 miles. The Feshie makes a fan across the flat middle section of the Spey valley. It is assumed that the Spey once had a normal slope, and it is suggested that a relatively recent uplift in its lower third flattened the middle course and steepened the lower course. Explanation is thus found for the action of the stream in aggrading its middle portion with drift and in cutting down its lower portion in bed rock; but no confirmation for the suggestion of recent uplift is looked for in the neighboring valleys; the success of the suggestion in explaining what it was invented to explain is taken as its verification, without looking for unexpected consequences.

THE RIES.

THE divide between the headwaters of the Main and Neckar on the northwest and the Danube on the southeast is in general determined by the crest of a rather pronounced cuesta of Jurassic limestone, part of which is known as the Swabian Alp. The escarpment of the cuesta, facing northwest, is usually well defined; the back slope, towards the Danube, is on the whole remarkably simple and systematic; but near the middle of its curved length there is a curious, roughly hexagonal depression, called the Ries, about 18 k. in diameter, rather flat floored and well enclosed by the hilly borders of the uplands, with Nordlingen as its chief town. This highly abnormal feature has been likened to a gigantic *maare*, or pit-crater; but although volcanic rocks are confusedly mixed with many others—decomposed granite, schists, mesozoic, tertiary and quaternary—in the floor of the depression, a detailed study by Gruber ('Das Ries, eine geographisch-volkswirtschaftliche Studie,' *Forsch deut. Landes u. Volkskunde*, XII., 1899, 193–291, map, 12 figs.), ascribe the basins to dislocations, similar to those by which various other depressions have been produced in central Germany. It is not clearly explained, however, in just what shares dislocation and denudation are responsible for the basin; no definite statement is made as to the form that the surface had when dislocation took place, as to the form that dislocation produced, or as to the work of denudation on the dislocated form. It is, therefore,

difficult to form a clear mental picture of the theoretical forms by which the observed forms are to be explained. In the second part of the essay, the people, settlements, occupations and products of the Ries are described.

W. M. DAVIS.

BOTANICAL NOTES.

'SAVE YOUR PUFF-BALLS.'

UNDER this title Mr. C. G. Lloyd, the well-known student of the higher fungi, has issued a circular asking botanists and others to save puff-balls of all kinds (excepting the large ones) for him. He intends to publish 'in the near future a detailed description of all the Gasteromycetes' and solicits specimens from every one who can help him. Due credit is promised for all specimens sent to him for this purpose. The monograph is to be profusely illustrated with photo reproductions of typical specimens of the species and also with micro-photographic enlargements of the spores and capillitium by Dr. Edward Thompson, an expert in this line of work.

In his directions to collectors Mr. Lloyd says: "For the purpose of study puff-balls must be ripe, that is, they must be full of dry dust. When young most kinds are white and when you cut them they appear like 'cottage cheese.' They are mostly good to eat in this condition, but not to study. The best time to gather them is just when they are getting ripe, just when the white has become moist and discolored and the spines are just drying up and beginning to flake off." * * * "Simply pick them up, handle them carefully so as not to mash them, and if they are just ripening and are moist, spread them out on the floor in a garret or where they will be out of the way and let them dry. Then pack them loosely in a little wooden box; don't squeeze or bruise them." "If your boxes are not full, pack in loosely a little cotton or tissue paper (cotton is better) to fill out. Do not wrap in paper or put in paper bags." Send the boxes, securely wrapped, by mail or express, to Mr. Lloyd at Court and Plum streets, Cincinnati, Ohio.

A NEW WORK ON TREES AND SHRUBS.

THE announcement is made by Messrs. Houghton, Mifflin & Co., of Boston, Mass., that

Professor Charles S. Sargent, author of 'The Silva of North America,' has under preparation a work to be known as 'Trees and Shrubs' and to consist of illustrations and brief descriptions of new and little-known trees and shrubs, chiefly from material obtained from the Arnold Arboretum. It will not be confined wholly to North American plants, but 'will include also the woody plants of other regions, especially those of the northern hemisphere, which may be expected to flourish in the gardens of the United States and Europe, and those of special commercial or economic interest and value.' It is to be published at irregular intervals, and each part will contain twenty-five plates. It is the hope of the publishers that one part will appear in the fall of 1901, and that at least two parts may be issued each year. From the specimen plates and pages of text it is evident that this is to be a work second only to the 'Silva' in importance and value to working botanists and horticulturists.

THE OAKS OF THE CONTINENTAL DIVIDE.

BOTANISTS who have puzzled over the little oak trees of the Pike's Peak region in Colorado will be interested in a paper by Dr. Rydberg in a *Bulletin of the New York Botanical Garden* (Vol. II., No. 6), in which he attempts to bring something like order out of the chaotic condition which has existed hitherto. After several seasons of field work in the Rocky Mountains, Dr. Rydberg finds that the Colorado oaks heretofore referred to *Quercus undulata* and *Q. gambelii* are more properly to be referred to ten or eleven species, three of which prove to have been undescribed. About Pike's Peak there are no less than six species, instead of the single species *Q. undulata*; these are *Q. utahensis*, *Q. leptophylla* (new), *Q. gunnisonii*, *Q. nitescens* (new), *Q. novo mexicana* and *Q. gambelii*. Dr. Rydberg found it necessary to extend his studies throughout the mountain region, and as a result he has very considerably enlarged the list of species for this portion of the continent. His descriptive list includes no less than twenty-nine names, of which the new species are: *Q. submollis* (Arizona), *Q. vreelandii* (Colorado to New Mexico), *Q. leptophylla* (Colorado), *Q. nitescens* (Colorado to Utah), *Q. eastwoodiæ* (Utah), *Q.*

havardi (Texas), *Q. pauciloba* (Arizona), *Q. wilcoxii* (Arizona to Utah and Nevada).

CHARLES E. BESSEY.

THE UNIVERSITY OF NEBRASKA.

CONFERRING OF DEGREES AT THE UNIVERSITY OF CHICAGO.

As we have already recorded, the University of Chicago conferred in connection with its decennial eleven honorary degrees. President Harper, in welcoming the men of science on whom the LL.D. degree was conferred, spoke as follows:

Edward Charles Pickering,

during twenty-five years Payne Professor of Astronomy and Director of the Astronomical Observatory of Harvard College, an observatory developed through your labors into an institution foremost in research on two continents; organizer in the United States of a system of laboratory teaching of great influence on education in physical science; student of optics; discoverer of variable stars and investigator in stellar photometry; originator of many astronomical applications of photography and spectroscopy, which have revealed the constitution of the stellar universe:—for these distinguished services, and especially for the last-named, by the authority of the Board of Trustees of the University of Chicago, upon nomination of the University Senate, I confer upon you the degree of Doctor of Laws of this University, with all rights and privileges appertaining thereunto.

Jacob Henry van't Hoff,

Professor of Physical Chemistry in the University of Berlin, investigator who has brought to bear upon chemical problems a keen and logical mind, endowed with speculative and imaginative powers of the highest order, founder of the theory explaining the space relations of atoms in molecules—a theory which is essential to a comprehension of the chemistry of organized and inorganized matter; master in the field of dynamic chemistry; investigator and brilliant discoverer in the domain of the modern theory of solutions, a theory which constitutes one of the greatest advances made by chemical science in the last quarter of a century:—for these splendid and fertile achievements, by the authority of the Board of Trustees of the University of Chicago, upon nomination of the University Senate, I confer upon you the degree of Doctor of Laws of this University, with all the rights and privileges appertaining thereunto.

Charles Doolittle Walcott,

Director of the United States Geological Survey, Superintendent of the National Museum, author of

numerous paleontological and geological contributions of eminent merit, notable among which are a series of monumental works on the Cambrian System of North America: for these distinguished contributions, and for signal ability displayed in the administration of the scientific and educational interests committed to your charge, by the authority of the Board of Trustees of the University of Chicago, upon the nomination of the University Senate, I confer upon you the degree of Doctor of Laws of this University, with all the rights and privileges appertaining thereunto.

Edmund Beecher Wilson,

Professor of Zoology in Columbia University, zoologist and worker in the field of biology, teacher and leader of many young investigators, writer of standard text-books in general biology and of numerous philosophical essays and classical memoirs on zoology; author of a masterpiece of research and presentation, 'The Cell in Development and Inheritance,' which embodies the writer's original contributions in embryology and cytology, as well as the results reached by other workers in these fields—for these eminent services in science, especially for the work last named, by the authority of the Board of Trustees of the University of Chicago, upon the nomination of the University Senate, I confer upon you the degree of Doctor of Laws of this University, with all the rights and privileges appertaining thereunto.

THE AMERICAN PHILOSOPHICAL SOCIETY.

THE American Philosophical Society, at its meeting on May 17, adopted the following resolution:

Whereas, The American Philosophical Society is and always has been a society of national scope, whose place of meeting was originally fixed at Philadelphia for reasons of convenience now less potent than formerly; and

Whereas, The growth and wide extent of our country and the multiplication of local societies tends to keep from our regular meetings those members who do not reside within a short distance of Philadelphia; and

Whereas, It is desirable that measures be taken to bring the distant members into more active participation in the work of the Society; therefore be it

Resolved, (1) That a committee of five be appointed by the President to consider the advisability and, if deemed advisable, to arrange for a general meeting at a time most convenient to all the members;

(2) That this meeting shall cover one or more days as may be considered advisable, and it is hoped

that the high scientific character and broad interest of the papers to be presented shall insure the attendance of a good proportion of distant members;

(3) That this committee shall have power to add to its number and to make all necessary arrangements to further the success of the proposed general meeting.

The committee appointed, consisting of Professors George F. Barker, Chairman, Edwin G. Conklin, Charles L. Doolittle, William B. Scott, William Powell Wilson, has enlarged its number, and has asked for suggestions which will tend to promote the success of the proposed general meeting. It is suggested that the meeting be held on the Friday and Saturday following Thanksgiving Day, on the Friday and Saturday following New Year's Day, or in Easter week.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

ADDITIONS AND CORRECTIONS TO THE PRELIMINARY ANNOUNCEMENT.

THE preliminary announcement of the Denver meeting of the Association has been mailed to all members, and it will undoubtedly have been noticed that the question of railroad rates has been left incomplete, except for the announcement of the Western Passenger Association, the statement being made that further arrangements will be announced in SCIENCE. The following arrangements have been made: *The Western Passenger Association*, covering the territory west of Chicago and St. Louis, has made a rate of one fare plus \$2 for the round trip, from all points in their territory to Denver, tickets to be sold July 10 to August 31, with final return limit of October 31.

The New England, Trunk Line, Central and Southeastern Passenger Associations, covering the territory east of Chicago and St. Louis, have made a rate of a fare and one-third for the round trip from all points in their territory to Denver, on the certificate plan, the conditions of which are as follows:

1st. Each person desiring to avail himself of the reduced rate must purchase a first-class ticket (either limited or unlimited) to the place of meeting, at the regular tariff rate and at the same time procure from the ticket agent a certificate of the standard form. If through ticket cannot be procured at the starting

point, the person should purchase to the most convenient point at which such ticket can be obtained and there repurchase through to the place of meeting, procuring a standard certificate from each agent from whom a ticket is purchased.

2d. *It is absolutely necessary that certificates be procured, indicating that the full fare has been paid for going passage and the route for which ticket or tickets for the return journey should be sold. No refund of fare can be expected because of failure to secure such certificates.*

3d. Tickets for the return journey will be sold at one-third the first-class tariff fare only to persons holding certificates of the standard form duly signed by the Permanent Secretary of the A. A. A. S., and signed by the special agent appointed for that purpose.

4th. No certificate will be honored that was procured more than three days (Sunday not included) before the meeting assembles (except that when meetings are held at distant points to which the authorized transit limit is more than three days, the authorized transit limit will govern), nor more than two days (Sunday not included) after the first day of the meeting. No certificate will be honored for return ticket unless presented during the time that the meeting is in session, or within three days (Sunday not included) after adjournment.

5th. Tickets for return journey will be limited to continuous passage on first train after purchase.

6th. Certificates will not be honored by conductors; they must be presented to ticket agents.

7th. Neither the certificates nor tickets furnished for this occasion are transferable, and if presented by any other person than the original purchaser, they will not be honored but will be forfeited.

Members desiring longer time than that allowed in connection with certificate reduction, viz., 3 days before the meeting assembles to 3 days after adjournment (Sunday not included) are advised to take advantage of the Colorado tourist fares or summer excursions, which, while costing a little more than the fare and one-third, are good from July 10 to October 31.

CORRECTION TO PROGRAM OF MONDAY AFTER-NOON, AUGUST 26.

(See page 26 of the preliminary announcement.)

Through some clerical or printer's blunder the vice-presidents elect are here announced to give their addresses at 3 o'clock at the high-school building. As a matter of fact, this is all

wrong. The vice-presidential addresses which will be given are those of four of the retiring vice-presidents, as follows:

Vice-President Brashear, before the Section of Mechanical Science and Engineering.

Vice-President Davenport, before the Section of Zoology.

Vice-President Butler, before the Section of Anthropology.

Vice-President Woodward, before the Section of Social and Economic Science.

It will probably be arranged so that two of these addresses will be given at 3 o'clock and two at 4 o'clock, in order to allow members interested to hear two addresses.

THROUGH PULLMAN SERVICE.

If a sufficient number of passengers can be guaranteed, arrangements can be made for through Pullman service, to connect at Chicago or St. Louis, so that members from different sections of the country can make the trip to Denver together. The Permanent Secretary therefore invites all members who plan to attend the meeting and who wish to take advantage of this through Pullman service to communicate with him at once, stating the name of the road over which they intend to travel and the date of their departure. If a sufficient number of replies are received, the arrangement will be made and members notified.

SCIENTIFIC NOTES AND NEWS.

PROFESSOR JAMES DEWAR, the eminent chemist, has been elected president of the British Association to follow Professor A. W. Rücker, and will preside at the Belfast meeting in 1902.

OXFORD UNIVERSITY has conferred its D.Sc. on Philip Lutley Sclater, M.A., F.R.S., secretary of the Zoological Society, London, and its D.C.L. on C. N. Dalton, C.B., comptroller-general of patents, designs and trade-marks.

DR. JOHN S. BILLINGS, director of the New York Public Library, has been elected president of the American Library Association.

M. MAUPAS has been elected a correspondent of the Paris Academy of Sciences in the

section of anatomy and physiology, replacing the late M. Marion.

The following have been appointed members of the visiting committee of the National Bureau of Standards: Dr. Ira Remsen, president, Johns Hopkins University; Professor Elihu Thomson, electrician, General Electric Company; Professor E. L. Nichols, professor of physics, Cornell University; Dr. Henry S. Pritchett, president, Massachusetts Institute of Technology; Mr. Albert Ladd Colby, metallurgical engineer, Bethlehem Steel Company, and secretary of the Association of American Steel Manufacturers. Professor E. B. Rosa, of Wesleyan University, has been appointed physicist.

DR. HENRY WOODWARD, F.R.S., keeper of the Department of Geology of the British Museum (Natural History), will retire in November, having some time since reached the age limit. It is expected that he will be succeeded by Dr. Arthur Smith Woodward, F.R.S., under whom the department would certainly be administered in accordance with the best scientific methods. Dr. Woodward's visit to this country last year is remembered with great pleasure by many American men of science.

PROFESSOR C. LE NEVE FOSTER, of the Royal School of Mines, London, has resigned the position of inspector of mines, which he has held for the past twenty-eight years.

WE regret to learn that Professor Rudolf Virchow has met with an accident, cutting his head by a fall, on June 13. His health has for some time past not been very good. Professor Virchow will celebrate his eightieth birthday on October 13.

PROFESSORS DAVID HILBERT (Göttingen), Georg Cantor (Halle) and Ulisse Dini (Pisa) have been elected foreign members of the London Mathematical Society.

J. W. LOWBER, PH.D., F.R.G.S., Austin, Texas, has been elected a fellow of the Royal Meteorological Society of London.

THE Belgian quinquennial jury of medical sciences has awarded its prize of the value of 5,000 francs to Professor Van Gehuchten of Louvain, for his researches on the brain and spinal cord.

PROFESSOR J. H. AMES, of the Johns Hopkins University, has accepted the position of associate editor of the *American Journal of Science* held by the late Professor H. A. Rowland.

DR. R. A. DALY has resigned his place as instructor of physiography at Harvard University to accept a position on the Geological Survey of Canada, where he will be attached to the party that is marking the international boundary on the Pacific slope. Mr. A. W. G. Wilson, who has just received the degree of Doctor of Philosophy in geology at Harvard, has also been appointed to the Canadian Survey for work in the country about Lake Nipigon.

GEORGE G. HEDGCOCK, B.Sc., 1899, and A.M., 1901, of the University of Nebraska, and sometime fellow in botany, has been appointed by the United States Department of Agriculture to investigate the diseases of the sugar beets of Nebraska and other western states.

PROFESSOR JOHN B. JOHNSON, dean of the College of Mechanics and Engineering of the University of Wisconsin, opened the discussion on present tendencies in technical and professional education at the twenty-ninth annual Convocation of the University of the State of New York, held at Albany last week.

AT a meeting of the Western Society of Engineers on June 26, Professor B. E. Fernow, of the New York State College of Forestry, delivered an address on 'The Relation of Forestry to Engineering.'

A COMMITTEE has been formed to erect in Bern a memorial to the great anatomist and physiologist Albrecht v. Haller, who was born in Bern in 1708 and died there in 1777.

DR. JOHN FISKE, the well-known lecturer and author, died on July 4 after a short illness caused by the excessive heat. Born in 1842, he graduated from Harvard University in 1863 and was for a time connected with the University as lecturer on philosophy and later as assistant librarian. Fiske did much by his books, lectures and articles to popularize the doctrine of evolution, especially on the lines laid down by Mr. Herbert Spencer. His 'Out-

lines of Cosmic Philosophy,' published in 1874, was followed by a long series of books, his contributions to history being in large measure influenced by his earlier work on evolution. Fiske enjoyed the personal friendship of Darwin, Huxley, Spencer and other great leaders, and the esteem of a large section of the general public.

PROFESSOR PETER GUTHRIE TAIT, who has held for the past forty years the chair of natural philosophy in Edinburgh University, died at Edinburgh on July 4. Born at Dalkeith in 1831, he attended Edinburgh University, and afterwards Cambridge University, where he was senior wrangler, first Smith's prizeman and fellow of Peterhouse. In 1854 he became professor of mathematics at Queen's College, Belfast, whence he removed to Edinburgh in 1860. He was the author of a long series of publications, both technical and popular in character. These include the 'Dynamics of a Particle,' 'Quaternions,' 'Thermodynamics,' and works on 'Heat,' 'Light' and 'The Properties of Matter.' His scientific papers were collected and published in 1898. In conjunction with Professor Balfour Stewart, he was the author of 'The Unseen Universe,' and, in cooperation with Lord Kelvin, prepared the well-known 'Natural Philosophy' of Thomson and Tait.

DR. THEODORE GREELY WHITE died in New York city on July 7, aged twenty-nine years. After having graduated from the School of Applied Sciences of Columbia University, he received the Ph.D. degree two years ago for work in geology. He was also assistant in the department of physics. Dr. White had made valuable contributions to geology and botany, and leaves a considerable amount of unpublished material. He was always active in good work, being last year one of the secretaries of the New York Academy of Sciences and acting editor of the publications of the academy.

THE small band of New Mexico naturalists has suffered a severe loss by the death of Mr. Francis J. Birtwell, of Albuquerque, who had spent two years investigating the ornithology of the territory, and who had in preparation an elaborate paper on the birds of New Mexico. Mr. Birtwell was married on May 24, and went

with his wife to study the birds of the Upper Pecos. On June 28, at Windsor's Ranch, 31 miles from Glorieta, he climbed a tall fir tree to obtain a bird's nest. Becoming dizzy, he signalled for help, and was being let down on a rope when by some means he jerked one arm out of the noose, and the rope tightened around his neck and strangled him before anyone could come to his assistance. Thus perished a man who was expected by those who knew his work to take a prominent place among American ornithologists. It is understood that his manuscript on the birds of New Mexico is in good order, and it is much to be hoped that the means will be found for its publication.

DR. JOHN CURWEN, a specialist in mental diseases, who for fifty years has been superintendent of hospitals for the insane at Harrisburg and Warren, Pa., died on July 2, aged eighty years.

MR. JOHN H. TEGMEYER, a well-known civil engineer, died at Baltimore on July 4, aged eighty years.

PROFESSOR LANGENBUCH, the eminent surgeon, director of the Lazarus Hospital, Berlin, died on June 9.

THE late Jacob S. Rogers, of Paterson, N. J., a locomotive builder, has bequeathed nearly his entire estate to the Metropolitan Museum of Art, New York City. The value of the bequest is estimated at from \$6,000,000 to \$8,000,000.

MR. ANDREW CARNEGIE has offered to give to the cities of San Francisco and Detroit \$750,000 for the establishment of public libraries.

THE Newberry Library, of Chicago, has acquired the philological library collected by the late Louis Lucien Buonaparte. It contains 15,000 volumes and is said to be the best philological library in the world.

IN connection with the census of India, a sum of at least £10,000 will be spent in collecting statistics relating to ethnology and anthropology.

A MAGNIFICENT specimen of the elephant seal (*Macrorhinus leoninus*) from the Macquarie Islands has lately been presented to the British Museum by the Hon. Walter Rothschild, one

of the trustees. The skin has been stuffed by Messrs. Gerard, who have imparted to the animal with its enormous fleshy nose a most lifelike, not to say human, appearance.

PLANS have been made to collect funds for a research scholarship at Trinity College, Dublin, in memory of the late Professor G. F. Fitzgerald.

AN anatomical museum fund, in memory of the late A. H. Hughes, who died in South Africa, has been established in connection with University College, Cardiff. Mrs. Hughes, the widow of Professor Hughes, has contributed £1,000 to this fund.

The deaths from the plague in Cape Colony to June 8 have numbered: Europeans, 58; colored persons, 164; Malays, 36; Indians, 9; Chinese, 0; natives, 59; total, 326. Only one case has occurred under naval and military control.

THE National Bureau of Standards was opened on July 1, with headquarters in the building of the Coast and Geodetic Survey. Plans are being prepared for the new building, for which Congress has made provision.

It is expected that the new Horticultural Building in Boston will be completed by the end of August, when there will be a special exhibition, arranged by Professor Charles S. Sargent, of the Arnold Arboretum.

THE observatory at Nice and its branch on Mt. Mourier has recently been visited by the board of control, consisting of MM. Gréard, Henri Poincaré, Barrot, Cornu, Lippmann, Loewy, Darboux, Mascart, Troost, Bischoffsheim.

THE Philippine Commission has established a government biological and chemical laboratory at Manila, which will have branch stations elsewhere. A superintendent will be appointed with a salary of \$4,000. A board of health has been established with a commissioner with a salary of \$6,000.

The Navy Department has purchased a tract of land surrounding the naval observatory, in order to protect the instruments. It was deemed advisable not to have any highways within 1,000 feet of the clock room, where the instruments are stationed, and a circle with a

radius of 1,000 feet was therefore drawn round the observatory. At the last session of Congress \$145,000 was appropriated to purchase the inclosed land, and of this sum \$122,000 has been expended for the purchase of about sixteen acres.

DR. C. W. ANDREWS, assistant in the Department of Geology, British Museum, Natural History, has been making collections in Egypt, which he has this month brought back with him to London.

THE expedition, planned by the South Dakota Geological Survey, into the Grand River region for this season has been postponed, because of smallpox in the Indian reservations where much of the work would have been done. It is hoped that next year circumstances will be more favorable.

THE Southeastern Union of Scientific Societies (England) held its sixth annual congress at Haslemere and Hindhead last month, under the presidency of Mr. G. A. Boulenger, F.R.S. The congress next year will be held at Canterbury, under the presidency of Dr. Jonathan Hutchinson, F.R.S.

WE learn from *Nature* that a committee has recently been appointed by the Institution of Civil Engineers, with the support of the Institutions of Mechanical Engineers and Naval Architects and of the Iron and Steel Institute, to consider the advisability of standardizing the various kinds of iron and steel sections, and, if found advisable, then to consider and report as to the steps which should be taken to carry such standardization into practice.

THE civil service commission reports that no applications have been received for the examination which was to have been held on July 6 for the position of laboratory assistant in physics at the national bureau of standards, as announced in this Journal several weeks ago. There are two vacancies to be filled as a result of this examination, one paying \$1,200 and the other \$1,400 a year. These openings are extremely desirable, as the work is largely research and the way is open for promotion.

THE civil service commission announces that it is desired to establish an eligible register

for the position of assistant physicist. It will not be necessary for applicants to appear at any place for examination. The examination will consist of the subjects mentioned below which will be weighted as follows :

Subjects.	Weights.
Education and training, with particular reference to the subjects of mathematics and chemistry	20
Experience in general laboratory manipulation, including glass-blowing, photography and assembling and making apparatus.....	10
Experience in advanced quantitative measurements, including determination of physical constants, comparison with standards, etc.....	20
Experience in original experimental research, particularly that relating to the physics of solutions and of finely divided solids. (In connection with this subject will be considered the various theses of published papers concerning investigations or experiments which the applicant has directed or assisted in).....	40
Training in mathematical physics. (This subject will include the consideration of theses of published papers on this line of work).....	10

From the eligibles resulting from this examination it is expected that certification will be made to the position of assistant physicist, Bureau of Soils, Department of Agriculture, at a salary of \$1,600 per annum, and to other similar vacancies as they may occur.

WE learn from the *Electrical World* that *L'Éclairage Électrique* is organizing a technical excursion to the United States to visit the Pan-American Exhibition in Buffalo, and to attend at the same place the convention in August of the American Society of Electrical Engineers. The party will leave Paris Aug. 3, arrive at New York Aug. 11, and leave for Philadelphia the same day. Aug. 13 will be spent in Washington, and the party will remain in New York from the 14 to the 18. The program from the 18 to the 26 coincides with that of the American Institute of Electrical Engineers. From Buffalo the party will go to Chicago, and from that city by way of the Lakes and the St. Lawrence River to Montreal and Quebec, returning to New York on Sept. 3, and sailing from the latter city Sept. 5.

CONCERNING the influence of chemical trans-

formation on weight, Lord Rayleigh writes to *Nature* as follows: Careful experiments by Heydweiller, published in the last number of *Drude's Annalen* (Vol. V., p. 394), lead their author to the conclusion that in certain cases chemical action is accompanied by a minute, but real, alteration of weight. The chemical actions here involved must be regarded as very mild ones, *e. g.*, the mere dissolution of cupric sulphate in water, or the substitution of iron for copper in that salt. The evidence for the reality of these changes, which amount to 0.2 or 0.3 mg., and are accordingly well within the powers of a good balance to demonstrate, will need careful scrutiny; but it may not be premature to consider what is involved in the acceptance of it. The first question which arises is: Does the *mass* change as well as the *weight*? The affirmative answer, although perhaps not absolutely inconsistent with any well-ascertained fact, will certainly be admitted with reluctance. The alternative—that mass and weight are not always in proportion—involves the conclusion, in contradiction to Newton, that the length of the seconds' pendulum at a given place depends upon the material of which the bob is composed. Newton's experiment was repeated by Bessel, who tried a number of metals, including gold, silver, lead, iron, zinc, as well as marble and quartz, and whose conclusion was that the length of the seconds' pendulum formed of these materials did not vary by one part in 60,000. At the present day it might be possible to improve even upon Bessel, or at any rate to include more diverse substances in the comparisons; but in any case the accuracy obtainable would fall much short of that realized in weighings. As regards Heydweiller's experiments themselves, there is one suggestion which I may make as to a possible source of error. Is the chemical action sufficiently in abeyance at the time of the first weighing? If there is copper sulphate in one branch of an inverted U and water in the other, the equilibrium can hardly be complete. The water all the time tends to distil over into the salt, and any such distillation must be attended by thermal effects which would interfere with the accuracy of the weighing.

UNIVERSITY AND EDUCATIONAL NEWS.

AFTER a long discussion of the report of the committee on 'A National University,' published above, the national council of education passed on July 9 the following resolution :

Resolved, That the report of the committee be received and the committee discharged ; and that while we express our appreciation of their labors we are not prepared to abandon the position taken by the National Educational Association in favor of a National University.

AT the Johns Hopkins University the following promotions have been made :

Henry F. Reid, Ph.D., now associate professor, to be professor of geological physics.

William J. A. Bliss, Ph.D., now associate, to be collegiate professor of physics.

Duncan S. Johnson, Ph.D., now associate, to be associate professor of botany.

Oliver L. Fassig, Ph.D., now instructor, to be associate in meteorology.

Charles R. Bardeen, M.D., now associate, to be associate professor of anatomy.

Thomas B. Fletcher, M.B., now associate, to be associate professor of medicine.

Walter Jones, Ph.D., now associate, to be associate professor of physiological chemistry.

Robert L. Randolph, M.D., now associate, to be associate professor of ophthalmology and otology.

Stewart Paton, M.D., now assistant in neurology, to be associate in psychiatry.

Percy M. Dawson, M.D., now instructor, to be associate in physiology.

Engene L. Opie, M.D., now instructor, to be associate in pathology.

Frank R. Smith, M.D., now instructor, to be associate in medicine.

Henry B. Jacobs, M.D., now instructor, to be associate in medicine.

Thomas McCrae, M.B., now instructor, to be associate in medicine.

Frank W. Lynch, M.D., now assistant, to be associate in obstetrics.

AT Washington University, St. Louis, Mr. Alexander S. Chessin, formerly associate professor of mathematics in the Johns Hopkins University, has been appointed professor of mathematics to succeed Professor Edmund A. Engler, now president of Worcester Polytechnic Institute. Alexander S. Langsdorf, graduate of Washington University, was appointed assistant professor of electrical engineering. It is announced that before the beginning of next

term, a professor of zoology and a professor of philosophy will be appointed.

JOSEPH MARSHALL FLINT, Ph.D. (Johns Hopkins), instructor in the University of Chicago, has been appointed to the newly established chair of anatomy in the University of California.

C. W. MARX, professor of mechanical engineering in the University of Missouri, has accepted the professorship of engineering in the University of Cincinnati.

DR. FREDERIC E. CLEMENTS, of the University of Nebraska, has been promoted from an instructorship to the adjunct professorship of botany. Dr. Clements is conducting a summer school of ecological botany in the Pike's Peak region in the Rocky Mountains of Colorado. About twenty students are registered for the work.

JOHN JAMES THORNER, B.Sc., 1897, and M.A., 1901, of the University of Nebraska, for several years teacher of science in the High School of Nebraska City, Nebr., and special botanical collector for the University of Nebraska for the present season, has been elected to the professorship of botany in the University of Arizona. He will assume his new duties on August 1, after which his address will be Tucson, Arizona.

MISS MINNIE A. STONER, dean of the Woman's Department and professor of domestic science in the Kansas State Agricultural College, has been elected professor of domestic science in the Ohio State University.

THE place left vacant in the State Normal School at Charleston, Ill., by the resignation of Dr. J. Paul Goode to accept the position of instructor of geography in the University of Pennsylvania, has been given to Mr. G. D. Hubbard, graduate of the University of Illinois and M.A., Harvard.

MR. W. V. B. VAN DYCK has resigned an instructorship in electrical science in Rutgers College, to engage in industrial work.

SIR MARTIN CONWAY, known to scientific men for his explorations in the Himalayas, in Spitzbergen and in the Andes, has been made professor of fine arts in Cambridge University.

JOSEPH LE CONTE, the most honored and beloved of American men of science, professor of geology and natural history in the University of California, the author of important contributions to geology, natural history, psychology and education, president in 1892 of the American Association for the Advancement of Science, president in 1896 of the Geological Society of America, one of the editors of this Journal, died in the Yosemite Valley, on July 6, at the age of eighty-eight years.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE : S. NEWCOMB, Mathematics ; R. S. WOODWARD, Mechanics ; E. C. PICKERING, Astronomy ; T. C. MENDENHALL, Physics ; R. H. THURSTON, Engineering ; IRA REMSEN, Chemistry ; CHARLES D. WALCOTT, Geology ; W. M. DAVIS, Physiography ; HENRY F. OSBORN, Paleontology ; W. K. BROOKS, C. HART MERRIAM, Zoology ; S. H. SCUDDER, Entomology ; C. E. BESSEY, N. L. BRITTON, Botany ; C. S. MINOT, Embryology, Histology ; H. P. BOWDITCH, Physiology ; J. S. BILLINGS, Hygiene ; WILLIAM H. WELCH, Pathology ; J. MCKEEN CATTELL, Psychology ; J. W. POWELL, Anthropology.

A CENTURY OF CIVIL ENGINEERING.*

THE century which has just passed, the nineteenth of the Christian era, is distinguished from any of the preceding hundred-year periods in the world's history by the advances made in the cooperation of investigators in numerous branches of science in the formulation of doctrines regarding the nature and coordination of natural phenomena, which stand the test of experiment and calculation, thus leading to a nearer approximation to the understanding of the laws which govern such phenomena, and so to the development into a profession of the 'Art of directing the great sources of power in Nature for the use and convenience of Man,' which Art is entitled Civil Engineering. This definition is itself one of the most noteworthy products of the Nineteenth Century, and a study of the sequence of events and reasoning which led to its formulation is not without interest.

Ever since man became endowed with consciousness and the power of reasoning, he has been striving to solve the problems of the physical world around him in which he perceived matter in motion, which was evidenced to his senses by sight and touch, by sound and taste and smell, but which was devoid of sentience, so far as he could

* President's address before the American Society of Civil Engineers at the Annual Convention at Niagara Falls, N. Y., June 25, 1901. *Transactions Am. Soc. C. E.*, XLV., 599.

discover. He observed at once that by its different manifestations his physical comfort was materially affected, and it did not take long for him to learn that certain sequences of sensation, of one sort or another, followed certain manifestations occurring singly or in combination, and then that the order of many such manifestations could be controlled by him at will, while that of multitudes of others could not be so controlled at first, their methods and causes not being appreciable by his unassisted senses.

But until about three hundred years ago there does not seem to have been any systematic and well-directed effort to investigate the reasons why material changes occurred naturally, or how certain changes could be artificially produced with certainty.

To discover the sequence of natural events is first of all an empirical task: facts must be observed systematically, and recorded, and then their combinations reasoned upon. Hypotheses can then be formed as to the probable effects of slightly different collocations and sequences of events, and these subjected to experiment and computation. An hypothesis cannot be established as a scientific fact until it has been verified by observation and also proved to be in accordance with mathematical laws. Tennyson's apothegm, that 'knowledge comes, but wisdom lingers,' is profoundly true.

Now, up to the beginning of the seventeenth century of the Christian era, there had been no organized physical experimentation, on a comprehensive scale, and intelligent reasoning therefrom. The speculations as to the laws of nature which had been made from time to time had been purely efforts of the imagination, and were unsustained by either practical demonstration or analytical reasoning. Various hypotheses had been framed, on insufficient or incorrect premises, and some of them had been so near the truth as actually to delay

the progress of the truth, by the appearance of exactness in the reasoning from them, up to a certain point.

Really, the civil engineer had been practicing his art and directing the forces of nature for the use and convenience of man, but without any conception of what those forces were, or how they acted, or of why he did anything, or what the result of it would be, unless he had done the same thing before in the same way. He did not know that the earth moved, and he had no idea why or at what rate a stone fell to the earth, or water ran down hill. He had no measure of heat or light, and used no power but that which the muscles of an animal produced. And yet he had built the Pyramids, the Parthenon and the Pantheon; had constructed aqueducts, canals and sewers; had regulated and maintained the rivers of China for thousands of years; and had just been recognized, on account of his labors in protecting the lowlands of Holland and the shores of Italian rivers from the encroachments of the water, as holding a distinct rank among the workers of the world.

Of the application of the forces of nature to aiding his labors, he seems to have been ignorant, except by the use of a flowing stream to turn a wheel. The earliest recorded application of this mode of producing power in England was in 1582, when Peter Moryss, a Hollander, procured from the City of London a franchise for five hundred years for supplying water to the city by pumping from the Thames, using a wheel driven by the ebb and flow of the tide under London Bridge.

With the beginning of the seventeenth century, the world entered on a new era of science, theoretical and applied. The casual observation by a little child of the curious optical effect obtained by looking through two pieces of glass led to the invention of the telescope and the microscope, which

disclosed to man objects beyond the reach of his unassisted vision. The swinging of a hanging lamp suggested to a thoughtful man the idea of an unseen force, and Galileo, by experiment and reasoning, discovered the law of terrestrial gravitation and first grasped the idea of force as a mechanical agent.

Turning his newly invented telescope upon the heavens, he was the first man in the world to witness the actual motion of the planets and their satellites, and to prove that they and the earth revolved about the sun, as Pythagoras had imagined two thousand years before, Copernicus had asserted a hundred years before, and his own contemporary, Kepler, had reasoned from the imperfect data then possessed, and had actually formulated the laws of their motion in forms which the science of our day confirms exactly. He was the first to conceive the theory of transverse strains in solids, but the facility of experimentation with fluids diverted his attention from more rigid bodies, and the fundamental principles of hydraulic science were established by him and by his pupils and immediate successors in the fascinating studies he had introduced.

To Galileo also is due the invention of the thermometer, which enabled definite measurement to be made of the mysterious phenomenon of heat which his great contemporary philosopher in England, Lord Bacon, conceived to be 'an expansive undulatory motion in the particles of a body whereby they tend with some rapidity toward the circumference, and also a little upward.' But Bacon was two hundred years in advance of the physicists, and the century was occupied almost exclusively in the elucidation of the laws of gravitation as exemplified in the action of fluids. For the study of liquids and their action demonstrated that they were, under certain conditions of temperature, transformed into

invisible and elastic substances governed in general by the same laws, and also that there were all around other similar substances which could not be condensed into liquid inelastic form, but could be weighed by the barometer which Torricelli invented in 1643. And so the laws of gases came to be investigated and formulated by Mariotte, who, to aid him in his researches, invented the rain gauge in 1677, and measured the liquids condensed from the atmosphere. The value of the data thus obtained, to the hydraulic engineer, was appreciated by the French engineers at once, and ever since 1681 records of the rainfall have been kept continuously at Paris, and the practice has gradually extended over the whole world. But it is worthy of note that fifty years after the invention of the rain gauge, Belidor, in his magnificent treatise on Hydraulic Architecture (1728), the first compendium of engineering theory and practice, in treating of the sources of water supply for domestic use, did not mention the rain gauge or the amount of rainfall, but dwelt on the divining rod as the recognized means of discovering subterranean streams of water.

The close of this century saw the final establishment of the law of gravitation by Newton's proof of its governing the whole material universe. And any review of the progress made during the century toward the understanding of the laws of nature would be incomplete without allusion to the two great steps taken in it toward the facilitating of mathematical computations, the invention of logarithms at the beginning of the century and of the calculus at its close.

That heat produced dynamic effects had been recognized for ages. That it destroyed some solids, that it converted others into different forms possessing entirely different properties, that it caused the dissipation and disappearance of liquids, were facts

well established. That by its application to certain combinations of materials an explosive effect could be produced which overcame the force of gravity had been discovered three or four hundred years before when gunpowder was invented, but that a mechanical effect could be produced by the use of heat was not understood, and the nature of the phenomenon itself was not comprehended. It was looked upon by physicists as an 'element' or primary form of matter, and in 1690 Stahl conceived the idea of 'phlogiston,' an elementary substance, invisible and inappreciable by the senses, which entered into the composition of combustible substances, and which, by the process of combustion, was separated from them and passed off in the form of corpuscles which, striking the sensory nerves, were perceived as heat. Sir Isaac Newton espoused this phlogiston hypothesis and also conceived that light was the product of certain corpuscles which were perceived by the optical nerves. The discussion of these hypotheses occupied the attention of the philosophers for the whole of the eighteenth century, and, in the meantime, the physicists were busy experimenting on the methods of utilizing the vapor into which heat converted water. By degrees, the steam engine was developed into a practical machine, capable of doing work which before could only be accomplished by animal labor, and the engineer availed himself of it in the handling of materials. But although the chemists had been striving for centuries to learn the composition of matter and the means of transforming and combining its several natural conditions, they had not, at the beginning of the nineteenth century, learned how to produce either heat or light, except by the aboriginal method of striking flint and steel together. In the lack of knowledge of the properties of these phenomena and the fact that they could be utilized on a large scale, there was

no occasion for the devotion of any special class of men to their production and development. There were two other classes of phenomena which seemed as if they ought to be controlled by man, but the laws of which had so far eluded discovery—electricity and magnetism. So that, really, all that the civil engineer had to deal with was the force of gravity acting on such materials as the earth yielded him, in their natural state or as they could be modified by heat and manual labor.

But he had been making progress. In Italy, where the first application of science to construction had been made, the study of the laws of hydraulic science had been constantly pursued, and those laws applied to the regulation of the rivers; in France, ever ready to grasp new ideas and to pursue their application to practical results, the principles of hydraulics had been studied and applied to the construction of great canals, and to the supply of water to Paris, where, in 1671, water was pumped by a water wheel driven by the current of the Seine and distributed through cast-iron pipes. In England, Hugh Myddelton had supplied London with water, and, in 1638, Nicholas Vermuyden had been called in from Holland to protect the lands along the River Ouse from overflow, a task so well accomplished that his work stood for a hundred years, and only failed then from lack of proper maintenance, the English having by that time apparently concluded that, as Dr. Franklin wrote in 1772, 'rivers were unmanageable things,' and, inspired by the success of the public waterways of France, turned their attention to the construction of canals and the improvement of harbors. Many important works of this class were built in England during the last half of the eighteenth century. The men by whom these works were constructed were not educated men or men experienced in scientific research. They certainly were

men of great natural ability and good judgment, and capable of conceiving and executing great projects. One of the greatest of them, John Smeaton, who was the first Englishman to call himself a civil engineer, thus expressed his conception of the profession which he adorned :

“ Civil engineers are a self-created set of men whose profession owes its origin not to power or influence, but to the best of all protection, the encouragement of a great and powerful nation, a nation become so from the industry and steadiness of its manufacturing workmen and their superior knowledge in practical chemistry, mechanics, natural philosophy and other useful accomplishments.”

Smeaton was himself an investigator, but he is the only one of the civil engineers of Great Britain during the eighteenth century who strove to discover the laws which governed the operations of Nature.

The most eminent civil engineer in England in the year 1800 was Thomas Telford, who was born in 1757. Beginning life as a mason, he developed an extraordinary faculty of generalization, combined with an intimate acquaintance with the details of workmanship in all the methods of construction known in those days. In the building of canals, highways, harbors, bridges and docks he displayed great grasp of the subject of the improvement of transportation facilities, as then existing, and great boldness of design and ingenuity in construction.

But it must be borne in mind that at that time the canal was considered the only possible mode of increasing facilities of transportation and reducing cost, no motive power except animal force was known, the metals were but little used in construction, and a framed structure adapted to bear heavy loads was unknown. As ‘an eminent mathematician,’ quoted in the *Edinburgh Review* in 1805, remarked :

“ While we give ourselves infinite trouble to pursue investigations relating to the motions and masses of bodies which move at immeasurable distances from

our planet, we have never thought of determining the forces necessary to prevent the roofs of our houses from falling on our heads.”

It is related of Telford that when on one occasion he was consulted by a young man as to the advisability of his engaging in civil engineering, he said to him : “ I have made all the canals and all the roads and all the harbors. I don’t see what there is that you can expect to do.”

His ideas regarding the training of the civil engineer are given at some length in his Personal Memoirs prepared shortly before his death.

“ Youths of respectability and competent education who contemplate Civil Engineering as a profession, are seldom aware how far they ought to descend in order to found the basis for future elevation. Not only are the natural senses of seeing and feeling requisite in the examination of materials, but also the practiced eye, and the hand which has experience of the kind and qualities of stone, of lime, of iron, of timber, and even of earth, and of the effects of human ingenuity in applying and combining all these substances, is necessary for arriving at mastery in the profession. For how can a man give judicious directions unless he possesses personal knowledge of the details requisite to effect his ultimate purpose in the best and cheapest manner ?

“ It has happened to me more than once, when taking opportunities of being useful to a young man of merit, that I have experienced opposition in taking him from his books and his drawings and placing a mallet, chisel or trowel in his hand, till rendered confident by the solid knowledge which experience only can bestow, he was qualified to insist on the due performance of workmanship and to judge of merit in the lower as well as the higher departments of a profession in which no kind or degree of practical knowledge is superfluous.”

This is doubtless good, sound doctrine, but it does not betoken any very lofty conception of the aims and ends of the profession. But during the first quarter of the nineteenth century Telford stood at the head of the profession of civil engineering, and when, in 1820, the recently formed association of its practitioners for mutual advancement in science, which was termed the Institution of Civil Engineers, desired

a prominent leader, he was chosen its president, and held that office until his death in 1834. He does not appear to have contributed to the Institution any papers or discussions on engineering subjects.

Among the members of the Institution at that time was a man thirty years the junior of the president, who, like him, had risen from humble origin, and by his own exertions attained a high rank in the profession, and who, rather oddly, had the same forename, and a surname of two syllables, the initial and final letters of which and the vowel sounds of which were the same as Telford's. This similarity of name has led to some confusion and sometimes to the attributing to one of these men the sayings and doings of the other.

Thomas Tredgold, born in 1788, began life as a carpenter, but soon devoted himself to the study of engineering science and its practice in the office of the Chief Engineer of the Ordnance Bureau. He early recognized the deficiency of the knowledge then existing as to the nature and strength of the materials used in construction, and he studied, experimented and reasoned systematically, and published the results of his labors. His 'Treatise on Carpentry,' in 1820, was the first published attempt to determine scientifically and practically the data of resistance of beams to transverse flexure. During the next seven years he contributed to the *Transactions* of the Institution of Civil Engineers papers showing the mode of application of science to engineering problems, and he also published treatises on Warming and Ventilation, on Steam Navigation, on Railroads and Carriages, and on the Steam Engine. It was to him that the Institution turned when it wished to apply for a royal charter, in 1828, and requested him to prepare a definition of civil engineering.

As we look back upon the history of science, theoretical and applied, during the

first quarter of the nineteenth century, we can see how a new definition of the profession of civil engineering was needed at that date.

At the very beginning of the century there had occurred a marvelous revolution in the conception of the nature and operation of the laws governing matter and its motion. Lavoisier had revolutionized chemical science and Dalton had propounded a theory of atomic constitution of matter which has been sustained by observation and reason. All matter is composed of a few primal elements in an atomic or minutely subdivided form. These atoms have varying chemical affinity for each other, and, combining in certain proportions, form molecules of matter of various kinds. The study of these combinations has been the business of chemists for the last hundred years, and the laws of combination have been so successfully elucidated that many forms of matter which before were found only in a state of nature can now be artificially produced, and many other forms have been produced which are never found in nature and which are useful for purposes and under conditions where no natural product can be used to advantage. The impetus given to chemical research by the formulation of Dalton's theory was sufficient to establish the fact, early in the century, that chemical affinity was a source of power which could be directed by man intelligently and with prospect of advantage.

Just with the incoming of the century, too, came Rumford's demonstration of the fact that heat was not a material substance, but only a mode of motion. Almost simultaneously was propounded the theory of Thomas Young, that light, too, was not material, but was simply due to vibratory motion in an all-pervading medium to which he gave the name of the luminiferous ether.

It was in 1800, too, that Volta demon-

strated that an electric current could be artificially produced. How it could be controlled and applied to practical use did not yet appear, but a new direction had been given to the minds of those engaged in physical research.

As it became manifest that chemical affinity and heat and light could be controlled and directed and converted into Energy, as Young termed it, the men who had been trained in utilizing the force of gravity turned their attention to the development of these newly understood sources of power. Fitch and Fulton, with the aim of reducing the cost of water transportation, succeeded in applying the steam engine to the propulsion of boats, and Trevithick made successful application of steam propulsion to vehicles on land. Murdock had proved that illuminating gas could be produced and distributed to consumers. The civil engineers of the day had seized on all these inventions and discoveries, and in both Europe and America were designing and constructing works to render them useful to the greatest number of people.

Reviewing then what had been accomplished during the first quarter of the century, Tredgold could not but perceive that civil engineering was something broader and more comprehensive than the mere construction of harbors, breakwaters and canals, and he presented on January 4, 1828, in response to the request of the Institution, this ever-memorable definition of civil engineering :

" Civil Engineering is the art of directing the great sources of power in Nature for the use and convenience of man ; being that practical application of the most important principles of natural philosophy which has, in a considerable degree, realized the anticipations of Bacon, and changed the aspect and state of affairs in the whole world."

After a brief sketch of the objects of civil engineering, he added :

" The real extent to which it may be applied is

limited only by the progress of science ; its scope and utility will be increased with every discovery in philosophy, and its resources with every invention in mechanical or chemical art, since its bounds are unlimited, and equally so must be the researches of its professors."*

A more concise and comprehensive definition of a great truth can hardly be conceived. From a physical and intellectual standpoint, a nobler aim for the exercise of the mental powers cannot be imagined than the direction of the great sources of power in nature for the use and convenience of man. Psychology deals with mind alone, Physics considers the nature and the laws of matter, but Civil Engineering treats of the intelligent direction of the laws governing matter so as to produce effects which will reduce to a minimum the time and physical labor required to supply all the demands of the body of man and leave more opportunity for the exercise of the mental and spiritual faculties. Philosophy, Physics and Civil Engineering must work hand in hand. The philosopher must imagine, the physicist prove by experiment and mathematical computation, and the engineer apply to practice, the laws of matter. Each must keep himself informed of the progress made by the others and must aid them by suggestions as to the lines on which research needs to be carried forward. The civil engineer, in attempting to solve some problem of construction, finds that he needs a material which shall possess a certain quality which he cannot discover that any natural product possesses. He calls the chemist to his aid, and he, from a study of the combinations of existing forms of matter which most nearly approach the desired ideal, reasons that some special combination of elements will entirely fulfill the conditions, and he experiments to find whether such combination can be made. Sometimes he is successful in his first attempt and some-

* *Minutes of Proceedings*, Institution of Civil Engineers, Vol. XXVII., p. 181.

times not. But, whatever the result, he has added to his knowledge of the laws of combinations and has furnished to the philosopher fresh data for his generalizations, and to the engineer a new material for his use.

It not infrequently occurs that, from investigations made for a specific purpose, results are obtained of the greatest usefulness for an entirely different purpose. Thus, in 1855, when Henry Bessemer, inspired solely by that desire 'to kill something' which is alike the ruling passion of the rudest savage and the most highly civilized man, bent all his energies to the production of a metallic combination which should be able to resist the force of the highest explosive and so enable a cannon ball to be projected from a gun to a greater distance than ever before, he discovered a method of expelling all foreign substances from iron and then adding a minute quantity of another element, carbon, in such proportions that the original mass was materially changed in character and made more ductile, stronger and stiffer. The product was exactly what the railroad engineer wanted at that time for the bearing surface of his roadway, and the material which had been sought for destructive purposes became a most important factor in facilitating the transportation of men and goods with certainty and safety at high speeds.

As the knowledge of the nature of steel and the precise methods in which it can be manufactured have progressed, the engineer has gradually come to know just what he wants and how it can be produced, and, in his specifications, requires that the particular material of this class which he desires shall be of a certain chemical composition and also possess certain characteristics. The same is the case with almost every material which enters into the construction of engineering works of the present day. Matter in its original state is rarely used.

Its chemical condition must be transformed before the engineer can utilize it with any confidence. That almost any desired transformation can be effected was not realized until late in the century. Starting with the atom, the ultimate particle of matter so far comprehended by us, the chemist found that several different kinds of atoms could be identified, and that these would combine in certain ways according to laws which could be formulated. But in the application of these laws and the tabulation of the results gaps were found to exist which could not be filled without the supposition that other elements existed than those already known. The existence of such elemental substances was confirmed by the revelations of the spectrum analysis, and, later on, several of such elements have been actually identified by the use of the electric current in creating vibrations in the ether. The limit is probably not reached yet, but as each new element is discovered its affinities are sought by the chemist, its sensibility to various forms of vibratory motion are investigated by the dynamist, as we may term the physicist who is seeking the laws of either heat or light or electricity, and then it is the function of the civil engineer to study how it can best be applied to the use and convenience of man. For, ever since the beginning of the nineteenth century, the evidence has been cumulative that matter in motion accounts for all physical phenomena, that motion produces energy, that energy is never wasted, but is simply transformed, and that it manifests itself to the senses of man in various modes which are appreciable by the several organs of sense.

What our senses recognize as chemical affinity, heat, light and electricity, are simply conditions of matter induced by vibrations or quivers or waves or strains, whatever we may call them, of different kinds and at different velocities. Neither matter

nor motion can be originated by man, but, by a careful study of the sequence of events, control can be acquired of their modes of interaction, and natural phenomena can be artificially reproduced and other phenomena be produced. The intelligent application and direction of such means of control is the function of the civil engineer.

With the advance of science, the scope of civil engineering widened and advanced. The study of the action of forces induced analytical investigation of the means by which forces could be resisted and the best results obtained from proper distribution and arrangement of materials of different kinds. Steamships and locomotive engines were constructed by which the products of the earth and the manufactures of man, by machines and methods not before conceived, could be transported across the seas and overland by artificial highways and across bridges of previously unimagined span; and light and heat and electricity and water could be delivered in the apartment of every person to be used at will.

It was in the carrying out of the delivery of pure and wholesome water and the removal of its unused surplus that the civil engineer first was called on to deal with organic life. That minute organisms affected the comfort and the health of man had been recognized for hundreds of years. In the middle of the seventeenth century Leeuwenhoek, a Dutch maker of microscopes, discovered and described bacteria, and Nicholas Andry, a pathologist, ascribed to them the causation of disease. But later scientists discarded the idea, and it was not until 1831 that any real advances were made in the study of these microorganisms, and it is only within the last twelve years that it has become thoroughly recognized that the regulation of the growth of living organisms in air and water and sewage is necessary and practicable, and comes within the domain of civil engineering.

Indirectly, however, biological research has been one of the most important factors in the progress of engineering science, by calling the attention of students of physics to the fact that advance and not retrogression is one of the fundamental laws of nature. For the first half of the century, the old ideas of cosmogony, based on an hypothesis unsupported by proof, were prevalent everywhere. It was assumed that the world, in all its details, had been created perfect and had since been simply deteriorating and tending to a final dissolution. 'Change and decay, in all around I see,' was the dogma of the theologian, the philosopher and the scientist alike. While it had come to be recognized that the forms of inorganic matter could be changed by man, and that by the exercise of man's intelligence, certain characteristics of organic matter and the vital forces with which it was imbued could be modified and perpetuated, it was not considered possible that the superior intelligence which controlled everything could modify or transform such characteristics in any special form of matter.

But in 1859, Charles Darwin, after twenty years of study of the sequence of events in biological phenomena, demonstrated that there was an intelligence beyond that of man, which was constantly acting to change and modify the forms, the habits and the mode of life of animals and plants, and that such action resulted in the perpetuation of the fittest type of organism. The proof was irrefragable, and the effect of his wonderfully clear exposition of the processes by which his conclusions had been reached was marvelous in inducing a co-ordination of thought and a cooperation in methods of procedure in intelligent research in the investigation of all natural phenomena, whether relating to organic or inorganic matter.

In considering the means of directing the great sources of power, the psychological

element must not be forgotten. A mere intellectual application of the laws discovered by physical research is not enough to make a civil engineer. Breadth of view, the faculty of analyzing what has been done so as to discover how and why some enterprises have been successful and others have not, and the ability to forecast the future, are essential. These qualities are largely natural, but may be cultivated to a great extent by study and experience. That there has been a wonderful advance in this direction during the nineteenth century is shown by the great number of civil engineers who hold positions of prominence in the management and control of large enterprises which require the exercise of faculties which cannot be acquired in any other way than by experience in the designing, construction and management of engineering works.

A prominent factor in causing this advance in engineering science which has occurred simultaneously on the Continent of Europe, in Great Britain and in America, has been the collaboration of scientists. Early in the century it became evident that the multiplication of lines of research demanded a differentiation of the labor of their prosecution and a close cooperation of the workers in any special line, and various associations of specialists were formed to promote various branches of scientific research. By the middle of the century it had become apparent that civil engineering was not the prosecution of a specialty, but was the coordination and direction of the work of all specialties in science and its applications. And so in 1852, James Laurie and his associates, following the example of their English brethren, founded the American Society of Civil Engineers, the first and only national organization devoted to 'the professional improvement of its members, the encouragement of social inter-

course among men of practical science, the advancement of engineering in its several branches and the establishment of a central point of reference and union for its members.' To the privileges of its membership may be admitted not only every 'professional engineer,' but also 'any person who, by scientific acquirements or practical experience, has attained a position in his special pursuit qualifying him to cooperate with engineers in the advancement of professional knowledge and practice.' This meeting of that Society, which now has 2,500 names upon its rolls of membership, and owns a commodious society house with a reference library of some 40,000 titles, is sufficient proof of the wisdom of its founders.

Recognizing, then, that progress is a law of nature, the acceleration of progress is the aim of civil engineering. It strives to stimulate the results of the slow processes of nature, by causing the sources of power to act rapidly in any desired direction. Appreciating, too, the fact that there is constant progress, and that what now seems admirably adapted to our needs may in a short time require to be superseded by improved structures and processes, the tendency of the time is toward the production of works which will have a definite term of life, rather than toward the construction of everlasting monuments. We see that in the old nations, where the effort to build for eternity was made, time has outstripped the intent of the builders and what is antiquated is useless, and we see the same thing in our own streets to-day. The idea of building a monumental structure which will hand one's name down to future ages is a fascinating one, but it is simply a survival of the engineering of the Pharaohs.

The most thorough exemplar of the condition of civil engineering at the beginning of the twentieth century is the modern office-building in a great city. One hundred

years ago, the man of enterprise who resided fifty miles from a large city and wished to consult an engineer regarding a project for a new canal, arose before daylight, struck a spark from his flint and steel, which, falling on a scrap of tinder, was blown by him into flame and from that a tallow dip was lighted. In the same primitive manner the wood fire was kindled on the kitchen hearth and his breakfast was cooked in a pot and kettle suspended from the iron crane in the fireplace. Entering the cumbrous stage coach, hung on leather springs, which passed his door, he was driven over muddy roads, crossing the narrow streams on wooden trestle bridges and the navigable rivers on a ferry boat, the paddle wheels of which were turned by a mule on a treadmill. At last he was landed in the city, where he walked through dirty streets paved with cobble-stones until he reached his destination, a plain three-story brick building founded on sand, with a damp cellar and a cesspool in the back yard. Entering a dark hall, he climbed a wooden staircase and was ushered into a neat room, rag-carpeted, warmed by a wood fire on the open hearth and lighted by a sperm-oil lamp with one wick, for it was dark by this time. No wonder that before proceeding to business he was glad to take a good stiff noggin of New England rum.

To-day, his grandson, living at the old homestead, while comfortably eating his breakfast which has been cooked over a gas range, reads in his morning paper that the high dam of the irrigation reservoir in Arizona, in which he is interested, sprang a leak the day before, and he telegraphs to his engineer in the city that he will meet him at his office at noon. Then, striking a match, he lights the lamp of his automobile which is fed by petroleum brought 200 miles underground in pipes from the wells, rolls over macadamized roads to the railroad station, where he boards a luxuriously ap-

pointed train, by which he is carried above all highways, through tunnels, under rivers, or across them on long-span steel bridges, and in an hour is deposited in the heart of the city, where he has his choice of proceeding to his destination through clean and asphalt-paved streets in electric surface cars at 9 miles an hour, elevated steam cars at 12 miles an hour, or through well-lighted and ventilated tunnels at 15 miles an hour. Reaching the spot his grandfather had visited, he finds there a huge and highly decorated building, twenty or more stories high. Founded on the primeval rock, far below the surface of the natural ground, the superjacent strata of compressible material having been penetrated by caissons of sheet metal sunk by the use of air compressed by powerful pumps driven by steam or electricity generated at a power station half a mile or more away, and these caissons filled with a manufactured rock such as the ordinary processes of nature would require millions of years to produce, there is erected a cage of steel, the composition of which has been specified, and the form and mode of construction of which have been so computed that the force of the elements cannot overthrow the structure or even cause it to sway perceptibly. Towering above the courts of Law, the temples of Religion and the palaces of the Arts, the meshes of this mighty cage are filled with products of the earth, the mine and the forest, transformed so as to be strong and light and incombustible, and all interwoven with pipes and wires, each in its proper place and noted on the plans. In one set of these pipes there is pure water, which has been collected from a mountain area of igneous geological formation, depopulated and free from swamps, on which a record of the daily rainfall is kept, and in which impounding reservoirs have been constructed by masonry dams across its valleys. From these reservoirs the water,

after filtration through clean sand, is conveyed 30 or 40 miles through steel or masonry conduits to covered reservoirs, whence it is drawn as needed through cast-iron pipes to the building where it is to be used, and there distributed to all parts of it, chilled nearly to the freezing point through one system of pipes or heated nearly to the boiling point, through another system. Another set of pipes carries steam, which, passing through radiators, keeps the temperature of the air throughout the building at the proper standard for comfort. Sanitary conveniences are provided everywhere, and all wastes are consumed within the building by the surplus heat generated, leaving only ashes to be removed. Wires convey electric currents to all points, so that the occupant of a room, sitting at his desk, can by the touch of a button ventilate his apartment, illuminate it, call a messenger, be kept informed of every fluctuation in the markets, converse with anybody who is not 'busy' within 40 miles of where he sits, and if entirely 'up to date' can require his autograph and portrait to be reproduced before his eyes for identification. He dictates his correspondence and his memoranda, and 'takes his pen in hand' only to sign his name. He need not leave his seat except to consult the photograph hanging on his wall, which shows to him the latest condition of the mine, the railroad, the arid lands irrigated, the swamps reclaimed, the bridge in progress, the steamship, the water-works, the tunnel or the railroad, the dam, the filter or the sewage works, the town, the machine, the power plant or the manufacturing establishment in which he is most interested.

Entering the brilliantly lighted hallway of this building, the air of which is kept in circulation by the plunging up and down of half a dozen elevators, the visitor is lifted at a speed of 500 feet a minute, past floor after floor, crowded with the offices of finan-

ciars, managers and promoters of traffic and of trade, lawyers, chemists, contractors, manufacturers, to the headquarters of the controlling genius of the whole organism, the civil engineer. For he it is to whom all the members of this microcosm must apply for aid and advice in the successful operation of their respective occupations. It is not his to mechanically transform elements into matter, or matter into other forms, or to show how energy may be produced, but to direct the application of energy to the various forms of matter, original or produced, in such way as to bring about the most satisfactory results in the most speedy and economical manner.

He has grown with the growth of the nineteenth century, and is, so far as the relations between man and matter are concerned, its most striking product. And so, while the definition given in the 'American Edition of the Encyclopedia,' which appeared at the beginning of the century, that "civil engineers are a denomination which comprises an order or profession of persons highly respectable for their talents and scientific attainments and eminently useful under this appellation," is still true, it is hardly probable that the compiler of the Twentieth Century Encyclopedia will be content to let it stand without further explanation.

But the end is not yet; there are still many problems of nature unsolved. The experience of every day shows that there are sources of power not yet fully developed, and we cannot but say with the great poet:

"I doubt not through the ages one increasing purpose runs,
And the thoughts of men are widened with the
process of the suns." J. JAMES R. CROES.

*THE BRITISH NATIONAL ANTARCTIC
EXPEDITION.*

DR. GEORGE MURRAY, F.R.S., keeper of
the Department of Botany in the British

Museum, has been appointed director of the civilian staff of the British expedition, to fill the vacancy caused by the resignation of Professor J. W. Gregory. Dr. Murray will not, however, take part in the expedition, except in so far as he will proceed with the ship to Melbourne. He will edit the scientific results. A geologist is to be appointed to do the work in this direction that would have been carried on by Professor Gregory. The other members of the scientific staff are Dr. R. Koettlitz, Mr. Hodgson, Mr. E. A. Wilson, Mr. William Shackleton and Mr. R. Skelton. Full instructions to the commander and to the scientific director of the civilian scientific staff have been drawn up and are signed by Sir William Huggins, president of the Royal Society, and Sir Clements Markham, president of the Royal Geographical Society. They are as follows :

INSTRUCTIONS TO THE COMMANDER.

1. The Royal Society and the Royal Geographical Society, with the assistance of his Majesty's Government, have fitted out an expedition for scientific discovery and exploration in the Antarctic regions, and have entrusted you with the command.

2. The objects of the expedition are: (a) to determine, as far as possible, the nature, condition and extent of that portion of the South Polar lands which is included in the scope of your expedition ; and (b) to make a magnetic survey in the southern regions to the south of the 40th parallel, and to carry on meteorological, oceanographic, geological, biological and physical investigations and researches. Neither of these objects is to be sacrificed to the other.

3. The scientific work of the executive officers of the ship will be under your immediate control, and will include magnetic and meteorological observations, astronomical observations, surveying and charting, and sounding operations.

4. Associated with you, but under your command, there will be a civilian scientific staff, with a director at their head. A copy of his instructions accompanies these instructions to you.

5. In all questions connected with the scientific conduct of the expedition you will, as a matter of course, consider the director as your colleague, and on all these matters you will observe such consideration in respect to his wishes and suggestions as may be consistent with a due regard to the instructions under which you are acting, to the safe navigation of the ship, and to the comfort, health, discipline and efficiency of all under your command. Those friendly relations and unreserved communications should be maintained between you which will tend so materially to the success of an expedition from which so many important results are looked for.

6. As the scientific objects of the expedition are manifold, some of them will come under the immediate supervision of the director and his staff ; others will depend for their success on the joint cooperation of the naval and civil elements ; while some will demand the undivided attention of yourself and your officers. Upon the harmonious working and hearty cooperation of all must depend the result of the expedition as a whole.

7. The expedition will be supplied with a complete set of magnetic instruments, both for observations at sea and on shore. Instructions for their use have been drawn up by Captain Creak, R.N., and yourself and three of your officers have gone through a course of instruction at Deptford with Captain Creak and at Kew Observatory. The magnetic observatory on board the *Discovery* has been carefully constructed with a view to securing it from any proximity to steel or iron, and this has involved considerable expense and some sacrifice in other respects. We, therefore, impress upon

you that the greatest importance is attached to the series of magnetic observations to be taken under your superintendence, and we desire that you will spare no pains to ensure their accuracy and continuity. The base station for your magnetic work will be at Melbourne, or at Christchurch, in New Zealand. A secondary base station is to be established by you, if possible, in Victoria Land. You should endeavor to carry the magnetic survey from the Cape to your primary base station, south of the 40th parallel, and from the same station across the Pacific to the meridian of Greenwich. It is also desired that you should observe along the tracks of Ross, in order to ascertain the magnetic changes that have taken place in the interval between the two voyages.

8. Geographical discovery and scientific exploration by sea and land should be conducted in two quadrants of the four into which the Antarctic regions are divided for convenience of reference—namely, the Victoria and Ross Quadrants. It is desired that the extent of land should be ascertained by following the coast lines, that the depth and nature of the ice cap should be investigated, as well as the nature of the volcanic region, of the mountain ranges, and especially of any fossiliferous rocks.

9. A German expedition will start at the same time as the *Discovery*, and it is hoped that there will be cordial cooperation between the two expeditions as regards magnetic and meteorological observations, and in all other matters if opportunities offer for such cooperation. It is understood that the German expedition will establish an observatory on Kerguelen Island, and will then proceed to explore the Enderby Quadrant, probably shaping a course south between the 70° E. and 80° E. meridians, with the object of wintering on the western side of Victoria Land, whence exploring sledge parties will be sent inland. The

Government of the Argentine Republic has undertaken to establish a magnetic observatory on Staten Island.

10. You will see that the meteorological observations are regularly taken every two hours, and, also, in accordance with a suggestion from the Berlin committee, every day at Greenwich noon. It is very desirable that there should, if possible, be a series of meteorological observations to the south of the 74th parallel.

11. As regards magnetic work and meteorological observations generally, you will follow the program arranged between the German and British committees, with the terms of which you are acquainted.

12. Whenever it is possible, while at sea, deep-sea sounding should be taken with serial temperatures, and samples of sea water at various depths are to be obtained, for physical and chemical analysis. Dredging operations are to be carried on as frequently as possible, and all opportunities are to be taken for making biological and geological collections.

13. Instructions will be supplied for the various scientific observations; and the officers of the expedition will be furnished with a manual, prepared and edited by Dr. George Murray, on similar lines and with the same objects as the scientific manuals supplied to the Arctic expedition of 1875.

14. On leaving this country you are to proceed to Melbourne, or Lyttelton (Christchurch), New Zealand, touching at any port or ports on the way that you may consider it necessary or desirable to visit for supplies or repairs. Before leaving your base station you will fill up with live stock, coal, and other necessaries; and you will leave the port with three years' provisions on board, and fully supplied for wintering and for sledge travelling.

15. You are to proceed at once to the edge of the pack and to force your vessel through it to the open water to the south.

The pack is supposed to be closer in December than it has been found to be later in the season. But this is believed to depend rather on its position than on the time; and the great difference between a steamer and a sailing vessel perhaps makes up for any difference in the condition of the pack.

16. On reaching the south water you are at liberty to devote to exploration the earlier portion of the navigable season; but such exploration should, if possible, include an examination of the coast from Cape Johnson to Cape Crozier, with a view to finding a safe and suitable place for the operations of landing in the event of your deciding that the ship shall not winter in the ice.

The chief points of geographical interest are as follows:—To explore the Ice Barrier of Sir James Ross to its eastern extremity; to discover the land which was believed by Ross to flank the barrier to the eastward, or to ascertain that it does not exist; and generally to endeavor to solve the very important physical and geographical questions connected with this remarkable ice formation.

17. Owing to our very imperfect knowledge of the conditions which prevail in the Antarctic seas, we cannot pronounce definitely whether it will be necessary for the ship to make her way out of the ice before the winter sets in, or whether she should winter in the Antarctic regions. It is for you to decide on this important question after a careful examination of the local conditions.

18. If you should decide that the ship shall winter in the ice, the following instructions are to be observed:

a. Your efforts, as regards geographical exploration, should be directed, with the help of depots, to three objects—namely, an advance into the western mountains, an advance to the south, and the exploration of the volcanic region.

b. The director and his staff shall be allowed all facilities for the prosecution of their researches.

c. In carrying out *a* and *b* due regard is to be had to the safety and requirements of the expedition as a whole.

d. You have been provided by Sir Leopold McClintock and by Dr. Nansen with complete details respecting sledge work both by men and dogs, and you have yourself superintended every item of the preparations connected with food, clothing and equipment. You will be guided by the information and knowledge thus acquired.

e. Lieut. Armitage, R.N.R., who has been appointed second in command and navigator to the expedition, has had experience in the work of taking astronomical, magnetic and meteorological observations during three Polar winters. He has also acquired experience in sledge traveling and in the driving and management of dogs. You will, no doubt, find his knowledge and experience of great use.

f. Early in 1903 your ship should be free from the ice of the winter quarters, and you will devote to further exploration by sea so much of the navigable season as will certainly leave time for the ship to return to the north of the pack ice. Having recruited at your base station, you will then proceed with your magnetic survey across the Pacific and return to this country.

19. If, on the other hand, you should decide not to winter, you will bear in mind that it is most important to maintain scientific observations on land throughout the winter, and therefore if you are able, in consultation with the director, to find a suitable place for a landing party between Cape Johnson and Cape Crozier, and decide that such a party can be landed and left without undue risk, the following instructions will apply:

a. You will land a party under the command of such person as you may ap-

point. Such party shall include the director, the physicist, and one of the surgeons, and such other persons as you may consider desirable. But no person is to be left without his consent in writing, which you will be careful to obtain and preserve.

b. You will give every practicable assistance in establishing on land this party, which you will supply with all available requisites, including a dwelling hut, an observer's hut, three years' provisions, stores, fuel, sledges and dogs.

c. No landing party is to be established on any other part of the coast than that between Cape Johnson and Cape Crozier, as it is above all things essential that in case of accident the approximate position of the party should be known.

d. Before it is so late as to endanger the freedom of your ship, you will proceed north of the pack and carry out magnetic observations with sounding and dredging over as many degrees of longitude (and as far south) as possible, so long as the season and your coal permit, and then return to your base station, whence you will telegraph your arrival and await further instructions.

20. You are to do your best to let us have, and to leave where you can, statements of your intentions with regard to the places where you will deposit records, and the course you will adopt, as well as particulars of your arrangements for the possible need of retreat, so that in case of accident to the ship, or detention, we shall be able to use our best endeavors to carry out your wishes in this respect.

21. In an enterprise of this nature much must be left to the discretion and judgment of the commanding officer, and we fully confide in your combined energy and prudence for the successful issue of a voyage which will command the attention of all persons interested in navigation and science throughout the civilized world. At the

same time, we desire you constantly to bear in mind our anxiety for the health, comfort and safety of all entrusted to your care.

22. While employed on this service you are to take every opportunity of acquainting us with your progress and your requirements.

23. In the unfortunate event of any fatal accident happening to yourself or of your inability, from sickness or any other cause, to carry out these instructions, the command of the ship and of the expedition will devolve on Lieutenant Armitage, who is hereby directed to assume command and to execute such part of these instructions as have not been already carried out at the time of his assuming command. In the event of a similar accident to Lieutenant Armitage the command is to devolve on the executive officer next in seniority on the articles, and so on in succession.

24. All collections and all logs (except the official log), journals, charts, drawings, photographs, observations and scientific data will be the joint property of the two societies, to be disposed of as may be decided by them. Before the final return of the expedition you are to demand from the naval staff all such data, which are to be sealed up and delivered to the two presidents, or dealt with as they may direct. The director of the civilian scientific staff will be similarly responsible for the journals, collections, etc., of the officers under his control. You and the other members of the expedition will not be at liberty without our consent to make any communication to the press on matters relating to the affairs of the expedition, nor to publish independent narratives until six months after the issue of the official narrative. All communications are to be made to us, addressed to the care of the Secretary of the National Antarctic Expedition, London.

25. The *Discovery* is not one of his Maj-

esty's ships, but is registered under the Merchant Shipping Act, 1894, and is governed by it. Copies of this act will be supplied to you. You will see that the officers and crew sign the ship's articles as required by the act. The scientific staff will not sign articles, but are to be treated as cabin passengers. You must be careful not to take more than 12 persons as passengers.

26. The vessel has been covered by insurance, and, in the event of her sustaining any damage during the voyage, to recover the claim from the underwriters it will be necessary for you to call in the services of Lloyd's agent, or, in his absence, an independent surveyor, at the first port of call, in order that the damage may be surveyed before repairs are effected. His survey report, together with the accounts for repairs and supporting vouchers should be sent to us by first mail, together with a certified extract from the official log reporting the casualty.

In the event of damage occurring after you have left civilized regions precise particulars should be entered in the log, and the damage should be surveyed and repaired as soon as you return to a port where Lloyd's agent or other surveyor is available.

27. The *Discovery* is the first ship that has ever been built expressly for scientific purposes in these kingdoms. It is an honor to receive the command of her; but we are impressed with the difficulty of the enterprise which has been entrusted to you and with the serious character of your responsibilities. The expedition is an undertaking of national importance, and science cannot fail to benefit from the efforts of those engaged in it. You may rely upon our support on all occasions, and we feel assured that all on board the *Discovery* will do their utmost to further the objects of the expedition.

INSTRUCTIONS TO THE SCIENTIFIC DIRECTOR
OF THE CIVILIAN SCIENTIFIC STAFF.

1. The Royal Society and the Royal Geographical Society have approved your appointment as Director of the Civilian Scientific Staff of their Antarctic Expedition.

2. A copy of the instructions to the commander of the expedition accompanies these instructions, which are supplemental to them. You will see from the instructions to the commander what the objects of the expedition are, and your position relatively to them.

3. You will direct the scientific work of the gentlemen who have been appointed to assist you.

4. The names of the gentlemen associated with you are as follows:—(1) Mr. Hodgson (biologist); (2) Mr. Shackleton (physicist). The services of the two medical officers will be at your disposal for scientific work when not engaged on the work of their own department—namely, Dr. Koettlitz (botanist), and Dr. Wilson (zoologist).

5. You will note that the commander of the expedition has been instructed to communicate freely with you on all matters connected with the scientific objects of the expedition, and, as far as possible, to meet your views and wishes in connection with them. The societies feel assured that you will cooperate and act in concert with him, with a view, as far as possible, to secure the success of an enterprise which it is hoped will be attended with important results in the various branches of science which it is intended to investigate.

6. All collections, logs, journals, charts, drawings, photographs, observations and scientific data will be the joint property of the two societies, to be disposed of as may be decided by them. Before the final return of the expedition, you are to demand from the staff under your control all such data, which are to be sealed up and delivered to the two presidents, or dealt with as they

may direct. On the return of the expedition you will be expected to superintend the distribution of specimens to specialists approved of by the two councils or their representatives, and to edit the resulting reports. You will also be expected to contribute a report on the scientific results of the expedition for the official narrative. As it may be desirable during the progress of the voyage that some new scientific discovery should be at once made known in the interests of science, you will, in such a case, inform us of it by the earliest opportunity.

7. You and the other members of the expedition will not be at liberty, without our consent, to make any communication to the press on matters relating in any way to the affairs of the expedition, nor to publish independent narratives until six months after the issue of the official narrative. All communications are to be made to us, addressed to the care of the secretary of the National Antarctic Expedition, London.

8. Should any vacancies in the scientific staff occur after the expedition has sailed from England, you may, with the concurrence of the commander, make such arrangements as you think desirable to fill the same, should no one have been appointed from England.

9. You and the members of the scientific staff will be cabin passengers joining the expedition at your own risk, and neither the owners nor the captain are to be responsible for any accident or misfortune which may happen to you. You will obtain from each member a letter to this effect.

The instructions are signed by the Presidents of the Royal Society and the Royal Geographical Society.

TEACHING OF CHEMISTRY IN SCHOOLS—
1876, 1901.*

BEFORE comparing, or contrasting, the teaching of chemistry twenty-five years ago

* Read at the 25th anniversary of the American Chemical Society.

with that of to-day, it seems desirable to trace briefly the evolution of chemistry from a much earlier period. This will enable us to see at what part of the evolutionary line high-school chemistry had arrived when the American Chemical Society was founded, and where it now is.

In the alchemistic age the effort was to conceal, not reveal, facts. All the language is most obscure, and writers are pervaded with the idea that the wrath of God will rest upon them if they reveal the secrets of their laboratories. Basil Valentine says he fears he has spoken so plainly that he shall be doomed at the last great day; but the modern French writer Figuier facetiously remarks that all the adepts who have ever tried to decipher his language regard it as certain that he was one of the elect. There was no teaching, as there was no science. A little later, when an alchemist disclosed the philosopher's stone or the elixir it was to a few persons for large money considerations. If he made pretended transformations into gold in presence of spectators, the *methods* were kept secret.

With the advent of scientific chemistry, even among the phlogistics, secrecy became a lost art. Experiments began to be written about and talked of, but were not at first made in public. Books contained no illustrations. The question and answer method got into chemistry as in all other teaching. Jane Marcet's little book 'Conversations on Chemistry,' first published in London in 1806—which ran through 20 editions and was revised as late as 1855—set two generations to thinking of the marvelous revelations of nature. It consisted wholly of questions and answers, only the later editions being illustrated.

With the Lavoisierian chemistry—in fact, antedating it somewhat—came the demonstrative lecture method of teaching. As the professor—for this was a feature of colleges and medical schools only—performed his

experiments before the class, and called attention to the phenomena, which he explained either by phlogiston or according to the doctrine of Lavoisier, his hearers gained much. If there was still something of the alchemistic glamour, the subject could be studied afterwards in a suitable text-book. All in all, it was the most noteworthy advance in teaching that had taken place up to that time. As the question and answer method will never disappear from educational systems, so the best in the lecture method came to stay, and will always have its place. But it was far from being ideal, or final. During that period the man who could deliver the most faultless lecture was the best teacher.

But another step was to be taken, in which, in place of a passive observer, the student must prepare and set up his own apparatus, mix his chemicals, adapt the conditions, watch the phenomena and arrive at conclusions. This was a more radical revolution than even the lecture method, and it merits more than passing notice. Liebig is accredited as the inventor of the laboratory method as applied to chemistry. This method, transplanted in America by one of his pupils, Eben Horsford, who in 1848 was appointed professor of chemistry at the Lawrence Scientific School, Cambridge, Mass., gained a slow and struggling popularity. It was at the same institution and about the same time that Louis Agassiz began to employ the laboratory method in natural science. In 1850 Professor Cooke fitted up as a laboratory, mostly at his own expense, a basement room in University Hall at Harvard College, where a few selected students were admitted. There was no gas or running water. After seven years more, against great opposition, he succeeded in having laboratory work a requirement for Harvard students in chemistry. The first laboratory instruction in chemistry for *medical students* in this country

was in 1853 at the Harvard Medical School. It took another quarter of a century for the laboratory idea to permeate any but the larger colleges, and chemistry continued to be taught by the recitation method. One of the earliest, perhaps the first, secondary school to adopt the new idea was the Girls' High and Normal School of Boston, about 1865. It was followed by the Cambridge, Mass., High School in 1866, and the English High of Boston, in 1871. One of the early teachers says: "A chemical laboratory for pupils was a rarity; all foreigners and visitors to the city were brought to see it, and they opened their eyes in amazement at the strange sight." This was in 1870, and plans and photographs of this workshop for students were in demand from various parts of the United States.

But, generally speaking, the laboratory method, as regards high-schools, is a development of the past twenty-five years. A new era in chemistry teaching was dawning. It was greatly stimulated by the summer schools of science which sprang up in colleges all over the land. The first teachers' school of science was that of Louis Agassiz in natural history, held on the island of Penekese during the summer of 1869. In subsequent years this school, enlarged and broadened to include chemistry and other branches of learning, was held in Cambridge, Mass., the example of Harvard being followed by other institutions, and the laboratory idea was spread broadcast.

At first the workshop was usually put in the basement of the school building, and laboratory work was an extra subject, or voluntary exercise to be done after school hours by those sufficiently interested; hence very little was required. As the work grew and its value became apparent, note-taking was introduced. 'Observation' and 'conclusion' made up the notes, mostly mechanical, without much connection. After a time, this being found insufficient,

the teacher tried to put the student in the attitude of an investigator. He must describe the apparatus—which he has himself set up—the chemicals and how he has mixed them, the operations he has performed; must trace the phenomena and try to ascertain what the experiment shows, must test his products, and, so far as he is concerned, do real, original work. Finally he must write out in fairly good English all the above operations, observations and results. Later on, when he becomes somewhat familiar with the principles of the science, problems of a practical nature are given him to solve—to make given compounds, or to separate mixtures. This leads on to qualitative analysis, a brief course in which is quite generally taken now in the high-school, always following general chemistry and often put into a second-year course.

This accuracy of detail naturally led to two further developments: (1) A logical or scientific sequence of experiments. (2) Quantitative work—which is one of the latest phases of this method. In fact, quantitative work for beginners, who have not had thorough training in general, qualitative manipulations, is still a doubtful experiment—one which the colleges, technological and medical schools, are so far answering, for the most part, in the negative. Those in favor of the scheme in elementary work reason that it inculcates greater accuracy and skill in manipulation than mere qualitative work, gives the student an idea of research methods, and makes his work complete. The opponents claim that to a beginner the underlying facts and principles of science are of paramount importance, that the *qualitative* in evolution precedes the *quantitative*, and—since time is limited—research methods are better suited to such students as pursue the subject further. A well-known teacher writes: “The attempts to beat out methods theoret-

ically correct, the putting quantitative before qualitative and the ignoring of the great primal facts which lead easily into those parts of the subject which concern the great body of men and women, have a tendency to lessen the interest.”

The introduction of the laboratory method presented a new problem. When text-book work was the only feature, every chemistry hour was a reciting period. With the advent of the lecture table came a division of time between demonstration and recitation. The laboratory feature necessitated a further division, involving the question: How much time, relatively, ought to be given to laboratory, to lecture and to recitation? In the solution of this question there has been no unanimity, rather the greatest diversity, of result, each school with its peculiar environment making its own answer. In some instances the entire time is devoted to laboratory work, and in such cases the text-book is usually discarded. A new method always runs to extremes in individual cases. As a recent writer says: “Chemistry has suffered from the irresponsible wave of laboratory madness which has swept over the whole educational world. Laboratory work has been carried far beyond its limits, and things have been expected of it which it never did and never can do.” It seems safe to believe that the problem will finally resolve itself into a proper equating of the time ratio between text-book, lecture work and laboratory.

Another outgrowth of the last quarter is the conference, and reciprocal recitation—to coin an expression—in which the student becomes a questioner and the teacher recites and explains. The great value of this method—which may take up half or the whole of a recitation period—can be revealed only on trial. It shows what the teacher never knows before hand, *viz.*, the standpoint from which a pupil views a sub-

ject, and that, after all, is the case to be diagnosed. The opposite view that nothing should be told the student, but everything evolved, by a series of questions, from his brain—callow and ignorant of first principles though it be—is still advocated by a few in authority. It is the inductive method gone to seed.

Applied to chemistry teaching the inductive method, though in use earlier in some schools, was largely a growth of the decade beginning about 1885. The first text-books avowedly inductive began to appear. Like other good things, this Socratic, time-killing process was almost run into the ground by enthusiasts. Newth says: "In actual practice the *purely* inductive method of instruction breaks down. There is so much that the student is required to learn that life itself is not long enough, and certainly the limited time at the disposal of the student is all too short to admit of his going through the necessarily slow process of gaining this knowledge by his own investigation."

That part of induction which has the stamp of perpetuity consists in the teacher's quizzing the student while the latter is making an experiment. In this manner a world of thought and suggestiveness may be opened up to the imagination, and the method thus employed subserve a highly useful end.

In some schools the time allotted to chemistry is not more than it was 25 years ago, and certain laboratories blossomed into full maturity almost at the outset, but not so with the great majority. The chemical theory is taught more effectively now than then by the use of charts and blocks. Laws which cannot well be shown by experiment are illustrated by simple mechanical devices and diagrams, so that, instead of mere words, the pupil can get a clear mental picture of the given law. Many problems in practical chemistry are introduced and the bearing of equations, valence and stereo-

chemistry is studied as it was not 25 years ago. *Non multa, sed multum* is the watchword of the best teachers in chemistry, as in other branches. How much these improvements are due to the meetings and the *Journal of the American Chemical Society*, it is impossible to state. In the dissemination of chemical knowledge this magazine has been a great power. The history of important chemical discoveries, and something of biography are also taught in high-schools to-day. Instead of one text-book, students in the best schools have access to a large number of books and are encouraged to do outside reading in scientific periodicals.

What then have we found in high-schools as the result of our inquiry?

In 1876 a prevalent view that chemistry has little educational value.

In 1901 chemistry found in practically every high school curriculum.

In 1876 school committees very loath to expend anything for laboratories or equipment.

In 1901 the laboratory and lecture room among the first considerations in constructing a high-school building.

In 1876 practically no laboratories, the text-book recitation dominant, very few demonstrative lectures.

In 1901 chemical work mostly divided into lecture, laboratory and conference periods.

In 1876 no notes of work.

In 1901 notes containing description of apparatus, manipulation, chemicals, phenomena, inferences, reactions, couched in more or less correct English.

In 1876 deductive methods almost wholly.

In 1901 methods partly inductive, partly deductive.

In 1876 the student committing facts to memory.

In 1901 the student more or less an investigator.

In 1876 a smattering of general chemistry only.

In 1901 both general chemistry and qualitative analysis, with some quantitative work, to illustrate laws.

The object and aim of chemical study in the two periods may be illustrated by excerpts from the prefaces of two books. The one in 1876 says that the author "has sought to make a pleasant study which the pupil can master in a single term, so that all its truths may become to him household words. This work is designed for the instruction of youth, and for their sake clearness and simplicity have been preferred to recondite accuracy."

The 1901 author says: "The tendency of the present day is to make the student, from the very beginning, an *investigator*; to train and develop his faculties for observation; to make him find out facts and discover truths for himself; in other words, to make him *think* instead of merely committing to memory what others have thought."

What will be the next progressive movement in secondary-school chemistry? Already a few dim shadows are being cast which may materialize. In schools of the larger cities there is a growing demand for elective courses and elective studies in every department of learning. Elective *courses* are not a new idea, but should high-school pupils be allowed to choose *all their studies* throughout a three or four years' course, it would profoundly affect the scope of teaching and indirectly the methods. Another coming event is the reaching down of chemistry into the grammar grades. This has been successfully done in some few cities and towns. Should the grammar grades teach chemistry and the high-schools have elective studies, the higher grades of quantitative, volumetric, organic and theoretical chemistry may be forced into the high-school, and a minimized university result.

Another indication is that of cooperation. Chemistry teachers are beginning to

form associations for discussion of methods and aims. There is at present a wide diversity in methods of chemistry instruction. While these can never be wholly unified, nor is it desirable that they should be, owing to varied environments, yet discussions of methods, aims and results are most stimulating, and secondary schools may, in this respect, take a step in advance of colleges and universities. Magazines and periodicals for the discussion of what is latest and best in science-teaching mark also the new era, and are an indication in the same direction. The *Journal of the American Chemical Society*, whose 25th anniversary we celebrate to-day, may join hands with its infant sister, *School Science*, the youngest representative of scientific education.

From the twentieth century aspect of chemistry study, is it too much to say that it realizes more fully than perhaps any other single subject the ideal for combined manual, observational and intellectual training?

RUFUS P. WILLIAMS.

SCIENTIFIC BOOKS.

Public Water Supplies: Requirements, Resources, and the Construction of Works. By F. E. TURNEAURE and F. H. RUSSELL, professors in the University of Wisconsin. New York, John Wiley & Sons. 1901. Octavo. Pp. xiv + 746.

This volume has been prepared with particular reference to the needs of teachers and students in engineering colleges, and it is from this point of view that the following remarks are made: The field covered is a large one and in no other branch of engineering has there been a greater growth during the past twenty-five years. In particular the methods of purification of water have, by the aid of the sciences of chemistry and bacteriology, become so thoroughly understood that they are now of equal importance with the operations for storage and distribution.

Part I. of the volume, covering 197 pages, relates to the sources of supply, rainfall, flow of

streams, chemical and bacterial examinations, and the diseases caused by impure water. Part II., consisting of 549 pages, treats of hydraulics, works for the collection and storage of water, purification systems, and the methods of distribution by tanks, pipes and pumps. The space devoted to the different topics appears well proportioned to their relative importance, the subjects themselves are usually thoroughly treated and descriptions of the most modern practice are freely given.

The question of economy in engineering construction is a controlling one in all comparative designs, and this book is one of the few to bring it prominently to the notice of the student. The annual interest on the first cost, plus the annual cost of operation and maintenance, is to be made a minimum, and the general method of doing this is set forth clearly and satisfactorily. Even in cases where the general method is not of direct application, the economic arrangement of details is often discussed. Thus, the economic size of one sand filter bed is shown to depend upon the number of beds, and upon the cost of walls and bottom filling as compared with the cost of piping, valves and other appurtenances. Such discussions are a characteristic of modern engineering and their introduction into text-books should be welcomed, for economic construction is the corner stone of sound engineering practice.

The general subject of hydraulics is set forth only to a limited extent, as a full treatment could scarcely be given in a single chapter. The laws of flow of ground water are, however, fully presented and useful formulas developed, while the subject of water hammer is discussed in a novel manner. Reservoirs, dams, filtration systems, conduits and pipes, pumping machinery, and the distribution of water, are well and thoroughly treated, with numerous examples of constructed works. In short, it may safely be said that the book constitutes one of the very best treatises on water-supply engineering now before the American public.

At the end of each chapter, with the exception of the brief one on hydraulics, there is given a useful list of literature. Periodicals are cited in italics, while transactions and books

are in Roman type. Few engineering students will know what is meant by *Hyg. Rund., Cent. f. Bakt.*, and other similar abbreviations which should properly have been written out in full. The book seems, however, remarkably free from errors that are apt to occur in a first edition. The most serious ones noted are on page 213, where it is said that one U. S. gallon is 0.1605 cubic feet, and on page 216 where the word 'longitudinally' should have been 'transversely.' The book is well printed with the exception of the cuts, many of which properly deserve severe criticism.

The chapter on chemical and bacterial examinations of water appears to be the only one that is likely to prove unsatisfactory to engineering students. Bacteria are not defined and described in respect to size, form, color and functions, and the impression is given that all are specific germs of disease, while there is no hint as to the useful work performed by many species in transforming injurious decaying matter into harmless constituents. At the foot of page 123 a statement is made implying that bacteria in water are found in the suspended matter and not in solution. On page 125 it is said that a water rich in bacteria is not necessarily poor in quality. On the whole this discussion lacks that definiteness and logical method which is demanded by engineers. The chemical part of the chapter is better, but it is also lacking in definiteness, as no records of analyses are given and little is said which will enable a student or engineer to interpret the results of a water analysis.

The field of water supply on both the sanitary and construction side has become so vast that special treatises on the chemistry and bacteriology of water, filtration, reservoirs, standpipes and distribution plants are demanded by practicing engineers. For the student, however, such differentiation is neither feasible nor desirable, and this volume, with the exception above noted, presents such a satisfactory review of the theory and practice of the entire subject that it will undoubtedly prove of great service in technical education, and at the same time take high rank as a manual for young engineers.

MANSFIELD MERRIMAN.

LEHIGH UNIVERSITY.

Zoological Results based on Material from New Britain, New Guinea, Loyalty Islands and elsewhere, collected during the years 1865, 1896 and 1897, by Arthur Willey. Cambridge, Eng., the University Press. 4to. Part V. December, 1900. Pp. 531-690; pls. LIV.-LXXIV.

The fifth installment of Dr. Willey's 'Zoological Results' contains six papers, one of which deals with coelenterates, two with worms, two with crustaceans, and one with vertebrates. The first of these is by E. M. Pratt who describes the soft parts of the rare coral *Neohelia porcellana*. This species, which was previously known only from material obtained by the *Challenger*, belongs to the Oculinidæ, and as all its nearest relatives are fossils the importance of supplementing the earlier description of Moseley by a full account of its anatomy as given in the present paper is obvious.

The parasitic worms gathered by Dr. Willey were studied by A. E. Shipley who found that the collection contained seventeen species, nine of which were new. Two were trematodes and of these sufficient material was obtained of *Monostomum trigonocephalum* to enable Shipley to give a very full description of the anatomy of this form. Of the seven species of tapeworms six were new; two of minute size were taken from the intestine of a ray, one each from the digestive tract of a lizard, a snake, a fruit-eating pigeon and an albatross. Of the six species of round worms only one was new. Two specimens, however, were particularly interesting because of new light thrown on their geographical distribution. *Physaloptera obtusissima* had previously been recorded only from South American snakes, but apparently it also infests the native snakes of New Britain, and *P. retusa*, previously found only in Brazilian lizards, is now for the first time recorded from New Britain. A new species of *Gordius* and a new representative of the family Linguatulidæ are described.

The nemertines are reported upon by R. C. Punnett. Six of the twelve species collected were new. Five belong to the genus *Eupolia* whose headquarters seems to be the Malay archipelago. A new species, *Carinesta orientalis*, on the other hand, is the first Protonemertine

to be recorded from regions outside the Atlantic and Mediterranean.

The extensive collection of lower crustaceans contains, according to T. R. R. Stebbing, forty-six species, of which twenty-three are new. Eight of these represent new genera. Of special interest is *Panaietis incamerata*, a semi-parasitic copepod occurring in the pallial chamber of gastropods, and *Anchicaligus nautili*, a parasitic copepod infesting the mantle chamber of *Nautilus pompilius* and certain slimy portions of the shell of *N. macromphalus*.

The young of the robber crab, *Birgus latro*, have been made the subject of a short but interesting report by L. A. Borradaile. The adult robber crabs are land animals living some distance from the coast and, according to report, have been supposed to bring forth young resembling the parent. Thus it has been surmised that their development was without the larval metamorphosis usually characteristic of other crustaceans. Direct evidence of this has been wanting, for accurate observers have not heretofore happened on the crabs in the breeding season. Dr. Willey, however, reports the capture close to the sea of females with large masses of brown eggs attached to their abdominal appendages. An examination of this material showed that the young hatched as in allied species, in the zœa stage. When hatching begins the females presumably shake the young off in the water. The further development of *Birgus* is without doubt accompanied by a metamorphosis as in other hermit crabs.

G. A. Boulenger describes a new blind snake, *Typhlops willeyi*, from the island of Lifu. This is of interest since it is only the second species of land snake recorded from this island.

G. H. PARKER.

Ergebnisse der neueren Sporozoenforschung. M.

LÜHE. Jena, Gustav Fischer. Price, 2 M. 80.

Lühe's summary of the results of more recent investigations on Sporozoa is practically a revised reprint of his articles which recently appeared in the *Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten*, Volumes XXVII. and XXVIII., and represents a summary of the zoological data contained in nu-

merous zoological and medical articles published in different languages and in different parts of the world.

First he gives a discussion of the general life cycle of the coccidia. This is followed by a classification of the coccidia. Chapter II. discusses the life cycle of the malaria plasmodium, while Chapter III. is given up to a general discussion of the more recent results in the other groups of Sporozoa. Taken as a whole, the material is well digested, and makes an excellent summary for any one who wishes to inform himself quickly regarding the most recent results in investigations concerning Sporozoa.

The work contains 35 illustrations, which add to a proper understanding of the text. One of the great difficulties in following the articles of the present day on the Sporozoa is the fact that so many different authors have considered it necessary or advisable to introduce so many new terms designating the different stages of development. If, for instance, we compare Ross's articles of 1898 with those of 1899 or 1900, we find different terms used for the same stage. Ray Lankester in 1900 uses still other terms; Harvey Gibson an entirely different terminology; while Grassi has repeatedly changed his technical terms. One almost needs a separate dictionary to-day to understand the literature on the Sporozoa. Lühe has in the main followed the terminology adopted by Schaudinn, 1899, and he gives a table by which it is possible to follow the terminology adopted by most of the other authors.

So far as the coccidia are concerned, Lühe's discussion compares quite favorably with the recent summary given by Rafael Blanchard in the *Société zoologique de France*, but it certainly is not superior to Blanchard's work in either style or presentation; in fact, it would be very difficult to improve on Blanchard's article. Lühe's discussion of the malaria parasite compares very favorably with the discussion recently published by Blanchard, Laveran and others in the French Academy of Medicine, but in addition to the abstract discussion of the life cycle of the parasite, he gives a general historical introduction to the subject, with a review of recent literature, and

makes an effort to establish the priority of certain discoveries. We are somewhat surprised to miss in this introduction all reference to the valuable contribution by Dr. King, of Washington, who was apparently the first author to give a scientific summary of the reasons in favor of the view of the transmission of malaria by mosquitoes.

Chapter III. assumes on the part of the reader a certain amount of knowledge of the groups discussed.

One point in connection with the work we can hardly leave unmentioned, and that is the antiquated method of citing literature. Each group has its own bibliography arranged alphabetically by authors. This results not only in unnecessary repetition, but also in confusion; for instance, Max Braun's treatise on animal parasites of man is No. 2 in the first bibliography, No. 12 in the second bibliography, and No. 2 in the third. The work would be greatly improved if the Harvard system of bibliography had been adopted.

C. W. STILES.

SCIENTIFIC JOURNALS AND ARTICLES.

THE May number of the *Bulletin of the American Mathematical Society* contains the following articles: 'Non-Oscillatory Linear Differential Equations of the Second Order,' by M. Bôcher; 'Concerning Real and Complex Continuous Groups,' by L. E. Dickson; 'On Holomorphisms and Primitive Roots,' by G. A. Miller; 'Reviews of Graf and Gubler's Bessel Functions II., by V. Snyder, and of Ricci's Theory of Surfaces,' by H. S. White; 'Notes'; 'New Publications.' The June number contains reports of the April meeting of the Society, by E. Kasner, and of the April meeting of the Chicago Section, by T. F. Holgate; 'The Value of a Certain Integral,' by F. Morley; 'On the Algebraic Potential Curves,' by E. Kasner; 'Review of Steinmetz's Alternating Current Phenomena,' by J. B. Whitehead, Jr.; and of de Tannenberg's Applications of the Calculus to Geometry, by L. P. Eisenhart; 'Notes'; 'New Publications.' The July number, concluding Volume 7 of the *Bulletin*, contains: 'Surfaces whose First and Second Fundamental Forms are the Second and First Respectively

of Another Surface,' by L. P. Eisenhart; 'On Groups Generated by Two Operators,' by G. A. Miller; 'A Curious Approximate Construction for π ,' by G. Peirce; Review of Manning's Non-Euclidean Geometry, by J. L. Coolidge, and of Bianchi's Differential Geometry, by J. K. Whittemore; 'Notes'; 'New Publications'; 'Tenth Annual List of Papers Read before the Society and Subsequently published'; and a sixteen-page Index of the Volume.

The Popular Science Monthly for July opens with an important article on 'The Transmission of Yellow Fever by Mosquitoes,' by George M. Sternberg, detailing the long and careful series of experiments which seem to clearly point out the mosquito as the active agent in the spreading of this disease. Incidentally it may be noted that no less than eighteen men voluntarily exposed themselves to the disease in order to test the theory of its diffusion. Under 'Climate and Carbonic Acid,' Bailey Willis discusses the evidence in favor of the theory that the glacial epochs have been caused by the absorption of carbonic dioxide from the atmosphere, permitting the radiation of heat and lowering the temperature of the earth's atmosphere. A translation is presented of the article on 'The Peopling of the Philippines,' by Rud. Virchow, and Havelock Ellis continues his 'Study of British Genius,' this instalment being devoted to pathology, from which it appears that there is a special connection between genius and gout. Edward L. Thorndike treats of 'The Intelligence of Monkeys,' deciding that they carry the animal method of learning beyond a point reached by any other of the lower animals. 'Cocaine Analgesia of the Spinal Cord' is discussed by Smith Ely Jelliffe, and Henry A. Pilsbry considers 'The Evidence of Snails on Changes of Land and Sea,' while Frank Waldo describes the work of 'The Blue Hill Meteorological Observatory,' which he considers the most successfully conducted meteorological observatory in America. The final article is on the organization and aims of 'The American Association for the Advancement of Science' apropos of its coming meeting in Denver. There is much in-

teresting reading to be found in 'The Progress of Science.'

IN *The American Naturalist* for June, W. M. Wheeler presents the first part of a paper on 'The Compound and Mixed Nests of American Ants.' Glover M. Allen describes 'The Louisiana Deer' as a subspecies under the name of *Odocoelus virginianus louisianæ*. It is a rather curious fact that the antlers of the type of the subspecies and of the two forms shown for comparison are all abnormal. R. W. Shufeldt gives an excellent paper 'On the Osteology and Systematic Position of the Screamers' (Palamedea: Chauna), in which their points of agreement and disagreement with the ducks and fowls are well shown. 'Normal Respiration and Intramolecular Respiration' are discussed by George J. Peirce, and Abram V. Mauck contributes an article 'On the Swarming and Variation in a Myriapod' (*Fontaria virginiensis*). The fifteenth instalment of the fine series of 'Synopsis of North American Invertebrates' is by Hubert L. Clark and is devoted to the Holothuriodea. 'Editorial Comment' and the customary reviews complete the number.

The Auk for July is mostly devoted to systematic papers: 'Bendire's Thrasher,' by Herbert Brown; 'Birds of the Black Hills,' by Merritt Cary; 'Unpublished Letters of William MacGillivray to John James Audubon,' by Ruthven Deane; 'The Resident Land Birds of Bermuda,' by Outram Bangs and Thomas S. Bradlee, containing descriptions of several new species; 'A New Ground Dove from Western Mexico,' by Outram Bangs; 'The Monterey Hermit Thrush,' by Joseph Grinnell; 'The Winter Birds of Pea Island, North Carolina,' by Louis B. Bishop, a list of 42 species, and 'A New Sharp-tailed Finch from North Carolina,' by Louis B. Bishop. The 'General Notes' and 'Reviews of Recent Literature' are very full.

SOCIETIES AND ACADEMIES.

PHYSICS AT THE AMERICAN ASSOCIATION.

THE officers of section B, Physics, Professor De Witt B. Brace, chairman, and Professor John Zeleny, secretary, have received the following titles of papers for presentation at the

joint meetings of Section B of the A. A. A. S. and the American Physical Society, to be held in Denver :

'Note on the Transmission of Radiation by Thin Films of Asphalt': Professor E. L. Nichols, Cornell University.

'The Visible and Infra-red Absorption Spectrum of Iodine in Solution': Professor E. L. Nichols and W. W. Coblenz, Ithaca, N. Y.

'Results of the Recent Magnetic Work of the U. S. Coast and Geodetic Survey': Dr. L. A. Bauer, Washington, D. C.

'The Physical Decomposition of the Earth's Permanent Magnetic Field': Dr. L. A. Bauer, Washington, D. C.

'Discharge of Electrification by Glowing Platinum and Velocity of the Ions': Professor E. Rutherford, McGill University, Montreal.

'The Absorption Spectrum of Colloid Ferric Hydrate Solutions': Professor B. E. Moore, University of Nebraska.

'Index of Refractions and Dispersion of Dilute Aqueous Solutions': Professor B. E. Moore, University of Nebraska.

'On the Calorimetric Properties of the Ferro-Magnetic Substances with Special Reference to Nickel-Steel': B. V. Hill, University of Berlin.

'Note on Strains in very Dilute Solutions of Gelatine': B. V. Hill, University of Berlin.

'On Electro-Striction': Professor Z. S. Shearer, Cornell University.

'The Distribution of Energy in the Spectrum of the Acetylene Flame': George W. Stewart, Ithaca, N. Y.

'The Visible Spectrum of the Incandescent Lamp at Various Temperatures': Ernest Blaker, Ithaca, N. Y.

'The Heat of Combustion of Acetylene': H. A. Rands, Ithaca, N. Y.

'The Radiant Efficiency of Vacuum Tubes': Edward E. Roberts, Ithaca, N. Y.

'The Fall of Temperature through a Wedge-shaped Wall of Glass': Albert Ball, Ithaca, N. Y.

'Notes on the Supposed Elongation of a Dielectric in an Electrostatic Field': Professor L. T. Moore, University of Cincinnati.

'On the Cavendish Experiment and the Law of Inverse Squares in Electrostatics': Professor S. J. Barnett, Stanford University.

'On Gauss's Flux Theorem': Professor S. J. Barnett, Stanford University.

'The Diminution of the Potential Difference between the Electrodes of a Vacuum Tube Produced by a Magnetic Field': Dr. John Almy, University of Nebraska.

'The Discharge Current from a Surface of large Curvature': Dr. John Almy, University of Nebraska.

'Experiments on a New Form of Standard High Electrical Resistance': H. C. Parker, Columbia University.

'Variation of Contact Resistance with Change of E.M.F.': H. C. Parker, Columbia University.

'On the Demagnetization of a Discharge in Iron when Electromagnetically Compensated': Zeno Crook, Lincoln, Nebraska.

'On the Forces produced on Adjacent Spherical Surfaces by the Flux of a Viscous Fluid': S. R. Cook, Lincoln, Nebraska.

'On the Determination of Dispersion by Means of Channeled Spectra with the Concave Grating': P. J. Antes, University of Nebraska.

'On the Faraday Effect during Hydrolysis of Ferric Chloride': F. G. Bates, University of Nebraska.

'The Absorption and Dispersion of Fuchsin': W. B. Cartmel, University of Nebraska.

'On Conditions controlling the Drop of Potential at the Electrodes in Vacuum Tube Discharge': Professor C. A. Skinner, University of Nebraska.

'The Influence of Temperature upon the Photoelectric Effect': Professor John Zeleny, University of Minnesota.

'On the Resolution of the Faraday 'Effect' in the Case of Liquids': Professor D. B. Brace, University of Nebraska.

'On the New Method of determining the Curve of Luminosity by Homogeneous Comparisons': Professor D. B. Brace, University of Nebraska.

SECTION OF BIOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

At a regular meeting of the Section held on May 13, Professor C. L. Bristol presiding, the following program was offered :

R. WEIL : 'A Contribution to the Problem of the Ear-Bones.'

A. G. MAYER : 'On the Variation of Snails of the genus *Partula* in the Valleys of Tahiti.'

O. S. STRONG : 'A Case of unilateral Atrophy of the Cerebellum.'

Dr. Weil's paper was a critical discussion of the theory of the ear-bones, as embodied in the recent articles of Kingsley and Gaupp. Two main contentions were considered : first, that the malleus and incus of mammalia were homologous with the quadrate and articular of lower forms, while the temporo-maxillary articulation is a new formation ; second, that the ossicles of mammalia cannot possibly have de-

scended from those of Sauropsida. The first contention is based upon the embryonic connection of malleus and incus with the Meckelian bar, upon the embryonic situation of the last anterior to the Eustachian tube, and upon the innervation of the muscle of the malleus by a branch of the trigeminus. Embryonically, however, the malleo-incudal complex, in addition to its continuity with the Meckelian bar, arises from the auditory capsule, which contributes to both malleus and incus, the stroma of the tympanic cavity, contributing to the manubrium mallei, and a membrane bone which forms the Fallopian process. Furthermore, as Gegenbaur points out, the continuity of malleus and incus, if they be the quadrate and articular, is itself in contradiction to the independent embryonic origin of these elements in the lower forms. The pre-trematic origin of the ossicles in the pig, as described by Kingsley, is contrasted with their post-trematic, or hyoidean, origin in lower forms. Dr. Weil stated that his studies of a full series of pig and opossum embryos did not enable him to decide whether the malleus, and still more, the incus, lay primarily in front or behind the tube. The bones cross the anlage of the tube in a transverse direction, lying above it; by the gradual absorption of the intervening stroma they come to occupy the cavity of the tympanum. Finally, the innervation of the tensor tympani muscle of the malleus by a branch from the otic ganglion of the trigeminus is taken to indicate the relation of the malleus to the mandibular arch. But lesions of the trigeminus at its root do not involve hearing, while the contrary is true of lesions of the facial. This fact would point to the origin of the above-mentioned nerve from the seventh nerve, and would make the malleus a part of the second arch. The second contention is supported, first by the difference in the embryonic relations of the bones to the Eustachian canal, an argument already considered, and second, by the differences in the relations of the chorda tympani nerve, which in Sauropsida crosses *above* the chain, and in mammalia *below* it. The speaker showed that the pathologists, from a comparison of a large number of lesions of the trigeminus and of the facial at the base of the brain, had demonstrated the exit of the

chorda tympani in man with the roots of the former. But since it leaves the brain in lower forms with the seventh, its relations to bony structures are evidently not sufficiently constant to constitute a criterion of homologies. From these facts, it would appear that the homology of malleus and incus with the quadrate and articular has not yet been demonstrated.

Dr. Mayer showed that the snails in question are subjected to conditions of isolation very similar to those affecting the Achatinellidæ of Oahu in the Hawaiian Islands, occurring in valleys which are separated by comparatively barren ridges. The farther apart the valleys, the less intimate is the relationship between their snails. Although geographical isolation is probably the chief factor in determining the establishment of definite varieties, yet the differing environmental conditions obtaining in each valley may exert considerable influence.

Dr. Strong presented a preliminary report, illustrated by lantern slides, upon a case of unilateral atrophy of the cerebellum in a child which lived to the age of three years and four months. The principal external anomalies noted were the following: The left hemisphere of the cerebellum was almost entirely absent; the right olive was wanting and the transverse pontile fibers on the left side were deficient; the left half of the pons protruded more than the right; the right crus cerebri was much narrower than the left; the left restiform body was smaller than the right, and the superior cerebellar peduncle of the left side was deficient; the posterior corpora quadrigemina were asymmetrical, while the left anterior corpus quadrigeminum was apparently lacking; the median line of the fourth ventricle was curved with its convexity toward the left, and such structures of the medulla as the clava, cuneus, ala cinerea, and eminentia teres were located or extended further cephalad on the left side than on the right. Preliminary transverse sections cut at various levels through the medulla, pons, isthmus and posterior corpus quadrigeminum showed the following points: only small parts of the right olive and the left corpus restiforme were present, and there was a corresponding deficiency of the cerebello-olivary fibers; the transverse pontile

fibers on the left side were reduced, but the nuclei pontia were larger on the left side; the longitudinal pontile fibers were deficient on the right, as shown by the smaller crus cerebri of this side; the left lemniscus was the smaller, and the left superior cerebellar peduncle was reduced. Other deficiencies were noted, which, however, require further study. Full discussion of the case was postponed, as the research is as yet uncompleted.

HENRY E. CRAMPTON,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE WASHINGTON MEMORIAL INSTITUTION.

TO THE EDITOR OF SCIENCE:

A curious incongruity appears in the plan for the Washington Memorial Institution as outlined in the report on 'A National University' in the current number of SCIENCE, as well as elsewhere. The first paragraph in the platform of the new institution provides that 'it will be independent of government support or control' (p. 51). Yet the seventh paragraph assumes that the institution will depend on the governmental departments (including the Smithsonian Institution, the Library of Congress, etc.) for its facilities, or in other words for the essential part of its support; and it also provides that 'students working in government laboratories or collections will be subject to the rules and regulations there prevailing,' *i. e.*, will be under governmental control. It should be pointed out that this unfortunate incongruity is much more glaring in statement than in thought; the projectors of the enterprise merely desired to emphasize the independence of the prospective institution from direct federal appropriation. Nevertheless, the incongruity has given rise to criticism in various influential quarters; it would seem, indeed, to have been one of the factors leading to the rejection of the report made by the committee of the National Educational Association.

As a matter of fact, the publications hitherto made concerning the Washington Memorial Institution have been of preliminary character, and have emanated from committees and individuals rather than from the Institution. Accordingly, criticism might well be withheld

pending the issue of official statements by the Institution itself.

WASHINGTON, D. C.,

July 13, 1901.

ROYAL SOCIETY OF CANADA. SUPPLEMENTARY NOTE.

IN the account given of the twentieth meeting of the Royal Society of Canada held in May, 1901, and published in the June 28 issue of SCIENCE, the writer inadvertently omitted to mention Professor T. Wesley Mills's paper presented to Section IV. (geological and biological sciences). The title of the paper was: 'The Anatomy and Physiology of the Brain of the Bird.' It was a continuation of a former one presented to the Society two years ago. The author outlined his plan of investigation which was somewhat extensive and which, for its execution, would require much time yet. He showed that the anatomical results would probably modify the views of conduction in the nervous centers until recently prevailing, and that the entire subject would require reconsideration in view of his own and other researches in various directions. The effects of ablation of portions of the brain on the psychic condition of birds were traced in brief outline with their general implications. This part of the subject had already been worked out by the author pretty fully, but was also being continued at the present time. Remarks were made by Professor R. Ramsay Wright, of Toronto University, by Professor E. E. Prince, Commissioner of Fisheries for Canada, Dr. F. Slater Jackson, and Dr. A. M. Mackay.

H. M. AMI.

OTTAWA, July 9, 1901.

A HORNED LIZARD AT A HIGH ALTITUDE.

ON June 30, at the head of John's Cañon, Las Vegas Range, N. M., I was somewhat surprised to find a horned lizard in the uppermost part of the Canadian Zone, above 10,000 feet (the aneroid indicated 10,500, but is not quite reliable at that altitude). The species is *Phrynosoma hernandes* (Girard), and the specimen is dark gray, beneath white mottled with gray. The top of the range is Hudsonian, and no lizards are found there.

SHORTER ARTICLES.

THE GEOLOGIC DISTRIBUTION OF *POLLICIPES*
AND *SCALPELLUM*.

IN a valuable memoir on the 'Hudson River beds near Albany and their taxonomic equivalents,' published as Bulletin of the New York State Museum, No. 42, April, 1901, Dr. Rudolph Ruedemann describes a number of variously shaped valves found in the Upper and Lower Utica Shale of Green Island and Mechanicsville, N. Y. (p. 573, pl. ii.). These he believes to 'find their homologues in parts of the capitula of the pedunculate cirriped genera *Scalpellum* and *Pollicipes*, notably of the latter. On this account the various valves have been united under the caption *Pollicipes siluricus*, in full consciousness of the enormous gap existing between the appearance of this Lower Siluric type and the next Upper Triassic (Rhaetic) representatives of these genera.' Confirmation of Dr. Ruedemann's ascription may be derived from the fact that 'the enormous gap' does not exist. Early in 1892 Dr. C. W. S. Aurivillius* published the descriptions of *Pollicipes signatus* from bed *e* (= Lower Ludlow), *P. validus* from bed *c* (= Wenlock Shale), *Scalpellum sulcatum*, *S. varium*, *S. granulatum*, *S. strobiloides*, *S. procerum*, *S. cylindricum*, and *S. fragile*, all from bed *c*, of the island of Gotland. The species of *Scalpellum* are founded on peduncles, *Pollicipes validus* is represented by a broken scutum only, but *P. signatus* is based on an almost perfect specimen. The occurrence of more than one species of both these genera in the Silurian lends significance to the diversity of form presented by Dr. Ruedemann's specimens. The ornament on his Fig. 18 most nearly resembles that of *P. signatus*, while the rostrum, Fig. 22, is also not unlike that species. Figures 16, 17, 19 may belong to more than one other species, while 24 (with which presumably 25 is to be associated) may belong to a *Scalpellum*, as Dr. Ruedemann seems to hint. In the circumstances it is specially regrettable that Dr. Ruedemann has selected no one of these specimens as the holotype of *Pollicipes siluricus*. If he does not do so soon, confusion is pretty certain to arise.

* Bihang Sveska Vet.-Akad. Handl., XVIII., Afd. IV., No. 3.

Figures 13, 14, 15, are referred to *Turrilepas* (?) *filosus* n. sp. A recent examination of the plates of that genus suggests to me that the note of interrogation is fully justified.

Aurivillius considered that *Pollicipes signatus* showed a closer approach to the Balanidæ than any other of the Lepadidæ, but he too, in ignorance of the Devonian *Protobalanus* Whitf., discoursed needlessly about the gap in the distribution. Now that the range of the Lepadidæ has been extended to the Ordovician, we may look confidently for further discoveries. We may also hope that the time has now come when even the text-books may awake to the fact that the genera *Pollicipes* and *Scalpellum* existed in Palæozoic times. It was pointed out in your own columns a year ago (Vol. XI., p. 984), and in other reviews before that. But perhaps the reviewer and the author reviewed are the only readers of a review.

My apology for insisting on this is not merely that both Dr. Aurivillius and Professor Lindström, who supplied him with the material, have unhappily passed away, but that I had the good fortune to be the discoverer of the beautiful specimen of *Pollicipes signatus*, when developing a specimen of *Gissocrinus verrucosus* from the *Pterygotus* bed of Wisby Waterfall in May, 1891. The very fragile specimen was subsequently licked into shape (no metaphor is intended) by Mr. G. Liljevall, to whom the excellent drawing of it is due. F. A. BATHER.

LONDON, June 5, 1901.

QUOTATIONS.

THE SALARIES OF SCIENTIFIC MEN IN THE
EMPLOYMENT OF THE GOVERNMENT.

WITHIN the past few years our Government has come to fully recognize the wisdom of utilizing in every way possible the results of modern science, particularly in the conduct of its internal affairs. The amount appropriated by the late Congress for scientific purposes was somewhere in the neighborhood of \$9,000,000—a larger sum than is devoted by any other Government to like purposes. Yet the liberal and enlightened policy evinced by legislation of this sort has been accompanied by a short-sightedness—not to use a less complimentary term—hard to account for in a legislative body made up largely

of business men. The head of the Division of Forestry, for example, with \$187,520 at his disposal, receives a salary of \$2,500. If a thoroughly competent man has been secured for this important position at this ridiculously low figure the Government is, indeed, to be congratulated. As soon, however, as he shall have established a reputation he will very probably be 'lifted' by some more generous Government. This actually happened last year in the case of an officer of the Department of Agriculture who received \$1,800 a year. He now holds a like position in Japan at a salary of \$7,000.

If in spite of this Congressional niggardliness many very capable men be now engaged in governmental scientific work, this result has been brought about more by good luck than by good management, and the broad truth is not thereby affected that in every business, whether private or public, the higher salary appeals to the higher order of talent, with its consequence of greater efficiency in the work done. At the late session of Congress an unsuccessful effort was made to rectify this mistaken policy. It is to be hoped that another session of Congress will not pass without a further and a successful effort to readjust the salaries of all government scientists, and to fix them at figures which will at least bear a comparison with those paid for similar work by many private firms and corporations.—*Philadelphia Record*.

Two important government positions at Washington are going begging because there are no applicants for them. The reason is simple: they can be filled only by men of technical skill and scientific training, and the salaries attached to them are \$1,200 and \$1,400 a year, respectively. The politicians who fixed these low salaries for high-class work knew that the incumbents would be worthless for political manœvering, and hence did not care to 'waste' much money on them. It is a rule that holds good all through the scientific side of government work.—*Philadelphia Ledger*.

THE NATIONAL UNIVERSITY PROJECT.

THE action taken at Detroit by the National Educational Association on the subject of the

projected national university leaves that matter in a peculiar but not a necessarily disappointing status. A committee of the Association had investigated the general project of utilizing, for higher university education, the facilities afforded by the governmental establishment and appurtenances at this capital. It reported in favor of the plan recently proposed by the George Washington Memorial Association and the Washington Academy of Sciences for the creation of an establishment to be known as the Washington Memorial Institution, to direct the energies of students desiring to avail themselves of the educational facilities here, without endowing a specific educational organization. The association declined to adopt this view and passed resolutions declaring its unwillingness to abandon its favorite project of establishing a distinct national university in this city.

Thus it appears that the issue at Detroit is between two plans to accomplish the same purpose. There is no division on the score of the desirability of utilizing the exceptional educational advantages of the capital city. All the educators agree that here lie chances for higher education which are not to be found elsewhere and which could not be duplicated with any expenditure. The majority of the delegates to the convention believe, as have many leaders of pedagogic thought in the past, and as did George Washington in the beginning, that the best way to make use of this plant is by direct means to create a university which shall stand for the national progress and prestige. Others contend that this is impracticable, and that the most promising method is to respect the existing educational establishments as sufficient in themselves and to create a supplement for the special use of those who desire a post-graduate course afforded only by the governmental facilities here.

The capital desires nothing more than that the fullest possible use be made of its exceptional opportunities for education. It hopes to see George Washington's ideal realized in some form as early as possible. It will aid to the extent of its ability any promising project to this end. It will safeguard the interests of any educational creation here, whatever its form or name. It

hopes that the discussion of the particular method whereby his object is to be attained will arouse the interest of every educator in America, and will create a determined purpose to accomplish something definite without further delay.—The *Boston Transcript*.

A NEW MAMMALIAN GENUS.

PROFESSOR E. RAY LANKESTER writes from the Natural History Museum, under the date of June 17, to the *London Times*, as follows :

I have this afternoon received and unpacked the case shipped at Mombasa on April 19, containing the skin and two skulls of the remarkable new giraffe-like animal obtained from the Semliki forest by Sir Harry Johnston, and sent by him to me for preservation in the Natural History Department of the British Museum. I write without loss of time to say that the specimens have arrived in perfect safety and they fully and completely bear out Sir Harry Johnston's statements and inferences.

The animal is a giraffe-like creature devoid of horns, with relatively short neck and with color stripes on the limbs, but nowhere showing spots or areolæ like those of the giraffe. Sir Harry Johnston was amply justified in assimilating the animal to the extinct *Helladotherium*, but after an examination of the skulls I am of opinion that the 'Okapi' (the native name by which the new animal is known) cannot be referred to the genus of the *Helladotherium*, but must be placed in a new genus.

I must say that, although the horny hoofs are not present, yet the double bony supports of the hoofs are preserved with the skin, and leave no doubt, even without reference to the accompanying skulls, that the animal which bore the skin was not a horse-like creature, but one with cloven hoofs.

P. S.—The 'five-horned giraffe' recently reported as having been discovered by Sir Harry Johnston is (I am told by Dr. Forsyth Major) due to a misunderstanding of a French translation of Sir Harry Johnston's description of the Okapi as 'une girafe sans cornes' (grafe à cinq cornes).

Harry Johnston has written as follows: Perhaps I may be allowed to correct a slight misapprehension that has arisen owing to a postscript attached to my friend Professor Ray Lankester's letter in *The Times* of June 18. It has been thought by the authorities of the British Museum that the telegram of a press agency from east Africa announcing that my expedition had recently discovered a giraffe with five horns was a misleading variant of the account sent some months ago as to the other discovery made by us in the summer of 1900 of the existence in the forests bordering the Semliki River of a giraffe-like animal, without horns, which has just been named 'Ocapia' by Professor Ray Lankester. Quite independently of this interesting discovery, the credit of which, it must not be forgotten, has to be shared by Mr. Karl Ericsson, of the Congo Free State, who furnished me with a complete specimen, my expedition has been the means of discovering a species or variety of giraffe, which, in the male, possesses five horn cores, instead of the two or three found in other known species of giraffe. Specimens of the five-horned giraffe were shot by Mr. Doggett and myself about five weeks ago in the country lying to the east of Mount Elgon in the northeastern part of the Uganda Protectorate. Of these specimens, two are males and two females. The female has only three horns, while both the male specimens exhibit five horn cores.

In coloration it is my opinion that this species of giraffe differs from those already known. I have in my possession now drawings and photographs confirming these statements, and the four specimens (bones of the head and neck and skins) are on their way to England for presentation to the Natural History Museum.

Until these specimens are in the hands of competent authorities it is rather premature to discuss the worth of the discovery, or the question of its substantiating the existence of a hitherto unknown giraffe.

Perhaps I may be allowed to add that the fact that a month ago my expedition was still travelling through a very wild part of the Uganda Protectorate, and was passing through enormous herds of wild game, recalling the

In connection with the above letter, Sir

best days of Gordon Cumming, is indirect evidence of the rapid extension of the Uganda railway and of the remarkable facilities which it affords for travelling in a short space of time to and from London and the heart of Africa.

*THE NEW BUREAU OF FORESTRY.**

ON the first of July the Division of Forestry and three other scientific divisions of the U. S. Department of Agriculture were advanced to bureaus. This was provided for by the last session of Congress, which appropriated for the expenses of the Bureau of Forestry during its first year \$185,440. The appropriation for the Division of Forestry during the year just ended was \$88,520. For the year 1898-99 it was \$28,520.

These figures show how rapidly the forest work of the Government has expanded of late, and also how well it has commended itself to Congress. There was a time when the practical value of the scientific investigations carried on by the Government was not fully understood, and farmers were inclined to think that the money spent on experiment stations and chemical laboratories was of little benefit to them. Now the case is very different. The improvements in agriculture due to the work of the Department have increased the value of the farm products of the country by many millions of dollars annually. As this kind of work has proved its practical utility, Congress has shown itself generous toward it. The readiness with which Congress has increased the appropriations for the Division of Forestry is the best evidence that forestry has proved its importance from a business standpoint.

The change from a division to a bureau, and the larger appropriation, will make possible both an improved office organization and more extended field work. The bureau will be provided with a much larger office force and will be organized in three divisions. But field work, not office work, is what the bureau exists for. This work has been going on during the last year from Maine to California and from Georgia to Washington. It includes the study of forest conditions and forest problems all over the country, the giving of advice to owners of

forest lands, and the supervising of conservative lumbering operations which illustrate forest management on business principles. This work can now be greatly extended. Private owners of some three million acres have applied for this advice, which in every case requires personal examination, and about 177,000 acres have been put under management. This land is in many tracts, large and small, and is owned by individuals, clubs and corporations. Several State governments have also asked the aid of the bureau. But the greatest demand is that of the Department of the Interior of the National Government, which has asked for working plans for all the forest reserves, with the enormous total area of about 47,000,000 acres.

The Bureau of Forestry is made up of the Division of Forest Management, the Division of Forest Investigation, and the Division of Records. Each of these continues, with enlarged facilities, work which was in progress under the old Division of Forestry.

The Division of Forest Management is in charge of Mr. Overton W. Price, the former superintendent of working plans. When the owner (private or public) of woodland wishes to consider the possibilities of his property if handled as a constant source of timber supply, the tract must be examined by an expert to ascertain the condition of the standing timber, the prospects of reproduction, the facilities for marketing, the best method of harvesting the present crop so as to secure the largest present and future yield, and the likelihood of success under management. A preliminary report is then made. If the owner decides on management, a working plan follows. This involves a careful study of the rate of growth of the different kinds of marketable timber, the computation of the proper interval between cuttings and of the amount of timber to be harvested, and, if desired, the recommendation of the necessary regulations to enable the work to go on under contract. All this falls to the Division of Forest Management.

The Division of Forest Investigation, under the charge of Mr. Geo. B. Sudworth, makes studies of trees—of their rates of growth, distribution, reproduction and habits—and investigates all the forest problems connected

* Press bulletin.

with fires, lumbering, grazing, tree-planting, stream flow and erosion.

The Chief of the Division of Records is Mr. Otto J. J. Luebker. It takes charge of all office and routine matters, and also has custody of the library of literature bearing on forestry, and of a unique collection of photographs, which is continually being added to, illustrating forest conditions all over the United States.

The result of the work of the Division has been to turn practical forestry in the United States from a doubtful experiment into an assured success. Special studies of some of the most important trees, commercially, have been made, from which can be calculated their probable future yield. Cheap methods of harvesting the present lumber crop without injuring the productivity of the forest have been put in operation. Such concerns as the Great Northern Paper Company and the Deering Harvester Company have been led to undertake conservative management of their forest properties. Meanwhile, the work of tree-planting, particularly in the almost treeless Western States of the plains, has been furthered; the relation of the forest to the volume of streams, erosion, evaporation and irrigation have been studied; matters connected with irrigation and water supply have been investigated; hopeful progress has been made in the direction of regulating grazing in the Western reserves in a manner fair both to the important interests of cattle and sheep owners and to those who look to the reserves as a source of continuous supply of wood and water; and studies of forest fires were conducted with a view of reducing the great yearly loss from this source, a loss which has been estimated at \$50,000,000.

Field work is to go on this summer in 17 States. There are in all 179 persons engaged in the work of the Bureau. Of this number 81 are student assistants—young men, largely college students, who expect to enter forestry as a profession, and who serve during the summer on small pay for the sake of the experience gained.

SCIENTIFIC NOTES AND NEWS.

PROFESSOR RUDOLF VIRCHOW has been appointed a Knight, with the right to vote, of the

Prussian Order 'Pour le Mérite' for Science and Art.

TRINITY COLLEGE has conferred the honorary degree of M.S. on Mr. John H. Sage, secretary of the American Ornithologists' Union.

CAPTAIN SCOTT and the other officers and the members of the scientific staff of the British National Antarctic Expedition were entertained at a farewell dinner by the Savage Club, on July 6.

THE annual dinner of the Royal Institute of Public Health will take place on July 24, in London, when the Harben Gold Medal of the Institute will be conferred on Professor R. Koch, of Berlin. Lord Lister, Lord Strathcona, Professor Brouardel and other guests will be present.

F. W. DYSON, chief astronomer at the Greenwich Observatory, arrived at San Francisco on June 8, after having observed the total eclipse of the sun in Sumatra. He visited the Lick Observatory on the ninth, and intends to inspect other American observatories before his return to England.

DR. THEO. GILL, after having attended the ninth jubilee of Glasgow University as a representative of the Smithsonian Institution and the National Academy of Sciences, is at present on the continent, where he will visit scientific institutions, including the Zoological Station at Naples.

PROFESSOR WILLIAM OSLER, of the Johns Hopkins University, and Dr. Edward G. Janeway, of the University and Bellevue Hospital Medical College, are among the delegates who will attend the Congress of Tuberculosis to be held in London next week.

MR. F. H. NEWELL, in charge of the hydrographic work of the U. S. Geological Survey, and Mr. Gifford Pinchot, chief of the Bureau of Forestry, left Washington on July 11 for the West, having in view, among other things, the investigation of the forests and water supply of eastern Oregon. Mr. H. Gannett, of the U. S. Geological Survey, is already in Oregon inspecting the work of the various parties surveying the forests.

THE Secretary of Agriculture has recently

made a reconnoissance of a portion of the area of a proposed Appalachian forest reserve designed for the protection of forests and the preservation of the water resources and soils of the Appalachian region. He was accompanied by Messrs. Gifford Pinchot, chief of the newly created Bureau of Forestry; F. H. Newell, chief of the Hydrographic Division of the U. S. Geological Survey; W. J. McGee, of the Bureau of American Ethnology, and J. A. Holmes, state geologist of North Carolina.

PROFESSOR O. P. PHILLIPS, of the Southern California University, is in the Pueblo region, under the auspices of the Bureau of American Ethnology, for the purpose of obtaining motion-pictures illustrating the industries, ceremonies and domestic customs of the Pueblo peoples.

DR. FRANZ BOAS, of Columbia University, received on July 1 an honorary appointment as philologist in the Bureau of American Ethnology; and under an arrangement completed just before his departure for Europe, Messrs H. H. St. Clair and W. A. Jones have taken the field and commenced the collection of several Indian languages.

As we have already stated Dr. Paul C. Freer, professor of chemistry in the University of Michigan, has received a year's leave of absence to go to the Philippines. We are now informed that he will there organize the laboratories recently established by the civil government.

DR. W. W. FORD, of McGill University, will undertake researches on some subject connected with preventable diseases under the auspices of the trustees of the Rockefeller Institution for Medical Research. He will spend the next six months at the Pasteur Institute at Paris, returning to McGill University, when the new laboratories are completed, to work under Professor Adami.

SIR ROBERT BALL, professor of astronomy at Cambridge University, will lecture in the United States during the autumn, under the auspice of Major Pond.

SIR HENRY ROSCOE, the eminent chemist, has been reelected vice-chancellor of the University of London.

SIR A. R. BINNIE has resigned the position of chief engineer to the London County Council. Under his direction many important public works, such as the Blackwell Tunnel, were carried out.

PROFESSOR A. JACOBI, New York City, has sent a notice, calling attention to the fund being collected in honor of Rudolf Virchow's eightieth birthday, to which we have already referred. The fund is to be added to that collected ten years ago, its income being used for furthering biological, anthropological and medical research. Professor Virchow will celebrate his birthday on October 13, and contributions should be in Professor Jacobi's hands not later than the first of September.

DR. ROBERT MAYER, eminent for his announcement of the law of the conservation of energy, was born at Heilbron in 1814 and practised medicine in that city until his death in 1878. The Berlin branch of the German Association of Engineers has recently placed a memorial tablet on the house in which he lived.

A BUST of Dr. Armauer Hansen, the discoverer of the bacillus of leprosy, will be unveiled with appropriate rites in the Lungegaards-Hospital at Bergen on August 10.

DR. WILLIAM H. HARKNESS, known for his contributions to entomology and botany, died in San Francisco on May 10.

WILLIS H. BARRIS, D.D., corresponding secretary and curator of the Davenport Academy of Sciences died last month in his eightieth year. Dr. Barris was professor in a theological school of the Protestant Episcopal church and was at the same time much interested in science, having published in the *Proceedings* of the Davenport Academy of Sciences' numerous papers on geology and paleontology. He was a trustee of the Academy from the time of its foundation, and was elected president in 1876, and for many years acted as curator and corresponding secretary.

PROFESSOR JOHANNES LAMP, one of the scientific members of the expedition which is demarcating the boundary between German East Africa and the Congo State in the neighborhood of Lake Kivu, died on June 21 of sun-

stroke. He was for some time employed at the Geodetic Institute in Berlin, and was afterwards appointed to the observatory at Kiel, and held a professorship at the university of that city.

DR. AXEL ERICSSON, the Swedish explorer, died in the interior of Africa on May 31.

It is this week reported that Mr. Andrew Carnegie has offered to give \$100,000 for a library building at Leadville, Colo.; \$35,000 for Alameda, Cal., and \$75,000 for Coatbridge, Scotland.

MR. T. G. YOUNG has bequeathed £3,000 to the Technical College, Glasgow, for the purpose of establishing exhibitions in connection with the chemical laboratory.

AN institute for the official examination and analysis of new drugs and remedies is to be established in connection with the Imperial Board of Health in Berlin.

THE newly established Health Board for the Philippines will shortly begin to work in cooperation with the army surgeons throughout the archipelago in studying the relation of mosquitoes to malaria.

THE library of the late Dr. Felix Birch-Hirschfeld, professor of pathological anatomy in the University of Leipzig, has been purchased by the Cornell University Medical College. It contains about 5,000 volumes, and cost about \$10,000.

THE Worshipful Company of Goldsmiths has purchased for £10,000 the library of economic literature collected by Professor H. S. Foxwell. This was done just in time to prevent the removal of the library to the United States.

MR. GEORGE GRANT MCCURDY, of Yale University, secretary of Section H, Anthropology, of the American Association, has sent to members the following notice:

The Fiftieth Meeting of the American Association for the Advancement of Science will be held in Denver, Colorado, August 24-31, 1901. Dr. J. Walter Fewkes, of the Bureau of American Ethnology, will preside over the Section of Anthropology.

You are cordially invited to attend and to contribute papers upon subjects connected with your field of research.

In order that a preliminary sectional program may be distributed in advance of the meeting, titles of communications should be sent to the secretary as soon as possible. Abstracts of papers or the papers themselves may be sent later at the convenience of the authors, who are reminded that no title will appear on the final program until the paper either in full or in abstract has been passed upon by the Sectional Committee.

Excursions to points in the southwest, of special interest to anthropologists, are being planned.

THE president of the Davenport Academy of Sciences, Mrs. M. L. D. Putnam, requests us to extend an invitation in the name of the Academy to the members of the American Association to visit its museum and archeological collections in going to, or returning from, Denver. Davenport, Ia., is on the Chicago, Rock Island and Pacific Railway on the direct route to Denver.

THE International Association for the Advancement of Science, Arts, and Education will hold its second meeting at Glasgow, in the University and in the Exhibition, from July 29 to September 27. One of the most important functions of the meeting will again be, as at Paris last year, to study and interpret the matters of scientific, geographic and other interest afforded by the exhibition by means of lectures and conferences, with demonstrations and visits under skilled guidance.

It appears from the London medical journals that the Congress of Tuberculosis which will open in London on July 22 will be of considerable importance. Over 1,200 applications for membership have already been received, and it is expected that more than 2,000 members will be in attendance. The sum of about \$25,000 has already been collected for the expenses of the meeting. The program includes addresses by Professors Koch, Brouardel and Macfadyean.

THE American Philological Association held its thirty-third annual meeting at Harvard University last week with a full program. The meeting will be held next year at Union College, Schenectady, N. Y., under the presidency of Professor Andrew F. West, of Princeton University.

A CIVIL service examination will be held on

August 20 for the position of chief taxidermist in the U. S. National Museum at a salary of \$125 a month. The subjects and weights are :

Practical questions.....	25
Practical tests.....	50
Experience.....	25

The practical tests will comprise the submission of photographs or other illustrations of large animals or groups of animals which have been prepared by the competitor. Applicants should submit as complete and perfect representations of their work as they can secure. Applicants will be required to make sworn statements that the photographs or other illustrations submitted by them are taken from work which they executed. The position to be filled is an unusually responsible one and involves on the part of the appointee a rare combination of qualifications. He should not only have mechanical ability to execute first-class taxidermic work, but should possess the qualifications of an artist and some knowledge of the life history of animals. Applicants should have considerable experience in the preparation of large mammals, animals of the size of the grizzly bear or larger.

THE University of California has established a marine laboratory at San Pedro, as part of its proposed biological survey of the waters along the California coast.

THE new pathological institute of the London Hospital was opened by Sir Henry Roscoe, F.R.S., vice-chancellor of the University of London, July 10.

MR. JOHN LEWIS CHILDS, of New York, has purchased a large collection of birds' eggs and nests made by Mr. H. C. Parker, of Ridley Park. The collection is said to be very complete, including a specimen of the great auk's egg and other rare sorts.

MR. ABRAHAM E. SMITH, consul at Victoria, writes to the Department of State that a surveying party has located the landing site of the British Pacific telegraph cable (which is to connect the Dominion of Canada with the Australian Confederation) on Kelp Bay, near Banfield Creek, 7 miles from the entrance to Barclay Sound, and something over 100 miles from

Victoria. The location is described as admirably adapted for the purpose—a good harbor, 12 fathoms of water close to the shore, so that vessels of 10,000 tons can find safe anchorage. The harbor is landlocked, and has a bottom of ooze that it is said will furnish good protection for the wire. Work has already begun in England on the cable. It is to be 5,834.5 miles in length, the longest yet constructed, and will be transported and laid in one ship, which is now being specially built for the purpose. The cable will run from Vancouver Island to Fanning Island, a distance of 3,337 miles, before a landing is effected ; thence to the Fiji Islands thence to Norfolk Island, and thence to Queensland. The first instalment of cable, including the sections from Queensland to Norfolk, Fiji and Fanning Islands, is expected to leave England in January, 1902. The second and longest portion is to leave in August, 1902, come direct to Vancouver Island, and be laid from Barclay Sound to Fanning Island. According to the contract, the whole cable is to be laid and working by January 1, 1903. Unforeseen disaster excepted, those engaged in the work believe this great enterprise, which will cost \$10,000,000, will be completed at the date promised.

UNIVERSITY AND EDUCATIONAL NEWS.

GENERAL A. C. BARNES, of Brooklyn, has undertaken to build and equip an astronomical observatory for Cornell University.

THE will of the late Signor Villeneuve of Montreal, leaves \$25,000 to Laval University.

THE sum of about £100,000 has been subscribed toward converting University College, Liverpool, into Liverpool University.

MR. CHAMBERLAIN has asked the city of Birmingham for a contribution towards the maintenance of the new engineering buildings of the University. It appears that Nottingham contributes £7,380 a year to Nottingham College, that Sheffield gives nearly £6,000 a year to Firth College, that Leeds gives £1,500 a year to the Yorkshire College, that Manchester gives £1,100 a year, and that Liverpool gives £1,800 a year to University College, and has in addition given land worth £30,000.

As we recorded last week the National Council of Education did not adopt the report of its committee on a national university. The National Educational Association passed the following resolution, offered by President R. H. Jesse, of the State University of Missouri :

Resolved, That this Association hereby reaffirms its former declaration in favor of the establishment by the National Government of a national university devoted not to collegiate but to true university work.

THE Berkeley correspondent of the New York *Evening Post* reports that the summer session of the University opened with a registration of 720 ; but as some schools have not yet closed, whose teachers are to join the attendance later, the total attendance is certain to pass 800. To this body of students sixty-eight courses are offered by forty-two instructors. Last year there were 433 students and twenty-five instructors, the latter giving thirty-five courses. In 1899 there were 161 students.

THE chair of geology and natural history in the University of California, held by the late Professor Joseph Le Conte, will, it is understood, be divided, Professor Andrew C. Lawson being placed in charge of the geology and associate Professor William E. Ritter in charge of the department of zoology.

THE professorship of astronomy in the University of Missouri, which has been vacant since the resignation of Professor Milton Updegraff, to accept appointment in the United States Naval Observatory at Washington, has been filled by the selection of Dr. Frank H. Seares, of California, now studying in Paris. Dr. Seares is a graduate of the University of California.

PROFESSOR WILLIAM ESTY, of the University of Illinois, has been appointed assistant professor of electrical engineering in Lehigh University.

DR. E. C. LUNN, of the University of Chicago, has been appointed instructor in mathematics and astronomy in Wesleyan University.

PROFESSOR JAMES P. C. SOUTHALL, M.A. (Virginia), of Hobart College, New York, has been appointed associate professor of physics at the Alabama Polytechnic Institute, at Auburn,

filling the vacancy caused by the resignation of Professor H. H. Kyser. Professor Southall was for three years instructor in mathematics and physics at the University of Virginia. He has been professor of physics at the Miller Institute, in Virginia, for five years, fellow and associate in physics at the Johns Hopkins University, and for two years professor of physics at Hobart College, New York.

THE usual twenty fellowships have been awarded at the Johns Hopkins University, including the following in science :

Arthur Byron Coble, of Lykens, Pa., A.B., Pennsylvania College, 1897. Mathematics.

Rheinart Parker Cowles, of Los Angeles, Cal., A.B., Stanford University, 1899. Zoology.

Charles Fowler Lindsay, of Halifax, N. S., A.B., Dalhousie University, 1899. Chemistry.

Robert Edward Loving, of Wilmington, Va., A.B., Richmond College, 1896. Physics.

Benjamin LeRoy Miller, of Oskaloosa, Ia., A.B., University of Kansas, 1897. Geology.

Louis Alexander Parsons, of Burlington, Ia., A.B., Iowa State University, 1895. Physics.

Dorothy M. Reed, of Leyden, N. Y., B.L., Smith College, 1895, M.D., Johns Hopkins University, 1900. Pathology.

Daniel Naylor Shoemaker, of Fair Haven, O., S.B., Earlham College, 1894. Zoology.

William Stone Weedon, of Baltimore, S.B., Maryland Agricultural College, 1894. Chemistry.

THE following appointments to fellowships and scholarships in physics have been made in the University of Nebraska :

Fellows : W. B. Cortmel, Case School, Cleveland ; F. T. Bates, University of Kansas. Scholars : L. B. Tuckerman, Adelbert College, Cleveland ; I. Summers, University of Missouri ; S. Williams, Iowa College, Grinnell.

DR. ISAMBARD OWEN has been elected principal of Cardiff College in succession to the late Viriamus Jones.

THE Council of University College, Liverpool, has elected Edgar Walford Marchant, D.Sc., senior demonstrator at Finsbury Technical College (London), to the lectureship in electro-technics vacated by Mr. Alfred Hay's appointment to a professorship at Cooper's Hill.

At the very outset of this discussion is encountered a great difficulty. What is culture? The writer has been asking this of his friends. An answer has been sought for in the printed page where is recorded the best thought of the best minds. Great thoughts and lofty ideals have been disclosed, but nowhere has been found a satisfactory definition, a phrase or paragraph that succinctly and clearly sets forth the heart of the matter.

People often recognize, appreciate and reverence its possession without being able to fully analyze and set down its elements. There is something subtle and emotional about it that eludes a close pursuit.

The reason for this perhaps lies in its essential individual quality, in its being the result of a personal life, developed, it is true, on lines similar to those used in other lives, yet including something that pertains exclusively to the human unit that is different from all other units.

Nevertheless, there seem to be certain fundamental qualities which must be possessed before a man can be classed with cultured people, qualities which are only acquired after a considerable experience in

*Address of the President of the Society for the Promotion of Engineering Education, Buffalo meeting, June 29, 1901.

life, but which are influenced greatly by the years of student training and therefore fit subjects for discussion here. Far be it from the purpose of this paper to attempt a definition of culture or a setting forth of its elements in any completeness; rather the emphasizing of some things that relate to it, especially with reference to the education of young engineers.

First: The man of culture must be a thinking and reflecting being. There must be not only the ability, but the habit; and this is no easy thing to acquire. Modern American life is full of hurry, full of affairs that demand instant attention, and one matter follows another with rapid succession. We get news from Pekin to-day, from Havana to-morrow and from the Philippines within a few hours. We build railways, erect bridges and fill large orders for locomotives for foreign shipment in such short space of time as to astonish the world. Men seek short cuts to fortune. In the popular opinion, the men who act quickly, the men of decision, are those who succeed. But there is a danger here. For, back of the action, behind the sharp decision, must lie a mature judgment, and how else is this to be formed except as a result of deliberate reflection. However quickly one may reach a conclusion, its correctness or faultiness will depend not on intuition, but on the degree of true comprehension. The decisive act which is also right rests on a process of thinking and judging that has been long fostered, until it has become a habit, until there are established certain standards by which things are to be measured.

The early steps of this training are necessarily slow, and we, as teachers of engineers, must recognize this and not yield to the temptation to crowd our students over too much ground on the one hand, or, on the other, to lead them through short cuts across country by empirical paths that may give

them ease and quickness of travel, but little or no reason why the path is chosen. Let them go the long road. I do not by any means wish our teaching to be non-practical—rather more practical in the best sense; but first, last and all the time, let students be trained to do their own thinking and to form their own judgments; to test the statements of others by the workings of their own mental processes.

Second: There is another element of culture that comes in here, an ethical one, that of forming right judgments. Men may have the appearance of culture without its true spirit, which is essentially honest. This is especially important, as culture seeks to make a man's life satisfactory to himself when measured by his own conscience, as well as successful in the field of affairs. So his standards must be based on sound principles of right and wrong; and it is only when these are so placed that his life becomes one of freedom, freedom from the bondage that wrong thinking and acting always bring. A class room is no place to preach a sermon, but there can be there imparted a respect for truth and perfect honesty. A teacher's attitude should always be open and frank, that of a sincere seeker after truth. He should never dodge an honest question, and be ever ready to say 'I do not know' if he does not. There is an incalculable power that 'makes for righteousness' and the happiness of the after life of the student in the true teacher's conduct of even such a material subject as mechanics.

Back behind the subject with its subdivisions, its formulæ and rules, lies something larger, a sort of spiritual quality that binds it to all other subjects, to the universe as a whole, and makes it a part of the truth of God's realm. The student that gets hold of this significance learns much more than facility in the manipulations of processes or the application of principles. He gets some-

thing that makes his life richer and better and his mastery of the subject more complete.

Third : There can be no true culture for a man that does not work, that does not put his cultivated powers to some useful service : and here there must be such degree of mastery over the chosen profession or business as will result in a special skill and dexterity—a doing of some one thing better than others can do it. A man expresses himself through his work, and whether he will or no, he thus discloses to all who know him his own peculiar qualities. It is this intensity of application, this concentration of purpose and directness of aim, that gets the world's work done. Here in early years the engineering student has the advantage of the student in arts. Study for knowledge's sake may be stimulating to the few, but for the many there is needed the goal of a special calling to secure the close application that results in ability to concentrate one's energy to the attainment of a certain end. But here again comes a danger, that of too early, or over, specialization, and the following of short cuts to professional life that are advocated by some who, in the eyes of the world as well as in their own, have been eminently successful as specialists. Whether these can be called men of culture of the highest attainments is another matter. The extreme specialist may be supreme in his own line of details, but may fail when there comes up a question involving the relation of his specialty to other things. Even within his own domain, his conclusions will be modified by his general knowledge and experience. All one-sided people, whether they be linguists or naturalists, poets or merchants, preachers or engineers, are quite liable to the forming of erroneous judgments. To the few geniuses, whose capacities and powers seem to be abnormally developed, though of limited scope, much is forgiven ; but for

the average man of the day there is demanded an ability to form good and wise conclusions.

Fourth : In order to form those that are appropriate and correct there is needed, then, breadth of view—a quality that has been expressed by the word poise. A man of poise, of even balance, will see things in their right relations and due proportions ; he will weigh matters, giving to each component part its just degree of importance. He will the better understand the motives that underlie other men's actions and the more readily use them to suit his own purpose. He will be more apt to rightly interpret the new movements in the world of thought or action and can seize opportunity for a personal advantage or a larger sphere of service before others see that there is such.

This demands a considerable range of knowledge. Not the close mastery of many lines in all their details, but a fair degree of familiarity with their general phenomena and principles ; and there is scarcely any field that will not contribute something to the result. It is admitted at once that the average man is of limited capacity and unable to grasp a comprehension of all knowledge that may influence his life and work ; what is pleaded for is such degree of breadth as may be needed to make one of great efficiency in his chosen profession and of most value to himself, not only in a financial way, but also in the sense of gaining a joyful recognition of the worth of developing all the powers that one has.

The value of mathematics and the physical sciences with their applications to technical things needs no discussion here, for these are the engineer's tools ; but it is a fair question whether, in our desire to graduate students that can be early useful, we do not place too much stress on technical things to the exclusion of others that give greater breadth of training. We must

not forget that we are educating men for a life; that we must look forward to the time when these young people will be fifty years old, and at the period of their maximum productiveness as workers and of maximum value in society and as citizens.

Engineers have to deal with other things besides materials and physical laws; they must manage men and matters of finance. If they are to rightly influence those whose capital they are employed to expend, they must be able to meet them socially and intellectually, to discuss intelligently matters outside the pale of strictly professional life. Evidence of professional ability and skill is of course first demanded, but breadth of culture creates an added confidence in the wisdom of the conclusions reached and the advice given.

Heretofore much of our engineering work has been concerned with the opening and developing of new country or new business and industrial enterprises. So engineers have found their work away from contact with men. But engineering practice is changing, as conditions become older and more settled, and more and more practitioners find their work in communities and busy centers of trade where they are constantly thrown into close contact with strong and cultured men. Present engineering courses do little to prepare a man for this thorough instruction concerning human nature and human relations. Something of history, economics and sociology should be included.

Fifth: It is not sufficient to form correct judgments only; there must be added a skilful and effective presentation of them in well chosen and fitting English. The ability to do this involves more than training in the writing of compositions, themes, forensics and reports. The cultured man should have a taste for reading the best that has been written in his mother tongue, and for several reasons: The great

thoughts of great minds are stimulating and broadening to his own mind; he thereby absorbs a knowledge of words and their shades of meaning; he gains an appreciation of style and insensibly better knows how to form his own; and, not least by any means, he makes of his books friends that are life-long, that cheer and console him under all happenings, adding much to his internal resources for happiness.

The time given to English in our courses is not enough to train students properly in its use and at the same time open the doors to our best literature. It may be said that all this English work should be done in the preparatory school, and it is probably true that the character and quality of the high-school English is better to-day than it has been heretofore. Yet it seems to me that engineering students should have some training of a college grade along the line of literature.

Sixth: To the writer's mind, there is another element of culture that should enter into an engineer's training, viz., an appreciation for beauty. As he has said at another time* the engineer is a designer, and it is important that he should embody his design in artistic form if he is to fulfil his whole mission and please and gratify others by the perfection of his work. The engineering student devotes a good share of his time to the drawing-board, and much can be done here toward the cultivation of this quality by an instructor who possesses it, without lessening at all the amount or force of the technical exercises for which the process is primarily used. There should be, however, something further by way of giving instruction in elementary aesthetics and by opening the students' eyes to what is beautiful in nature.

Seventh: The possession of agreeable manners and tact is another evidence of

* *Proceedings* of the American Association for the Advancement of Science, Vol. 45.

culture. Not merely the conventional bearing of polite society, though this has its value. This alone is but a husk which must cover the real kernel, refined and gentle feeling; and such feeling is the result of moral and intellectual convictions. Manners, then, are not to be taught from a text or by lecture; they rather follow as a consequence from the whole course of training and are crude or refined, just as the character of the instruction makes them. The teacher's personality has very much to do with this matter. If he is of coarse grain, of domineering or selfish disposition, his influence will not tend toward the production of true gentlemen.

And now for the real question—does engineering education tend to produce culture? According to old standards, when men limited culture chiefly to a knowledge of language, literature and philosophy, the reply would be in the negative. However, standards are not the thing itself, only methods of measurement; moreover, standards change. Science has modified and is still changing the ideas of culture that men hold, and this evolution makes it all the more difficult to find a common ground upon which all can stand when considering things concerning it. This much is clear, however, that no one existing course of educational training has a monopoly of cultural methods; nor will the completion of any college course necessarily secure its attainment because of its personal quality. Further, culture is the result of a life, and the most that can be expected of a college course is to open the students' eyes to its real worth, to start them rightly with certain leanings and aptitudes, and furnish them with the means of a continuous growth toward its maturity.

It is maintained that an engineering course can tend in this direction, and that in some of our best colleges, under the instruction of people themselves cultured,

it does so tend to-day. Our best engineering courses are stiffer and more exacting both as to time and effort than those in the college of arts, and the resulting acquisition of mental power and the ability to focus it proportionately greater.

The fixed course with its correlated parts and the certain definite end to be strived for are advantageous. The training is a continuous testing and trying of the truth of knowledge, and teaches the student to ask 'why' and to reflect. He gains respect for nature's laws, and learns that his professional success will depend on his ability to work in harmony with her. He gathers a fair degree of knowledge of himself, his strong points as well as his limitations. He acquires a habit of thought and action that leads to further growth. He learns how to adapt means to an end, and within what limits of precision to work that it may be reached with economy. In short, he becomes a trained and educated man, cultured to a certain degree, but with limitations; just as the arts student who has specialized to a like degree in language and literature, with little of science training, becomes cultured, but also with limitations. Let the latter retain his A.B. On the other hand, let it be recognized that the engineering B.S. stands for culture as well, of equal worth and value, though of different kind.

As between the two specialists, I think the advantage lies with the engineering graduate as being on the whole, better equipped for a life of useful service and one that will possess the greater capacity for further development.

As one looks forward ten or twenty years and attempts from present tendencies to forecast the work and social standing of engineers, he must see that the profession will be doing a larger work and exerting a greater influence.

Further, that an engineering training will be more and more recognized as the one best

fitted to lead to positions of an executive nature in connection with industrial enterprises, and in the administration of public works. Everywhere will be demanded expert skill, sound judgment and broad views, primarily because these will be found to be economical. The entire class of men that a recent writer has called 'mattoids,' the ill-trained, narrow and egoistic, will be pushed out because their service is costly.

There are two tendencies in the present-day engineering education that are, in my judgment, opposed to the desirable result. First, a tendency to crowd too much of the foundation work back upon the preparatory school, already overloaded. This Society's Committee on Entrance Requirements has advocated a standard which is high enough. Second, the allowing of technical subjects to crowd the fundamental general ones from the college course, in a vain attempt to do what from the very nature of the case cannot be done, make an engineer by college study. The result of this in some institutions is further seen in too early a differentiation between the various engineering courses; so that, for instance, the civil student knows nothing of applied electricity and the electrical student nothing of surveying, while neither has a chance to acquire a taste for literature.

The whole problem is an involved and complicated one, but there is a way out that must be found if the engineer is to fill the important place that awaits him. One part of the solution will be probably found in a refining of the methods of instruction, so that better results may be reached in the same time. In the end, however, the writer thinks that there must come a deeper sense that after all life is long, that it should be taken with more of deliberation, and that it is the end that is important, rather than the beginning. The feverish rush and haste to be earning must be re-

placed by a recognition of the real necessity for a full rounded-out preparation if the largest and best service is to be given. Then the student will be glad to spend the one or two extra years in college that may be demanded. The wise student now will do this without its being required.

The Chief Justice of my own State has said, "The spirit of an age is that which makes finally for the happiness of the race. I have absolutely no fear as to the final end of things, nor as to the steps and incidents of evolutionary development. The aspirations, the great universal possessions of a people, can never move them to other ends than their happiness and good. The spirit of this age is commercial enterprise and conquest, and as to it I have an unspeakable conviction that it will, as the spirits of other ages have done, work itself into forms and institutions of beauty and eternal worth to men."

It is largely through the engineer that this is to be done. The finest result requires the most skilful labor; the noblest workman demands the most fitting training.

Herein lies our responsibility!

FRANK O. MARVIN.

UNIVERSITY OF KANSAS.

PHYSICAL CHEMISTRY.*

As I am to deliver in the course of the next few days a series of lectures upon some parts of physical chemistry in their details, I should like to use this educational conference as an occasion for presenting an introduction to my lectures.

I add at once that one of our best modern historians, Ladenburg, in his 'Development of Chemistry in the Last Twenty Years,' sustains that the more and more prominent position of physical chemistry characterizes the development of our whole chemical

* An address given at the decennial celebration at the University of Chicago, published in the *University Record*.

science during the last twenty years. Let me briefly trace how this physical chemistry has grown, and what it is at present. Allow me in doing this to rely partly on personal observations.

When, as a student of the Bonn University, I studied chemistry first, about thirty years ago, under the guidance of one of the most famous men, Kekulé, chemical science had, according to our master, come to a dead point.

The existence of atoms, though an indirect chemical conclusion, seemed to have been well established, corroborated as it was by the conception of molecules—a conception which rested merely on physical grounds. The details about the mutual relation in which these atoms stood in the molecule either were already known, or in the case of complicated or new compounds a knowledge of them was but a question of time. Thus H_3COH was used to represent the mutual relations of the atoms in the molecule of a simple compound, methyl alcohol; that is to say, it was known that three atoms of hydrogen are held in some unknown way by the atom of carbon, the fourth hydrogen atom is held by the atom of oxygen, and this in turn again by the carbon atom. Yet all such formulas were merely schemes in the mind, or diagrams on paper, and chemistry was looking out for a kind of Newton who might tell us the laws which hold together these atoms in their constellations, the molecules.

You know as well as I that up to the present time this Newton has never come. Yet, only a few years after Kekulé's disappointing prophecy (which, by-the-by, a teacher should never express before his pupils) stereochemistry awoke, and is now a fully developed and well-founded branch of chemistry. By stereochemistry so much at least was attained that, admitting the existence of atoms, we now know to a large extent, not only the mutual *relations*, but

also the mutual *positions*, which these atoms occupy in the molecule. H_3COH becomes

That is, the three atoms of hydrogen and the atom of oxygen were found to be arranged in space around the carbon atom in such a way as to occupy the four corners of a tetrahedron, in the center of which the carbon atom lies.

But there we stood, and still stand, since more than twenty-five years, still ignorant of the laws to which their relative position is subordinated, though a recent attempt seems to me hopeful.

Nevertheless, research went on in a way which had very little to do with that architecture constructed by the mind whose building stones are atoms. So, fifteen years after Kekulé's discouraging prophecy, a second child of hope awoke, and this was physical chemistry. It did not appear at once—a scientific branch hardly ever does—it developed as a plant unseen in the shadow, till it felt the sun, and then grew up to be a giant tree.

Some, as Duhem, even say that physical chemistry is a third fundamental science, entitled to be placed between physics and chemistry. Others, like Winkler and Ladenburg, say that, to begin with, we might allow it a prominent place in chemistry and substitute for the division into the two branches, organic and inorganic, a division into three. It will be of interest to add that the University of Göttingen has recently organized the chemical department on this principle. But, apart from all principle of division, which in the end is always arbitrary, because our whole science, like nature, which it reflects, is only one thing, though rather large, we ask: What has physical chemistry achieved?

There are two ways along which a reply to such a question can be given. I might trace in outline the general conclusions, and might speak to you of the laws of chemical change, of reaction velocity, of electro-chemical processes, but I should not be able to do much without the use of a rather complicated formula, which the character of this introduction excludes.

The second way is of a special nature, and I will venture on it, to trace on what lines physical chemistry wrought out its conclusions and what success it met with. The particulars will apply to one of the best known and farthest reaching achievements, to the investigations on osmotic pressure.

Let me begin with that particular attraction for water which we find in some substances very familiar to us, say in ordinary burnt lime. If the lime is kept in a well-filled flask or bottle, which is not hermetically sealed, water from the surrounding air will be attracted by the lime. This will augment the volume of the lime, and the flask or bottle will eventually give away; a tremendous force is thus developed, too large, perhaps, to be exactly measured.

But, on a smaller scale, we may follow up quantitatively the analogous process with sugar, for instance, in a dilute solution, say a 1-per-cent. solution. This will attract water also, as may be shown by filling with the solution a flask, porous, but permeable for water only, and by placing this flask, when well sealed, in water. Then water will enter it till, if the flask holds, a pressure of two-thirds of an atmosphere is attained, as was measured by Pfeffer.

We may generalize and say every solution has the tendency to diffuse into the solvent as if it were attracted by the solvent, and this tendency will produce a pressure if the diffusion is prevented by a membrane. This pressure, for more than

a century studied as osmotic pressure, has a well-defined amount; it was known to vary with concentration, with temperature, and with the nature of the substance dissolved, etc., and this was all we knew about it until the way in which physical chemistry worked was applied to it. The result was so transparent that every student may now calculate readily for any dilute solution what its osmotic pressure is; for all may be summed up in this one expression:

$$P = 0.08 CT,$$

with P , the osmotic pressure in atmospheres, T , the absolute temperatures, C , the concentration or number of gram molecules of dissolved substance in one liter of the solution. The above value of the pressure for a 1-per-cent. sugar solution is, at once, got at by this formula. Let me only insist on the different way in which physical chemistry works as compared with stereochemistry. Physical chemistry does not seek the solution of problems by trying to reveal the constitution of matter, but it works out between measurable things relations to which the calculus may be applied.

This is not all. Looking upon the tremendous work which atomic chemistry has achieved, one must acknowledge that in research relatively little up to the present has proved of value as to what most interests us, the problem of life. Quite the opposite can be maintained with the lines followed up in physical chemistry; and even ten years ago, I used an occasion like this at Utrecht to point out the large part which this osmotic pressure, the laws of which physical chemistry revealed, plays in physiology.

I could indicate the result of many a physiological investigation, pointing to the fact that osmotic pressure is a fundamental factor in the most different vital functions in plant and animal existence. According to de Vries, it regulates the growth of the

plant; according to Daudres it regulates the functions of the blood; according to Mussart it regulates some functions of the human eye as well as the life of the most deadly infectious poisons, like the typhus bacilli.

Since then literature on the same subject has appeared which might fill a new and most interesting volume, in which the most startling fact up to the present would be the fact realized here by that splendid discovery of Professor Loeb, that the act of fertilization in lower organisms, as sea urchins, may be substituted by a given increase in the osmotic pressure of the surrounding medium.

And I may well quote in conclusion his summary that: "At no time since the period immediately following the discovery of the law of conservation of energy has the outlook for the progress of physiology appeared brighter than at present, this largely being due to the application of physical chemistry to the problems of life."

J. H. VAN'T HOFF.

PSYCHOLOGY AND THE MEDICAL SCHOOL.

IT requires only a minimum amount of consideration for a person thoughtful of the matter to recognize that in the most essential meaning of the proposition, psychology is the most fundamental of all the sciences: psychology discusses the mental processes whereby all perceptible nature is perceived. As long as men continually and of necessity study each other, subject and object alike in modes of consciousness, that body of related facts and principles concerning mind will remain basal, and, consciously or unconsciously, universal. Chemistry, for example, treating of the composition of matter, arrives at its analyses only through mental processes which it is the business of psychology to explain and to facilitate. Astronomy tells us of the planets and the stars, but the astronomer who is

consciously or unconsciously nothing of a psychologist may readily deceive not alone himself, but the scientific public, as has happened more than once. To the psychologist no longer 'seeing is believing,' as the ancient adage runs, for the nature of man unfolds itself apace and shows fold within fold undreamed.

Yet on other grounds than these, which are theoretical and philosophic, lies the interest of the science of psychology to all who have the opportunity to intelligently learn its principles—men and women value it and usually become more or less absorbed in it because it describes themselves, and, ever more successfully, attempts to explain what is and must ever be the most regarded of subjects to every agent, namely himself, as individual and as social unit. The biologic egotism implanted deep in every soul sees to it inevitably that all one's life, whatever the social status or the life-pursuit, that soul shall study continually itself, with however apparent indirectness or however elaborate the social system of real or hypocritical altruism may be. Indeed, altruism has nothing to do with the deeper aspects of the interest in question, this interest being beneath all altruism, in the organic mechanism. The degenerate criminal and the flower of ethical manhood play alike on the same fragile instrument, one miserably and the other with far better harmony; this instrument is consciousness and the changes that it manifests are constant in one only thing—it is I, I, I, the type, the sum. It is chiefly on this account that psychology is an interesting science.

But besides being the basal and an eminently interesting science, psychology is a sound science, 'new' but soundly scientific, a thoroughly self-reliant and deep-set department of systematized human knowledge. In substance older than Thales, known as methodical since Aristotle, yet

every century has added alike to its mass and to its dignity as a science, every year of late has better shown its interpenetrating relations with other topics of learning and dug its foundations ever deeper into the rock-based ground of human knowledge. From one point of view the science is sometimes at a relative disadvantage because it merges in its upper rarefied air with metaphysics and 'divine philosophy,' so that some have left it in their eagerness to loiter on the paths less fixed, less final; let us hope their wings will bear them there. It is as if the astronomer should become a dreamer wandering among his stars, hoping thus best to make out the almanac or to satisfy the yearning curiosity animating all men on the humble earth. In psychology as in astronomy it is the workers who count most, men and women to whom a sphygmograph or a chronoscope is an instrument as dignified as the pen which writes without experimental mediation the reasoned imaginings of the seer.

But there is a class of persons who harm the fame and progress of psychology among the mass of average men, and the injury these do is devoid of any sort of recompense. These are the irresponsible multitude who know little or nothing of science and who have no desire to know, quite, nay more than, satisfied if in one or the other of a host of shiny masks they can fleece a willing public either of their dollars or their sense, succeeding ordinarily in abstracting both at once. These are the 'mental healers,' the 'metaphysicians,' the 'Christian scientists,' the 'psychologists,' the astrologers, the palmists, the 'mediums,' and their ilk, all of whom more or less of the public consider in some way or other allied with the science of psychology. Mysticism of this grade is for the scientific student an absorbingly interesting topic of research, leading him meanwhile to wonder and to pray—wonder at the shal-

low deeps of the human mind, pray for the day to hasten when education shall be for all men, share and share alike, each according to his needs and his ability. Psychology bears the brunt, necessarily, of many a false system and falser creed whose names any who reads the signs along the pavement may learn full easily, the list above containing some of those most known. But the science of psychology looks on with serenity, complacently expressed with the consciousness that phenomena like these are part of its own subject-matter, to analyze and to explain. It is the public who are fooled and who wish to be, and them in turn, as the loci of ever-recurring phenomena, psychology studies and characterizes. Deplorable indeed is the ignorance of the mass of men, even in America, concerning this science. To many the name means psychical research, to others some phase of mental healing, to others something, which, chiefly because spelled p-s-y-c-h instead of s-i-c-h, can never come within their knowledge, to others, finally, nothing whatever for they never heard the word.

But even among the educated, too often the notion of this science is such that it is not valued at its proper worth, because its *practicality* is too little understood. Here is suggested one of the future duties of the psychologist—it is time that he demonstrated to the world, the great world as well as to the lesser world of letters, that psychology is properly a very practical science, thoroughly useful to the average man. It is on this basis alone that it is worthy of life. A science seemingly should not be classed with belles-lettres or with pure philosophy, as the means of satisfaction of man's eagerness for abstract knowledge or for an understanding of the æsthetics of existence. These things may in one sense be more than science, but they are at the same time in a different sphere and incomparable. The

progress of the race depends not on the products of pure reason ; did it so depend Plato and Kant would be more than names to the millions of our countrymen, and this splendid Greek of so long ago would be the world's idol in the place of the men who have *done* things and who *do*. Men at large desire science rather than philosophy, for to them rightly the sciences mean progress in living ever better and more easily. Utility is and must remain the unchanging standard by which a science, like all other things in the last resort, is measured. This fact many psychologists apparently have overlooked, so brief at present has been the time since their science freed itself, by working out the outlines of its proper sphere, from the conservatism of philosophy. Right well and exceedingly is psychology fitted by its subject-matter to demonstrate and then to enlarge its human usefulness. By necessity of the 'struggle for existence' (so inevitably often emphasized in every sociological discussion), all men are psychologists and not less so that only one in a million thinks of himself as such. Somewhat in proportion to his practical success as a psychologist, consciously or unconsciously, in proportion, that is, to his knowledge of his fellow-men and of himself, does a man or woman succeed in life. It means more than anything else this wisdom in human nature. The schoolboy knows his teacher more or less well as he recites to him or seeks to win his favor ; the candidate for the doctorate very likely has studied the faculty only less than his research, and at the time when each word counts he uses well his information. The merchant studies the man from whom he buys his stock, and doubtless still more carefully the 'market,' which is only a convenient term for the balance of the hour between merchandise and men's desire therefor. The business man depends even more largely on his knowledge of human nature in his dealings

with a public which is always more or less suggestible. The actor studies humanity that he may imitate it, the conjurer that he may deceive it. The judge in court is pre-eminently a practical psychologist, the policeman less so, while the value of the jury system and the virtue of a particular juror often depends directly on the jury's rightly weighing the human probabilities of motive and of action. Such values are practical and real.

But more than others, if possible, 'professional men' should be good, that is, practical, psychologists. They should understand completely the psychophysical nature of men and women to be successful. The clergyman must preach the Gospel, but he must preach it both in the spirit of the times and in the spirit of his hearers—not preaching hell-fire when the advancing rationality has put hell-fire forever out and named it cruelty ; not preaching sermons two hours long when men in general might fairly be satisfied with half-an-hour. So too the lawyer (and in a perhaps even larger degree) must be a psychologist, whether he knows it or not, if he is to please his client and enlarge his practice. He must know well the relative value in a particular man of feeling and of cognition, must value rightly his client's strength of will and perhaps his cleverness under cross-examination. In every phase almost of the lawyer's professional life his knowledge of himself and of man in general forms his chief stock-in-trade. The lawyer's success largely depends on his acquaintance with man's mind and how it works—his science above all is the 'science of the soul.'

To medicine, the third of those pursuits long classed as professions, we now turn to see how, in a more immediate way than has so far been considered, psychology is naturally related to it. Like other men, the physician is of course a practical psychologist so far as his native instincts lead him

to become so. For reasons, however, which will be pointed out below, the medical man needs a more exact and systematic knowledge of the relations of the human mind than the hereditary common wisdom of the race provides him with, while at the same time his opportunities for acquiring this knowledge at present are either entirely lacking or quite impracticable for the average practitioner. It is a fact that the men who, for the public benefit, require the largest amount of insight into mind and its relations with body, have had thus far the least convenience for acquiring it. This condition is probably a relic of that same ancient fallacy so very frequently encountered everywhere, that material objects (here the tissues of the body) are more real and more important than things which are immaterial, ideas and emotions and the determinations of the will. Yet most old men and women would tell you that these latter things had influenced their lives far more than matter of any sort whatever. For every person maimed by a material accident a dozen are maimed by some one's will or emotion or idea.

The physician needs some direct acquaintance with the science of psychology, because, in part, he is properly the self-elected teacher of the public, and to every teacher, of whatever sort, psychology is by reason of its nature necessary foundation-knowledge; to argue otherwise is sophistry, convincing to none. The average physician, that is to say, most physicians, are not teachers of the public in hygiene, physiology and general prophylaxis to half the measure that they might be, some from inability, some from thoughtlessness, some from 'inertia,' some possibly from indisposition so to do. But this duty of the medical man is a privilege and its compensations out of proportion to its costs. Herein lies the general affection for the old-time family doctor, the most contented and best re-

quited of his profession, the friend and confidant rather than the hireling of his neighbors. Practical psychologist that he was, when he entered a house, patient and household at once felt better even though death were near.

In ways, however, more immediate to his cases than in this position as medical educator to the public does the physician need to know the principles of modern psychology in a broad meaning of the term. He requires it because always in his practice he is concerned with living and social organisms who invariably are compounded of *both* body and mind. As regards the wholly obvious necessity of acquaintance with the normal mind for the many medical graduates who pay chief attention to mental and to nervous diseases, much might be said, although little will be, here. Even these, alienist and neurologist (although usually versed more or less, late or soon, in the substance of empirical psychology, while some are competent and even distinguished psychologists), even specialists in the mind, have at present no adequate opportunity to learn the substance of the science in a thorough systematic way. Many of our distinguished alienists have enjoyed a general college education and some have been led by the psychology learned meanwhile to 'specialize,' when their medical degree was acquired, in the diseases of the mind. But these educational privileges are relatively infrequent and with our present system of college education must remain so some time, most medical schools being not yet, by probably many years, post-graduate institutions. Yet insanity appears, by reliable statistics, to be on the increase; and to meet the certain demand for the care and proper treatment of these patients, a larger proportion of all medical graduates will, by economic principles, devote their attention to this most important branch of therapeutic science.

To meet the necessities of this class of practitioners alone the establishment in the medical schools of courses in normal medical psychology is urgently demanded. To graduate a psychiatrist without this knowledge is like pretending to qualify a general practitioner without teaching him physiology. Exceedingly few of the graduates, eager to get at actual cases, and the best of them soon enough crowded for time, will or can take up the long-drawn unadapted psychological courses in the universities and colleges, nor, did they desire to do so, would funds be often at their disposal, the debts of the young doctor being often, as it is, quite sufficiently appalling to the young man anxious then to earn as fast as possible. For the sake of these men alone, then, courses in medical psychology should be provided where alone they will be studied with the splendidly productive medical-student eagerness and attention.

The education given, or rather sold, to the medical student seems in general, however, too grossly materialistic, too somatic. He learns but one side of this two-sided story; from the first year to the fourth, from the dissecting room to the gynecological or otological clinic, the routine student sees and hears of muscles and bones, and viscera, sense-organs, nerves and vital fluids, but little, unaccountably little, of that other aspect of men and women which to these very men and women is their life, while these other, these organs, are but needful instruments of that life's attainment. And their point of view, it need not be said, is also that of philosophy; shift it, and illogical confusion follows. The layman cares little or nothing for his stomach's condition so long as it gives him no pain and takes good care of what his will and his appetite lead him to supply to it. The woman in search of a happy family life thinks seldom of her reproductive mechanism so long as it gives her healthy children whom she can love.

There is something besides cell-built tissue for the gynecologist in charge of an operative case to consider when of two women, alike in vigor, who undergo identical ovariectomies, for example, one goes in three weeks from the hospital a new woman, cheerful, capable and happy, while the other becomes an hysteric wreck never perhaps to equal her former self in happiness or in health. As every surgeon knows, such differences are met continually and they puzzle him. Why is it that present medical education takes no account of the principles underlying phenomena like this? So far as the student is concerned, the course, four years or three years long, quite ignores in general the emotional and temperamental factors which in one way or another, directly or indirectly, less or more, enter into almost every chronic case and into many of the acute cases which the general practitioner is called upon to treat. Instead of striving to teach the student what conditions underlie mental habits and idiosyncrasies, medical instructors are now content practically to ignore them, regardless of possible great benefits to come from their study as psychological data. Too often is the medical man the most materialistic-minded member of a community, when his view should be much deeper, into the controlling forces of life. This is the natural outcome when in a long medical course no part of the individual is presented to the student except what he can feel with his hands or see through the microscope. Yet how commonplace is the assertion that the man, the real man or woman, is not his or her body, but the will, affections, habits, character, of the individual, while (what is more immediate to our argument) these same aspects of consciousness are often the direct molders or destroyers of disease and, as one side of an inseparable psychophysical organism, have more control or influence over the functions purely somatic

than the average practitioner of medicine appreciates. Not mind controlling body nor body controlling mind, but both together always sensitive to the stimuli of a common environment combined into the actual individual.

The conventionalized and systematized knowledge of conditions thus important in treating disease is a portion of psychology. Crude indeed are its names and its conceptions as crystallized in names compared with the empirical reality, but it is of necessity that they are crude and only representative or symbolic that a science may be constructed and discussed. A new medical psychology adapted to its special usefulness would very soon develop a terminology of its own, fitted to the case. The term temperament, for example, vague and little really explained by general psychology, would, as a subject in medical psychology and in the minds of physicians, soon take to itself more explicit meaning, adapted to its use. By this natural process of specialization of sense medical psychology would suffer relatively little from that variation in meaning among different writers, from which general psychology (from the abstract nature of its matter) suffers much misunderstanding within itself. By thus fixing the meaning of certain terms, and that probably in more or less direct relation with concomitant somatic conditions, medical science would do a distinct service to empirical and physiological psychology, and more substantially than any dictionary could do it.

A normal medical psychology, to be at once scientific and comprehensive of the field, would very likely set out with a relatively brief exposition of genetic and of empirical psychology, discussing thus in certain and uninvolved terms the classification of mental processes under cognition, feeling and will in the ordinary elementary way. The more physiological in nature the treat-

ment of this portion of the subject, the better would the medical student connect it with his knowledge of the body gained earlier in his course. With these principles of the science as a basis and point of departure into allied branches of science, the topics more immediately practical to the physician might be taken up in a series as much unified logically as possible. In this, the immediately practical portion of the work, the field would naturally and necessarily spread out somewhat so that it would be important to enter briefly at times into anthropology (anthropometry especially, perhaps), criminology and certain departments of biology, notably that regarding the heredity of mental traits. Still, obviously, the greater part of the discussions would lie strictly within the domain of psychology as it is empirically studied to-day, using for its own purposes, as it does, the products of many different varieties of scientific research.

The topics of medical and surgical importance which such a course might examine into with benefit and interest are very many, as any medical man will recognize. They are subjects such as those below are examples of, placed here almost at random so far as order is concerned, namely, temperament, mood, idiosyncrasy, pleasure, pain, emotion, anæsthesia, hypochondriasis, dynamogeny, will power, sleep, subconsciousness, habit, sexual, racial and epochal differences, suggestibility, hallucinations and other scarcely abnormal phenomena of the sense-organs and their neural centers. To mention only suggestibility, the habits and sexual psychology out of this list will perhaps be sufficient to show how important a course treating of such topics might be made by a competent man. Continually is suggestive therapeutics taking a larger share in the treatment of certain chiefly psychical diseases, and to explain its nature, uses and limitations is to equip every physician

better than now he is equipped. Again, who could exaggerate the importance of the habits in causing misery and in curing it? And lastly, in these days sex is taking ever more rapidly its proper place in the science of 'things as they are,' monstrous often to the layman, and properly, but to the physician natural and preeminently important. A widely related discussion of such topics as these, it seems to the present writer, would furnish to a medical student of the necessary mental development, facts and relations as important for his professional purpose as most of those which are at present taught him. Such a course would do much to supply the lack of knowledge of man's dual nature, which, as has been sufficiently suggested, usually obtains in the average physician. This would be its chief value in a medical curriculum, but not its only one. It would also supply that needful amount of psychology which would allow the usual courses in psychiatry and neurology to be better appreciated and more completely understood, especially of course as concerns those conditions, such as hysteria, neurasthenia, paranoia, dementia paralytica and the rest in which a purely 'mental' aspect is often or always prominent. It would help to make such conditions really understandable so far as their description at least is concerned, whereas at present, the ideal disturbances, notably in paranoia (very commonly met with), are far beyond the understanding of the medical student, for lack of acquaintance with the theory of normal ideation. It would make such conditions seem like scientific problems pressing for his solution rather than like mere arbitrary sets of ill-understood events which he must learn by rote and the memory of which, when occasion offers, he must mechanically apply.

In form such a subject might easily be comprehended in a course of weekly lec-

tures during the former half of the fourth year of the medical curriculum, either elective or required. It need involve of course no laboratory work, nor would this be fitting, sufficient demonstrations being used to illustrate certain points and to increase still more the students' interest.

It is not difficult to understand why something of this sort has not already been introduced, instruction which would impart the suitable product of the progress in these directions in the last few years. The progressive spirit of the various medical faculties has been employed of late, for the most part, in establishing departments of bacteriology, pathology and experimental physiology, and in enlarging various modes of clinical experience. These have now in all schools of the first class become flourishing departments, demonstrating well their importance. Thus other fields have naturally been neglected in these new years of the sciences of the bacteria. It seems time now that the growing energy of the medical schools should look around more widely and realize, with practical benefit, that if emotions cause at times disease as well as the bacteria, so it is equally important that the conditions of the one should be taught the student as well and as certainly as those of the other. Not at once as a universal means of progress will this enlarged and more scientific mode of viewing every patient be shown the student of the medical sciences, but assuredly it will come, and in some form not wholly unlike that which has here been all too rudely sketched and for reasons similar to those here pointed out. Such a course by a psychologist of wide interests and information among branches of learning of allied aims, a medical man if possible, would seem to be worthy at least of trial in every medical school whose avowed purpose it is to provide its graduates with a knowledge of men as they are, and not

alone to furnish them with the science of one-sided and therefore false somatology.

GEORGE V. N. DEARBORN.

TUFTS COLLEGE MEDICAL SCHOOL.

*THE BOTANICAL WORK COMMITTEE.**

A BLUE-BOOK (205) of 247 pages has been issued containing the report of the committee on botanical work and collections at the British Museum and at Kew. The Committee was appointed by the Treasury on February 1, 1900, 'to consider the present arrangements under which botanical work is done and collections maintained by the Trustees of the British Museum, and under the First Commissioner of Works at Kew respectively; and to report what changes (if any) in those arrangements are necessary or desirable in order to avoid duplication of work and collections at the two institutions.' The chairman of the committee was Sir Michael Foster, M.P., and the other members were Lord Avebury and Mr. F. D. Godman, representing the Trustees of the British Museum, Mr. S. E. Spring Rice, C.B., Mr. H. A. D. Seymour, C.B., Professor I. B. Balfour, Queen's botanist for Scotland, Mr. F. Darwin, reader in botany in the University of Cambridge, and Sir John Kirk. Mr. B. D. Jackson, secretary of the Linnean Society, was afterwards appointed secretary to the committee. The report opens by pointing out the essential differences between the Botanical Department of the British Museum and the Royal Botanic Gardens at Kew.

The former is a collection of such objects as can be placed in a museum, and is not concerned with the applications of botany; whereas the latter, besides constituting a public garden, is an organization which gives assistance to the government on questions involving botanic science in all parts of the Empire. Both possess herbaria with

libraries attached; and the two herbaria, though each possessing some special features, are to a very large extent duplicates of one another. This duplication of specimens entails, of course, a duplication not only of housing room, but of scientific work and of the scientific staff; and the existence of this waste is a strong *prima facie* argument against the maintenance of the collections in their present form. The report observes that the question of amalgamating the two collections has been considered by committees again and again, and after considering the arguments urged on both sides, the Committee, with the exception of Lord Avebury, pronounce in favor of their union. Their report discusses at length the possible methods of union, the relative convenience of Kew and the British Museum as sites, and the question of constituting a special advisory board, on which the Trustees of the British Museum should be adequately represented, in the event of the removal of the greater part of the British Museum collections to Kew. The recommendations on these points are summed up as follows:

(1) That the whole of the botanic collections at the British Museum now administered by the Keeper of the Department of Botany under the Trustees, with the exception of the collections exhibited to the public, be transferred to the Royal Botanic Gardens, Kew, and placed in the charge of the First Commissioner of his Majesty's Works and Public Buildings under conditions indicated below, adequate accommodation being there provided for them. (2) That a board, on which the Trustees of the British Museum, the Royal Society, and certain departments of his Majesty's government should be directly represented, be established in order to advise on all questions of a scientific nature arising out of the administration of the gardens, the powers and duties of the

*From the London *Times*.

board, its relations to the First Commissioner and to the Director, as well as the position of the latter and the functions of the gardens, being defined by Minute of the Lords Commissioners of his Majesty's Treasury. (3) That the illustrative botanic collections now publicly exhibited at the British Museum be maintained, and, so far as it is possible and expedient, enlarged and developed with the view of increasing popular interest and imparting popular instruction in the phenomena of the vegetable world, and be placed under the charge of an officer of adequate scientific attainments, responsible to the Director of the Natural History Departments. (4) That upon the transference of the botanic collections from the British Museum to the Royal Botanic Gardens such arrangements be made both in respect to the accommodation of the collections and the staff administering them that they shall fully serve the purposes which they have hitherto served. (5) That the botanic collections consisting of fossil plants, now in the charge of the Keeper of the Department of Geology in the British Museum, be maintained for the present under the same conditions as heretofore. We desire to express our warm appreciation of the valuable services which have been rendered to us by the secretary, B. Daydon Jackson, Esq., secretary of Linnean Society. Not only has he performed his duties as secretary with great zeal and ability, but also throughout the inquiry we have repeatedly derived great assistance from his very intimate acquaintance with the botanic collections under our consideration, as well as from his wide knowledge of botanic science and literature.

This report is not signed by Lord Avebury, who cannot concur in recommending a removal of the British Museum herbarium to Kew, for the following reasons:

It seems, no doubt, at first sight, an an-

omalous arrangement that there should be two national herbaria; first, on account of the expense; and, secondly, because botanists in some cases have to consult two collections instead of one. But the evidence shows that the saving of annual expense through the suggested fusion would be small, and that the initial outlay for building, cabinets, etc., would be heavy. The alleged inconvenience seems to me to be exaggerated and affects only a few of those engaged in systematic botany who are thus obliged to consult two herbaria instead of one: while, on the other hand, to those engaged in other departments of botany, the existence of the two herbaria is an advantage. I deprecate the proposals contained in the majority report for the following reasons: (1) The British Museum is the greatest museum in the world, and is justly the pride of the nation. To dismember it, by depriving it of so integral a part as the Botanical Department, would be destructive of its unique character as a fully representative museum, and specially of a natural history museum; would be vehemently opposed by many, if not most, British botanists, and, as it seems to me, would be a great injury to science. (2) To London and country botanists the British Museum is much more accessible than Kew. (3) The plan proposed would separate the fossil from the recent plants. (4) It would involve the creation of a new board. If, on the other hand, Kew Gardens and the British Museum were brought into closer relations, as recommended in the report which I have signed in conjunction with Mr. Seymour, several advantages would result; for instance, the officers of the Museum would have access to the living plants; while those of Kew Gardens would have access to the British Museum library and the collection of fossil plants.

Lord Avebury and Mr. Seymour also ob-

ject to the constituting of an advisory board. They say :

If we were starting *de novo* it seems obvious that the whole of the national biological collections in and near the metropolis would be placed under one management. The Trustees of the British Museum are established by statute, and are partly selected and partly *ex-officio* members, more than one-third being high Ministers of State. Those to whom the active duties of management and superintendence are entrusted possess special knowledge in the various subjects illustrated by the collections, and they appear to us to be more fitted both by their experience and their position in the scientific and cultured world to be the governing body of the amalgamated botanic collections at Kew than any other that can be built up in their place. If those collections form part of the British Museum, the Director at Kew would become an officer of the Trustees in the same manner as is the Director of the Museum at South Kensington. It is true that in the report it is stated, 'Were Kew placed under the Trustees of the British Museum, unless their control were a merely nominal one, a thing in itself most undesirable, the demands of the Colonial, India and Foreign Offices on the resources of Kew would be subject to the control of the Trustees, a situation fraught with difficulties and dangers.' This assertion does not appear to us convincing. No example is quoted of these difficulties, the dangers are not indicated. It is far from clear why one controlling authority is more likely to produce them than a lay authority and a scientific authority with an advisory board interposed as a buffer between them. * * * We feel that the introduction of a new board such as is proposed is at least as likely to produce friction and difficulties as the present authorities, and will tend to weaken responsibility, and on this account,

as well as because we do not attach much reality to the 'difficulties and dangers' which would arise from the substitution of the control of the Trustees of the British Museum for the present control, we dissent from the second recommendation of this report.

THE FUNCTION OF THE STATE UNIVERSITY.

WHEREVER in this paper the word university occurs, it means State university; wherever the word college is used, it means a private or denominational institution. Let me describe the function of the State university as it appears to me.

I. It should be *within* :

- a. Non-partisan, but patriotic to the State and to the Nation ;
- b. Non-sectarian, but religious ;
- c. Free as to tuition in all departments, academic and professional ;
- d. Every inch a university.

a. While the obligation named first binds every institution of learning in our country, it binds the State universities in a peculiar degree. Their foundations are federal land grants. The funds for their maintenance come from their respective commonwealths. In the highest and broadest sense they should be nurseries of patriotism, but they should shun partisan politics as they shun death.

b. Non-sectarian, but religious.

The State universities have not yet realized their opportunity for developing in students a life that is religious and yet not sectarian. Freedom from denominationalism is apt to be construed as license to subordinate unduly religion in education. No good reason appears why the universities should not each maintain one professor at least to lecture upon sacred literature, natural religion and practical morals, and to serve as chaplain of the students. If, unfortunately, the law or Constitution forbids such teaching at public expense, an appeal should be made for an endowment

by private benefactions. What a blessing for a long time has Dr. Peabody been to Harvard. Such a man ought to be at every seat of higher learning.

Moreover, why should not a large State university maintain a department of theology, without which it is not complete and which does not belong necessarily to any denomination. In Germany, in spite of an established church, theology is non-sectarian. Men of all creeds go there for training. Why should not our American State universities show that ethics, religion and even theology of the highest and best type may be divorced entirely from denominationalism?

c. Free as to tuition in all departments, academic and professional.

This proposition ought to be established by the mere statement that in every commonwealth the university is the head of public instruction, which is free up to the higher learning and ought to be free there also. The reasoning that people have indulged in as to free tuition is very curious. In early times the doctrine was preached that schools should be maintained at public expense, but should be limited to the elements of learning—reading, writing, arithmetic, geography and United States history. A little learning the public might give the individual, but no more. After strenuous opposition, this doctrine was established in New England, in the Middle States, in the West, and finally in the South. Then came the second step forward, in which in many places high-schools were smuggled in. In Kansas City, for example, the first high school, now one of the best in America, was for years maintained surreptitiously. Later the people throughout the union came to the belief that a chance at secondary education also, without charge for tuition, was due from the commonwealth to every soul on its soil; but it was still argued gener-

ally that college or university training should be paid for by the individual. Not long ago, some Western States reached the third stage of progressive belief that free instruction should be given through the college of liberal arts, but that professional training should be paid for. In the process of evolution, however, the fourth era is near at hand, in which it will be recognized, I think, that the discrimination between academic and professional instruction is wholly specious. If it be granted that the State owes to every soul on its soil a chance at free instruction through the college of liberal arts, by what legerdemain of logic can it be denied in medicine or engineering? In these so-called professional courses perhaps half the studies are academic, and the other half are applications of the academic. Is it reasonable for the State to teach a man freely physics, chemistry, mechanics, drawing and mathematics, but refuse to teach him freely their applications to engineering? Should one learn at public expense, such academic subjects as physics, chemistry, neurology, embryology, anatomy, histology, physiology, physiological chemistry and bacteriology, but learn at personal expense their applications to medicine? All such reasoning is to my mind artificial. It is said that law, medicine and engineering are gainful pursuits, and, therefore, the beneficiaries should pay for training in them. The argument is not worth refuting, but, if it were, it might be pointed out that bachelor of arts is a gainful degree. Moreover, academic graduates are not more useful to the people than are lawyers, physicians, pharmacists, dentists, engineers, etc., of superior quality. As soon as you admit that the commonwealth must furnish its people free instruction in any degree you are compelled to admit that it must furnish free instruction in every degree and in every useful form. But the same argu-

ment, it is said, might be advanced for free clothing or board or books. To my mind this does not follow at all, but if any man will demonstrate that they should be furnished in any stage of education, it would be easy to prove that they should be furnished in every stage thereof and in every useful form.

It is questionable whether, in view of the superb training at Harvard, Massachusetts is bound to found a free university, but in my opinion she is bound to give her citizens that desire it and are prepared to receive it free instruction in some accessible university of high rank. Whether free tuition should be extended by one State to citizens of another is a question that I will not now discuss. Those who, like the writer, exalt the Nation above the State will favor it.

In closing this division of my subject let me say with emphasis that free tuition in any department without high standards of admission and of graduation is akin to crime.

d. Every inch a university.

There is danger that through eagerness to take in new territory, to swell enrollments, and to provide instruction for special classes, some of our universities may forget that to deserve richly their titles is the highest obligation they owe to the people. Policies of expansion and adaptation are sometimes commendable and occasionally are forced upon us by circumstances, but they take money and subtract from the energy due to higher teaching. Never should they be allowed for a moment to obscure the main purpose, which is to be from circumference to center a great university. Particularly objectionable is the tendency too often exhibited to swell enrollments by adding professional schools in the nearest metropolis. These *morganatic* unions rarely bear good fruit. A university is much more than a college or an aggregation of them. Its great work is graduate and pro-

fessional studies based upon an academic degree. To attain this end is far harder when the work is not concentrated on one campus.

II. The university *without* should care for the State and should serve as a buttress to a National University.

It has been preached strenuously that the State should care for its university but scarcely has the idea been broached that the university should care for the State. It is possible to do this in a variety of ways, in material, in social, in political and in spiritual things. The possibilities in spiritual things have been discussed in the second paragraph of this paper. What can a great seat of learning do for the public good in other directions?

a. Through the College of Agriculture, or in conjunction with it and other public agencies, it should look after the material welfare of the people.

The loftiest learning should not scorn to help men in their material interests. If in its laboratories a dietary can be discovered whereby the fattening of swine is made cheaper to swineherds, the university should promulgate that dietary. The Babcock Milk Test, discovered at the University of Wisconsin, has been a blessing to dairymen in all the world, and almost as beneficial to another class of husbandmen has been the discovery in the University of Missouri of a method of inoculating cattle against Texas fever, whereby the mortality in blooded animals carried south has been reduced from ninety to less than eight per cent. Our colleges of agriculture have devised better dietaries for domestic animals than the wit of medicine has yet invented for growing children.

Expeditions have been sent out by our universities to measure accurately remote water power and to survey routes for transmitting it electrically to railway stations; to measure beds of coal and test their ther-

modynamic values; to measure beds of cement and quarries of stone and try their quality; to collect flora, fauna, rocks and minerals; and for other useful purposes. The results, carefully tabulated, have been widely distributed. Diseases of animals and plants have been held firmly in check. What has been done shows what may be done for things material by the scientific skill of universities. But what has been accomplished has been mainly along the paths prescribed by the United States, in the Hatch Act, establishing Agricultural Experiment Stations. Except under federal leadership, our universities have not done very much, I fear, for the material welfare of the people, when one considers the immense possibilities.

b. In collaboration with State boards, bureaus and commissions, the university should look after social and economic conditions.

How many States can point with pride to their penal institutions—their jails, penitentiaries, reformatories, almshouses, tenement houses and asylums? Yet the university of each commonwealth perhaps maintains a chair of sociology. On the campus are students from every county. In their summer vacations they could visit every reformatory and eleemosynary institution, reporting accurately its condition. A judicious publication of the results, with a statement of fundamental principles, would lead often to radical reforms in the treatment of the criminal and defective classes.

No State is without municipal problems and few can boast of a rational system of taxation. Why should not the department of economics take up these subjects? If the professors understand what scientific taxation is, why can they not apply it wisely to prevailing conditions? The wisest teaching of political economy in municipal problems should be spread broadcast. The

Federal Government maintains in every commonwealth an Experiment Station to find out what is wise in agriculture and to disseminate among the people the knowledge gathered. The departments of sociology and political economy ought to be experiment stations after their kind in the full meaning of the Federal Government, and the university should not begrudge the cost of publishing and distributing among the people whatever information may be necessary to enable them to adjust wisely their systems of taxation, to solve municipal problems, and to improve the condition of their penal institutions, reformatories, asylums, almshouses, tenement houses, etc. It is the function of a university to investigate, to teach and to publish.

A painstaking study of the State laws, in the light of the broadest learning and in comparison with other codes, if embodied in timely publications and spread broadcast, would not be without good results anywhere. The achievements of David Dudley Field in this direction are well known.

The early history and archeology of every State is an inviting field for investigation, while the editing of early local writers of the better sort might well employ some of the literary skill of the faculty. A *spicelegium* in some cases it might be, but in every case it would be valuable.

The departments of chemistry, sanitary engineering and medicine find a wide field of usefulness in things pertaining to public health: pure foods and drugs, pure water, good sewers, the ventilation of buildings and so on. In this broad direction it is possible by scientific work and by helpful publications to diminish sensibly the rate of sickness and of death.

c. In cooperation with boards of education and the State Superintendent the university should build up the schools below it.

The writer has talked on this subject so often that he feels inclined now to dismiss it hastily. Elementary schools cannot be brought to efficiency, unless there be high-schools to lead them, and high-schools cannot become ideal without the help of a university. The whole system of public education from the kindergarten to the graduate department, and through it, should be strongly knit together. This principle is accepted universally, the chief discussion being about instrumentalities. My own experience causes me to place high value upon examiners of schools appointed by the university. The examiner should be an instructor or assistant professor of pedagogy, and should lecture sometimes on the campus. In large States it might prove convenient to have an examiner for town high-schools, another for rural schools, and a third for elementary schools. The examiners should all be extension teachers of practical pedagogy. Their function is not so much to examine as to build up. If the university will pay for the cost of this service, the money will come back two-fold. As an example of what may be done by an institution for the schools below it, let me point to the University of the State of New York. Few universities could engage in all its manifold work, but according to our means we should adopt its best methods. Traveling libraries and galleries and extension lecturers as well as examiners of schools are educationally important means of grace.

Moreover, the university is not without obligation to the private and denominational colleges which, chartered by the State and protected by its laws, teach a large percentage of the educable youth. It is a blunder of the first magnitude to assume towards these colleges an attitude of hostility. One of the best things that we have tried in Missouri is the College Union, consisting of the University, and of every other

respectable institution of higher learning. At the meetings, held at each institution in succession, we discuss common problems, talk of common troubles, and help one another to the common end—the uplifting of the people. In spite of provoking opposition occasionally from the churches, any university should be held largely responsible if bad feeling continues between the denominational colleges and itself. Stepping grandly over small animosities, it should remember that, while officially it is the head of public instruction alone, in a broader sense it should be the loving helpful head of all sound education in the commonwealth.

The State university should serve as a buttress to a National University.

Education will not be complete in these United States until we have at Washington a national university with State institutions as its buttresses. Some day our education will conform to our system of government. I for one would not be willing to see institutions of any class enjoying privileges in the national university that are denied to other institutions of equal or superior grade, but close affiliation between the State and nation seems inevitable in education also.

In conclusion let me answer some possible objections to the positions taken in this paper as to the outward obligations.

Should the university invade the provinces of the boards, bureaus, and commissions—the Geological Survey, the Natural History Survey, the Health officers, the Tax Commission, the Superintendent of Public Instruction, and the College of Agriculture and the School of Mines, if, unfortunately, these stand on separate foundations? If the interests of the State are adequately served by others, the university might let well enough alone. Under no condition should it officiously invade the territory of any officer or organization appointed by

the State. But ninety-nine per cent. of the difficulty will disappear if only the university will do the work admirably and let others take the credit. If the purpose be to promote public welfare why should one care who gets the praise? In every instance, hitherto, in the writer's experience, the scientific, philanthropic and statistical departments of the State and the nation have been eager for cooperation, wherever the university has demonstrated ability to do work superbly, and in most cases they have supplied the money. Besides, it is one thing to appoint commissions and quite another to induce them to fulfill strenuously the purposes for which they were appointed. Many a yawning gap of deficiency in public officials may be quietly bridged by the patriotism and skill of the university, which should be the eye of the people, searching in every direction for opportunities to serve their welfare.

Will not the discussion of social and civil questions embroil the university in partisan politics? The most important problems of sociology and politics are not often embodied in State platforms, which usually consist of the national structure with a few more planks lauding one party and vilifying the other.

Do you ask where the money for all this is to come from? False to the core is the idea that the resources of a university are solely for instruction on its campus. The administration has no right to wait always on needed investigations for special appropriations from the Legislature. It should rather assume that in part the income must be consecrated, as need arises, to promoting the public good wherever it can be reached by scientific skill. Ultimately no use of money will pay better, even as an investment of capital. At last, we are not required to do more than our resources permit. It is the spirit that maketh alive. The important thing is for the university to

construe its functions liberally and to choose intelligently what can be done now and what should be postponed. Time as well as money is necessary for perfect performance of its whole function.

In conclusion, let me say that the State University, founded by the Federal Government and supported by a mill tax upon the property of a great commonwealth, with broad outlook and intense devotion to the welfare of the people, can be made the best institution yet devised by the wit of man for the promotion of human progress. University mottoes are sometimes inspiring, but the one that appeals to the writer most is from Cicero, *De Legibus*—'Salus Populi Suprema Lex.' The welfare (*salus*), construed broadly, is coextensive with public interests, which, beginning in the soil of earth and rising through human society, mount upwards finally to the Kingdom of Heaven.

R. H. JESSE.

SCIENTIFIC BOOKS.

Le système métrique des poids et mesures. Par G. BIGOURDAN. Paris, Gauthier-Villars. 1901.

A hundred years have passed since the inauguration of one of the most important reforms yet undertaken by civilized man, considered as to its far-reaching effects upon social, economic and scientific interests and conditions. Although the establishment of a universal and uniform system of weights and measures among all enlightened nations is not yet an accomplished fact, that most desirable end is so nearly reached that no reasonable person can for a moment entertain a doubt as to the final result. Only two great nations, constituting the English-speaking people of the world, still hold out against the irresistible movement in favor of uniformity of standards and they are both wavering very decidedly, preparatory to the inevitable yielding which the most thoughtful of their people are endeavoring to hasten. During the last decade in both England and America popular interest in the subject of

metrological reform has been unprecedentedly great and there is a general conviction that abandonment of the antiquated, inconvenient and unscientific systems of measure now in use must soon become an absolute necessity.

Under these conditions the excellent treatise of M. Bigourdan is a most timely and welcome contribution to available literature relating to the history of the origin and the gradual propagation of the metric system of weights and measures. In its preparation the author has had the advantage of convenient reference to original papers, state, scientific and personal, and in his résumé of the very important operations of the last quarter of a century, as embodied in the work of the International Bureau of Weights and Measures, he has been able to avail himself of the thorough knowledge of Messrs. Benoit and Guillaume, the two distinguished experts of that bureau.

The book begins with a brief discussion of the chaotic state of all matters relating to standards of measure during a few centuries preceding the coming of the metric system, in which little is said of anything outside of France. At a very early period in the history of metrology attempts were made to establish natural standards—that is, to refer ordinary standards of measure to something in nature fixed and unchangeable. It was not until 1670, however, that a really rational and scientific scheme was proposed by Gabriel Mouton, vicar of the Church of St. Paul in Lyons.

A few years earlier than this it had been proposed to refer the standard of length to the pendulum making a single vibration in one second or in some fraction of a second. Perhaps this suggestion came first from Sir Christopher Wren, and it was made about 1670–73 by Picard and by Huyghens. Mouton's system was *in principle* the metric system of to-day; he proposed to refer the standard of length to an arc of the terrestrial meridian; his multiples and submultiples of the unit were decimal, and he also proposed for convenience of reproduction a reference to the seconds pendulum. It is interesting to note that when Picard proposed the seconds pendulum as a standard of length in 1671, he expressed a suspicion that such a pendulum must be somewhat shorter

near the equator than near the pole, although it was only in that same year that Richer went to South America to make a series of astronomical observations, during which this fact was actually proved.

During the next hundred years many suggestions looking to a reformation of standards were made in France and many projects drawn up to bring about a unification of weights and measures throughout the nation, but it was not until one was presented by Talleyrand, about 1789, that the real movement set in. In this project he advocates the use of the pendulum as a standard of length, and with evident appreciation of the importance of the matter with which he is dealing, he suggests a reference of the subject to a joint international commission, to be composed of an equal number of members of the French Academy of Sciences and of Fellows of the Royal Society of London. At about the same time an active agitation in favor of metrological reform began in England and also in the United States, its chief exponent in our own country being Thomas Jefferson. Unhappily neither of these movements came to much, for reasons that cannot here be gone into. The history of the creation of the metric system and its adoption by the French Government, which followed within a few years after Talleyrand's project was submitted, is pretty well known to those interested in this phase of the subject, and the details of it constitute the larger part of the volume under review.

The whole subject was in the beginning referred to a Commission which, with those that were subsequently appointed, fortunately included such men as Laplace, Lagrange, Borda, Mongé, Condorcet, Lavoisier, Delambre, Coulomb, Cassini and others, constituting a most brilliant array of Frenchmen most eminent in science.

Consideration was given to three 'natural' standards to which the unit of length might be referred: The length of a pendulum beating seconds, the quarter of the terrestrial equator and the quarter of the terrestrial meridian. The pendulum was rejected, principally because its use involved the elements time and force, both foreign to length; the equator was rejected because of the difficulty of measuring it, climatic

and other conditions rendering it relatively somewhat inaccessible; and the quarter of a terrestrial meridian was finally adopted. It is pleasing to note that throughout the discussion which led to this result, the influential members of the Commission, as well as many others not members, stood out against the use of any unit of length or mass already in use in France, as it was recognized that such use would be an obstacle to the introduction of the system among the people of other nations. An interesting episode of the initiative of the arc measurement was a controversy over the use of a sector in the determination of latitude or the newly invented repeating circle of Borda. Indeed it seems not unlikely that 'a desire to make the reputation of the circle of Borda' had some influence in the choice of the new standard as against the seconds pendulum. Delambre proposed to Borda to employ both sector and circle, but the latter dryly intimated that it was desired to ascertain if the sectors were good, and the matter was not pressed.

When the Commission was received by the King, Louis XVI., after its recommendations had been approved and before the formal beginning of its operations, his majesty, speaking to each one in turn of the special duties that had been assigned to him, asked Cassini (the fourth eminent astronomer bearing that name), to whom had been assigned the triangulation and measurement of latitudes, how it was that he was going to remeasure an arc of the meridian that his father and grandfather had already done before him. Did he hope to do better than they? To which Cassini replied that he would not so flatter himself, if he had not a great advantage over them in the fact that while the instruments which they used in measuring angles gave results correct to within fifteen seconds, that invented by Borda would enable him to reach a precision of one second.

M. Bigourdan's volume contains much detailed information relating to the work of the Commissions, with many interesting and important citations from original documents. The fundamental legislation by which the system was founded is fully discussed, the opposition to it is fairly presented, and the subsequent legislation and discussion leading to its final

adoption by the nation as a whole receive satisfactory treatment. There is a chapter on the propagation of the system among foreign nations which leads up to the appointment of an international metric commission about 1870, and to the establishment of the International Bureau of Weights and Measures about 1875. The splendid work of the latter during the twenty-five years of its activity is treated in some detail and forms a fitting close to a most useful and interesting contribution to the history of metrology.

T. C. MENDENHALL.

A Treatise on Electromagnetic Phenomena and on the Compass and its Deviations Aboard Ship, Mathematical, Theoretical and Practical. By Commander T. A. LYONS, U. S. Navy. John Wiley & Sons.

The first volume of this treatise, the only one yet published, deals with electromagnetic phenomena, or radiation in all its protean forms. If the reader wants information about sun-spots or auroræ, about Crookes's fourth state of matter or Bjerknæs's imitations of magnetic fields by pulsating discs, about the work of Hertz or the genesis and action of Röntgen rays, he will find it in this introductory volume. However many and however diverse the subjects discussed, they are all treated from the point of view of the wave-theory. Commander Lyons seems to hold a brief for the ether whose existence he seeks to remove from the condition of a working hypothesis and whose properties he tries very hard to define. This is indeed a difficult task; for he tells us, on page 9, that "the mathematician attributes to the ether properties necessary to the formation of equations expressing its energy; the physicist ascribes to it qualities essential to the explanation of facts; the electrician meets conditions that require further hypotheses; still others do not accept fully any one of these conceptions; and some even reject the ether altogether."

So conscious is the author of the paramount importance in physics and philosophical speculation of the medium which fills intermolecular as well as interstellar space, that he dwells with great insistence upon the experimental evidence which there is for its existence. He is so eager

to beget in the mind of the reader the strong etheric conviction of his own, that he does not hesitate to recall and repeat where such repetition seems to him necessary. It must be admitted that he has made out a very commendable case for the medium as well as for its magnetic, electric and luminous properties.

The book reads easily. The style is not severely didactic; it is clear, sometimes diffuse and occasionally rhetorical. Here and there we meet similes and metaphors that occasion surprise, partly by their unexpectedness and partly by their novelty or boldness. Thus we are told that when electromagnetic waves reach the more tenuous strata of our atmosphere, they illumine them, and as a consequence "we have those brilliant auroras that cap the magnetic poles like huge candle-extinguishers" (!) (p. 20). Again, "magnetic storms have overspread the continents of Europe and America at the same time, when every needle was affected as with a kind of frenzy—oscillating together, as if some gigantic Briareus reached out his hundred arms, and with a finger on every one moved them regularly or wildly as the mood was upon him" (p. 6). On page 41 we find 'a mote of ether' and on page 62 we are confronted with 'a jungle of electromagnetic manifestations.'

The following passage, which occurs on page 197, is quite Tyndallian:

From ships of war cruising in every sea; from merchant vessels plying between the ports of the world; from observatories equipped with delicate instruments in various countries; from expeditions afloat and ashore specially fitted out for the purpose; and from numerous other private and public sources of many kinds—have been gathered, during long years, a multitude of observations of the magnetic elements; collated, classified and stripped of all discernible errors, they afford, when plotted on charts of the globe, an excellent insight into its magnetic condition.

We can hardly, however, bring ourselves to define the dyne as 'the unit of measure of magnetic intensity' (page 434), for we have hitherto accepted it as the unit of force. On the same page we read that "the weight of a body is the product of its mass by the force of gravity; the mass is everywhere a constant but hazy (!) factor, while gravity varies slightly

from place to place, but is always accurately known. This being understood, the weight of a body will be spoken of as representing it." Adopting a word from this sentence, we cannot but qualify the above statement as somewhat 'hazy.' What we do know, and know clearly, is that the weight of a lump of matter depends conjointly on its mass and on the intensity of gravity, so that we can write

$$w = \lambda mg.$$

By a suitable choice of units, we can make $\lambda = 1$, and then we have

$$w = mg.$$

After stating that the mass of a body is constant, the writer might have said, in so many words, that its weight depends upon its position with respect to the center of the earth, and thence concluded that the important property of a body, both scientifically and commercially, is not its weight but its mass.

Ampère's theory of magnets is found on page 490 to be 'more rational than the theory of magnetized particles.' We should like to believe it, and consequently regret that the author did not give a few reasons in support of this opinion. The origin of the Ampèrian currents is no better known than that of the magnetization of the molecules in Weber's molecular theory, while the maintenance of the currents implies the further difficulty of a resistanceless circuit.

The author is very chary in the use which he makes of proper names. Doppler, it is true, gets credit on page 320 for his 'principle,' and Lissajous on page 52 for his 'figures.' Why not Lenz for his 'law' (page 410) and Zeeman for his 'effect' (page 503)? Peter the Pilgrim (Peregrinus) is mentioned *cum laude*, but Gilbert is passed *sub silentio*! Yet it was Gilbert, the philosopher of Colchester, who first explained the behavior of the compass and the dipping needle by his grand discovery that the earth itself is a huge magnet: *Magnus magnes ipse est globus terrestris* are his words. Surely Commander Lyons has read *De Magnete* either in the original Latin or in Mr. Mottelay's translation; so that his neglect of Gilbert's transcendent merits is hard to explain.

The magnetical discoveries of Columbus are

clearly stated on page 206, where is ascribed to him the first explicit record of a change in the variation (declination). "While Columbus," writes the author, "may not hence be said to have discovered the variation, he must be credited with having been the first to make it known, as well as the first to discover a line of no-variation." The author might have added that this agonic line lay a little to the west of the island of Fayal, one of the Azores; and he might also have informed the reader that the variation of the compass was not generally accepted as a fact until the middle of the sixteenth century—Gilbert's time—being supposed to be due to the mechanical defects of the compass itself.

The explanation of the earth-couple acting on the compass needle, given on page 383, is rather involved. The matter would be greatly simplified by discussing the usual expression, viz., $Hm \sin \theta$ deduced from a diagram on page 295. We notice that the author here resolves H at right angles to the length of the magnet, still the force acting at each end of the needle parallel to the magnetic meridian is not H but Hm ; and the arm of the couple is $l \sin \theta$ so that the twisting moment is $Hml \sin \theta$.

It is necessary, when studying the distribution of free magnetism in a bar magnet, by the method given on page 181, to point out that the bar must be so placed that the axis of the compass-needle when at rest will lie in the magnetic meridian, with its north-seeking pole pointing magnetic north.

We are told on page 152 that a small magnetized bar will place itself equatorially when suspended between the poles of a horse-shoe magnet of nearly equal strength. This surely is a *lapsus calami*, for the bar will set, not equatorially, but axially.

A very important feature of this treatise is to be found in the diagrams and illustrations distributed throughout every one of its twelve chapters. Many of them are original, and are excellent efforts at representing graphically some difficult points in what we may term the physics of the ether. Teachers and students alike will find them very useful.

The author's object in the first part of his treatise is to give such information about the

principal phenomena of magnetism and correlated subjects as will prepare the way for an intelligent grasp of the matter to be discussed in the second volume; and in this he has well succeeded. The work is full of up-to-date information set forth in a clear and frequently impressive manner. It makes one eager for the appearance of the concluding volume, which will treat of such practical matters as the compass, the ship considered as a magnet, swinging the ship, compensation of the deviations and the mathematical theory of these deviations.

Part I. extends to 556 pages and contains 368 figures, the whole put forth in the publisher's well-known excellent style.

M. F. O'REILLY.

Animal Life: a First Book of Zoology. By DAVID STARR JORDAN and VERNON L. KELLOGG. New York, D. Appleton & Co. 12mo. Pp. 329; frontispiece and 180 plates and figures in the text. Cloth, \$1.20.

This handy, beautifully printed and illustrated book is a distinct attempt to introduce to the reader the subject of zoology from the standpoint of the life of the animal rather than from the purely systematic or comparative anatomy side. It is a book to read and enjoy in the fields and woods or at home rather than a manual to study in the laboratory. Its scope is well stated in the general headings of its sixteen chapters: (I.) The Life of the Simplest Animals; (II.) The Life of the Slightly Complex Animals; (III.) The Multiplication of Animals and Sex; (IV.) Function and Structure; (V.) The Life Cycle; (VI.) The Primary Conditions of Animal Life; (VII.) The Crowd of Animals and the Struggle for Existence; (VIII.) Adaptations; (IX.) Animal Communities and Social Life; (X.) Commensalism and Symbiosis; (XI.) Parasitism and Degeneration; (XII.) Protective Resemblances and Mimicry; (XIII.) The Special Senses; (XIV.) Instinct and Reason; (XV.) Homes and Domestic Habits; (XVI.) Geographical Distribution of Animals. Following the text proper are a table of the systematic position of the animals mentioned, a glossary and finally an excellent index.

In the subject matter of the volume one can-

not help feeling the advantage of a combined authorship, the senior author being primarily a student of vertebrate, and the junior author of invertebrate, life. This has insured a fairly balanced discussion of the phases of animal life in the two great divisions.

While, as stated above, this book is upon the life of the animal world rather than upon the anatomy, it is to be remarked that wherever the life processes are illuminated by the structure or development, these are freely introduced according to the guiding principle laid down by the authors: "Function and structure are always associated in nature and should always be associated in our study of nature."

It is gratifying to read such a book as this from cover to cover and find it free from vagaries. The authors, from personal knowledge and from the rich stores of the knowledge of others, have selected with great skill the facts illustrating each chapter, and have impressed these facts by excellent pictures, many of which are of their own production. In the discussion of the various topics, beyond the mere statement of facts, one constantly feels the certain hand of a master, a hand trained by personal knowledge and reflection and not dependent on the opinion of others. The book is very free from infelicities of expression and also from what seem to the reviewer doubtful statements. If two of the few observed might be mentioned, it is with the hope that future editions will modify the statements concerning the plate of embryos taken from Haeckel (p. 86), and also the statement on p. 107, that bones are not really living, etc. Taken in their setting these and a few other doubtful statements are true in spirit, but not quite in the letter. They can easily be made to conform with the vast majority of illustrations and be true both in spirit and in letter.

As a conclusion of this review a quotation from the chapter on geographical distribution will give an idea of the spirit and method of the authors:

"In California numerous anomalies [in distribution] have been noted, as the occurrence of Tahoe trout in Feather River, and in the Blue Lakes of Amador, which are on the other side of the main crest of the Sierra Nevada

from Lake Tahoe, and the occurrence of the Whitney golden trout in Lone Pine Creek. In each case naturalists have found the man who actually carried the species across the divide. If this matter had been investigated a generation later, these cases would have been unexplainable anomalies in geographical distribution. Real causes are almost always simple when they are once known" (p. 288).

S. H. G.

GENERAL.

M. OCTAVE DOIN, Paris, has begun the publication of an elaborate 'Bibliothèque internationale de psychologie expérimentale.' The subject-matter of psychology has been divided among fifty volumes, each of which is being prepared by a different author. France is, of course, fully represented, though the absence of certain names might be unexpected to those unacquainted with the personal conditions. Italy and Russia are well represented and there is one volume from England, 'Metaphysics,' by Mr. G. F. Stout, of Oxford; and two from America, 'Judgment and Knowledge,' by Professor J. Mark Baldwin, of Princeton University, and 'Movement,' by Dr. R. S. Woodworth, of University and Bellevue Hospital Medical College. It is somewhat curious that the name of no German should appear on the list. The volumes, which will be on the average 300 to 400 pages in length, will be sold at the uniform price of 4 fr. Together they will form one of the most important encyclopedias that has been published in any science.

THE Syndics of the Cambridge University Press have undertaken the publication of the first part of the 'Index Animalium' to the preparation of which Mr. C. Davies Sherborn has devoted so many years. The object of the Index is to provide zoologists with a complete list of all generic and specific names given by authors to animals both recent and fossil since January 1, 1758, the date of the 10th edition of Linnæus' 'Systema Naturæ.' With each name will be given an exact date and a reference intelligible to the layman as well as to the specialist. The British Association appointed a special committee to watch over the incep-

tion and progress of the work, the preparation of which was undertaken in 1890. Financial support has been given by the British Association, the Royal Society and the Zoological Society, while the authorities of the British Museum have afforded continual assistance. The work will be to the student of animal life what the 'Index Kewensis' is to the botanist, and indeed far more, as the last-named work refers only to Phanerogams, whereas the 'Index Animalium' will include all groups of animals and both recent and fossil forms. The portion of the work already completed and in the press covers the period from 1758-1800 and consists of 61,600 entries.

THE Society of German Engineers, in Berlin, has undertaken the preparation of an international technical dictionary to be published in English, French and German.

SCIENTIFIC JOURNALS AND ARTICLES.

The *Journal of the Boston Society of Medical Sciences* completes its fifth volume with the double number for May 23 and June 4, the index to the volume being issued with this number. From a small 16mo the *Journal* has grown to a volume of over 500 pages, although it shows at the same time the modern tendency towards specialization by containing more bacteriological and pathological papers than formerly. There is, however, much of general interest as well as important contributions to our knowledge of anatomy and physiology.

The *Plant World* for June contains 'Botanizing in Bermuda,' by Marshall A. Howe; 'Suggestions for the Study of the Hawthorns,' by W. W. Ashe, which notes that in place of ten species formerly recognized we know that at least 120 species occur on the Atlantic coast; 'Cuban Uses of the Royal Palm,' by William Palmer, and 'Botanizing in and around a Lake,' by E. L. Morris, besides briefer articles, notes and reviews. The supplement devoted to 'The Families of Flowering Plants,' by C. L. Pollard, treats of the Mimosaceæ, Cæsalpiniaceæ, and the Pæpilionaceæ. The number is well illustrated.

SOCIETIES AND ACADEMIES.

ONONDAGA ACADEMY OF SCIENCE.

At the June meeting Mr. Chas. G. Rogers presented a series of observations made during March, April and May, on the dates of arrival of birds on their spring migration, the blue-bird being first seen on March 15, and the robin appearing three days later.

Mr. Geo. D. Lynch read a paper on 'Hawks,' in which he described the food, and the nesting and defensive habits of Cooper's hawk, the sparrow hawk and the red-shouldered hawk, illustrating his remarks with specimens of skins and eggs of each of the three species.

Principal John D. Wilson read a paper embracing his observations on a family of blue-birds. He constructed a box in the shape of a prism about six inches square and fifteen inches deep, two opposite sides stopping about two inches short of the top, thus forming two entrances, protected from rain by a projecting roof. A narrow shelf was placed just beneath each entrance. Sparrows seemed unable to utilize the box for nesting purposes and so left it alone. They gathered about, however, when the young birds began to appear at the entrances, but were soon driven away by the parent birds. After the young were hatched they seemed to be fed solely by the mother, who invariably entered and left the nest by the opening on the south side. The male entered either opening indifferently, never brought food, and usually brought out excreta from the nest. Mr. Lynch spoke of similar observations on a robin's nest. The young birds were fed entirely on caterpillars, while the parent birds ate freely of cherries, monopolizing one tree, and even brushing their wings against the head of any person attempting to climb the tree.

Mr. Horace W. Britcher spoke briefly of the habits of some of the forms of life inhabiting a small springtime pond in which a form of the fairy shrimp (*Branchippus gellidus* Hay?) occurs. The pond is usually dry from July to November. Larval *Branchippus* appear in February, and eggs are deposited during late April and early May, the water becoming so warm by the middle of May that the *Branchippus* are rapidly killed. A year ago eggs were collected and an attempt

made during the summer, and again during the winter, to hatch them in aquaria, but without success.

H. W. BRITCHER,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE LARYNX AS AN INSTRUMENT OF MUSIC.

It is with considerable hesitation that I venture to enter into a discussion that has arisen in this Journal under the above title. It is so likely to become a discussion of terms that may be defined by different writers in different ways that it is, perhaps, a question whether a prolonged discussion of the subject is desirable. In spite of this fact, however, I take the liberty of expressing an opinion to which I have been brought by the past several years of observations upon the larynx. Of course, we may call that part of the larynx which vibrates a 'cushion,' a 'reed,' a 'membranous reed,' a 'cord,' a 'membranous cord' or other names, and still find much justification in each case. It seems to me that if we wish to discuss the question as to the class of instruments to which this belongs, we must judge it by two series of facts: first, what elements control the pitch of the fundamental tone produced; second, what is the quality of the tone produced. If we examine the larynx with these points in view, we find, in the first place, that the pitch of the tone produced is controlled by three mechanisms: first, one for increasing tension; second, one for decreasing the length; third, one for lightening the weight of the vibrating part. These three factors are those used for controlling the pitch of a string. If we examine the quality of the tone produced we find that the fundamental and over-tones form a series whose rates of vibration are to each other in the order of the natural numbers, 1, 2, 3, 4; etc., this quality of tone is the quality produced by a string and not the quality produced by a reed or membrane, in both of which the quality is much more complex and contains many intermediate over-tones. It seems to me, in view of these considerations, that we refer to this vibrating part as a 'cord' quite properly. It will be admitted, undoubtedly, by all that the tilting of the cricoid cartilage on the thyroid cartilage in-

creases the tension on the vocal cords, and in so doing raises and tends to control their pitch. The arytenoid cartilages when brought together bring out the edges of the vocal cord from the side of the tube, and by their rotation may decrease the free length of the vocal cords, as is clearly shown by photographs that have been taken of the larynx when producing tones of different pitches. In Fig. 1 we have a section

FIG. 1.

through the vocal cord and its immediate surroundings. It is shown in the relaxed position against the wall of the tube. The dotted line between *a...g...f* shows, approximately, the position and form of the cord in action. In Fig. 2 is shown, diagrammatically, a cross-section

FIG. 2.

tion of the vocal cord, the point extension at *k* being rather exaggerated. *m* is the vocal muscle extending from the inside front of the thyroid to the outer side of the arytenoid, and passing through the back of the vocal cord. This muscle serves to rotate the arytenoid, and

thus shorten the vibrating portion of the cord ; at the same time certain fibers from this muscle extend outward into the cord toward *s*, *t*, *u*, etc. The action of these fibers, when the vocal muscle is contracted, tends to hold rigid more and more of the cord, allowing less and less of the extreme edge to vibrate. This action lessens the weight of the vibrating part of the cord.

Other minor facts tend to confirm the belief that the action is essentially that of a cord. For example, the extreme edge, as indicated at *k*, is of a different material from the rest of the cord and the whole structure of the cord is entirely different from that of the lips, or from what could be properly defined as a cushion. In observations upon the vocal cords when producing a tone it is very often easy to recognize certain secondary nodal points in the cord. If a little mucus happens to be upon the vocal cord at the time of producing a continued tone, the mucus collects at the secondary nodal points, just as sand upon a vibrating plate, and is easily apparent as a white spot upon the edge of the cord.

Of course, in those cases where the larynx has been removed and an artificial voice apparatus has been introduced, the source of sound has been a reed, but this has been simply from a mechanical difficulty of introducing a vibrating string which should have the proper range. The reed is extremely simple mechanically and answers the purpose quite satisfactorily. But this offers no argument in support of the belief that we are dealing with a reed instrument in the human voice. It is true that Helmholtz and others have referred to the larynx as a reed instrument, but it is curious to note that after this reference has been made, Helmholtz continues in the most elaborate way to treat the quality of the sound produced by the human voice as if it had been produced by a vibrating string, discussing the pitches and intensities of the over-tones of a string and never referring to other over-tones of a reed or a membrane.

It is claimed that the vibrations of the air in the mouth cavity are 'free vibrations' and not 'forced' ones and that these free vibrations in the mouth cavity are excited by the impulses from the larynx formed by the explosive open-

ings between the vocal cords. In this connection Professor Scripture, in his contribution from the Yale Psychological Laboratory, describes an experiment of making a key whistle by blowing in its end a stream of air, which has been rendered intermittent by artificial vocal cords. No one denies for a moment that impulses or a succession of impulses may set up the natural vibrations of a resonance cavity, but it must also be borne in mind that a continuous stream of air under the same circumstances will produce a more forcible result just in proportion as the energy in the continuous stream is greater than in the interrupted stream. Thus, we know that a continuous current will cause a key to whistle, and there is no mechanical reason why an interrupted current should not produce a similar result while the puffs last. Applying this to the mouth cavity as related to speech, we have a natural vibration set up in the case of a whisper by the continuous current of air rushing through these cavities. Interruptions in this current will not increase the intensity of the natural vibrations of the air in the cavities. We have precisely an analogous case if we simply blow through a clarinet or cornet or flute without establishing the primal source of sound by the vibration of the reed, the lip, or the air jet.

It seems to me that, fundamentally, there can be no difference between a vowel as sung and that same vowel as spoken. Of course, the duration of the vowel sound may be very short, but during that period it must have its perfectly definite quality in order to be recognized, and it seems incorrect to assume one set of determining factors in case of a spoken vowel and another set in the case of the vowel as sung. The problems involved in this discussion, overlapping the subjects of anatomy, physiology and mechanics, are naturally very troublesome, and it is readily to be expected that the physicist is perhaps inclined to lay too much stress upon the mechanics of air vibrations. But on the other hand, the physiologist and the students of phonetics have in too many cases brushed aside serious mechanical obstacles with a non-chalance that is scarcely justified by the facts. In those cases where the synthesis of the vowel

sounds has been most satisfactory they have been made up of the fundamental and *string* over-tones and not by the combination of the pitch tone with a 'characteristic pitch' having no harmonic relations between the two. In the case of spoken vowels it seems to me of fundamental importance that the individual should speak upon a known pitch, otherwise the case is hopelessly confused by a constantly changing fundamental. In a great many of the investigations involving the so-called characteristic pitch of the different vocal sounds, it seems uncertain as to whether or not this so-called 'characteristic pitch' may not be more directly due to some inherent rate in the apparatus itself, rather than in the sound which it is supposed to record impartially. In this connection it must be borne in mind that the widest possible variations in tone quality are still recognized as the same vowel spoken by different individuals under different conditions. This discussion has wandered from the musical instrument to the articulator. In music the vowel is everything, the consonant usually inconspicuous; in speech the vowel is secondary and the consonants all-important.

WILLIAM HALLOCK.

PHYSICAL LABORATORY,

COLUMBIA UNIVERSITY, June, 1901.

'IS LARVÆ CONTAGIOUS?'

THE following cross interrogatories were prepared by the district attorney of a county in a western State for a deposition.

What is larvæ? What does larvæ come from? Is larvæ injurious to fruit trees? Is it contagious?

What is pupæ? Describe it fully? Is it injurious to fruit trees? Is it contagious?

It seems to me that the questions furnish an answer to the frequent question in the scientific laboratory, 'Will this ever be of any use to me?' If such knowledge furnish nothing else to a man, it would prevent him from making such questions as these.

H. S. GAUS.

CURRENT NOTES ON PHYSIOGRAPHY.

GLACIAL CORRIES IN THE BIGHORN MOUNTAINS.

THE glaciated district near Cloud Peak, Bighorn Mountains, at altitudes above 10,000 feet,

contains over forty corries or cirques of more or less pronounced form, as mapped and described by Matthes ('Glacial Sculpture of the Bighorn Mountains, Wyoming,' 21st Ann. Rep. U. S. Geol. Surv., 1900, pt. II., 167-190). A contour map shows the summit of the range in general with rounded forms free from sharp peaks and precipitous cliffs. The valleys on the slopes below 10,000 are usually broadly open; but on ascending towards the stream sources, the valley walls steepen on either side of a broad floor where rock basins hold many little lakes, and at or near the valley head the walls close in a great cliffed amphitheater. Highland streams cascade down from shallow hanging valleys into the deep cirques. It is concluded that these peculiar forms are here, as elsewhere, to be regarded as glacial modifications of preexistent valleys that once had more ordinary form. In a few cases, the widening and headward recession of the valley walls have resulted in the consumption of the rounded uplands of the mountains so far that only a narrow, sharp, serrate wall remains; this is well seen around Cloud Peak, thus giving support to Richter's views regarding the importance of glacial action in producing sharp peaks and arrêtes in the Alps. In a single remarkable example, an east-sloping valley (No. 20) receives the drainage of the uppermost mile of a southwest-sloping valley (No. 18) in such a way as to suggest very strongly the glacial capture of the latter by the former; and this is made the more probable when it is noted that the capturing valley has a distinctly stronger slope than the captured. If it be admitted that glacial erosion has made significant changes in the valley forms—and this does not seem to be open to dispute—the present pattern of drainage in these two valleys could not have existed in preglacial time.

It is a curious commentary on the education of our topographers that articles of the kind here referred to should be so rare.

THE NORTH GERMAN LOWLAND.

THE accounts of the North German lowland as a region of glacial topography by Berendt, Wahnschaffe, Keilhack and others are supplemented to an extraordinary degree of detail by

the folio sheets of the geological map (1:25,000) of Prussia and the Thuringian states, with explanatory texts. Several sheets of the area north of Berlin may be cited. In the neighborhood of Oderberg (46th Lieferung), the Oder turns sharply from the ancient westward waterway along the glacial margin past the site of Hamburg to the North Sea, into its present northward course past the site of Stettin to the Baltic. Hereabouts are several looped moraines with uneven hills and hollows, holding many pools and ponds; the loops are nicely marked by boulder belts, which have long furnished material for road-making. Outside of the morainic loops (southwest), stretch outwashed sand plains, the barren 'upper sands,' with deep-lying ground water. Inside of the moraines come the rolling uplands of the ground moraine, with a fertile soil. Overlaid sands and silts are common here, the deposits of ice-margin lakes held in the loops during glacial retreat; the outlets of the lakes are frequently found in trenches through the morainic hills. Some of the larger existing lakes of the district remain in shallow basins, roughly central to the morainic loops.

South of the outwashed sand plains, the broad channel of the ancient waterway (the Thorn-Eberwalder channel, the northern of the three chief ice-margin waterways) is strewn with the 'valley sands.' Once as smooth as the bed of a large river may be, these sands are now trenched and terraced to moderate depths west of Oderberg, where they are traversed only by small streams; but they are largely swept away southeast of Oderberg, where the ice-margin river sank to a lower level when the northern outlet past Stettin was opened. A new, broad channel was eroded at the lower level, with great sweeping curves appropriate to the course of a large river; the channel bed now remains as a marshy alluvial plain on which the diminished Oder wanders. One of the great curves of the channel rounds a spur of drift uplands by Oderberg; the 'new Oder' is led through the narrow neck of the spur by an artificial canal, while the 'old Oder' still straggles around the spur.

Where the ancient waterway departed somewhat from the moraines, a low upland slopes

southward to it from the morainic loops and their sand plains. The upland here is a gently rolling drift plain, traversed now and again by the sandy beds of larger or smaller streams that for a time came out from the ice on the north. A striking example of this kind is found near Kyritz (Lieferung, northwest of Berlin). The sandy stream bed was probably washed by sprawling currents in many braided channels, which acted partly as an aggrading agent, for the bed is hardly incised beneath the rolling drift plain. Later a narrow trench was cut through it, as if the ice-water had for a brief interval been changed from a turbid sand-bearing stream to a clear stream (perhaps the outflow of an ice-margin lake); the trench is now floored with peat, or occupied by long shallow lakes, as if it were barred here and there with unwashed alluvium.

The casual traveller often describes the north German lowlands as a 'flat and uninteresting country.' It is as meaningless to him as a cuneiform inscription would be; yet how significant its delicate details become when interpreted! To American students, the elaborate treatment of this remarkable field foreshadows what may in time be provided for us concerning the Illinois and other glacial lobes, whose general features only have now been sketched.

W. M. DAVIS.

MUSEUM REPORTS.

THE 'Annual Report of the Director' of the Carnegie Museum for the year ending March 31, 1901, was issued a short time ago, as well as the report on the 'Prize Essay Contest.' From the report we learn of the rapid progress of the institution particularly in the field of vertebrate paleontology, the explorations conducted last year by Mr. J. B. Hatcher having resulted in the acquisition of nearly 200 boxes of specimens, some of the more notable of which were described a short time ago in SCIENCE. As Mr. Hatcher again began field work in April, the present year will doubtless see other important accessions of fossils.

In zoology the announcement is made that the Museum has acquired a specimen of the almost extinct *Rhinoceros simus*, only four other ex-

amples of which are in existence. It is also announced that the Museum last year purchased the Ulke collection of Coleoptera. Among other illustrations the report contains a fine view of a remarkable lot of 'cannon-ball' concretions in Laramie sandstone.

It is announced that no less than 843 scholars participated in the Prize Essay Contest, the subject being 'An Afternoon at the Carnegie Museum.' The successful essay is printed in full and the names and addresses of the other contestants are given.

THE Annual Report of the President of the American Museum of Natural History for the year 1900 is also at hand. The most evident progress has been made in arranging the extensive anthropological collections of the Museum, and the new West Hall, devoted to the American Indian and Eskimo, was opened on November 1, 1900.

No less than seven expeditions were sent out during the year to conduct ethnological and archeological researches, including one to Siberia and another to the vicinity of Lake Titicaca. This extended work was made possible through the liberality of friends of the Museum.

The Department of Vertebrate Paleontology, which completed its first decade in May of this year, comprises in its collections 8,534 specimens of fossil mammals and about 4,000 of reptiles. The most important accessions during 1900 were a complete skeleton of the herbivorous dinosaur, *Thespesius*, and one of a carnivorous dinosaur, several partial skeletons of horses from Texas, and a skull of elephant.

The attendance during the year was 523,522, an increase of a little more than 65,000 over the previous year. It is announced that the income from the endowment fund is now \$20,280, and while this is gratifying it is to be wished that it were ten times as great. For the first time in many years the report contains no illustrations, but this is more than compensated for by the publication of the *Museum Journal*, which chronicles the current progress of the institution.

F. A. L.

THE AMERICAN CHEMICAL SOCIETY.*

THE Twenty-Fourth General Meeting of the American Chemical Society will be held in the High-School building, on the block bounded by Nineteenth, Stout, Twentieth and California Streets, Denver, Colorado, Monday and Tuesday, August 26 and 27, 1901.

The same arrangements as heretofore will prevail between Section C of the American Association for the Advancement of Science and the American Chemical Society. Monday and Tuesday of the Association week will be devoted mainly to the sessions of the American Chemical Society, and the remainder of the week to those of Section C. A few minutes will be given to Section C for organization on Monday morning, and in the afternoon the American Chemical Society will adjourn in time to afford the opportunity of listening to the address of the Vice-President of Section C.

The first session of the Society will convene on Monday morning, August 26, immediately after the organization of Section C of the A. A. S., probably at about 11.30 A. M.

The afternoon session will be called to order at 1.30 P. M., and will be adjourned in time to listen to the address of Vice-President Long before Section C.

At the close of Vice-President Long's address, a meeting of the Council and Directors of the American Chemical Society will be held at some convenient place to be announced.

The hour for the morning and afternoon sessions of the Society on Tuesday will be announced on the program. Other arrangements for the meeting will also appear in the official program, or be announced at the sessions of the Society.

Hotel headquarters for the meeting will be at the Brown Palace Hotel, Seventeenth and Tremont Streets. Rates: American plan, \$3.00 to \$5.00 per day; European plan, \$1.50 up. This hotel is within five minutes' walk of the Denver High School Building, and is reached from the Union Depot by the Seventeenth Street electric car line.

The following is a list of other hotels and boarding houses easily accessible to the Denver High School:

* Announcement of the secretary.

The Albany, 17th and Stout Streets. American plan, \$2.00 to \$4.00; European plan, \$1.00 to \$2.00 per day.

The New St. James, Curtis Street, between 15th and 16th Streets. American plan, \$2.00 to \$3.50; European plan, \$1.00 to \$2.50 per day.

The Oxford, 17th and Wazee Streets, one block from Union Depot. European plan only, \$1.00 to \$2.00 per day.

The Windsor, 18th and Larimer Streets. American plan, \$2.00 to \$3.50; European plan, \$1.00 to \$2.00 per day.

American House, 16th and Blake Streets. American plan, \$2.00 per day.

Hotel Metropole, opposite Brown Palace Hotel. American plan, \$2.50 to \$5.00 and up; European plan, \$1.00 to \$3.00 per day and up.

Hotel Albert, 17th and Welton Streets. European plan, \$1.00 to \$1.50 per day.

The Belvoir, 737 East 16th Avenue. Room and board, \$1.50 to \$2.00 per day.

The Bonaventure, 18th and Glenarm Streets. European plan only, 75 cents to \$1.50 per day.

The Broadway Hotel, Broadway and Cheyenne Street. American plan, \$1.50 to \$2.00 per day.

The Drexel, 433 17th Street. European plan, 75 cents to \$2.00 per day; \$4.00 to \$8.00 per week.

Douglas Place, 1439 California Street. Room and board, \$1.50 per day; \$7.00 per week and up.

The Grant, 1922 Grant Avenue. Room and board, \$1.25 per day; \$8.00 per week.

The Holland, 17th Street and Pennsylvania Avenue. Room and board, \$1.50 to \$2.00 per day.

The Princeton, 2137 Stout Street. Room and board, \$5.00 to \$7.00 per week.

The Vallejo, 1420 Logan Avenue. Room and board, \$2.00 to \$4.00 per day.

The Vaille, 208 17th Street. European plan, \$1.00 to \$2.00 per day.

Warren Hotel, 17th and Larimer Streets. Rooms, 75 cents to \$2.00 per day.

Young Women's Christian Association, 18th Street and Sherman Avenue. Ladies only.

Reservations for accommodations should be made as early as possible, by direct corres-

pondence with the hotels and boarding houses. The Local Committee on Hotels and Boarding Houses will also be glad to give information on this subject. Address communications to Arthur Williams, Local Secretary, P. O. Box 1504.

The Western Passenger Association, covering the territory west of Chicago and St. Louis, has made a rate of one fare plus \$2.00 for the round trip, in their territory, to Denver, Colorado Springs and Pueblo. The tickets may be bought from July 10 to August 31, and are good for return up to October 31. At this rate the fare from Chicago to Denver and return will be \$31.50. The Pullman fare is \$6.00 extra each way. Rates from points east of Chicago will be announced later in the columns of SCIENCE.

It is probable that there will be, however, a choice of the following terms:

1. A rate of one and one-third fare on the certificate plan for the round trip from starting-point to Denver and return.

2. Full fare from starting-point to Chicago and return, and the above rate of \$31.50 from Chicago to Denver and return.

3. Regular season rates for Colorado tours.

Which of these terms will be the most advantageous must be ascertained by inquiry at the various local ticket offices.

The Pullman rates from New York to Chicago will be \$5.00 extra each way, and those from other points can be ascertained upon inquiry at the various local offices.

If rates are obtained on the certificate plan, the name 'American Association for the Advancement of Science' should appear on the certificate, as all arrangements of this kind are made by that body and not by the American Chemical Society.

Various visits and excursions will be arranged by the Local Committee of the A. A. S. and the Local Committee of the American Chemical Society. These will probably include visits to the smelting and reduction works in the vicinity of Denver, and other places of special interest to chemists.

Members who have papers to present at the meeting are requested to mail to the Secretary, in the enclosed envelope, as soon as possible, name of author, title of paper, and estimated

time for reading the same. It is also earnestly requested that *all members of the Society fill out and return the enclosed slip at once*, whether they expect to attend the meeting or not, being careful to give the name and address as they should stand on the official roll of the Society, which is now being revised for the annual directory.

Manuscripts and abstracts of papers may be sent to the Secretary, Albert C. Hale, addressed to Jewett, Greene Co., N. Y., till August 15; after that date they should be addressed to him at the Brown Palace Hotel, Denver, Colorado.

Many of the members responded with praiseworthy interest and zeal in the effort to increase the membership of the Society to 2,000 before the date of the 25th anniversary meeting last April. The time, however, was not sufficient in which to attain the desired result, but it has been suggested that a sufficient effort now on the part of every member of the Society would enable us to raise the roll of membership to 2,000 before the presentation of the Secretary's annual report in December. *Will you not give your personal attention to this matter*, and see that the enclosed blank is properly filled out with the name and qualifications of some eligible chemist, not now upon our roll, whom you will nominate for membership, returning the blank to the Secretary at your earliest convenience? Additional blanks may be obtained from the Secretary at any time, or will be forwarded by him to any chemists whose names are furnished him for that purpose.

ALBERT C. HALE,

Secretary of the American Chemical Society.

July, 1901.

RAILWAY TIME TABLES BETWEEN THE EAST AND DENVER.

At the request of the permanent secretary of the American Association, Dr. L. O. Howard, we publish time tables of some of the railways between the East and Denver. We hope to give subsequently further details.

PENNSYLVANIA RAILROAD COMPANY.

Leave New York.	Leave Philadelphia.	Leave Baltimore.	Leave Washington.	Arrive Chicago.

SCIENTIFIC NOTES AND NEWS.

AT the meeting of the Senate of London University on July 11, Professor A. W. Rücker, professor of physics in the Royal College of Science and secretary of the Royal Society, was elected principal of the University.

AT the first congregation of the University of Birmingham, on July 6, the degree of Master of Science was presented to the following officers of the University: Dr. Oliver Lodge, principal; Robert S. Heath, vice-principal and professor of mathematics; Bertram C. A. Windle, dean of the faculty of medicine and professor of anatomy; John H. Poynting, dean of the faculty of science and professor of physics; Thomas Bridge (zoology), Charles Lapworth (geology), William Hillhouse (botany), Percy F. Frankland (chemistry), Frederick W. Bursall (engineering), Adrian J. Brown (brewing), Bostock Hill (public health), Gilbert Barling (surgery), Bennett May (surgery), Alfred H. Carter (medicine), Robert Saundby (medicine), Edward Malins (midwifery), Priestly Smith (ophthalmology), Arthur Foxwell (therapeutics), Robert F. C. Leith (pathology), James T. J. Morrison (forensic medicine), Edmond W. W. Carlier (physiology), John W. Taylor (gynecology).

SECRETARY of Agriculture Wilson, Mr. E. Henry Stevens, of the House Committee on Agriculture, and Professor Milton T. Whitney, chief of the division of soils of the Department of Agriculture, made last week a trip through Connecticut and western Massachusetts, seeking facts and information relative to the growing of tobacco under cloth in those sections.

UNDER the auspices of the New York Botanical Garden, Professor Lucien M. Underwood, of Columbia University, has visited Porto Rico, and Dr. M. A. Howe, assistant curator of the museum, has explored the coasts of Nova Scotia, Newfoundland and New Brunswick.

SURGEON KINYOUN, recently of San Francisco, and now in charge of the Marine Hospital at Detroit, has been detailed to visit Japan and China to inspect the work of the marine hospital service with special reference to the plague.

DR. FESHENKO, of the University of St.

Petersburg, has been sent by the Imperial Geographical Society to the Pamir, and is at present at Tashkent making geological, botanical and zoological researches.

DR. E. J. LEDERLE, chief chemist of the Health Department of New York City, sailed on July 18 for Europe, where he will inspect the municipal laboratories of Europe, including Paris, Brussels, Cologne, Berlin, London, Glasgow, Edinburgh and Dublin.

MESSRS. DARTON, Hatcher and Fraas have completed the special study of the Titanotherium Beds in South Dakota for the U. S. Geological Survey. The work was greatly impeded by exceptionally rainy weather. Mr. Darton will report upon the results which will subsequently be used in the monograph on 'The Titanotheres' by Professor Osborn.

PROFESSOR LESTER F. WARD, of the U. S. Geological Survey, has recently made a two months' trip in the Triassic of Arizona, studying the geology and collecting fossil plants. A small but valuable collection of fossil vertebrates was made at the same time for the U. S. National Museum.

PROFESSOR STEWART CULIN, curator of the Pennsylvania University Museum, has returned to Philadelphia, after a visit to Cuba in search of traces and relics of the aboriginal Indian tribes.

THE American astronomers who went to Sumatra to observe the eclipse of the sun in May arrived at San Francisco on the *Indiana* on July 16. The members of the party include Professor E. E. Barnard, Professor A. N. Skinner, Commander U. S. N.; Professor W. S. Eichelberger, U. S. N.; F. B. Littell and H. D. Curtis.

REUTER'S AGENCY telegraphs from St. Petersburg that Baron Toll, the leader of the Russian Arctic expedition, has sent to the Academy of Sciences the following despatch from Yeniseisk, dated April 16: "Safely arrived in the Gulf of Taimyr, where I am wintering. We have erected a station for meteorological observations in the neighborhood of Archer Harbor. Mathiessen has explored the Nordenskiöld Islands, traveling in sledges. Kolomeizeff has been sent to the mouth of the Yenisei with

orders to establish a coaling station. I myself shall traverse the Cheliuskin Peninsula with Koltshak. Matthiessen has been appointed commander of the *Sarja*. All are well."

PROFESSOR ERNST HAECKEL has consented to give a course of lectures on paleontology in London.

DR. TRACY F. HAZEN, recently fellow in botany at Columbia University, has been appointed director of the Fairbanks Museum of Natural Science at St. Johnsbury, Vt.

MR. E. G. HASTINGS, who has held the position of assistant bacteriologist at the University of Wisconsin Experiment Station, has been granted leave of absence for a year's study in Europe. His position will be filled in the interim by Mr. John F. Nicholson.

A STATUE of Chevreul was unveiled on July 11 in the Paris Museum of Natural History.

DR. JAMES MARVIN died at his home at Lawrence, Kansas, July 10 last, aged 81 years. Dr. Marvin was educated at Alfred Academy (now Alfred University) and Allegheny College, in both of which institutions he was subsequently a teacher. For a number of years he was superintendent of schools at Warren, Ohio, from which place he went to Allegheny College as professor of mathematics and astronomy. In 1874 he was called to the chancellorship of the University of Kansas, doing much during his ten years' service to build up that institution. Later he became the first principal of Haskell Institute, one of the leading government schools for Indians, and laid the foundations for what has since become a great school. His public service closed with a six years' term as pastor of a Methodist church at Lawrence. For several years he had been an invalid, slowly declining under the action of paralysis.

THE death of H. W. Harkness, which we announced last week, will be a serious loss to science in San Francisco. Born eighty years ago in Massachusetts, he went to California in 1849, and, having amassed a considerable fortune by the practise of medicine, retired in 1869 and devoted himself chiefly to scientific interests. He was from 1887-1896 president of the California Academy of Sciences. He was the author of numerous contributions to

botany, chiefly on the cryptogams. He presented his collections, containing 10,000 specimens, to the Academy of Sciences.

MISS EVA M. REED, indexer in the library of the Missouri Botanical Garden at St. Louis, was instantly killed by a train while walking on the tracks near Louisiana, Missouri, on July 7. The body was interred at St. Louis. Miss Reed had been connected with the Botanical Garden for about seven years, going to that institution from the University of Wisconsin. She was deeply interested in botanical pursuits, giving attention to the mosses, as well as to the winter characters of trees, a subject on which she had written for publication. Not long ago she began working on plant ecology, under the direction of the botanical department of the University of Chicago, and it was in the prosecution of investigation in the field that she met her death.

SIR CUTHBERT EDGAR PEEK, who maintained at Rowsdon an astronomical and meteorological observatory, died on July 5, at the age of forty-six years. He went to Queensland on the last transit-of-Venus expedition, and made numerous contributions to astronomy and meteorology. He was an active supporter of scientific work, being a member of the council of the Royal Geographical Society and of the Royal Meteorological Society and honorary secretary of the Anthropological Society.

THE death is announced of Miss Eleaonor A. Ormerod, known for her contributions to economic entomology, on which subject she had published a number of works. She was recently given the LL.D. degree by the University of Edinburgh, where she had been examiner in agricultural entomology.

THE death is also announced of Dr. Gino Ciaccio, professor of comparative anatomy at the University of Bologna, and of James Hamblin Smith, of Gonville and Caius College, Cambridge, a famous coach of the University and the author of several works on elementary mathematics.

THE New York City Municipal Civil Service Commission will hold on July 31 an examination for the position of assistant bacteriologist with a salary of \$1,200.

It is stated in *Nature* that the London Institution of Mining and Metallurgy will award twenty-five guineas each for the best papers on the comparative merits of circular and rectangular shafts for mines of great depth.

THE Association of Military Surgeons proposes as a subject of its Enno Sander prize for 1901-1902 'The Most Practicable Organization for the Medical Department of the United States Army in Active Service.' The prize is a gold medal and \$100. The essays must be submitted before the end of February, 1902. Further particulars may be obtained from the secretary, James Evelyn Pilcher, Carlisle, Pa.

THE physiological laboratory given to the University of Edinburgh by Mrs. Cox in memory of her father, the late Professor John Hughes Bennett, was dedicated on July 20, an address being made by Sir J. Burdon Sanderson.

THE Board of Supervisors of San Francisco adopted a resolution on July 15 accepting the offer of Mr. Carnegie to give to this city \$750,000 for the establishment of a central and branch libraries. The concluding sections of the resolutions read as follows:

Be it resolved, That the gift of Andrew Carnegie be and the same is hereby accepted, and that the thanks of the Board of Supervisors of the city and county of San Francisco be and are hereby extended to him. And be it further

Resolved, That the example set by Mr. Carnegie in distributing his vast private fortune to great public purposes, and at the same time inducing municipal cooperation in channels which might otherwise be neglected, should serve as an example to other citizens and meet the approval and encouragement of all.

BARON IWASAKI has purchased the library of the late Professor Max Müller, containing 13,000 volumes, for presentation to the University of Tokyo.

AIDED by a special fund presented by a friend of the American Museum, Professor Osborn has sent out two expeditions especially in search of fossil horses—one to Texas and one to eastern Colorado. Word has just been received at the museum that the very first discovery made by the Texas party included a deposit of skulls of the three-toed horse, *Protohippus*, associated

with parts of the limbs, feet and backbone. This is one of the stages especially desired in the long series leading up to the modern horse. The skulls are reported to be the best that have thus far been found, and this discovery is an auspicious opening to this special series of explorations. *Protohippus* belongs to the Pliocene, and is believed to be the immediate ancestor of the true horse.

THE New York Zoological Park has just received from the Galapagos Islands via San Francisco, five very large giant tortoises, representing three species, *Testudo microphyes*, *vicina* and *elephantopus*. The largest is a very old specimen measuring, in straight lines, 42 inches in length, 30½ in width, and in height 20 inches. Its weight is 310 pounds. Three other specimens weigh respectively 156, 129 and 118 pounds. These five specimens represent the pick of a lot of 13 collected in the Galapagos group last winter by Capt. William Johnson, of San Francisco.

THE *Bulletin* of the New York Botanical Garden states that the first instalment of the Vignier Herbarium, the purchase of which was arranged by Dr. Britton while in Europe last fall, has lately been received. This portion of Mr. Vignier's herbarium contains the Schaffner Mexican collection numbering about 4,500 specimens, many of them duplicated, and thus valuable for future exchanges, and that part of a general collection consisting of cryptogams, and the flowering plants from the *Ranunculaceæ* to the *Leguminosæ*, according to the DeCandollean system, numbering 10,877 specimens. This important accession was made by means of funds provided by Mr. Andrew Carnegie.

THE Paris correspondent of the *London Times* writes under date July 2: I went yesterday to Vesinet, a pretty little village between Paris and St. Germain, where I witnessed some most interesting experiments in wireless telegraphy by Colonel Eugene de Pilsoudski, an engineer of the Russian army. His system depends in no way upon the air for transmission of the current. The earth itself is his conductor. He established his apparatus in two villas about one kilometer apart. The messages were transmitted clearly, rapidly,

and without the slightest hitch. The current passes from the transmitter to an underground plate, and then to a box containing the isolating elements of pitch and petroleum, whence it is carried to the receiver at a distance and read off by a Morse apparatus, which in turn reproduces the communications transmitted back to the starting-point. The realization within a limited space of the theory of wireless tellurian telegraphy is therefore complete. A demonstration of the feasibility of the system is shortly to be made between Paris and Compiègne, and immediately afterwards between Paris and Brussels. Of course the radius of action depends upon the power of the electrodes, but Colonel de Pilsoudski declares that messages can traverse not only mountains and streams, but more easily still the sea.

AN exposition will be held at Osaka in Japan from March 1 to July 31, 1903. The articles to be exhibited include agricultural, horticultural, forestry and water products; mining, industrial, and mechanical exhibits; and those pertaining to education, science, sanitation, economy and the fine arts. The articles shall be those collected, produced or manufactured by the subjects of the Empire, or by foreigners residing in Japan. The cost of the exposition is to be paid by the imperial treasury, except the expense of exhibiting, which will be borne by the exhibitors.

UNIVERSITY AND EDUCATIONAL NEWS.

THE New York *Evening Post* states that Mrs. Mary Austin Carroll, of Boston, has just made a gift to the University of Virginia, by which the institution will receive during the remainder of her life an annual income of about \$11,000. Mrs. Carroll's father, the late Arthur W. Austin, at his death twenty years ago left his estate of \$400,000 in trust for the benefit of his daughter during her life, and at her death to go to the institution founded by Thomas Jefferson. Mrs. Carroll, sharing her father's love for the University, has just arranged to give for the rest of her life all her income except \$5,000 a year, which she reserves for her own support.

THE first meeting of the Trustees of the Carnegie Educational Fund was held in Edinburgh

on July 15. Lord Elgin, who presided, read a letter from Mr. Carnegie announcing that he had signed a deed placing \$10,000,000 at the disposal of the trustees.

THE last general Assembly of Connecticut passed a bill giving an appropriation of \$3,000 per annum to the Agricultural Experiment Station at New Haven for insect work and requiring that the station appoint a State entomologist and pay his salary. Mr. W. E. Britton was appointed to that office by the Board of Control at its meeting, June 10. The law also requires that all nurseries in the State be inspected once each year and that all nursery stock shipped into the State shall bear on each bale or package a certificate of inspection.

THE position of Austin teaching fellow in histology and embryology at the Harvard Medical School is vacant. The value of the fellowship is \$500, the appointment being annual. The holder is expected to give about one-third of his time to teaching in the laboratory and the remainder wholly to an original research, which must be approved by the professor in charge. In the prosecution of the research the large resources of the laboratory may be utilized. Applications should be accompanied by a statement of previous experience and work, and should be addressed to Dr. Charles S. Minot, Harvard Medical School, Boston, Mass.

DR. F. L. STEVENS, who has just returned from a year of study at Bonn, Halle and Naples in the capacity of travelling fellow of the University of Chicago, has been elected instructor in biology, in full charge of the department, in the College of Agriculture and Mechanic Arts, Raleigh, N. C.

N. E. GILBERT, A.B. (Wesleyan, 1895), Ph.D. (Johns Hopkins, 1901), has been appointed instructor in physics at Lehigh University.

FREDERICK H. SAFFORD, Ph.D. (Harvard), has resigned from the mathematical staff of the University of Cincinnati.

AT Birmingham University, Dr. A. H. R. Buller has been appointed lecturer in botany and Dr. R. C. Farmer demonstrator in chemistry.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE : S. NEWCOMB, Mathematics ; R. S. WOODWARD, Mechanics ; E. C. PICKERING, Astronomy ; T. C. MENDENHALL, Physics ; R. H. THURSTON, Engineering ; IRA REMSEN, Chemistry ; CHARLES D. WALCOTT, Geology ; W. M. DAVIS, Physiography ; HENRY F. OSBORN, Paleontology ; W. K. BROOKS, C. HART MERRIAM, Zoology ; S. H. SCUDDER, Entomology ; C. E. BESSEY, N. L. BRITTON, Botany ; C. S. MINOT, Embryology, Histology ; H. P. BOWDITCH, Physiology ; J. S. BILLINGS, Hygiene ; WILLIAM H. WELCH, Pathology ; J. MCKEEN CATTELL, Psychology ; J. W. POWELL, Anthropology.

FRIDAY, AUGUST 2, 1901.

DOCTORATES CONFERRED BY AMERICAN UNIVERSITIES.

THE following table, compiled from official sources, gives details in regard to the conferring of the degree of Doctor of Philosophy during the past academic year :

	Humanities.	Sciences.	Total for 1901.	1900.	1899.	1898.
Yale.....	21	18	39	26	30	34
Chicago.....	20	16	36	37	24	36
Johns Hopkins..	11	19	30	33	38	33
Harvard	14	15	29	36	24	26
Columbia	12	13	25	21	33	22
Pennsylvania..	13	12	25	9	20	24
Cornell	8	13	21	19	7	19
Virginia	4	4	8	2	2	0
Clark.....	0	7	7	9	5	13
New York.....	5	1	6	7	9	5
Wisconsin	2	3	5	5	7	5
Columbian.....	2	1	3	5	0	1
Michigan.....	3	0	3	5	4	7
Princeton	3	0	3	3	3	0
Brown	1	1	2	3	3	1
Minnesota	2	0	2	3	2	1
California	0	2	2	2	3	1
Stanford	1	1	2	2	0	2
Bryn Mawr.....	0	2	2	1	3	3
Vanderbilt.	0	1	1	3	0	0
Nebraska.....	0	1	1	1	1	2
Washington.....	0	1	1	0	2	0
Tulane.....	0	0	0	1	0	0
Colorado.....	0	0	0	0	1	0
Kansas.....	0	0	0	0	1	0
Missouri.....	0	0	0	0	1	0
Syracuse.....	0	0	0	0	1	0
Total.....	122	131	253	233	224	234

The table shows that the degree was conferred on 253 candidates, an increase of 20

as compared with 1900, of 29 as compared with 1899, and of 19 as compared with 1898. This probably represents the largest number of degrees conferred during any year since the development of our university system. The degree was conferred in the sciences in nine more cases than in the humanities, a gain for the sciences as compared with preceding years. In 1898 there was an excess of 24 degrees in the humanities; in 1899 of six degrees in the sciences, and in 1890 of seven degrees in the humanities. There appears to be consequently a relative increase in the number of those who pursue advanced studies in science. We have in previous years called attention to the fact that the division of the subjects into sciences and humanities is somewhat artificial. Those that have been allotted to the exact and natural sciences are shown in the accompanying table. Of the 253 degrees, three were doctors of science, one each being given by Cornell, New York and Vanderbilt. In view of the rareness with which this degree is conferred and the desirability of using it for an honorary degree, it seems evident that it should no longer be used as a practical equivalent for the Ph.D. The Ph.D. degree, we are glad to note, was not given *causa honoris* by any university from which reports have been received. It will be noticed that the universities are divided into two fairly distinct classes. Seven—namely, Chicago, Columbia, Cornell, Harvard, Johns Hopkins, Pennsylvania and Yale—have almost invariably given between 20 and 40 degrees each year, whereas none of the other universities reaches an average of 10. This year, for example, the seven universities mentioned gave 205 degrees as compared with 48 degrees by the twenty other universities on the list. We may doubtless, however, expect a rapid increase in the number of degrees given by the State universities of the Middle and Western States.

Harvard and Yale have this year given as many degrees in the sciences as in the humanities, whereas in previous years the humanities have predominated, as the sciences have at Johns Hopkins and Cornell. There was a relative excess in the number of degrees in chemistry at Johns Hopkins; in physics at Cornell and Johns Hopkins; in mathematics at Yale; in zoology at Chicago; in psychology at Clark, Yale and Harvard, and in geology at Johns Hopkins and Harvard.

The number of doctorates in the sciences last year and in the three preceding years is as follows:

	1901.	1900.	1899.	1898.
Chemistry	28	26	32	27
Physics.....	23	15	7	11
Mathematics.....	18	11	13	11
Zoology.....	15	11	11	12
Psychology.....	13	9	15	18
Geology.....	10	5	5	6
Botany.....	8	12	11	11
Astronomy.....	5	4	2	3
Sociology.....	3	3	5	—
Education.....	2	8	5	—
Physiology.....	1	4	1	4
Anthropology.....	1	2	0	2
Paleontology.....	1	2	4	0
Anatomy.....	1	—	—	—
Bacteriology.....	1	1	1	0
Engineering.....	1	—	—	—
Mineralogy.....	0	0	2	0
Meteorology.....	0	0	1	0
Total.....	131	113	115	105

The names on whom the degrees were conferred and the titles of their theses are as follows:

JOHNS HOPKINS UNIVERSITY.

1898. Robert Montgomery Bird: The Action of Ammonia and of Alcohols and Alcoholates on the Chlorides of Orthosulphobenzoic Acid.
1899. Jay Allan Bonsteel: The Soils of St. Mary's County, Md., showing the Relationships of the Geology to the Soils.
1900. Lyman James Briggs: On the Absorption of Water Vapor, Carbon Dioxide and certain Substances in Aqueous Solution by Finely Divided Quartz.
1901. Benjamin Palmer Caldwell: On the State of Equilibrium of Certain Double Iodides, Cyanides, Nitrates and Sulphates in Aqueous Solution.

Victor John Chambers : A Further Investigation of the Action of Phenols and Alcohols on the Chlorides of Paranitroorthosulphobenzoic Acid.

William Chambers Coker : Observations on the Gametophyte and Embryo of *Taxodium Distichum*.

Winterton Conway Curtis : Life History, Normal Fission and Reproductive Organs of *Planaria Maculata*.

James McDowell Douglas : The Dissociation of certain Acids, Bases and Salts at different Temperatures.

Joseph Christie Whitney Frazer : I. On Relations between the Color and the Composition and Constitution of the Alkali Salts of Nitrophenols. II. Comparison of the Metasulphaminebenzoic Acids made by Different Methods.

Norman Everett Gilbert : Some Experiments upon the Relations between Ether, Matter and Electricity.

Gilbert Logan Houser : The Neurones and Supporting Elements of the Brain of a Selachian.

Norton Adams Kent : Notes on the Zeeman Effect. George Curtis Martin : The Miocene Gastropod Fauna of Maryland.

Francis LeJau Parker, Jr. : A Study of the Preparation of Permanganic Acid by Electrolysis.

Harold Pender : On the Magnetic Effect of Electrical Convection.

Israel Euclid Rabinovitch : The Foundation of the Euclidean Geometry, as viewed from the Standpoint of Kinematics.

George Burr Richardson : A Study of the Red Beds of the Black Hills of South Dakota and Wyoming.

Ward Weaver Simmons : A Further Study of the so-called infusible Diamide of Parasulphobenzoic Acid.

Charles Carroll Schenck : Some Properties of the Electric Spark and its Spectrum.

YALE UNIVERSITY.

Katherine Jeannette Bush : Descriptions of three New Genera and sixteen New Species belonging to the Tribes Sabellides and Serpulides.

Charles Montague Cooke, Jr. : The Hawaiian Hepaticae of the Tribe Trigonatheae.

Walter Wells Davis : Researches in Cross Education.

Edgar Selah Downs : The Induced Alternating Current Discharge studied with reference to its Spectrum and especially the Ultra-Violet Spectrum.

Arthur Sullivan Gale : On a Particular Class of Algebraic Minimum Curves and Surfaces.

Laurence Ilsley Hewes : Some Properties of Path-Curves of Continuous Projective Groups.

Treat Baldwin Johnson : Researches on Amidines and Imidoesters.

J. E. Wallace Wallin : Researches in the Rhythm of Speech.

Stuart Weller : Studies of the Paleozoic Faunas of the Interior Continental Basin of North America, Two Volumes.

Joshua Larson : A Computation of the Orbit of Σ 3062.

Edwin Hoyt Lockwood : Atmospheric Stability as affected by Water Vapor.

Ishiro Miyake : Researches in Rhythmic Action.

John Treadwell Norton, Jr. : The use of Sodium Thiosulphate in Analysis.

Charles Adams Peters : Oxalic Acid and the Oxalates in Analysis.

Chauncey Brewster Rice : An Experimental Study of the Wehnelt Interrupter.

Edward Christian Schneider : The Excretion of Kynurenic Acid.

Edwin Bidwell Wilson : The Decomposition of the General Collineation in Space into three Skew Reflections.

Ruth Goulding Wood : Non-Euclidean Displacements and Symmetry Transformations.

UNIVERSITY OF CHICAGO.

Charles Joseph Bushnell : The Development of the Corporation in England in Relation to the Sentiment of Antagonism.

John Gaylord Coulter : A Contribution to the Life History of *Sium*.

Elliot Rowland Downing : The Spermatogenesis in Hydra.

Minnie Marie Enteman : Coloration of *Polistes* (the Common Paper Wasp).

William Findlay : The Sylow Subgroups of the Symmetric Group on K Letters.

John Morris Gillette : The Culture Agencies of a Typical Manufacturing Group, South Chicago.

Ralph Stayner Lillie : Excretory Organs of *Arenicola Cristata*.

Anne Moore : The Effect of Electrolytes on Rigor Mortis.

Virgil Everett McCaskill : The Metamerism of *Hirudo Medicinalis*.

Ralph Harper McKee : The *Isourea* Ethers.

James Bertram Overton : Parthogenesis in *Thalictrum purpurascens*.

John McClellan Prather : The Skeleton of *Salax* Microdon.

Fritz Reichmann : Capacities at Small Distances.

Samuel Bower Sinclair : The Possibility of a Science of Education.

Ernest Brown Skinner : On Ternary Monomial Substitution—Groups of Finite Order with Determinant ± 1 .

Helen Bradford Thompson : Psychological Norms.

HARVARD UNIVERSITY.

- Charles Hamlin Ayres, Jr. : Measurements of the Internal Resistance of Galvanic Cells.
- Maurice Alphens Bigelow : The Early Development of Lepas, A Study of Cell-Lineage and Germ-Layers.
- Charles William McGowan Black : The Parametric Representation of the Neighborhood of a Singular Point of an Analytic Surface.
- George Ashley Campbell : On Loaded Lines in Telephonic Transmisson.
- Clarence Augustus Chant : The 'Skin'-effect in Electric Oscillators ; with a Method of determining Wave-Lengths.
- Thomas Harvey Haines : The Temporal Relations of Mental Processes : An Experimental Study of Objective and Subjective Simultaneity.
- Robert William Hall : The Development of the Mesonephros and the Müllerian Ducts in the Amphibia.
- Charles Nelson Haskins : On the Invariants of Quadratic Differential Forms.
- George William Heimrod : The Silver Voltmeter.
- Edwin Bissell Holt : The Motor Element in Vision.
- Ernest Howe : The Pre-Cambrian Intrusive Rocks of the Animas Canyon, Colorado.
- Benjamin Shores Merigold : A Revision of the Atomic Weight of Uranium.
- Raymond Herbert Stetson : Rhythm and Rhyme.
- Reuben Myron Strong : The Development of Color in the Definitive Feather.
- Alfred William Gunning Wilson : Physical Geology of Central Ontario.

COLUMBIA UNIVERSITY.

- Grace Andrews : The Primitive Double Minimal Surface of the Seventh Class and its Conjugate.
- Frederick Mark Becket : Electrolysis of Fused Salts.
- Walter Richard Crane : Investigations on Magnetic Fluids with reference to Magnetic Ore Concentration.
- Bergen² Davis : On a Newly Discovered Phenomenon Produced by Stationary Sound Waves.
- Alfred² Newton Richards : A Chemical Study of Yellow Elastic Connective Tissue.
- Arthur Cleveland Hall : Civilization and Crime.
- Edward Frank Kern : The Quantitative Determination and Separation of Uranium.
- Alfred [Louis] Kroeber : Decorative Symbolium of the Arapahoe.
- George² W. A. Lucky : The Professional Training of Secondary Teachers in the United States.
- Joseph Warren Miller, Jr. : Elastic Properties of Helical Springs.

Herbert Raymond Moody : Reaction at the Temperature of the Electric Arc.

Francis Bertody Sumner : Kupfer's Vesicle and its Relation to Gastrulation and Concrecence.

Clark Wissler : The Correlation of Mental and Physical Tests.

CORNELL UNIVERSITY.

- William Suddards Franklin : Poynting's Theorem.
- Ernest Blaker : A Spectrophotometric Comparison of the Relative Intensity of Light from Carbon at Different Temperatures.
- Judson Freeman Clark : On the Toxic Action of Certain Salts of Mercury and Copper.
- Benton Dales : Contributions to the Chemistry of the Rare Earths of the Yttrium Group.
- Margaret Clay Ferguson : The Development of the Pollen Tube and the Division of the Generative Nucleus in Certain Species of Pines.
- William Benjamin Fite : On Metabelian Groups.
- Henry Waldo Kuhn : On Imprimitive Substitution Groups.
- Charles Philo Matthews : On Certain Improved Photometric Apparatus and Results therewith obtained.
- Wilton Marks Munson : The Horticultural Status of the Genus Vaccinium.
- Rolla Roy Ramsey : The Effect of Gravity and Pressure on Electrolysis.
- John Sandford Shearer : Some Effects of High Elective Tension on Dielectrics.
- Carrie Ransom Squire : A Genetic Study of Rhythm.
- George Walter Stewart : Distribution of Energy in the Spectrums of Acetylene.

UNIVERSITY OF PENNSYLVANIA.

- Gilbert Hillhouse Boggs : I. The Separation of Vanadic Acid from Metals by means of Hydrochloric Acid Gas. II. The Occurrence of Molybdenum in the Mineral Endlichite.
- Henry Shoemaker Conard : Water Lilies : a Monograph on the Genus Nymphaea.
- Burton Scott Easton : Substitutions and Substitution Groups.
- William Clarence Ebaugh : On the Atomic Weight of Arsenic.
- Henry Brown Evans : The Right Ascensions of One Hundred and Eighty Latitude Stars.
- Alice Macmichael Jefferson : Aromatic Bases as Precipitants for Rare Earth Metals.
- John Raymond Murlin : The Digestive System of the Land Isopods, with special reference to the Morphology of Absorption and Secretion.
- Marie Louise Nichols : The Spermatogenesis of

Oniscus asellus with especial reference to the History of the Chromatin.

Jonathan Taylor Rorer : A Definitive Determination of the Orbit of Comet 1898 χ —Brooks.

Thomas Maynard Taylor : I. The Atomic Weight of Tungsten. II. On the Ammonium Tungstates.

Caroline Burling Thompson : *Zygeupolia Litoralis* : A New Herteronemertean.

Roxana Hayward Vivian : The Poles of a Right Line with Respect to a Curve of Order n .

CLARK UNIVERSITY.

Clemence J. France : Psychology of Gambling.

Samuel B. Haslett : A Plan and Rationale of Sunday School Work.

James Edmund Ives : Contributions to the Study of the Induction Coil.

Herbert G. Keppel : The Cubic 3-spread Ruled with Planes in 4-fold space.

Melanchthon F. Libby : Influence of the Idea of *Æsthetic* Proportion on the Ethics of Shaftesbury.

Charles H. Sears : Studies in Rhythm.

John N. Van der Vries : On the Multiple Points of Twisted Curves.

UNIVERSITY OF VIRGINIA.

Dr. Wm. A. Lambeth : Geology of the Monticello Area.

C. J. Moore : On the Products of Interaction between the Aliphatic Amines with certain Metallic Salts.

Herbert R. Morgan : The Orbit of Enceladus.

L. D. Skeen : Bacterial Flora of Charlottesville Reservoir Water.

UNIVERSITY OF WISCONSIN.

A BASIS OF SCIENTIFIC THOUGHT.*

LÉMERY in his *Cours de Chimie* (1675) was the first to separate that branch of science termed chemistry into organic and inorganic. The latter embraced those bodies found in the mineral world and those produced by means of such substances. Berzelius, recognizing that organic bodies contained carbon, maintained that they came about through the influence of a particular force—*vis vitalis*. In 1828, however, Wöhler synthetically prepared, from strictly inorganic materials in the laboratory, urea, the eventual product of animal metabolism. This discovery was followed by the synthesis of numerous other bodies hitherto thought to be possible of preparation only through the mysterious life-force.

Although the fundamental laws underlying these divisions of chemistry are the same, yet for pedagogic convenience this classification is adhered to by many; oth-

* Read at the April meeting of the N. C. Section of the American Chemical Society.

ers even diversify at greater length and we have physical chemistry, technological, analytical, agricultural and physiological chemistry. Chemical laws prevail and are the same, it matters not how one classifies his facts.

By mathematics through ages we have sought expression, whether by definite exact numbers, equations or indeterminates. It is the language of physics, making possible the expression of the invention of means for measuring force and calculating its effect upon matter. Joule, Helmholtz, Robert Mayer and Maxwell in their refined discoveries in mechanics touched chemistry, for the explanations of the phenomena of dissociation, solution, vapor pressure, osmotic pressure, etc., as developed by Arrhenius, Van't Hoff and Nernst, and taught by Ostwald, could never have gained currency save through the invention of a mode of quantitative expression by the former *savants*. J. B. Richter over a hundred years ago said that chemistry was a branch of mathematics. In fact, recently Lord Kelvin said 'Nothing can be clearly understood until we can express it in figures.'

It has only been within the past three-tenths of the present century that the barriers between physics and chemistry have been completely removed. This came about through the necessity of applying more closely certain laws of physics for the explanation of chemical facts, as, for example, electrolytic conductivity, heat of reaction and so on, and reciprocally by conversion of chemical force into electrical energy, heat, phosphorescent light, etc., and measuring the same. Mathematics has served as the medium of quantitatively determining these changes—in short, physical chemistry.

Geology may be termed the chemistry and physics of the earth's crust, more particularly applied to the inanimate portion of the world, although full cognizance is

taken of alterations of the shell by animals. Latterly geology and biology, the chemistry and physics of animal life, may be said to merge. Only recently chemistry and biology have been more firmly welded into a unit by the interesting work of Bredig and Müller von Berneck on 'Inorganic Ferments,' in which was demonstrated that certain life processes, hitherto regarded as possible only through the intervention of bacilli, could be carried out by means of an active chemical. This step is far in advance of even Büchner's enzyme fermentation. Attention has been called by the sensational press to the incomplete, but fruitful and promising, researches of Loeb and E. B. Wilson on parthenogenesis or chemical fertilization.

Cognizant of the persistent outcropping of favorable evidence for Darwin's evolution, we observe a unity of purpose in animal growth. Astronomy is the chemistry and physics of celestial bodies, and our knowledge of them is based upon observations dependent upon mathematical considerations. By the term mathematics here used of course must be meant simply a method by which the senses judge.

Accepting, therefore, the articulated relation among the various utilitarian divisions of science, we may develop our theme along the lines of those teachings of which we feel best qualified to write, namely, physics and chemistry, and regard all science as these two differently applied, either as to method of application, or class to which we would direct the application. We are perfectly aware of valid arguments that may be put forward strenuously against such a conception, yet feel that we shall be reduced to the study of a unity, as we must eventually express our knowledge of all science, qualitative and quantitative, mathematically.

Despite this unifying tendency to which we would call attention, chemists persist in discovering new elements, as argon, helium,

neon, krypton, radium, polonium, etc., and seem to have *facts* in direct opposition to our ideas. Over a century ago the same Richter noted resemblances of what chemists now term elements. Lavoisier by chemical and physical means proved the law of conservation of matter. Then Dalton ascribed weights to these elements composing matter, from which came our satisfactory atomic theory. None of these, as well as Joule's masterful proof of the conservation of energy, was possible without a medium of expression, namely mathematics, whereby the necessary comparison of weights and other measurements could be made. The triads of Döbereiner and Dumas, and Newlands' octaves foreshadowed a periodicity in atomic properties as later clearly and definitely set forth by Mendeléeff and Lothar Meyer. This periodic law, so long accepted, has had shadows cast upon its universality by the failure of scientists so far to satisfactorily arrange the new elements noted (and several old ones) in accord with it. Naturally we lend ourselves to the thought that this is due to our insufficient knowledge of these novel and striking members of the chemical family.

Prout may not have been so far wrong in conception when he asserted that all the elements were compounded of hydrogen, then known to have the lowest of all atomic weights. Stas's classical researches and re-determinations of the atomic weights and Morley's accurate proof of the mass relations of hydrogen and oxygen prevent absolutely the acceptance of the fact of the statement, but the germ of thought bears fruit. The idea is still prevalent, and Crookes has termed that initial, universal substance of which all else is composed, *protyle*. In fact, J. J. Thomson has only recently, in very wonderful researches on electric discharges in gases, been able ingeniously to demonstrate, by mathematical interpretation of the experimental results, that the atom is

made up of a number of smaller bodies, which he terms *corpuscles*.

Thus we are brought almost face to face with the most ancient alchemical teachings. Within recent years, Hartley, thoroughly orthodox, has written that "one element in a group differs in its properties from another not because it consists of another kind of matter, but because the quantity of matter in an atom is different." While we are not inclined to give over-serious consideration to Fittica's recent assertion that he has actually transmuted phosphorus into arsenic under one set of conditions and into antimony under another, doubtless later transmutation will become an experimental fact; not that all our base metal will be converted into a precious one, but we shall secure more refined methods and further decompose our present elements; or the increased number of elements, yearly augmented, shall give us a more perfect periodicity, demonstrating the relationship of the elements and their unity without requiring the actual experimental proof. The speculative hylozoists may thus have foretold events.

We have other experimental evidence pointing in the direction indicated. Some of our chemistries, not so long ago, dogmatically taught that hydrogen was the lightest known gas and impossible of liquefaction; or if it could be solidified, it would be metallic in character. Dewar, Olzewsky and Wroblewsky have secured that gas as a limpid liquid by intense refrigeration in vacuum-jacketed apparatus. And but recently the first named in classical researches reduced the temperature of liquid hydrogen to within eighteen degrees of the absolute zero (-255° C.) and obtained white, crystalline, solid hydrogen. These researches with extreme cold and Moissan working at from three to four thousand degrees give us the widest ranges of temperature. The latter has already secured many elements hitherto regarded as non-volatile in a gas-

eous condition. Like Dewar's work at the low temperatures, it appears that a refinement of skill will secure all elements in a gaseous condition. Thus all matter, that is, elemental, may exist in the three physical states.

In the domain of physics, observation of the marvelous effects of the Röntgen rays, Becquerel rays, the characteristic property of certain old and some recently discovered elements, as barium, thorium, radium and polonium, show new things undreamt of. We cannot say that these discoveries, praise-deserving and wonder-creating as they are, will give us final proof of the truth of our premise as put forth, yet they do point in that direction.

All forms of energy are interchangeable, hence we have but one force, whether it exhibit itself as heat, electrical energy, chemical force, or what not. These new rays, active and specific in their demonstration, are but altered forms of the *one* force. Why not therefore a *one matter*? Having reached that point we may con within reason Ostwald's dictum, that all is force, there is no such thing as matter. We may well conclude by repeating the query of the elder Büchner, that *aberwitzig* youth: "Is it a duty to believe things that can not be proven?"

CHARLES BASKERVILLE.

FORMATIVE MUSEUM PERIOD.*

SCIENTIFIC activity developed more slowly and was less encouraged in New York in the earlier years of this century than in its neighboring rivals Boston and Philadelphia. The expression of a mercantile, or more harshly described as that of a money-making city was early acquired, and baffled or obscured the spirit of scientific research. In a measure this suggestion, applied to the miscellaneous avenues of enterprise and the accumulation of wealth, was sensibly deceptive. It would be quite impossible to

stifle the incentives to the study of nature in a population of nearly one million people, and the limited consideration given to physical, chemical and geological science in the colleges, high-schools and seminaries, which aroused unflinching increased interest in the objects of nature, led to their collection, and stimulated local societies in their study and record.

An examination of the decade immediately prior to the establishment of the American Museum of Natural History, and by implication a reference to the conditions somewhat earlier, show us the formative stages shaping public needs for its appearance and public appreciation of its value.

Philanthropic and social designs, historical research, theological learning, medical study and literary invention were significant in the more intellectual life of New York City from 1830 to the date of the foundation of the Museum in 1870; the active participation in education of three colleges, a normal school for women, two medical schools, and numerous lesser centers of learning, including the invaluable services of the Cooper Institute with two seminaries devoted to religious instruction, were distinctive evidence that New York was not oblivious to the claim of knowledge.* But science in its purer forms and especially the study of nature in its animal and vegetable life, received scant recognition in the curricula of instruction. Two societies, the New York Academy of Sciences, later (1876) the Lyceum of Natural History, and the Torrey Botanical Club (1870), were the guardians and shrines of the scientific life of the city, and collected in a compact coterie the separated enthusiasts

* Columbia University (King's College) dates from the last century (1754); the New York University was opened 1831; the College of the City of New York (Free Academy) in 1849; The Normal College in 1855; Union Theological Seminary in 1836; General in 1817.

in the study of nature. The Lyceum was in a precarious condition for many years, and, at least until 1836, led a shifting, and in some respects shiftless, life. In the latter year it occupied its own building at 563 Broadway, and here the elder Stillman began a series of lectures on geology, seven in all, which produced a moderate sensation in the controversies of the day. A museum was a part of the appropriate features of the society and these were increased by donations to such an extent that Mr. J. H. Redfield, a competent judge, alludes to them as 'large,' a term certainly of variable significance in the mouth of a collector. The exact nature and contents of these collections can be determined from the chapter on collections in Professor Fairchild's 'History.' In view of the many local features now introduced in the halls of the Museum and as a means of determining the advance made in the expectations and ambitions of a Museum, a glance at these collections is instructive. As early as 1817, Messrs. Torrey, Rafinesque and Knevels were made a committee 'to travel and explore the natural history and productions of the neighboring countries'; with them in this work were associated Drs. Mitchill and Townsend. Bones of a mastodon were found in Orange Co., later were added a right whale and a swordfish, from the Atlantic, while specimens of the Wallkill carp and pike, and 'white wild sheep' from the Rocky Mountains, formed the nuclei of an increasing cabinet. 'Measures for completing a catalogue of the vegetables growing within 100 miles of the city' were early instituted, a device now variously illustrated in the collections of plants, buds and insects made to-day. Minerals were added, and repeated additions of snakes and fishes, fossils, skeletons, plants and shells gave it a local reputation and naturally engendered some self-congratulation amongst its members. But

when we learn that it was all accommodated in sixty-two boxes, the reader, familiar with existing needs, is recommended to realize how ideas and ideals advance.

It is not incumbent upon a historian of the American Museum to dwell upon the struggles of the Lyceum, but it would be an error in precision not to indicate the influence this and similar or affiliated movements had in determining its inception, and especially pointing out the critical relations in 1865 of the Lyceum to the projected

The Lyceum Building, No. 563 Broadway.*

American Museum. The Lyceum increased in its membership and the papers read at its meetings by Jno. J. Audubon, De Witt Clinton, James E. DeKay, Jno. LeCompte, Samuel L. Mitchill, Jno. Torrey, Asa Gray, G. Troost, Thos. Bland, James D. Dana, Theodore Gill, Gen. L. Lawrence, Jno. H. Redfield, Temple Prime, Alexander Agassiz, W. A. Dall, J. S. Newberry, William Stimpson, Benj. N. Martin, Augustus R. Grote, while listened to by a small audience, were contributions to the development of scientific feeling in New York. Dr. Jno. C. Jay, whose collections in conchology formed the nucleus of the present cabinet

of shells in the American Museum, as his library was the foundation of its present

University Medical College, Fourteenth St.

library, was one of the most enthusiastic and sedulous advocates of its interests while in its financial necessities the Lyceum leaned rather too heavily on his generous sympathy. Amongst the friends and officers of the New York Lyceum from 1860 to 1869 were names afterwards identified with the opening and even the later years of the American Museum. Amongst these were William A. Haines, Robert L. Stuart, George M. Lawrence, J. Carson Brevoort, D. Jackson Steward. These gentlemen were in several instances themselves collectors and possessed libraries and cabinets of commanding interest. They became interested in 1865 in a movement to secure moneys for the furtherance of the object of

the Lyceum with a possible reference to a permanent home and a hall for its collections. Quoting from Professor Fairchild's 'History of the New York Academy of Sciences' (p. 49) we learn that "the circular letter explaining the plan had affixed to it the names of the active members of that time, which were these: William A. Haines, Robert L. Stuart, George N. Lawrence, J. Carson Brevoort, H. D. Van Nostrand, Chas. A. Jay, Dr. John W. Greene, D. Jackson Steward, Charles M. Wheatley, Temple Prime, with Livingston Satterlee as Chairman." This effort was unsuccessful and the disappointed hopes of its authors were later revived and the cooperation of the more influential embodied in the creation of the American Museum of Natural History. All expectation of securing in the rehabilitation of the Lyceum a permanent museum was destroyed, when, on May 21, 1866, the Medical College building, in which the collections of the Lyceum were placed, was burned. The collections were not insured and only its valuable library escaped de-

Stuyvesant Institute, University Medical College.

struction. For years before this the Lyceum had been engaged in a despairing

struggle to perpetuate itself and secure an autonomous existence. It had become after the foreclosure of its own building the guest of the University, moving from the Stuyvesant Institute on Broadway to the Medical College upon the site of the present Tammany Hall. With the disappearance of its collections, and the abrupt termination of plans of its growth into a substitute for a museum, its formative relations to the American Museum ceased. Its scientific work continued, and the spirit of research it fostered helped the objects of the Museum. Such addresses as that of Dr. Barnard at its Semi-Centennial on 'The relation of science to the advancement of civilization and the expediency of a public provision for the support and encouragement of scientific inquiry' were directly stimulating to the project of a museum, at that moment ready to take place. Besides the slender and perhaps almost imperceptible influence of the Lyceum in creating a demand for a great museum, a small measure of regard can be bestowed upon the effect, on the public-spirited citizens at least, of the Brooklyn Institute, which during all these years from 1845 onward had been engaged in the study of science, in developing scientific discussion, scientific education, and in stimulating the acquirement of scientific collections. A few details of the history of this institution can hardly be disregarded in any exhaustive sketch of the scientific tendencies then surrounding or immanent in New York City. The Brooklyn Institute originated in the Brooklyn Apprentices' Library Association in 1825. It expanded rapidly. Lectures under its auspices were amongst the first public expositions of natural science near New York. In 1843 it assumed the pres-

ent name and function of the Brooklyn Institute, and was really an important factor in the educational life of Brooklyn. Here Agassiz, Dana, Gray, Henry, Morse, Mitchell, Torrey, Guyot and Cooke brought the treasures of their learning and thought during the conspicuously brilliant period of its activity from 1843 to 1867. Mr. Augustus Graham endowed it, and while for some time the interests of history and the claim of religion somewhat disabled the efforts of its scientific members, collections were made, notably that of coleoptera of Harvey

New York Dispensary, White and Centre Streets.

G. Rich, and the interests of science through its remarkable educational work advanced. It served its useful purpose in preparing the ground, in cultivating public feeling for the erection and support of a great museum. A stream of influence, not very perceptible, perhaps, but of some importance as the years drew near to 1876, emanated from the School of Mines in Columbia College (1864), where from the exertions of Professor J. S. Newberry the study of botany and zoology was more technically pursued than anywhere else in New York, and from which groups of young students

in geology and mineralogy were annually issuing.

Apart from the gradually educated demands amongst the studious classes, the public-spirited citizens of New York were intelligently sensitive to the reputation of the city, and when they recalled the museums of foreign cities whose collections and arrangements had challenged their admiration, they regretted that New York was yet without its own museum. In the United States it was behind other cities.

College of Physicians and Surgeons, Barclay St.

The Academy of Natural Sciences, founded in Philadelphia in 1812, possessed some collections with which were associated the names of Morton, Conrad, Nuttall, Audubon, Lucian Charles Bonaparte, Harlan, Rafinesque and others, and had created a provisional museum. Thomas Say, the distinguished conchologist, was its first curator, and through the generosity of William Maclure, the geologist, a building was opened in 1840 to the public, abundantly stored with the objects of nature, later succeeded by the structure at Nineteenth and

Race avenues; at Washington, the Smithsonian Institution, embracing the aims of the National Institute, was provided with a museum, apologetic, perchance, to the taste of an exacting critic, but still a dignified place for public instruction. Boston, from the exertions of the members of its Society of Natural History, had dedicated its museum on the 2d of June, 1864, when Professors Wyman and Wm. B. Rogers, with Mayor Lincoln, gave distinction to the ceremony. In Cambridge, as early as 1860,

rapid progress had been made on the new Museum of Comparative Zoology through the enthusiasm of Agassiz, whose definite relations to the creation of the American Museum of Natural History are presented later in this history. Chicago had created a museum under the auspices of Major Robert Kennicutt and later through the stimulus of Stimpson, and although it was damaged by fire in June, 1866, it still survived, and furnished, long prior to the erection of the great Field Museum, entertainment and information to the public.

There had been indeed in New York, outside of the immediate limits and influence of the Lyceum, efforts at museum installation. But they were industrial or historical or artistic and but slightly regarded the natural sciences. It must be remembered that the impulse which finally resulted in the Museum of Natural History was twofold, and enclosed the divergent tendencies towards nature and art, for the American and Metropolitan museums were simultaneous creations.

These preliminary efforts to give a mu-

seum to New York are significant in this connection. Perhaps the first museum in which a regard for scientific arrangement was shown in New York was that described in a rare and old pamphlet printed in 1804 entitled, 'Catalogue of the Natural Productions and Curiosities which Compose the Collections of the Cabinet of Natural History, opened for Public Exhibition at No. 33 William St., New York.*' This catalogue, apparently prepared by a Delacoste, in an introduction of four pages states that "there is scarce a city or town of any importance in Europe that is not possessed of a cabinet of that kind; but in the United States of America, the variety of whose productions and their dissimilarity from those of the Old World offer ample field for the researches of the naturalist, there is scarcely a collection deserving the name, except the one in Philadelphia belonging to Wm. Peale, whose indefatigable researches and laudable exertion to promote the knowledge of natural history entitle him to the gratitude of every friend of science." This collection was exhibited as the 'Delacoste Cabinet of Natural History,' at Federal Hall and apparently at No. 80 Greenwich Street. The collections, according to the examination instituted by Mr. Avery, appear to have been gathered on the coast of Guyana in South America, presumably by this Delacoste, and were made up of 'Quadrupeds, Birds, Fishes, Insects, Reptiles and Natural Productions of Cayenne.' The information is further elicited from the pages that "this above collection, which was originally put up for a Cabinet in St. Petersburg, would be sold here, if any purchaser should offer, and in case of the contrary will be forwarded next

spring to its first destination." Delacoste inaugurated the plan of subscriptions now familiar under a different form to his successors, and we find amongst his subscribers the names of leading New York people of that early day, as the Clintons, Hamiltons, Depeysters, Hosacks, Livingstons, Pringles, Seymours, Rutherfords, VanDykes, etc. Amongst these is the name of Jerome Bonaparte. Delacoste wished to make his establishment "permanent in New York, to augment his collections in proportion to the encouragement which he will receive, * * * and binds himself, if enabled by an adequate support, to travel through the whole continent of North America for the purpose of securing a skeleton of that anonymous animal called the mastodon." The subscriptions ranged from \$3.00 to \$1.00.

Before this in 1790 the Tammany Society 'established a museum for the purpose of collecting and preserving everything relating to the history of the country.' (Manual of the Common Council of New York, 1865, D. T. Valentine.) This museum was subsequently relinquished to Gardiner Baker, whose expenditure of time and money upon it had been considerable. After the death of Baker it was sold to W. J. Waldron, and finally was merged in the Scudder Museum, of which it formed the foundation, in Chatham Street. This embryonic effort was called the American Museum.

John Scudder, the predecessor of Barnum and Peale, established a pay museum of some merit in 1810. It was praised in very mellifluous English by a contemporary who rejoices that "it continues daily to improve, by extensive and valuable additions of the *works of nature* and artificial curiosities, from all parts of the world. Its immense collections are well arranged and beautifully displayed in four spacious saloons, each 100 feet in length; in addition

*We were indebted to the kindness of S. D. Avery, Esq., for the privilege of inspecting this interesting pamphlet, a notice of which was first printed in the *New York Times*, *Saturday Review*, July 1, 1899.

to which another department has recently been added of still larger dimension." This museum was on the ground now occupied by the St. Paul Building, opposite St. Paul's Church, Broadway. Fitz Green Halleck describes it as :

"Once the almshouse, now a school of wisdom,
Sacred to Scudder's shells and Dr. Griscom."

Peale's Museum and Gallery of Fine Arts stood on Broadway opposite to City Hall Park. It was founded in 1825. It is impossible to withhold at least a partial quota-

style in which the articles are mounted, render it one of the most interesting places of public amusement in the country. The 2d is a large and valuable collection of paintings, by eminent artists, amongst which may be particularly mentioned a portrait of Napoleon by Le Fevre ; a Magdalen by Le Brun, together with portraits of at least 150 celebrated citizens and foreigners. The 3d contains a very superior Cosmorana, several wax figures of good workmanship, fossil shells, minerals and miscellaneous curiosities."

As early as 1801 botany at least achieved in New York a notable recognition. It was then that Dr. David Hosack purchased the Elgin domain and created there a botanical garden. This property of twenty acres was between 5th and 6th avenues on 47th and 51st streets. Here, to quote the elegant Dr. Francis, "were associated in appropriate soil, exposed to the native elements or protected by the conservatory and hothouse, examples of vegetable life, and of variety of development—a collection that might have captivated a Linnæus or a Jussieu : and here indeed a Michaux and a Barton, a Mitchill, a Doughty, a Pursh, a Wilson or a Le Comte

often repaired to solve the doubts of the cryptogamist or to confirm the nuptial theory of Valliant."

This effort of Dr. Hosack's was a natural, though distant, precursor of a scientific museum.

Associated with Gardiner Baker in the organization of the American Museum was John Pintard, who laid the foundation of the N. Y. Historical Society. This institution gathered strength rapidly, as might have been expected, and its museum of his-

New York Institution. 'The Old Almshouse.' Western end facing Broadway.

tion depicting its attractions as given by the veracious Disturnell.* "It contains four spacious apartments, which are arranged in the following order : The 1st contains *specimens of natural history in all its branches*, and for beauty of arrangement, and the exquisite

* 'New York as it is in 1837 containing a general description of the City of New York, list of officers, public institutions, and other useful information. Including the public officers, etc., of the city of Brooklyn, accompanied by a correct map—published by J. Disturnell, 1837.'

torical treasures increased and expanded, and led a migratory life of more than 50 years, in which it wandered successively from the old City Hall, in Wall Street, to the Government House, in Bowling Green, to the N. Y. Institution, to the Remsen Building, on Broadway, to the Stuyvesant Institute, to the N. Y. University, until finally, in 1857, they rested permanently in the present home of the society at Eleventh Street and Second Avenue (History of N. Y. City, Benson J. Lossing). This society's collections assumed at this latter date the character of a museum in a popular sense, for at this time it secured the possession of Dr. Abbott's collection of Egyptian antiquities.

As early as 1854 Dr. Abbott's collection of Egyptian antiquities was brought to this country by its distinguished owner and an effort made to secure for it an appropriate home in America. Dr. Abbott, during a residence of more than twenty years in Egypt, where he had served as a physician in the army of Mehemet Ali during the Syrian war, had spared no pains and apparently little expense in the accumulation of a museum of Egyptian antiquities. The reception of his project was disappointing and hardly creditable to New York, where the collection it was expected would receive a proper reception. It did not, however, undergo the misfortune of being lost to the city. Several friends of Dr. Abbott and many gentlemen of influence and means, amongst whom was Peter Cooper, secured for it at least temporary security and it was placed in an apartment in the then New Institution, now the Cooper Union Hall, in Astor Place. The amount required was \$60,000. The editor of *Harper's Magazine* urged its purchase on the grounds that it 'would be the nucleus of a generous and extensive historical, scientific and artistic museum, which would give New York an elevated rank as a real, and

not a pretended and assumed, metropolis among the great cities of the world.' Such opinions, prevalent in the prints of the time, show how widely emphasized was the need of a great museum for the city. The Historical Society subsequently became the possessor of an immense art collection, numbering 1,000 examples of paintings and sculpture.

The project of a permanent crystal palace is familiar perhaps to the older men of our day, and the history of that elusive scheme, from the day when it opened as a World's Fair to its extraordinary half-ludicrous climax as a stock company, and a faint reflex of Sydenham Palace, under Barnum's direction, a well-remembered chapter in the events of half a century ago. In May, 1853, the approaching completion of the Crystal Palace was hailed by the New York public and by the large expectant population of its suburbs with delight and pride. It was at first a World's Fair, and in the sketches of the time we meet expressions of interest in which are mingled quite indiscriminately delight over its completion, and pleasure at the prospect of the Franconi hippodrome and a stupendous tower for panoramic views. The Crystal Palace was a wonderfully attractive building. It was modeled after the Crystal Palace of London, but was a really more admirable architectural work. It occupied the ground now known as Bryant Park, and covered five acres of ground. Its roof was supported on iron columns and the spaces between them were closed in by glass. It was a marvelous creation of Moorish and Byzantine composition. The annual fairs of the American Institute were held here, and it was perhaps the first seriously and generously conceived effort at the work and mission of a museum. It was known as the New York's Industrial Exhibition, and while it largely partook of the ephemeral bizarre and commercial character of a fair, it enlarged the

mind of the public by a display of both nature and art, and was a logical excitant of those desires in the scientific and artistic spirit of New York that led finally to the establishment of our art and scientific museums. During the season of the World's Fair the art and the products of Denmark, France, England, Germany, Belgium, Holland, were here superbly housed, and the illuminating effect upon our people cannot be overestimated. Its mention is essential for an appreciation of the conditions preliminary and formative to the erection of the present Museum of Natural History.

Those various enterprises and events so briefly epitomized would not of themselves have provided exactly the sort of stimulus required to bring to a procreant stage the undefined wishes of the leading citizens of New York for a great museum. This stimulus was provided, however. It arose from two separated centers of scientific activity, the organization of a Natural History Survey of New York State, and the persuasive influences emanating from Louis Agassiz at Cambridge.

Zoology in New York State received an early recognition in the labor of Samuel L. Mitchill, who in 1813 commenced an account of the fishes of the State, which, however, when published became a local review of the fishes near New York City. Contributions to the ornithology of the State were frequent, apart from the general works of Wilson, Bonaparte, Audubon, Cooper and DeKay, and William Cooper; Bachman, Le Conte, Barnes, Jay, Bailey, added fresh studies in herpetology, mammalogy, conchology and microscopy. As early as 1799 Mitchill had collected facts relative to the mineralogy of New York State, and he was succeeded by less-known names, until T. Romeyn Beck published in 1813 a more valuable review of this subject. The interest in the natural productions grew, and public attention and public funds became

gradually involved in the examination. Stephen Van Rensselaer in 1820 authorized Amos Eaton and T. Romeyn Beck to make a survey of the county of Albany. This was later extended to Rensselaer County, and over the line of the Erie Canal, the latter exploration producing Eaton's famous geological nomenclature and scheme of New York geology. The realization amongst public officers that the time was ripe for a thoroughly organized survey was more and more strengthened. In 1835, upon the motion of Charles P. Clich, a representative from New York, the Assembly of this State passed a resolution directing the Secretary of State, John A. Dix, to report upon the most expedient plan for a complete geological and natural-history survey of the State. Secretary Dix made the report, and on the 15th of April, 1836, this great survey was sanctioned by the Legislature, its maintenance provided for, and James E. DeKay, John Torrey, Lewis C. Beck, William W. Mather, Ebenezer Simmons, Timothy A. Conrad, Lardner Vanuxem and later James Hall were organized into a scientific directorship of its interests. The immediate result of this survey was the erection of a museum in Albany, and a new conception given throughout its publications to the importance of natural science. In 1869, the year immediately preceding the foundation of the museum, the survey had been in operation some thirty years, and Professor James Hall had gathered together a private collection of remarkable dimensions, representing the paleontological history of the State. A lesson, if exhibited instructively to the public, in geological events was here concealed, and only the facilities and purposes of a great museum could properly present it. The entire range of facts embodied in the reports of the survey and those of the New York State Cabinet had sensibly deepened the growing impression and expectancy that a great city must

assume the responsibilities of such an institution. This collection of Professor Hall's was for sale and its possession would be of inestimable value to a new institution.

The second and presumptively more effective influence shaping the thought of our citizens in this direction was the enthusiasm over the work and lectures of the great Swiss naturalist, Louis Agassiz. Agassiz's own success in securing the cooperation of the Massachusetts State Legislature to create the Museum of Comparative Zoology at Cambridge was a pioneer effort along lines followed quite closely by the American Museum of Natural History. It was indeed upon the inauguration of the Museum of Comparative Zoology that the second group, as Marcou has observed, of Agassiz's pupils, was formed, a group that disseminated over the entire United States a new love for natural science, and formed in themselves a radiant center of genius and industry.

Louis Agassiz, the Swiss naturalist who had declined the flattering and profitable offers of the French government to fill a position of superintendence over the Museum of Natural History or Jardin des Plantes in Paris, also the chair of paleontology in the State University of Switzerland, had established himself in the affections of America. His lectures were revelations, and the public of New York, as of almost every other great city, had been awakened to a new sense of appreciation of the study of nature. A series of distinguished men had imbibed from his contagious enthusiasm for nature, and had elevated the fame and established the permanence of American science; amongst these were Allen, Scudder, Verrill, Putnam, St. John, Morse, Emerton, Hyatt, Shaler, Ordway, Stimpson, Niles, Lyman, Clark, Mills, Packard, Dall, Mann, Uhler.

Agassiz's association with Bache, Gray, Morton, Leidy, Baird, Wyman, Pourtales,

Lesquereaux, Rogers, Conrad, Guyot, Marcou, in the higher scientific circles of America, and his intimacy with Emerson, Whittier, Longfellow, Felton, Lowell, Holmes, Binney, Hoar, Ticknor, Howe, Sumner, in the social regency of Boston, had created for him a personal preeminence quite unique in the United States. Certainly Agassiz's relations with all his pupils had not been invariably honorable to himself, but even the famous 'Salem Secession' with its resulting publication of *The American Naturalist* only served to give a wider prominence to his peculiar and fascinating enthusiasm.

And in 1860 Agassiz's long-cherished scheme of founding a great museum materialized in a conspicuous inauguration of the building of the Museum of Comparative Zoology in Cambridge. The Governor and his staff and a great concourse of people, with the faculty of Harvard College, were present, and the event, dwarfed indeed by the imminence of a terrible conflict, distinctly foreshadowed the development and expansion of the museum idea in the large cities of the Union.

Amongst those early engaged in the duties of this museum was Albert S. Bickmore, a young man then, who, in a succeeding year, entered the service, and being detailed to duty near the seashore, seized the occasion to revive his studies of sea-life by making a collection of the coast shells of North Carolina. Professor Bickmore had noted with interest Agassiz's supple combination of tact, eloquence and personal charm in securing the effective alliance of the Commonwealth of Massachusetts, and his adaptability to the methods of private importunity. Through these combined agencies the Legislature of Massachusetts had granted \$100,000, the citizens of Boston raised \$71,000, Mr. Francis C. Gray left \$50,000, and a sentiment of generous appreciation for the purposes of the museum had

been created. Agassiz's success in this way was remarkable. He obtained under the most discouraging circumstances, even in the darkness of the war, large sums of money from the Legislature of Massachusetts, and his appeal to individuals was always irresistible.

It seems pertinent, in view of the analogous relations of the New York museum to the Legislature of the State and private benefactors, to quote Marcou's expressive description of Agassiz's methods. Agassiz's biographer writes: "The amount of scientific diplomacy he made use of is something astounding; for instance, he would detail with great clearness the working of the institution, and make it clear that the museum is an element of education even in the most elementary school of commonwealth, and that in the future generations there would not be a child who would not have the opportunity of understanding the scheme of creation as thoroughly as he understood his multiplication table. He had the tact to adapt his explanations and his description of the absolute poverty of the institution to the listener and his official position in the State. Then, after weeks of such preparatory work at the State House, came the annual visit of the whole legislative body, with the Governor at its head, to the museum. Everything was in readiness for the reception when the six or ten street cars, filled with legislators, arrived at the University grounds. Agassiz conducted them at once into the various exhibition halls, showing the treasures of each and briefly describing the departments. Afterwards in the lecture room, in an informal conversation, he detailed the methods and needs of the institution. He always succeeded in winning to his side farmers, tradesmen and politicians. After such a visit the Legislature always voted a new appropriation of public money; it was only necessary for the President of the Sen-

ate and the Speaker of the House to make speeches in its favor, and the resolution would easily pass the three readings without further debate."

Celebrated collections of the Old World, constant accessions from the new, were pouring into the museum at Cambridge. In 1869 Professor Agassiz reported that though the income of the British Museum and the Jardin des Plantes was more than ten times that of the Museum of Comparative Zoology, yet the last "in certain departments, such as corals and fishes, was superior to both, and that in activity of research and publication it yields to neither, while the increase of its collections since its existence, and the prominence it has attained among the museums, are such as no like establishment has reached in the same time and with the same means."

It was with anxious eyes that the naturalists of New York and those citizens of the great metropolis that were devoted to the advancement of its intellectual interests noted this rapid progress. The formative period closed, and the crystallization of an idea, so definitely recognized, quickly succeeded in those years, which included the incorporation of the American Museum of Natural History.

OF NATURAL HISTORY.

SCIENTIFIC BOOKS.

Publications of the Japanese Earthquake Investigation Committee. Nos. 5 and 6. Tokyo. 1901.

These two volumes are continuations of the series of publications in foreign languages of the investigations of the Imperial Japanese Seismological Committee, the earlier numbers of which received a somewhat extended notice in the columns of this journal some time ago. They are written by Dr. Omori, a member of the Committee in immediate charge of the investigations, and they contain horizontal pen-

dulum observations of earthquakes during 1898 and 1899, together with a detailed description of the horizontal pendulum seismographs used and some discussion of the results.

In the 'compound,' or park, at Hongo, Tokyo, in which the buildings of the Japanese Imperial University are located, there has been erected an 'earthquake-proof' house in which two of the large horizontal pendulums are placed. They are of rather unusual dimensions, the vertical distance from the point of suspension to the point of support being nearly three meters. The pendulum is excellently planned for stability and convenience of adjustment, and is capable of a vibration period of as long as three minutes, being, therefore, extremely sensitive. When adjusted to a period of two minutes it will show an index displacement of about 1 mm. for a change of level of about one two-hundredth of a second. Two of these seismographs, exactly alike, are mounted, one to give the N. and S. component of the disturbance and the other E. and W. component. They are designed, of course, for the registration of very feeble but often long-continued disturbances whose seismic origin is remote from the point of observation. Concerning the transmission of such disturbances many extremely interesting observations have been made, only a few of the most important of which can be referred to here.

Broadly speaking, the motion of an earthquake may be divided into three successive stages, which are always more or less well defined; the *preliminary tremor*, consisting usually of vibrations of small amplitude and short period; the *principal portion*, the active and often destructive part of the earthquake, during which the amplitude is much greater and the period usually longer; the *end portion*, which is the feeble, small amplitude finishing of the disturbance. The first of these is again usually quite sharply divided into two stages, which may be designated as the first preliminary tremor and the second preliminary tremor, and the *principal portion* is also made up of three tolerably distinct phases, of which the last, designated as the *quick-period phase*, is of the greatest importance in the present discussion.

Several seismologists have already pointed

out the fact that the duration of the *preliminary tremor* of an earthquake increases with the distance of the seismic center from the place of observation, and this proposition is not only confirmed by Dr. Omori's observations, but from them and some others he has been able to deduce an equation which represents the relation between duration and distance with astonishing closeness. Sometimes the total duration of these disturbances, due to distant earthquakes, is as long as four hours, but the equation here given is based upon first preliminary tremors varying in duration from five minutes to eleven minutes. It is as follows:

$$x = 17.1y - 1360$$

in which x is distance in kilometres (on the surface of the earth along the arc of a great circle passing through the two points) and y is the duration of the *first preliminary tremor* in seconds. This equation is based on long-distance observations of several earthquakes, three of which, occurring respectively in Alaska, Smyrna and Japan were observed in Japan, while others originating in Japan were observed in Potsdam and Italy. The agreement of the calculated values of x with the actual values is shown in the following table:

Earthquake.	Actual Distance.	Calculated Distance.
Alaska,	6,100	6,500
Smyrna,	4,800	4,560
Java,	9,200	9,240
Japan,	8,999	8,840
Japan,	9,580	9,540

Perhaps the most interesting subject discussed in these volumes is the transmission velocities of the various phases of an earthquake disturbance. Dr. Omori has given much attention to this important question, considering it in considerable detail in the light of his own and other recent observations. It has long been known that all seismic waves did not travel with the same velocity, and it was long ago suspected that different phases of the same disturbance might be transmitted at very different speeds. During the past few years the development of 'long-distance seismology,' as it may be called, has added greatly to our knowledge of velocity of transmission, and at the same time it has materially increased the difficulties by which the subject is surrounded.

Dr. Omori has compared the time of the arrival of the beginning of three of the phases mentioned above, namely the *first preliminary tremor*, the *second preliminary tremor*, and the *quick-period* phase of the *principal portion*, and he has assumed, as he is quite justified in doing, that they originated simultaneously at the seismic origin. He has compared the velocities of transmission of these three phases between Italy and Japan, in ten earthquakes, with results which agree among themselves in the most remarkable way.

The means are, for the *first preliminary*, 12.8 km. per second; the *second preliminary*, 7.2 km. per second, and for *quick period* of the principal portion 3.3 km. per second. The latter quantity, it will be observed, is what is usually thought of in speaking of the velocity of an earthquake wave.

Now no known rock has a modulus of elasticity high enough to transmit a wave, of either compression or distortion, with the speed of the *first preliminary tremor* as shown above, and it seems impossible to avoid the conclusion that this disturbance must be transmitted along some shorter path within the earth's crust, while the *principal portion* undoubtedly travels along the earth's surface. This question is greatly complicated, however, by the fact that the duration of the *first preliminary* at a given observation station is very nearly simply proportional to the *surface* distance from the origin of the disturbance.

It is impossible to close even so brief a notice as this must be, without again congratulating Dr. Omori and his colleagues of the Earthquake Commission upon the splendid way in which they are making use of the rare opportunities which they enjoy for seismological study. The indirect results of this study, especially as they are related to the general subject of terrestrial physics, promise to be of the greatest importance, and the Japanese seismologists may well feel assured that they are practically in control of a field worthy of their highest efforts.

The general form and style of these publications is so excellent that it may be worth while to call attention to the existence of a few blemishes, doubtless due to careless proof-reading. One is tempted to especially mention one of

these, which is the frequent appearance of *Alasca* or *Alaskan*, in which form alone, indeed, is found the name of the territory, or whatever it may really be, known to us who own it as Alaska.

T. C. MENDENHALL.

Beitrag zur Systematik und Genealogie der Reptilien. By MAX FÜRBRINGER. Abdruck aus der *Jenaische Zeitschrift für Naturwissenschaft*, XXXIX. Bd. (N. F. XXVII.). Jena, Verlag von Gustav Fischer. 1900. Pp. 1-91.

The paper to which the attention of all who are interested in the class of reptiles is here called is only a portion of an extensive memoir, a summing up of the results of studies detailed in the twenty-seventh volume of the *Jenaische Zeitschrift* and occupying over four hundred pages of that journal. In view of the author's important contributions to zoological literature, especially of his great work on the morphology of birds, anything that he may have to say on the kindred group of reptiles must attract attention.

The author first discusses the position of the most primitive Reptilia and the origin of the Sauropsida (I.); then a survey is made of the systematic and genealogical relationships of the various orders (II.); and finally, these are grouped into subclasses, and their genealogical relation to the other Tetrapoda is treated (III.).

I. Of the living reptiles the Lacertilia and the Rhynchocephalia are regarded as the most primitive; of the latter a single representative exists; of the Lacertilia about 1,600. Contrary to what is generally held, the author does not regard *Sphenodon* as the most primitive reptile, although it possesses many primitive features. A just appraisal of all its characters places it lower than the highest Lacertilia, but higher than the lowest representatives of the latter. The author contends that in the primitive reptiles the quadrate bone was movable (streptostylic), and that its fixed (monostylic) condition is the result of secondary modifications. Some of the earlier Rhynchocephalia, as *Patteohatteria*, were probably the lowest of known reptiles. Notwithstanding their differences, the Lacertilia and the Rhynchocephalia had a common ancestor.

As to the origin of the Sauropoda, Fürbringer holds that they sprang from amphibian ancestors whose quadrate was streptostylic.

II. The author regards the lizards and snakes as constituting two distinct orders. The snakes are not further considered. The Lacertilia are divided into five suborders, viz., Lacertilia vera, Varano-Dolichosauria, Mosasauria, Amphibænia, and Chamæleontia. Among the true Lacertilia, the Geckos are the lowest of living reptiles. In many characters the Varanidæ stand apart from other Lacertilia. The Mosasaurs are regarded as Lacertilia which at an early period branched off from perhaps near the ancestors of the Varanidæ, and became pelagic. The author finds in the Chamæleontia numerous points of resemblance with the Lacertilia vera, especially with the Uroplatidæ. They are hence placed closer to the lizards than in the system of Boulenger, but farther removed from them than in the system of Cope.

As regards the Ichthyopterygia, Fürbringer holds that they possess close relationships with the Rhynchocephalia, but are widely removed from the Sauropterygia. The Chelonia are not thought to be related to the Theromorpha, but rather to the Sauropterygia. The special phylogeny of the Chelonia is veiled in darkness. The Trionychidæ are considered to be the lowest in rank of living tortoises, the Pleurodira the highest. The isolated position in which *Dermochelys* has been placed by some writers is not accepted. The small group of Mesosauria of the Permian and Lower Triassic find their relationships with the Sauropterygia, Chelonia and Theromorpha; nevertheless they display many peculiarities.

The Theromorpha appear in the Permian and lower Triassic in great numbers and in varied forms; but with the Triassic they disappear. Many of them became highly specialized, attained considerable size, and developed, to a remarkable degree, stoutness of body and of its component parts. Their relationships are held to be with the Rhynchocephalia, but not close. They have no affinities with the Chelonia. In connection with this group the author discusses the origin of the Mammalia. His conclusion is that they have sprung from no group of reptiles, but directly from the Batrachia.

The Crocodilia are held to be the highest of living reptiles. They have distant connections with the Lacertilia and the Rhynchocephalia; closer ties with the Dinosaurs. The extinct groups Parasuchia and Pseudosuchia are to be retained close to the crocodiles.

In rank the Dinosauria stand above the Crocodilia, with which group they show many affinities. Two characters possessed by the higher forms lift the Dinosauria above the Crocodilia, the upright mode of progression and the development of cavities in the bones. The Dinosaurs are accepted as a single order, to be divided into two or three suborders.

The Pterosauria are estimated to be the highest in rank of all known Reptilia. They are specially related to the crocodiles and the Dinosaurs. Any close relationship to the birds is rejected.

III. Finally, the various orders are grouped by our author into subclasses. The first contains the Lacertilia, Ophidia, Rhynchocephalia and Ichthyopterygia; and for his subclass Haeckel's name Tocosauria is appropriated. The second subclass is constituted by the Theromorpha. A third subclass is formed of the Mesosauria, Sauropterygia and Chelonia; and to this the name Synaptosauria is applied. The Crocodilia, Dinosaurs and Pterosauria make up the subclass of Archosauria.

O. P. HAY.

AMERICAN MUSEUM NATURAL HISTORY,
NEW YORK, July 4, 1901.

Alleghany County, Maryland. By WM. B. CLARK, State Geologist. Md. Geol. Surv., Baltimore, Md. 1900.

This royal octavo volume of 323 pages, accompanied by a folio of 6 pages containing topographic, geologic and soil maps of the county on a scale of one mile to the inch, is the first of a series of descriptive reports by counties to be published by the Maryland Survey. Not only the geology, mineral resources and physiography are described, but also the soils, climate, hydrography, magnetic declination, forests, flora and fauna. In addition to its general scientific value, it is of unusual interest to the county, presenting invaluable data for the farmer and manufacturer, and furnishing a

most excellent means of education and instruction to the inhabitants by interesting them in the local phenomena and the history of the mountains and the rocks forming them.

The physiography is by Cleveland Abbe, Jr., and the geology by Cleophas C. O'Hara. The county is in the western part of the State, embracing parts of the Allegheny Plateau and the Great Appalachian Valley. The rocks exposed in the plateau district are of Carboniferous and possibly Permian age and have been folded into a flat northeast-southwest syncline. The upturned resistant Pottsville conglomerate forms the eastern edge of the plateau in a straight even-crested ridge, and the interior of the plateau is composed of the softer overlying rocks protected in the syncline to the west. The Ridge district, embracing that part of the county in the Great Appalachian Valley, is composed of Silurian and Devonian rocks folded into numerous open parallel northeast-southwest folds, generally with steeper dips to the northwest, but not overturned or overthrust. Erosion has produced long parallel sharp-crested ridges separated by narrow valleys.

The remains of two physiographic plains have been recognized in the topography. The older, called the Schooley Plain, is preserved only in the crests of the higher ridges. The younger, called the Shenandoah Plain, is represented by the tops of low ridges and knolls between 900 and 1,100 feet elevation along the margins of the larger streams. This latter plain consisted of broad valleys between high ridges which were not reduced during that cycle of erosion. Two terraces of recent date were observed in the stream gorges, marking temporary halts in the downward cutting of the streams. Some very interesting stream adjustments are described. The geologic history of the region is also interestingly presented.

Among the mineral resources mentioned, the more important are coal, fireclay, cement rock and iron ore. Excellent steam coal has been mined in the county for many years, and the district is known as the Cumberland-Georges Creek Basin. Several important beds are mined and are distributed vertically through the Pottsville and Coal Measures. The Big

Vein or 14-foot Vein occurs in the upper part of the series, and is noted for its great size, purity and fine steam quality. The report on the economic products is by Wm. B. Clark, C. C. O'Hara, R. B. Rowe and H. Ries.

The soils of the county are represented on the geological map, the subdivisions corresponding to the divisions of the underlying rocks, but a separate legend giving the descriptions of the soils. Mechanical and chemical analyses of the various soils are given in tabular form and their value for agriculture is discussed. Clarence W. Dorsey is the author.

The hydrography and the remaining subjects presented in the report, as well as the soils, were surveyed in cooperation with branches of the U. S. Government and the reports are presented by members of the government corps.

The volume is handsomely printed and illustrated with half-tone cuts in the same excellent manner as in former publications of the Survey. The atlas accompanying the report is a high-grade lithographic production. The topographic map is that prepared by the U. S. Geological Survey in cooperation with the State. The colors and patterns used on the geologic maps are the same as those used by the U. S. Government and the results obtained are very pleasing. The publication by counties, however, makes it necessary to dissect the maps awkwardly and print them on three sheets, and makes the folio of unhandy size.

GEORGE W. STOSE.

WASHINGTON, D.C.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *American Geologist* for May contains a biographical sketch of Elkanah Billings with portrait by Henry M. Ami. Dr. J. B. Woodworth contributes an article on 'Cross-Banding of Strata by Current Action.' He describes micaceous bedding in the glacial sand near Lake Walden and attributes its formation to the vertical movements of the water about the crest of a current mark. This is followed by 'A Historical Outline of the Geological and Agricultural Survey of the State of Mississippi,' by E. W. Hilgard. This is followed by 'Reviews of Recent Geological Literature' and 'Scientific News.' The June number contains the follow-

ing articles: 'The Ontario Coast Between Fairhaven and Sodias Bays,' by J. O. Martin. Some peculiar features of the landscape due to the rapid erosion of the glacial drumlins along the shore line are described. 'Eighth Session of the International Congress of Geologists, Paris, 1900,' is written up by Persifer Frazer. 'Two New Genera and Some New Species of Fossils from the Upper Paleozoic Rocks of Missouri,' by R. R. Rowley. Mr. Rowley describes two new genera of blastoids and proposes the names *Lophoblastus* and *Carpenteroblastus*, following which he describes two new species of the first, one of the second, and fourteen of the other genera of fossils from the same region. The article is accompanied by a plate. 'Ore Formation by Surface Decomposition,' is discussed by C. R. Keyes, in which he concludes "that with the exception of possibly a few isolated unimportant instances ore concentration does not generally take place through surface decomposition of rock masses, in areas such as the Ozark lead and zinc region." 'Gold and Other Minerals in Iowa,' by Samuel Calvin. The author undertakes to destroy the fallacious ideas that gold, gas or oil exist in paying quantities in Iowa. He also exposes the fallacy that any so-called geologist with a drilling outfit is to be trusted in his predictions to a public-spirited community.

DISCUSSION AND CORRESPONDENCE.

THE LARYNX AS A MUSICAL INSTRUMENT.

THE wide prevalence of the mistaken notion that the vocal cords vibrate in the axial direction of the larynx makes it desirable to point out that observations by the laryngostroboscope—a combination of a laryngoscope and an adjustable intermittent source of illumination—have proved to the contrary for the male chest register. With this method it is possible to follow a vibration slowly through its phases. This has been done by Musehold, who reports that in singing in the chest register the cords touch along their whole length; that in loud tones the edges have a slightly rounded form, especially in the middle, indicating strong contact in the middle and weaker contact at the ends of the glottis; that in weaker tones the

line of contact appears even and thin while the top of the cord becomes flatter; that the edges of the cords move out sidewise and not in the axial direction of the larynx. Two of Musehold's diagrams are reproduced here. The upper one shows the bunching of the cord edges due to the firm contact; the lower one is an indication of the way the air pressure in the trachea presses the cords apart.

In connection with the remarks of Professor Le Conte on a previous occasion, it is interesting to note that with the same method Musehold was able to observe the lips of a performer on a horn, with the result of seeing that the lips vibrate as cushions and not in the direction of the axis of the horn.

In Professor Hallock's interesting communication in the last number of *SCIENCE*, the microscopic section of one of the cords is correctly given, but the diagram of the supposed way in which the muscle turns into a thin sheet is certainly incorrect. It is hardly the place here to give a summary of the facts in regard to the action of the vocal cords and the nature of the vowels in speech and song; I have stated in a previous communication that the proof is clear and complete that a vowel both in speech and song is not essentially a fundamental from the cords with a series of overtones reinforced by the vocal cavities. I may, perhaps, be pardoned for saying that I have given a digest of the many investigations on this and related subjects in a work on experimental phonetics now in press.

SHORTER ARTICLES.

THE ORIGIN OF TRAVERTINE FALLS AND REEFS.

In a recently published article, Professor Davis, in speaking of certain travertine cascades and reefs, says: "We could not find any satisfactory explanation for the growth of these travertine reefs,"* and he refers to an occurrence of falls over travertine reefs in Central America as if such deposits were unusual.

In the limestone regions of East Tennessee travertine cascades are common. A creek that enters the Frenchbroad river a mile and a half above Dandridge, Jefferson county, has a series of travertine falls where the stream emerges from the hills upon the bottom lands of the river. The narrow valley of the stream is in places completely floored over with travertine. Similar deposits occur in the town of Dandridge, especially near the ferry over the Frenchbroad, where a small stream pitches over the edge of the bluff. At many of the falls the deposit has grown outward until the water pours over belled protrusions of the travertine. It is worthy of note in that particular region that springs whose waters are equally charged with lime deposit no travertine where they flow quietly into the river.

In the vicinity of Stanford University, California, some of the streams descending from the calcareous areas of the Coast Range are heavily charged with lime and deposit travertine wherever the waters are thrown into spray. Like most mountain streams they descend by a series of terraces, or steps, represented by quiet stretches having little cascades at their up-stream and down-stream ends. These cascades are made of rocks, frequently water-worn boulders, and in every instance the boulders at the cascades are covered with more or less travertine, while similar boulders along the quiet stretches and especially in the deeper waters are without the travertine.

The waters of Congress Springs, in Santa Clara County, California, are highly charged with carbon dioxide and carry much lime in

solution. The water is now conducted through open wooden troughs to storage tanks, and wherever the troughs are so steep that the water is rippled the travertine is rapidly deposited and has to be removed from time to time in order to prevent the complete filling up of the troughs. The old stream bed along which this Congress Spring water formerly ran is covered with travertine wherever the water was rippled. At one place along this old channel there is a bank of travertine eight or ten feet high.

These phenomena are to be seen at many other places in the foothills around the sides of the Santa Clara Valley.

At Santa Cruz, California, a stream flowing out of a hilly limestone region, where it emerges from the hills, has deposited a bed of travertine that is probably fifty feet or more in thickness and covers an area of several acres.

Perhaps the most remarkable deposits of the kind are those along the western coast of Palestine and the southern coast of Asia Minor, where the streams pass over regions of limestone. They are frequently spoken of in works upon that region.*

Whether these deposits are all made in the same way or by a single process is doubtful. In the case of the highly carbonated waters of Congress Springs it seems most probable that the deposition of the lime is due chiefly to the escape of the carbon dioxide when the water is exposed to the air by rippling or spraying. In the cases of streams that run for some distances in open channels before giving up their lime it may be that the deposition is due, at least in part, to the increase of the temperature of the water and the loss of carbon dioxide. But inasmuch as the travertine is formed most abundantly at the falls, it appears that the spraying of the water is an effective agency in the escape of the gas. It is well known also that certain aquatic plants help precipitate lime from water by the absorption of carbon dioxide. An interesting case of the kind is mentioned by Clarke,† and other papers have lately been pub-

* 'Karamania, or a Brief Description of the South Coast of Asia Minor,' etc., by Francis Beaufort, 2d ed., London, 1818.

† *Bull. New York State Mus.*, VII., 195-98.

* 'An Excursion into Bosnia, Hercegovina and Dalmatia,' by W. M. Davis, Geological Society, Phila., III., 42-44.

lished by C. A. Davis* and by Blatchley and Ashley.†

My observations upon the growth of stream deposits of travertine in Tennessee and California led me to the following conclusions:

1. The deposits grow more rapidly in the summer and at low-water stages.

2. The channels become locally choked up with travertine and the streams are compelled to shift from side to side.

3. The thin horizontal beds of travertine are formed in the shallow waters immediately above the falls.

4. Although the larger streams appear to be eroding and do erode at high stages and at certain parts of their courses, the process on the whole is constructive.

5. The travertine tends to form a series of terraces along the streams depositing it.

J. C. BRANNER.

STANFORD UNIVERSITY, July 4, 1901.

PSEUDOSCOPIC VISION WITHOUT A PSEUDOSCOPE.‡

A METHOD of securing an illusion of binocular vision wholly without instrumental aid occurred to me recently, which is interesting in connection with the study of pseudoscopic vision. It is fully as startling as any of the results obtained with the lenticular pseudoscope, which I described in SCIENCE (about Nov., 1899), and, requiring the aid of no optical instrument, is very much more impressive. A lead pencil is held point up an inch or two in front of a wire window screen, with a sky background. If the eyes are converged upon the pencil point, the wire gauze becomes somewhat blurred and of course doubled. Inasmuch, however, as the gauze has a regularly recurring pattern the two images can be united, and a little effort enables one to accommodate for distinct vision of the united images of the mesh. To accommodate for a greater distance than the point upon which

the eyes are converged requires practice, but the trick is very much easier in this case than in the case of viewing stereoscopic pictures without a stereoscope. As soon as accommodation is secured the mesh becomes perfectly sharp, and appears to lie nearly in the plane of the pencil point, which still appears single and fairly sharp. If now the pencil is moved away from the eyes, which are to be kept fixed on the screen, the point *passes through the mesh* and appears double, the distance between the two images increasing until the point touches the screen.

If now the pencil be removed it will be found that the sharp image of the combined images of the gauze persist, even though the eyes be moved nearer to or farther away from the screen. Move the eyes up to within six or eight inches of the plane in which the screen appears to lie and try to touch it with the finger. *It is not there.* The finger falls upon empty space, the screen being, in reality, a couple of inches further off. This is by all means the most startling illusion that I have ever seen, for we apparently see something occupying a perfectly definite position in space before our eyes, and yet if we attempt to put our finger on it, we find that there is nothing there.

It is best to begin by holding the pencil an inch or less in front of the screen. As the eyes become accustomed to the unusual accommodation the distance can be increased. The greater the distance, the greater the illusion, of course. I have succeeded in bringing up the apparent plane of the mesh five or six inches, but this requires as great a control over the eyes as is necessary in viewing stereoscopic views without an instrument.

THE BOTANIST'S JOURNEY TO THE DENVER MEETING OF THE A. A. A. S.

FOR the observing botanist (and what kind of a botanist is he who is not observing?) the journey to the Denver meeting of the American Association for the Advancement of Science will be of the greatest interest. Leaving the originally wooded country some distance east

* *Jour. of Geology*, Sept.-Oct., 1900, VIII., 485-503.

† 'The Lakes of Northern Indiana and their Associated Marl Deposits,' by Blatchley and Ashley, 25th Ann. Rep. State Geologist of Ind., pp. 43-51.

‡ Since writing this note I have learned that a similar illusion is described in Le Conte's 'Sight.' It may however be new to some.

of Chicago, he enters the level prairies of Illinois, originally treeless except along the water-courses, and passes from these to the rolling prairies of Iowa, whose undulating surface was wanting in woody vegetation except in the broad valleys which border the streams. Now, as in Illinois, all over the landscape are lines and clumps of vigorous trees, all the result of man's work. What was once a treeless view is now as freely dotted over with trees as in the case of many a landscape in the originally wooded portions of the eastern United States. Crossing the Missouri River he soon enters the region of the Great Plains, with an elevation of 1,200 feet above the sea at the eastern border, rising rapidly across Nebraska to 2,000, 3,000 and 4,000 feet above the sea. If he follows the broad valley of the Platte River from Omaha to Denver, he will receive the impression that the Plains are 'as level as a house floor,' since he sees only the flat alluvial plain worn by the great river, and is ignorant of the fact that on each side are hills and valleys stretching away for hundreds of miles, the hills treeless as in the prairies, and the valleys with groves of trees along the margins of the streams. If he is fortunate enough to choose a route which crosses the hills and valleys of the Plains instead of following a single valley, he will see for himself this relation of the trees to the general surface of the country, and he may even see evidence of the westward march of the trees, where the fires no longer check their growth. With the increase in elevation the fringes of trees along the streams grow narrower and narrower, until at last they disappear altogether on the high plains at the foot of the mountains, 4,500 feet or more above the sea. This is the land of the 'sage brush,' 'dagger weed,' 'buffalo grass,' 'bunch grass' and 'cactus.' It is not a desert, and yet is as uninviting as one—until man runs little streams of water over it, when as if by magic it is transformed into a garden of flowers and fruits, or a farm of golden wheat and purple alfalfa. What water is to the plant is nowhere better shown than on these high Colorado plains, a mile above the sea. Then, still beyond, are the mountains, with a vegetation entirely unlike that of the plains at their base. Pines, spruces, firs,

cedars are all of different species from those of the east, and not many of the deciduous trees are of species which are common along our Atlantic border. For the botanist who sees this flora for the first time it will be a novel experience to find that he can name scarcely a plant that he sees, whether herb, shrub or tree. He will need his collecting case and plant press, as it will be impossible for him to resist the desire to make specimens of the many interesting plants he finds at every turn.

THE SAND HILLS OF NEBRASKA.

THE interesting region known as the Sand Hills of Nebraska may be visited by the botanists who attend the Denver meeting in August. They occupy an area of from 15,000 to 20,000 square miles in central and northern Nebraska, having a width of from 100 to 200 miles. The prevailing contour of the surface is irregular, consisting of rounded, swelling hills with gentle depressions between them, or elongated ridges with steep sides, enclosing deep valleys. These hills consist of sand or gravel, and when the surface vegetation is removed the sand is driven by the winds, and forms moving dunes. To a very large extent the surface configuration is such that the water which falls in the rains is not drained off in streams, but disappears in the porous soil or evaporates from the surface. Here and there are streams which find their way through the valleys and hills, and where these streams are of considerable size they have worn deep canyons. Such streams are always fed by many springs which burst out from the sides of the canyons, and doubtless in this way the water which falls upon the areas which have no surface drainage finds its exit.

The vegetation in the Sand Hills consists almost entirely of grasses and sedges intermingled with deep-rooted perennial herbaceous or woody plants. The perennial herbaceous plants are coarse, strong-growing species, and the woody plants are to a very large extent of low stature and with large, widely-spreading roots. Among these shrubs are the sand cherry (*Prunus besseyi*), shoe string (*Amorpha canescens*), one or more species of prairie clover (*Kuhnistera*), one or two species of wild roses (*Rosa arkansana* and *Rosa woodsii*), New Jersey tea (*Ceanothus ovatus*),

etc. In the wet valleys occur wild plums (*Prunus americana*), and the dwarf wild cherry (*Prunus demissa*), the former a shrub or small tree, and the latter an upright little-branched shrub, both usually forming close thickets.

The trees are almost entirely confined to the narrow belts which border the streams in the canyons. Where the canyons are deep these forest belts are entirely hidden as one glances over the undulating surface of the plain. In the eastern part of the Sand Hill region the forest belts are wider, but in passing westward they are narrower, the trees are lower, and eventually they are mere straggling shrubs, finally disappearing altogether. The species are to a large extent those found in the eastern portion of the State, there being but few cases in which the Rocky Mountain trees have taken possession of such protected areas. They are the white elm, occasionally the red elm, the box elder, red ash in small numbers, green ash in larger numbers, sometimes the hackberry, with the common cottonwood and several species of willows, and occasional hawthorns, with here and there the remnants of groves of bull pine (*Pinus scopulorum*).

THE GRASSY COVERING OF THE GREAT PLAINS.

THOSE who visit the Great Plains for the first time are usually interested in the grassy covering, which is the most marked feature of the vegetation of the region. This covering is mostly composed of a mixture of several species, there being few places where a single species occupies the ground to the complete exclusion of all others. In the eastern portion of the region the grassy plants (including sedges) number about 130 species, in the central portion (the Sand Hills) there are 170 species, while in the western portion (the Foot Hills) there are about 110 species. The eastern visitor will notice with interest the 'buffalo grass' (*Bulbilis dactyloides*) in well-marked patches, the different species of 'grama' (*Bouteloua oligotachya*, *B. hirsuta*, and *B. curtipendula*) scattered over the surface, the 'wheat grasses' (*Agropyron pseudorepens* and other species) usually mingled with species of *Bouteloua*, the 'bunch grasses' (*Andropogon scoparius*, *A. furcatus* and *A. hallii*) scattered in bunches over the

surface, the 'needle grasses' (*Stipa spartea*, *S. comata* and *S. viridula*) scattered in bunches over the surface, with other species known in general as 'prairie grasses' (species of *Koeleria*, *Eatonia*, *Sporobolus*, etc.). Should he go into the Sand Hills he would find the 'blowout grasses' (*Muhlenbergia pungens*, *Eragrostis trichodes*, *Oryzopsis cuspidata* and *Redfieldia flexuosa*) in or on the margins of the naked sand pits blown out of the hillsides. In the Foot Hills he would find great areas covered almost exclusively with the yellowish-brown foliage of the little sedge (*Carex filifolia*) known throughout the region under the names 'nigger wool,' 'nigger root,' or 'black root,' highly esteemed by the stockmen for its nutritious qualities, and whose tough and durable black roots form a persistent sod much used by the settlers in the construction of their 'sod houses.'

TREES OF THE RYDBERG COTTONWOOD.

It may be of interest to some of the botanists who will visit the Rocky Mountains this summer to know that they can see many fine specimens of the 'Rydberg cottonwood' (*Populus acuminata*) in the town of Colorado Springs. They have been planted along the streets and avenues mingled with trees of the common cottonwood (*Populus deltoides*). Especially fine trees may be seen along the east side of Cascade avenue. Botanists will remember that in 1893 this tree was first described by Dr. Rydberg in the *Bulletin of the Torrey Botanical Club* (February, 1893) from material collected in the canyons of the Wildcat Mountains of Western Nebraska. Since the publication of the species it has been found to extend from the Black Hills southward to Southern Colorado, New Mexico and Arizona. In the plantings along the streets of Colorado Springs this species was not distinguished from the common cottonwood. The two trees may, however, be very easily distinguished by the shape and particular contour of the leaves, which are rhomboid-lanceolate with serrulate margins in the new species, in contrast to the broadly deltoid-ovate leaves of the common species with their incurved-dentate margins.

CHARLES E. BESSEY.

THE UNIVERSITY OF NEBRASKA.

THE AMERICAN FORESTRY ASSOCIATION.

THE principal summer meeting of the American Forestry Association for 1901 will be held at Denver, Colorado, Tuesday, Wednesday and Thursday, August 27-29, in affiliation with the American Association for the Advancement of Science, as we learn from the *Forester*, the official journal of the Association.

There will be two sessions daily, at 10 a. m. and 2:30 p. m., which will be held in the Denver High School building, and, in addition, an open evening meeting, in the Central Presbyterian Church, Wednesday, August 28, at 8 p. m. At the latter meeting there will be short addresses by Hon. Thomas M. Patterson, Hon. Thomas F. Walsh, Hon. Platt Rogers, and others, followed by an illustrated lecture by Mr. Gifford Pinchot, Forester of the United States Department of Agriculture, entitled 'The Government and the Forest Reserves.' This meeting will be a distinctively Western one, and its proceedings of special interest to all concerned with the forest problems before the Western States—fires, grazing, relation of forests to water supply, etc.

The address of welcome at the opening session, Tuesday, August 27, 10:30 a. m., will be delivered by Hon. Thomas M. Patterson, United States Senate. It is expected that the President of the Association, Hon. James Wilson, Secretary of Agriculture, will attend the meeting, and preside at one or more sessions.

A partial list of speakers at the meeting, and their subjects, follows:

Mr. A. L. Fellows, Denver, Col., 'The Hydrography of Colorado'; Mr. Geo. B. Sudworth, Chief of Division of Forest Investigation, Bureau of Forestry, Washington, D. C., 'Forests and their Relation to Agriculture and Manufacturing Industries'; Mr. S. J. Holsinger, Phoenix, Arizona, 'The Boundary Line between the Forest and the Desert'; Professor R. H. Forbes, Tucson, Arizona, 'The Open Range and the Irrigation Farmer'; Mr. R. L. Fulton, Reno, Nevada, 'The Reclamation of the Arid Region'; Mr. William L. Hall, Superintendent of Tree Planting, Bureau of Forestry, Washington, D. C., 'Progress in Tree Planting'; Professor A. J. McClatchie, Phoenix, Arizona, 'The Eucalypts as American Forest

Trees'; Mr. T. P. Lukens, Pasadena, California, 'The Reforestation of Watersheds'; Professor L. H. Pammel, Ames, Iowa, 'Some Phases of the Growth of the Cultivated Trees in Iowa'; Mr. F. H. Newell, Hydrographer, U. S. Geological Survey, Washington, D. C., 'Forests as Reservoirs'; Mr. Gifford Pinchot, Forester, Washington D. C., 'Grazing in the Forest Reserves.' Other speakers are: Professor William R. Dudley, Stanford University, California; Mr. William H. Knight, Los Angeles, California; Mr. George H. Maxwell, Chicago; Edward M. Griffith, Bureau of Forestry, Washington, D. C.

*THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE.*

FOR the benefit of members who will attend the Denver meeting of the Association beginning on August 24, we reproduce the arrangements made with the railways:

The Western Passenger Association, covering the territory west of Chicago and St. Louis, has made a rate of one fare plus \$2 for the round trip, from all points in their territory to Denver, tickets to be sold July 10 to August 31, with final return limit of October 31.

The New England, Trunk Line, Central and Southeastern Passenger Associations, covering the territory east of Chicago and St. Louis, have made a rate of a fare and one-third for the round trip from all points in their territory to Denver, on the certificate plan, the conditions of which are as follows:

1. Each person desiring to avail himself of the reduced rate must purchase a first class ticket (either limited or unlimited) to the place of meeting, at the regular tariff rate and at the same time procure from the ticket agent a certificate of the standard form. If through ticket cannot be procured at the starting point, the person should purchase to the most convenient point at which such ticket can be obtained and there repurchase through to the place of meeting, *procuring a standard certificate from each agent from whom a ticket is purchased.*

2. *It is absolutely necessary that certificates be procured, indicating that the full fare has been paid for going passage and the route for which*

ticket or tickets for the return journey should be sold. No refund of fare can be expected because of failure to secure such certificates.

3. Tickets for the return journey will be sold at one-third the first-class tariff fare only to persons holding certificates of the standard form duly signed by the Permanent Secretary of the A. A. S., and signed by the special agent appointed for that purpose.

4. No certificate will be honored that was procured more than three days (Sunday not included) before the meeting assembles (except that when meetings are held at distant points to which the authorized transit limit is more than three days, the authorized transit limit will govern), nor more than two days (Sunday not included) after the first day of the meeting. No certificate will be honored for return ticket unless presented during the time that the meeting is in session, or within three days (Sunday not included) after adjournment.

5. Tickets for return journey will be limited to continuous passage on first train after purchase.

6. Certificates will not be honored by conductors; they must be presented to ticket agents.

7. Neither the certificates nor tickets furnished for this occasion are transferable, and if presented by any other person than the original purchaser, they will not be honored but will be forfeited.

Members desiring longer time than that allowed in connection with certificate reduction, viz., 3 days before the meeting assembles to 3 days after adjournment (Sunday not included), are advised to take advantage of the Colorado tourist fares or summer excursions, which, while costing a little more than the fare and one third, are good from July 10 to October 31.

If a sufficient number of passengers can be guaranteed, arrangements can be made for through Pullman service, to connect at Chicago or St. Louis, so that members from different sections of the country can make the trip to Denver together. The Permanent Secretary therefore invites all members who plan to attend the meeting and who wish to take advantage of this through Pullman service to

communicate with him at once, stating the name of the road over which they intend to travel and the date of their departure. If a sufficient number of replies are received, the arrangement will be made and members notified.

SCIENTIFIC NOTES AND NEWS.

THE Smithsonian Institution, having provisionally undertaken to represent the 'International Catalogue of Scientific Literature' in the United States, begs to bring this fact to the attention of men of science in the United States, and to request them to furnish the Institution with copies of all their writings which appear in separate form. It is intended to index all original scientific matter published since January 1, 1901.

THE position of State Geologist of New Jersey, vacant by the resignation of Mr. John P. Smock, has been offered to Professor I. C. Russell, of the University of Michigan. Professor Russell agreed to accept the office a year hence, and the board of managers has not yet decided whether to wait. In the meanwhile Dr. H. B. Kümmel is acting geologist.

PROFESSOR H. C. BEELER has been appointed state geologist of Wyoming.

PROFESSOR GEORGE E. HALE, director of the Yerkes Observatory, has been elected a foreign member of the Società degli Spettroscopisti Italiani.

THE Paris Academy of Sciences has elected M. Maupas, of Algiers, a corresponding member in the section of anatomy and zoology.

WE learn from *Nature* that Professor A. W. Rücker will resign the secretaryship of the Royal Society in consequence of his appointment as principal of the University of London.

PROFESSOR PASQUALE VILLERI has been elected president of the Reale Accademia dei Lincei, of Rome.

PROFESSOR E. B. POULTON, of Oxford University, will give one of the lectures at the Fifth International Congress of Zoology which meets next week at Berlin. His subject is 'Mimicry and Natural Selection.'

PROFESSOR WILLIAM B. SCOTT, of Princeton University, has arrived in La Plata, Argentina,

on his way to Patagonia where he will continue the paleontological studies that have been carried forward by several Princeton expeditions.

PROFESSOR OSBORN, accompanied by Professor Eberhard Fraas, of Stuttgart, has recently made a tour of the chief typical Jurassic exposures of Colorado, Utah and Wyoming, especially the beds of Cañon City, Green River, Como and the Black Hills. This is preliminary to a careful survey of these beds, which will be made for the monograph upon the Sauropoda. Valuable geological studies of the Jurassic have recently been published by Knight, Logan and especially by Loomis. Professor Fraas is very familiar with the Jurassic of Europe, having personally studied all the Jurassic exposures, and as a result of this trip he will undertake a careful correlation of the American and European Jurassic horizons which will be published by the American Museum. Messrs. Wieland and Loomis are also independently studying the Jurassic sections in the Black Hills region.

PRESIDENT DAVID STARR JORDAN has returned from the expedition to the Hawaiian Islands, sent by the U. S. Fish Commission.

DR. THEODORE GILL, of the Smithsonian Institution, has just returned from a European trip during which he enjoyed opportunities of examining ichthyological and other collections in various museums, and thus of materially advancing his comparative studies.

DR. HENRY S. PRITCHETT, superintendent of awards at the Pan-American Exposition, has announced as jurors in the department of electrical exhibits: Carl Hering, chairman; F. B. Crocker, A. V. Abbott, D. C. Jackson, W. S. Franklin, W. S. Barstow, W. E. Goldsborough, A. E. Kennelly, Henry S. Carhart and William L. Puffer.

CHIEF OFFICER HANS RUSSEK, of the Baltimore and Hamburg liner *Batavia*, has been appointed captain of the German Antarctic expedition.

SIR NORMAN LOCKYER, having reached the age of sixty-five years, will at the end of the present year give up his duties as professor of astronomical physics in the Royal College of Science, London.

JUDGE ADDISON G. BROWN, of the United States District Court for the Southern District of New York, having served twenty years and having reached the age of 72 years, has resigned. Judge Brown is known among scientific men as a botanist. He was long president of the Torrey Botanical Club, and cooperated with Professor N. L. Britton in the publication of the illustrated 'Flora of the Northern United States and Canada.'

MEMBERS of the Indiana Forest Board, established at the recent session of the Legislature, have been appointed by Governor Durbin as follows: Professor William H. Freeman, of Wabash, secretary of the board; Professor Stanley S. Coulter, Purdue University, Lafayette; Finlay P. Carson, Michigan City, representing the Indiana Retail Lumber Dealers' Association; John Cochrane, Indianapolis, representing practical woodworkers; Albert Lieber, Indianapolis, representing the Indiana Forestry Association.

THE Executive Committee of the National Physical Laboratory of Great Britain have made the following appointments: *Superintendent of the Engineering Department*: T. E. Stanton, D.Sc., Victoria; *Assistants in the Physics Department*: J. A. Harker, D.Sc., Victoria; A. Campbell, B.A., Cambridge; H. C. H. Carpenter, M.A., Oxon., Ph.D., Leipzig; *Junior Assistants*: B. F. E. Keeling, B.A., Cambridge; F. E. Smith, Royal College of Science. It is expected that one or two more junior assistants will be appointed shortly. The *London Times* states that the alterations to Bushey-house and the new buildings for the engineering laboratory are well advanced, and it is hoped to begin work early in October. Of the staff, Dr. Stanton, after serving an apprenticeship with an engineering firm in the Midlands, has had a distinguished career at Manchester and Liverpool, and is now professor of engineering at University College, Bristol. His paper on 'Surface Condensers,' published in the *Philosophical Transactions*, is well known to engineers. Dr. Harker and Mr. Campbell have both done work of real value in thermometry and electric measurements; while Dr. Carpenter, who will have charge of the chem-

cal researches, after a successful course at Oxford, has gained further experience at Leipzig under Ostwald, and more recently at Owens College. Mr. Keeling obtained a double first in natural science and mechanical science respectively at Cambridge; while Mr. Smith was the most distinguished student of his year at South Kensington, and for two years has been one of Professor Rucker's assistants.

DR. CHARLES T. MOHR, the well-known botanist, died at Asheville, N. C., on July 17. He had been a resident of Mobile, Ala., for a number of years, but about a year ago moved to Asheville, N. C.

THE western press announces the death of Dr. Joshua Miller, of Arizona. Dr. Miller was an enthusiastic student of the archeology of the Territory, and was instrumental in creating the Arizona Antiquarian Association, of which he was made president; he was also instrumental in securing the enactment of a law for the protection of the antiquities of the territory from ruthless destruction.

GEORGE K. LAWTON, of the U. S. Naval Observatory, died at Washington on July 25.

THE death is announced of Felix Joseph Henri Lacaze-Duthiers, the eminent French naturalist. Born in 1821, he began the study of medicine, but soon turned to zoology, and was appointed professor at Lille at the age of thirty-three years. In 1865 he became professor of zoology at the Paris Museum of Natural History, and three years later he was appointed to a similar position in the faculty of sciences. He was elected a member of the Academy of Sciences in 1871. In 1875 he established a zoological laboratory on the coast of Brittany.

M. JOSEPH HIRSCH, professor at the Paris Conservatoire des arts et métiers and inspector of bridges and highways, has died at the age of sixty-five years.

DR. W. SCHUR, professor of astronomy and director of the observatory at the University of Göttingen, died on July 1, aged fifty-five years.

WE also regret to record the death of Dr. Antonio Piccone, professor of botany at Genoa,

and Dr. Otto Wiedeburg, professor of physics in the Institute of Technology at Hanover.

ON August 31, there will be a civil service examination for the position of instrument-maker, Coast and Geodetic Survey, at a salary of \$1,000. On September 3, there will be an examination for the position of computer in the Survey at the same salary.

MR. ANDREW CARNEGIE has presented the city of Winnipeg with \$100,000 for a free public library. The gift has been accepted by the City Council. Mr. Carnegie has also offered \$50,000 to build a library at St. Johns, Newfoundland.

WE learn from the *Astronomical Journal* that the government of the Republic of Ecuador has placed the Observatory of Quito at the disposal of the French Commission charged with the remeasurement of the Peruvian arc. M. Gonnessiat, astronomer of the Observatory of Lyons, has been entrusted with the direction of the establishment. The new director has taken possession of his post, and is actively engaged in organizing astronomical, meteorological and magnetic services.

THE Guttenberg Museum at Mayence was opened on June 23.

TWO further tracts of land, together somewhat less than an acre in extent, have been purchased for the U. S. Naval Observatory at a cost of \$6,000.

Nature states that the biological station which had been kept on Lake Baikal for a year by the East Siberian Geographical Society, at Goloustnaya, on the west coast, has been closed. A rich collection of fishes, especially of *Cottus* species, and a great variety of *Gammarus* species have, however, been secured, and the latter are in the hands of Professor Sars, of Christiania.

PROFESSOR TODD's eclipse expedition to Singkep, an island of the Netherlands Indies, secured 28 photographs of the corona on May 18, partly through clouds. Mr. Percy Wilson, of the New York Botanical Garden, who went out as collector of the expedition, has obtained many valuable exhibits and living plants, among them numerous orchids. Mr. Wilson is

now in Java, making further collections in Buitenzorg, and will return home in August.

THE daily papers say that Dr. A. H. Doty, health officer of the port of New York, proposes to try to exterminate the mosquitoes of Staten Island. Men are said to be at work mapping all the marshes, stagnant pools, etc., and crude petroleum is to be released beneath the surface of the water. The marshes, etc., will also be drained.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. A. C. BARTLETT has increased his gift for a gymnasium for the University of Chicago from \$125,000 to \$200,000.

MR. JOHN S. NEWBURY, of Detroit, has given Yale University \$25,000 for an organ, to be placed in Memorial Hall.

A NEW astronomical observatory with increased equipment, including the equatorial telescope which formerly belonged to the late Judge Knapp of New Jersey, is being erected at Lincoln University, Pa. This will be used mainly for purposes of instruction under the directorship of Professor Walter L. Wright, Jr. who has, for a number of years, been in charge of the department of mathematics at that institution.

THE General Purposes Committee of the Birmingham City Council has decided to recommend a grant of the proceeds of a half-penny rate which will provide the University with the sum of £5,000 annually.

FOUR members of the faculty of the Connecticut Agricultural College, Storrs, Conn., have been asked to resign, as a result, it is said, of their alleged opposition to the policy of President Flint. They are: Nelson S. Mayo, M.S., D.V.M., professor of anatomy, physiology and veterinary science; Henry A. Ballou, assistant professor of forestry, botany and military science; Thomas D. Knowles, instructor in English, mathematics, history and physical culture; Charles E. Myers, instructor in farm accounts and business methods, and secretary of the faculty.

WE learn from *The Botanical Gazette* that the regents of the University of West Virginia

have abolished the professorship in botany without notice to the present incumbent, Dr. E. B. Copeland. Dr. Copeland is spending the summer at the Cold Spring Biological Laboratory.

THE chair of pathology in the University of Sydney is vacant and applications for it are invited. The salary is £900 per annum and a pension of £400 per annum is allowed on certain conditions after twenty years' service. The sum of £100 will be allowed for passage expenses from Europe or America. The successful applicant is to begin his duties on March 1, 1902. Further particulars may be obtained from the Agent-General for New South Wales, 9 Victoria Street, London, S. W., to whom applications, stating applicant's age (which must not be more than forty years) and qualifications, and accompanied by four copies of each testimonial submitted, should be sent not later than September 14, 1901.

AT the July meeting of the Board of Regents, Mr. L. W. Hartman was elected to the professorship in physics at the Kansas State Agricultural College for the coming year. For the past year and a half Mr. Hartman has been on the staff of the department of physics at Cornell University.

KARL WILHELM GENTHE, PH.D. (Leipzig), has been appointed instructor in natural history in Trinity College.

THE following have been appointed assistants in histology and embryology at Cornell University: Arthur M. Bean, A.B., of Iowa College; Charles W. Bunker, B.S., of the University of Nebraska; Bert R. Hoobler, B.S., of Wabash College; William C. Thro, A.M., of Cornell University; Gersham F. White, B.S., of Ohio University, and William F. Wismar, A.B., of Rochester University.

DR. ALFRED KOCH, of Oppenheim, has been appointed associate professor and director of the Institute of Agricultural Bacteriology at the University of Göttingen.

DR. EDMUND LANDAU has qualified as docent in mathematics at the University of Berlin, and Dr. G. Senn as docent in botany in the University of Basle.

SCIENCE

THE ORIGIN OF THE MAMMALS.

SPECULATIONS as to the origin of the various existing groups of animals and plants are always dangerous, and yet they have for many a certain fascination. They partake, somewhat, of the nature of an algebraic problem in that there are unknown quantities to be discovered, but they differ from any such soluble problem in that we have not equations enough to allow us accurately to ascertain the values of x , y , z and the like. Here is a chance for the play of the imagination and a chance for close guessing at the values of some of the unknown elements. Different students have assigned different values to them, and hence the varying character of the answers we have had given to us. Recall the different forms which we have been asked to consider as ancestral to the vertebrates—coelenterates, nemertines, annelids, *Phoronis*, crustacea, arachnids, tunicates, *Balanoglossus*! Certainly there has been some error in the assignment of values to the unknown to produce such discordant results as these.

Yet these speculations have a certain value; they call attention to problems, they suggest lines of research, they are exercises of the logical powers. One of these genealogical problems is that which deals with the origin of the mammals. It has been twice 'settled,' and yet there is some new evidence, and there are new points of view.

Theromorphs

Until 1884 the general opinion among those who speculated on phylogenetic matters was that the group of mammals had an amphibian ancestry. Huxley was especially prominent in advocating such a line of descent, basing his conclusions upon the naked, scaleless skin, the double occipital condyle and other cranial features, some of which will be mentioned later. Yet this view was not universal, since Owen, in 1876, and Cope, in 1878 and in later papers, had suggested a reptilian ancestry for the group. Still, these speculations attracted but little attention until 1884, when Caldwell's famous dispatch, 'Monotremes oviparous, eggs meroblastic,' excited the enthusiasm of the British Association for the Advancement of Science, then meeting in Montreal. At that date embryology was the ruling force in deciding questions of phylogeny, and the discovery by Caldwell that the *Echidna* laid eggs, and that these eggs were like those of the reptiles rather than those of the amphibia in their segmentation, at once suggested to every zoologist a reptilian ancestry for the mammals. This was still further emphasized a few days later by Cope's paper upon the relations of the theriomorphous reptilia and the monotreme mammalia, read before the American Association at its Philadelphia meeting.

Since that day numerous students have built upon that foundation, and I need but allude to the papers of Cope, Seeley, Osborn, Howes, Lyddeker, Baur and Case, all of which accept the reptiles as the progenitors of the scaleless, hairy, milk-producing vertebrates that we know as mammals. They have brought forward much evidence—but solely osteological in character—in support of their views, and for the summary of this which follows I am largely indebted to the able papers of Osborn.

The particular group of reptiles which they have selected for this high honor is that

known as Theriomorphs, the fossils of which are found in rocks of Permian and Liassic age in Illinois, Texas, New Mexico, Scotland, Bavaria, Bohemia, the Urals, Bengal and South Africa. Then they suddenly disappear, for no traces of them occur in rocks of more recent age, and there is a vast gap between them and the earliest mammals of which we have any adequate knowledge. This group shows several features in which they approach the mammalia more closely than do any other reptiles, and a summary of these points may be of value now.

In the mammalia the skull is articulated to the atlas, the first bone of the vertebral column, by a pair of oval articular surfaces, the occipital condyles. These are borne one on each exoccipital bone. In most reptiles, on the other hand, there is but a single condyle, largely or wholly basioccipital in origin. In many of these theriomorphs the exoccipitals partake in the formation of this structure, and in some the basioccipital portion exhibits a tendency to recede, thus exhibiting a condition which, carried still farther, would result in two condyles like those of the mammals.

In the mammals there is a heterodont dentition; that is, there are different kinds of teeth—incisors, canines and molars. In recent reptiles and in amphibia there is no such differentiation, but in these theriomorphs one group presents a dentition which is strikingly suggestive of that of the mammals. Indeed, one species, described from a lower jaw, was at first regarded as a mammal.

In the mammals the anterior dorsal ribs bear peculiar relations to the vertebræ. These ribs bear two 'heads,' by which they are articulated with the backbone. One of these, the so-called tubercular head, articulates with a process, the diapophysis, which arises from the neural arch, while the other, or capitular head, has its articulation with

the bodies or centra of two vertebræ, in such a way as to suggest that its proper place was between them; that is, intercentral in position. This condition has led Cope and others to the view that a vertebral element, the intercentrum, once existed here as it does in many lower vertebrates, and that the rib formerly articulated with this. By the disappearance of this intercentrum the mammalian relations have been brought about. In some of the theriomorphous reptiles the capitular head is also intercentral.

In many mammals there is a small hole, with the disproportionately large name of entepicondylar foramen, in the inner lower end of the humerus, the bone of the upper arm. This opening is for the passage of the brachial artery and the median nerve. In the lower vertebrates such a foramen is unknown, except in the theriomorphs.

Again, in the mammals the lower jaw articulates directly with the cranium by means of a shallow pit, the glenoid fossa, on the ventral surface of the squamosal portion of the temporal bone, no other element intervening between the two. In most of the lower vertebrates the lower jaw does not articulate direct with the cranium, but a movable bone, the quadrate, is inserted between them, and forms a suspensor

FIG. A. Skull of a Theriomorphous Reptile (*Gordonia*). Showing the quadrate bone (*q*) firmly united to the enlarged squamosal (*s*). After Newton.

of the lower jaw. In the theriomorphs and crocodiles the quadrate is fixed and immovable, and is held in position by a second

bone, the squamosal, which, together with the quadrate, takes part in the formation of the articulation of the lower jaw. Now, say the advocates of the reptilian ancestry of the mammals, if the quadrate were to become completely fused with the squamosal, the result would give a condition from which the mammalian articulation could readily be derived. In support of this view, they cite the case of a human skull, described by Albrecht, in which a separate bone, which he interpreted as the quadrate, appeared in this very region.

Further evidence, which is regarded as pointing in this same direction of a theriomorphous ancestry, is furnished by the pelvis, while the imperfectly known tarsal bones of these reptiles are doubtfully interpreted as supporting the same view. These features, however, are of secondary importance in comparison with those already enumerated, for the peculiarities of the mammalian pelvis and tarsus are as readily derived from the amphibibia as from the theriomorphs. The foregoing enumerates the chief osteological evidence for the reptilian ancestry of the mammals. The only other evidence recalled at present which points in the same direction is the character of the segmentation of the monotreme egg, already alluded to.

Within more recent years there has been a tendency upon the part of some zoologists to return to the support of an amphibian parentage of the mammals. Klaatsch, Maurer, Hubrecht and Beddard have pointed out features of the soft parts of mammals, which are more easily interpreted by this assumption; but, of course, this cannot be conclusive, for we can know nothing of these structures in the theriomorphs. Hence this evidence, which will be summarized later, can only be regarded as cumulative and not of first importance.

The osteological facts which have already been enumerated need analysis, for it is

possible that they will bear another interpretation than that usually accorded them.

The argument from the heterodont dentition can have but moderate value, for we know that different types of teeth have been developed independently in different groups of vertebrates, and it is possible that they could have arisen in the mammals and not have been inherited from the theriomorphs. So, too, with the entepicondylar foramen. The nerve and blood vessels exist in lower forms, and it is conceivable that the existence of the foramen in the two groups may be explained upon the ground of homoplasmy and without implying inheritance. This foramen certainly is of too little importance to be used as the basis of great speculations.

The matter of the ribs is more important. In the amphibia with bicipital ribs, the capitular head rests upon the so-called centrum, and not between two centra, as in theriomorphs and mammals. Yet, with our present knowledge, this is far from conclusive, for we know almost nothing of the morphology of the vertebræ in most groups of vertebrates. The researches of Fritsch upon the fossil stegocephalan amphibia have shown that the vertebral centra are by no means simple affairs, but are really composed of several (at least five) separate elements. Traces of at least some of these, more or less distinct, appear in the higher vertebrates; but until the homologies of these are worked out for the existing amphibia, the reptiles and the mammals, arguments based upon the relations of the ribs to centra and intercentra must remain inconclusive. As it stands at present, it must be admitted that the burden of proof, so far as the ribs are concerned, is against the advocates of amphibian ancestry.

The matter of the occipital condyles is even less conclusive. Until the discovery of the theriomorphs, the fact that both amphibia and mammals have two condyles

and the sauropsida but one condyle, was regarded by Huxley as the very strongest argument for amphibian ancestry, and the most that is claimed for the double condyles of the theriomorphs is that they show that these animals are not to be counted out upon reasons based upon the articulation between cranium and vertebral column.

Yet in none of these is there an exact reproduction of the mammalian conditions, for in all the basioccipital participates to a greater or less extent in the formation of the condyles, these structures being described at times as distinctly bilobed, at times having the basioccipital portion receded below the level of the rest, but still rather prominent. In other words, the double condylar condition of the theriomorphs—and hence that of the mammals—is supposed to have arisen from the single condyle of other forms by recession of the basi-occipital. In the development of the mammals there are, however, no traces of such a stage. All this, however, is aside from the more fundamental question, Is the occipital region of the skull homologous throughout the vertebrates?

Of far more importance than all these features is the problem of the quadrate. In fact, the whole matter of the ancestry of the mammals may almost be said to hinge upon the decision arrived at as to the fate of the quadrate in the mammals.

A brief review of some points of an anatomical character may make clear the discussion of the quadrate. In the first place, it must be kept in mind—and this is too frequently ignored by those who deal with bones alone—that there are two kinds of bones which differ greatly from each other in history, both ontogenetic and phylogenetic, and that while one may seemingly replace the other, there is no evidence whatever of one passing into the other. These two types are known respectively as cartilage bones and membrane bones. A

cartilage bone is always preformed in the peculiar substance known as cartilage, and in this only later is the chondrin matrix replaced by salts of lime. Membrane bones, on the other hand, never have a cartilage stage. They arise by the direct ossification of connective tissue membranes. Further, investigations seem to show that there may be at least two types of membrane bone, one of which, exemplified by most of the membrane bones of the skull and by the bony plates of the alligator, has arisen by the fusion of the bases of dermal scales or teeth, and the sinking of these to a deeper position. The other type, familiar in the kneecap and the bony strands so well known in the drumstick of the turkey, arises from the ossification of tendons.

In the sharks the skeleton of the jaws arises from a continuous stroma or anlage on either side of the head. Each of these strands—known as the mandibular arch—becomes interrupted in the middle as it becomes converted into cartilage. The upper half of each arch forms the upper jaw—the pterygo-quadrate of anatomy, while the lower half in a similar way gives rise to Meckel's cartilage, the skeleton of the lower jaw. These jaws do not articulate directly with the cranium, but the pterygo-quadrate is suspended in front by ligaments, while behind, besides a ligament, the upper half of the next or hyoid arch intervenes as a hyomandibular element between the jaws and the cranial wall, thus forming a suspensorium for these parts.

In the teleosts, or bony fishes, where bone largely replaces cartilage in the adult, the hyomandibular still acts as a suspensor, while the pterygo-quadrate, relieved of its functions as the upper jaw, ossifies in two portions; in front, as a pterygoid bone; behind as a smaller element, the quadrate. The quadrate articulates, on the one hand, with the hyomandibular; on the other, it supports the Meckelian, the hinge of the

lower jaw being formed by the articulation of Meckel's cartilage with the quadrate.

In the vertebrates higher than the fishes the hyomandibular disappears as a suspensor, and it is not to be recognized with absolute certainty in this region. As will be seen shortly, there is some evidence that it is not entirely lost, but persists with changed functions. In contrast to what obtains in the fishes, in amphibia, reptiles and birds, the quadrate articulates directly with the cranium in the region of the ear, and forms a suspensor for the lower jaw. In its history in all these groups the quadrate is preformed in cartilage, and hence, when it ossifies, it becomes converted into cartilage bone. In amphibia, reptiles and birds in the embryonic stages, the Meckelian cartilage, of course, articulates with the quadrate, but when the definitive lower jaw is formed, some features are introduced which must be described. In all the bony vertebrates the Meckelian does not furnish the bones of the lower jaw, but these arise as membrane bones arranged round the cartilage bar. In the amphibia and reptiles the most constant of these bones is a very large, tooth-bearing dentary in front, extending backwards on the outer side of the Meckelian. Further back, on the inner side, is a smaller bone, the splenial, which also may bear teeth. The third of these is the angular, which is placed behind those already mentioned on the lower and inner sides of the proximal end of Meckel's cartilage. The Meckelian ossifies only at its posterior end, where it articulates with the quadrate, giving rise at this point to a cartilage bone, the articular. In short, the lower jaw consists of a single cartilage bone, the articular, and three or more membrane bones.

The articular surface of quadrate and articular presents features which must be mentioned. In all the non-mammalian groups the quadrate has a rounded or some-

what semi-cylindrical surface which fits into a corresponding groove or cavity in the articular.

Another set of bones may be mentioned now. These are the bones of the middle ear, the ossicula auditus of anatomists. It seems probable that the sense of hearing appears in the vertebrates only with the assumption of a terrestrial life, and that the so-called ears of the fishes are organs for the maintenance of equilibrium. In the amphibia, then, true hearing appears. In the salamanders an opening occurs in that part of the cranium which surrounds the inner ear. This opening is the fenestra ovale, and is partly closed by a small cartilage or cartilage bone, the stapes, possibly to be homologized with the hyomandibular already referred to as apparently lacking in the non-piscine vertebrates. This interpretation receives some confirmation from the fact that in several salamanders the stapes articulates with the quadrate, a point which is of importance when we come to a consideration of mammalian structures.

In the frogs, reptiles and birds the stapes is a long slender rod,* frequently called the columella, and is in no way connected with

FIG. B. Diagram of Ear Region in a Lizard. *s*, stapes; *c*, columella; *q*, quadrate; *m*, lower jaw; *ct*, chorda tympani nerve.

the quadrate. It rather extends straight outwards from the fenestra ovale, across the cavity of the tympanum, or middle ear, to

* The columella is more than stapes, but for present purposes the details are not necessary.

reach the tympanic membrane. It thus becomes a sound-conducting apparatus, conveying the sound waves across the tympanum to the inner ear. This columella arises in the posterior wall of the tympanum, and, although it later moves forward into the tympanum, must consequently be regarded as a structure belonging to the post-tympanic region.

In the mammals, on the other hand, the sound-conducting apparatus is greatly different. Instead of a columella there is a chain of three bones leading from the fenestra ovale to the tympanic membrane. These are called, in order from within out, the stapes or stirrup bone, incus or anvil, and malleus or hammer, the stapes being situated in the fenestra ovale, the malleus being connected with the tympanic membrane and the incus intervening between these two. Many attempts have been made to homologize these bones with the columella of lower forms, but none of these attempts have been successful, and it is probable that complete homology does not exist. This is shown almost conclusively by two facts of anatomical relationship. In the first place, the middle member of the mammalian chain—the incus—arises in front of the tympanic cavity, and hence cannot correspond to any part of the columella, which, as we have seen, is post-tympanic in origin. Again, the incus lies in front of that branch of the seventh or facial nerve which is known as the chorda tympani, while the columella lies behind it. Now, nerves are older structures than skeletal elements, and any cartilage or bone placed in front of a major branch of a nerve cannot be homologized with a skeletal element lying behind the same nerve in another vertebrate.

Now, if these ear bones of the mammals are not homologous throughout with the columella, with what structures in the lower vertebrates can they be compared?

Here embryology comes in to assist. The development of these bones has been followed by many, and it is a rather significant fact that while the embryologists are in substantial agreement in their interpretations, their opinions are at variance with those of the students who have attacked the problem from the stand-

FIG. C. Diagram of the Ear Region in a Mammal. *s*, stapes; *i*, incus; *m*, malleus; *ct*, chorda tympani nerve.

point of adult structure. Now, since the embryologists have the wider view, the larger basis of facts at command, on *a priori* grounds their conclusions should be given the greater weight. Embryology plus comparative anatomy certainly forms a better basis for conclusions than comparative anatomy alone.

In the embryonic mammal, before the appearance of cartilage, a strand of denser mesenchyme extends from the point where the anlage of the stapes can be recognized into the lower jaw. Position and relationships show that this strand is the first appearance of the mandibular arch. With the formation of cartilage this arch becomes divided into a proximal portion, which can be traced, step by step, until it develops into the incus and a more distal portion, which is as clearly Meckel's cartilage, extending into the lower jaw. This incus soon develops an articular surface for connection with the stapes, while a second set of sur-

faces is found between the incus and the proximal end of the Meckelian cartilage. The incudal surface of this last is convex, while the corresponding articular surface on Meckel's cartilage is concave. It follows from these facts of development and structure, as well as from others which cannot be detailed here, that the incus fulfills, in the embryonic stages, every condition demanded for the quadrate, while the great size of these elements in the early condition can only be interpreted as indicative of some function in their ancestral history different from that of a sound-conducting apparatus. Again, it is a matter of no little importance in what will follow, that this quadrate articulates with the stapes just as in many urodele amphibia, while such relationships are unknown in any reptile, living or fossil. In the third place, this incus for a time articulates directly with the skull, just as does the quadrate in the lower forms, a condition not easily explicable upon any other view than that regarding this as the quadrate.

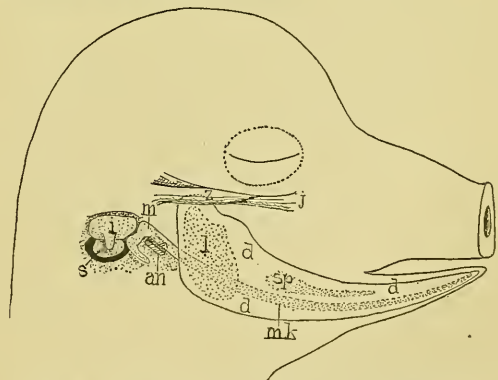

FIG. D. Diagram of the Ear and Lower Jaw in the Pig. *an*, angular; *d*, dentary; *i*, incus; *j*, jugal; *l*, cartilage of articular region of lower jaw; *m*, malleus; *mk*, Meckelian cartilage; *s*, stapes; *sp*, splenial; *z*, zygomatic process of temporal—the letter lies just in front of the glenoid fossa.

The malleus is largely formed by the ossification of the proximal end of Meckel's cartilage, and this fact, together with every

other relation except one to be mentioned immediately, goes to prove that it is the equivalent of the articular. In the formation of the malleus a membrane bone is concerned. This arises in front of the articular proper on the inner and lower side of the cartilage—that is, in the right position for the angular—and forms the process Folianus of the malleus. At some distance from the malleus two membrane bones form the lower jaw of the adult. The larger of these, from its relations and position, is clearly the dentary, while the smaller and inner one is as plainly the splenial. Thus we can apparently recognize in the mammalian lower jaw the articular and the three membrane bones most constant in the lower vertebrates. In some mammals, according to Parker, two additional membrane bones, each with its equivalent in the lower vertebrates, are said to occur. Besides all these there exists a patch of cartilage in either half of the lower jaw which arises entirely independently of the Meckelian, never unites with it, and which is, so far as I know, without any equivalent in any amphibian, reptile or bird.

To the identification of the bones of the lower jaw which have just been given, there is one very serious objection. The articulation with the cranium is not homologous with that of the lower vertebrates. After the formation of all the bones of the jaw the Meckelian cartilage becomes absorbed between the Folian process and the hinder margin of the dentary, leaving the jaw proper without connection with the quadrate. The posterior portion of the dentary extends up around the second cartilage mentioned, and articulates with the squamosal, the dentary furnishing the articular condyle, the squamosal the glenoid fossa. It is not easy to say how this new articulation can have been introduced, for it is hard to see how an organ in constant use like the jaw

could transfer its hinge from the quadrate to the squamosal. And yet, from any point of view, it seems impossible to escape the conclusion that it is not homologous with the articulation of the lower vertebrates, for the articulation in the non-mammalian forms is at the proximal end of Meckel's cartilage, while in the mammals the Meckelian does not come anywhere near the region of the glenoid fossa. Again, in the glenoid fossa there is no trace of any cartilage which could be used as a basis for the view that the quadrate has disappeared at this point.

A word about Albrecht's supposed quadrate may be inserted here, since it has often been quoted in this connection. Albrecht found, on one side of the skull of an idiot, a separate bone in the region of the zygomatic process of the temporal bone, and since the lower jaw articulates at this point, he at once jumped to the conclusion that this bone must be the missing quadrate. Now, the fact that cartilage is unknown in this region would at once negative any such conclusion, while the further fact that the skull in question was that of an imbecile and the additional bone occurred on one side only, is certainly suggestive. No history of the case was given, but it is not beyond the bounds of possibility that an injury to the head may, at the same time, have caused the imbecility and have produced the supernumerary bone, upon which, as a very slender basis, a considerable superstructure of speculation has been built.

There is one series of facts which may possibly lead to an explanation of this change in point of articulation. In certain sharks there occur labial cartilages which lie outside of the jaws and perfectly free from them. Now, the cartilage mentioned above as occurring in connection with the dentary bone of mammals, occupies the position of one of the lower of these labial cartilages—Parker has, indeed, identified

it as a labial—and this has apparently been concerned in the transference of the hinge of the lower jaw. This, however, is mentioned only as a suggestion; details have yet to be worked out, and further study may show that this view is untenable.

Now, summing up the evidence of the bones, we may say that the characteristics of the ribs, the heterodont dentition, and the entepicondylar foramen point more strongly towards a reptilian rather than towards an amphibian ancestry for the mammals. On the other hand, the occipital condyles are even stronger evidence in the other direction. But, when we consider the relations of the ear bones and the quadrate, the weight of argument is very strongly opposed to a reptilian ancestry, while these same relations, and especially the articulation of the quadrate with the stapes, go far towards supporting the theory that the mammals have descended from the amphibia.

There is another series of osteological facts which also seems to point in the same direction. In the mammals, as in the amphibia, the ankle joint is formed between the bones of the shank (tibia and fibula) and the proximal row of tarsal bones. In all reptiles of which we have adequate knowledge, the joint is between the proximal and distal rows of tarsal bones—is intratarsal. This, however, is not conclusive, since the foot structure of the theriomorphs is very imperfectly known.

Besides the osteological evidence for the descent of the mammalia from amphibian-like forms, there are facts derived from the soft parts which have a cumulative value. They, however, are not conclusive, for we cannot say what may have been the relations in the theriomorphs. It may be that these extinct reptiles possessed one or all of these features, but the fact that they are lacking in all modern reptiles lends plausibility to the view that they were ab-

sent from the older members of the group. A detailed account of these would far transcend the limits of this paper, and but the briefest mention can be made of them.

In the first place, mammals are strongly marked off from all other vertebrates by the existence of hair. For a long time it was thought that hair, feathers and scales were homologous structures, but Maurer has shown that hair is totally different from the others. It is true that Weber has criticised Maurer, but his criticisms seem far from conclusive. According to Maurer—and he offers a large mass of facts in support of his contention—the only structures in the lower vertebrates which can be conceived to have given rise to hair are lateral-line organs of the amphibian type. Now, lateral-line organs are unknown in any terrestrial form. Even in the frogs and salamanders they are lost during the metamorphosis which precedes a life on land. Hence it is very probable that they were lacking in the theriomorphs, all of which were apparently terrestrial in habit.

The student should also read Klaatsch's account of the mesenterial structures, especially of the superior mesenteric artery, to see how impossible it is to derive the relations of these from any known condition in the reptiles. In the mammals these structures are far more primitive than in the reptiles, and Klaatsch concludes that their origins must be sought in forms below the existing amphibia.

Mammals alone have well-developed external ears, and these, as well as the tube leading to the drum—the external meatus—are supported by cartilages. All who have worked at these agree that they must have been derived from opercular structures, like those of fishes, supported by the hyoid arch. Now, all such structures are absent from all known reptiles, nor do we know of them in the amphibia. They must be sought in

forms between the fishes and the stegoccephali.

The thoracic duct of the mammals is the primitive lymphatic duct of the left side; that of the right is greatly reduced and receives no lymph from the lower part of the body. Exactly the same conditions occur in the urodeles, but not in the reptiles.

Another item of interest in this connection is that mammals and amphibia get rid of their nitrogenous waste in the form of urea, while reptiles void uric acid.

As we saw earlier, embryology was an important factor in directing attention to the reptiles as ancestors of the mammals, but now the weight of its evidence is in the opposite direction. The fact that the monotreme eggs are meroblastic is far from conclusive, since similar conditions have arisen independently several times in the animal kingdom. Hubrecht, however, has pointed out that certain other features of development—those connected with the foetal envelopes of the mammals—are not to be derived from the conditions known in any reptile, but that they are easily explained as arising from a type of egg found in the amphibia. As these arguments, so far as I am aware, have not been summarized in English, they may be given in a brief form here, omitting all points which have no immediate bearing upon the question at issue, such as the two types of foetal circulation, the nutritive functions of the trophoblast and the like.

As is well known, the mammals, like the sauropsida, form a foetal envelope, continuous with the sides of the body—known as the amnion; and from the fact that the sauropsida are lower than the mammals, the natural view has been that the reptilian type has been the ancestral one, from which that of the mammals has been derived. Were this envelope to arise in all mammals in the same way that it does, for instance, in the sheep or the rabbit, this conclusion

could not be gainsaid; but when the amnion of the guinea-pig, the hedgehog, the flying fox and that of man are considered, we meet conditions which it is extremely difficult, if not impossible, to explain in such a way.

Forget for the moment the well-known diagrams of amnion formation which appear in any text-book, for they will confuse. In the hedgehog there arises very early in development a two-layered vesicle, the layers being, according to Hubrecht's interpretation, ectoderm and entoderm. At one end of the vesicle the ectoderm is much thicker than elsewhere, and projects like a cone or papilla into the central cavity. Soon a splitting occurs in this ectodermic thickening, so that the whole structure now forms a double vesicle, its two cavities being separated by a partition formed of ectoderm and entoderm, the larger and older cavity having walls of ectoderm and entoderm, the later one walls of ectoderm alone. From this partition the embryo will arise.

There are now clearly two kinds of ectoderm present in the germ; one the embryonic, the other forming the outer walls of both vesicles. For this latter Hubrecht has proposed the name trophoblast in allusion to its nutritive functions, and he distinguishes two kinds or regions of trophoblast; that of the smaller cavity being called the allantoidan, that of the larger the omphalidian trophoblast, from their future relations to allantoic and vitelline circulations.

With the development of the mesoderm, which, of course, arises between the ectoderm and entoderm of the germinal area, an important change is introduced. The somatic sheet of this layer grows outward and then turns upward into the angle between the embryonic ectoderm and the omphalidian trophoblast, and then bends downward on the inner side of the latter, while the splanchnic mesothelium follows the deeper surface of the entoderm into the

same region. This last, however, has no concern for us at present.

From the angle just mentioned the somatic mesothelium now gradually extends upwards and inwards between the cells of the allantoidan trophoblast as a double sheet, dividing the trophoblast of this region into two layers. Finally, the mesothelium growing in from all sides meets and fuses above the embryo, which now lies in a cavity roofed in by an internal layer of ectoderm and an outer of meso-

but, of course, these are derived in a greatly different way. We see from this that the first splitting in the ectoderm described above is the separation of amnion from the rest of the ectoderm. In the sauropsida and in some mammals, as is well known, the amnion arises in quite a different manner; not by the splitting of the ectoderm, but by the upgrowth and overgrowth of folds from all sides of the embryo—each fold consisting of ectoderm and somatic mesothelium—the folds at

FIG. E. Diagrams of the Origin of the Amnion. 1. Section of an egg of *Erinaceus* after Hubrecht, showing the two layers and a cavity in the ectodermic thickening. 2, 3 and 4, diagrams of successive stages of formation of the amnion; ectoderm white; mesoderm dotted; entoderm black. *a*, Cavity of amnion; *c*, coelom. 2. Diagram of the stage of Fig. 1, the amniotic cavity formed by splitting of the primitive ectodermic thickening. 3. Appearance of the mesoderm and coelom, the somatic layer of the mesoderm growing upwards above the amniotic cavity, the roof of which is beginning to split into amnion and serosa. 4. Process of the amnion formation complete, the result closely similar to what is found in reptiles and birds.

thelium. Between this roof and the trophoblast there is now a space, lined on either wall by mesothelium, and hence clearly a part of the coelom. The cavity above the embryo is the amniotic cavity, and its ectodermal lining is the amnion. It now shows in every relation exactly the same features as are well known in the chick;

last meeting and fusing above the embryo, the final result closely simulating that described for the hedgehog. The question now arises, which of these two modes of amnion formation is the primitive and which the derived condition? Hubrecht's line of reasoning in settling this question is, in outline, as follows: The am-

nion, filled with fluid and surrounding the embryo, is clearly a protective apparatus. Its origin can in no way be explained by the presence of the large yolk or of an egg-shell, for in the sharks which have both no amnion appears. As a protective apparatus it, of course, would have the greatest value in an embryo developing inside the mother, protecting it, like a water cushion, from the peristaltic and other movements of the mother. Hence, it is more reasonable to look for the origin of the amnion in viviparous rather than in oviparous forms. Now, an amnion formed after the type found in the hedgehog can act as a protection from the very first, while one arising as in reptiles cannot have any protective value until the folds have completely closed over the embryo, and so it is difficult to account for the incipient stages in the reptilian type. Again, it is easy to derive the reptilian condition from that described, while the amnion of the hedgehog or of man is not easily explained on an hypothesis of descent from the reptilian condition. Hence it follows that there is no inherent improbability, and that there is much plausibility, in the view that the amnion formed by splitting is the primitive, that by overgrowth the derived type.

Now, where are there features that could have given rise to such structures? The ancestral form must have been viviparous, and it must have had a two-layered ectoderm. Now, the amphibia fulfill the conditions in both respects, for there are salamanders which bring forth living young, and nowhere in vertebrates, except in the amphibia, do we find a two-layered ectoderm, while here a two-layered condition occurs throughout the group; and further the outer layer does not participate in the formation of the embryo.

In conclusion, it may be said that at present the weight of evidence is in favor of an amphibian ancestry for the mammals,

but when the known forms of amphibia are examined none is found which will meet exactly the requirements of the case. The limbless cæcilians are, of course, out of the line; the anura, with their reduced vertebral columns and reptilian ear structures, are equally out of the question. The urodeles approach more nearly to the ancestral form, but their skull is so degenerate that it cannot give rise to the zygomatic arch so characteristic of the mammals. There remains only the group of stegocephala. These are extinct forms, the earliest fossils of which appear in the Carboniferous, the subclass dying out in the Triassic. In every known feature these are closer to what the ancestors of the mammal must have been than are any of the other groups, and yet not a single form of stegocephalan is known which can be said to meet the demands required for the ancestor of the mammals. This ancestor must be some form closely allied to, but yet more primitive than, any known stegocephalan. Further, it may be said that we cannot derive urodeles, cæcilians or anura from any stegocephala as yet discovered.

The earliest known stegocephala are well differentiated and widely distributed, and they have a structure greatly different from that of the crossopterygian ganoids from which they have in all probability descended. The ancestor of the mammals partakes of characters intermediate between those of the crossopterygians and those of the most primitive stegocephalan known, and yet one in which the amphibian characters predominate over the ganoid features.

We must, however, remember that the geological record is as yet imperfectly known. We have as yet found no form which serves to bridge the gap between the finned and the limbed vertebrates. Footprints have been found in Devonian rocks in Pennsylvania which, in the light of our present

knowledge, we can interpret only as those of a stegocephalan, but no hard parts have been found to show us what the animal was like. We may hope, yes, almost expect, that future exploration will show us stegocephalans in rocks of Devonian age, and when those are found it is possible that they will embrace types which will be decisive as to mammalian ancestry. Yet how slight are the chances of such discovery is shown by one fact concerning our knowledge of the mesozoic mammals. Nearly half of the known species of these were found in a bed of clay in southern England, the whole deposit measuring forty feet in length, ten in breadth and five inches in thickness.

J. S. KINGSLEY.

TUFTS COLLEGE.

THE RELATION OF PHYSICAL GEOGRAPHY
TO OTHER SCIENCE SUBJECTS.*

IN geography we have not as yet reached that stage when vague spheres of influence give place to definite territorial boundaries. Our science is still unorganized, its frontiers are not demarked and the dividing lines of its provinces are not yet drawn. My subject compels me to take up a number of questions still so unsettled that I can hardly hope to suggest even a *modus vivendi* which in this time of boundary disputes will be acceptable in all its details to many besides its author.

At least in America, we shall all agree that physical geography is not identical in its limits with what our English friends term physiography. It is not a summation of our knowledge of nature. Such was the older physical geography, and valuable as was its view over the entire kingdom of science, it was found impracticable as an educational instrument. With its string of disconnected chapters on the elements of

physics, chemistry, astronomy, geology, botany, zoology, and ethnology, concluding perhaps with a chapter on precious stones, it is no wonder that there was sometimes applied to it the sacred definition of a circle whose center is everywhere and whose circumference is nowhere. And yet to many a boy it gave his only world-view, his only touch with nature. When Huxley spoke of it, this *Erdkunde*, as 'a peg on which the greatest quantity of useful and entertaining scientific information can be suspended,' it was not in disparagement; for he termed it one of the essentials of a liberal education.

Physical geography has often been treated as though it were equivalent to the 'science of geography,' as Strachey has defined it, or as synonymous with the 'general geography' of the Germans. But its note is neither the introduction of the causal notion nor a topical treatment of the subject. It is not to be set over against either descriptive or a real geography. Surely the adjective in the phrase may well have a restrictive influence. Either 'physical' as here used is equivalent to 'natural,' in which case our science reverts to physiography, or else it limits the subject to physical as distinct from biologic phenomena. Accepting this restriction, we may set the divisions of geography in the following scheme:

1. Chorographic geography.
2. Physical geography, with its subheads of the geography of the planet, the geography of the air, the geography of the sea, and the geography of the land.
3. Biotic geography, the distribution of animals and plants.
4. Anthropic geography, the geography of man.

The chorographic member, dealing with position, direction and dimension, is the rudiment from which the entire body of geography has developed. The map, its first product, remains its chief vehicle of

* Read before the Department of Science Instruction, National Educational Association, Detroit, July 12.

expression. I can only stop here to notice that in education this member has but recently passed its culmination. The leading American geography of twenty-five years ago, on account of its many excellencies called by Col. Francis Parker in 1894 'the best geography in English ever issued,' touched the highwater mark of topography. Its map questions on the continent of South America required a knowledge by the pupil of 9 capes, 48 cities and 30 rivers. The boy who knew his lesson in Guyot could tell you that the leading affluents of the Orinoco are the Venture, Coroni, Auraca, Meta, and Guaviari rivers. To-day the pupil in Frye escapes from South America with a burden of but 1 cape, 11 rivers and 25 cities, a total of 37 place-names of these three kinds, as against the 87 which his father learned in Guyot.

The space saved by this shrinkage is largely given in recent texts to the physical side of the subject. Our 'advanced' or 'complete' school geographies open with a compend of physical geography, and a wealth of physiographic material is scattered with free hand throughout the text. In the high-school our science is commonly reviewed as a distinct study.

In its opening chapter on the geography of the planet, physical geography borrows freely from astronomy. Its view-point, however, is geocentric. Its astronomy is planetary, not sidereal. No fact nor theory is introduced except in direct and important relations to the earth.

The geography of the air is practically conterminous from our standpoint with meteorology. It makes drafts on the elementary principles of physics. It everywhere introduces the causal notion. Both the physical and the purely geographical contents are indispensable, and it would be futile to attempt to isolate either.

Under whatever name meteorology is

taught, it should have a large place in school programs, so many and so vital are our relations to this ocean of air at whose bottom we dwell, so fundamental are its effects on land forms, so immediate are its controls of the distribution of life. Few studies offer so good facilities for scientific observation. The apparatus it requires is inexpensive. The daily reading of its instruments, the search for the causes of to-day's weather changes and the effort to predict those of to-morrow, give training of high value. The school becomes in a way a member of a corps of scientific observers, since it receives each morning the records of the work of the Weather Service to compare with its own. Indeed, so valuable is meteorology as an educational instrument that it surely will win place as a distinct study in the high-school.

The geography of the sea is of minor importance to our subject, and we may pass at once to the pith of physical geography, the geography of the land, the science of land forms, or geomorphology, as it is technically and rather lengthily termed. It is here that our science presents the largest range and variety of phenomena. It is here that its relations to life are most direct and complex. So central is this portion of geography that all other divisions may be grouped about it in subordinate relations and the whole thus attain organization and unity. The geography of the planet, the sea and the air are prerequisite to the geography of the land, since it is by the action of the mobile envelopes that the forms of the lithosphere have been sculptured, while the applications of these physical conditions lead directly into the biotic and anthropic divisions.

It is not strange, therefore, that with the organization of the science the study of land forms has taken a large place. It is called by Penck 'the main part of geography proper.' The masterly treatise of de Lap-

parent 'Leçons de géographie physique,' is geomorphology pure and simple from beginning to end. Is this distinguished geologist of France biased by his profession? Well, here then is Boulangier, who in his 'Traité de géographie physique' reassures his readers that the author is *not* a geologist, and still defines his subject as 'the methodical and rational study of the surface forms of the planet.' Wagner excludes from our science both anthropic and biotic geography, while Supan admits, of the two, only the latter. Davis has given us under the name of physical geography the most complete and luminous treatise on land forms in the language, in which, however, there are everywhere introduced applications of physical conditions to the life of plant, animal and man—matter of great value usually omitted in European texts.

So rapidly, so lusty and so big has geomorphology grown that it has been suggested by Professor Dryer that it aims to play the part of the young cuckoo and oust from the nest the remainder of the geographical brood. It is scarcely of age, and yet the science of land forms has already rejuvenated geology and rationalized the domain of geography. Geomorphology is the child of geology and geography, and it inherits its father's strength and its mother's beauty. From geography it brings the 'half artistic' description of the features of the earth and their distribution; from geology it brings the reasoned processes of their formation. Just now it seems to be an educational question as to which of the parents the child should be given in keeping. Should land forms be taught in high-schools chiefly as physical geography or as geology? This is perhaps the most important question raised by my subject. It involves the relations of the two sciences and their educational values.

The overlap-land of geomorphology may be claimed by geology with as sure a right

as any of its other provinces, such as paleontology. It was by geologists that it was explored. The Committee of Fifteen accredits the advance in scientific geography the last few decades to the work of geographical societies, and to a limited extent this is surely true, in Great Britain especially. And yet, as one of the foremost British geographers, H. R. Mill, has stated, it is 'the recent work of three geologists, Penck, Davis and Lapparent,' that 'has brought this aspect of the relation between geography and geology boldly to the front.' Without question it is by geologists that the science of land forms has been created. The list of the founders and leaders of the American school of physiographic geology, whose primacy is so generally admitted, is quite too long for mention, but I cannot omit the names of Powell, Lesley, Gilbert, Davis, Dutton, McGee, Chamberlin, Russell and Tarr. How large, also, have been the contributions of foreign geologists, such as Ramsey and Geikie, Richthofen, Suess, Heim and Walther, Noe, Margerie and Lapparent. If some of these, as Penck and Davis—to the latter of whom Lapparent justly attributes 'the preponderating influence in the development of the new conceptions'—are officially known as professors of physical geography, they belong, notwithstanding, to the brotherhood of the hammer.

The attention of geology was early diverted from the study of land forms, but it brings on its return a wealth of material which compensates amply for its absence. The reports of the U. S. Geological Survey contain a body of physiographic information and doctrine unequaled in the publications of any scientific society. Our recent State surveys show the splendid results of the application of the methods of the geologist to the study of reliefs, as in the work of Salisbury in New Jersey, Calvin in Iowa, and Marbut in Missouri. The new geology describes the forms of the land with a pre-

cision and detail hitherto unknown. It refers them to their places in a genetic classification. It assigns them to their order in an evolutionary life history. Furthermore, it uses them as the older geology used fossils and the succession of strata; it reads in reliefs the story of the geological past. It not only explains the present by the past, but it also reveals the past by means of the present. The physiognomy of a region may be the record of a large part of its geological history. While the geomorphologist requires the special equipment and competence of the geologist, it is no less true that the geologist must now perform be a geomorphologist.

In the geological courses now offered in American universities land forms have a large and increasing place. It is given under different names, but with essentially the same content. In some, as in the University of Wisconsin, applications to human life are included, an essentially geographic subject. In the higher American schools, with one notable exception, Harvard, it is only in the laboratories and lecture rooms of the department of geology that the student of land forms can obtain adequate training. "The surest foundation," as Richthofen has said, "for the study of geography is geology, in its whole compass, as being the only means to an understanding of the earth's surface." Geology thus retains possession of the field both in research and in advanced instruction.

As Davis has pointed out, land forms are functions of three variables—structure, process and time. The first of these, structure, together with the causes which have produced it, is undoubtedly a geological subject, and it is from geology that the geomorphologist must here draw all his data. Process has always been treated under dynamic geology, and yet as a part of geophysics, as treating of agents now in action upon the earth, it belongs also to geography. The cycle of time, 'that un-

measured part of eternity,' during which process produces upon structure the evolving series of topographic forms may well be claimed by the science which deals with the past history of the earth. The position of geologists is well stated by Sir Archibald Geikie in answer to the argument of Sir Clements Markham, President of the Royal Geographic Society, who had drawn the line between the two sciences at the dawn of history, excluding geology from the study of the changes of the earth's surface since that time. "Since geology may be regarded as the history of the earth, whatever is necessary for the elucidation of that history will be claimed by the geologists as part of their domain. Only as they understand what is going on at the present day can they understand what took place in past time. If you take away from the geologist the study of all that is taking place now, and maintain that this study is not geology but physical geography, he will answer, 'I do not care what you call it. I must be at liberty to investigate the processes which are operating now, in order that I may be able to explain what has happened in past time.'"

The dependence of geography on geology often has been compared with that of painting or sculpture upon anatomy. But the simile is far from complete, unless the former science is content to remain descriptive only, dealing with the delineation of external form. For the reliefs of the land must be studied and classified not primarily or chiefly as to form, but by structure and genesis. So soon as the description of the features of the earth's surface and their distribution yields to an inquiry into their origin, the line is passed which divides the -graphy from the -logy.

These questions are not perhaps without some practical outcome. The organization of these sciences, and the theoretic limits between them in the field of research in-

fluence our high-school courses sooner or later. It is in this somewhat remote field that the deciding factor may be found which shall at last settle the matter as to whether the physiognomy of the land be chiefly taught in secondary schools as geology or as geography.

Fortunately certain criticisms of each science have been laid by recent educational progress. In view of our present textbooks, physical geography can no longer be called 'hash' nor can geology now be termed dry and dull. Neither of these earth sciences is dull except to the dullard. So large is the place of land forms in both the new physical geography and the new geology, that it is now a question of approach to a common content of knowledge.

Let me claim for geology the easier path of approach, the clearer and more natural method of presentation, the greater coherence and the vaster and more inspiring view.

The geological path is that of process. It studies the agents now in operation with the resulting structures and forms that are produced at each stage of the evolutionary cycle. It thus binds together cause and effect as closely as possible. It admits an inductive treatment based on the observation of common things. The geographical path is normally that of form. In many of our physical geographies this has been avoided and the geological approach frankly taken in its stead, this portion of the subject becoming an epitome of dynamic geology. It is perhaps owing to the personal equation that to me the method of classification by form seems somewhat miscellaneous and scrappy. It throws together, for example, phenomena as diverse genetically as the glacial plains of Iowa, the base plains of Russia, the lava fields of Oregon, the old lake floor of the Red River of the North, and the coastal plains of the Gulf. Supan is compelled by his method of arrange-

ment to take up the glacier under three of the five great divisions of his Physical Geography—under the atmosphere where the general description is given, under the Dynamics and under the Morphology of the Lands. There is no question of the value of such a classification to the advanced student. Is it as good for the high-school pupil as that of geology, which, in the case of the glacier, for example, draws from meteorology the climatic conditions, and from geography the description of its features, and then proceeds forthwith to treat of its work as a geological agent and of the land forms thus produced? It is perhaps because of the easier path and better method which geology offers that in the courses at Cornell University, N. Y., a year in it precedes the year offered in physical geography.

Geology also gives what a painter would term atmosphere to this common body of knowledge. It sets it in perspective. To an extent this is also done by physical geography, and I confess that I have been surprised to see how readily students of recent texts, such as Davis's, gain a realization of the time-element in the geographical cycle, though they have had no geological preparation. But these conceptions are enlarged and vivified by the detailed study of geologic time. It is well to know the geography of the Allegheny mountains, it is better still to know their morphogeny, but it is best of all to set the whole in geological perspective, to view their folding in the remote close of the Palæozoic, and their long waste during the Middle Age of geology to a plain whose gradual dissection after uplift and during subsequent cycles has sculptured these mountains to the forms we behold to-day.

It is also something to set to the credit of geology that it teaches the history of organic evolution. Perhaps we have not as yet learned to paint the panorama of creation so that its salient features are not

smothered in detail. But to know what the earth is we must know what the earth has been. The story of the planet and the life it has sustained is prerequisite to a complete understanding of the earth sciences and of the life sciences as well.

As an educational instrument geology has the advantage of concentration and homogeneity. If, like mathematics or physics, it lacks the warm human interest, the applications of geography to human life, yet its current is not shoaled by division into numerous channels. If either physical geography or geology must be omitted from our crowded high-school courses, let it not be geology, the more fundamental, the more coherent, the more educative of the two.

What then should be the place and sequence of the earth sciences in secondary programs? Can they be arranged so as to include the outlines of all, and yet without repetition? It seems to me that certain changes are desirable to secure this end. I should like to see nature study so enlarged in the lower grades that the common physiographic processes early become familiar. There is an evident trend toward the enlargement of the physical geography with which our advanced geographies are now introduced. To me this seems the proper place for the study, but while the treatment of all essential forms and processes which bear directly on the life and work of man may be expanded, all matter irrelevant to this should here be omitted. I should like to see the areal and descriptive geography which follows so enlarged that it will take in the American high-school the place it holds in the German *Realschulen* and *Gymnasia*. Each geographic unit, each region of our country, each national domain may then be treated thoroughly in all departments of the science. With the physical environment everywhere made basal, we need not fear to give anthropic geography the largest pos-

sible place. It may be that much might be brought in which a strict definition of geography would exclude. But with due selection of material, with grasp of principles, with historic perspective, and especially with a thorough knowledge of physiographic controls, the wise teacher of geography can afford to take as his motto, I consider nothing alien to myself that relates to man. The extension of anthropic geography, however, cannot be brought about by discussion, or criticism, or the writing of text-books. It must come in precisely the same way as has the extension of physical geography—by scientific research. It awaits the masters who will some time do for the sciences relating to man what geology is doing for the science of land forms.

The proper place, then, for physical geography is a place preliminary to the areal geography which applies its principles and consequences to special regions. To review it later as a separate study would then seem unnecessary. Instead, let the course in the earth sciences be concluded by meteorology and geology. The earth sciences may thus be so closely articulated as to form the vertebral column of secondary scientific instruction. So close is their touch with human life, so thorough and comprehensive is their discipline, so simple, so natural, so rational, and so real is their culture, that their extension only awaits their connection into one continuous line of study.

WILLIAM HARMON NORTON.

CORNELL COLLEGE, IOWA.

PROFESSOR FRAAS ON THE AQUEOUS VS. AEOLIAN DEPOSITION OF THE WHITE RIVER OLIGOCENE OF S. DAKOTA.

A SPECIAL expedition of the United States Geological Survey into the Bad Lands of South Dakota was led by N. H. Darton, of the Survey, assisted by J. B.

Hatcher, of the Carnegie Museum; with the party was also Professor Eberhard Fraas, of Stuttgart. The object of the expedition was to secure exact geological data for the monograph 'The Titanotheres,' now in preparation by Professor Osborn. The matters of chief importance were: first, to determine the mode of deposition of these beds in view of the arguments recently brought forward by Matthew, Davis and others that they were æolian rather than aqueous in origin; second, to determine the exact stratigraphical levels upon which the different types of skulls and skeletons have been found, verifying and extending the very careful records made by Mr. Hatcher between 1886 and 1888 while collecting for the United States Geological Survey, under Professor Marsh.

Mr. Darton will prepare the formal report of the geological results of this expedition, including a map showing the extent and exact thickness of the beds in different portions of this region. In the meantime it is interesting to learn the opinions of a highly trained European geologist, Professor Fraas, upon the nature of these beds, expressed in an informal letter to Professor Osborn:

"I take this opportunity to briefly present my opinion on the origin of the Oligocene of the Bad Lands. So far as I have been able to observe the beds during the past eight days, one can by no means speak of their structure as æolian in the ordinary sense of the word. It is quite possible that wind-transport may have taken some part in their formation, but the strata themselves appear to me to have been chiefly laid down under water. We ought, I think, to take into consideration the following series of different petrographical and structural conditions:

"(1) The *Titanotherium Beds*, which constitute the base of the Oligocene, I take to be the deposit of a slowly flowing river, which

emptied in the broad delta upon the level stretches of the Ft. Pierre [Middle Cretaceous]. This view is supported by the occurrence of large boulders of ground-conglomerate at the base of the *Titanotherium Beds*, as well as by the frequent embedding of sand and gravel in the clays and marls. The current was manifestly very gentle and laid down a continuous substratum, resulting in cross-bedding in the sands and gravels. Against the dune-structure (æolian) testify the widespread layers of sand banks, often very thin, the heavy gravel and the fine lamination of the clays. The current was directed from west to east, and corresponding to this the thickness of the gravel and sand layers diminishes as we pass eastwards. (2) It is very difficult to determine the origin of the overlying *Oreodon Beds* [Middle Oligocene, 560 feet in thickness]. We must take the following facts into consideration: (a) The entire material has undergone a strong metamorphosis; the sandy, non-calcareous clays were formerly marls rich in calcareous matter, the concretionary structure of the harder banks and the texture of the material giving positive evidence on this point. (b) Certain layers were very rich in gypsum and barite; both minerals are now represented only in pseudomorphs of chalcedony, formed out of gypsum and barite. Probably there was united with the tendency to gypsum formation, a similar tendency to rock-salt formation, but I have found no evidence of this. (c) The structure of the layers: In the *Lower Oreodon Beds* concretions are abundant, which originally were composed of clays rich in calcareous matter. (This is the principal layer of *Testudo* and of the mammals.) Here are also thin banks of clear limestone, now strongly silicified; land and fresh water snails are found here (*Helix* and *Limnæa*); sand layers are not found here. The very massive *Middle Oreodon Beds* are splendidly laminated and

horizontally banded; that is, the colors change regularly from clear to dark. At times, in the darker portions are observed harder layers of limestone rich in clay. In the lowest layers of these middle beds we find the greatest abundance of gypsum and pseudomorphs. A layer of compressed smooth lenses of sandstone frequently appears (*Metamynodon* and *Protoceras* sandstone). Where the lenses are thin and smooth the lamination is even, where the layers are thicker, with coarser material, we observe cross-bedding. The *Uppermost Beds* of the White River Oligocene are altogether different. They are composed of very uniform material (often of volcanic ashes according to Dr. Darton), containing numerous nodules and round concretions; there are also large concretions, with the turtles again abundant, in fact, arranged quite differently from the Lower and Middle Beds. This sedimentation is manifestly of æolian character.

"When we put together all these observations to form a conclusion as to the structure of these beds we come to the following result: At the beginning [of the Oligocene] a broad, slowly flowing stream spread out towards the east and formed a broad, widespread and uniform delta landscape (*Titanotherium* Beds); this even, swampy land was dry during the dry seasons, but was flooded in every high-water period; besides the water the wind frequently took part in the transport of the dust and materials. The concretions are structures of the percolating waters (Lower Oreodon Beds, numerous land mammals). Now followed a long period in which this region was flooded by a shallow rather than deep lake. The inflow of water did not exceed the evaporation, and so through the varying concentration there was a precipitation of the dissolved materials which gave rise to the banded layers. In the same manner the gypsum

and barite in these layers is explained. Stronger currents poured in sand, which accumulated in low elevations (Middle Oreodon Beds). At last there came a widespread æolian condition in the form of loess, which spread out upon the gradually retreating or evaporated levels of the lake."

CHARLES ANTHONY SCHOTT.

WITH the death of Charles Anthony Schott, Assistant, United States Coast and Geodetic Survey, closes a most useful life, led by a remarkable man.

He was born at Mannheim, Baden, Germany, August 7, 1826, and began his studies very early, learning to read before reaching four years of age, and it is stated that his work began as a small boy. He graduated from the Polytechnic School at Karlsruhe with the degree of C.E. in 1847.

He came to the United States in 1848 and entered the United States Coast Survey, thus beginning his life of enthusiastic work in the advancement of science by the solution of the problems which confronted this organization created to obtain accurate charts of the extension coasts of the United States. He was immediately attached to the Computing Division in the office of the Survey where he remained until October, 1849, when he was assigned to the schooner *J. Y. Mason* and steamer *Walker* as hydrographic draftsman. In July, 1850, he returned to the Computing Division and on July 1, 1852, he was regularly appointed to the position of computer. From time to time he acted as chief of the Computing Division in the absence of the regular Chief and in 1855 was permanently placed in charge of this most important Division. In 1856 he was advanced to the grade of assistant, the highest in the survey after the superintendent.

The ability, zeal, indefatigable industry and vast mental resource so eminently

shown throughout his career, was thus recognized by Superintendent A. D. Bache at an early day. This assignment was most fortunate for the interest of science in general and particularly so for the advancement of the work undertaken by the Survey. In the Computing Division the fundamental data obtained in the field is digested and discussed for publication and this data, after passing through the Division, furnishes the foundation upon which the work of the Survey is built up. A wonderful opportunity was thus offered to a man capable of distinguishing himself, and this opportunity was seized by Mr. Schott and utilized to the fullest extent. The results of his painstaking labor are shown in the numerous publications bearing his name in the annual reports of the Superintendent and in scientific journals.

Mr. Schott's regular duties in the office were interrupted from time to time by assignments to special duty in the field. As early as 1855 the records show that he was in charge of the magnetic work of the survey and in 1863, during the time of the national peril, he was engaged in surveying the defences of Washington. In 1869 he took a party to Illinois to observe the total eclipse of the sun and in 1870 went to Catania, Sicily, as a member of the Superintendent's party to observe an eclipse of the sun. At various times during the absence of the assistant in charge of the Survey Office, he acted in his place.

Mr. Schott continued in charge of the Computing Division until December 31, 1899, and on January 1, 1900, was relieved of this duty and assigned to the discussion of the arc measurements in the United States resulting from the extension triangulation already executed by the different organizations engaged in survey work. All the available triangulation of a sufficient degree of accuracy is utilized in these discussions. 'The Transcontinental Triangu-

lation and American Arc of the Parallel,' has already appeared as Coast and Geodetic Survey Special Publications No. 4, and 'The Eastern Oblique Arc of the United States' is now ready for the printer. The discussion of an oblique arc in California was far advanced before Mr. Schott's health failed and will bear the mark of his genius when it finally appears in print.

It is impracticable to give a *résumé* of Mr. Schott's work in the survey at this time and reference can only be made to the 'Annual Reports' of the survey covering the years of his services for the innumerable results of his labor.

The following extract from SCIENCE of January 12, 1900, is a fitting tribute to Mr. Schott's work as Chief of the Computing Division.

With the close of the year, assistant Charles A. Schott, who for nearly fifty years has been the distinguished and energetic chief of the Computing Division of the Coast and Geodetic Survey, retired from that important position in order to devote his whole time to special scientific work.

Under Mr. Schott's careful supervision and training has developed a corps of skilled computers equalled by no other scientific bureau. To his labors, perhaps more than to any other one man's, is due the high scientific character of the results which the Survey has given to the world. The completion last year of the great arc, begun over a quarter of a century ago, marks an epoch in the history of the Division, and the beginning of the triangulation on the 98th meridian would seem to be a fitting occasion for relieving Mr. Schott of the burden he has borne for so many years.

His official career has been coincident with the development of the Survey, and his untiring zeal and fidelity have done much to bring about its present standard.

In 1898 Mr. Schott attended the 'International Conference on Terrestrial Magnetism' held in Bristol, England, as the representative of the United States Coast and Geodetic Survey.

He took part in the discussion, and his proposal that a permanent magnetic observatory should be maintained for a series of

years in the Hawaiian Islands was received with acclamation.

Later in the year the French Academy of Sciences awarded him the Wilde Prize on account of his researches and publications in the field of terrestrial magnetism. This prize was founded by Henry Wilde, an English scientist who gave the French Academy of Sciences a sum of money, the income from which forms a prize described as follows, in the *Comptes Rendus Académie des Sciences*, France, No. 126, p. 144: "This prize will be awarded each year, beginning with 1898, by the Academy of Sciences, without regard to nationality, to the person whose discoveries or publications under astronomy, physics, chemistry, mineralogy, geology, or experimental mechanics, shall be judged by the Academy most worthy of reward, whether that discovery or publication was made in the same year or in some other year before or after the foundation of the prize."

In accordance with the deed of gift this prize was awarded for the first time in 1898, and Mr. Schott received it in due form through the Department of State and from the hands of the President. The following extracts are of interest from their bearing on this memorable incident:

Extract from *Comptes Rendus Académie des Sciences*, France, No. 127, p. 1097.

The Henry Wilde Prize.

Committee M. M. Sarrau, J. Bertrand, Berthelot, Michel Lévy; Mascart, Secretary.

At the session of July 12, 1897, M. H. Wilde presented to the Academy of Sciences, under the name of Magnetarium, a remarkable apparatus now in the Museum of Arts and Industries which permits of the reproduction on the surface of a sphere, with marvelous accuracy, the distribution of the elements of terrestrial magnetism and their secular variations.

The Commission has decided that, in order to render homage to the inventor of that great work, it is desirable to make the first award of the prize founded by M. Henri Wilde to researches relating to terrestrial magnetism.

Since 1869, the 'Annual Reports' of the United

States Coast and Geodetic Survey contain, almost every year, memoirs of the greatest interest by Mr. Charles A. Schott, on the determination of the magnetic elements at the permanent observatories of the United States, and at a great number of temporary stations. The extensive work accomplished by Mr. Schott can not be stated in a brief *résumé*. * * * One finds in his memoirs an explanation of the methods employed in the observatories and in the course of journeys; a comprehensive view of the results obtained since the first observations on the American continent and a certain number of foreign stations; an exhaustive discussion of the readings made of the apparent variations in certain observatories with the study of the diurnal change for the different months of the year, of the lunar influence and perturbations; and lastly a considerable number of personal observations in many isolated stations; this work permits the establishment of the lines of magnetic distribution in North America. The whole of this work furnishes one of the most important contributions in the history of terrestrial magnetism and the Commission is unanimous in awarding the Henry Wilde prize to Mr. Charles A. Schott.

From the *Public Press*, February 4, 1899.

"An interesting episode took place at the White House this afternoon at 4 o'clock, when, in the presence of the Secretary of the Treasury, the Superintendent of the Coast and Geodetic Survey, and twenty-five of Mr. Schott's colleagues, the President presented to Mr. Charles A. Schott the prize recently conferred upon him by the Academy of France. This prize of 4,000 francs was founded by an Englishman about two years ago, and was to be conferred by the Academy on any person, in any country, whose discoveries in science, or whose original investigations had been most valuable and had contributed most to human knowledge, in the direction of mathematics, mechanics, physics, chemistry or geology. The Academy, after due consideration, conferred the prize on Mr. Schott for his investigations into the laws of terrestrial magnetism.

"After the officers of the survey had been duly introduced to the President and to the Secretary, by the Superintendent of the Coast and Geodetic Survey, the official papers containing the award were placed by

the President in Mr. Schott's hands, and in doing so he alluded in the following words to the international character of the prize, and to the catholicity of scientific work :

"I have great pleasure in placing in your hands the formal papers which convey to you the 'Wilde Prize.' This prize, founded by an Englishman who has a deep interest in science, has been adjudged to you by a committee of eminent men chosen from the most famous organized body of scientists in the world—the Institute of France. According to the terms accepted by the Institute of France in founding the prize, it was to be given to the person from any nation whose discoveries in physics or mathematics, mechanics, chemistry or geology are most valuable, or whose original researches in these branches of science have been most successful. The prize has been awarded to you for researches in the important field of terrestrial magnetism.

"I congratulate you and American science, and in particular the Coast and Geodetic Survey (the scientific organization of which you are a member), that you have been chosen from all the world as the most worthy to receive this great honor.

"It is especially pleasant in this age when international relations are of high importance, when the methods of modern applied science have brought all nations, however geographically remote, into close contact, to know that in science there are no international boundaries ; and no pleasanter proof of this catholic spirit could well be given than this fine prize—one of the highest that can be conferred by a scientific body—founded by an Englishman, has been awarded by a Frenchman and won by an American."

Mr. Schott's ability and attainments have been widely recognized by learned bodies and scientific societies as shown by his election to membership on the following dates :

1871. Philosophical Society of Washington, D. C. (Founder).

1872. National Academy of Sciences.

1874. American Association for Advancement of Science (Fellow).

1896. Sociedad Científico Antonio Alzate, Mexico.

1898. Washington Academy of Sciences (Founder).
Accademia Gioconia di Scienze Naturali, in Catania, Sicily.

The long list of publications bearing Mr. Schott's name bear testimony to his untiring industry and his devotion to the interest

of the service, which he honored as a member and to the advancement of human knowledge.

ISAAC WINSTON.

GEORGE K. LAWTON.

IN the unexpected death of George K. Lawton, of the U. S. Naval Observatory, a young astronomer of great promise has passed away. The loss to American astronomy can be appreciated as yet only by those who had the good fortune to know him intimately. He was born October 20, 1873, and died at Washington, July 25, 1901, after a brief illness of twelve days, of typhoid fever; and was thus less than twenty-eight years of age. Under the guidance of his father, Professor U. W. Lawton, of Jackson, Michigan, he had enjoyed from childhood excellent educational advantages, and in 1895 graduated in classics at the University of Michigan, where he also pursued advanced astronomical studies under Professor Asaph Hall, Jr., at the Detroit Observatory. He then spent a year in post-graduate study at the University of Chicago, where the writer had the honor to be one of his teachers. He showed distinguished abilities in the study of celestial mechanics and of higher mathematics. He was afterwards attached to the Observatory of Yale University for a short time, occupied mainly with work on meteors; and then came to the Naval Observatory as one of the regular computers. In 1897 he took the degree of M.A. at the University of Michigan. While attached to this Observatory he participated in all the transit circle observations of the past five years, much of which has recently appeared in the *Publications of the U. S. Naval Observatory*, Vol. I., new series. Last year he bore an important part in the observations of the total eclipse of the sun, at Pinehurst, North Carolina. More recently he took a leading part in the reductions and revision of the Eros observations of this Ob-

servatory, and has been occupied partly with equatorial work. Only a month ago he was assigned to the 26-inch equatorial, and had entered upon researches of great promise.

On account of his extreme modesty, and the arreages of our publications, his scientific reputation at the time of his death was in no way commensurate with his merits. Yet he was already a member of the American Association for the Advancement of Science, and last year participated in the meeting of the Astronomical and Astrophysical Society of America.

His mind was developed in admirable symmetry and harmony, and his scholarship was almost as good in Latin and Greek and general literature as in modern science. He had that happy faculty of cool, quiet judgment, combined with good nature, which made him adequate to any occasion. Besides possessing scientific and literary talents of a high order, he was of a very high-minded and noble disposition, universally beloved by his associates. Unseen by men he continually did many acts of benevolence, and bestowed gracious remembrances which add to the charm of life and make us realize that the high types written of long ago have not wholly passed away. He was an active member of St. Thomas's Church in this city and of the Brotherhood of St. Andrew and of the Alumni Association of the University of Michigan. During his residence here of five years, he became fairly well known in the city, more by the reputation of his high character than by any very extensive mingling with the people. When the writer had to send the saddest of messages to his grief-stricken family, the telegraph operator who knew him only by reputation was nearly overcome, and said, 'That good man is not long for this world.' In all my experience I have never met quite so modest, so noble, and so lovely a character.

The sudden death of Mr. Lawton, almost at the very beginning of what promised to be a brilliant career, has cast a deep gloom over the entire Observatory. He was indeed the noblest of the noble, and his place can never be filled.

T. J. J. SEE.

WASHINGTON, D. C.,
July 27, 1901.

SCIENTIFIC BOOKS.

Astronomischer Jahresbericht. Mit Unterstützung der Astronomischen Gesellschaft herausgegeben von WALTER F. WISLICENUS. II. Band, enthaltend die Litteratur des Jahres 1900. Berlin, Georg Reimer. 8vo. Pp. xxv + 631. Price, M. 19.

This series of annual volumes, whose somewhat cumbrous title is officially abbreviated to the symbol AJB, owes its inception to its editor, Professor Wislicenus, who in September, 1898, submitted to the Astronomische Gesellschaft a well-elaborated plan for a year-book that should serve both as an annual summary of current astronomical literature and as a bibliography sufficiently complete for the use of students and other investigators. The proposal was favorably received by the Society, which not only gave its official sanction and pecuniary support to the undertaking, but also appointed a committee, consisting of Professors Seeliger, Bruns and Müller, to confer with the editor as to the contents of the future volumes and the manner of their arrangement.

The plans thus agreed upon and incorporated in the first volume, that for 1899, have been closely followed in principle in the present volume, although with greater completeness of detail, as is shown by the addition of nearly a hundred pages to its size. That so few modifications should be found necessary in the second year of publication is sufficient indication that future volumes may be expected to appear in substantially the same form and character as the two already issued.

Premising that in its entire scope the AJB is to be purely expository and not critical in its summaries, the editor indicates it to be his purpose to treat with all possible completeness the purely scientific and technical literature of

theoretical and practical astronomy and astrophysics, together with, in smaller measure, that of the higher geodesy. Mathematical and physical papers are to be included in the scope of the work only in so far as they have a direct bearing upon one or more of the topics above named, while the literature of meteorology and geophysics is wholly set aside as foreign matter. With regard to the popular literature of astronomy the editor sagely remarks that while for the most part it is of small scientific value, the bibliographic purposes to be served by the AJB call for a fairly complete summary of this literature, including even 'crank' papers, all of which are to be presented in a purely objective manner without comment or criticism, in order that 'the reader may be given an opportunity to form for himself a provisional judgment of the article abstracted.'

In respect of arrangement the subject matter of the AJB is divided into four principal categories, entitled: General and Historical; Astronomy; Astrophysics; Geodesy and Nautical Astronomy. These are appropriately subdivided, while a brief supplement, of only four pages, contains the miscellaneous matter that the editor has not found expedient to classify under any of the preceding titles. Noteworthy in this connection is the following criterion by which papers upon astronomy and astrophysics are assigned to their respective classes: Problems involving only space and time relations of the celestial bodies constitute astronomy; problems of the celestial bodies involving other elements than the above are to be classified under astrophysics. As the editor himself notes, this rule of classification assigns to astrophysics the visual estimation of stellar magnitudes even though made in connection with meridian circle work, while the spectroscopic determination of motions in the line of sight is assigned to astronomy. This reversal of the popular classification seems to the reviewer sound in principle and well adapted to become the general practice.

Some conception of the amount of labor involved in the preparation of the abstracts here presented may be formed from the list of nearly 200 periodical publications, including publications of observatories, which have been so

largely drawn upon for abstracts that the editor has found it convenient to assign to their names abbreviations for permanent use. To this material there must be added books independently published and periodicals rarely cited. As a type of the latter and a source not usually included under astronomical literature we note *The Congressional Record* and several of the monthly magazines commonly sold at news-stands and on railway trains. The bulk of material to be digested is beyond the competence of any one man, and the editor has therefore associated with himself seven foreign colleagues who are charged with the supervision of special portions of the work, in large part pertaining to the literature of their own countries. The American representative is Dr. H. S. Davis, who has elsewhere requested that papers of American origin which are germane to purposes of the AJB and are published in such manner as not to be readily accessible through the ordinary channels may be sent to him for review at the address, International Latitude Station, Gaithersburg, Md.

In respect of scope and plan the AJB is beyond question a welcome addition to the literature of astronomy, but one whose actual value must be tested by the experience of many persons in using it as a work of reference. A subject index is hardly to be expected in a volume of this character and no attempt at furnishing one is made, but the well-classified Table of Contents and an extended Index of Names, including institutions as well as persons, will be found of service by whoever uses the volume for serious purposes. A feature of special value to computers of orbits is the tabular Index of Observations of Comets and Minor Planets occupying no less than 34 pages of the volume, which cannot fail to save much time that has hitherto been spent in the endeavor to make complete the computer's list of observations of the object with which he is concerned.

So far as may be judged from its apparatus of classification, cross references, indexes, etc., there is no reason apparent to the reviewer why the AJB should not stand the test of time and use, and in those parts of its subject matter with which the writer is specially conversant he has found the work eminently complete,

satisfactory, and convenient to use. It is certainly worthy of a cordial reception by all who are interested in the progress of astronomy, and the editor should receive that cooperation which he solicits for future volumes by bringing to his notice all published articles which come properly within the scope of the work.

GEORGE C. COMSTOCK.

Les plantes tinctoriales et leurs principes colorants. By V. THOMAS (Chef des travaux de chimie appliquée à la Faculté des Sciences de Paris). Une publication de l'Encyclopédie Scientifique des Aide-Mémoire. Publiée par Gauthier-Villars, Paris, sous la direction de M. Léauté (Membre de l'Institut). Pp. 196. The author divides the study of tinctorial plants as follows:

1. The coloring matters themselves.
2. The glucosides; the form of combination in which coloring matters exist most frequently in plants.
3. The ferments capable of decomposing these glucosides into sugars and the coloring matter.
4. The tinctorial plants themselves, from the point of view of the coloring principles which they contain.

In a previous volume in this same series, 'Matières colorantes naturelles,' the author has already discussed those natural coloring principles which belong to the keton, xanthou, and pheno- γ -pyron groups.

Part I. (pp. 7-142), therefore, of the present volume, treats of the remaining important plant-coloring principles, arranged in the following chapters:

Chapter 1. Colors of the anthraquinon group; alizarin, xanthopurpurin, munjistin, rubiadin, chrysazin and chrysammic acid, purpurin, pseudopurpurin, alkannin, morindon and ventilagin.

Chapter 2. Brasilin and brasilein; including isobrasilein, and derivatives of brasilin and dehydrobrasilin, together with a review of the work done by Perkin, Kostanecki, Herzig and others, to establish the constitutional formula of brasilin.

Chapter 3. Hæmatoxylin and hæmatein; also isohæmatein and derivatives of dehydrohæmatoxylin.

Chapter 4. Miscellaneous coloring matters, as follows: cyanomaclurin, genistein, gossypetin, rottlerin, flemingin, orcein, santalin, carthamin, lokanic acid, crocetin, curcurmin, lapachol, lomatiol, and bixin.

A brief history of every color is given, then the most interesting and important methods for obtaining it, together with its most characteristic physical and chemical properties and a discussion of its structural formula. The tinctorial properties are dealt with briefly, tables being freely employed to show change of color with change of mordant, effect of various substituting groups upon the color, comparison of shades obtained from the natural colors with those obtained from the same colors prepared synthetically, etc.

Part II. (pp. 143-180), Glucosides. Includes the consideration of the following: ruberythric acid, glucosides of quercetin and its derivatives, apiin, vitexin, morindin, datiscin, crocin, fustin, lokaonic acid.

Then follows a list of the principal tinctorial plants, arranged alphabetically according to their botanical names, and showing the coloring matters which they contain; also an alphabetical table of the coloring principles themselves, giving their melting points and the references to the text where the same are described in detail.

The references to the literature form a commendable feature of the work, thus affording ready access to the original articles.

Upon the whole, the book gives a very good digest of the work in this field and should prove of value to the chemist.

MARSTON TAYLOR BOGERT.

Mosquitoes: How they live; how they carry disease; how they are classified; how they may be destroyed. By L. O. HOWARD, PH.D. New York, McClure, Phillips & Co. 1901.

One of the triumphs of the combined labors of modern biologists and students of medicine is the discovery of the animal parasite of malaria and of the fact that the parasite of yellow fever, whether it be an animal or a bacterium, is, like the malarial one, transmitted by the mosquito.

Already has the number of workers become numerous, and the literature extensive, while the probability that man will be able to cope with these two dreadful scourges of his race, and at least greatly curtail their ravages is very great. We need, then, the fullest knowledge of the structure, habits and transformation of mosquitoes, particularly of the genus *Anopheles*, the bearer and transmitter of these diseases, and of the nature and life-history of the parasitic organisms which cause these diseases.

As regards the mosquito Dr. Howard has given us a capital book. It is both popular and entertaining, and yet truly careful and scientific in its scope and treatment. The physician cannot do without it. As for the entomologist, we venture to say that nowhere will he find a more fresh and up-to-date account of the mosquito. He will look elsewhere in vain for the many details which have recently been discovered by Dr. Howard and other American and European observers.

The figures of the different forms, particularly of the malaria-bearer, *Anopheles*, are new and very carefully drawn; the larval and pupal forms are rendered with great apparent accuracy. Of the greatest interest is the new matter relating to the subject of parthenogenesis among mosquitoes, the food and mode of getting it by the mosquito larvæ, and the food of the adult. The latter subject is treated with a fullness of new details which is most satisfactory. It is some comfort to learn that mankind does not form the sole pasturage of the female mosquitoes, but that they will sting terrapins and puncture the head of young fish, besides sucking the blood of birds. We had previously only known of Dr. Hagen's observation of a mosquito feeding on the chrysalis of a butterfly. We also are told that mosquitoes are plant-feeders, apparently piercing the flowers of the wild cherry, and feeding readily on fruit, especially bananas; and that the male mosquito is exclusively vegetarian in its diet.

The life-history and oecology of the malarial mosquito, *Anopheles*, is very well done. First we have a full and well-illustrated account of the common *Culex pungens*, with which may be compared, thanks to the abundant and well-

drawn figures, the life-history and structure of the pestiferous *Anopheles*. The egg, the larva of different ages, with anatomical details, the pupa, as well as the fly, male and female, are represented, and there is added an account of the North American species. The food of the larva seems to be the spores of algæ, and in Sierra Leone a unicellular protococcus. How *Anopheles* bites and its length of life are also described.

The chapter on mosquitoes and yellow fever; mosquitoes and filariasis; the account of the mosquito (*Stegomyia fasciata*) which conveys the infection, with figures of the winged insect, its scales, larva and pupa, are of much value. It is refreshing to read of the immense inroads made by fishes upon the larvæ, by dragon flies and by birds, six hundred mosquitoes having been found in the crop of a single night hawk, but it will afford the reader still more satisfaction to know how easily these dangerous pests can be exterminated by the use of so simple a remedy as petroleum. On the last subject the book is strong.

A. S. PACKARD.

SOCIETIES AND ACADEMIES.

THE AMERICAN CHEMICAL SOCIETY.

THE following is a list of the papers thus far offered for the joint meeting of the American Chemical Society and Section C of the A. A. S. to be held in Denver during the last week in August:

1. 'Solid Hydrocarbons of the Series C_nH_{2n+2} and Liquid Hydrocarbons of the Series C_2H_{2n} in the Less Volatile Portions of Pennsylvania Petroleum' (by title): CHARLES F. MABERY.
2. 'Specific Heats and Heats of Volatilization of Hydrocarbons of the Series C_nH_{2n+2} , C_nH_{2n} , and C_nH_{2n-4} , in Pennsylvania, Texas, California and Japanese Petroleums' (by title): CHARLES F. MABERY.
3. 'Composition of Commercial Paraffine, Vaseline, and Solid and Pasty Mixtures of Hydrocarbons, collected in Oil Wells' (by title): CHARLES F. MABERY.
4. 'Composition and Properties of Asphalts from Different Petroleums' (by title): CHARLES F. MABERY.
5. 'Analysis of a Few Southwestern Coals' (10 min.): HERMAN POOLE.

6. 'Summary of Analyses of the Massive Rocks of Boulder County, Colorado': CHARLES S. PALMER.
7. 'The Indirect Weighing of Quantitative Precipitates' (by title): R. W. THATCHER.
8. 'An Automatic Filter Washer' (20 min.): J. M. PICKEL.
9. 'Some New Laboratory Furniture': PROF. LACHMAN.
10. 'Recent Developments in Physical Chemistry': WILDER D. BANCROFT.
11. 'Proper Methods of Teaching Physical Chemistry': WILDER D. BANCROFT.
12. 'Some Points on the Teaching of Chemistry': CHARLES S. PALMER.
13. 'What Constitutes Instruction in Technical Chemistry' (15 min.): EDWARD HART.
14. 'Discussion of Methods used in Different Universities for Giving Instruction to Large Classes in Elementary Laboratory Work': WM. MCPHERSON.
15. 'The Teaching of Chemistry in Secondary Schools': FREDUS N. PETERS.
16. 'Chemistry in Manual-Training High-Schools' (15 min.): ARMAND R. MILLER.
17. 'The Determination of Sulphur in Iron and Steel' (15 min.): WM. A. NOYES and L. LESLIE HELMER.
18. 'Copper as allied to the Sciences, and its Commercial Value' (7 min.): W. S. EBERMAN.
19. 'On the Decomposition of Sodium Nitrate by Sulphuric Acid'—Part III.: C. W. VOLNEY.
20. 'Quantitative Determination of Hydrofluoric Acid' (3 min.): W. E. BURK.
21. 'Methods of Standardizing Acid Solutions' (15 min.): CYRIL G. HOPKINS.
22. 'The Sulphohalides of Lead' (10 min.): VICTOR LENHER.
23. 'Hydrochlorated Mercury and Cadmium Sulphates' (5 min.): CHARLES BASKERVILLE.
24. 'Evidences of the Probable Complexity of Thorium' (10 min.): CHARLES BASKERVILLE.
25. 'Constitution of Alloys': J. A. MATHEWS.
26. 'Cryoscopic Experiments with Sulphur' (12 min.): ALEXANDER SMITH.
27. 'The Electrolytic Method applied to Uranium' (15 min.): LILY GAVIT KOLLOCK and EDGAR F. SMITH.
28. 'The Electrolytic Determination of Molybdenum' (15 min.): LILY GAVIT KOLLOCK and EDGAR F. SMITH.
29. 'The Precipitation and Separation of Silver in the Electrolytic Way' (15 min.): W. H. FULWEILER and EDGAR F. SMITH.
30. 'The Electrolytic Separation of Mercury from Copper': C. ROSCOE SHAW and EDGAR F. SMITH.
31. 'The Identification and Properties of Alpha and Beta-Eucaine' (15 min.): CHARLES L. PARSONS.
32. 'A Comparison of the Solubility of Acetylene and Ethylene' (15 min.): SAMUEL AUCHMUTY TUCKER and HERBERT R. MOODY.
33. 'On the Estimation of Urea in Urine' (10 min.): JOHN H. LONG.
34. 'On the Determination of Formaldehyde' (15 min.): A. G. CRAIG.
35. 'A Modification of the Sulphuric Acid Test for Formaldehyde in Milk' (5 min.): A. GUSTAV LUEBERT.
36. 'The Synthesis of Ketodihydroquinazolins from Anthranilic Acid' (by title): AUGUST HENRY GOTTHELF.
37. 'Researches on Nitrocellulose' (by title): G. LUNGE.
38. 'The Reduction in an Alkaline Solution of 2.4.5. Trimethylbenzaldazine' (20 min.): E. P. HARDING.
39. 'Preparation of 2.5. Dimethylbenzaldehyde; the Estimation and Preparation of some of its Derivatives': EVERHART P. HARDING and LILIAN COHEN.
40. 'A Study of the Chemical Composition of Meat Extracts' (10 min.): H. S. GRINDLEY.
41. 'Chemical Changes Produced by the Action of Bacteria' (10 min.): H. S. GRINDLEY.
42. 'Derivatives of Diphenyl Ether' (25 min.): A. N. COOK.
43. 'The Constitution of Azoxybenzine': PROFESSOR LACHMAN.
44. 'The Action of Zinc Ethyl on Nitro and Nitroso Compounds—a Reply to I. Bewad': PROFESSOR LACHMAN.
45. 'Recent Developments in Organic Chemistry': PROFESSOR LACHMAN.

DISCUSSION AND CORRESPONDENCE.

PSEUDOSCOPIC VISION.

THE experiment described by Professor Wood (SCIENCE, August 2, p. 185) is always striking and attractive when performed for the first time, and he is probably only one of many who have attained this binocular result independently. I did so twenty years ago; and my attention was called to such phenomena more than thirty years ago by the late Professor Joseph LeConte.

But the use of the unaided eyes for the at-

tainment of either orthoscopic or pseudoscopic binocular effects was described by Sir David Brewster as long ago as 1844 (*Edinburg Transactions*, 1844, Vol. XV., Part III., p. 360), and quite fully discussed in his book on 'The Stereoscope,' published in 1856. On the optical illusions due to cross vision Brewster based his geometric theory of binocular vision, which was fully elaborated in his book. In 1855 and 1856 the same theory was applied by Professor W. B. Rogers, founder of the Massachusetts Institute of Technology, in a series of articles published in the *American Journal of Science*. It has since been applied by various writers. The incorrectness of this theory is conclusively proved by the possibility of binocular vision by optic divergence (*Am. Jour. Science*, Nov. and Dec., 1881, March, April, May, Oct. and Nov., 1882).

Nevertheless, the subject is attractive, and the results attainable when the visual lines are made to cross at a high angle, such as 50° or 60° , suggest some interesting and perfectly legitimate geometric applications. But these experiments are somewhat trying to the muscles of the eyes.

W. LE CONTE STEVENS.

WASHINGTON AND LEE UNIVERSITY,

SHORTER ARTICLES.

ADAPTATION IN VISION.

APPARENTLY no one has noticed formally the bearing upon brain physiology of one of the commonest phenomena of vision. Within certain very wide limits the percept we have of any object does not change at all while we approach or recede from it. If, for instance, I look at a chair thirty feet off and then walk straight toward it, the appearance of the chair does not alter. Now the retinal elements excited are totally different according to the distance I am from the object. We have then a succession of different physiological processes in the retina with the final result in consciousness of a constant feeling. We naturally suppose that a continuance of the same feeling is due to a continuance of substantially the same physiological processes in the central nervous system. If this is true we can account for the

phenomenon mentioned only by supposing that all the differing successive processes in the end organ somehow get shunted into the same central process. This involves a practical infinitude of associative systems of the subtlest and most complex sort. For with each of the objects of which we thus have a constant perception in spite of varying retinal conditions, different sets of associations are needed corresponding to different views of the object. Moreover, totally new objects suffer like treatment. This latter fact almost tempts one to put faith in a mysterious mental construction on the basis of sense stimuli. Surely if the brain itself does the work of unifying these multitudes of series of retinal events into constant processes corresponding to our percepts, the complexity of its mechanism has never been fairly stated. This, I take it, is what we must believe. We must find in this commonest case of vision a notable example of the fact that our feelings do not parallel outside events or even the sensory processes aroused by them, but are the results of selected adaptations, adaptations in this case presupposing much more involved neural action than the common reflex-arc conception of the brain seems to permit.

EDWARD L. THORNDIKE.

TEACHERS COLLEGE, COLUMBIA UNIVERSITY.

THE INJURY OF FUNGICIDES TO PEACH FOLIAGE.

THE writer has devoted several seasons to an investigation of the injury produced by fungicides to peach foliage. A bulletin giving the results of this work is soon to appear from the Tennessee Agricultural Experiment Station. A preliminary report on this investigation may not be out of place here. Following are some of the points established or rendered probable:

1. Pure copper hydroxide, copper oxide, or even metallic copper spread on the leaves is injurious to the foliage of the peach, but without visible injury to that of either the apple or the grape.

2. A solution of copper sulphate 0.00005 normal (=0.000795 per cent.) proved fatal to water cultures of the apple, while grapes and peaches under like conditions, though evidently injured, soon recovered, and the peaches thus

treated on October 8 remained alive over winter.

3. Peach foliage protected from rain and dew, as in a greenhouse, sustains no externally visible injury from spraying with either Bordeaux mixture or copper hydroxide. Under normal orchard conditions the leaves sprayed with Bordeaux in a situation so as to be partially protected from falling rain or dew are the last to succumb to the injurious action of the copper.

4. The presence of deliquescent salts (as $\text{Ca}(\text{NO}_3)_2$ and CaCl_2) greatly accelerates the injurious action of copper hydrate on the foliage of the peach.

5. Peach seedlings growing in a saturated atmosphere are not injured by Bordeaux mixture and but slightly by pure copper hydrate.

6. Peach leaves growing in a saturated atmosphere possess a thinner and much more easily permeable cuticle than those growing in a dry or less moist atmosphere. Following is a summary of measurements of paraffine sections stained with chloriodide of zinc :

Peach leaves.	Thickness of cuticle of upper surface.
Orchard Knoxville.....	1.17 micromillimeters
Orchard California.....	1.21 " "
Seedling greenhouse.....	0.86 " "
Seedling in moist chamber.....	0.60 " "

7. The presence of a certain excess of lime accompanying the copper hydrate on peach foliage retards or possibly entirely prevents the injurious action of the latter. This holds true of lime applied either as the hydrate or at once as the carbonate. The sulphate of lime does not produce this effect.

The writer believes that the above results go far toward explaining the conflicting testimony of different investigators along this line in this country. So far as shown to date, no injury will result to peach foliage sprayed with ordinary Bordeaux mixture until a certain proportion of the lime carbonate is washed out by heavy dews or rain, when it at once begins to manifest itself. One would thus expect but little injury in an arid region like parts of California. On the other hand, an atmosphere containing abundant hygroscopic moisture, such as is to be found in Georgia and Florida, would supply conditions similar to those produced in

the moist chamber as stated above, and thus atone to a certain extent for the washing out of calcium carbonate caused by precipitated water.

The practical application of this principle is readily suggested. It may be possible to follow up a spraying with Bordeaux mixture with one or more of milk of lime and thus prevent the injury which would otherwise occur. Experiments carried out here this season thus far show this method to be a success. Whether it will remain so to the end of the season is yet to be determined. There are, of course, other questions to be taken into consideration, such as the practical application of the method in the commercial orchard, the effect of the lime on the fungicidal action of the copper, etc.

It is hoped in the forthcoming publication above mentioned to describe in detail the experiments above outlined, in addition to a number of others finished and now nearing completion, looking toward the physiological explanation of the results obtained.

SAMUEL M. BAIN.

UNIVERSITY OF TENNESSEE, KNOXVILLE.

CURRENT NOTES ON PHYSIOGRAPHY.

THE NORTHERN ADIRONDACKS.

A 'Preliminary Report on the Geology of Franklin County,' N.Y., by H. P. Cushing (18th Rep. State Geol., Albany, 1900, 73-128, 8 pl., colored outline map) describes the northern side of the Adirondack mountains and the drift-covered paleozoic plain at their base. The transition from one area to the other is rather abrupt, but the height of the mountains decreases with some regularity towards the plain, and branches of the plain enter valleys among the hills. An old baselevel is inferred from the systematic northward decrease of summit heights, although its horizon is admittedly not closely definable. The present valley system is explained as of later origin, the result of erosion following a slanting uplift. No dates are given in this connection, although it is said that 'the Adirondack region has been continuously above sea level since Lower Silurian times' (78), a statement that seems open to doubt. The step-like descent of the mountains toward Lake Champlain is explained 'by a

series of meridional faults with downthrow to the east,' and the depression occupied by the lake itself is said to be 'a fault valley.' It is not stated whether these faults, more or less worn, are yet so recent that they dominate the topography, or whether they are ancient faults produced while yet a heavy series of strata overlay the present surface, and only developed into existing topographic features by erosion long subsequent to faulting. Glacial erosion is regarded as having rounded off the northern slopes of many of the mountains, leaving the southern slopes of greater declivity; and a few cliff-walled cirques are ascribed to local glaciers. Lakes are very numerous and are as a rule referred to drift obstruction; 'there is yet no evidence that any of them occupy rock basins' (84). The rivers have all developed reaches ('still-waters' or 'levels') on drift, interrupted by rapids on ledges. The drift plain bordering the mountains is well occupied, while the mountains are largely a rugged wilderness.

SLATE MOUNTAINS OF THE MIDDLE RHINE.

THE report of an excursion conducted by Professors Rein and Philippson over the plateaus and valleys of the middle Rhine ('Wiss. Ausflug, Siebengebirges-Rhein-Eifel-Mosel,' 19-25 Sept., 1899; Verhandl. VII. Internat. Geogr. Kongresses, Berlin, 1900, 328-344) presents some interesting details concerning that attractive region, its physiographic features being described by Philippson. The lofty mountains of Carboniferous deformation were reduced, partly by subaerial denudation, partly by marine abrasion, to a low torso, afterwards broken into blocks which were irregularly elevated and depressed. The Rhine crossed the region along a depressed block, whose surface it modified, producing a broad trough, which now stands at altitudes of 300-350 m. The Mosel eroded a branch trough, whose altitude is now 350-400 m. Pauses in the uplift of the region to its existing position are indicated by terraces, of which the principal one, strewn with river waste, reaches heights of 200 m. It is in the floor of this terrace that the narrow gorges of the Rhine and Mosel are cut. Troughs, terraces and gorges are the work of Pliocene and later time. Frequent mention is made of the extended views

over the plateau in which the troughs and the deeper valleys have been cut, of the volcanic cones and maare that ornament it, and of the ridges of resistant quartzite that rise over it. Yet it is concluded that the plateau is not a peneplain and that its history is still to be made out. Truly it is not a peneplain, everywhere almost completely worn down and still lying undisturbed close to sea-level; but the description given of it strongly suggests that it is a somewhat unevenly uplifted peneplain, bearing some linear residual mountains on its back, and more or less dissected by its revived streams. For example, "The High Eifel is a broad, flat-arched dome, which descends southward as a gently inclined plain towards the valley of the Mosel; beyond the Mosel, the same surface is continued in the Hunsrück as a nearly horizontal plain, rising wall-like in the high quartzite ridges of the Hochwald" (p. 332). To exclude a region thus described from the class of uplifted and dissected peneplains makes one wonder what conception the author attaches to this category of forms. The report forms a very serviceable guide for a physiographic excursion over this district. It is in many ways more satisfactory than the more elaborate essays by Pollman on the Eifel and by F. Meyer on the Hunsrück (*Forsch. deut. Landes und Volkskunde*, VIII., 1894, 195-282; XI., 1899, 73-106), which unfortunately leave much to be desired in this respect.

PHYSIOGRAPHY OF ACADIA.

THE general progress of physiographic development that has been found applicable to the Appalachian belt within the United States by various observers is extended by Daly to the provinces of New Brunswick and Nova Scotia with the adjoining islands ('The Physiography of Acadia,' *Bull. Mus. Comp. Zool., Harvard Coll.*, XXXVIII., 1901, 73-104, 10 pl., map). The uplands of inner New Brunswick and the 'southern plateau' of Nova Scotia are regarded as areas of Cretaceous peneplanation, now uplifted and dissected; while central New Brunswick, together with certain areas now submerged in bays, represent lowlands etched out of weak rocks beneath the Cretaceous peneplain, and now partly drowned. The author

concludes that Acadian land forms may be described in terms of these two topographic facets, each a nearly perfect plain of denudation, interrupted by residual hills and incised valleys. Regarding the uplands of Nova Scotia, it is remarked that undue emphasis has been placed on the hills, "apparently with the mistaken notion that the true lover of nature cannot be especially interested in her land-forms when they are subdued. Yet the marvel of Nova Scotian scenery lies in its flatness." Although the region borders the sea, preference is expressed for a subaerial origin of the peneplains here described; marine erosion is given a relatively subordinate value in their preparation, however active it has become upon them since submergence has brought the sea in over the land.

PREGLACIAL DRAINAGE OF OHIO.

SEVERAL papers on 'The Preglacial Drainage of Ohio' by Tight, Bownocker, Todd and Fowke are published by the Ohio State Academy of Science (Special papers, No. 3, Dec., 1900, 75 pp., plates and maps). Tight describes some of the drainage changes along a part of southeastern Ohio, with special references to the preglacial and postglacial valleys that lie to the southwest of the trenched col by New Martinsville, from which the preglacial streams flowed opposite ways and through which the Ohio now connects basins that were formerly separate. A high-level and broad-floored ancient valley is traced through the hills southwest of Parkersburg; it is now trenched across by several deeper-cut valleys. The most novel point is presented by Fowke, regarding a former northward discharge through the Miami valley of the waters from several rivers (Licking, Kentucky, etc.) whose courses lie between ancient cols at Manchester and Madison, east and west of Cincinnati. The northward discharge is now blocked by drift; the cols are cut across by the Ohio, and the gathered rivers are discharged westward. This involves an impounding of many north-flowing rivers by the ice sheet and the production of a temporary lake, compared to which the reputed lake caused by the supposed ice dam at Cincinnati would have been a comparatively small affair. Independent evidence of

the existence of the lakes is not yet announced. Both Fowke and Todd suggest that some of the preglacial streams followed courses that were determined in paleozoic time, a suggestion that seems to give too little importance to the many possible changes of secondary and tertiary time.

The technical book-making of this publication is not altogether creditable to a State Academy. There is no table of contents, except an imperfect one on the paper cover, which disagrees with the title page and with the titles of some of the articles; the same page heading is continued throughout; some of the maps are unnumbered, and all of them are poorly lettered.

SCHLESWIG-HOLSTEIN.

AN east-west section across the base of the Danish peninsula is described by R. Gredner ('Excursion nach Ost-Schleswig-Holstein und der Insel Sylt.,' Greifswald, 1900), from which it appears that the chief features of the district are systematically arranged with respect to the glacial moraine that forms its strongest relief. The eastern border shows the hills and hollows of the typical moraine, of rich soil and divided into well-cultivated fields by numerous hedges. The eastern shore line is irregular in consequence of a slight postglacial submergence; embayments known as Föhrde (etymologically related to fjords and firths) occur where interglacial valleys were deepened by scouring ice lobes; they lead navigable water in among the morainic hills, thus locating such towns as Flensburg and Kiel. Beyond the moraine comes a broad plain of washed sands and gravels, sloping gently to the west and traversed by shallow channels; it is covered with pine forests or heathery moors, and is infertile and thinly occupied compared with the moraine. As the plain slopes westward, its materials become finer and ground water stands nearer its surface; thus the moors become meadows, and at last dikes are needed along their borders to hold off high tides. The shallow edge of the sea is known as the Wattenmeer, where a great expanse of fine mud, traversed by winding channels, is laid bare at low tide. Fields are occasionally gained by diking in the shallowest

border of the tidal flats. The outlying islands, of which Sylt is here described, consist of remnants of Tertiary strata, overlaid by drift. Long wings of beach and dunes stretch north and south from the western front of the island, with slightly convex outline towards the North sea and in-bent hooks at their end. The wings are much longer than the front of the island from which they are spread.

W. M. DAVIS.

JESSE WILLIAM LAZEAR MEMORIAL.

ON the 25th of September, 1900, Jesse William Lazear, at that time Acting Assistant Surgeon in the United States Army and a member of the Government Commission for the investigation of yellow fever, lost his life from that disease at Quemados, Cuba.

Doctor Lazear was born in Baltimore County, Maryland, in 1866, and graduated from the academic department of the Johns Hopkins University in 1889. In 1892 he received the degree of M.D. from Columbia University. From 1892 to 1895 he spent his time in study and investigation in Europe and as an interne at the Johns Hopkins Hospital in Baltimore. During the following three years and a half, while a member of the staff of the Out-Patient Department of the Johns Hopkins Hospital, he did much valuable work as a teacher and investigator in the laboratory of clinical pathology. In February, 1900, induced by the opportunity for research concerning malarial and yellow fevers, Lazear became an acting assistant surgeon in the United States Army and was assigned special laboratory duties at Columbia Barracks, near Havana. Later, he was appointed member of a special government commission for the investigation of yellow fever. The brilliant discoveries of this commission concerning the ætiology and manner of infection of yellow fever have recently been referred to in public by a distinguished pathologist as the most important piece of work by American students since the discovery of anæsthesia. To these results Lazear, as a member of the commission, contributed largely. The final proof of their discovery that the disease is transferred by the bite of a certain mosquito could only be obtained by direct experiment

upon a human being. To this experiment Lazear, with another of the committee, courageously and heroically subjected himself, and in the performance of this noble duty he lost his life.

The many friends and admirers of the talented and accomplished student, of the brave, true, self-sacrificing man, desire to establish a lasting memorial to him and to his work. To this end a meeting was held on the evening of Wednesday, May 22, which was presided over by Professor William Osler. At this meeting it was concluded that the nature of the memorial could better be decided upon when some idea could be obtained as to the amount of money available. It was, therefore, decided that a committee consisting of Dr. Stewart Paton and Dr. William S. Thayer be appointed to arrange for the distribution of a circular among the friends and admirers of Lazear, setting forth the object of the meeting. It is earnestly hoped that not only those who have known and admired Lazear and his work, but also others, who appreciate courage and manliness and self-sacrifice, may contribute to the fund for the Jesse William Lazear Memorial.

Subscriptions may be sent to Dr. Stewart Paton, treasurer, 213 West Monument Street, Baltimore, Md. It is to be hoped that the response to this circular may be made early, as it is hoped to be able to decide upon the nature of the memorial by the middle of June.

WILLIAM OSLER, *Chairman.*

STEWART PATON, }
WILLIAM S. THAYER, } *Committee.*

THE AMERICAN LIBRARY ASSOCIATION.

AT the annual meeting of the American Library Association, held at Waukesha, Wis., the 3d to 10th of July, a Round Table meeting was devoted to professional instruction in bibliography. The chairman, Mr. A. G. S. Josephson, of Chicago, in his introductory remarks, pointed out the need of solid bibliographical scholarship as a prerequisite of the librarian and urged the establishment at some university of a post-graduate school of bibliography. Such a school should, in the opinion of the speaker, offer instruction in bibliography

proper—*i. e.*, knowledge of the repertories and the record literature; classification of knowledge and history of science as the foundation of the classification of books; bibliographical methodology—*i. e.*, the principles of cataloging; history of libraries and library administration; history of printing and publishing. A communication had been received from Dr. Med. J. Leche, of Göttingen, assistant to Professor C. Dziatzko, outlining the course of bibliography given by the latter. This outline was supplemented by reminiscences from a sojourn at Göttingen by Mr. A. S. Root, librarian and professor of bibliography at Oberlin College, who also spoke of the courses given by himself. Mr. G. W. Harris, of Cornell, and Mr. J. I. Wyer, of Nebraska, told of courses given by them. A most important contribution to the discussion was made by Professor Charles H. Haskins, of the University of Wisconsin, who not only told of the course in historical bibliography given by himself, but enlarged on the importance of bibliographical studies, not only for librarians but for scholars in general. He heartily endorsed the views of the chairman in regard to the importance of a special school of bibliography.

Several speakers, among them the librarian of the John Crerar Library, Chicago, Mr. C. W. Andrews, spoke of the difficulty of obtaining for library service men trained in science and at the same time familiar with bibliographical and library methods.

MR. CHAMBERLAIN ON THE FUNCTIONS OF
A UNIVERSITY.

At the first congregation of the University of Birmingham, Mr. Chamberlain made an address in the course of which, as reported in the *London Times*, he said: What should constitute an ideal university? It may be presumptuous in me to attempt a definition, and yet when we are at the outset of our career it is necessary, it is desirable, that we should have some clear conception of the standard at which we are going to aim. And I would venture to lay down four qualifications as necessary to a perfect university. In the first place, it should be an institution where all existing knowledge is taught. Such a university

may, perhaps, never yet have been attained; want of means may always prevent it, but at least that is the object at which we should aim, and we should never rest satisfied until we can say that no student desirous of instruction in any branch of learning shall be turned hungry away from the doors of this University. No doubt the enormous development of knowledge, and especially of its scientific side, during the present century requires a certain specialization in the teaching of that knowledge, and I think it may be desirable, I think it may be necessary, that universities also should be specialized, and that one university should pay more attention than another to particular studies; but I believe at the same time that it would be fatal if in our desire as a modern university to give a special development to the practical and thorough teachings of our scientific work, it would be a great mistake, I say, if we were to exclude or to neglect the older branches of learning. Well, then, in the second place, a university is a place where the knowledge that has been acquired has to be tested. And as to that I will only say that in the multiplication of examining bodies I hope that nothing will be done, either by us or by our successors, to lower the standards of proficiency, whether in the ordinary pass or in the highest honors. I conceive that common prudence should teach us to keep up the value of the degrees which we have begun to confer to-day, and nothing would be more unwise, more fatal to our reputation and to our ultimate success than that we should endeavor to multiply the number of our students at the expense of their quality. Then the third feature to which I should call attention, and which I am inclined to say is the most important of all, is that a university should be a place where knowledge is increased and where the limits of learning are extended. Original research, the addition of something to the total sum of human knowledge, must always be an essential part of our proposals. We want to secure that those who teach in this University shall never cease to learn, and that those who are students shall unite with them in the work of fresh and new investigation. And, lastly, a university is a place where the

application of knowledge must be indicated and directed. That perhaps brings us nearer to what may yet be the distinctive feature of our University. At all events we start with the belief that here we are going to combine theory with practice, and to see that in our University we shall combine both in one course of instruction, with due regard to the needs of our own time and of our own district. And now, if I may summarize in one sentence what I have been saying, it is that a university should be a place where knowledge is taught, tested, increased and applied.

PROFESSOR STARR'S RECENT WORK IN
MEXICO.

WITH his last journey to Mexico, which extended over four months, Professor Frederick Starr brings the field-work of four years' study of Mexican Indians to a close. This study has had for its object the careful definition of the physical types of the tribes of southern Mexico. Three kinds of work were done—measurement, photography and modeling. In each tribe one hundred men and twenty-five women were measured, fourteen measurements being taken of each individual. Photographic portraits were taken of typical subjects, a front view and a straight profile being made of each. Busts in plaster were made of those who appeared most perfectly to present the racial type, the molds being made directly upon the subject. During the four seasons over which his work has extended Professor Starr has visited the following twenty-three tribes: Otomis, Tarascans, Thaxcalans, Aztecs, Mixtecs, Triquis, Zapotec-Mixtecs, Mixes, Tehuantepec Zapotecs, Juaves, Chontals, Cuicatecs, Chinantecs, Chochoas, Mazatecs, Tepehuas, Totonacs, Huastecs, Mayas, Zoques, Tzendals, Tzotzils and Chols. While the physical types of the natives formed the chief subject of study, many views were also taken of the scenery, villages, houses, groups of Indians, native industries, etc., etc. The material results of the investigation include measurements from 2,850 persons, 1,200 or more negatives, varying in size from 8 x 10 inches to 4 x 5, 100 busts in plaster, and a large collection of objects—dress, weap-

ons, implements and products—illustrating the ethnography of the region. Several months will be necessary for putting all this material into shape for exhibition and publication. The printed results of the study will comprise five volumes. Of these, two will be albums of plates, illustrating the people and the country, under the title 'The Indians of Southern Mexico,' two will be pamphlets, printed by the Davenport Academy of Natural Sciences, entitled 'Notes on the Ethnography of Southern Mexico,' the fifth will probably be issued as a bulletin of the Department of Anthropology by the University of Chicago, and will present the results of the anthropological measurements and observations under the name of 'The Physical Characters of the Indians of Southern Mexico.' The first volume of the 'Indians of Southern Mexico,' and part first of the 'Notes on the Ethnography of Southern Mexico' have already been published. The remaining three volumes will be printed as soon as possible. It may be added that this work of Professor Starr is the first of its kind undertaken in Mexico.

SCIENTIFIC NOTES AND NEWS.

DR. PATRICK MANSON, F.R.S., has been awarded the Stewart prize of the British Medical Association, for his researches in the pathology of tropical diseases, especially in regard to the malaria of man and to the life-history of the malarial parasite both in man and in the mosquito, and in recognition also of the stimulating influence which he has exerted for many years on the study of tropical diseases in the British Empire.

PROFESSOR KOCH was entertained at dinner on July 24, by the Royal Institute of Public Health and was presented with the Harben medal for 1901. The presentation was made by Dr. W. R. Smith, president of the Institute, who was in the chair.

The British Medical Journal states that among the honors to be paid to Professor Rudolf Virchow on the occasion of his eightieth birthday will be the foundation of a *Virchow Haus*, at Berlin, with objects similar to those of the *Hofmann Haus*, which serves as a club house, library, etc., for chemists.

THE Royal Society has elected Professor Franz von Leydig, of Bonn, a foreign member.

THE University of Basle has conferred the honorary degree of Ph.D. on Dr. Robert Billwiller, director of the Meteorological Institute of Bonn, and on Professor Alfred Wolfer, director of the Astronomical Observatory at Zurich.

WE learn from *Nature* that the French Société d'Encouragement pour l'Industrie nationale announces the following awards of prizes: Grand gold medal to the Chamber of Commerce of Lyons for the organization of the commercial mission to China; 2,000 francs to M. Horsin-Déon for his work on beet root sugar; 500 francs to M. R. Fosse for his works on β -dinaphthol, and the same amount to M. Marcel Guichard for his works on molybdenum; 1,000 francs to M. Triboudeau for his study of the Pas-de-Calais, and 1,000 francs each to MM. Faure and Thénard for memoirs on the utilization of waters in agriculture.

THE Council of the Royal Society has awarded the Mackinnon studentship to Mr. J. J. R. Macleod, M.B., demonstrator of physiology in the London Hospital Medical College, for the purpose of enabling him to carry out researches in pathological chemistry. The studentship is founded under a bequest to the Royal Society by the late Sir William Mackinnon, director general of the Medical Department of the Army, for the foundation and endowment of prizes or scholarships for the special purpose of furthering natural and physical science, and of furthering original research and investigation in pathology. There were fourteen applications for the studentship which is of the annual value of £150.

MR. H. N. WHITFORD has been appointed collaborator in the Bureau of Forestry, U. S. Department of Agriculture.

C. E. VAN ORSTRAND, of the Nautical Almanac Office, has been transferred to be assistant physical geologist in the U. S. Geological Survey.

GOVERNOR STONE, of Pennsylvania, has appointed Miss Myra L. Dock of Harrisburg a member of the State Forestry Commission.

PROFESSOR J. BEHRENS has been appointed director of the agricultural experiment station at Augustenberg, in Baden, and Dr. R. Meissner, of Geisenheim, director of the station for grape culture at Weinsberg, in Würtemberg.

MR. HARLAN I. SMITH, of the American Museum of Natural History, has returned from a trip through the lower peninsula of Michigan, where he made a survey of the recently discovered 'Hauptman Earthwork,' a few miles southwest of West Branch, Ogemaw County. Three camp sites were also discovered along Indian River in Cheboggan County.

DR. A. W. NIEWENHUIS, medical officer of the Dutch colonial army, is at present in San Francisco, after having spent several years in scientific exploration in Borneo.

DR. FELIPE CALDAS, the Brazilian bacteriologist, sailed on July 24, for Cuba, accompanied by Dr. Angel Bellinzaghi, his assistant. They will conduct experiments with the serum that Dr. Caldas discovered.

PROFESSOR HERBERT B. ADAMS, who was connected with the department of history of the Johns Hopkins University since the opening of the University in 1876, has died at the age of fifty-one years.

DR. P. CALVIN MENSCH, since 1894 professor of the biological and chemical sciences at Ursinus College, at Collegeville, Pa., died on July 30.

CHARLES MOHR, Ph.D., whose death at his home in Asheville, N. C. we announced last week, was for many years connected with the U. S. Department of Agriculture, as special agent of the Forestry Division, and with the Geological Survey of Alabama, as botanist. His most important works during the past ten years have been: A study for the Forestry Division of the long leaf pine, a monograph on which was recently published by the Department of Agriculture; The 'Plant Life of Alabama,' a systematic account of the flowering plants and ferns growing without cultivation in Alabama; and 'The Botanical Resources of Alabama,' being an account of the useful and noxious plants of the State. The 'Plant Life of Alabama' was prepared under the joint auspices

of the U. S. Department of Agriculture and the Geological Survey of Alabama, and is now in press and about ready for distribution as a Bulletin of the Botanical Division of the Department. It will also be published as a report of the Geological Survey of the State. The volume on the economic botany of the State was being prepared for the Geological Survey, and was only partly in manuscript. The death of Dr. Mohr before the completion of this report must be counted as a misfortune both to the State of Alabama and to science in general, since there is no one else so well qualified as Dr. Mohr to write upon this subject. The collections in the Museum of the University of Alabama, in great part brought together, arranged and installed by him, will remain as enduring monuments to his memory. These are: A collection of dried specimens of the flowering plants and ferns of Alabama representing some 2,500 species; a similar collection of the mosses, liverworts, lichens and fungi of the State, numbering some 1,000 species; a forestry collection, consisting of about 150 blocks in book form illustrating the native woods, and a collection in about 150 individual glass front cases, showing the foliage, flowers and fruits of the timber trees of the State.

THE British Medical Association held its sixty-ninth annual meeting at Cheltenham last week, under the presidency of Dr. G. B. Ferguson.

The Botanical Gazette states that, under a commission from the United States Government, Dr. H. von Schrenk, of the Shaw School of Botany at St. Louis, is to spend the summer in Europe, in an investigation of the problems connected with the decay of railroad ties on the principal roads, this work being done in connection with a series of investigations on the same subject which he is undertaking for the U. S. Department of Agriculture, in which the principal American railroads are cooperating.

As we learn from the same source, Dr. J. N. Rose left about June 20 for his third botanical trip to Mexico. He expects to go first to the City of Mexico, working out from this point as a base southward towards Acapulco and eastward toward Vera Cruz, probably ascending

Mount Orizaba and Popocatepetl. The objects of his trips are to make a general botanical collection; to collect at type localities certain species of Humboldt, Galeotti, Schiede and other early collectors; and to acquire information in regard to the economic uses of Mexican plants, especially such as will supplement a second paper on the useful plants of Mexico which is now nearly completed.

THE examination for the position of assistant ethnologist in the Bureau of American Ethnology, recently announced in this journal, was passed creditably by Albert Ernest Jenks, Ph.D., of Madison, Wisconsin, and he has just been appointed to the position and assigned to work on the foods and other economic resources of the Amerind tribes about the Great Lakes.

WE are requested to state that the fossil vertebrates, to which we recently referred as having been collected under the auspices of the U. S. Geological Survey in the Triassic of Arizona were collected by Mr. Barnum Brown. They filled two boxes weighing nearly half a ton, and have been unpacked under the direction of Mr. F. A. Lucas, who will probably soon report as to their scientific value.

A CASE of the bubonic plague is at present on Swinburne Island, New York City, having been removed from a steamship that arrived in the port from Calcutta. The case was diagnosed by the quarantine laboratory and the diagnosis confirmed by the marine hospital service. The disease has not been exterminated in San Francisco and appears to be spreading at Capetown and in Egypt.

THE Liverpool School of Tropical Medicine will send another expedition, probably under the direction of Dr. Annett, to Sierra Leone. This is the seventh expedition sent by the school for the investigation of malaria.

THE British National Antarctic Expedition steamship *Discovery* left London on July 21. She will proceed to Spithead to complete her equipment and will stop at Cowes, where the King will bid good-bye to the members of the expedition.

A TELEGRAM from Reuter's Agency states that the St. Petersburg Academy of Science re-

ceived, on July 11, a telegram from the leader of the expedition which is shortly to bring to St. Petersburg the mammoth found in Siberia. The telegram, which is despatched from Yakutsk, reports that the expedition arrived at that place on June 14. It is proceeding by steamer up the river, and will then journey overland to Kolymsk, which is 3,000 versts off, and where it expects to arrive in two and a-half months. The mammoth found is unique of its kind. Its hair, skin and flesh are entirely preserved, and there are remains of undigested food in its stomach.

THE University of Montana biological collecting expedition has spent five weeks in the mountains of the State, and four weeks more are being devoted to the work of the station on Flat-head lake. During the trip several peaks have been ascended in the Mission and Kootenai ranges, and new names have been given to a number of unnamed peaks. Dr. Henry C. Cowles, of the University of Chicago, with a party of about twenty students, will spend ten days at the station studying the botany of the region. The work of the station will close August 16, when the instructors will attend the Denver meeting of the American Association.

A REPORT of the Geological Survey on the operations of the Kowak River party in Alaska has been submitted by Mr. Mendenhall, the geologist in charge of the work. He says the party reached Dawson, Yukon Territory, on June 4. Mr. Reaburn, of the party, with three camp hands, immediately began to survey a line from Fort Yukon to the mouth of Dall River, approximately 150 miles. This region of the Yukon flats offered no geologic problems other than those involved in the history of a large area of fluvial silts.

THE Council of Birmingham University has agreed to subscribe to a working 'table' at the Port Erin (Isle of Man) biological station, under Professor Herdman, to be placed at the disposal of Professor Bridge, for the use of his senior students when studying marine organisms, one student to occupy it for a month or more at a time.

DURING the opening week of the Minnesota Seaside Station on the west coast of Vancouver

Island, evening lectures were delivered as follows:

Professor Conway MacMillan, Univ. of Minn.: 'Waste in Nature.'

Mr. K. Yendo, Univ. of Tokio: 'Distribution of Algae in Japan.'

Mr. Harold Lyon, Univ. of Minn.: 'Phylogeny of the Cotyledon.'

Professor Conway MacMillan, Univ. of Minn.: 'Laminariaceae of the Straits of Fuca.'

Miss Eloise Butler, Central High School, Minneapolis: 'Collecting Seaweeds in Jamaica.'

Dr. Francis Ramaley, Univ. of Colorado: 'Distribution of Plants in Colorado.'

The new seaside station has had in attendance during its first season thirty students, most of whom have specialized in botany, but some zoological work has also been done.

PROFESSOR B. E. FERNOW, director of the New York State College of Forestry, Cornell University, and formerly chief of the U. S. Division of Forestry, gave a course of lectures at the University of Chicago, beginning June 24. He treated forestry in its botanical, practical and political aspects. The subjects were as follows:

'What is Forestry?' (Economic significance of forest resources and need for their management; definition of terms and historic development of the art of forestry.)

'The Forest as a Resource.' (Commercial value of forest products, extent of their use, relation to other industries, significance in the United States.)

'The Forest as a Condition.' (Forest influences claimed and observed on climate, water-flow, health.)

'How Trees grow.' (A chapter of biological dendrology: the development and life-history of the individual forest tree.)

'The Mathematics of Forest Growth.' (Accretion and its measurement; quantitative and qualitative wood production.)

'The Evolution of Forest Growth.' (Development of forest growths as organisms, ecologic relations.)

'Timber Physics.' (Characteristics, properties and uses of wood.)

'Principles of Silviculture.' (The art of planting, reproducing and improving forest growths.)

'Forest Exploitation and Forest Protection.' (Tending and harvesting the forest crop.)

'Business Aspects of Forest Management.' (Forest survey, forest regulation and forest finance.)

'Forest Policies of Foreign Nations.' (The relation of the state to forest resources and how it has evolved itself in Europe.)

'Forests and Forestry in the United States.' (A brief sketch of forest conditions in the United States, and history of the movement to establish forest management.)

THE following table, originally published in the Baltimore Sun, gives the maximum temperatures during the months of July in several different cities :

Day of Month.	Eastport.	Boston	New York.	Baltimore.	Atlanta.	Cincinnati.	Chicago.	St. Louis.	Kansas City.	St. Paul.
1	82°	92°	98°	103°	90°	96°	92°	100°	100°	82°
2	72	94	98	103	86	92	86	96	100	84
3	80	96	94	97	90	92	84	98	102	92
4	76	72	86	96	92	92	94	98	104	82
5	72	70	90	94	90	92	90	100	90	78
6	60	66	82	96	90	88	86	96	92	78
7	62	76	84	90	86	80	66	84	94	74
8	64	84	78	77	88	78	68	86	98	78
9	60	64	80	83	88	82	88	92	104	90

ON or about September 1, 1901, the Bird Club of Princeton University will publish its first *Bulletin*, edited by Mr. Wm. E. D. Scott, curator of ornithology, Princeton University. It will contain an annotated list of the birds of Princeton and vicinity, by William Arthur Babson, B.S., 1901. This list is the result of four years of scientific observation and study of the birds of Princeton. The *Bulletin* will contain about seventy or eighty pages, will be plainly bound in paper and will be sold for one dollar.

THE Regents of the University of Colorado have ordered the publication of an annual to be called the 'University of Colorado Studies.' It will contain papers from the various schools and departments—the result of experiment and investigation during the year. The first number will be issued soon.

THE council of the Institution of Electrical Engineers arranged a fortnight's visit of the members to Germany, where the leading installations and establishments connected with the science and practise of electricity were inspected. The party was divided into three sections, the first of which visited Berlin only, whilst the second visited Berlin and Dresden, and the third Nüremburg, Frankfurt-on-Maine, etc., in addition to the foregoing places.

THE work of the new anti-toxine laboratory of the N. Y. Department of Health, the establishment of which was provided for by the late Legislature, has begun. The scientific part of the work will be done in a part of the Bender Laboratory Building, Albany. Dr. H. D. Pease, of the Sheffield Scientific School, has been appointed director. An animal house is to be fitted up near the laboratory so as to secure the most perfect hygienic conditions attainable for such purposes. It will house about fifteen horses for the manufacture of serum. The laboratory will supply state institutions with diphtheria and other anti-toxines.

SURGEON GENERAL WYMAN, of the marine hospital service, has sent to the supervising architect of the treasury a request that plans be prepared for a laboratory for the marine hospital service. Congress, by the act approved March 3, 1901, appropriated \$35,000 for the buildings. A two-story main building and an animal house will be erected. The basement of the main building will contain heating apparatus, storage room for fuel, incinerator and store rooms; the first story will have one office room, library, quarters for attendant, rooms for the study of rabies, special investigating room, disinfecting room of 1,000 cubic feet and a room for micro-photography, with a dark room. The second story will have two special laboratory rooms, one office, animal room and two laboratory rooms of large dimensions. The animal

building, to contain apartments for animals, will be one story high, with loft for storage of food supplies; the interior of the walls and the floors to be moisture proof and to have ample water and sewer connections. Both buildings are to be lighted with electricity.

THE London *Times* quotes from the *Journal* of the Board of Trade, a report from the locomotive superintendent of the Oudh and Rohilkund Railway, on the working of ten American Baldwin engines supplied to that line last year. After describing the changes made in the engines to suit them to local requirements, and the chief defects which have shown themselves, the superintendent concludes: "Those ten engines have been working passenger trains, running at 30 to 35 miles an hour, and goods trains, running at 20 miles an hour, chiefly the former, and they have done their work well. They steam capitally and are remarkably good starters; they get away from a station with 55 loaded (wagons or coaches?), equal to about 1,300 tons, with the greatest ease. They are a little higher in coal consumption than our new B class. They are easily repaired, but repairs will have to be kept up, as, if not, they will go to pieces sooner than our other engines would. They do not, as far as I can see at present, cost more in repairs than other engines, and I am very satisfied with them." The cost of these engines, turned out complete, was Rs. 42,020 each, and the cost of the new B class engine, which is the engine used on the line for similar work, is Rs. 44,826.

UNIVERSITY AND EDUCATIONAL NEWS.

MESSRS. MCKIM, Mead and White have been commissioned to draw up general plans for the future buildings of the University of Cincinnati. The University has recently received \$25,000 to be applied to its engineering shops and laboratories.

At a meeting of the University Court of Glasgow University on July 11, it was announced that under the will of the late Mrs. M'Roberts, of Todhill, a sum of £10,000 had been bequeathed to the University for the purpose of founding and endowing a chair as the court may direct.

THE University of St. Andrews has received, by the will of the late Miss Malcolm, the sum of £4,000 for the establishment of medical scholarships.

WILLIAM STOKES WYMAN, LL.D., was elected President of the University of Alabama at the last meeting of the trustees in June, 1901. Dr. Wyman received his education at Harvard University and at the University of Alabama, and has for many years been connected with the latter institution as professor of Latin. He has served the University as president *pro tem.* on several occasions in the past, and his election to the presidency meets the hearty approval of all the alumni and friends of the institution.

At the University of Cincinnati, Professor Charles H. Judd, recently of New York University, has been appointed professor of psychology and pedagogy. Messrs. J. E. Ives, H. C. Biddle, E. F. Alexander and Wm. Baur, have been appointed instructors in physics, and Mr. Wm. Osburn instructor in zoology.

DR. S. S. COLVIN, Ph.D. (Strasburg), has been appointed assistant professor of psychology in the University of Illinois.

RALPH S. LILLIE, who this year received the degree of Ph.D. in zoology at the University of Chicago, has been appointed assistant in physiology in the Harvard Medical School.

HANNAH B. CLARK, Ph.D. (Chicago), has been made assistant professor of sociology in the West Virginia University, at Morgantown, W. Va.

DR. G. BREDIG, docent in chemistry in the University of Leipzig, has been called to an associate professorship in the University of Heidelberg; Giovanni Ossunna, chief engineer of the firm of Siemens & Halske, has been called to a full professorship of electrical engineering in the Technical Institute at Munich.

DR. MORITZ VON RUDZKI has been promoted to a full professorship of mathematical geodesy and meteorology in the University at Cracow; Dr. Ludwig Tetmajer, professor in the Zurich Polytechnic Institute, has been appointed full professor of engineering in the Technical Institute at Vienna.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE: S. NEWCOMB, Mathematics; R. S. WOODWARD, Mechanics; E. C. PICKERING, Astronomy; T. C. MENDENHALL, Physics; R. H. THURSTON, Engineering; IRA REMSEN, Chemistry; CHARLES D. WALCOTT, Geology; W. M. DAVIS, Physiography; HENRY F. OSBORN, Paleontology; W. K. BROOKS, C. HART MERRIAM, Zoology; S. H. SCUDDER, Entomology; C. E. BESSEY, N. L. BRITTON, Botany; C. S. THE DENVER MEETING.

THE Denver Meeting of the American Association for the Advancement of Science is an important event in the history of

science in America, giving as it does official recognition to the development of science in the west. The scientific men of the country have been mostly collected together on the Atlantic seaboard between Boston and Washington, and the membership of the scientific societies has been chiefly in this region. The American Association has not hitherto met further to the west than St. Louis, and at the meeting in that city, twenty-three years ago, there were only 134 members in attendance, while two years later at Boston the attendance was 997.

During its first hundred years the nation was in scientific matters somewhat in the relation of a colony to Europe. Our students went abroad for study; we depended on Europe for our journals and books, and did not contribute our share to the work of the world. During the subsequent twenty-five years great progress has been made. The opening of the Johns Hopkins University in 1876 marked and helped to create a new epoch in university education. In the same year, the American Chemical Society was organized, leading the way in the establishment of our national societies devoted to special sciences. At about the same

time our special scientific journals were first established. In the intervening period the scientific work under the Government has remarkably expanded. The membership of the American Association increased from 867 in 1876 to 2,033 in 1883.

But this period of scientific activity has been to a large measure confined to the Atlantic seaboard. Even at the present time, we find that of the 86 members of the National Academy only one lives west of Chicago, and of the 864 fellows of the American Association only about 60 live west of that city. The central and western states have been in the colonial relation to the Atlantic seaboard that it had previously held to Europe. Students have come to the eastern universities, and the scientific men for the central and western States have been drawn from the east. But the establishment of Chicago and Stanford Universities and the development of the State universities represent the same movement that occurred earlier in the east. Within a few years the center of population — slowly moving westward and now in southern Indiana — may be the center of scientific men and scientific activity. Omens and coincidences may not appeal to men of science, but it is perhaps worth noting that the fiftieth meeting of the Association in the first year of the new century should celebrate an epoch in the development of science in America.

A little while since (June 21) there was published in this journal an article calling attention to the importance of the American Association for science in America, and it is not necessary to repeat now what was

then said. We wish, however, to emphasize the significance of the approaching meeting and to urge the need of a large attendance and of a representative scientific program. The responsibility here rests with each member individually. It is not easy to say anything except the trite on such a subject, for we all know that scientific work, like everything else, depends on the willingness of all to unite for a common cause. The trip to Denver, either from the east or from the scientific centers of the west, is certainly long and expensive. When, however, the National Educational Association met recently in that city there was an attendance of 10,000 members, the largest in its history. The members of the American Association should at least aim at making the same record.

The permanent secretary informs us that many prominent scientific men from the east have signified their intention to be present, and that the representatives of science in the central and western states guarantee a large attendance. It cannot be expected that as many affiliated societies will meet at Denver as last year at New York, but the names of nine will be found on the preliminary program. We published last week a list of forty-five papers offered in chemistry, and other sciences are correspondingly well represented. The address of the President, Professor Woodward, of Columbia University, entitled 'The Progress of Science,' is certain to be an event of more than ordinary importance; and one of our most eminent students of the physical sciences will be succeeded in the chair by one of our most eminent students of the

biological sciences, Professor Minot, of Harvard University. The Association is promised a welcome by the Governor of the State, the Mayor of Denver and other dignitaries, and the people of the city are noted for their hospitality.

A few words in regard to routes may be of service to members in the East. The way to Denver is either by Chicago or St. Louis, the former being the quicker. Chicago may be reached from New York in about twenty-four hours by the Pennsylvania and New York Central Railways. For example, a train leaving New York at 7:55 A. M. by the Pennsylvania reaches Chicago at 7:45 the next morning, or a train leaving New York at 5:30 P. M. by the New York Central and Lake Shore reaches Chicago at 4:30 the next afternoon. The best train from Chicago leaves at 10 A. M. by the Chicago and Northwestern; at 1 P. M. by the Rock Island Route and 4 P. M. by the Burlington, reaching Denver at 1:40, 4:45 and 6:30, respectively, the next afternoon. Those who leave Chicago on Saturday, the twenty-fourth, by one of these trains will doubtless travel in good company. The rate from New York to Denver and return at one and one-third fare would be about \$65; the ordinary fare to Chicago and return is \$40, and the return ticket from Chicago to Denver is \$31.50. The latter method is not much dearer than the former and may be cheaper to members living west of New York. It is more convenient, as the tickets from Chicago may be purchased as early as August 10 and are good for return until October 31, and the route to Chicago may be varied and a stop may be made at

Buffalo or elsewhere. The headquarters of the Association are at the Brown Palace Hotel, and those wanting rooms should engage them in advance. There are, however, a number of good hotels at Denver.

Everyone knows that Denver is one of the great centers for excursions of scientific and general interest. The geologists, under the leadership of Professor Van Hise, have planned a ten days' excursion before the meeting. Other excursions of interest to chemists, engineers, geologists, zoologists, botanists, anthropologists and indeed to all members of the Association may be made during the meeting or at its close. It is sufficient to mention Pike's Peak, the Garden of the Gods, and the Grand Canyon of the Colorado, to all of which excursions have been planned. The trip to Colorado should be made by everyone and should be made now by all members of the American Association for the Advancement of Science.

REGENERATION AND LIABILITY TO INJURY.*

THERE is a widespread belief amongst zoologists that a definite relation exists between the liability of an animal to injury and its power of regeneration. It is also supposed that those individual parts of an animal that are more exposed to accidental injury, or to the attacks of enemies, are the parts in which regeneration is best developed, and conversely, that those parts of the body that are rarely or never injured do not possess the power of regeneration.

Not only do we find this belief implied in many ways, but we find this point of view definitely taken by several eminent

* One of a course of lectures on 'Regeneration' delivered at Columbia University, and shortly to be published in the Columbia University *Biological Series*.

writers, and in some cases carried so far that the process of regeneration itself is supposed to be accounted for by the liability of the parts to injury. In order that it may not appear that I have exaggerated the widespread occurrence of this belief a few examples may be cited.

Réaumur in 1742 pointed out that regeneration is especially characteristic of those animals whose body is liable to be broken, or, as in the earthworm, subject to the attacks of enemies. Bonnet (1745) thought that such a connection exists as has been already stated, and that the animals that possess the power of regeneration have been endowed with germs set aside for this very purpose. He further believed that there would be in each animal that regenerates as many of these germs as the number of times that it is liable to be injured during its natural life. Darwin in his book on 'Animals and Plants under Domestication' says: "In the case of those animals that may be bisected, or chopped into pieces, and of which every fragment will reproduce the whole, the power of re-growth must be diffused throughout the whole body. Nevertheless, there seems to be much truth in the view maintained by Professor Lessona* that this capacity is generally a localized and special one serving to replace parts which are eminently liable to be lost in each particular animal. The most striking case in favor of this view is that the terrestrial salamander, according to Lessona, can not reproduce lost parts, whilst another

species of the same genus, the aquatic salamander, has extraordinary powers of re-growth, as we have just seen; and this animal is eminently liable to have its limbs, tail, eyes and jaws bitten off by other tritons."

Lang, referring to the brittleness of the tails of lizards, points out that this is a very useful character, since the bird of prey that has struck at a lizard gets hold of only the last part of the animal to disappear under cover; the lizard escapes by breaking off its tail. The brittleness of the tail is, therefore, an adaptive character that has become fixed by long inheritance.

To this example may be added that of certain land snails of the Philippine Islands. The individuals of the genus *helicarion* live on trees in damp forests, often in great droves. They are very active, and creep with unusual swiftness over the stems and leaves of the trees. Semper has recorded that all the species observed by him have the remarkable power of breaking off the tail (foot) close behind the shell, if the tail is roughly grasped. A convulsive movement is made until the tail comes off, and the snail drops to the ground, where it is concealed by the leaves. Semper adds that in this way the snails often escaped from him, and from his collectors, leaving nothing behind but their tails. The tail is said to be the most obvious part of the animal, and it is assumed that this is, therefore, the part that a reptile or bird would first attack.* Lang states that in this case external influences have produced an extraordinarily well developed sensitiveness in the animal, so that it reacts to the external stimulus by voluntarily throwing off the tail. It would be, of course, of small advantage to be able to throw off the tail un-

* Delage and Giard give Lessona (1869) the credit for first stating that the phenomenon of regeneration is an adaptation to liability to injury; but Réaumur first suggested this idea in 1742 and Bonnet in 1745. Delage's interpretation, viz., that Lessona ascribed this to a '*prévoyance de la nature*' has been denied by Lessona's biographer, Camerano ('*La Vita di M. Lessona*' *Acad. R. d. Torino* (2), XLV., 1896) and by Giard ('*Sur L'autotomie Parasitaire*,' etc., *Compt. Rendus de Séances de la Société de Biologie*, May, 1897).

* Whether, having once failed in this way to obtain the snail, the bird or lizard would not learn to make a frontal attack is not stated. Or shall we assume the tail is all that is wanted?

less the power of regenerating the lost organ existed, or was acquired at the same time as the extreme sensitiveness that brings about the reaction. Lang does not state, however, explicitly that he believes the regenerative power to have arisen through the exposure of the tail of the lizard and the tail of the snail to injury, although he thinks that the mechanism by means of which these parts are thrown off has been acquired in this way. Several other writers have, however, used these same cases to illustrate the supposed principle of liability to injury and power of regeneration.

Weismann in his book on 'The Germ Plasm' has adopted the principle of a connection between regeneration and liability to injury and has carried it much further than have other writers. We can, therefore, most profitably make a careful examination of Weismann's position. His general idea may be gathered from the following quotation:* "The dissimilarity, moreover, as regards the power of regeneration in various members of the same species, also indicates that adaptation is an important factor in the process. In proteus which in other respects possesses so slight a capacity for regeneration, the gills grow again rapidly when they have been cut off. In lizards again this power is confined to the tail, and the limbs cannot become restored. In these animals, however, the tail is obviously far more likely to become mutilated than are the limbs, which, as a matter of fact, are seldom lost, although individuals with stumps of legs are occasionally met with. The physiological importance of the tail of a lizard consists in the fact that it preserves the animal from total destruction, for pursuers will generally aim at the long trailing tail,† and thus the ani-

mal often escapes, as the tail breaks off when it is firmly seized. It is, in fact, as Leydig was the first to point out, specially adapted for breaking off, the bodies of the caudal vertebrae from the seventh onward being provided with a special plane of fracture so that they easily break into two transversely. Now if this capability of fracture is provided for by a special arrangement and modification of the parts of the tail, we shall not be making too daring an inference if we regard the regenerative power of the tail as a *special adaptation, produced by selection, of this particular part of the body, the frequent loss of which is in a certain measure provided for*, and not as the outcome of an unknown 'regenerative power' possessed by the entire animal. This arrangement would not have been provided if the part had been of no, or only of slight, physiological importance, as is the case in snakes and chelonians, although these animals are as highly organized as lizards. The reason that the limbs of lizards are not replaced is, I believe, due to the fact that these animals are seldom seized by the leg, owing to their extremely rapid movements." Overlooking the numerous cases of the regeneration of internal organs that have been known for several years, and basing his conclusion on a small, unconvincing experiment of his own on the lungs of a few salamanders, Weismann concludes: "Hence there is no such thing as a general power of regeneration; in each kind of animal this power is graduated according to the need of regeneration in the part under consideration; that is to say, the degree in which it is present is mainly in proportion to the liability of the part to injury."

After arriving at this conclusion the following admission is a decided anticlimax: "The question, however, arises as to whether the capacity of each part for regeneration results from special process of adaptation, or whether regeneration occurs

* 'The Germ-Plasm.' Translation by W. Newton Parker, 1893, page 116.

† There are no facts that show that this statement is not entirely imaginary. T. H. M.

as the mere outcome—which is to some extent unforeseen—of the physical nature of an animal. Some statements which have been made on this subject seem hardly to admit of any but the latter explanation.” After showing that some newts confined in aquaria attacked each other, “and several times one of them siezed another by the lower jaw, and tugged and bit at it so violently that *it would have been torn off if I had not separated the animals,*” * and after referring to the regeneration of the stork’s beak, Weismann concludes: “Such cases, the accuracy of which can scarcely be doubted, indicate that the capacity for regeneration does not depend only on the special adaptation of a particular organ, but that a general power also exists which belongs to the whole organism, and to a certain extent affects many and perhaps even all parts. By virtue of this power, moreover, simple organs can be replaced when they are not specially adapted for regeneration.” The perplexity of the reader, as a result of this temporary vacillation on Weismann’s part, is hardly set straight by the general conclusion that follows on the same page: “We are, therefore, led to infer that the general capacity of all parts for regeneration may have been acquired by selection in the lower and simpler forms, and that it gradually decreased in the course of phylogeny in correspondence with the increase in complexity of organization; but that it may, on the other hand, be increased by special selective processes in each stage of its degeneration, in the case of certain parts which are physiologically important and are at the same time frequently exposed to loss.”

There are certain statements of facts in this chapter that are incorrect, and the argument is so loose and vague that it is difficult to tell just what is really meant. As a misstatement of fact I may select the

* The *italics* are, of course, my own. T. H. M.

following case. It is stated that *lumbriculus* does not have the power of regenerating laterally if cut in two, and it is argued that a small animal of this form could rarely be injured at the side without cutting the animal completely in two. As a matter of fact, *lumbriculus* can regenerate laterally, and very perfectly, as any one can verify if he takes the trouble to perform the experiment; but, of course, if the whole animal is split in two lengthwise the pieces die, or if a very long piece is split from one side the remaining piece usually disintegrates. If, however, the anterior end is split in two for a short distance, or if a piece is partially split in two, the half remaining in contact with the rest of the piece completes itself laterally. The same result follows also in the earthworm.

As an example of looseness of expression I may quote the following from Weismann: “A useless or almost useless rudimentary part may often be injured or torn off *without causing processes of selection to occur which would produce in it a capacity for regeneration.* The tail of a lizard again, which is very liable to injury, becomes regenerated because as we have seen it is of great importance to the individual and if lost its owner is placed at a disadvantage.” And as an example of vagueness, the following statement commends itself: “Finally the complexity of the individual parts constitutes the third factor which is concerned in regulating the regenerative power of the part in question; for the more complex the structure is, the longer and the more energetically the process of selection must act in order to provide the mechanism of regeneration, which consists in the equipment of a large number of different kinds of cells with the supplementary determinants which are accurately graduated and regulated as regards their power of multiplication.”

Without attempting to disentangle the ideas that are involved in these sentences,

let us rather attempt to get at a general idea of Weismann's views. In a later paper (1900); in reply to certain criticisms, he has stated his position somewhat more lucidly. In the following statement I have tried to give the essential part of his hypotheses: Weismann believes the process of regeneration to be regulated by 'natural selection'; in fact, he states that it has arisen through such a process in the lower animals—since they are more subject to injury—and that it has been lost in the higher forms except where, on account of injury, it has been retained in certain parts. Thus when Weismann speaks of regeneration as being an adaptation of the organism to its environment, we must understand him to mean that this adaptation is the result of the action of natural selection. We should be on our guard not to be misled by the statement that because regeneration is useful to the animal, it has been acquired by natural selection, since it is possible that regeneration might be more or less useful without in any way involving the idea that natural selection is the originator of this or of any other adaptation. It will be seen, therefore, that in order to meet Weismann on his own ground it will be necessary to have a clear understanding in regard to the relation of regeneration to Darwin's principle of natural selection. With Weismann's special hypothesis of the 'mechanism,' so-called, by which regeneration is made possible we have here nothing to do, but may consider it on its own merits in another chapter.

In order to have before us the material for a discussion of the possible influence of natural selection on regeneration, let us first examine the facts that bear on the question of the liability of the parts to injury and their power to regenerate, and in this connection the questions concerning the renewal of parts that are thrown off by the animals themselves in response to an external stimulus are worthy of careful consid-

eration. A comparison between the regeneration of these parts with that of other parts of the same animal gives also important data. Furthermore, a comparison may be made between different parts of the same animal, or between the same parts of different animals living under similar or under dissimilar conditions.

There are only a few cases known in which a systematic examination has been carried out of the power of regeneration of the different parts of the body of the same animal. Spallanzani's results show that those salamanders that can regenerate their forelegs can regenerate their hind legs also. Towle, who has examined in my laboratory the regeneration of a number of American newts and salamanders, finds also that both the fore and hind legs regenerate in the same forms. The tail and the gills, in those newts with external gills, also regenerate. It has also been shown in triton that the eye regenerates if a portion of the bulb is left. Broussonet first showed (1786) that the fins of fish have the power to regenerate, although, strangely enough, Fraisse and Weismann state that very little power of regeneration is present in the fins of fish. I have found that the fins of several kinds of fish regenerate, belonging to widely different families.* In *Fundulus heteroclitus* I have found that the pectoral, pelvic, caudal, anal, and dorsal fins have the power of regeneration. In reptiles the feet do not regenerate, at least no cases are known, but the tail of lizards has this power well developed. In birds neither the wings nor the feet regenerate, but Fraisse has recorded the case of a stork in which, the lower jaw being broken off, and the upper being cut off at the same level, both regenerated. Bordage has recorded the re-

* *Fundulus heteroclitus*, *Stenopus chrysops*, *Decap-terus macralla*, *Menticirrhus macralla*, *Carassius auratus*, *Phoxinus funduloides*, *Noturus* sp., and a few others.

generation of the beak of the domesticated fighting cocks (of the Malay breed) of Mauritius. In the mammals neither the legs nor the tail, nor the jaws regenerate, although several of the internal organs, as described in the next chapter, have extensive powers of regeneration.

The best opportunity to examine the regenerative power in similar organs of the same animal is found in forms like the crustacea, myriapods and insects in which external appendages are repeated in each or many segments of the body. In decapod crustacea, including shrimps, lobsters, crayfish, crabs, hermit-crabs, etc., regeneration takes place in the walking legs of all the forms that have been examined, and this includes members of many genera and families. I have made a special examination of the regeneration of the appendages of the hermit-crab. In this animal, which lives in an appropriated snail's shell, only the anterior part of the body projects from the shell. The part that protrudes is covered by a hard cuticle, while the part of the body covered by the shell is quite soft. Three pairs of legs are protruded from the shell. The first pair with large claws are used for procuring food, and as organs of offense and defense; the second and third pairs are used for walking. The following two pairs that correspond to the last two pairs of walking legs of crabs and crayfishes, are small, and are used by the animal in bracing itself against the shell. The first three pairs of legs have an arrangement at the base, the 'breaking-joint,' by means of which the leg is thrown off, if injured. The last two pairs of thoracic legs can not be thrown off. The first three pairs of legs are often lost under natural conditions. In an examination of 188 individuals I found that 21 (or 11 per cent.) had lost one or more legs. If one of the first three legs is injured, except in the outer segment, it is thrown off at the

breaking-joint, and a new leg regenerates from the broken-off end of the stump that is left. The new leg does not become full size, and is of little use until the crab has moulted at least once. The leg breaks off so close to the body, and the part inside of the breaking-joint is so well protected by the bases of the other legs, that it is scarcely possible that the leg could be torn off inside of the breaking-joint, and, as a matter of observation, all crabs that are found regenerating these legs under natural conditions do so from the breaking-joint. If, however, by means of small scissors, the leg is cut off quite near the body, a new leg regenerates from the cut end, even when the leg is cut off at its very base. The breaking-joint would thoroughly protect from injury the part of the leg that lies nearer to the body, and yet from this inner part a new leg is regenerated. Moreover, the new leg is perfect in every respect, even to the formation of a new breaking-joint. In this case we have a demonstration that there need be no connection between the liability of a part to injury and its power of regeneration.

In still another way the same thing may be shown. If the crab is anesthetized, and a leg cut off outside of the breaking-joint it is not, at the time, thrown off—the nervous system, through whose action the breaking off takes place, being temporarily thrown out of order. After recovery, although the leg is thrown off in a large number of cases, it is sometimes retained. In such cases it is found that from the cut end the missing part is regenerated. In this case also we find that regeneration takes place from a part of the leg that can never regenerate under natural circumstances.

The third and fourth legs of the hermit-crab can not be thrown off, but they have the power of regeneration at any level at which they may be cut off. They are in a

position where they can seldom be injured, and I have never found them absent or injured in crabs caught in their natural environment. The soft abdomen is protected by the snail's shell. At the end of the abdomen the last pair of abdominal appendages serve as anchors to hold the crab in the shell. These appendages are large and very hard, and can seldom be injured unless the abdomen itself is broken, and under these circumstances the crab dies. Yet if these appendages are cut off they regenerate perfectly, and after a single moult can not be distinguished from normal ones.

The more anterior abdominal appendages are present only on one side of the adult, although they are present on both sides of the larva, and to judge from a comparison with other crustacea these appendages have degenerated completely on one side, and have become rudimentary in the male, even on the side on which they are present. These appendages regenerate if they are cut off. In the female the appendages are used to carry the eggs, and are, therefore, of use. They also have a similar power of regeneration. The maxillæ and maxillipeds of the hermit-crab have also the power of regeneration, as have also the two pairs of antennæ, and the eyes.

In other decapod crustacea also it has been shown that the power of regeneration of the appendages is well developed. It has been long known that the crayfish and the lobster can regenerate lost parts. The first pair of legs, or chelæ, in these forms has a breaking-joint, at which the leg can be thrown off, yet in the crayfish I have seen that if the leg is cut off inside of the breaking-joint it will regenerate. The four pairs of walking legs do not possess a breaking-joint, but may be thrown off in some cases at a corresponding level. They regenerate from this level, as well as nearer the body and further beyond this region. Pizibram

has recently shown that, in a number of crustacea, regeneration of the appendages takes place, even when the entire leg is extirpated as completely as possible.

Newport has shown that the myriapods can regenerate their legs, and it is known that several forms have the power of breaking off their legs in a definite region at the base if the legs are injured, and I have observed in *Cermatia forceps* that this takes place even when the animal is thrown into a killing fluid. Newport (1844) has also shown that when the legs of a caterpillar are cut off new ones regenerate during the pupa stage. It has been long known* that the legs of mantis can regenerate, and Bordage, who has recently examined the question more fully, has shown that a breaking-joint is present at the base of the leg. The tarsus of the cockroach also regenerates, producing only four, instead of the five, characteristic segments.†

A number of writers have recorded the regeneration of the legs of spiders.‡ Schultz, who has recently examined more thoroughly the regeneration of the legs in some spiders, finds that the leg is renewed if cut off at any level. He removed the leg most often at the metatarsus, but also at the tibia, and generally between two joints. In some cases the leg was cut off at the coxa, at which level it is generally found to be lost under natural conditions. Wagner observed in tarantula that when the leg is removed at any other place than at the coxa the animal brings the wounded leg to its jaws, and bites it off down to the coxa. In the *Epeirideæ*, that Schultz chiefly made use of, this never happened. He observed,

Wagner, W., *Bull. Soc. Imp., Naturel.*, Moscow, '87.

however, even in these forms that when the leg is cut off at the coxa it regenerates better than when cut off at any other level. Schultz adds that we see here an excellent example of how regeneration is influenced by natural selection, since regeneration takes place best where the leg is most often broken off. On the other hand, the author hastens to add that since regeneration also takes place when the leg is cut off at any other level this shows that the power to regenerate is characteristic of all parts of the organism, and is not *only* a phenomenon of adaptation, as Weismann believes. It seems highly improbable that a spider could ever lose a leg in the middle of a segment, *i. e.*, between two joints, since the segments are hard and strong, and the joints much weaker, but nevertheless the leg has the power to regenerate also from the middle of the segment, if cut off in this region.

The formation of the new part takes place somewhat differently, according to Schultz, when the leg is amputated between two segments than when cut off at the coxa. In the latter case, there is produced from the cut end of the last segment a solid rod which, as it grows longer, bends on itself several times. Joints appear in the rod, beginning at the base. The leg is set free at the next moult. If the leg is cut off nearer the distal end a smaller rod is formed, that extends straight forward, or may be thrown into a series of folds. It lies, however, inside of the last segment, since the surface exposed by the cut is quickly covered over by a chitinous covering. The piece is set free at the next moult.

Loeb has found that if the body of the pycnogonid, *Phoxichilidium maxillare*, is cut in two there regenerates from the posterior end of the anterior half a new body-like outgrowth.

Without attempting to describe the many cases in worms and molluscs in which there

is no obvious connection between the power of the part to regenerate and its liability to injury, but where it is more difficult to show that it may not exist, let us pass to an examination of the regeneration of the starfish. It has been known since the time of Réaumur that starfish have the power of regenerating new arms if the old ones are lost. It has been claimed that in certain starfishes an arm itself can produce a new starfish (Haeckel ('78), P. and R. Sarasin ('88), von Martens ('84) and Sars ('75)), but this has been denied by other observers. It has not been found to take place in several species of starfishes, but if a portion—even a small piece—of the disc is left with the arm a new disc and arms may develop (Fig. 38, F). When the arm of *Asterias vulgaris* is injured it pinches off in many cases at its base, and a new arm grows out from the short stump that remains. These same starfishes that are regenerating new arms in their natural environment have the new arms almost always arising from this breaking region.* Thus King found out of 1914 individuals of *Asterias vulgaris* collected at random, 206, or 10.7 per cent., had one or more new arms, and all these except one arose from near the disc. In other species it appears that the outer portions of the arm may be broken off without the rest of the arm being thrown off. King has found that in *Asterias*, regeneration takes place

* The Sarasins have described several cases in *Linkia multiformis* in which an old arm has one or more new arms arising from it. In one case, copied in our Fig. 38, G, four rays arise from the end of one arm, producing the appearance of a new starfish. In fact the Sarasins interpret the result in this way, although they state that there is no madreporite on the upper surface, and they did not determine whether a mouth is formed at the convergence of the rays, because they did not wish to destroy so unique a specimen—even to find out the meaning of it. There seems to me little probability that the new structure is a starfish, but the old arm has been so injured that it has produced a number of new arms.

more rapidly from the base than at a more distal level. It may appear at first thought, that the more rapid regeneration of the arm at the place at which it is usually thrown off may be associated with its more frequent loss at this region—in other words, that the more rapid regeneration has been acquired by the region at which the arm is generally broken off. This interpretation is, however, excluded by the fact that, in general, the nearer to the base the arm is cut off, so much the more rapid is its regeneration. In other words, the more rapid regeneration of the arm at the base is only a part of a general law that holds throughout the arm. If the proposition is reversed, and it is claimed that the arm has acquired the property of breaking off at the base, because it regenerates more rapidly at that level, the following fact recorded by King is of importance, viz., that although the arm regenerates faster at the base, yet a new arm is not any sooner produced in this way, since there is more to be produced, and the new arm from the base may never catch up to one growing less rapidly from a more distal cut surface, but having a nearer goal to reach.

The results of our examination show that those forms that are liable to have certain parts of their bodies injured are able to regenerate not only these parts, but at the same time other parts of the body that are not subject to injury. The most remarkable instance of this sort is found in those animals having breaking-joints. We find in these forms that regeneration takes place both proximal and distal to this region. If the power of regeneration is connected with the liability of a part to injury, this fact is inexplicable.

If we turn now to the question as to whether regeneration takes place in those species that are subject to injury more frequently or better than in other species, we find that the data are not very complete

or satisfactory for such an examination. It is not easy to tell to what extent different animals are exposed to injury. If we pass in review the main groups of the animal kingdom, we can at least gain some interesting facts in this connection.

In the Protozoa nucleated pieces have been found to regenerate in all forms that have been examined, including amœba, difflugia, thalassicolla, paramœcium, stentor, and a number of other ciliate infusoria.

In the sponges it has been found by Oscar Schmidt that pieces may produce new individuals, but how widely this occurs in the group is not known. In the cœlenterates many forms are known to regenerate, and it is not improbable that in one way or another the process occurs throughout the group. The hydroid forms, hydra, tubularia, parypha, eudendrium, antennularia, hydractinia, podocoryne, etc.; the jelly-fish, gonionemus, and certain members of the family *Thaumantidae*, have been found to regenerate. Amongst the *Scyphozoa*, the metridium, cerianthus and the scyphistoma of aurelia regenerate and the jelly-fishes belonging to this group have a limited amount of regenerative power.

In the Platodes we find all the triclads, that have been examined, including planaria, phagocata, dendrocœlum, and the land triclad bipalium, regenerate. It has been shown that the marine triclads also regenerate, but less rapidly and extensively, while the marine polyclads have very limited power of regeneration. The regeneration of the trematodes and cestodes has not, so far as I know, been studied, neither have the nematodes been examined from this point of view.

Some of the nemerteans regenerate, others do not seem to have this power. A small fresh water form, tetrastemma, that I examined did not regenerate although some of the pieces, that were filled with eggs, remained alive for several months.

In the annelids we find a great many forms that regenerate—many marine polychæta have this power; all earthworms that have been studied regenerate; both land forms, as *lumbricus*, *allolobophora*, etc., and fresh-water forms, as *lumbriculus*, *nais*, *tubifex*, etc.

In the crustacea the appendages have the power to regenerate in all the forms that have been examined.

Several kinds of myriopods as well as a number of spiders are known to regenerate their legs. In the insects, however, only a few forms are known to have this power, as caterpillars, mantis and the cockroach. The large majority of insects, in the imago state, do not seem to be able to regenerate, although they have not been sufficiently examined.

In the molluscs regeneration of the head takes place under certain conditions. Spallanzani thought that if the entire head is cut off a new one regenerates. This conclusion was denied by at least eleven of his contemporaries and confirmed by about ten others. It was found later that the result depends in part on the time of year, and in part on the kind of snail. Carriere, who more recently examined the question, found that even under the most favorable conditions regeneration does not take place if the circumoesophageal nerve-commissure is completely removed with the head, but if a part remains, a new head develops. It has been stated that a new foot regenerates in *helicarion*, and I have found the foot regenerates also in the fresh-water snails, *physa*, *limncea* and *planorbis*. If the margin of the shell of a lamellibranch or of a snail is broken off it is renewed by the mantle. The arms of some of the cephalopods are known to regenerate, particularly the hectocotylyzed arm.

In all the main groups of echinoderms, with one possible exception, regeneration has been found to take place. Probably all

starfishes and brittle-stars regenerate their arms, and even if cut in two or more pieces new starfishes develop. The crinoids regenerate lost arms, and even parts of the disc; also the visceral mass. The holothurians have very remarkable powers of regeneration. In some forms regeneration takes place if the animals are cut in two, or even in more than two pieces. The remarkable phenomena of evisceration that take place in certain holothurians, if they are roughly handled, or kept under unfavorable conditions, are well known, and have been described by a number of writers. It has even been suggested that the holothurian may save itself by offering up its viscera to its assailant! Unfortunately for this view, it has been found that the viscera are unpalatable, at least to sea-anemones and to fishes. Ludwig and Minchin suggest that the throwing off of the cuvierian organs, that are attached to the cloaca, is a defensive act, and if carried too far, according to the latter writer, the viscera may also be lost. The holothurians have remarkable recuperative powers and may regenerate new viscera in a very short time. The sea urchins, form, perhaps, an exception in this group since there are no records of their regenerative power, but no doubt this is because they have not been as fully investigated as have other forms.

In the vertebrates we find that the lower forms, amphioxus, petromyzon and sharks, have not been studied in regard to their regenerative power. In the teleostean fishes, the fins of a number of forms have been found to regenerate. It is probable that this takes place in most members of the group.

In the amphibia we find a large number of forms that regenerate their limbs and tail, and other parts of the body, but limitations appear in certain forms. The rapid regeneration of the legs in the smaller urodeles has been often described. In larger

forms it takes place more slowly, at least in large forms having large legs. In proteus the regeneration may extend over a year and a half, and in necturus it takes more than a year to make a new limb, at least in animals in confinement. In the large form, amphiuma, that has extremely small legs regeneration takes place much more rapidly than in a form like necturus having much larger legs.

In amphiuma the feet are not used by the animal as organs of locomotion, since they are too small and weak to support the heavy body. They can be moved by the animal in the same way that the feet are moved in other forms, and yet are useless for progression. It is said by Schreiber that the regeneration of the legs of *Triton marmoratus* is relatively very slight as compared with that of other forms. Fraisse also found in this form that an amputated leg did not grow again, only a deformed stump being produced. The tail, also, is said to regenerate to only a slight extent, but, so far as I know, there is nothing peculiar in the life of this form that makes it less liable to injury than other large urodeles.* Weismann cites the case of proteus that is said also to regenerate less well than do other forms. It lives in the caves of Carniola, where there are few other animals that could attack or injure it, and to this immunity is ascribed its lack of power of regeneration, yet Goette states that he observed a regenerating leg in this form, but that the process was not complete after a year and a half. In necturus also, which is not protected in any way, regeneration is equally slow. Frogs are unable to regenerate their limbs, although they are sometimes lost, but the larval tadpole can regenerate at least its hind legs. In the reptiles the tail regenerates, though this is ac-

* I do not know whether this animal was kept long enough to make it certain that the legs do not regenerate.

complished more readily in some groups than in others, but at present we do not know of any connection between this condition and the liability of certain forms to injury. Turtles and snakes do not regenerate their tails. I do not know of any observations on crocodiles.

In birds, the legs and wings are not supposed to have the power to regenerate,* but in two forms † at least the beak has been found to possess remarkable powers of regeneration. There are a few very dubious observations in regard to the regeneration in man of superfluous digits that had been cut off. ‡

These examples might be added to by others in the groups cited, and also by examples taken from the smaller groups of the animal kingdom, but those given will suffice, I think, to show that the power to regenerate is characteristic of entire groups rather than individual species. When exceptions occur, we do not find them to be forms that are obviously protected, but the lack of regeneration can rather be accounted for by some peculiarity in the structure of the animal. If this is borne in mind as well as the fact that protected and unprotected parts of the same animal regenerate equally well, there is established, I think, a strong case in favor of the view that there is no necessary connection between regeneration and liability to injury. We may, therefore, leave this side of the question and turn our attention to another consideration.

It will be granted without argument that the power of replacement of lost parts is of use to the animal that possesses it, especially if the animal is liable to injury. Cases of usefulness of this sort are generally

* A statement to the contrary quoted in Darwin's 'Animals and Plants under Domestication,' is doubted by Darwin himself.

† The stork and the fighting cocks.

‡ See Darwin, *loc cit.*

spoken of as adaptations. The most remarkable fact in connection with these adaptive responses is that they take place, in some cases at least, in parts of the body where they can never, or at most very rarely, have taken place before, and the regeneration is as perfect as when parts liable to injury regenerate. Another important fact is that in some forms the regeneration is so slow that if the competition amongst the animals was very keen, those with missing legs, or eyes, or tails, would certainly succumb; yet if protected they do not fail to regenerate. If, therefore, the animal can exist through the long interval that must elapse before the lost part regenerates, we can not assume that the presence of the part is of vital importance to the animal and hence its power to regenerate could scarcely be described as the result of a 'battle for existence,' and without this principle 'natural selection' is powerless to bring about its supposed result.

It is extremely important to observe that some cases, at least, of regeneration are not adaptive. This is shown in the case where a new head regenerates at the posterior end of the old one in *Planaria lugubris*, or where a tail develops at the anterior end of a posterior piece of an earthworm, or when an antenna develops in place of an eye in several crustacea. If we admit that these results are due to some inner laws of the organisms, and have nothing to do with the relation of these organisms to the surroundings, may we not apply the same principle to other cases of regeneration in which the result is useful?

So firm a hold has the Darwinian idea of utilitarianism over the thoughts of those who have been trained in this school, that whenever it can be shown that a structure or a function is useful to an animal it is without further question set down as the result of the death struggle for existence.

A number of writers, being satisfied that the process of regeneration is useful to the animal, have forthwith supposed that, *therefore*, it must have been acquired by natural selection. Weismann has been cited as an example, but he is by no means alone in maintaining this attitude. It would be entirely out of place to enter here into a discussion of the Darwinian theory, but it be well worth while to consider it in connection with the problem of regeneration.

We might consider the problem in each species that we find capable of regenerating; or if we find this too narrow a field for our imagination we might consider the process of regeneration to have been 'acquired by selection in the lower and simpler forms' and trace its subsequent progress as it decreased in the course of phylogeny 'in correspondence with the increase in complexity of organization' or with the decrease of exposure to injury. At the risk of following the narrower point of view I shall confine the discussion to the possibility of regeneration being acquired, or even augmented, through a process of natural selection in any particular species.

The opportunity to regenerate can only occur if a part is removed by accident or otherwise. On the Darwinian theory we must suppose that of all the individuals of each generation that are injured *in exactly the same part of the body*, only those have survived or have left more offspring that have regenerated. In order for selection to take place it must be supposed that amongst these individuals injured *in exactly the same region* regeneration has been better in some forms than in others, and that this difference is, or may be, decisive in the competition of the forms with each other. The theory does not inquire into the origin of this difference between individuals, but rests on the assumption of individual differences in the power to regenerate, and assumes that

these differences can be heaped up by the survival and inbreeding of the successful individuals, *i. e.*, it is assumed that, by this picking out or selection through competition in each generation of the individuals that regenerate best, the process will become more and more perfectly carried out in the descendants until at last each part has 'acquired' the power of complete regeneration.

There are so many assumptions in this argument, and so many possibilities that must be realized in order that the result shall follow, that, even if the assumptions were correct, one might still remain skeptical in regard to the possibilities ever becoming realized. If we examine somewhat more in detail the conditions necessary to bring about this supposed process, we shall find ample grounds for doubt, and even, I think, for denial, that the results could ever have been brought about in this way.

In the first place the assumption that the regeneration of an organ can be accounted for as a result of the selection of those individual variations that are somewhat more perfect, rests on the grounds that such variations occur, for the injury itself that acts as a stimulus is not supposed to have any direct influence on the result, *i. e.*, for better or worse. All that natural selection pretends to do is to build up the complete power of regeneration by selecting the most successful results in the right direction. In the end this really goes back to the assumption that the tissue in itself has a fuller power to regenerate completely in some individuals than in others. It is just this difference, if it could be shown to exist, that is the scientific problem. But, even leaving this criticism to one side, since it is very generally admitted, it will be clear that in many cases most of the less complete stages of regeneration that are assumed to occur in the phyletic series could be, in each case, of very little use to the

individual. It is only the completed organ that can be used; hence the very basis of the argument falls to the ground. The building up of the complete regeneration by slowly acquired steps, that can not be decisive in the battle for existence is not a process that can be explained by the theory.

There is another consideration that is equally important. It is assumed that those individuals, that regenerate better than those that do not, survive, or at least have more descendants; but it should not be overlooked that the individuals that are not injured (and they will belong to both of the above classes) are in even a better position than are those that have been injured and have only incompletely regenerated. The uninjured forms, even if they did not crowd out the regenerating ones, which they should do on the hypothesis, would still intercross with them, and in so doing bring back to the average the ability of the organism to regenerate. Here we touch upon a fatal objection to the theory of natural selection that Darwin himself came to recognize in the later editions of the 'Origin of Species,' viz., that unless a considerable number of individuals in each generation show the same variation the result will be lost by the swamping effects of intercrossing. If this be granted, there is left very little for selection to do except to weed out a few unsuccessful competitors, and if the same causes that gave origin to the new variation on a large scale should continue to act, it will by itself bring about the result, and it seems hardly necessary to call in another and questionable hypothesis.

Finally, a further objection may be stated that in itself is fatal to the theory. We find the process of regeneration taking place not only at a few vulnerable points, but in a vast number of regions, and in each case regenerating only the missing part. The leg of a salamander can regenerate from every

level at which it may be cut off. The leg of a crab also regenerates at a large number of different levels, and apparently this holds for all the different appendages. If this result had been acquired through the action of natural selection, what a vast process of selection must have taken place in each species! Moreover, since the regeneration may be complete at each level and in each appendage without regard to whether one region is more liable to injury than is another, we find in the actual facts themselves nothing to suggest or support such a point of view.

If, leaving the adult organism, we examine the facts in regard to regeneration of the embryo, we find again insurmountable objections to the view that the process of regeneration can have been produced by natural selection. The development of whole embryos from each of the first two or first four blastomes can scarcely be accounted for by a process of natural selection, and this is particularly evident in those cases in which the two blastomeres can only be separated by a difficult operation and by quite artificial means. If a whole embryo can develop from an isolated blastomere, or from a part of an embryo without the process having been acquired by natural selection, why apply the latter interpretation to the completing of the adult organism?

Several writers on the subject of regeneration in connection with the process of autotomy (or the reflex throwing off of certain parts of the body) have, it seems to me, needlessly mixed up the question of the origin of this mechanism with the power of regeneration. If it should prove true that in most cases the part is thrown off at the region at which regeneration takes place to best advantage, it does not follow at all that regeneration takes place here better than elsewhere, because in this region a process of selection has most often

occurred. The phenomenon of regeneration in the arm of the starfish, that has been described on a previous page shows how futile is an argument of this sort. If, on the other hand, the autotomy is supposed to have been acquired in that part of the body where regeneration takes place to best advantage, then our problem is not concerned with the process of regeneration at all, but with the origin of autotomy. If the attempt is made to explain this result also as the outcome of the process of natural selection acting on individual variations, many of the criticisms advanced in the preceding pages against the supposed action of this theory in the case of regeneration, can also readily be applied to the case of autotomy.

T. H. MORGAN.

*SOME CONDITIONS INFLUENCING SUCCESS
AT SCHOOL.*

THE law of universal variation as demonstrated by the pupils of our public schools has presented a most difficult problem to the superintendent. He is 'between the devil and the deep sea' in his attempts to give the individual his rights, and at the same time conform to a system which is capable of turning out good material in large quantities. Procrustean beds, with semi-elastic foot-boards are about the best that can be provided for the little folks in the large cities, even under the best conditions. The problem is an important one and far from a satisfactory solution, but we have all confidence in the brains which are brought to bear upon it, and it cannot be very long before some one of the systems which are now in the experimental stage will show itself worthy of more extended adoption. Whatever variety there may be in the attempts to solve this problem of promotion in the schools—for after all, it resolves itself to that—there are certain facts

underlying it upon which there is a most perfect consensus of opinion. One of them is the universal variability already alluded to. In every grade known to modern school systems are found some pupils who seem to fit the conditions almost perfectly and others who are palpable misfits. They are not only misfits where they are, but have always been so wherever they have been, and will probably remain misfits to the end of the school chapter. This is not to characterize them as useless members of society, nor as vicious, but simply as odd-shaped cogs which do not quite fit the educational mechanism. Clumsy machinery might work fairly well with them, but not the carefully adjusted tools of a big public-school plant, and some modifications must be made for them. Nor are these failures to coincide all in the same degree. Some go through the whole mill with only a moderate amount of friction. Others find

This study does not present a panacea for these difficulties. It is not remedial, but rather in the nature of a further diagnosis of the conditions. It asks the question: What physical and mental conditions in the child most often accompany success and failure in grade work? It also attempts to answer the question for the limited field covered.

The method and scope of the problem are as follows: About 2,000 copies of the blank here printed were sent out to the superintendents of schools in eight cities and towns of the State of Colorado, who had, in response to a letter previously sent out, signified their willingness to help with the problem. Colorado towns were not chosen because of any special geographical value, but for the simple reason that I was a resident of the State and acquainted with its educators. In fact, the geographical restriction perhaps limits the value of the

the wheels revolving too rapidly or too slowly. For the former, some parts must be gone through twice, for the latter, time is wasted. The greatest good for the greatest number is all that can be hoped for and in its accomplishments some few may long have to suffer for the weal of the many.

study, rather than enhances it. With the blanks were sent out full directions for filling them out. (1) That they be given only to such teachers as the superintendent felt would do the work with care and good judgment. (2) That the teachers to whom they were intrusted fill out one blank for each pupil in the grade, putting an X in

the proper space under each question. (3) That for each question there be an equal number for every grade, included in each of the four divisions of the question—*i. e.*, in the case of the first question for a grade of 32 pupils, let 8 be put down as tall and the same number for each of the other three classifications, and the same be done as nearly as possible for all the other questions (except 8). This it may be seen demanded careful judgment and discrimination on the part of the teacher, and I cannot vouch for its accuracy, but knowing many of the teachers as I do, I believe the returns are as valid as can be expected from any work of this kind. In the directions especial attention was called to the fact that answers to 9 and 10 were not to be based upon immediate judgment, but upon that of the past as far as possible. No exact measurements were called for even in cases of 1 and 2. The values are in every case relative and in this respect differ from those of other studies of a similar nature. This method has some advantages and some disadvantages. It obviates the necessity for exact measuring apparatus which the teacher might not know how to use, although it introduces an error of individual judgment. The important thing is, however, that we have for every individual grade or room considered, the fourfold classification along nine different lines, by a tabulation of which it is possible to determine whether, right through the grades, the pupils successful with their school work were as a rule the tall or the short ones, the heavy or the light, the healthy or the sickly ones, and by a fuller analysis possibly throw more light on the relative values of other conditions of heredity and environment.

In the preparation of the accompanying curves the data for only 1,000 pupils were used, and those wholly from the grades below the 7th. This was done that with

a later study a comparison might be made between the non-adolescent stage covered by this paper and the adolescent, made up of pupils of the 7th and 8th grades and possibly the first year or two of the high school.

The curves shown on the accompanying figures are all constructed upon the same general principles, and show the relation between the conditions of heredity and environment covered by the questions 1 to 9, inclusive (except 8), and success in school work covered by question 10. In other words, an attempt to show graphically the influence of the former upon the latter. Each figure shows this relation for a single one of the first nine questions. Neither specific grade nor age is considered, the grades from one to six being taken as a group. For each figure, the four columns represent the 1st, 2d, 3d and 4th quarter of the 1,000 pupils considered with respect to the condition of question 10, which has to do with their grading in school work. In every case the 1st column has to do with the pupils at the head of the class; the 4th with those at the foot; the other two, those of intermediate grading.

The curves upon the figures are for the condition covered by the other questions, and by their ordinate distances (*i. e.*, height above the base-line) show the relation between them and the grading. To explain more fully, upon each figure the heavy entire curve is for the first part of the question, tall, heavy, perfect, bright, etc., according as it is on the figure for height, weight, health, native ability, etc.; the dotted curve for the 'above medium' points of the question; the broken curve for the 'below medium'; and the light, entire curve for the remainder—the short, light, poor, dull, etc. Ordinate distances show percentages of children of each condition of heredity and environment in any of the divisions of the class with reference to the grading.

To interpret Fig. 1, which is for condition of height in terms of this description, by following the heavy curve—that for children designated 'tall'—we find that 8 per cent. (in every case omitting fractions of percentages) of such children were in the 1st quarter of the class in their grading (left-hand column), 23 per cent. in the 2d quarter (3d column), 28 per cent. in the 3d quarter (3d column), and 32 per cent. in the quarter at the foot of the class as far as scholarship goes (last column). By following in the same way the dotted, the broken and the light entire curve we can see the relation between the children adjudged to be above medium, below medium and short of stature. To generalize from the figure as a whole, its indications are that the short children, as a class, were the ones for whom promotion was most probable, while the tall children seem to stand lower in their school work according to

FIG. 1. Height.

the estimation of their teachers. This is not in accordance with the conclusions of some others who have studied the same problem; notably, MacDonald (see 'Ex. Study of Children,' *U. S. Com. Ed.*, 1897-8, Vol. I.), who finds a slight preponderance of height in favor of the bright pupils. A fixed relation, however, may exist between

height and physical conditions, and since the latter forms the basis of study for another figure I shall allude to it under that.

WEIGHT.

The curves upon Fig. 2, and the succeeding ones are to be determined exactly as the preceding. We find from an inspection of Fig. 2 that the heavy children gravitate toward the foot of the class, though not to a very marked degree. From the study of the separate sexes I find this to be more marked for the boys than the girls, though showing slightly for the latter. In the re-

FIG. 2. Weight.

lation between weight and success in school work shown here we are also opposed by the authority just cited, as MacDonald states that in height, sitting height, weight and cranial circumference the bright boy excels the dull. This contradiction may be due to geographical differences. Something more than three-fourths of the children included in my study were residents of the mountain towns of an altitude of nearly two miles, and none were much lower than one mile. If the differences be due to this fact they are in accord with general anthropological studies made upon adults.

HEALTH.

We find upon Fig. 3 a very probable corroboration of the old dictum *mens sana in*

corpore sano. The seeming influence of good health upon good standing is certainly very marked, and the symmetry of the two curves for good and poor health is very striking. The study of the two sexes separately seems to throw some interesting side lights. For the boys and girls in perfect health about the same conditions are indicated as for the two groups, but for poor health it would seem that the direction is given the curve mainly by the boys. The percentages of girls of poor health in the 1st and 4th quarters of the class as to scholarship were the same (26 per cent.), while less than 1 per cent. of the boys in poor health were at the head of the class to 40 per cent. of them at the foot. This would seem to imply that even before the adolescent stage of development the girls have the power of forcing themselves to do work even when vitality is low, which has generally been attributed to them only at a

NATIVE ABILITY AND HABIT.

Conclusions based upon the answers to their questions have perhaps less value

FIG. 4. Native Ability.

than any of the others, because of the difficulty the teacher must have in disassocia-

FIG. 3. Health.

later stage. If so, it is a fact which deserves more attention from the teacher, for it can only be accomplished at the expense of energy which is demanded by other activities. Pride and over-sensitiveness are responsible for many evils and probably are in evidence here.

FIG. 5. Habit.

ting the conditions from those of scholarship

with which they are to be compared. When the teacher was answering them for a given pupil she could hardly fail to have in mind his class standing and be influenced by it; one can hardly tell how much influence this might have upon the results. We should expect, however, on other grounds to find the bright and industrious pupils in the 1st quarter of the class as to grading, and *vice versa*, and the curves show them to be there. Based upon the teachers' judgment, there seems to be little difference in the influence for the two sexes. In each case about half of the bright and industrious pupils were at the head of the class, while the other half were unequally distributed through the other three divisions, with very few at the foot.

TEMPERAMENT.

Fig. 6 shows that the children whom the teacher characterized as 'nervous' pre-

FIG. 6. Temperament.

ponderated in the upper half of the class, considered from the standpoint of work. No directions were given as to classification under this head, and we cannot say that all had the same conception as to its meaning. The term may be made to cover a multitude of different manifestations, but it is perhaps safe to conclude that for the most

it meant an excess of energy worked off through motor channels other than those of the legitimate business of the school. It will be noticed that the greatest percentage of 'nervous' children were in the 2d quarter of the class, with the first showing them next in abundance. This would seem to imply that an abundance of nervous energy is essential to good work but somewhat detrimental to the best of work. It has perhaps been noticed that in our treatment of the whole problem we have been forced to study each condition as if the others were not at the same time active. That is, in isolating the matter of temperament for the curves under discussion, we have disregarded native ability, habit, health and all the rest between which and temperament there may exist a fixed relation. In fact, it would be quite reasonable to suppose that such a relation did exist between some of them, and perhaps the most probable would be that between temperament and health. It was proved that children of poor health were seldom found at the head of the class. But children of poor health are not infrequently excessively nervous. Putting these two facts together, the failure to find the greatest number of nervous children in the 1st quarter of the class seems quite reasonable. For the other extreme of nervousness, which I have characterized as 'stolid,' there is a gradual increase in number from the head to the foot of the class. With the girls there seemed to be the greatest difficulty in overcoming the seeming impediment of stolidity, there being but a fraction over 1 per cent. of those so characterized in the 1st quarter of the class. Perhaps they lacked to an extreme the elements of pride, which is such an instigation to work.

HOME CONDITIONS.

The directions for answering this question stated that home conditions which

were to be considered as good were those which were considered as conducive to study and regular attendance at school, while bad home conditions were those that made this improbable. The latter might be due either to the general attitude of the parents toward school work in general, or the economic condition which left little time for study or caused frequent absences. The curves upon Fig. 7 are about what might with reason be expected, showing but a small chance for good scholarship under the latter condition. The study of the two sexes separately showed that the home influences had a wonderfully more tenacious grip upon the girls than upon the boys; less than 1 per cent. of the former whose home conditions were designated as poor, could force themselves into the 1st quarter of the class, while 20 per cent. of the boys managed to pull themselves out of the mire to that standing. Washing dishes

more dominating influence upon the girl of the attitude of the home toward educational matters. She can hardly escape from it. She carries it to school with her, and if it be poor it drags her down. With the boy it is different. A game of ball or of marbles before school puts him into another world, and he does not reenter the depressing one of home until he is forced to, and even then he makes an early escape.

DEPARTMENT.

I do not consider the curves upon Fig. 8 of much value. They show a very marked relation between good department and good

FIG. 7. Home Condition.

and doing other home duties may have had something to do with the difficulties of the girls—duties from which the boys frequently escape—but I am inclined to think that the difference is largely due to the

FIG. 8. Department.

class standing, but it takes a very hard-hearted teacher to give the best pupil in the grade, or those who are pushing him closely for honors, a mark for bad department, and I know the good teachers of Colorado too well to believe that they could easily do it. His marks, by a kind of mental osmosis intermingle, and with all respect for the good intentions of the teacher, I put this in more as a study of them and an apostrophe to

their good nature than as having any great scientific value from the standpoint of our problem.

EDWIN G. DEXTER.

UNIVERSITY OF ILLINOIS.

MEMBERSHIP OF THE AMERICAN
ASSOCIATION.

THE following have completed their membership in the American Association for the Advancement of Science during the month of July:

Frank Anderson, Mining Engineer, 255 East 2nd St., Salt Lake City, Utah.

William S. Andrews, Electrical Engineer, care of General Electric Co., Schenectady, N. Y.

Marshall H. Bailey, M.D., 47 Brattle St., Cambridge, Mass.

Professor Solon I. Bailey, Associate Professor of Astronomy, Harvard College Observatory, Cambridge, Mass.

Wm. C. Banks, Electrician, Gordon Battery Co., New York, N. Y.

Philip P. Barton, Superintendent Niagara Falls Power Co., 127 Buffalo Ave., Niagara Falls, N. Y.

James P. Baxter, President Maine Historical Society, Portland, Me.

Josiah H. Benton, Jr., Lawyer, Ames Building, Boston, Mass.

Clarence H. Blackall, Architect, 1 Somerset St., Boston, Mass.

Joseph E. Blackburn, State Dairy and Food Commissioner, Box 231, Columbus, O.

Miss Charlotte Bowditch, Pond St., Jamaica Plain, Mass.

Edward C. Briggs, Professor of Dental Materia Medica and Therapeutics, Harvard Medical School, Boston, Mass.

Paul T. Brodie, Professor of Mathematics, Clemson College, S. C.

Rev. Earle A. Brooks, 161 Laidley St., Charleston, W. Va.

Joseph S. Brown, 241 South 5th St., Reading, Pa.

Luther Burbank, Horticulturist, Santa Rosa, Cal.

I. Tucker Burr, Jr., Banker, Readville, Mass.

Irvin Butterworth, Denver Gas and Electric Co., Denver, Colo.

Charles T. Carnahan, Mining Engineer, Equitable Building, Denver, Colo.

Dr. Franklin R. Carpenter, Mining Expert, 1420 Josephine St., Denver, Colo.

Ermine C. Case, Professor of Chemistry and Geology, State Normal School, Milwaukee, Wis.

Ernest P. Clark, 229 W. 18th St., New York, N. Y.
Solomon S. Cohen, M.D., 1525 Walnut St., Philadelphia, Pa.

Professor Theodore B. Comstock, Mining and Metallurgical Engineer, 534 Stimson Building, Los Angeles, Cal.

Robert A. Cooley, Zoologist and Entomologist, Montana Agricultural College, Bozeman, Mont.

A. Beekman Cox, Civil Engineer, Cherry Valley, N. Y.

Hugh W. Crouse, M.D., Victoria, Texas.

Clayton E. Crafts, Lawyer, 5433 Washington Boulevard, Chicago, Ill.

John F. Crowell, Bureau of Statistics, Treasury Department, Washington, D. C.

Dr. Charles W. Dabney, President of University of Tennessee, Knoxville, Tenn.

Isaac N. Danforth, M.D., 70 State St., Chicago, Ill.

Francis H. Davenport, M.D., 419 Boylston St., Boston, Mass.

Major George M. Derby, Corps of Engineers, U. S. A., 3232 Prytania St., New Orleans, La.

Samuel G. Dixon, M.D., Bacteriologist, Academy of Natural Sciences, 1900 Race St., Philadelphia, Pa.

Russell Duane, Lawyer, Box 193, Northeast Harbor, Me.

Henry B. Duncanson, Professor of Biology, State Normal School, Peru, Nebr.

E. Dysterud, Electrical Engineer, Monterey, Mexico.

Richard H. Edmonds, Editor of *Manufacturers' Record*, Baltimore, Md.

Anton F. Eilers, Mining Engineer and Metallurgist, 751 St. Marks Ave., Brooklyn, N. Y.

Frederic A. Emmerton, 9 Bratenahl Building, Cleveland, Ohio.

John W. Finch, State Geologist, Victor, Colo.

Washington E. Fischel, M.D., 2647 Washington Ave., St. Louis, Mo.

Walter C. Fish, General Electrical Co., Lynn, Mass.

James S. Foote, M.D., Professor of Histology, Creighton Medical College, Omaha, Nebr.

Professor Chas. K. Francis, Adjunct Professor of Chemistry, Georgia School of Technology, Atlanta, Ga.

Charles W. Frederick, Computer, United States Naval Observatory, Washington, D. C.

Augustus H. Fretz, Doylestown, Pa.

Arthur L. Fuller, Brunner, Texas.

Edward L. Fullmer, Professor of Natural Science, Dakota University, Mitchell, S. D.

Robert B. Fulton, Chancellor, University of Mississippi, University, Miss.

George R. Gaither, Ex-Attorney-General of Maryland, 1310 Continental Building, Baltimore, Md.

Miss Emily R. Gregory, Ph.D., Biological Laboratory, S. Harpswell, Maine.

General Eugene Griffin, First Vice-president General Electrical Company, 44 Broad St., New York, N. Y.

Lyman Hall, President of Georgia School of Technology, Atlanta, Ga.

Judson B. Ham, Teacher of Natural Science, State Normal School, Johnson, Vt.

Dr. Henry J. Harnly, Professor of Biology, McPherson College, McPherson, Kan.

Dr. Chauncey G. Hellick, Architect and Engineer, 203 Washington St., Chicago, Ill.

Richard Herrmann, Secretary Institute of Sciences and Arts, Dubuque, Ia.

Adolph Herthel, Banker, 1739 Waverly Place, St. Louis, Mo.

John C. Higdon, Lawyer and Mechanical Engineer, 605 Union Trust Building, St. Louis, Mo.

Frederick J. Hillig, S. J., Professor of Sciences, Canisius College, Buffalo, N. Y.

Miss Caroline J. Hitchcock, Teacher, High School, Meriden, Conn.

Thomas E. Hodges, Professor of Physics, State University, Morgantown, W. Va.

Christian B. Hoffman, Enterprise, Kan.

Herman L. Holbrow, Electrical Engineer, Morro Villa, 17th Ave., Bath Beach, Brooklyn, N. Y.

Dr. Gilbert L. Houser, Professor of Animal Morphology and Physiology, University of Iowa, Iowa City, Iowa.

Michael W. Jacobs, Lawyer, Harrisburg, Pa.

Wm. J. Jenks, Electrical Engineer, 120 Broadway, New York, N. Y.

Wm. A. Johnston, Manufacturer, Prince Bay, Borough of Richmond, N. Y.

Jacob A. Kammerer, 87 Jameson Ave., Toronto, Canada.

Edward T. Keim, Superintendent American District Telegraph Co., 1447 Lawrence St., Denver, Colo.

Dr. John F. Kelly, Consulting Electrical Engineer, 284 West Housatonic St., Pittsfield, Mass.

Dr. Norton A. Kent, Assistant in Spectroscopy, Yerkes Observatory, Williams Bay, Wis.

S. L. G. Knox, Engineer of Draft Department, General Electrical Co., Schenectady, N. Y.

Adolph Koenig, M.D., Editor *Pennsylvania Medical Journal*, 122 Ninth St., Pittsburg, Pa.

Dr. Arthur Lachman, Professor of Chemistry and Dean of College of Science and Engineering, University of Oregon, Eugene, Ore.

Philip A. Lange, Superintendent Westinghouse Electrical and Manufacturing Co., Pittsburg, Pa.

Francis V. T. Lee, Electrical Engineer, 31 and 33 New Montgomery St., San Francisco, Cal.

Dr. Milton J. Lichty, Physician and Surgeon, East Market St., Alliance, O.

John Littlefield Tilton, Professor in Simpson College, Indianola, Ia.

James Lyman, Assistant Engineer, General Electrical Co., 1047 Monadnock Building, Chicago, Ill.

Henry McCalley, Chief Assistant State Geologist, University, Ala.

C. A. H. McCauley, Colonel and Deputy Quartermaster-General, United States Army, Manila, P. I.

Charles H. McMahan, Mining Engineer, Sombrerete Mining Co., Sombrerete, Zacatecas, Mexico.

John L. Malm, Cyanide and Mining Expert, First National Bank Building, Helena, Mont.

Miss Nellie M. Mason, Teacher of Science in Abbot Academy, Andover, Mass.

Ellwood V. Matlack, Secretary and Manager, Laclede Power Co., St. Louis, Mo.

Earle A. Merrill, 26 Courtland St., New York, N. Y.

Russell L. Morris, Professor of Civil and Mining Engineering, West Virginia University, Morgantown, W. Va.

Lycurgus R. Moyer, Civil Engineer, Montevideo, Minn.

John Neilson, Larchmont, N. Y.

John C. Olmsted, Landscape Architect, 16 Warren St., Brookline, Mass.

Robert Treat Paine, President Associated Charities of Boston, 6 Joy St., Boston, Mass.

C. Wellman Parks, U. S. N., Civil Engineer, Bureau of Navigation, Washington, D. C.

Fred S. Pearson, Consulting Engineer, Room 840, Cable Building, 621 Broadway, New York, N. Y.

Niels F. Petersen, Teacher, Plainview, Nebr.

Sidney Peterson, Teacher of Chemistry and Botany, Classical High School, Worcester, Mass.

Wm. J. Phelps, Manager the Phelps Co., Mfg. Hylo Inc. Lamps, Detroit, Mich.

Sloan J. Pierce, Geology, 512 Hickox Building, Cleveland, Ohio.

Alexander Pratt, Jr., 26 Bunnell St., Bridgeport, Conn.

John E. Randall, Superintendent and Electrical Engineer, Columbia Inc. Lamp Co., 4960 Lotus Ave., St. Louis, Mo.

Edwin W. Rice, Jr., General Electrical Co., Schenectady, N. Y.

William Henry Richmond, Coal Mining, 3425 North Main Ave., Scranton, Pa.

Dr. Theodore R. Running, Professor of Mathematics and Natural Sciences, St. Olaf College, Northfield, Minn.

Miss Eliza D. Sackett, Cranford, N. J.

Mariano L. Schiaffino, Chief Electrical Engineer of 'Campania de Luz de Guadalajara,' Belen, No. 2, Apartado 260, Guadalajara, Mexico.

Lawrence F. Schmeckebier, Ph.D., U. S. Geological Survey, Washington, D. C.

Samuel C. Shaffner, Engineer, Mobile Gas Light and Coke Co., Mobile, Ala.

Friench Simpson, Jr., Medical Student, Columbus, Texas.

George P. Singer, Professor of Physics, Central State Normal School, Lock Haven, Pa.

Dr. Robert L. Slagle, President State School of Mines, Rapid City, S. D.

Edwin E. Slosson, Professor of Chemistry, University of Wyoming, Laramie, Wyo.

Martin Smallwood, Professor of Biology and Geology, Allegheny College, Meadville Pa.

C. C. Sprague, 1900 Locust St., St. Louis, Mo.

William Stanley, Great Barrington, Mass.

Dr. Halbert S. Steensland, Director of Pathological Laboratory, College of Medicine, Syracuse, N. Y.

Frederick G. Strong, Box 959, Hartford, Conn.

H. A. Surface, Professor of Zoology, Pennsylvania State College, State College, Pa.

James Taussig, Jamestown, R. I.

Wilber J. Teeters, Instructor in Pharmacy, State University, Iowa City, Iowa.

Wm. Mayo Venable, Civil and Electrical Engineer, 713 Hennen Building, New Orleans, La.

Dr. Alex S. von Mansfelde, 'Quality Hill,' Ashland, Nebr.

Frederick K. Vreeland, Electrical Engineer, Box 1877, New York, N. Y.

Miss Kate Elizabeth Williams, 1450 Pearl St., Denver, Colo.

Wm. C. Woodward, Consulting Electrical Engineer, Union R. R. Co., Providence, R. I.

Alfred F. Wuensch, 1556 Detroit St., Denver, Colo.

SCIENTIFIC BOOKS.

RECENT BOOKS ON PHYSICS.

Natural Philosophy for General Readers and Young People. Translated from Ganot's 'Cours élémentaire de physique,' by E. ATKINSON. Ninth edition, revised by A. W. REINHOLD. Longmans, Green & Co. 1900. Pp. 752.

Elements of Physics. By C. HANFORD HENDERSON and JOHN F. WOODHULL. D. Appleton & Co. 1900. Pp. 388.

A Brief Course in General Physics. By GEORGE A. HOADLEY. American Book Company. 1900. Pp. 463.

One Thousand Problems in Physics. By WILLIAM H. SNYDER and IRVING O. PALMER. Ginn & Co. 1900. Pp. 142.

A Manual of Laboratory Physics. By H. M. TORY and F. H. PITCHER. John Wiley & Sons. 1901. Pp. 288.

Advanced Exercises in Practical Physics. By ARTHUR SCHUSTER and CHARLES H. LEES. England, Cambridge University Press; New York, The Macmillan Company. 1901. Pp. 368.

It was in 1863 that Dr. Atkinson first put before English readers his excellent translation of Ganot's 'Éléments de Physique,' a book which quickly won favor by its good arrangement and lucidity. In the first edition he graciously apologized for the use of the metric system. It has passed through fifteen or more editions since its introduction. A demand soon arose for the more elementary course by the same French author, as a text-book for the middle and upper classes of schools preparatory to college. The popularity of this is manifested by the appearance now of its ninth edition, a considerable part of which had been prepared for the press before the death of Dr. Atkinson. The present volume has all the excellences of its predecessors, the illustrations being abundant, and some of them possibly a trifle too expensive. Colored lithographs of metallic spectra and of Geissler tube discharges were formerly fashionable, but in a general treatise to-day they seem almost out of date. For the general reader it would be hard to find a more pleasant and satisfactory book than this volume. For American school purposes, however, it is too diffuse; and it seems adapted only for recitatorial purposes where oral answers are given to questions relating to descriptive details and general principles. Physics is nothing if not a quantitative science. This idea is best instilled into the elementary student, even though his mathematical attainments be not sufficient to warrant the use of complex problems.

The present volume illustrates the difficulty of maintaining a text-book up to date by slight modifications and additions applied in succession to a long series of new editions. As years pass on, the necessity for omissions becomes as

important as for additions. On page 207 a paragraph about the audiphone states that "not merely deaf people, but even those who are deaf and dumb, can hear musical sounds and even speech." The amiable admission implied in what the present writer italicizes is evidently due to the acceptance of a Chicago advertisement. On page 370, in discussing the mechanical equivalent of heat, the name of Rowland has been forgotten by the reviser. A few wood cuts might have been omitted, such as that (page 27) in which the source of the wind that propels a sail-boat is a cherub face nestled among the clouds, its cheeks distended to the bursting point.

The 'Twentieth Century Text-book,' by Henderson and Woodhull, is decidedly more modern, and is comparable with Ganot in the abundance and attractiveness of the illustrations. An appeal is made to the student's human sympathies by the introduction of portraits, with short life sketches, of men whose researches have enlarged the domain of physics, such as Newton, Franklin, Tyndall, Faraday and Lord Kelvin. To this list is added Mozart, naturally in the chapter on music. A comparison of this chapter with those on heat and electricity indicates plainly, without reference to the title page, that the book has been prepared by two men of quite different tastes and aptitudes. The introductory chapters and those on sound and music indicate a writer whose fondness for metaphysics and æsthetics is quite equal to his appreciation of physics. A prosaic student, after studying through the first chapter, is stimulated by such problems as these :

1. "Select five events and analyze them into their matter and motion content."

2. "If a monkey sit on the top of a pole, and always face a man who walks around the pole, with his face always turned toward the monkey, can the man be said to walk around the monkey?"

The mathematical solution of the second problem is easy. Teachers may differ about the metaphysical solution. In the chapter on music are introduced themes from Beethoven, Schumann and Palestrina, in musical notation, as illustrations of melody, harmony and coun-

terpoint, respectively. The authors in their preface give the opinion that "laboratory exercises, questions and problems given in a text-book are manifestly inadequate and unsatisfactory." This expresses quite a reaction from the popular tendency manifested some years ago, especially in the text-books by Gage and Avery. Many will sympathize with them in thinking that the laboratory guide book and the class text-book should be kept separate. Printed questions are often less valuable than those formulated for the occasion by an experienced teacher. It is not so obvious, however, that problems should be excluded; indeed there are probably few teachers of physics who would agree with the present authors on this point. In fact the first part of the book includes several dozen problems and experiments, a few of which are not very well selected. The general style, selection of material and mode of treatment are, however, good, and the book will probably be popular, particularly on account of the emphasis given to the relations of physics on all sides to human life and the interests of educated people.

The leading idea in Hoadley's text-book is to insure the coordination of reliability in the text, class demonstrations of stated laws, practical questions and problems on the application of these laws, and personal experimentation in the laboratory. The volume is a combination of text-book and laboratory manual intended to cover the work of a scholastic year in the high school. If it be admitted that two small separate volumes should be so combined—and every teacher has a perfect right to judge for himself about this—the work done by the author is exceedingly good. Considerable labor, it is true, will be required of the teacher who uses this book for the first time, and therefore has to secure the construction of the special apparatus for which the laboratory exercises are adjusted. But these exercises are well selected and well described. The practical questions and problems are numerous, and every page indicates that the author is methodical, careful and well informed regarding the needs and limitations of the class of students for whom he writes. He does not shun algebraic formulas or 'dodge' any real difficulties. Some formulas are given,

without deduction, as statements of physical laws. For elementary students this is often necessary, and the mathematical formulation is quite as desirable as verbal expression. Statements of fact are so generally accurate that the author can afford to be reminded of an error on page 188, where he has defined 'discord' more sharply than the facts warrant, by failure to recognize Mayer's law, which expresses the duration of the residual auditory sensation as a function of vibration frequency, the equation being expressible in a curve which Professor Mayer published in 1894 (*Am. Jour. Sci.*, Jan., 1894). In the chapter on electricity a very clear elementary discussion is given of such recent developments as the Wehnelt interrupter, self-regulating vacuum tubes, and wireless telegraphy. The book is abundantly worthy of commendation.

Snyder and Palmer's little volume on 'Problems in Physics' is a good collection intended for use in secondary schools, every problem having borne already the test of class use. For the convenience of overworked teachers it seems very desirable that a collection of answers should be published. Any competent teacher can work out all these problems for himself; but in the majority of cases it is only necessary that the pupil should work out such as have been assigned him. The teacher may assume the labor of verification wherever this may seem desirable, but he should not be subjected to unnecessary burdens.

Tory and Pitcher's 'Manual of Laboratory Physics' constitutes the course of elementary physics given in the laboratory of McGill University, Montreal. For each experiment there is a list of references, a list of apparatus, a short statement of the theory involved, practical directions, and a tabulated example. The arrangement is excellent, and the deductions of formulæ under the head of 'Theory of Experiment' constitute a good review of principles which the student is supposed to have mastered before entering the laboratory. Like all manuals of this kind, the book is a collection of the separate manuscripts prepared by the authors, while they were associated together as demonstrators in the physical laboratory of McGill University.

The manual by Schuster and Lees covers much the same ground as that of Tory and Pitcher, but the instructions given are more discursive and the book is not so well methodized. For somewhat advanced students, who are not so dependent as the beginner is apt to be on the oral guidance of an instructor, the book will be found very valuable. The authors have not aimed at completeness, 'being convinced that a student learns more by carefully working through a few selected and typical exercises, than by hurrying through a large number, which are often but slight modifications of each other.' They attach great importance to neat and accurate work, recorded in good form. The introductory chapter includes a satisfactory discussion of errors of observation.

The acceptability of a new book depends jointly on the author and the publisher. On opening it the reader expects to be able to consult any page without doing roughly by hand what the publisher ought to have done neatly by machinery. The manual just noticed is mechanically unsatisfactory, because the publishers have been guilty of the unreasonable slovenliness of issuing it with edges untrimmed. This fault is bad enough in the case of a magazine, where the insufficient excuse is to make allowance for future binding; but in the case of a book already bound it is inexcusable. American publishers have for the most part risen superior to such a senseless fad; but in England it seems still to hold sway. The present volume of 368 pages is most readily commended to any one who is willing to cut its leaves, to submit to the inconvenience of frayed edges, and to endure the untidiness of such edges after the book has been in use for some time in the laboratory.

W. LeCONTE STEVENS.

Lehrbuch der vergleichenden Anatomie der wirbellosen Thiere. VON ARNOLD LANG. Zweite umgearbeitete Auflage. Zweite Lieferung. Protozoa, vollständig neu bearbeitet von Arnold Lang. Jena, G. Fischer, 1901. Mk. 10.

That this account of the Protozoa in the second edition of Lang's well-known 'Lehrbuch' is practically a new work is at once evident on

comparing the number of pages it contains with the number devoted to the Protozoa in the first edition of the same work. In the first edition 22 pages with 21 figures were given to this group; here we have 311 pages with 259 figures. The account of the Protozoa has thus been expanded until it occupies more space than was devoted in the first edition to the Protozoa, Porifera, Cnidaria, Plathelminthes and Vermes all together.

This increase in size gives opportunity for a most valuable résumé of the recent investigations among unicellular animals. Research has been exceedingly active among the Protozoa in the last decade, and a connected, well-digested summing up of the results of this and previous work, such as we have here, is most welcome. In the first edition of the 'Lehrbuch' all direct reference by name to the various investigators to whom the work was due was excluded from the text. In this edition Professor Lang wisely gives up this practice, so that the book serves likewise as a valuable introduction to the recent literature and history of the subject.

In plan of treatment there is much similarity to that of the first edition, though with some modifications. Most important of these is perhaps the preliminary monographic treatment (after the systematic outline) of three typical protozoa—a simple rhizopod, *Amoeba* (pp. 35-47); a complicated radiolarian, *Cœlospathis ancorata* (pp. 47-55), and a ciliate infusorian, *Paramecium caudatum* (pp. 55-79). Besides an extended account of the structure, much attention is devoted here to the recent physiological work on these organisms, especially to their movements and reactions. The criticism may be made that the relation of the movements and method of reaction in the infusoria to the form and structure of the organisms is not brought out, although this appears to be the central point in the recent work on this subject.

In the remainder of the work the plan is followed of treating special topics throughout the entire group of Protozoa. Thus, we have chapters on the Protoplasm, the Pellicle, the Nucleus, the Centrosome, Protective Organs, Organs of Movement, Organs of Nutrition, Respiratory and Excretory Organs, Sense Organs,

Reproduction, etc. The treatment is usually satisfactory, and is comparatively full. Thus, in the first edition the Organs of Nutrition are disposed of in a paragraph, while here twenty-five pages are devoted to the subject. Especially full and valuable is the account of the reproductive processes, which occupies nearly half of the text. Here the recent work of Schaudinn and others on the most varied members of the group is reviewed. The prominence of the Sporozoa is throughout noticeable, as compared with any previous general account of the Protozoa. Mention may be made of the especially full accounts of the reproduction and alternation of generations in *Trichosphærium* (Schaudinn), *Coccidium* (Schaudinn), the malaria parasite (pp. 229-239), and the Volvocidæ.

The text is clearly written, in an attractive style, and is well illustrated. Exception may perhaps be taken to the large figure of *Paramecium* on page 56, which shows an unnatural shape, deformed by pressure, and is so coarsely drawn as to be misleading.

The book forms an essentially independent work on the Protozoa, and is furnished with extensive literature lists, a table of contents, a table indicating references in the text to organisms usually studied in laboratory courses, an alphabetical list of figures and a full index. It will be found valuable to every one interested in this fundamental group of animals.

H. S. JENNINGS.

Morphology of Spermatophytes. By JOHN M. COULTER, Ph.D., Head of the Department of Botany in the University of Chicago, and CHARLES J. CHAMBERLAIN, Ph.D., Instructor in Botany in the University of Chicago. New York, D. Appleton and Company. 1901. Octavo. Pp. x + 188.

Methods in Plant Histology. By CHARLES J. CHAMBERLAIN, Ph.D., Instructor in the University of Chicago. Chicago, The University of Chicago Press. 1901. Octavo. Pp. viii + 160.

It speaks well for the intellectual activity of the corps of botanists in an American university that these two books, whose preparation must have involved a great deal of labor, have appeared within the past three or four

months. This is all the more notable when we observe that Dr. Chamberlain's name appears on both title pages.

In the 'Morphology of Spermatophytes' we have Part I. of what is evidently to be a work of considerably larger proportions, the present volume being fragmentary, dealing with the Gymnosperms only, and closing somewhat abruptly, even wanting an index. The preface was evidently written for the complete work, and this fact suggests the intention of the authors to bring out Part II. at no distant day. The part before us takes up stem, leaf, root, microsporangium, megasporangium, female gametophyte, male gametophyte, fertilization, and the embryo, for Cycadales, Ginkgoales, Coniferales, and Gnetales, devotes a few pages to fossil Gymnosperms (Cordaitales, Bennettitales, Cycadales, Ginkgoales, and Coniferales), and a few more to the phylogeny, and geographic distribution of the various orders mentioned above. The volume closes with a most useful bibliography of one hundred and ten titles. More than one hundred excellent illustrations (largely original, and often from photographs) add materially to the usefulness of the work.

This book must prove very helpful to the student who is working along morphological lines, and will tend to bring him back to strictly scientific work, in case he has been wandering through the fogs of so-called 'elementary ecology.' A valuable feature of the book is the citation and discussion of the different views held by botanists as to the morphology of particular structures. While the conclusions reached are not always those which we can approve, the treatment is such that the student is led to look on all sides of every problem before a decision is reached. We can not accept the authors' views as to the morphology of the structure supporting the ovules of *Ginkgo* (which we hold to be foliar instead of axial), nor that of the 'ovuliferous scale' of the *Abietinæ* (which we interpret as an enlargement and extension of ovular tissue; *i. e.*, it is ovular instead of axial or foliar in nature).

Dr. Chamberlain's book must prove useful in histological work in botanical laboratories in high schools and colleges. The plan of the

work includes two parts, in the first of which are ten short chapters on apparatus, reagents, the making of mounts, killing and fixing agents, staining and the celloidin and glycerine methods. The author's success as an investigator and teacher is a guarantee of the value of the suggestions made in these chapters. The second part is mainly a series of selected examples of algæ, fungi, bryophytes, pteridophytes, and spermatophytes, in which the preceding suggestions are applied. This portion of the book is an admirable introduction to the vegetable kingdom, and must commend the volume to teachers and students. The book closes with a handy chapter of formulæ of reagents, and a good index.

These works are creditable to the university from which they appear, and deserve to be widely used.

CHARLES E. BESSEY.

SCIENTIFIC JOURNALS AND ARTICLES.

No. LIII. of the *Journal of American Folk-Lore* begins with a paper by Dr. J. W. Fewkes, in which he explains and interprets the *Katcina* worship of the Hopi or Moki of Arizona. The word is used to denote a masked personage, who, in a ceremonial dance, represents a divine being. Dr. Fewkes shows that these beings are spirits of clan ancestors, who are supposed to return from their dwelling in the underworld. Thus in mortuary prayers, the dying are addressed as about to become *Katcinas*, and are implored to send rain. Of the *Katcinas*, some are eponyms of Hopi clans; others are imported from abroad, or are imaginary creations. Chief of these spirits are the Sun Father and Earth Mother, parents of all clans. With sun worship also are connected some of the festivals; in the two great feasts of the *Katcina* clan are dramatized the arrival and departure of the *Katcinas*, who are supposed to leave the pueblo in July and return in February. They are said to go to the San Francisco mountains; but the underlying idea is that they enter the underworld through the gate of the Sun-house, the situation of which is indicated by a notch in these mountains, being the place of sunset at the time of the winter solstice. In the dramatic action held in the

sacred room or kiva, the Sun is personated by a man disguised as an eagle, whose performances symbolize the fertilization of the earth. In his most curious and interesting article, Dr. Fewkes makes it clear that the original significance of the ceremonies has long been forgotten by the Hopi. The editor, in treating of Kootenay medicine-men, makes clear the manner in which Christian ideas have intertwined themselves with Indian beliefs; he is of opinion that the Nootka god Kätse, whose name is kept secret, save that the dying chief communicates it to his grandchild, with instructions as to the manner of praying to this being, is none other than Jesus Christ. Miss A. C. Fletcher informs us that admonitions urging industry formed a part of Indian traditional teaching. Professor Rodney H. True discusses the relation of folk materia medica to modern knowledge. The 'Record of American Folk-Lore' is as full and instructive as usual. Altogether the new editor, Dr. A. F. Chamberlain, may congratulate himself on the presentation of a valuable number.

The American Naturalist for July opens with the second instalment of William M. Wheeler's paper on 'The Compound and Mixed Nests of American Ants,' this part being devoted to the known cases of social symbiosis among American species. Professor Wheeler gives Wasmann's table of the varied conditions under which symbiosis may occur, and then presents a scheme showing a more exact and natural grouping of the cases, to each of which an appropriate name is given. Under each of these headings the various species are treated in considerable detail; the article is of considerable length and much interest. R. W. Shufeldt presents a paper 'On the Osteology and Systematic Position of the Alcæ,' considering that the auks constitute a suborder standing between the gulls and petrels. A. W. Peters describes 'Some Methods for Use in the Study of the Infusoria' and 'Outram Bangs' gives some 'Notes on a Small Collection of Mammals from the Liu Kiu Islands' including the description of a new bat, *Hipposideros turpis*. C. W. Prentis describes in detail an interesting 'Case of Incomplete Duplication of Parts and Apparent

Regulation in *Nereis virens* Sars.' The fourteenth instalment of the 'Synopsis of North American Invertebrates' contains the Hydro-medusæ, Part III., by Charles W. Hargitt. Like the others of this valuable series, this comprises full keys to the families and genera, but it also has descriptions of the species. This number of the *Naturalist* contains the 'Quarterly Record of Gifts, Appointments, Retirements and Deaths.' The total amount of gifts reaches well into the millions, largely through the sums given by Andrew Carnegie to found libraries.

The Popular Science Monthly for August has as its frontispiece a portrait of Dr. Ira Remsen, the recently elected President of Johns Hopkins University. The first article, by J. J. Thomson, is 'On Bodies Smaller than Atoms.' Brother Potamian gives a sketch of 'Gilbert of Colchester,' the author of 'De Magnete,' showing his numerous discoveries in magnetism, and we have Part II. of 'The Peopling of the Philippines,' by Rud. Virchow. R. M. Wenley discusses 'Science and Philosophy,' noting the estrangement that seems to exist between the two and calling for harmony between them. The ninth part of 'A Study of British Genius,' by Havelock Ellis, is devoted to personal characteristics, and William James treats of 'FREDERIC MYERS'S SERVICE TO PSYCHOLOGY.' 'The Pose of the Body as Related to the Type of the Cranium and the Direction of the Visual Plane' is the subject of a paper by George T. Stevens, the writer considering that many benefits and ills depend upon the direction of the visual axis, and that when these are so directed as to be injurious they can be rectified. The final article on 'The Great Mortality,' by Edward P. Cheyney, is a description of the 'Black Death,' now known as the bubonic plague, which devastated Europe in the fourteenth century.

Bird Lore for July-August, opens with 'First Impressions of Hawaiian Birds,' by H. W. Henshaw, an article which rather impresses the reader with the comparative scarcity of bird life and the difficulties in observing it. Frank M. Chapman contributes 'A Nighthawk Incident,' with some excellent illustrations, after photographs of the bird, and Verdi Burtch de-

scribes 'The Birds of a Marsh' near Keuka Lake, N. Y. The fifth series of 'Birds and Seasons' is devoted to the birds to be seen and studied in August and September, as noted by contributors from Boston to Stockton, Cal., with suggestions for the season's study and reading.

THE first number of *The Museums' Journal* of Great Britain is issued promptly, and naturally commences with a statement of the objects of the Museums' Association and its journal. The address of the President, Sir William Turner, delivered at the Edinburgh meeting of the Association follows, and this is devoted to the history of 'The Public Museums of Edinburgh.' A sample is submitted of 'A Museum Label,' descriptive of British pottery and as criticism is invited it may be said that it will strike some as rather long, although it is undeniably replete with information. 'Museum Notes,' 'At Home and Abroad,' complete the number.

IN the issue of SCIENCE for April 26, 1901, there was given a somewhat detailed account of a proposed journal for the statistical study of biological problems, suggested by Professor Karl Pearson and Professor E. F. R. Weldon. We are glad to learn that the first number of the journal, which is called *Biometrika*, will be published in October. Professor C. B. Davenport, of the University of Chicago, is one of the editors, the others being Professors Pearson and Weldon. The journal will be published by the Cambridge University Press and will appear about four times a year. The following papers are ready or in preparation:

'Biometry': FRANCIS GALTON.

'On the Terminology and Notation of Biometric Investigations.'

'Variationsstatistische Probleme und Materialien': Professor Dr. F. LUDWIG.

'Criminal Anthropometry and the Identification of Criminals': Dr. W. R. MACDONELL.

'Critical Bibliography of Statistical Memoirs. I. Heredity': Professor W. F. R. WELDON.

'Anthropometric Data from Australia': W. POWYS.

'Variations in *Synapta inhærens*': Professor C. L. EDWARDS.

'Homotyposis in the Egg of the House-Sparrow': Dr. A. LEE and Professor K. PEARSON.

'The Cuckoo's Egg': OSWALD LATTEK.

'Variation in *Aurelia*': E. T. BROWNE.

'Inheritance of the Duration of Life and the Intensity of Natural Selection in Man': Miss M. BEETON and Professor K. PEARSON.

'Artificial Selection, being a Comparison of the Distributions of Conscripts and Recruits in various Italian Provinces': Professor W. F. R. WELDON.

'Results of Cooperative Investigation on the Laws of Inheritance in Plants. I. The Shirley Poppy.'

'Variation and Correlation of the parts of the Human Skull. A Quantitative Study of the Naqada Crania': Miss C. D. FAWCETT.

'Extended and Improved Tables of Probability Integrals': W. F. SHEPPARD.

'Variation in the Form of the Helix of the Shell in *Chausilia laminata* (Montagu)': Professor W. F. R. WELDON.

'Mathematical Contributions to the Theory of Evolution. XI. The Influence of Natural Selection on the Variability and Correlation of Characters': Professor K. PEARSON.

'On a Physico-statistical Theory of Heredity': G. U. YULE.

'A Statistical Study of the Wild Bee': Professor F. Y. EDGEWORTH.

AN Index to the *Experiment Station Record*, covering the first twelve volumes, and containing more than one hundred thousand entries, has been prepared and will probably be published in the autumn.

THE Senate of the University of London has decided to publish periodically an official organ, to be called *The London University Gazette*, which will contain class lists, new regulations, dates of examinations, etc. The paper will appear about twenty times in the first year, beginning in October.

DISCUSSION AND CORRESPONDENCE.

THE VISUAL PERCEPTION OF SPACE.

THE fact to which Professor Thorndike called attention in the last number of SCIENCE must appear extraordinary to those who have not

considered the senses from the point of view of psychology. The ordinary man tends to regard our perceptions as copies or models of an outside world. The sense organs intervene, of course, and knowing that in vision the rays of light form an image on the retina, one is likely to think of the mind as viewing this picture from behind. As Professor Thorndike remarks, if one walks toward a chair, the apparent size of the object does not alter—at least not greatly or obviously—although the image on the retina becomes smaller. As I lecture to my class, the retinal images of the heads of the students on the back seats may be only one-tenth the size of those in front, yet they look only slightly smaller. But this is by no means the only disparity between the image on the retina and my perception. To begin with, the image is upside down and there are two images. Then the corners of my desk look like right angles, although they are by no means such in the pictures. I know by experiment that I can at one time have a distinct image of only one of the nearer heads, yet in my perception all the heads are distinct. A photograph in which very near and comparatively distant objects are included will in its distortion of perspective and blurring give some idea of what the image on the retina is like and how different it is from the perception.

Some of these facts were known to Berkeley, who in his 'New Theory of Vision,' first published in 1709, argues that visible objects are a system of arbitrary signs. In regard to apparent magnitude he writes :

When we look at an object, the tangible figure and extension thereof are principally attended to ; whilst there is small heed taken of the visible figure and magnitude, which, though more immediately perceived, do less sensibly affect us, and are not fitted to produce any alteration in our bodies.

60. That the matter of fact is true will be evident to any one who considers that a man placed at ten foot distance is thought as great as if he were placed at a distance only of five foot ; which is true, not with relation to the visible, but tangible greatness of the object : the visible magnitude being far greater at one station than it is at the other.

Professor James, as always, discusses the matter admirably. He says ('Principles of Psychology,' II., 179) :

When the object by moving changes its relations to the eye the sensation excited by its image even on the same retinal region becomes so fluctuating that we end by ascribing no absolute import whatever to the retinal space-feeling which at any moment we may receive. So complete does this overlooking of retinal magnitude become that it is next to impossible to compare the visual magnitudes of objects at different distances without making the experiment of superposition. * * * As I look along the dining-table I overlook the fact that the farther plates and glasses *feel* so much smaller than my own, for I *know* that they are all equal in size ; and the feeling of them, which is a present sensation, is eclipsed in the glare of the knowledge, which is a merely imagined one.

Professor Newcomb recently called my attention to the paradox that while we are

FIG. 1. The man and boy are of the same size.

said to judge the distance of objects of known size by the angles they subtend, our

perception of distance is more accurate than our perception of the visual angle. Owing to the fact that we must commonly ignore the visual angle in order to get useful perceptions, our interest in it is small and our knowledge vague. The moon, for example, always subtending the same angle, looks much larger at the horizon than at the zenith. If the reader is asked whether the little finger if held before the moon will cover it, he will probably say 'No,' or else hesitate to answer. As a matter of fact, the little finger covers the moon, and when it is removed we have a further illustration of the subject in the fact that the moon appears decidedly reduced in size, owing doubtless to a vague comparison with the finger.

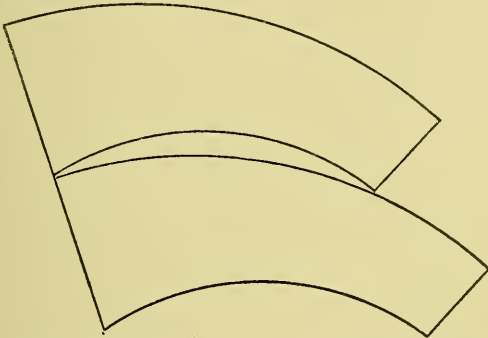

FIG. 2. The upper and lower areas are of the same size and shape.

I have made a few experiments on the accuracy with which the retinal area or visual angle can be judged under different conditions, and on the relation between the geometrical magnitude and the perception, and hope to continue them, though it is difficult to obtain quantitative results. The phenomena can be studied to advantage with the aid of mirrors, and it appears that data of interest can be secured by a consideration of photographs and of paintings and drawings. This I may illustrate by reproducing a figure from Professor Münsterburg's 'Pseudoptics,' in which the figures of the man and boy are of the same objective size.

While our ability to compare the retinal magnitude of objects at different distances and in different directions is very defective, the perception of visual magnitude when objects are side by side is perhaps the most accurate of all the senses, a difference of one-hundredth being noticeable. Yet even in this case the retinal area yields readily to suggestion as is shown by the accompanying figure, in which the two areas are of exactly the same size.

In a recent paper,* I have described what seems to me one of the most striking disparities between our perceptions and the physical world — no less than the perception of order in time as extension in space. If, for example, first a green and then a red surface pass rapidly behind a narrow slit, one does not see green followed by red, but simultaneously a surface with green below, white in the middle and red fading into black above. Physiologically we have a retinal process, consisting of a certain commotion caused by green light, lasting say 1/20 sec., then a mingling of this process with that excited by red, then that excited by red gradually subsiding. But this time series is perceived as a spatial continuum, and the field is, perhaps, three times as large as the window through which it is seen. If three squares, as shown on the left of the figure, are seen as they pass the window WW' , they do not appear one after the other, but are seen simultaneously as indicated to the right.

This conversion of a time into a space order is also what always happens in ordinary vision. If the eye moves so that the line of sight moves

FIG. 3. The squares at the left appear as shown at the right when seen as they pass the window (WW') of the size indicated.

* 'On the Relation of Time and Space in Vision,' *The Psychological Review*, 7 : 325-343, 1900.

over a row of fifty books, each retinal element is excited in succession by each book, but we do not see one book taking the place of the other, but all the books side by side. Further, when the eye sweeps over fifty books in 1/10 sec., each book is seen, or appears to be seen, with perfect distinctness, though if the books moved at the same rate over the eye they would completely fuse together. Our perceptions in no wise correspond to the physiological processes in the eye, but are what they should be for our safety and convenience.

J. McKEEN CATTELL.

COLUMBIA UNIVERSITY.

CIRCULAR OF INFORMATION IN REGARD TO
THE CAUSATION AND PREVENTION
OF MALARIAL FEVER.

RECENT investigations have shown that malarial fever belongs to that class of diseases which require for their transmission the active intervention of a definite kind of mosquito, *i. e.*, *Anopheles*. This genus is not the common one of this region, but is nevertheless present in many localities.

The organism causing malarial fever (*Plasmodium malarix*) is probably a true parasite, and, so far as we know at present, finds the conditions necessary for its existence only in the living human body and in this genus of mosquito, the latter becoming infected by sucking the blood from an infected human being. The malarial organism having thus entered the stomach of the mosquito, passes through certain changes in the body of the infected insect, and at the end of about ten days reaches the poison gland. After this time, if the mosquito bites another human being, the malarial organism is introduced into the circulation of the latter and malarial fever follows.

So far as we know certain localities are 'malarious' only because they furnish favorable conditions for breeding this mosquito. Malarial fever would not occur in any malarious district, unless some infected human being were in it, or came into it and infected the mosquitoes, which in turn infected other human beings.

Recent observations in the intensely malarial districts in Italy and Africa have shown that even newcomers in these regions who pur-

posely expose themselves by living in the most highly malarious area, for example the Roman Campagna, do not develop malarial fever, if they are carefully protected from the bites of mosquitoes; and further, it has been shown that this disease may be produced with certainty in any locality if a mosquito of the genus *Anopheles* is allowed to bite a person suffering from malarial fever and then, after a sufficient time, is allowed to bite a healthy person.

Certain simple precautions suffice to protect persons living in malarial districts from infection:

First.—Proper screening of the house to prevent the entrance of the mosquitoes (after careful search for and destruction of all those already present in the house), and screening of the bed at night. The chief danger of infection is at night, inasmuch as the *Anopheles* bite mostly at this time.

Second.—The confinement and continuous screening of persons in malarial districts who are suffering from malarial fever, so that mosquitoes may not bite them and thus become infected.

Third.—The administration of quinine in full doses to malarial patients to destroy the malarial organisms in the blood, and persistence in the use of the remedy even for a few weeks after apparent recovery.

Fourth.—The removal of the breeding places of the mosquitoes through drainage, filling up of holes and surface pools, and emptying of tubs, pails, etc., which contain stagnant water. These mosquitoes particularly breed in surface rain pools and surface stagnant water, where there are no fish; also exceptionally in pails, tubs, barrels and tanks of standing water, though they seem mostly to prefer natural accumulations.

Fifth.—In pools which cannot be drained or filled, the destruction of the mosquito larvæ by the use of petroleum thrown upon the surface, by the introduction of minnows and other small fish which eat the larvæ, or by both methods.

These measures, if properly carried out, will suffice greatly to restrict and largely to prevent the occurrence of new malarial infections.

It is the desire of the Department of Health to obtain information as to the location of the cases of malarial fever, so that the people may be instructed as to the danger of infection and the methods of avoiding it.

It must be remembered that when a person is once infected, the organism may remain in the body for many years, producing from time to time relapses of the fever. A case of malarial infection in a house, whether the person is actively ill or the infection is latent, in a locality where the *Anopheles* mosquitoes are present, is a constant source of danger, not only to the inmates of the house, but to the immediate neighborhood, if proper precautions are not taken.

Malarial fever is quite prevalent in certain boroughs of New York City. It is likely to extend to the boroughs of Manhattan and Brooklyn in view of the extensive excavations and consequent formation of rain-pools in various parts of these boroughs, if means are not employed for its prevention.

The Board of Health desires the cooperation of all physicians in its efforts to disseminate information in regard to the causation and prevention of malarial fever, and in its efforts to restrict the prevalence of this disease in New York City.

HERMANN M. BIGGS.

THE BRITISH CONGRESS ON TUBERCULOSIS.

THE Congress which met at London at the end of last month appears to have been remarkably successful. There were over 2,500 members, including the following delegates :

- United States : Professors Osler and Janeway.
- Austria : Professors von Schroetter and Davorak.
- Belgium : M. le Sénateur Montefiore Lévi and Van Ryn.
- Bulgaria : Mikailovsky.
- Denmark : Professor Bang and Dr. Charles Gram.
- France : Professors Brouardel, Boucharde and Nocard.
- Germany : Professors Gerhardt, Flügge, Von Leyden, Frankel, Koch, Werner, Dettweiler, Dr. Freund.
- Holland : Professor Thomassen.
- Hungary : Professor Koranyi.
- Norway : Dr. Malm.
- Portugal : Professor da Silva Amado.

Roumania : Dr. Cantacuzino was unavoidably absent.

Spain : Señor Don Antonio Espino y Capo.

Sweden : Hof Marshal Printzjold.

Switzerland : Dr. Neuman.

The Congress met in four sections : State and municipal, medical, pathology and veterinary, and there were besides a number of general meetings. The addresses of Professors Koch and Brouardel attracted special attention, more especially Professor Koch's claim that the bovine tubercle could not develop in the human body. No one present seems to have known of Professor Theobald Smith's careful research, showing that bovine and human tubercle bacilli are not identical. At the close of the Congress, the following resolutions were adopted :

That tuberculous sputum is the main agent for the conveyance of the virus of tuberculosis from man to man and that indiscriminate spitting should therefore be suppressed.

That it is the opinion of this Congress that all public hospitals and dispensaries should present every out-patient suffering from phthisis with a leaflet containing instructions with regard to the prevention of consumption and should supply and insist on the proper use of a pocket spittoon.

That the voluntary notification of cases of phthisis attended with tuberculous expectoration and the increased preventive action which it has rendered practicable has been attended by a promising measure of success and that the extension of notification should be encouraged in all districts in which efficient sanitary administration renders it possible to adopt the consequential measures.

That the provision of sanatoria is an indispensable part of the measures necessary for the diminution of tuberculosis.

That in the opinion of this Congress and in the light of the work that has been presented at its sittings medical officers of health should continue to use all the powers at their disposal and relax no effort to prevent the spread of tuberculosis by milk and meat.

That in view of the doubts thrown on the identity of human and bovine tuberculosis it is expedient that the Government be approached and requested to institute an immediate inquiry into this question, which is of vital importance to the public health and of great consequence to the agricultural industry.

That the educational work of the great national societies for the prevention of tuberculosis is deserving of every encouragement and support. It is through their agency that a rational public opinion

may be formed, the duties of public health officers made easier of performance and such local and State legislation as may be requisite called into existence.

That this Congress is of opinion that a permanent national committee should be appointed (*a*) to collect evidence and report on the measures that have been adopted for the prevention of tuberculosis in different countries; (*b*) to publish a popular statement of these measures; (*c*) to keep and publish periodically a record of scientific research in relation to tuberculosis; and (*d*) to consider and recommend measures of prevention. This Congress is further of opinion that such a committee should consist of representatives to be elected by the great national societies formed for the suppression of tuberculosis and also representatives nominated by the various governments. It is further of opinion that all international committees and great national societies whose object is the prevention of tuberculosis should be invited to cooperate.

That, in the opinion of this Congress, overcrowding, defective ventilation, damp, and general unsanitary conditions in the houses of the working classes diminish the chance of curing consumption and aid in predisposing to and spreading the disease.

That while recognizing the great importance of sanatoria in combating tuberculosis in every country the attention of governments should be directed towards informing charitable and philanthropic individuals and societies of the necessity for anti-tuberculous dispensaries as the best means of checking tuberculous disease amongst the industrial and indigent classes.

That the following question be submitted to the consideration of the next Congress: The constitutional conditions of the individual which predispose to tuberculosis and the means whereby they can be modified.

*GEOLOGICAL EXPLORATIONS AT PIKERMI.**

THE geological excavations which the Trustees of the British Museum have (by the kind permission of Mr. Skousés, the owner of the ground) been carrying on at the Pliocene deposits of Pikermi, near Athens, since the early spring, have now been brought to a conclusion for the season. Judging from the preliminary reports which have been received from Dr. A. Smith Woodward, who was sent out by the Museum to superintend the excavations, the results from a scientific and pecuniary point of view have well justified the trustees in their decision to undertake this important piece of

geological research. We believe that the initiative in the matter is due to Sir Edwin Egerton, H. M. Minister at Athens, who was also mainly instrumental in obtaining the necessary permit to excavate from Mr. Skousés, formerly Greek Minister for Foreign Affairs. The willing cooperation of the University of Athens in the person of Professor Skuphos, the accomplished paleontologist of the University Museum, was easily secured, and his help and advice have been invaluable throughout the whole period of the work. The most cordial relations have existed between Professor Skuphos and Dr. A. S. Woodward, and the division of the specimens which have been discovered has, it is understood, been amicably arranged by the British Museum and the University of Athens. It is said to be extremely doubtful whether there is any Greek law assimilating fossils to works of art; but, however that may be, we are happy in knowing that both the institutions concerned are satisfied with the agreement which has been arrived at as regards the portion of the collections which each is to retain.

Pikermi, where the fossils are found, is near the Marathon road, about 12 miles from Athens; and the specimens are usually found at a considerable depth below the bed of a mountain torrent. This is, of course, not the first time that excavations have been made in these deposits. In the early fifties Professor Albert Gaudry, the eminent French geologist, conducted some explorations which resulted in a great find of Tertiary mammalia, identical with those of Léberon, Samos and Maragab. Most of the specimens obtained by Gaudry are in the Paris Museum. Later, the Vienna Academy made a collection on a smaller scale from the same place; and about 1885 the Duke of Orleans was allowed to dig there, but he remained only a short time and found nothing of importance. Before the present occasion no Englishman had made any geological research at Pikermi, and the British Museum contained no collection from these beds. This deficiency in our great national storehouse has now been made good in a splendid manner, as may be judged from the fact that 47 large cases containing the Museum's share of the fossils found are at the present moment on their way to England.

* From the *London Times*.

Among the principal finds recorded may be mentioned remains of a huge proboscidean, including two femurs each over a meter in length, a fine series of excellently preserved skulls and other bones of rhinoceros; *Mesopithecus*, an old-world monkey, remains of which are rarely met with in any part of the globe as fossils; several almost complete skulls of *Mastodon*; skulls, teeth, and bones of *Machærodus*, the great saber-toothed tiger, remarkable for the great development of the canine teeth, and also for its wide geographical distribution. Remains of this animal have been met with in England in Kent's Cavern, Torquay, in Creswell Crag Caves, Derbyshire, and in the Norfolk forest-bed. Dr. Woodward also reports the discovery of innumerable bones of *Hipparion*, the three-toed and most immediate predecessor of the horse of the present day, hyæna and other carnivores, antelopes, giraffe with limb-bones very long and slender; *Helladotherium*, a short-necked giraffe allied to the *Okapi*, the new ruminant mammal recently brought home by Sir Harry Johnston from the Semliki forest in the Congo State; and *Samotherium*, a large ruminant, first discovered, it is believed, by Dr. Forsyth Major in the lower Pliocene beds of the Island of Samos, off Asia Minor, and said to connect *Helladotherium* and the giraffe with some of the ancient aberrant antelopes of Pikermi. Traces of *Chaloniens* were abundant and include, as one of the prizes of the explorations, remains of perhaps the largest tortoise ever found in Europe. Very few bones of rodents were met with, and birds do not seem to have been numerous; but a considerable collection of land shells was obtained. It is curious that no traces of plant life were observed.

The bones occur on definite horizons in immense numbers, and the marly material is quite soft until it is dried, when it hardens. In places the remains are so jammed together that it is difficult to extract or to separate them. The carcasses appear to have been buried entire, with the flesh and integument, in vast numbers, probably by torrential action, a great number having had their limbs sharply broken, evidently at the time of death. It is worthy of note that the extinct animals found in this

late Tertiary deposit at Pikermi mostly relate to the present African fauna.

Dr. A. S. Woodward, it will be seen, has carried out the official mission entrusted to him in a most creditable manner. By his exertions and careful superintendence the national collection of paleontology at South Kensington will be immensely enriched. Before returning home Dr. Woodward, at the request of Sir Edwin Egerton, has arranged to inspect another ossiferous deposit on the island of Eubœa.

SCIENTIFIC NOTES AND NEWS.

THE permanent secretary of the American Association, Dr. L. O. Howard, asks us to state that those who have responded to his invitation to send in their names and dates for special Association Pullman accommodation are so divided in their choice of route that it will be impossible for him to arrange to bring parties together on the journey in the way proposed. The Pennsylvania limited, which leaves New York at 9:55 A. M. and Philadelphia at 12:20 P. M., reaching Chicago at 8:55 A. M., was not included in the time-tables published recently in this journal. Neither were there given time-tables of the trains on the New York Central road, though for those living in New York and New England this is probably the most convenient route, as it is cooler than those further to the south. We may take occasion to call attention to the excursion to the Grand Canyon of Arizona arranged to follow the meeting, of which an advertisement will be found in this issue of SCIENCE. We are also requested to state that the meeting of the Council will be held at 3 o'clock on Saturday, August 24, instead of at 12.

THE seventy-third meeting of German Men of Science and Physicians will, as we have already stated, be held at Hamburg, from the twenty-second to the twenty-eighth of September. Professor R. Hertwig, of Munich, is president of the meeting, while Professor van't Hoff is president of the scientific sections and Professor Naunyn of the medical sections. There are in all twenty-seven sections for the medical sciences and eleven in the natural and exact sciences. The latter sections correspond in general with

those of our own Association, except that there are sections for applied chemistry, for geophysics and for geography, while there is none for social and economic science. Among the special lectures promised are the following: Dr. E. Lecher on 'Hertzian Waves,' Professor T. Boveri on 'Fertilization,' and Professor W. Nernst on 'Electro-chemistry.'

PRINCE HENRI D'ORLÉANS, who has made important geographical discoveries in Asia and Africa, died at Saigon, China, on August 9, aged thirty-three years.

We also regret to record the death of Professor August Tenne, curator of the mineralogical collections of the University of Berlin; of M. David Dickson, director of the practical School of Agriculture, at Berthonval, France, and of Mr. Carsten Holthouse, at one time lecturer on anatomy at the Aldersgate School of Medicine and the senior fellow of the Royal College of Surgeons, who was in his ninety-first year.

THE steamship *Discovery* of the British Antarctic Expedition, sailed from Cowes on August 6, and the *Gauss*, of the German Expedition, sailed from Kiel on August 11. The *Discovery* should reach the Cape about September 12 and Melbourne about a month later. It will proceed thence to Littleton, New Zealand, which place it will leave about the middle of December and will probably come in contact with the ice pack about the first of January.

MR. WILLIS L. MOORE, chief of the Weather Bureau, will leave Washington early in September for the Yellowstone National Park to make an inspection of that region with a view to the establishment of a meteorological observatory.

PROFESSOR LUCIEN M. UNDERWOOD, of Columbia University, and Mr. O. F. Cook, special agent for tropical agriculture for the Department of Agriculture, have returned from a botanical expedition to Porto Rico.

DR. PETER A. JODER has been appointed assistant chemist at the Utah Agricultural College and Station, and Mr. W. T. Shaw has been appointed assistant entomologist at the Iowa Station.

PROFESSOR H. C. WILSON, according to a telegram to the Harvard College Observatory, observed Encke's comet on August 5.

MR. A. L. ROTCH, director of the Blue Hill Observatory and the American member of the International Aeronautical Committee, made a balloon ascension from Strasburg, Germany, with his colleague, Professor Hergesell, on July 4, in connection with the eighteenth series in Europe. They reached a height of about 14,000 feet. The meteorological observations will be published in the United States *Monthly Weather Review*.

It is reported in *Nature* that the French Minister of War has asked the Paris Academy of Sciences to give an opinion as to the possibility of danger arising from the establishment of wireless telegraphy stations in the neighborhood of magazines containing powder or other explosives. It is suggested that the nature of the cases containing the explosive may be an important matter for consideration in connection with the subject.

THE British Institution of Mechanical Engineers held its summer meeting at Barrow-in-Furness, under the presidency of Mr. W. H. Maw, beginning on July 30.

MR. JAMES ANGUS, of West Farms, N. Y., who has given a valuable collection of butterflies to the American Museum of Natural History, and more recently a collection of Indian implements to the Providence Museum, has given to the latter institution his collection of corals and agates.

MR. J. EWING MEARS, of Philadelphia, has presented the George W. Mears Memorial Medical Library of Indianapolis with 4,000 medical books. The library was established as a memorial to his father, who practised medicine in Indianapolis.

ANDREW CARNEGIE has offered Montreal \$150,000 for a library, provided the city will contribute a site and spend \$15,000 yearly in maintenance.

THE secretary of the Marine Biological Association of the West of Scotland, Mr. John A. Todd, 190 West George St., Glasgow, has sent a notice stating that the General Committee of

the Association offers the following prizes, to be called the *Fred. P. Pullar Memorial Prizes*, provided by Sir John Murray, the honorary president of the Association, in memory of the late Fred P. Pullar, who was associated with him in the Bathymetrical Survey of the Scottish Fresh Water Lochs, who took much interest in the Millport Marine Station, and who lost his life in the unfortunate ice accident on Airthrey Loch, Bridge of Allan, on the 15th of February, 1901.

1. A prize of £50 for a paper on 'The Seasonable Distribution and Development in the Pelagic Algæ in the Waters of the Clyde Sea Area.'

2. A prize of £50 for a paper on 'The Reproduction, Development and Distribution of the Clyde Sea Area of the Genera *Nyctiphanes* and *Boreophausia*.'

3. A prize of £50 for a paper on 'The Formation and Distribution of Glauconite in the deposits of the Clyde Sea Area and the adjacent seas of Scotland.'

These prizes are open to investigators from any part of the world who conduct observations in the several subjects at the Millport Marine Station, and who produce, at any time before January 1, 1905, papers which, in the opinion of a committee of three scientific men, to be nominated by the committee of the Association and by Sir John Murray, shall be deemed of sufficient value to merit publication. Those proposing to work for any one of these prizes should make known their intention to the secretary of the Association in order that the necessary arrangements may be made.

At the last session of Congress the medical corps of the Army was increased from 192 to 321, and examinations for appointments as assistant surgeons in the U. S. Army will be resumed in Washington on September 2. The salary is \$1,600 per year, gradually increasing until after twenty years it amounts to \$2,500 and may be more if promotion to the position of lieutenant-colonel follows. The medical officers of the Army are also allowed free quarters, traveling expenses, instruments, books, etc. Candidates must have had a year's hospital experience or two years of private practice and must not be more than twenty-nine years of age. Details in regard to the examination can be obtained from the Surgeon-General's office, Washington.

THE United States Civil Service Commission announces that the examination which was announced to be held on September 3 for the position of computer in the Coast and Geodetic Survey has been cancelled, for the reason that the position for which the examination was to have been held has been filled by the transfer of a person already in the classified service.

THE organizing committee of the fourteenth International Medical Congress, which meets at Madrid next April, held a meeting on June 11, at which plans were discussed and promises of support given on behalf of the government and the municipality. The work of the Congress is to be divided into sixteen sections, as follows: (1) Anatomy (anthropology, comparative anatomy, embryology, descriptive anatomy, normal histology and feratology); (2) physiology, biological physics and chemistry; (3) general pathology, pathological anatomy and bacteriology; (4) therapeutics, pharmacology, and materia medica; (5) internal pathology; (6) neuropathology, mental diseases and criminal anthropology; (7) pædiatry; (8) dermatology and syphilography; (9) surgery and surgical operations; (10) ophthalmology; (11) otology, rhinology and laryngology; (12) odontology; (13) obstetrics and gynæcology; (14) military and naval medicine and hygiene; (15) epidemiology and technical sanitary science; (16) forensic medicine.

THE foreign trade of the United States during the fiscal year ended June 30 aggregated in value \$2,310,413,077, being an increase of \$65,988,811 compared with that of the previous year. Of this total the exports comprised \$1,487,656,544, exceeding those of the previous year by \$97,173,462, and the imports aggregated \$822,756,533, being \$27,184,651 less than those for the fiscal year 1900. The balance of trade in favor of the United States for that period reached a total of \$664,900,011, being an increase of \$120,359,113 over the balance for the previous year. Under the new relations with Hawaii and Porto Rico the commerce with those islands is no longer included in the regular statement of the foreign commerce of the United States. Had they been so included, as has been the case in former years, the total exports would have exceeded \$1,500,000,000,

as the exports to those islands during the year have aggregated about \$25,000,000.

THE St. Petersburg *Novoe Vremya*, as reported by Reuter's Agency, learns from Yeniseisk that Lieutenant Kolomütseff, in command of the steamer *Zaria*, which has on board the members of the Russian Polar expedition, under Baron Toll, has just arrived at that place to re-coal. Lieutenant Kolomütseff reports that the *Zaria* wintered in the Bay of Taimyr in $76^{\circ} 8'$ north latitude, and $95^{\circ} 6'$ east longitude, and that the winter passed fairly well except for some cases of scurvy among the crew. Lieutenant Kolomütseff twice endeavored to reach Kamchatka by land, but without success. He started on his first attempt on February 2, but was obliged to return at the end of 18 days, owing to lack of food for his dogs. His second fruitless attempt cost him 26 days, in the course of which he was able to explore the whole of the coast of Taimyr Bay. On April 18 he again left the *Zaria*, and arrived at Goldchik after a march of 40 days, during which he lived on the flesh of bears and reindeer. From Goldchik he proceeded with reindeer to Doudinki, and from there by boat to Yeniseisk. His present object is to establish coaling stations for the *Zaria* in Dickson Bay and on the islands of New Siberia.

PROFESSOR W. A. HERDMAN, as *Nature* learns, has received letters and natural history notes from Mr. Nelson Annandale and Mr. H. Robinson, who left Liverpool University College a short time ago for a year's exploration in the Siamese Malay States. Some of the observations made and material collected will be described at the forthcoming meeting of the British Association at Glasgow. Meanwhile, it is interesting to read the following notes from the naturalists: "We have obtained what is either a second species of *Periophthalmus* or a genus closely allied to it, and we have to-day ourselves collected a series of young specimens, which show that in extreme youth the eyes are normally placed on the sides of the head, and only migrate to the top later in life. We also got in water less than a fathom a most interesting case of commensalism, in which a small crab, with a very soft back, has the two last pairs of legs specially modified for holding on

a sea-anemone, which it grasps by the foot. * * * A good many cases of mimicry between different orders and families, principally between spiders and ants, homoptera and beetles, were noted—in at least ten cases the mimicked animal being an ant.

UNIVERSITY AND EDUCATIONAL NEWS.

MRS. CAROLINE STANNARD TILTON, of New Orleans, has given \$50,000 for a Tilton memorial library at Tulane University.

By the will of the late Herbert B. Adams, professor of history in the Johns Hopkins University, that University is made the residuary legatee. Amherst College is given \$2,000 for the library and the American Historical Association is given \$5,000.

WE are requested to state that in spite of the damage the building of the College of Physicians and Surgeons, Chicago, the medical school of the University of Illinois, suffered recently from fire, the administration of the College has suffered no serious disturbance and the institution will in the autumn be housed and equipped better than ever before.

DR. CHARLES BURTON THWING, professor of physics in Knox College, has been called to the same chair in Syracuse University.

PROFESSOR W. S. McCORMACK, of University College, Dundee, has been appointed secretary of the endowment for the Scottish universities, established by Mr. Carnegie.

THE Council of University College, London, has appointed Mr. J. D. Cormack, B.Sc., of Glasgow, to the chair of mechanical engineering vacant by the resignation of Professor Hudson Beare on his appointment as regius professor at Edinburgh, and Mr. Edgar Walford Marchant, D.Sc., to the lectureship in electro-technics vacated by Mr. Alfred Hay's appointment to a professorship at Coopers Hill.

DR. R. T. HEWLETT, of the Jenner Institute of Preventive Medicine, has been appointed professor of general pathology and bacteriology at King's College, London.

MR. R. C. PORTER, now lecturer in engineering at the government school at Cairo, has been appointed lecturer of mechanical engineering at Birmingham University.

Very truly yours
Joseph L. Carter

JOSEPH LE CONTE was born in Liberty county, Georgia, on February 26, 1823 ; he died in Yosemite Valley, July 6, 1901. In the years spanned by these dates he lived a life well worthy of respectful commemoration, a life whose record must exercise a benign influence upon the rising generation of scientific workers. To make such a record is not the purpose of this brief article. Here all that may be attempted is a grateful acknowledgment of having known and worked with the man, to outline his career, to indicate the goal he aimed at and the chief turning points on the highway of his life as he pursued that goal, and to make some loving comment on the most salient features of his personality. To those who feel keenly, as the writer does, the imperfection of this sketch, it will be a satisfaction to know that at the time of his death Professor Le Conte was engaged upon, and had practically completed, his autobiography, and that this will be published at an early date.

Joseph Le Conte was of French descent. His earliest American ancestor was Guillaume Le Conte, a Huguenot, who fled from Rouen after the revocation of the edict of Nantes, served under William of Orange in England, and finally settled in this country near New York, in the year 1698. His grandson Louis was born in 1782, graduated

from Columbia in 1800, and in 1810 moved to Liberty county, Georgia, where he had inherited a large plantation. Here he married Ann Quarterman, a lady of English Puritan descent. Of these parents Joseph Le Conte was born, one of a family of four sons and three daughters.

Louis Le Conte divided his time between the management of his estate and the pursuit of scientific studies, particularly chemistry and botany. He maintained a botanical garden which was famous in its day as one of the best in the country. Joseph Le Conte received his elementary education at a local school, but his father's tastes and scientific work exercised a powerful influence upon his youthful mind as it did also upon that of his brother John, and both were early drawn to the pursuit of science as their life work.

In those days almost the only profession that afforded an opening to scientific pursuit was that of medicine, so that, after graduating from the University of Georgia, both brothers entered upon the medical course at the College of Physicians and Surgeons, in New York, Joseph receiving the degree of M.D. in 1845.

It was in the summer vacation of 1844, when a young man of 21, that Joseph Le Conte made his first noteworthy geological excursion. In this year he joined the *first* prospecting and exploring expedition to the now famous mining district of the south shore of Lake Superior. The writer has several times listened with delight to Professor Le Conte's account of this boating cruise from the lower lakes to Keewenaw Point, of his camping adventures, and how, after a sojourn of a few weeks with the prospectors on Keewenaw Point, he and his cousin with some Indians proceeded on a long canoe voyage along the south shore to the present site of Duluth, and thence to the upper waters of the Mississippi and down to the Falls of St. Anthony, long before a

cabin existed on the site of the cities of Minneapolis and St. Paul.

After receiving his medical degree he practiced medicine at Macon, Georgia, from 1845 to 1850. In 1847 he married Caroline Elizabeth, the daughter of Alfred M. Nisbet, at Midway, near Milledgeville, Ga. His wife, one son and three daughters survive him. In 1850, feeling doubtless that the practice of medicine failed to afford those opportunities for the study of natural science to which he was so strongly inclined, and being drawn by the fame of Agassiz, he abandoned medicine and went to Cambridge. Here under the influence of the great interpreter of nature, his own career as a devoted student of science was finally determined. It is doubtful whether any other disciple of this great teacher has done more to advance the cause of nature study among the people of this country. In the early part of 1857 he was associated with Agassiz in a study of the keys and reefs of Florida, and it would be difficult to cite a more captivating study for two such kindred spirits, or a study where geological and biological interests are more intimately knit together. Late in the same year, having received the degree of B.S. at Harvard, he returned to Georgia and was elected to the chair of natural science in Ogelthrope University. This post he resigned the following year to accept the chair of geology and natural history in the University of Georgia, in which institution his brother John was the professor of natural philosophy. Here he taught for four years. In 1856 the brothers both resigned their chairs and accepted calls to South Carolina College, at Columbia, Joseph to be professor of geology and natural history and John to be professor of physics. They held these positions till 1862, when the college succumbed to the trouble arising out of the Civil War. These were busy years at Columbia; in the enjoyment of the con-

genial society of the place they were pleasantly spent, though sadly interrupted.

When teaching gave way to more serious duties Joseph offered his services to the Government of the Southern Confederacy, and was for a time engaged as chemist in the government laboratory for the manufacture of medicines, and later as chemist at the Nitre and Mining Bureau at Columbia, of which his brother John had been appointed superintendent. In this work he continued till the close of the war.

In 1866 the University of South Carolina was reorganized and the brothers resumed their professorships. But in the crippled condition of the community it soon became apparent that it would be long before opportunities for scientific work would be opened up. Their private fortune had been swept away by the war, and when in 1868 they were invited to join the initial staff of the University of California, then being organized, they both accepted. At the age of 46 Joseph Le Conte thus became professor of geology, botany and natural history in the University of California. The title of his chair was changed in 1872 to 'geology and natural history,' and this chair he held up to the time of his death.

From this brief sketch of the mere externals of Professor Le Conte's career, the character of his life-work as a student and teacher of natural science must impress the reader. This impression will be sustained and strengthened by a glance at the long list of his writings appended to this article. He was no narrow specialist, yet he was an authority in advance of his contemporaries in several distinct lines of scientific and philosophical inquiry. His earliest writings of scientific importance had to do with the phenomena of binocular vision, which he discussed in a long series of papers, published chiefly in the *American Journal of Science* and in the *Philosophical Magazine*, between the years 1868 and 1880.

These essays were enlarged and published in his well-known book of several editions entitled 'Sight.' This work is generally recognized as an important contribution to our knowledge of the subject and is remarkable for that lucidity of style and felicity of graphic illustration and simile which characterize, indeed, all his writings. While issuing these papers he was, after coming to California, actively engaged in geological studies. Various excursions in the Sierra Nevada and in the Cascade Mountains of Oregon led to important discoveries. He announced the age and character of the Cascade Mountains and their relation to the great Columbia lava flood; he described the ancient glaciers of the Sierra Nevada, and was among the first to recognize the post-Tertiary elevation of the Sierra Nevada, as shown by the river beds. His studies on mountain structure led him to important generalizations on the origin of mountains in general, and he became one of the chief exponents of the 'contractional theory' of mountain building. His studies on ore deposition at Steamboat Springs, Nevada, and Sulphur Bank, California, led him to a discussion of vein formation in general; and his classification of ore deposits has been widely recognized as resting on a sound basis and is not displaced in its essential features by the most recent attempts in the same direction. He also made important contributions to the subjects of seismology and coral growth in its geological aspects.

In 1878, he published his 'Elements of Geology,' a book which has had, perhaps, a more extensive use in the schools and colleges of this country than any other textbook in the natural sciences. This was followed in 1884 by his 'Compend of Geology,' a more elementary treatment of the same work. He was also interested in many other scientific and medical subjects such as 'The Problem of Flight,' 'The Func-

tions of the Liver,' 'Ptomaines and Leucomaines in their Relation to Disease,' 'The Larynx as an Instrument of Music,' etc. The mere mention of these varied subjects indicates the breadth of his interests and sympathies, but they by no means measure his intellectual activity. He was an active and successful exponent of the doctrine of evolution, and extended its principles to many fields of thought. Indeed, the evolutionary idea was the dominant note in nearly all his many philosophical writings and addresses. His strong advocacy of evolution as a principle running through all nature may be regarded as the most fruitful of his life's labors. On the battle ground, not long since so fiercely contested, between science and religion, he did splendid work, not, however, intensifying and embittering the strife, but in the work of conciliation, in the demonstration to thoughtful men in the camp of the churches that there could be no real conflict between seekers for truth whether in the pulpit or in the laboratory; that science sought simply the truth, nothing more, nothing less, and that in so far as scientific truth rested on a verifiable basis it was futile for the church to assail it.

But science, philosophy and religion failed to suffice his vigorous intellectual appetite. He was strongly interested in art; and the principles of art and their relation to science was one of his favorite themes.

It is needless to say that a man so fruitful of ideas as Professor Le Conte, so happy and so forceful in their expression, was eminently successful as a lecturer and public speaker. While he rather shrank from extempore addresses he was always willing to speak on public occasions and was always in demand.

Professor Le Conte's scientific work and influence extended beyond the writing of papers and books. He entered heartily

into the scientific life of the nation and took an active interest in various organizations which have for their purpose the strengthening and extending the love of science among the people. He was a member of the National Academy of Sciences, associate fellow of the American Academy of Arts and Sciences, corresponding member of the New York Academy of Sciences, member of the American Philosophical Society, fellow of the American Association for the Advancement of Science and past-president of the same, fellow of the Geological Society of America and past-president of the same, life member of the California Academy of Sciences, member of the Boston Society of Natural History, honorary member of the Brooklyn Ethical Association, member of the Iowa Academy of Sciences, member of the Davenport Academy of Sciences, member of the American Institute of Mining Engineers, member of the National Geographical Society, member of the International Geological Congress and once vice-president of the same, member of the California State Medical Society, honorary member of the South Carolina State Medical Society. He was also associated with the editorship of the *Journal of Geology* and of *SCIENCE*.

While Professor Le Conte, by his writings and by his active participation in the proceedings of the various societies just mentioned, had become a force in the intellectual life of the nation, this was only one element of his remarkable strength at the University of California. Here his intellectual achievements were overshadowed by the great and remarkable personality of the man. His singularly sweet and simple character seemed to seize upon all who came in contact with him and bind them to him as admiring friends. Indirection in any of its forms was utterly foreign to his nature. He was true to his ideals throughout life and his influence in the University

was always for the noblest and best in human effort. While too engrossed in his scientific and philosophic writings to take the initiative in University or public affairs, he was ever in touch with the progress of the time, and ever sympathetic and healthful in advance movements. He was of an exceptionally cheerful and happy disposition and was possessed of a fund of humor that made him a sparkling and entertaining conversationalist. He had the graces and manner and speech and chivalric instincts of a gentleman of the old southern school. He was beloved by the whole University, and with increasing years this love became a sort of veneration, so that he was in the later years of his life the veritable idol of the University community.

His death, without lingering pain, in the midst of the grand Sierra that he loved so well, surrounded by many of his friends, was a fitting close to his long life. His kindly presence and benign influence will long live in the memory of the University, and in the world of science he has certainly established for himself a monument more lasting than brass.

ANDREW C. LAWSON.

UNIVERSITY OF CALIFORNIA.

AN AMERICAN SENATE OF SCIENCE.

WHEN in the course of human events the most vigorous colonies of the New World deemed it necessary to found a nation, they cast aside tradition and example and invented a system of government based on the theory of human equality. The movement opened a new chapter in the history of nations; earlier governments grew into form much as the primitive implement takes shape by continued use, but this was a distinct creation, like the complex tool invented and made for a purpose; and the fundamental theory was new in application if not in thought. The invention of the colonists was applied experimentally, and

worked well; minor changes were found needful here and there in the adjustment of the mechanism to its work, yet remarkably enough the most sweeping changes led directly toward the fundamental theory of equality; and for a century and a quarter the world's first invented government has proved the world's most successful government. The device of governing by the people for the people was adopted by the component organizations with equally satisfactory results. The colonies, and after them the states, rested on the fundamental theory; the municipalities followed; counties and townships and villages adopted practice and theory together; and political organizations sprang from the theory to shape the practice of governmentation. In the smaller organizations as in the larger the governmental mechanism has worked well; difficulties have arisen, yet remarkably enough most of these have resulted from the opposition of one-man power to the theory of equal rights; and the world's most striking examples of growth in cities and States are found in numbers in the nation invented by its founders.

The essential mechanism of the invented government was that of control by equitably selected representatives. Provision for keeping the control adjusted to current needs was made by limiting tenure of office and excluding hereditary privilege; while provision against undue instability was made by arranging for the equitable selection of representatives of a second order, *i. e.*, representatives of representatives. In that branch of the government performing legislative (or constructive) functions, these representatives of representatives are organized in senates, whose powers are coordinate with those of the primary representative bodies. In general terms, the representative body is the progressive factor, the senate the conservative factor, of the body-politic; and it is the special function of the

senate to coordinate spontaneous movements, and thus to perpetuate the integrity and vitality of the organization. To borrow analogy from planetary assemblages, the representative body is as the centrifugal force, the senate as the centripetal force, combined in orbital progression. The important fact is that political organization of the modern and successful sort is incomplete without provision for the maintenance of internal harmony, of stability, of vitality—as in the senates of the invented nation and its constituent states.

Now America has become a nation of science. An unequaled proportion of her citizens are engaged in scientific research, while it is not too much to say that the masses of the people recognize the principles as well as the applications of science in their everyday avocations; the scientific spirit is fostered and diffused by a number of voluntary associations of scientific character probably larger in proportion to population than can be found in any other country; and our statesmen are guided by the conclusions of science, while our federal and State governments support science, in unequaled degree. Yet despite their activity and numbers, despite the extent and strength of their voluntary associations, American scientists have not profited by the example of the nation's founders, and have taken no steps toward shaping the further progress of science by representative organization. Many, if not most, of the voluntary associations indeed have executive bodies to exercise appropriate administrative and judicative functions, and perhaps to propose legislative action; but this mechanism merely simplifies the transaction of business, the powers of the elected representatives are limited to the affairs of a particular association of which the body is a part, and there are no representatives of the second order—no representatives of representatives—empowered to

act in the interests of science in general. It is not, of course, the function of science to govern, so that governmental organization *per se* is not required on the part of scientific men or their associations; but collective action for common interests demands organization—and one of the surprising features of American science (especially in view of the example set by statecraft) is its unorganized condition. True, each special science is fostered by one or more voluntary associations, sometimes of national character; true, general science is represented in each principal city by one or more voluntary associations, perhaps loosely confederated, as in New York and Washington; true, some fields of research have been preempted by the federal government in the public interest; true, different sciences are cultivated by the aid of special journals; yet the great fact remains that the scientists and scientific interests of America are not well coordinated, much less unified in a symmetric whole. The centrifugal tendency is strong; the centripetal factor requisite for independent character is lacking.

An effective mode of organizing American science is suggested by the constructive organization of the nation in which scientific progress has been most rapid—it is that of organizing the voluntary associations in what might be called a Senate of American Science. The successful example of American nationality would suggest that such a senate should be made up of delegates chosen by the voluntary scientific associations of the country, for limited terms, in numbers equitably proportionate to the size of the representative associations. The functions of the general body would naturally include (1) coordinating scientific interests and progress; (2) representing science in its broader aspects on behalf of the country; (3) forming a nucleus for scientific congresses, national and international; (4) fixing the bases of represen-

tation of the primary associations; and fulfilling any other duties connected with scientific interests and its own maintenance.

Two methods of procedure toward the organization of such a Senate of Science present themselves: The first suggestion is that of creation *de novo*, on the initiation of a few leaders in scientific thought. The chief advantage of this method would seem to lie in the freedom from entangling alliances; the chief obstacle would seem to grow out of the large initial energy required to set the mechanism in effective operation. The second suggestion is that of utilizing some existing organization, naturally of national character, as a nucleus. The chief advantage of this method would be that of economy in initial energy; while a serious obstacle might grow out of the indisposition of any existing association of national character to undertake the necessary reorganization. As between the two methods suggested, the sum of theoretical advantages would seem to favor the independent organization; though it might easily be that practical considerations would turn the advantage toward the method of reorganization of an existing society.

On reviewing the societies which might yield a nucleus for a national Senate of Science, several would seem worthy of consideration on various grounds; yet such consideration would seem to eliminate all but two or three from final review. These are (1) the American Association for the Advancement of Science, the oldest of our national scientific societies of general character, and the one most completely in touch with the scientists of the entire country; (2) the National Academy of Sciences, the most dignified and exclusive of our voluntary associations of scientific character; and perhaps (3) the Washington Academy of Sciences, one of the youngest and most vigorous of our scientific organizations, and

one already possessing (at least in inchoate form) a confederate character.

The availability of the last-named organization would seem questionable, primarily on the ground of its local character, partly because of its youth and the consequent uncertainty as to its real character and actual prospects. Although apparently available on casual consideration, the National Academy would seem on closer scrutiny to be fundamentally unsuitable as a nucleus for a coordinative super-organization; for it is based largely on foreign models, is out of accord with the theory and the practice of popular government, and has developed functions diametrically antagonistic to the limited tenure and representative character which would seem requisite for the success of a working senate. True, its membership comprises the most honored names in American science, men whose prestige and support would doubtless be essential to the success of a more general organization; but it would appear probable that most of the working members of this dignified body would enter in due course, by virtue of their standing, into a representative organization. The remaining society (the American Association for the Advancement of Science) would seem to offer an available nucleus through its Council, a body already representative in that it is made up largely of delegates nominated in the several nearly independent sections. It has the further advantage of serving already as a nucleus for other scientific organizations, a number of which meet with it annually, contributing materially to its standing and its influence on current thought concerning matters of scientific interest. This aspect of the Association and its Council was brought out clearly in a recent number of SCIENCE, and the exposition need not now be repeated; it suffices to note that the organization of the Association, its large and widely dis-

tributed membership, its strong hold on the sympathies of scientific men, the high appreciation in which it is held throughout the country, and the appropriate constitution of its Council, all point to the American Association for the Advancement of Science as a suitable nucleus for a Senate of Science—whenever the time arrives for establishing such an organization.

An obstacle in the way of instituting an American scientific body of general character may be noted: Our country is one of magnificent distances, so that the cost of attending meetings or sessions is necessarily large; and equitable representation in a general body would seem to require provision for meeting costs of travel incurred by delegates. Doubtless this could be effected through *pro rata* assessment on the constituent associations, if the central organization were once well under way; and it is possible that the burden might be measurably diminished by migratory meetings, after the fashion of the associations for the advancement of science in different countries. The difficulty might perhaps be overcome by securing a foundation through donation, bequest, or otherwise; certainly it is not insuperable in these days of unprecedented scientific prestige, and of rapid increase in material prosperity through the applications of science.

Summarily, it would seem appropriate for American scientists to draw inspiration and suggestion from American statecraft as to organization; it would seem timely to start a movement toward the more comprehensive organization of American science in connection with the first great assemblage of scientific men in the western half of the country; and it would seem especially fitting to initiate the movement at the approaching meeting in Denver of that organization which would most properly serve as a nucleus for an American Senate of Science.

W J M.

SOME STRANGE PRACTICES IN PLANT NAMING.

IN a recent issue of the *Bulletin* of the Catholic University of Washington, the distinguished professor of botany in that institution, Dr. Edward L. Greene, presents what he announces to be the first of a series of papers entitled 'Some Literary Aspects of American Botany.' It should be a source of gratification to the whole scientific fraternity that public attention has been thus called to the philological abuses so prevalent among the latter-day writers. This first paper contains a trenchant and forcible criticism of the titles applied to many recent botanical serials; and the author's commentary on such examples as 'Contributions to the Myxogasters of Maine,' and 'Contributions from the Herbarium of Franklin and Marshall College' is scarcely less instructive than entertaining.

It is a significant fact that this article by Professor Greene has already elicited a paper on a kindred topic, written by Dr. P. A. Rydberg and published in *Torreyia* for June. As the latter author confines himself, however, to a discussion of personal specific names and their mode of construction, I may be permitted to offer a brief commentary on the subject of plant names in general, from both the orthographical and etymological standpoint.

It has always been a widely accepted principle of scientific nomenclature that a specific once published cannot be subsequently altered in form except upon 'reasonable grounds'; but there has been, and still continues to be, a wide divergence of opinion as to what constitutes reasonable grounds for such alteration. The author of the name has usually been allowed more latitude in this respect than other writers; and in past botanical literature there are consequently many changes in orthography, corrections of typographical errors, etc., made either by the author himself, or more

frequently by other writers who may have had occasion to review his work. These alterations extend all the way from simple substitutions of one letter for another to the replacement of the name itself, generic or specific or both, by an appellation considered more appropriate. When to this uncertain element in plant nomenclature we add the whole vexed question of the principle of priority and the subject of type determination, it seems remarkable that in the progress of botanical science so few opposing schools of belief have been developed.

It may be profitable to give some consideration to the various views that have been entertained regarding the extent of alteration permissible in the case of incorrect or inappropriate scientific names. For convenience in discussion the various categories under which changes have been made will be taken up under separate headings.

1. *False Descriptive Names.*—Botanical nomenclature includes countless numbers of these, many of which have found acceptance from time immemorial. Thus *Polygala* is wholly destitute of milky juice; the stem-leaves of *Campanula rotundifolia*, which are frequently the only leaves discernible at maturity, are narrowly linear; *Viola villosa* is in no sense villous; and *Lunaria annua* is usually biennial. While the modern nomenclator would find little support in an attempt to change such names on the ground of their unsuitability, the practice was common among writers of the first half of the nineteenth century, as well as among the immediate successors of Linnaeus. Rafinesque, in particular, was fond of reading the riot act to his contemporaries for what he considered an outrageous disregard of natural characters in the assignment of plant names, as the following verbatim passage, selected at random from the 'New Flora of North America' (Vol. 2, page 95) will show:

"My genus *Diplostelma*, which Nuttall

had wrongly reduced to *Actinocarpus*, in Collins' herb. (there is no such genus, he meant probably *Actinospermum* of Elliott) has been described by him under the name *Chetanthera* in his new plants. * * * My name is the best, although Nuttall's dates of 1834, *Chetanthera* means bristly anthers, while this is not the case, he ought to have named it *Chetopappus*, but as the pappus is double and different mine is the best, and must be retained."

In the case of *Lunaria annua* mentioned above, published by Linnaeus in 1753, we find that Moench subsequently altered the name to *biennis* in recognition of its biennial character. Writers like Bentham and Gray did not adopt this extreme view, but if in the transfer of a species from one genus to another the specific designation became inappropriate through duplication of the idea contained in the generic name, they invariably took the liberty of changing it. Thus when *Anemonella thalictroides* was transferred to *Thalictrum*, it became *Thalictrum anemonoides*. Inasmuch as the acceptance of such a combination as '*Thalictrum thalictroides*' would imply an agreement with the doctrine of the entity of specific names it was entirely natural and logical for Bentham and his associates, who were strong opponents of that doctrine, to consider such cases exceptional to the rule of priority. If, however, we admit that a specific name is meaningless when disassociated with a generic, there seems no good reason why we should not continue the process of alteration, and follow in the footsteps of the immediate post-Linnaeans. There can be no half-way ground between him who would substitute '*biennis*' for '*annua*' on the one hand, and the botanist who believes in the immutability of specific names on the other.

2. *False Locality Names.*—The writings of Linnaeus and his contemporaries abound in instances of this sort. In many cases

the anomaly that now exists in such specifics as *Berberis Canadensis* and *Cercis Canadensis*—neither of the plants mentioned occurring beyond the Carolinian zone—results from the ignorance of geography displayed by the Old-World botanists of that day; frequently it is due to the great political changes that have taken place in this country during the last one hundred and fifty years. Even in modern times it is a common occurrence for a species to receive its designation from the State in which it was first discovered; and the fact that it may subsequently be found to extend into many other States has never been considered a sufficient reason for renaming it. But what are we to say of *Asclepias Syriaca*, which is exclusively an American milkweed? Decaisne promptly renamed it *Asclepias Cornuti*, and in this he was followed by Gray and other botanists. There are several writers of the present day who favor the alteration of names that state a geographical untruth.

A large number of genera, dedicated to individuals, have been incorrectly spelled, either through the author's ignorance or the compositor's blunder. Examples are Nuttall's *Wisteria*, dedicated to Dr. Wistar; Brown's *Lechenaultia*, named for Leschenault; and Rafinesque's *Scoria*, published as a misprint for *Hicoria*. De Candolle's rule in this connection was: "When a name is drawn from a modern language it is to be maintained just as it was made, even in the case of the spelling having been misunderstood by the author, and justly deserving to be criticized." Dr. Gray considered this rule too absolute, and admitted corrections not only of orthography, but also of errors in the construction of names of Latin or Greek derivation. If the eminent botanist of Harvard University were alive to-day it is to be feared that a large portion of his time would have to be devoted to this work if he wished to thoroughly revise the no-

menclatorial output of the present generation.

3. *Names falsely constructed.*—This includes words derived from modern languages without adaptation to the Latin or Greek form, and those compounded of elements from two or more languages. The writings of Adanson and Necker are full of generic examples of the latter type, and many of these have been taken up under the operation of the law of priority. Of the Adansonian names *Ananas*, *Sesban*, *Cajan*, *Sabal*, *Konig*, *Gansblum*, and *Rulac* it will be observed that none are in strictly correct Latin form, and with the exception of *Konig* and *Gansblum* they are all, I believe, of unknown derivation. It might naturally be inferred that the whole list should stand or fall alike; yet the curious inconsistency is found, that while *Sabal* has been accepted by botanists of every school for several generations, and while *Cajan*, *Sesban* and *Ananas* have been taken up under the Rochester code and are adopted by all its followers, the mere suggestion of *Rulac*, *Gansblum* or *Konig* as generic possibilities is received with amusement or contempt by the average botanist.

Before discussing these latter cases in detail, however, let us refer to the other class in my third category, consisting of so-called hybrid names constructed of elements from two distinct languages. Of these, modern botanical literature is furnishing a rich and ever-increasing store of examples. They may consist: (1) Of Greek terminations welded upon Latin nouns or *vice versa*, resulting in such products as 'graminoides' or the still more remarkable 'cenchrusoides.' (2) They may be compound adjectives, of which one element is Greek, the other Latin; this type is well illustrated by 'pseudocaudatum,' 'polyclavatum' and 'magnasora,' all of which have been recently published in the same journal. (3) Personal generic titles composed of an English proper name with a classical adjective used

as prefix or suffix, like *Vaseyanthus*, *Pringleophytum*, *Neonelsonia*, and *Paleohillia*. It was Dr. Otto Kuntze who astonished the world and carried off the palm in this class by the establishment of such genera as 'Sirhookera' and 'Peckifungus.'

I am quite well aware that these compound personal names have many defenders even among prominent scientists; it is argued that since personal genus-names are properly formed by the addition of the Latin suffixes *-a*, *-ia*, *-ella*, *-ina*, etc., there can be no objection to making these suffixes consist of an adjective or noun. But while the practice may not be technically incorrect, it is certainly not harmonious with the fundamental principles of etymology, and the results, whether we consider them from the standpoint of euphony or signification, are frequently ludicrous. Moreover, they often originate on account of an inordinate and misdirected desire to honor a collector with more than one generic dedication. This has become a common practice, although formerly it was held as a general principle that one genus, and one only, could be dedicated to a single individual; while in the case of species, it was customary to single out one striking new plant from the list and designate it in honor of the collector, other new species receiving descriptive names. But nowadays, if John Smith, let us say, visits some remote country and returns with a series of specimens containing several new genera and perhaps thirty new species, the botanist who determines his collection, finding a previously-published *Smithia*, establishes a '*Neosmithia*' and a '*Smithiophytum*,' perhaps also a '*Smithiocarpus*' or a '*Pseudosmithia*'; while among the new species we shall probably find a '*Smithii*' for each separate genus. The same traveler is likely to be similarly honored if he reaps an equally rich harvest in another locality the following year.

Another objectionable class of names belonging to the same general type are those derived from localities with the addition of the Latin suffix *-ensis*. Originally this was applied to names of States or countries already in the Latin form; and *Virginienensis*, *Carolinensis*, etc., are irreproachable. But then we began to have *Bostoniensis*, *Tennesseeensis* and *Wyomingensis*; one writer has furnished us with '*Bajensis*,' from Baja, the Spanish name of a small Californian town; and within the last few months a distinguished German systematist, having occasion to describe a new *Selaginella* from a certain locality in Africa, has applied to it the graceful and flowing designation '*njam-njamensis*.'

Whatever may be one's individual views concerning combinations of English personal names with Latin suffixes, I am sure that very few defenders will be found for the other classes mentioned, of which '*graminoides*' and '*pseudocaudatum*' are types. To those whose classical vocabulary is limited, the pages of the Latin lexicon afford numerous suggestions for specific names irreproachable in form and pregnant with meaning; it seems strange that so large a proportion of our systematists regard the rules of etymology and grammar as of so little importance in plant naming. Glancing over the pages of one or two of our prominent serials, I noted the following examples of Latin and Greek hybrids, many of which are as clumsy in their lack of euphony as they are faulty in their construction: '*paucicephala*,' '*pauciphylla*,' '*curvicarpus*,' '*crestencarpus*,' '*cuspidocarpus*,' '*arenicoloides*,' and '*polyclavatum*.' I have not thought it worth while to discuss such specific names as '*annulum*' for *annulatum*; '*areniculum*' for *arenicola*; and '*glabrissimum*' for *glaberrimum*, though these were actually published in all seriousness by authors of whom better work might have been expected.

In his review of De Candolle's 'Nouvelles Remarques sur la Nomenclature Botanique' Dr. Gray, in commenting upon the suppression of the fourth section of article 60 in the Paris Code, enjoining the rejection of names formed by the combination of two languages, observes: "Let us hope that we shall not be driven to the acceptance of the specific name 'acuticarpum' which one of our botanists has recently perpetrated." Whatever may be our views of nomenclature we must admit that in intellectual and philological attainments the botanists of the past generation are our superiors, and we cannot fail to award them respect and admiration for their vigorous efforts in behalf of the purity of scientific terminology. The list of recently published names above cited, on the other hand, may be accepted as evidence of what plant nomenclature in the twentieth century is coming to.

Having thus discussed at some length the various forms of false or otherwise objectionable plant names, with some slight indication of the historical practice in each case, we are led naturally to a consideration of the final question, what is to be done with these names? To my mind a serious discussion and an authoritative reply to this question are of vital importance at the present stage of botanical nomenclature in this country. We now have a working code, based on sound general principles and appealing in its practical operation to the spirit of law and order rather than to the fickle quality of individual judgment. Yet this code is absolutely silent upon the important question of correctness in plant naming. To be sure, it reaffirms the canons of the Paris code except where they conflict with its newly established principles. But the Paris Code is an instrument of considerable age, and, excellent as are most of its provisions, few botanists would now subscribe to all the Decandollean requirements. The modern tendency is to avoid interfer-

ence with any erroneously constructed terms unless the mistake is one of gender or orthography. The sentiment against altering false descriptive and false locality names like *Lunaria annua* and *Asclepias Syriaca* is even more strong; and this attitude seems reasonable, since these names are entirely correct in form, and the fact that they are untrue or anachronistic is frequently not the fault of the original author.

Objections, however, to the alteration of incorrectly constructed names like 'graminoides' are of little force in view of the position taken by many writers with regard to barbaric and other names not in the Latin or Greek form. I have already pointed out how certain Adansonian genera have been accepted without question while others of the same stamp are rejected. An attempt has been made to Latinize some of these by adding the termination *-a*; but the result is bastard Latin at best, and is far from the spirit of Adanson's original intention. Konig, for example, a word distinctly German in form, has been changed to Koniga! If by the mere Latinization of a name derived from some modern language it is to be considered legitimate, then why not take Gansblum of the same author and make it Gansblumia? The logical application of this theory would make it possible to adopt 'Washtubbia' and all of the other wonderful creations in the 'Nonsense Book of Botany.'

I am quite well aware that to retain in their present form the barbaric names of Necker and Adanson and the Aztec atrocities of ten or more syllables published by Hernandez in 1790 would be open to serious practical objection; but it is absolutely certain that all should stand or fall alike. *Sabal* has no more rights than *Rulac* or *Konig*; and if the Latin termination of *Bikukulla* entitles it to admission there is no shadow of an excuse for altering the *k*'s to

c's, as has been done in our recent manuals. If, on the other hand, we adhere to the view that a name, to be worthy of acceptance, must be in Latin form, we have no recourse but to abolish 'graminoides,' 'polyclavatum,' and the other hybrids, relegating them to the same limbo of obscurity with *Gansblum*, *Catjang*, *Rulac* and similar creations.

After uniformity in recognizing the rights of the doctrine of priority, the most important thing is to secure uniformity in our treatment of the names assured to us through the operation of that principle. It is true here, as in most other affairs, that the fewer exceptions we admit, the greater the practical benefit of the rule. At the present time our writers are serenely pursuing their individual preferences, correcting a name when they deem it advisable to do so, or even making substitutions of one name for another through one of the causes above discussed. It matters little whether we establish a rule of absolute permanency, retaining names in exactly the form in which they were first published, or whether we admit certain fixed exceptions; but the determination of a case should always be settled by authority and never left to personal caprice. No principle can be maintained if it is to be followed only at discretion.

One practical obstacle to any improvement of existing conditions is to be found in the tendency of the age itself. In this connection, let me quote a paragraph or two from the article by Professor Greene above referred to:

"It is easy to trace to its origin this condition of scanty mental equipment evinced by a great number of the botanical writers of to-day. Young men of the present are more than ever in haste to be earning wages and getting rich. It is a vulgar spirit which pervades—it is everywhere confessed—all classes of youth, as well as of older

people. Even they who aspire to what were once known as the learned professions, will hardly allow themselves the expenditure of time, not to say money, that is necessary to acquire anything beyond the most elementary and superficial education. * * * Nature study is captivating, perhaps much more so than grammatical, linguistic and metaphysical studies, to youth in general. There is no doubt of that. Neither need it be called in question that even a single branch of natural history study, long and ardently pursued, must have the effect of training a mind to careful and minute observation, and to reasoning and reflecting, and this is an important part of an education. But in our time few if any nature students are content with observing and thinking. All must write and print; and this whether they have or have not learned to write."

Against this somewhat discouraging state of affairs we are to set the tendency of the present time to recognize law as paramount and personal judgment as an uncertain guide. If botanists of all schools can be brought together in a strong and united effort to improve the literary and etymological side of nomenclature, it will not be difficult to secure agreement upon some sound general principle which will command the respect and win the adherence of every working scientist. There is here a subject upon which conservatives and radicals may unite, and a condition of affairs which cries aloud for attention and reform.

CHARLES LOUIS POLLARD.

U. S. NATIONAL MUSEUM.

THE USE OF HYDROCYANIC ACID GAS FOR EXTERMINATING HOUSEHOLD INSECTS.

WITH the growth of our population and the consequent crowding together of residences, the problem of the prevention and control of household insects is deserving of careful consideration from a sanitary stand-

point, but one that is usually overlooked. These pests are to be found in fewer or greater numbers of both species and individuals in every dwelling, office or storehouse, and no perfectly efficient means either to prevent their gaining an entrance, or to exterminate them when they are once established, has as yet been devised.

Recent successful applications of hydrocyanic acid gas for the extermination of insects infesting greenhouse plants have suggested the use of the same remedy for household pests. It is now no longer a theory, but an established fact, that .10 gram of 98-per-cent.-pure cyanide of potassium volatilized in a cubic foot of space will, if allowed to remain for a period of not less than three hours, kill all roaches and similar insects.

The experiments which led to this conclusion were made in a small building which is used for laboratory purposes by the Division of Botany. This structure has for some time been infested with several insect pests, the more numerous and troublesome being the common cockroach (*Periplaneta americana*). The building consists of one story and basement, the upper part being rather loosely built, as it is ceiled throughout with matched lumber. This method of construction provides numerous hiding places for the insects and also renders fumigation difficult, by permitting the gas to escape too quickly. Within the building are several sources of moisture, a rather high and constant temperature is maintained in some of the rooms, and large quantities of seeds and substances that serve as food for insects are stored, making conditions well adapted to the development of cockroaches.

During the early part of last year the roaches became so numerous as to be a detriment to the work of the laboratory and it was necessary to adopt some means of checking them. On the evening of May

10, 1900, the building was closed, and after opening up the interior of the rooms as much as possible the entire structure was fumigated experimentally with about .08 gram of 98-per-cent.-pure cyanide of potassium per cubic foot of space. The gas was allowed to remain during the night, or until it gradually escaped. When the rooms were entered the following morning there remained a perceptible odor of the gas, but this soon disappeared after opening the windows and doors. The ledges and window sills were strewn with dead houseflies and the floors bore abundant evidence of the effect of the gas on roaches. Not a single insect that showed indications of remaining life was to be found in the building. About a quart of the flies and roaches was gathered up and placed in a cage where they were allowed to remain until the following day, when two roaches showed signs of life by slow movements; these, however, could not walk when placed upon their feet and subsequently died.

For some time after this fumigation no roaches were to be found in the building, but eventually the eggs that had been previously deposited hatched and developed, adults were carried in from other buildings, etc., until in March of the present year the roaches had again become so numerous as to be a nuisance and a detriment to the work of the laboratory. The building was again treated with cyanide gas, this time at the rate of .10 gram per cubic foot of space, but was allowed to remain only fifty minutes, when the windows were opened and the gas permitted to escape. The roaches were strewn over the floors and several mice were found dead. A large number of the roaches were again collected and kept in a cage until the following day, when it was found that fully ten per cent. of them had not been killed and were as lively as before treatment; the mice, however, showed no

indications of life. The dose had been sufficiently strong, but had not been allowed to remain long enough to kill the more resistant of the roaches.

The third and most satisfactory experiment of the series was conducted on the evening of June 20, 1901, when an application of .10 gram per cubic foot was allowed to remain in the building over night. On the following morning the gas had not entirely escaped, and house-flies, centipedes, spiders, cockroaches, and mice were dead, with the exception of a few roaches that had secreted themselves between the sash and frame of a loosely fitting window and had thus secured enough pure air to prevent their being killed.

To convey an idea of the injury caused by the presence of large numbers of roaches in this laboratory it might be stated that frequently preceding this last fumigation, photographic plates placed on racks to dry and allowed to remain on a table for one hour were completely ruined by having the films eaten from the glass; packets of seeds stored in mouseproof tin boxes were so eaten as to allow the seeds to escape and in many cases the seeds themselves were destroyed. Since this fumigation no inconvenience has been caused by the work of roaches or mice.

By aid of the results obtained from the above experiments, together with our present knowledge of the action of hydrocyanic acid gas in exterminating greenhouse and scale insects, it may be stated that a dwelling, office, warehouse or any building may be economically cleared of all pests, provided that the local conditions will permit the use of this gas. It probably would be dangerous to fumigate a building where groceries, dried fruits, meats, or prepared food materials of any kind are stored. Air containing more than 25 per cent. of the gas is inflammable, therefore it would be well to put out all fire in an inclosure before fumigating. Hydrocyanic acid in all

its forms is one of the most violent poisons known and no neglect should attend its use. There is probably no sure remedy for its effects after it has once entered the blood of any of the higher animals. When cyanide of potassium is being used it should never be allowed to come in contact with the skin and even a slight odor of the gas should be avoided. Should the operator have any cut or break in the skin of the hands or face it should be carefully covered with court plaster to prevent the gas coming in contact with the flesh, or the possibility of a small particle of the solid compound getting into the cut, which would cause death by poisoning within a few minutes' time.

Hydrocyanic acid gas should not be used in closely built apartments with single walls between, as more or less of the gas will penetrate a brick wall. An inexperienced person should never use cyanide of potassium for any purpose, and if it be found practicable to treat buildings in general for the extermination of insects the work should be done only under the direction of competent officials. Our experiments have shown that a smaller dose and a shorter period of exposure are required to kill mice than for roaches and household insects generally, and it readily follows that the larger animals and human beings would be more quickly overcome than mice, since a smaller supply of pure air would be required to sustain life in mice, and small openings are more numerous than large ones.

The materials employed and the method of procedure are as follows: After ascertaining the cubic content of the inclosure, provide a glass or stoneware (not metal) vessel of two to four gallons capacity for each 5,000 cubic feet of space to be fumigated. Distribute the jars according to the space and run a smooth cord from each jar to a common point near an outside door where they may all be fastened; sup-

port the cord above the jar by means of the back of a chair or other convenient object in such a position that when the load of cyanide of potassium is attached it will hang directly over the center of the jar. Next weigh out upon a piece of soft paper 500 grams (about 17.1 ounces) of 98-per-cent.-pure cyanide of potassium, using a large pair of forceps for handling the lumps; wrap up and place in a paper bag and tie to the end of the cord over the jar. After the load for each jar has been similarly provided, it is well to test the working of the cords to see that they do not catch or bind. Then remove the jar a short distance from under the load of cyanide and place in it a little more than a quart of water, to which slowly add one and one-half pints of commercial sulphuric acid, stirring freely. The action of the acid will bring the temperature of the combination almost to the boiling point. Replace the jars beneath the bags of cyanide, spreading a large sheet of heavy paper on the floor to catch any acid that may possibly fly over the edge of the jar when the cyanide is dropped, or as a result of the violent chemical action which follows. Close all outside openings and open up the interior of the apartment as much as possible in order that the full strength of the gas may reach the hiding places of the insects. See that all entrances are locked or guarded on the outside to prevent persons entering, then leave the building, releasing the cords as you go. The gas will all be given off in a few minutes, and should remain in the building at least three hours.

When the sulphuric acid comes in contact with the cyanide of potassium the result is the formation of sulphate of potash, which remains in the jar, and the hydrocyanic acid is liberated and escapes into the air. The chemical action is so violent as to cause a sputtering, and frequently particles of the acid are thrown over the

sides of the jar; this may be prevented by supporting a sheet of stiff paper over the jar by means of a hole in the center through which the cord supporting the cyanide of potassium is passed, so that when the cord is released the paper will descend with the cyanide and remain at rest on the top of the jar, but will not prevent the easy descent of the cyanide into the acid. The weight of this paper will in no way interfere with the escape of the gas.

At the end of the time required for fumigation the windows and doors should be opened from the outside and the gas allowed to escape before any one enters the building. A general cleaning should follow, as the insects leave their hiding-places and, dying on the floors, are easily swept up and burned. The sulphate of potash remaining in the jars is poisonous and should be immediately buried and the jars themselves filled with earth or ashes. No food that has remained during fumigation should be used and thorough ventilation should be maintained for several hours. After one of our experiments it was noted that ice-water which had remained in a closed cooler had taken up the gas and had both the odor and taste of cyanide.

For dwellings one fumigation each year would be sufficient, but for storage houses it may be necessary to make an application every three or four months to keep them entirely free from insect pests. The cost of materials for one application is about fifty cents for each 5,000 cubic feet of space to be treated. The cyanide of potassium can be purchased at about thirty-five cents per pound, and the commercial sulphuric acid at about four cents per pound. The strength of the dose may be increased and the time of exposure somewhat shortened, but this increases the cost and does not do the work so thoroughly. In no case, however, should the dose exceed .22 gram or remain less than one hour.

The practical application of this method of controlling household insects and pests generally is to be found in checking the advance of great numbers of some particular insect, or in eradicating them where they have become thoroughly established. This method will be found very advantageous in clearing old buildings and ships of cockroaches.

DIVISION OF BOTANY,
U. S. DEPARTMENT OF AGRICULTURE.

*ENGINEERING EDUCATION IN LONDON.**

JUDGED merely by the magnitude and diversity of the work actually carried out within its boundaries, London is by far the most important center in the world for civil, mechanical and electrical engineering. Its vast population includes a larger number of engineering employers and engineering workmen of every grade and in almost every branch of work than any other city can show. The demand for engineering instruction of every type is large and steadily increasing. Yet the provision now existing for engineering instruction can only be described—if we compare it with the needs of London in this age of steel—as trivial. Out of six millions of inhabitants the total number of engineering students above matriculation standard is estimated at 600. What provision there is seems good, as far as it goes, but it is ludicrously below the requirements of London, alike in extent, comprehensiveness, and variety.

The engineering instruction at present available in London consists mainly of three separate 'schools'—the Central Technical College of the City and Guilds of London Institute, University College and King's College—of a high standard of excellence in the somewhat limited work that they undertake, with a small staff of first-rate professors, and good, though not very

extensive, equipment. Their main drawback is their limited size and scope, the high fees which they are compelled to charge, and their limitation to day students. Their work is, moreover, narrowly restricted by lack of space, lack of staff and lack of funds. They contain, in the aggregate, only about 350 students in all branches of engineering. Supplementing these three 'schools' (which are all situated in West Central London, within an area of three square miles) there are about a dozen less completely organized centers of engineering instruction, each with one or two professors and instructors of university rank, aided by subordinates dealing with the less advanced classes. These include the Finsbury Technical College of the City and Guilds of London Institute, where first-rate professors deal with junior students, and the several 'polytechnics,' dealing with all ages and classes of engineering pupils. These centers are conveniently distributed in the different parts of London; they provide both day and evening instruction, and their engineering departments are rapidly increasing in size and importance. Their equipment and workshop accommodation, so far as mechanical and electrical engineering is concerned, is usually good, though somewhat limited. Besides many hundreds of elementary students in various engineering subjects, they contain in the aggregate about 250 engineering students doing work of university standard. This work could easily be extended, by strengthening the staff and improving the equipment of the several institutions, to an almost indefinite extent.

If we turn now to different branches of engineering, it may be noted that (apart from the Royal Naval College at Greenwich, which is not open to the public) absolutely no provision exists in London for instruction in marine engineering and naval architecture. Though the Thames is still one of

* From the *London Times*.

the great shipbuilding ports, and this local industry, moreover, has lately shown encouraging signs of revival, no young man in the Thames shipbuilding yards or marine-engine works can get access to instruction in his profession.

For civil engineering some small provision exists of high quality. But the instruction is limited in scope, given almost entirely in the daytime, and barred to most students by high fees. The position of London, as the capital of a vast empire, the center of organization for important engineering enterprises all over the world, and itself the scene of great municipal and capitalistic works seems to call for a considerable extension in the scope and variety of instruction in civil engineering. In connection with this need may be specially mentioned the lack of any systematic instruction for the large and growing class of municipal engineers; the absence of any school of railway engineering, dealing, among other things, with permanent way construction; the need for specialized training in dock and harbor work, for which London is the natural center, and, indeed, the total lack of any adequate treatment of hydraulics (for which alone Cornell University has a fully-equipped and well-endowed department). Moreover, this is perhaps the place to notice that (beyond one or two courses of professional lectures) London has nothing in the nature of a school of architecture. It contains far more architects than any other city in the world, and annually adds a larger quota to the profession than any other center. But it leaves them to pick up their art in the old-fashioned way, and makes no organized attempt to provide modern instruction. The result is that, whether on the constructive or the artistic side, we lag far behind the United States, France and Germany.

The provision for electrical engineering,

though lately much increased, is still inadequate, both in extent and in variety. Above all, there is lacking any adequate opportunity for research and instruction in the more advanced and newer developments. How much of the future of industry may not turn on the proper working out of the possibilities of high-tension transmission and polyphase currents? Where, too, is our school of electric traction, which will enable us to keep, at any rate, some part of this rapidly-growing industry in our own hands? It is not to our credit that, though Great Britain supplies the original ideas, the greater part of the equipment of the 'tube' railways has to be made in the United States and Switzerland.

Dealing with the matter geographically, we may say that, if all the existing centers were enabled freely to expand to meet the growing demand, and brought up to a satisfactory standard of efficiency and comprehensiveness, the greater part of the six millions of population would, as far as mechanical and electrical engineering are concerned, be adequately served. There would, however, still remain in the outer suburbs such important centers of population as West Ham, Croydon, Willesden, and Tottenham, containing in the aggregate over three-quarters of a million people, or as many as all Glasgow, needing engineering schools; and even within the county area additional engineering schools are required in the neighborhood of Hammersmith, Hackney, and St. Pancras. If these were provided the number of engineering centers within the radius would be raised approximately from 15 to 20, and it may confidently be predicted that the number of engineering students above matriculation standard could be, within two or three years, certainly trebled (*i. e.*, raised from 600 to, including all departments, at least 2,000); and would then still be far behind the number for Belgium or Saxony, with

which kingdoms—not with any one city—London has to be compared.

What is wanted in the faculty of engineering is, therefore :

1. Increase in staff of professors and instructors at existing centers—say £10,000 a year (£330,000).

2. Extensions at existing centers in buildings and equipment to accommodate additional students—say £150,000.

3. New centers—building, equipment, and endowment of engineering departments at—say seven at £50,000 (£350,000).

4. New subjects—provision for buildings, equipment and endowment of centers for marine engineering and naval architecture (£100,000); civil and municipal engineering (£100,000); railway, dock and hydraulic engineering, etc. (£100,000); electric traction (£100,000); architecture (£100,000), etc. We may say, therefore, that the faculty of engineering needs a capital sum of £1,330,000.

SCIENTIFIC BOOKS.

Bibliotics, or the Study of Documents. By PER-SIFOR FRAZER. Third edition. Philadelphia, J. B. Lippincott Co. 1901. Pp. xxiv+266.

The subject-matter of this book, not very clearly suggested by the title, is the methods used by the handwriting expert and by the chemist, in the identification of writing and the detection of forgery. A scientific man desirous of getting some insight into these methods—or into the best of them—will find this book good reading. It is written with a scientific bent. It considers handwriting much as a zoologist considers animals. The determination of the characteristics of a given handwriting is like the determination of the characteristics of a natural species. The older methods relied on general impressions or on the description of salient features; the newer methods rely on measurement of the details. A person's handwriting, like a natural species, is a variable thing, and the exact study of it must deal in averages and ranges of variation. "It will be readily conceded that at least two factors are

present in the performance of an act which is often repeated. One is the general similarity, and the other is the variation in some details which prevents any two acts or results from ever being exactly identical. These are analogous to the two important factors of the theory of evolution, called, by Charles Darwin, hereditary transmission and accidental variation. In order to arrive at an ideal standard of similar recurrent actions, it is necessary to eliminate, as far as possible, the accidental variations. The most obvious way to do this is to take the average or mean of the records of a number of such actions." The first method devised by the author for arriving at the mean was the graphic method of composite photography. This appeals to the eye, and shows directly which parts of a signature are most uniform and which are most variable. A disputed signature may better be compared with a composite of several genuine signatures, than with any one of them.

The more exact method of averages, also devised by the author, begins with actual measurement of details; and it is the inconspicuous details that are most characteristic. The salient features can be changed more or less at the writer's will, or imitated by another person. But the little tricks of curvature and slant and proportions, the minutiae of shading and alignment, as they are the expression of unconscious habits, so they cannot voluntarily be laid aside, and as they are undetected by the eye, so they cannot be reproduced by a forger. The most useful details for measurement are angles and the ratios of different lengths; these are very inconspicuous, yet fairly constant, not changing with the size of the letters.

If, then, a signature is disputed, several genuine signatures are obtained, and a certain number of details are measured in all the specimens; the average measurements of the genuine signature are computed, and the measurements of the disputed signature compared with them. Close agreement throughout stamps the disputed signature as genuine; wide divergence as spurious. Some divergence is of course to be expected, and in fact complete identity is evidence of tracing. But just how much difference can be allowed? How sure is the expert of his decision? It does not appear that the theory

of probabilities has been used in any rigid way. The author's experience leads him to adopt a difference of 15% between the average and the disputed signature as ground for suspicion. Differences of 5 or even 10% are not uncommon in genuine specimens. But differences of 15% are uncommon, and, especially if repeated, are suspicious. The expert's decision must often rest on rather weak foundation as judged from a scientific standpoint, and the more so since he often has but half a dozen specimens from which to determine his average. The work of Mr. Frazer is very suggestive of what might be done in the study of handwriting. An extensive study of the variability of the individual, and of the differences between different individuals, as regards these ratios, angles, and other details, would show how sharply individualized they are, and furnish a scientific basis for the expert.

Another method of the author is the microscopic examination of the margins of the strokes. Under a magnification of 120 diameters, or even much less, a pen or pencil stroke is seen to have irregular edges; it is full of serrations of different sizes, the smaller superposed on the larger. There are usually more of them in one margin than in the other, depending on the position of the pen and other peculiarities of the writer. Whether they are completely individual, it would be premature to say, but they can at least be often used to distinguish between the writing of two persons. With the cooperation of Professor Witmer, the author has made micro-photographs and camera lucida tracings of these wavy margins, and inclines to regard some of them as records of the minute, normal tremor of the hands, produced by fluctuation in the nerve currents that control the muscles. Machine-ruled lines, though not free from irregular margins, showed fewer serrations than lines made by hand. The reviewer is much inclined to doubt this interpretation of the wavy margins, since he finds the serrations more marked on rough than on smooth paper, whereas the friction of the rough paper would tend to conceal the tremor. The rate, too, at which the serrations are produced is not approximately constant, as that of the tremor is, namely, at 8-15 pulses per second; a fast stroke and a slow show about

the same number of serrations per millimeter and those in the fast stroke must have been made, in one line measured, at about the rate of 480 per second. Many of the irregularities are probably due to the texture of the paper, and others to vibrations of the pen. Yet one's manner of holding the pen might give rise to characteristic forms of margin.

Still other chapters of the book treat of the chemical and physical tests for inks, of tests for erasure and other tampering, of tests for 'guided hands,' and of other problems incidental to the detection of forgery. There are several excellent plates.

R. S. WOODWORTH.

Taxidermy, Comprising the Skinning, Stuffing and Mounting of Birds, Mammals and Fish. With numerous engravings and diagrams. Edited by PAUL N. HASLUCK. London, Paris, New York and Melbourne, Cassell & Company. 1901. 16mo. Pp. 160.

Within the last ten years at least three admirable books on taxidermy have been brought out in the United States, and any new work on the subject should either bring forward some new and improved process of preserving animals, or at least present the most approved methods in a clear and detailed manner. The little book under consideration does neither; the methods described in its pages are the old ones, and not always the best of those, while the amount of space given to each group of animals is so limited that the descriptions are necessarily brief, while there is nothing whatever on the mounting of large mammals, although this is seldom acquired from books alone.

However, the book is intended for the amateur who wishes to preserve some trophy of the chase rather than for any one who really intends to master the art of taxidermy, and there are directions for making screens, polishing horns, tanning skins, and doing various bits of taxidermic fancy work. The small size of the book enables it to be readily put in the pocket, and, as it takes but little room, it might readily be carried to seashore or country on the chance that it might be desired to save some bird, mammal or fish, or make a pair of wings into a screen.

F. A. L.

La Democrazia nella Religione e nella Scienza—Studi sull' America. By ANGELO MOSSO. Milan. 12mo. Pp. 450.

This book is a striking proof of the remarkable versatility of Professor Mosso, the Italian physiologist. It purports to be a résumé of impressions gathered on his visit to this country in 1899, but the book has a wider bearing and goes quite beyond the scope of a journal of travel. It is a very suggestive survey of some of the most characteristic aspects of American life, and Professor Mosso, who was already known as a writer of unusual brilliancy and cleverness in his own field of physiology, shows here a decided taste for sociological investigations—a feature quite new in the personality of the author of 'La Paura.' He is too modest to consider himself anything but a dilettante in the study of social facts and problems. But the thoroughly scientific training of Mosso's mind, his experimental habits and trend of thought, his keen power of observation, raise the value of his sociological impromptu and give his studies of American life a deeper significance, which cannot fail to command the attention of the 'specialist' himself.

The book includes eleven chapters and, as an appendix, the lecture on 'Thought and Motion' delivered at Worcester, Mass., on July 7, 1899, on the 10th anniversary of the foundation of Clark University. The first chapter is mainly descriptive. It is a series of notes taken while travelling through the country. Mosso, who is a fine writer, shows here his characteristic qualities of vividness and brilliancy. The second is a study of the general features of the population. Here the physiologist has his way and shows himself at every step. The various aspects of the population, anthropological characters, mental and moral traits, the demotic composition, the birth-rate, the criminal and suicidal tendencies, etc., are all systematically taken up and discussed with great clearness and lucidity. Mosso is struck by the unmistakable evidence of nervous strain exhibited by the American population, as a whole. "Perhaps," he says (p. 38), "we have reached in this country the maximum limit of work that can be attained by the neuro-muscu-

lar system." Mosso is a firm believer in the influence of climate upon the race.

"The transformation of the anthropological characters under the influence of climate is," according to Mosso, "a physiological fact that cannot be doubted" (p. 75). Climate and education—meaning, of course, by the latter the action of social environment—are the only sources of dissimilarity in men (p. 106). This is the thought that runs through Chapter III., in which the racial question is taken up and discussed in the light of recent literature. Mosso does not believe in the form of the skull as being the differential element of racial types and an index of the psychical tendencies of each. "This is," as he puts it, "a puerile form of materialism. Our present knowledge of the structure and function of the nervous system does not warrant our attributing such a prominent importance to the form of the skull. The alleged measurements of the anthropologists are entirely worthless as a means of determining the psychical tendencies of a man or a nation" (p. 80). The difference in the form of the skull and in the color of the hair, upon which the entire structure of Ammon and Lapouge's anthropo-sociology is based, is due to the combined action of altitude and temperature—*i. e.*, to the climate. Inhabitants of the mountains have fair hair, while inhabitants of the plains have dark hair. Livi has conclusively shown that all over Italy—including Sicily and Sardinia, where the so-called northern races never reached—the mountains are inhabited by fair-haired men. Since the color of the hair is dependent upon the deposition therein of a varying amount of pigment ultimately derived from the blood, it is not difficult to trace the connection between the climate and the phenomena of oxidation which are at the bottom of the production of pigmentary matter. On the other hand, the dissimilarity in the form of the skull, upon which so much stress has been laid by anthropologists, is merely due to the lack of correlation between the size of the body, which is influenced by altitude and temperature, and the size of the brain, which is left unchanged (pp. 82–83). There are no races in the old metaphysical meaning of ethnic groups governed by congenitally blind impulses. The

differences among men are all traceable to the action of climate and education (p. 96). The Germans and the Scandinavians are, together with the Latins, the representatives of the same Mediterranean race, which, according to the most accepted view (Sergi, Ripley) was the primitive inhabitant of Europe. The so-called northern peoples are merely that part of the original racial stock that went north and became fair-haired, taller and dolicocephalic through the combined action of climate, social environment and natural selection (p. 97). This leads Mosso to refute the legend of Latin decline and to discard the assumption that there exists a congenitally organic difference between the Americans—as representing the northern races—and southern or Latin races.

While we agree with Mosso in his refutation of the fantastic theories of Ammon and Lapouge, we cannot leave unchallenged a statement made at the very beginning of this interesting chapter. Mosso says (p. 79) that “a physiologist cannot possibly admit the existence of differences among white men in regard to the aptitudes of the nervous system. Sociologists,” he says, “are largely responsible for the widespread belief that the causes of historical facts should be traced to different impulses originating from an alleged structural dissimilarity of the nervous system.” Without admitting the skull theory and all the nonsense connected with it, we cannot deny the existence of two mental types, a motor and a sensory, to which correspond, on the volitional side, the impulsive and the obstructed, as masterfully described by James. Now, these mental types cannot but be the outcome of some peculiarity in the ultimate structure of the nervous system. There must be some deep physiological condition to account for the fact that in one set of brains we have a quicker discharge into the muscles than in another set where we have a distinct damming up of the nervous impulse. We are as yet unable to determine what this deep-seated peculiarity is. Probably we have to deal with a chemical problem, and the difference between the two classes of brains in question is in some way related to the metabolism of the nervous element. The fact, however, is undeniable and Mosso, as a physiologist, cannot possibly think

that these two mental types have no physiological substratum. Space forbids an exhaustive discussion of this interesting topic, but we must say that the unequal distribution of these two types of brains within a definite social group is probably the fact which affords the most conclusive explanation of the so-called racial differences. According to the predominance of one or the other of those two mental types, within the group, we have a different mental tone in the community and these various shades of mentality are, after all, the very essence of racial dissimilarity.

In the next chapter—the fourth—Mosso takes up the problem of Democracy and Religion. He is struck by the wonderful growth of Catholicism in this country, a fact which is in harmony with the expansion of Catholicism in Europe, and especially in England, within the last fifty years. Seeking an explanation, Mosso remarks that religion is necessary only for the mentally weak—*i. e.*, for the masses. A nation of philosophers might do without it, just as the intellectual élite does. But no religion can help those who believe better than Catholicism because this latter appeals more vividly to the emotional element, which is the very essence of belief (p. 128). Protestantism is, like the northern climates, gray and sad. There is an element of dullness in it which is in striking contrast with the warmth and life of Catholicism, and since religions have always been, as Mosso vigorously puts it, ‘a form of festival’ (*una forma di festa*) it is the one that appeals more vividly to the senses which has the greater power of propagation (p. 129).

On the other hand, civilization makes men more exquisitely excitable. This ‘effeminating’ influence of civilization is also at work in the expansion of Catholicism (p. 128). The tendency to mysticism which is quite evident in art and literature is a result of the increased intensity of excitability brought about by the refining influence of civilization. And mysticism is fatal both to science and to Protestantism. The clearness of Mosso’s position is somewhat obscured by the fact that he refers to Catholicism as being both the religion of the ignorant masses and the religion of the hypercultivated mystical. Now, Catholicism can be

one or the other of these two things, but cannot be both at the same time. Perhaps the latter interpretation is the nearest to truth. The expansion of Catholicism in England within the last fifty years is evidently related to the undercurrent of mystical tendencies which has been pushing Saxon art towards archaic forms. But, as far as this country is concerned, the growth of Catholicism is dependent upon increase in immigration from Catholic countries, a factor which has been somewhat underestimated by Mosso.

In the following chapters—V., 'The Weakness of Religious Feeling,' VI., 'The Protestant Universities,' VII., 'The Catholic Universities and Canada,' VIII., 'Americanism,' IX., 'Modern Tendencies in Education'—Mosso takes up the different aspects of the problem upon which his interest is mainly centered, *i. e.*, the problem of the relation that democracy bears to religion and education. Particularly worthy of mention are the chapter on 'Americanism,' which gives a very clear account of the controversy waged between the Roman Curia and some prominent representatives of Catholicism in this country, and those in which he describes the peculiarities of American university life. Chapter X.—'The Crowd and the New Aristocracy'—is a study of American political life as influenced by the formation of a powerful aristocracy of millionaires. The tenth chapter, on 'Primitive America,' is a hymn to nature. It is a vigorous description of some of the most picturesque aspects of this continent, in its wildest regions, where civilization has not yet spoiled the divine charm of an enchanting nature. Here Mosso shows his decided literary tastes, and some of his pages are really beautiful.

On the whole, Mosso's book will prove both interesting and instructive to his own compatriots as throwing a fuller light upon this wonderfully growing country, which is called to play such a tremendous rôle in the drama of the century. While to the American reader who can afford to take hold of this charming book, it will undoubtedly be a source of deep gratification to see how the noble efforts of this valiant race towards a high ideal of civilization are appreciated by a scholar and a scientist of Mosso's standing and fame.

GUSTAVO TOSTI.

Atoms and Energies. By D. A. MURRAY, with an introduction by PROFESSOR FREDERICK STARR, of the University of Chicago. New York, A. S. Barnes & Co. 1901.

"It is a long time since I have read a work in physical science which has given me so much pleasure as 'Atoms and Energies.' The subject is interesting, the point of view novel, the argument clear, the book itself satisfactory."—Professor Starr.

In writing this short review our chief aim is to make reply to Professor Starr, for we too have been trying to interest him and others not specially devoted to the subject in physical science.

From the contents of the little book before us it appears that the author knows nothing of the works of the great builders of that marvelous Engine of Interpretation, the atomic theory. Among these works may be mentioned the following, each of which is monumental in character. The list will serve to indicate to the reader the present scope of the atomic theory. Maxwell's and Boltzmann's contributions to the 'Kinetic Theory of Gases,' Sohncke's 'Theory of Crystal Structure,' Poisson's contributions to the 'Molecular Theory of Elasticity,' van't Hoff's 'Stereo-chemistry,' Planck's 'Electro-atomic Theory of Radiation,' and J. J. Thomson's 'Corpuscular Theory of the Electric Discharge,' to say nothing of such works as Johnstone Stoney's on 'The Electron Theory,' and Lord Kelvin's on 'The Vortex-atom Theory,' both of which are devoted to 'many an assumption that is not exactly necessary,' to use Helmholtz's words, which are quoted in the next paragraph.

What are atoms? we are inclined to ask when we take up Mr. Murray's book, although under ordinary circumstances the question does not much concern us. In so far as we have anything to do with them we believe they are mere logical constructions. Bacon long ago listed in his quaint way the things which seemed to him needful for the Advancement of Learning. Among other things he mentioned 'A New Engine or a help to the mind as a tool is a help to the hand,' and the greatest achievement of the nineteenth century in physical science is the realization of Bacon's idea, in a great body of useful theory. As Helmholtz

says: "It is a great advantage for the sure understanding of abstractions if one seeks to make of them the most concrete picture possible, even when the doing so brings in many an assumption that is not exactly necessary." Just how much of this useful theory is to become the common property of all men it is impossible to say. For one thing, the theory is not by any means fixed and may not be for a century to come, and no one but the most determined specialist can be expected to appropriate and use the more complex theories which depend upon the keenest mechanical sense, the sharpest algebraic faculty, the strongest geometrical imagination and the most devoted study; but there is a great and growing body of simple conception and theory which can and does represent to the understanding a vast array of fact. Every one should know that the physicist's idea of a thing such as a gas, an electric current, or a beam of light comes very near to being a working model of the thing. The elements out of which such models are made are purely notional, and although the physicist habitually speaks of them in objective terms for the sake of concreteness and clearness, it is of the utmost importance that the thought be chiefly directed to the physical facts which are represented and not to the models themselves. Thus the chemist may speak of the tetrahedral carbon molecule with assymmetrically attached molecular groups, while the thought is directed chiefly to those remarkable physical properties of sugar and tartaric acid which are intended to be represented.

There is a tendency among reflecting men to confuse the boundaries between our logical constructions and the objective realms which they represent to the understanding. In fact, Münsterberg maintains that this confusion is the gravest danger of our time. It seems to us that these logical constructions constitute the noxious gases mentioned by Professor Woodrow Wilson as escaping from our laboratories, and that they become noxious by confusion and misuse. The old idolatry is the worship of external form—imagine a remote ancestor worship fully contemplating the newly invented club instead of using it—and the new is the con-

templation of our logical constructions in an aspect in which they are not real, a vaporous idolatry which is frightfully prevalent.

We are impressed more and more every day with the fact that the most satisfactory specialist to talk with is the biologist. His knowledge is not represented to his mind by means of that mathematical-mechanical system of conceptions which is the basis of all our knowledge in physical science, but it approaches art in its close association with external form. Conversation with a physicist, however, is very like looking into the mechanism of a Mergenthaler type-casting machine with the machine out of sight, feasible enough among designers and builders, but scarcely a satisfactory basis for the flow of thought when one party in the conversation happens to be unfamiliar with and perhaps not interested in the mechanism in question. Nevertheless a seriously minded physicist cannot help feeling mortified when he sees a colleague of Professor Starr's standing examining a more or less fanciful, inoperative, and obsolete pea-shooter with the pleasurable conviction that he is unraveling the intricacies of a complicated mechanism of the latest and most approved construction.

W. S. FRANKLIN.

SCIENTIFIC JOURNALS AND ARTICLES.

The American Anthropologist for April-June, which has just reached us, contains the following articles:

'The Owaküiti Altar at Sichomovi Pueblo': J. WALTER FEWKES.

'Chalehuhuitl in Ancient Mexico': ZELIA NUTTALL.

'Notes on the Alsea Indians of Oregon': LIVINGSTON FARRAND.

'Kootenay Group-drawings': ALEXANDER F. CHAMBERLAIN.

'Ethnology in the Jesuit Relations': JOSEPH D. MCGUIRE.

'Rare Books relating to the American Indians': AINSWORTH R. SPOFFORD.

'Summary of the Archeology of Saginaw Valley, Michigan': HARLAN I. SMITH.

'Mummification, especially of the Brain': D. S. LAMB.

'Decorative Symbolism of the Arapaho' (with plates V. and VI.): A. L. KROEBER.

'Initiation Ceremonies of the Wiradjuri Tribes': R. H. MATHEWS.

'The Development of Illumination': WALTER HOUGH.

THE contents of the *American Journal of Science* for August are:

'Experiments on High Electrical Resistance,' Part II.: O. N. ROOD.

'Mineralogical Notes': A. J. MOSES.

'Motion of Compressible Fluids': J. W. DAVIS.

'Action of Sodium Thiosulphate on Solutions of Metallic Salts at High Temperatures and Pressures': J. T. NORTON, JR.

'Secondary Undulations shown by Recording Tide-gauges': A. W. DUFF.

'Mathematical Notes to Rival Theories of Cosmogony': O. FISHER.

'Studies of Eocene Mammalia in the Marsh Collection, Peabody Museum': J. L. WORTMAN.

'Electromagnetic Effects of Moving Charged Spheres': E. P. ADAMS.

'The Nadir of Temperature and Allied Problems': J. DEWAR.

The *American Geologist* for July contains a 'Sketch of the Life and Work of Augustus Wing,' by Henry M. Seeley. In this article the work of Mr. Wing, the teacher and preacher, in solving the early problems in New England geology is set forth. A portrait accompanies the article. 'Beach Structures in the Medina Sandstone,' is discussed by Professor H. L. Fairchild. The Medina sandstone is described as shallow water deposits, following the conclusions of Dr. James Hall and controverting the theory of Dr. Gilbert, who recently maintained that certain structures in said sandstone are giant ripples formed in deep ocean. The writer compares the structures in question to the beach formations on Lake Ontario at the present time. The article is accompanied by five plates from photographs. 'The Michipicoten Huronian Area,' by S. B. Wilmott, describes an area north of Lake Superior. It is accompanied by a geological map of the region. Mr. Oscar H. Hershey discusses 'The Age of the Kansas Drift Sheet,' and gives reasons why the Kansas drift as well as others of the lower Mississippi is a very old one. 'The Georgia Bauxite Deposits: Their Chemical Constitution and Genesis,' by Thomas L. Watson, is accompanied by a plate showing the distribution of

that mineral in Georgia. 'The Age of the Kansas-Oklahoma Redbeds' is discussed by J. W. Beede. The author put the deposits in question in the Permian. This paper is followed by 'A Short Discussion of the Origin of the Coal Measure Fire Clays,' by T. C. Hopkins, and the usual Comments and Reviews.

SOCIETIES AND ACADEMIES.

SECTION H. ANTHROPOLOGY. TITLES FOR PRESENTATION AT THE DENVER MEETING.

'Sculptured Stone Images of Man by the Aborigines in Nicaragua': J. CRAWFORD.

(1) 'The Stanley McCormick Hopi Expedition of 1901'; (2) 'The Sacred Bundle of the Osage'; (3) 'Games of the Pawnees'; (4) 'Hand or Guessing Games of the Wichitas': GEORGE A. DORSEY.

'Influences of Racial Characteristics on Socialization': FRANK W. BLACKMAN.

'Exhibit of curves of speech': E. W. SCRIPTURE.

'The Physical Characters of the Various Pueblo Indians, including the Mokis and Zuñis': ALES HRDLICKA.

'Current Questions in Anthropology': W J McGEE.

'A Plea for Greater Accuracy and Greater Simplicity in the Writings of the Future regarding the American Aborigines': CHARLES E. SLOCUM.

QUOTATIONS.

PRIORITY IN THE DISCOVERY OF THE MALARIAL PARASITE.

AN unfortunate controversy having arisen on the question of priority in the proof of the mosquito theory of the transference of malarial infection, Major Ronald Ross has published some correspondence on the subject which shows that the claims of some of the Italian observers cannot be substantiated ('Letters from Rome on the New Discoveries in Malaria,' 1900). These eight letters were written by Dr. Edmonston Charles, a resident in Rome, to Major Ross, then in India, and date from November 4, 1898, to January 14, 1899; a letter from Dr. Daniels is included, and they are preceded by a critical

introduction, and terminate with a postscript and bibliography by Ross. At this period the Italians, notably Grassi, Bignami and Bastianelli, were endeavoring to follow Ross's investigations on the development of the malarial parasites in the mosquito, and Dr. Charles acted as an intermediary, informing Ross of the progress made by the Italians, and similarly communicating to the latter Ross's observations and handing them his specimens. In the first letter, Charles asks for specimens for Marchiafava 'of the mosquito in which human malaria develops.' Grassi now denies that Ross ever detected this species. It is pointed out how closely the Italians followed and how well informed they were of the details of Ross's work, yet now Grassi states that his labors were independent of Ross. In the third letter, with regard to the cultivation of crescents in the 'dappled winged mosquito' by Ross, Charles says, "He (Grassi) seemed perfectly satisfied that your description referred to the *Anopheles claviger*." Grassi now contends that he could not identify the malaria-bearing mosquito from Ross's description. Bignami, Grassi and Bastianelli have frequently stated that Ross's first successful experiments with human malaria were unsound, because the insects employed might have already bitten another animal before having been fed on man. Yet in Ross's publication it is clearly premised that the insects had been bred in bottles from the larvæ.—*Nature*.

IMPRESSIONS OF A GERMAN CONGRESS.

AN occasional correspondent, who speaks from experience, has been moved to unburden his soul as to the mode in which discussions are carried on at some German scientific congresses. The picture he draws is not, he declares, exaggerated, but his remarks must be understood as applying only to those congresses which are not divided into sections but in which the discussions take place in plenary session. There is a large room where the congress is to take place, filled with hundreds of our colleagues, of German and other nationalities. These gentlemen are prepared for several days' *ennui*, but are also resolved not to let it be all dull. They present a very varied ap-

pearance, and produce a very varied impression by the complexity of sound which their conversation, before the commencement of the proceedings, creates. The management consists of a chairman, who is changed at each sitting, and his *confrères*, the president, the secretary, and the other members of the council. The chairman opens the day's proceedings by informing the readers of papers that the time limit, namely, half of an hour for papers, and ten minutes for discussion speeches, will be rigidly adhered to. At first all goes smoothly until a speaker has occupied the attention of the House for twenty minutes or so, when there is heard an ever-increasing buzz of conversation from the back part of the room. Of this the speaker takes no heed, and when the half-hour is past, the chairman merely stretches himself and remains quiet. The next speaker has obviously not been fortunate in the impression that he has made on the House, for the conversation, begun during the last speech, continues, and becomes disturbing. But he, being accustomed to such trivial inconveniences, labors on steadily. The hands of the clock steal slowly onward, and when they register that the speaker has been standing at the desk for nearly twenty minutes, a single cry of 'End!' (*Schluss*) is heard. Soon the air is rent with wild delighted cries of 'End!' and feebly tempered by a few subdued remonstrating '*Gsch.*' The chairman rings his bell. Some order is restored, and he tells the speaker that he has two minutes more. Poor speaker! He has lost the thread of his argument (for papers must be given from memory, not read), he is face to face with the fact that he has but two minutes more to live—as a speaker—and he thereupon invariably pitches himself headlong into his subject, at such an enormous rate, and with so much energy, that it becomes a matter of impossibility to understand what he is speaking of. The noise at the far end of the room continues, and in one minute the second 'sound' of the bell is heard. The chairman now shows his humanity and asks the House to decide whether the speaker shall continue or not. This is done either by direct appeal and an interpretation of the responsive sound, as to what the

wish of the majority is, or by a show of hands. There is a subtlety in the decision, for if the chairman wishes he can rule on a single show, or he may ask for 'Ayes' and 'Noes,' or he may compare the number of hands shown with the number of persons present. But it is decreed that our friend, the speaker, must stand down, and there is something pathetic in his self-conscious, proud and satisfied bow, and the death-like silence which follows it for one moment. A discussion now takes place. At first absolute oblivion of time seems to surround the Chair, and the first intimation which the occupant of it receives of the fact that one member has occupied the platform for nearly half an hour is that his conversation with a colleague is interrupted by a dozen eager members who wish to have their say. Then he rings the bell and asks if the speaker has much more to say, but to do this he waits until the latter has reached the middle of a sentence. 'I am just finishing,' is the reply. Five minutes later a further ring, the same question, the same reply. Still five minutes later the chairman says that Herr X. is in possession of the platform, and requests the loquacious one to stand down. He forgets to bow, and, collecting his notes and papers slowly mumbles that he has had no time to give his most important points of argument. Will he try to continue his arguments at next year's congress?—*British Medical Journal*.

CURRENT NOTES ON PHYSIOGRAPHY.

THE MARYLAND COASTAL PLAIN.

A LUMINOUS generalization concerning the geological history and the geographical features of our Atlantic coastal plain has lately been announced by Shattuck ('The Pleistocene Problem of the North Atlantic Coastal Plain,' Johns Hopkins Univ. *Circulars*, No. 152, 1901). Five shore lines with wave-cut and wave-built terraces, accompanied by spits, bars and lagoon deposits, are recognized. The uppermost is the Lafayette on the margin of the Piedmont uplands at altitudes of from 300 to 500 feet. The lowest is on the present coast. The development of each shore line was preceded by a period of erosion during a somewhat higher stand of the land; hence when submergence to

the new level occurred, the shore was of irregular outline. Valleys were thus repeatedly drowned, and rivers transformed into estuaries; for one may trace the younger terraces along the sides of the older valleys. The changes of level do not seem to have been accompanied by so much warping as has been inferred by other observers: the conclusions thus announced are thought to be applicable to the coastal plain for some distance northeast and southwest of Maryland. A fuller description of the topographic details on which these changes are based will be waited for with interest.

DUNMAIL RAISE.

THE low pass between Windermere and Keswick in the English Lake district, annually crossed by thousands of tourists in stage and on foot, is known as Dunmail Raise. Its elevation is 782 feet, between Helvellyn, 3,118, and Scafell pikes, 3,210. R. D. Oldham ('On the Origin of Dunmail Raise, Lake District,' *Quart. Journ. Geol. Soc.*, LVII., 1901, 189-195) points out the striking disproportion between the size of the local streams and the dimensions of the opposing valleys that head in the open pass, and concludes that it is the work of a large river which once flowed from north to south through the mountains, long maintaining its course in spite of their upheaval, until at last overcome by a too rapid warping. While the conditions of such an origin are readily conceived, the consequences by which the conditions may be tested are not explicitly stated, and the reality of the postulated river is left in doubt. The present form of the opposing valleys being held to be beyond production by the existing streams, the valleys are taken as the product of the extinct river. The valleys being still but little modified by their streams, the warping by which the river was broken in two must have been relatively recent. The slopes of the opposing valley floors being strong and of recent origin, the warping that produced the slopes must have been rapid. As the present north-sloping valley descends against the slope of the extinct river for ten miles or more, the warping must have affected the district for a number of miles north of the pass. So rapid and extensive a warping can hardly have been

limited to the valley of only one river; its effects should be visible in all the neighboring valleys of the lake district, and until these effects are carefully deduced and systematically searched for, it seems safer to regard the erosion of the pass by a recently extinct river not as a probable conclusion, but only as an open suggestion.

A possible origin of the pass by glacial erosion in a preglacial notch of less depth is considered by Oldham and dismissed, because traces of glaciation were not found at a sufficient height; but on the latter point other observers do not agree, some maintaining the occurrence of an extensive local glaciation before the minor glaciation referred to by Oldham. Hanging valleys are not rare in these mountains ("We find in the Lake district a number of tributary valleys occurring in the hearts of the ridges, and opening out far above the bottoms of the main valleys, discharging their waters down the slopes in cascades." Marr, 'Scientific Study of Scenery,' 136), and one of them may be seen opening in the mountain side on the east just north of Dunmail summit. Glacial erosion as well as river erosion may, therefore, still deserve consideration in discussions as to the origin of the pass.

BRITTANY.

ONE of the excursions of the International Geological Congress held at Paris a year ago was led through Brittany by Barrois. An interesting account of it has been prepared by H. Credner under the title of its ancient name ('Armorika,' *Geogr. Zeitschr.*, VII., 1901, 21 p.). In contrast to the great deformation of the ancient rocks, moderate reliefs prevail to-day, much of the surface being nearly level to the eye for long distances. The region is peneplain, with occasional ridges and uplands maintained by the stronger rocks, but even there the forms are well subdued. The plain is usually clothed with a deep soil. It is here and there incised by narrow, steep-sided valleys, on whose walls the firm rock is exposed. The uplift of the peneplain, whereby the incision of young valleys has been permitted, is not explicitly stated, and the assertion that 'the valleys are extraordinarily old' is liable to misunderstand-

ing, until the reader infers that it is the predecessors of the present valleys that must be meant. The coast is generally marked by cliffs, torn into a ragged outline by a violent sea. The destructive work of the waves has been aided by a submergence of the land, of which there is not only geographical evidence in the form of bays and drowned valleys, but historical also, in the form of the ruins of a submerged town, of Roman roads that lead into the sea, and of megalithic monuments visible only at extreme low tide. The separation of England from France is ascribed to this submergence as well as to marine abrasion.

W. M. DAVIS.

A NEW ARCHEOLOGICAL PUBLICATION.

COMMENCING about September 1, the Archeological Section of the Wisconsin Natural History Society will publish, at regular intervals, a little 6- or 8-page sheet to be devoted to the cause of Wisconsin archeology. By this means it is hoped to keep alive and further the interest of the students, educators and collectors of Wisconsin in bringing about a better state of affairs as regards the preservation of the prehistoric monuments of the State.

The as yet uninterested attitude of the legislators argues that, for a year or two, at least, no bill favoring a State survey can be introduced. It is best, at present, to band together all persons interested until the time for action shall arrive so that the project can be carried to a successful issue.

The Bulletin is to be the organ of the campaign for a State archeological survey. It will not trespass upon the field of the journals now being published and which, being of too high price for the majority of State collectors and of a nature technically beyond their training, are not available for this purpose. It is intended to publish articles of local interest, short, general articles intended to train the average student, editorials favoring the free study and preservation of antiquities, notes, contributions of state collectors and students, notices of books bearing upon Wisconsin archeology, and all matter which will make the Bulletin of particular value to the archeologist of Wisconsin.

Dr. Charles E. Brown, of the Milwaukee Public Museum, is acting editor of the Bulletin, which will be known as the *Wisconsin Archæologist*.

HARLAN I. SMITH.

GOVERNMENT RAILWAYS IN EUROPE.

DR. A. VON DER LEYEN, a railroad expert, has published an article in the June number of the *German Review*, concerning the management of the government railroads of Prussia, of which Consul General Günther sends an abstract to the Department of State.

He demonstrates that the example of Prussia in buying the private railroads and running them on government account has contributed to popularize this system in other countries, and states that not only have the other German states followed it, but that almost all the other European countries have purchased the existing railroads.

The Austrian government railroad net has to-day a mileage of almost 6,300 miles; that of Hungary, about 8,150 miles. Since 1882 a great change has taken place in Russia; of the then existing 14,000 miles of railroad, only about 40 miles were owned by the government. The total mileage in 1897 was about 24,300 miles, of which 15,780 miles belonged to the government. To this must be added the government railroads in Finland and Asiatic Russia, the Trans-Caspian and the Siberian railroads. The Servian, Roumanian and Bulgarian railroads are owned exclusively by the respective governments. Of the northern European kingdoms, Denmark has a government railroad system of 1,167 miles and 525 miles of private railroads. Norway's railroads belong almost exclusively to the government. Sweden has 2,303 miles of government and 4,387 miles of private railroads. The government has not yet succeeded in acquiring the latter, although efforts have been made to do so. Belgium, in 1898, through the purchase of the Grand Central Belge and some minor private roads, became the possessor of the whole Belgium railroad system. Holland acquired all the remaining private railroads in 1890; they are, however, operated by two private companies. The Italian Government purchased all

private main railroads of Italy in 1885 and leased them for twenty years to private corporations. Mr. von der Leyen states that both the last countries have had unpleasant experiences with this arrangement. Switzerland, after long discussion, resolved by federal law in October, 1897, to gradually purchase all the private railroads. On January 1, 1901, the first federal railroads were operated by the Government. By agreements of 1883, the six large French private railroads had their rights recognized by the Government, and no change has been made in the policy in that country. The relatively small Government railroad system, located between the Orleans and the Western railroads, has remained intact. As the private railroads, however, have received large subsidies from the Government, and as they will revert to the State in the second half of the present century, they can hardly be considered purely private railroads. Of the countries which have a private railroad system exclusively, only England and the United States remain.

SCIENTIFIC NOTES AND NEWS.

THE fiftieth annual meeting of the American Association for the Advancement of Science, as all the readers of this Journal are doubtless aware, opens with a meeting of the council, at three o'clock on the afternoon of Saturday, August 24. The first general session of the Association, however, begins at ten o'clock on the following Monday, when Professor Woodward, the retiring president, will introduce the president-elect, Professor Minot. Addresses of welcome will be made by the Hon. J. B. Orman, Governor of Colorado, and Hon. R. R. Wright, Jr., Mayor of Denver. Honorary President, J. B. Grant, will introduce General Irving Hale and Aaron Gove, who will welcome the Association on behalf of the business men of Denver and the educators of Colorado. To these addresses President Minot will reply. After announcements have been made by the secretaries, the general session will adjourn and the sections will be organized. The addresses of the vice-presidents are delivered in the afternoon, and the retiring president will give his address entitled 'The Progress of Science' on Tuesday evening. The Sections of

the Association and the nine societies affiliated with it will hold their regular sessions on Tuesday, Wednesday, Thursday and Friday. The general committee will meet on Thursday evening for the election of officers and agreement on time and place for the next meeting.

Two of the prizes created by the will of Alfred Noble will be awarded to Dr. Niels R. Finsen, of Denmark, for discovering the light treatment for lupus, and to Professor I. P. Pavlov, the Russian physiologist, for his researches in nutrition.

Nature quotes from a London daily the statement that Professors Haeckel, Conrad and Fraas, of Jena, Halle and Stuttgart Universities respectively, announce that the sum of 1,500*l.* has been placed at their disposal as a prize for the best work on the question, "What do we learn from the principles of the theory of heredity in reference to the inner political development and legislation of States?" Manuscripts must be in German and sent not later than December 1, 1902, to Professor E. Haeckel, Jena.

THE University of Glasgow has appointed John Ferguson, professor of chemistry, F. O. Bowers, professor of botany, and R. M. Wenley, formerly of the University of Glasgow and now professor of philosophy at the University of Michigan, as representatives at the bi-centennial celebrations of Yale University.

E. R. BUCKLEY, assistant superintendent of the Wisconsin Geological and Natural History Society and instructor of commercial geography in the University of Wisconsin, has been appointed State geologist of Missouri.

THE Baly Gold Medal of Royal College of Physicians of London for special distinction in the science of physiology has been awarded to Dr. F. W. Pavy, F.R.S.

PROFESSOR A. C. HADDON expects to retire from the chair of zoology at the Royal College of Science, Ireland, in order to devote himself more exclusively to anthropological work.

DR. ERNST MACH, professor of philosophy in the University of Vienna, has been compelled by ill health to retire from the active duties of his professorship.

PROFESSOR E. HAECKEL, of Jena, has made public the announcement that owing to the state of his health, his advanced age and pressure of work, he will not in future make any public addresses or attend any scientific congresses.

PROFESSOR ED. SUESS, the eminent geologist, gave on July 13 a formal lecture to his present and former students on the occasion of his retirement from the chair of geology. He has reached his seventieth year and his forty-fourth year as a university teacher. A scholarship has been established in the University at Vienna in his honor.

IN honor of the sixtieth birthday of Dr. A. Kirchof, of the University of Halle, and at the same time of his twenty-fifth year of service to the university, a fund amounting to 12,500 Marks has been collected for the furtherance of geographical research.

THE Saxon Academy of Sciences at Leipzig has elected to membership Dr. Arthur von Oettingen, honorary professor of physics at Leipzig, and Dr. E. Ernst Abbe, honorary professor of meteorology and astronomy at Halle.

PROFESSOR A. R. CROOK, who holds the chair of mineralogy and petrography at Northwestern University, is at present engaged in explorations in Mexico. He is intending to ascend Mount Orizaba.

DR. CHARLES E. BROWN, of the Milwaukee Public Museum, is continuing his studies, begun several years ago, in the department of anthropology of the Field Columbian Museum, Chicago.

THE town of Amalfi has arranged to have this month a celebration in honor of Flavio Gioja, who lived in that city six hundred years ago, and is supposed to have invented or improved the compass.

A MEDALLION of Charles Hermite, the great mathematician, who died this year, will be placed in the Court of Honor of the Sorbonne.

WE learn from the *British Medical Journal* that a portrait of Dr. Thomas Young, from the painting by Sir Thomas Lawrence, has been placed in the Victoria Hall, Milverton, Somerset, with the following inscription: "Thomas

Young, M.D., F.R.S., etc. Born at Milverton, 1773. Died 1829. Physician, Natural Philosopher, and Master of many languages; he first established the undulatory theory of light, and translated the Rosetta Stone, which is the key to our understanding the Egyptian hieroglyphics."

DR. ADOLF ERIK NORDENSKJÖLD, the well-known arctic explorer and naturalist, died on August 13, in his sixty-ninth year. He first visited Spitzbergen in 1858 and again in 1861, 1864 and 1868, and visited Greenland in 1870 and 1875. In 1878-79 he made his famous voyage in the *Vega* through the northeast passage. He was professor in the Royal Museum of Natural History at Stockholm.

THE deaths are announced at the age of 55 years of Dr. W. Schur, professor of astronomy at Göttingen, and of Dr. E. Rehnisch, professor of philosophy at the same university, at the age of 62 years.

M. CASIMAR DE CANDOLLE was elected honorary president of the recent International Congress of Botanists at its meeting in Zurich on August 8, and Professor Claudet, of Geneva, was elected acting president.

THE British Mycological Society will hold a meeting at Exeter during the week beginning September 23. Professor H. Marshall Ward, of Cambridge University, will give a presidential address.

AMONG the Americans in attendance at the International Congress of Zoology are Professors Wilson of Columbia, Mark of Harvard, Patten of Dartmouth, McMurrich of Michigan, Woodworth of California, Dr. Allen of the American Museum of Natural History, Dr. Elliot of the Field Columbian Museum, Dr. Stiles of the U. S. Department of Agriculture and Mr. Stejneger of the U. S. National Museum. News has not yet reached this country regarding the meeting of the Congress, but about 150 papers have been promised in advance to be presented before seven sections, as follows: (1) General zoology; (2) vertebrata (biology, classification, distribution); (3) vertebrata (anatomy, histology, embryology); (4) invertebrata, except arthropoda; (5) arthropoda; (6) economic zoology (fisheries, etc.); (7) nomenclature. Lec-

tures before the Congress as a whole have been arranged by Professor G. B. Grassi on 'The malaria problem from a zoological standpoint,' by Professor A. Forel on 'The physical characters of ants,' by Professor E. B. Poulton on 'Mimicry and natural selection,' by Professor Wilhelm Branco on 'Fossil human remains' and by Professor Ives Delage on a subject not announced. Dr. P. L. Selater is expected to exhibit the skull of the *Okapi Johnstoni*, the remarkable mammal recently discovered in the Semliki forest of the Congo State. The entertainments were expected to include an excursion to Potsdam, a theatrical performance, a luncheon by the Berlin Zoological Society and a dinner in the Zoological Gardens. Following the Congress an excursion is planned to Hamburg and Heligoland.

THE American Institute of Electrical Engineers began its annual meeting in New York City on August 14, with a large number of foreign delegates in attendance. The members then proceeded to Buffalo, stopping to visit the works of the General Electric Company at Schenectady, and are this week holding meetings for the presentation of scientific papers and inspecting the electrical equipment installations at the Exposition and at Niagara Falls.

A HISTORICAL Congress will be held in Rome in the spring of 1902. We understand that the history of science will be specially included in the scope of the Congress.

DR. C. W. DANIELS left Liverpool, on July 8, for Sierra Leone, West Africa, to join the sixth malarial expedition of the Liverpool School of Tropical Medicine under Major Ronald Ross. Dr. Daniels was a member of the Royal Commission on Malaria, in which capacity he spent a long time in Central and East Africa recently. He will join Major Ross in Sierra Leone, and will probably proceed to the Gold Coast and Lagos. The expedition is now composed of Major Ronald Ross, Dr. Logan Taylor, Dr. McKendrick (officially attached to the expedition on behalf of the Indian Government), and Dr. Daniels. The seventh expedition of the Liverpool School, which will be despatched to the Gambia, is expected to leave for Bathurst about the end of the present month.

LARGELY through the agency of the 'Semper-virens Society' the State of California has appropriated \$250,000 to purchase and preserve the grove of redwoods near Santa Cruz.

THE exhibits of the German chemical industry at the Paris Exposition, valued at \$150,000, has been presented to the Technological Institute of the University of Berlin.

MR. CARNEGIE has offered \$50,000 to Burlington, Vt., for a library building on the usual conditions. He has also offered a building for Montrose, Scotland.

THE French Society for Colonial Expansion in France has instituted a special branch devoted to the assistance of doctors and chemists who desire to emigrate.

UNIVERSITY AND EDUCATIONAL NEWS.

BY the will of Mrs. Louise Frisbie, bequests amounting originally to \$28,000, but which may now amount to much more, are left to Smith, Vassar and Wellesley Colleges.

MRS. D. BANDY, who recently gave \$25,000 to Eureka College, Illinois, has given the institution land valued at \$60,000, subject to a life interest on the part of her daughter.

PROFESSOR W. VON ZEHENDER, of Munich, has given his valuable ophthalmological library to the University of Bern.

IT is reported in the medical journals that the University of Pennsylvania Veterinary Department will be moved to Thirty-ninth and Woodland avenue, instead of to the Flower Farm, on the West Chester Pike, as formerly intended. The reason assigned for the change in the plans is that the department would be too inconvenient for the public on the West Chester Pike, and too far from the university for the students. It is also stated that the work on the new \$60,000 buildings will begin in October.

THE Technical Education Board of the London County Council has directed the higher education subcommittee to inquire and report (a) as to the need and present provision for special training of an advanced kind in connection with the application of science (especially chem-

istry and electricity) to industry ; (b) as to what, if any, developments are needed to secure efficient training in these subjects for senior county scholars and other advanced students who desire to qualify themselves to take leading positions in scientific industries.

A COMMITTEE of the Birmingham City Council has recommended the council to make a grant to the Birmingham University of the proceeds of a halfpenny rate, which would provide an annual sum of about \$25,000.

THE University of Zurich has enlarged its anatomical building. A dissecting room with overhead light to accommodate two hundred students has been added and on the floor below a microscopical room of the same size. There is also a demonstration room with overhead light, a laboratory for anthropology, and a laboratory for advanced embryological study, together with rooms for the director. The old part of the building will be rearranged for a large lecture room, a reading and study room for the students, a museum, and the laboratories for assistants.

THE University at Erlangen announced a summer school for clergymen on the lines of the summer schools for teachers. It appears, however, that not sufficient clergymen felt the need of instruction, and the plan has been abandoned.

J. E. LOUGH, Ph.D. (Harvard), for the past four years professor of psychology at the State Normal School at Oshkosh, Wis., has been appointed to the professorship of psychology in the School of Pedagogy, New York University.

N. O. BOOTH has resigned his position as horticulturist in the University of Missouri to accept a position in the New York Agricultural College at Geneva.

MR. ROLLA R. RAMSEY, Ph.D., Cornell, '01, has been appointed instructor in physics in the University of Missouri. Dr. Ramsey is a graduate of the University of Indiana and has held graduate scholarships at Clark and Cornell. He has also been assistant in physics at Cornell and instructor at Indiana.

DR. VICTOR UHLIG, professor of paleontology at Vienna, succeeds Professor Ed. Suess in the chair of geology.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE : S. NEWCOMB, Mathematics ; R. S. WOODWARD, Mechanics ; E. C. PICKERING, Astronomy ; T. C. MENDENHALL, Physics ; R. H. THURSTON, Engineering ; IRA REMSEN, Chemistry ; CHARLES D. A CONSTITUTIONAL provision of our Association stipulates that "it shall be the duty of the President to give an address at a General Session of the Association at the meeting following that over which he presided." Happily for those of us who must in turn fulfill this duty, the scientific foresight of our predecessors set no metes and bounds with respect to the subject-matter or the mode of treatment of the theme that might be chosen for such an address. So far, therefore, as constitutional requirements are concerned, a retiring president finds himself clothed for the time being with a degree of liberty which might be regarded as dangerous, were it not for an unwritten rule that one may not hope to enjoy such liberty more than once. But time and place, nevertheless, as well as the painful personal limitations of any specialist, impose some rather formidable restrictions. One may not tax lightly, even in a summer evening, the patience of his audience for more than an academic hour, the length of which in most cases is less than sixty minutes. One must confine himself to generalities, which, though scientifically hazardous, serve as a basis for semi-popular thought; and one must exclude technical

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

* Address of the president of the American Association for the Advancement of Science, given at the Denver Meeting, August 27, 1901.

details, which, though scientifically essential, tend only to obscure semi-popular presentation. Courtesy, also, to those who are at once our hosts and our guests requires that, so far as possible, one should substitute the vernacular for the 'jargon of science,' and draw his figures of speech chiefly from the broad domain of every-day life rather than from the special, though rapidly widening, fields of scientific activity.

Between this nominally unlimited freedom on the one hand, and these actually narrow restrictions on the other, I have chosen to invite your attention for the hour to a summary view of the salient features of scientific progress, with special reference to its effects on the masses, rather than on the individuals, of mankind. We all know, at least in a general way, what such progress is. We are assured almost daily by the public press and by popular consent that the present is not only an age of scientific progress, but that it is preeminently the age of scientific progress. And with respect to the future of scientific achievement, the consensus of expert opinion is cheerfully hopeful, and the consensus of public opinion is extremely optimistic. Indeed, to borrow the language sometimes used by the rulers of nations, it may be said that the realm of science is now at peace with all foreign parts of the world, and in a state of the happiest domestic prosperity.

But times have not been always thus pleasant and promising for science. As we look backward over the history of scientific progress it is seen that our realm has been taxed often to the utmost in defense of its autonomy, and that the present state of domestic felicity, bordering on tranquility, has been preceded often by states of domestic discord bordering on dissolution. And, as we look forward into the new century before us, we may well enquire whether science has vanquished its foreign enemies and settled its domestic disputes for good and

all, or whether future conquests can be made only by a similarly wasteful outlay of energy to that which has accompanied the advances of the past. Especially may we fitly enquire on an occasion like the present what are the types of mind and the methods of procedure which make for the progress, and what are the types of mind and the methods of procedure which make for the regress, of science. And I venture to think that we may enquire, also with profit, in some prominent instances, under what circumstances in the past science has waxed or waned, as the case may be, in its slow rise from the myths and mysticism of earlier eras to the law and order of the present day. For it is a maxim of common parlance, too well justified, alas! by experience, that history repeats itself; or, to state the fact less gently, that the blunders and errors of one age are repeated with little variation in the succeeding age. This maxim is strikingly illustrated by the history of science, and it has been especially deeply impressed upon us—burnt in, one might say—by the scientific events of our own times. Have we not learned, however, some lasting lessons in the hard school of experience, and may we not transmit to our successors along with the established facts and principles of science the almost equally well established ways and means for the advancement of science? Will it be possible for society to repeat in the twentieth century the appalling intellectual blunders of the nineteenth century, or have we entered on a new era in which, whatever other obstacles are pending, we may expect man to stand notably less in his own light as regards science than ever before? To a consideration of these and allied questions I beg your indulgence, even though I may pass over ground well known to most of you, and encroach, perhaps, here and there, on prominences in fields controversial; for it is only by discussion and rediscussion of such questions

that we come at last, even among ourselves in scientific societies, to the unity of opinion and the unity of purpose which lead from ideas to their fruitful applications.

From the earliest historic times certainly, if not from the dawn of primitive humanity, down to the present day, the problem of the universe has been the most attractive and the most illusive subject of the attention of thinking men. All systems of philosophy, religion and science are alike in having the solution of this problem for their ultimate object. Many such systems and sub-systems have arisen, flourished and vanished, only to be succeeded by others in the seemingly Sisyphean task. Gradually, however, in the lapse of ages there have accumulated some elements of knowledge which give inklings of partial solutions; though it would appear that the best current opinion of philosophy, religion and science would again agree in the conclusion that we are yet immeasurably distant from a complete solution. Almost equally attractive and interesting, and far more instructive, as it appears to me, in our own time, is the contemplation of the ways in which man has attacked this perennial riddle. It is, indeed, coming to be more and more important for science to know how primitive, barbarous and civilized man has visualized the conditions of, and reached his conclusions with respect to, this problem of the centuries; for it is only by means of a lively knowledge of the baseless hypotheses and the fruitless methods of our predecessors that we can hope to prevent history from repeating itself unfavorably.

Looking back over the interval of two to three thousand years that connects us by more or less authentic records with our distinguished ancestors, we are at once struck by the admirable confidence they had acquired in their ability to solve this grand problem. Not less admirable, also, for their ingenuity and for the earnestness

with which they were advanced, are the hypotheses and arguments by which men satisfied themselves of the security of their tenets and theories. Roughly speaking, it would appear that the science of the universe received its initial impulse from earliest man in the hypothesis that the world is composed of two parts; the first and most important part being in fact, if not always so held ostensibly, himself, and the other part being the aggregate of whatever else was left over. Though dimly perceived and of little account in its effects, this is, apparently, the working hypothesis of many men in the civilized society of today. But the magnitude of the latter part and its inexorable relations to man seem to have led him speedily to the adoption of a second hypothesis, namely, that the latter part, or world external to himself, is also the abode of sentient beings, some of a lower and some of a higher order than man; their rôle tending on the whole to make his sojourn on this planet tolerable and his exit from it creditable, while yet wielding at times a more or less despotic influence over him.

How the details of these hypotheses have been worked out is a matter of something like history for a few nationalities, and is a matter absorbing the attention of anthropologists, archeologists and ethnologists as it concerns races in general. Without going far afield in these profoundly interesting and instructive details, it may suffice for the present purposes to cite two facts which seem to furnish the key to a substantially correct interpretation of subsequent developments.

The first of these is that the early dualistic and antithetical visualization of the problem in question has persisted with wonderful tenacity down to the present day. The accessible and familiar was set over against the inaccessible and unfamiliar; or what we now call the natural,

though intimately related to, was more or less opposed to the supernatural; the latter being, in fact, under the uncertain sway of, and the former subject to the arbitrary jurisdiction of, good and evil spirits.

The second fact is that man thus early devised for the investigation of this problem three distinct methods, which have likewise persisted with equal tenacity, though with varying fortunes, down to the present day. The first of these is what is known as the *à priori* method. It reasons from subjective postulates to objective results. It requires, in its purity, neither observation nor experiment on the external world. It often goes so far, indeed, as to adopt conclusions and leave the assignment of the reasons for them to a subsequent study. The second is known as the *historico-critical* method. It depends, in its purity, on tradition, history, direct human testimony and verbal congruity. It does not require an appeal to Nature except as manifested in man. It limits observation and experiment to human affairs. The third is the method of science. It begins, in its elements, with observation and experiment. Its early applications were limited mostly to material things. In its subsequent expansion it has gained a footing in nearly every field of thought. Its prime characteristic is the insistence on objective verification of its results.

All these methods have been used more or less by all thinking men. But for the purposes of ready classification it may be said that the first has been used chiefly by dogmatists, including especially the founders and advocates of all fixed creeds from the atheistic and the pantheistic to the theistic and the humanistic; the second has been used chiefly by humanists, including historians, publicists, jurists and men of letters; and the third has been used chiefly by scientists, including astronomers, mathematicians, physicists, naturalists, and more recently the group of investigators falling under the

comprehensive head of anthropologists. The first and third methods are frequently found to be mutually antithetical, if not mutually exclusive. The second occupies middle ground. Together they are here set down in the order of their apparent early development and in the order of their popularly esteemed importance during all historic time previous to, if not including, this first year of the twentieth century.

No summary view of the progress of science, it seems to me, can be made intelligible except by a clear realization of these two facts, which may be briefly referred to as man's conception of the universe and his means of investigating it. What, then, in the light of these facts, has been the sequel? The full answer to this question is an old and a long story, now a matter of minute and exhaustive history as regards the past twenty centuries. I have no desire to recall the dramatic events involved in the rise of science from the Alexandrian epoch to the present day. All these events are trite enough to men of science. A mere reference to them is a sufficient suggestion of the existence of a family skeleton. But, setting aside the human element as much as possible, it may not be out of place or time to state what general conclusions appear to stand out plainly in that sequel. These are our tangible heritage and upon them we should fix our attention.

In the first place, the progress of science has been steadily opposed to, and as steadily opposed by, the adherents of man's primitive concepts of the universe. The domain of the natural has constantly widened and the domain of the supernatural has constantly narrowed. So far, at any rate, as evil spirits are concerned, they have been completely cast out from the realm of science. The arch fiend and the lesser princes of darkness are no longer useful even as an hypothesis. We have reached—if I may again use the cautious

language of diplomacy—a satisfactory *modus vivendi* if we have not attained permanent peace in all our foreign relations. Enlightened man has come to see that his highest duty is to cooperate with Nature, that he may expect to get on very well if he heeds her advice, and that he may expect to fare very ill if he disregards it.

Secondly, it appears to have been demonstrated that neither the *à priori* method of the dogmatists nor the historico-critical method of the humanists is alone adequate for the attainment of definite knowledge of either the internal or the external world, or of their relations to one another. In fact, it has been shown over and over again that man cannot trust his unaided senses even in the investigation of the simplest and most obvious material phenomena. There is an ever-present need of a correction for personal equation. Left to himself, the *à priori* reasoner weaves from the tangled skein of thought webs so well tied by logical knots that there is no escape for the imprisoned mind except by the rude process applied to cobwebs. And in the serenity of his repose behind the fortress of 'liberal culture,' the reactionary humanist will prepare apologies for errors and patch up compromises between traditional beliefs and sound learning with such consummate literary skill that even 'the good demon of doubt' is almost persuaded that if knowledge did not come to an end long ago it will soon reach its limit. In short, we have learned, or ought to have learned, from ample experience, that in the search for definite, verifiable knowledge we should beware of the investigator whose equipment consists of a bundle of traditions and dogmas along with formal logic and a facile pen; for we may be sure that he will be more deeply concerned with the question of the safety than with the question of the soundness of scientific doctrines.

Thirdly, it has been demonstrated equally

clearly, and far more cogently, that the sort of knowledge we call scientific, knowledge which has in it the characteristics of immanence and permanence, is founded on observation and experiment. The rise and growth of every science illustrate this fact. Even pure mathematics, commonly held to be the *à priori* science par excellence, and sometimes called 'the science of necessary conclusions,' is no exception to the rule. Those who would found mathematics on a higher plane have apparently forgotten to consider the contents of the mathematician's waste-basket. The slow and painful steps by which astronomy has grown out of astrology and chemistry out of alchemy; and the faltering, tedious, and generally hotly contested, advances of geology and biology have been made secure only by the remorseless disregard which observational and experimental evidence has shown for the foregone conclusions of the dogmatists and the literary opinions of the humanists. Thus it has been proved by the rough logic of facts and events that the rude processes of 'trial and error,' processes which many philosophers and some men of science still affect to despise, are the most effective means yet devised by man for the discovery of truth and for the eradication of error.

These facts are so well known to most of you, so much a matter of ingrained experience, that the categorical mention of them here may seem like a rehearsal of truisms. But it is one of the paradoxes of human development that errors which have been completely dislodged from the minds of the few may still linger persistently in the minds of the many, and that the misleading hypotheses and the dead theories of one age may be resuscitated again and again in succeeding ages. Thus, to cite one of the simplest examples, it doubtless appeared clear to the Alexandrian school of scientists that the flat, four-cornered earth of contemporary myths would speedily give way

to the revelations of geometry and astronomy. How inadequate such revelations proved to be at that time is one of the most startling disclosures in all history. The 'Divine School of Alexandria' passed into oblivion. The myth of a flat and four-cornered earth was crystallized into a dogma strong enough to bear the burden of men's souls by Cosmas Indicopleustes in the sixth century; it was supported with still more invincible arguments by Martin Luther in the sixteenth century; and it was revived and maintained with not less truly admirable logic, as such, by John Hampden and John Jasper in the last decades of the nineteenth century. To cite examples from contemporary history showing how difficult it is for the human mind to get above its primitive conceptions, one needs only to refer to the daily press. During the past two months, in fact, the newspapers have related how multitudes of men, women and children, many of them suffering from loathsome if not contagious diseases, have visited a veritable middle-age shrine in the city of New York, strong in the hoary superstition that kissing an alleged relic of St. Anne would remove their afflictions. During the same interval a railway circular has been distributed explaining how tourists may witness the Moki snake-dance, that weird ceremony by which the Pueblo Indian seeks to secure rain in his desert; and a similar public, and officially approved, ceremony has been observed in the heat-stricken State of Missouri.

Such epochs and episodes of regression as these must be taken into account in making up an estimate of scientific progress. They show us that the slow movement upward in the evolution of man which gives an algebraic sum of a few steps forward per century is not inconsistent with many steps backward. Or, to state the case in another way, the rate of scientific advance is to be measured not so

much by the positions gained and held by individuals, as by the positions attained and realized by the masses, of our race. The average position of civilized man now is probably below the mean of the positions attained by the naturalist Huxley and the statesman Gladstone, or below the mean of the positions attained by the physicist von Helmholtz and His Holiness the Pope. When measured in this manner, the rate of progress in the past twenty centuries is not altogether flattering or encouraging to us, especially in view of the possibility that some of the more recently developed sciences may suffer relapses similar to those which so long eclipsed geography and astronomy.

It must be confessed, therefore, when we look backward over the events of the past two thousand years, and when we consider the scientific contents of the mind of the average denizen of this planet, that it is not wholly rational to entertain millennial anticipations of progress in the immediate future. The fact that some of the prime discoveries of science have so recently appeared to many earnest thinkers to threaten the very foundations of society is one which should not be overlooked in these confident times of prosperity. And the equally important fact that entire innocence with respect to the elements of science and dense ignorance with respect to its methods, have not been hitherto incompatible with justly esteemed eminence in the divine, the statesman, the jurist and the man of letters, is one which should be reckoned with in making up any forecast. It may be seriously doubted, indeed, whether the progress of the individual is not essentially limited by the progress of the race.

But this obverse and darker side of the picture which confronts us from the past has its reverse and brighter side; and I am constrained to believe that the present status of science and the general enlightenment

of humanity justify ardent hopefulness if not sanguine optimism with respect to the future of scientific achievement. The reasons for this hopefulness are numerous; some of them arising out of the commercial and political conditions of the world, and others arising out of the conditions of science itself.

Perhaps the most important of all these reasons is found in the general enlargement of ideas which has come, and is coming, with the extension of trade and commerce to the uttermost parts of the earth. We are no longer citizens of this or that country, simply. Whether we wish it or not we are citizens of the world, with increased opportunities and with increased duties. We may not approve—few men of science would approve, I think—that sort of ‘expansion’ which works ‘benevolent assimilation’ of inferior races by means of a bible in one hand and a gun in the other; but nothing can help so much, it seems to me, to remove the stumbling blocks in the way of the progress of science as actual contact with the manners, the customs, the relations and the resulting questions for thought, now thrust upon all civilized nations by the events of the day. That sort of competition which is the life of trade, that sort of rivalry which is the stimulus to national effort, and that sort of cooperation which is essential for mutual protection, all make for the cosmopolitan dissemination of scientific truth and for the appreciation of scientific investigation. I would not disparage the elevated aspirations and the noble efforts of the evangelists and the humanists who seek to raise the lower to the plane of the higher elements of our race; but it is now plain as a matter of fact, however repulsive it may seem to some of our inherited opinions, that the railway, the steamship, the telegraph and the daily press will do more to illumine the dark places of the earth than all the apos-

ties of creeds and all the messengers of the gospel of ‘sweetness and light.’

A question of profound significance growing out of the extension of commercial relations in our time is what may be called the question of international health. An outbreak of cholera in Hamburg, the prevalence of yellow fever in Havana, or an epidemic of bubonic plague in India is no longer a matter of local import, as nations with which we are well acquainted have learned recently in an expensive manner. The management of this great international question calls for the application of the most advanced scientific knowledge and for the most intricate scientific investigation. Large sums of money must be devoted to this work, and many heroic lives will be lost, doubtless, in its execution; but it is now evident, as a mere matter of international political economy, that the cost of sound sanitation will be trifling in comparison with the cost of no sanitation; while further careful study of the natural history of diseases promises practical immunity from many of them at no distant day. International associations of all kinds must aid greatly also in the promotion of progress. Many such organizations have, indeed, already undertaken scientific projects with the highest success. Comparison and criticism of methods and results not only lead rapidly and effectively to improvements and advances, but they lead also to a whole-hearted recognition of good work which puts the fraternalism of men of science on a plane far above the level of the amenities of merely diplomatic life.

When we turn to the general status of science itself, there is seen to be equal justification for hopefulness founded on an abundance of favorable conditions. The methods of science may be said to have gained a footing of respectability in almost every department of thought, where, a half-century ago, or even twenty years ago,

their entry was either barred out or stoutly opposed. The 'Conflict between Religion and Science'—more precisely called the conflict between theology and science—which disturbed so many eminent though timid minds, including not a few men of science, a quarter of a century ago, has now been transferred almost wholly to the field of the theological contestants; and science may safely leave them to determine the issue, since it is evidently coming by means of scientific methods. The grave fears entertained a few decades ago by distinguished theologians and publicists as to the stability of the social fabric under the stress put upon it by the rising tide of scientific ideas, have not been realized. And, on the other hand, the grave doubts entertained by distinguished men of science a few decades ago as to the permeability and ready response of modern society to that influx of new ideas, have likewise not been realized. It is true that we still sometimes read of theological tests being applied to teachers of biology, and hear, occasionally, of an earnest search for a good methodist or a good presbyterian mathematician; but such cases may be left for settlement out of court by means of the arbitration of our sense of humor. It seems not unlikely, also, that there may persist, for a long time to come, a more or less guerilla 'warfare of science' with our friends the dogmatists and the humanists. Some consider this conflict to be, in the nature of things, irrepressible. But I think we may hope, if we may not confidently expect, that the collisions of the future will occur more manifestly than they have in the past in accordance with the law of the conservation of energy; so that the heat evolved may reappear as potential energy in the warmth of a kindly reasonableness on both sides, rather than suffer degradation to the level of cosmic frigidity.

Great questions, also, of education, of

economic, industrial and social conditions, and of legal and political relations are now demanding all the light which science can bring to bear upon them. Though tardily perceived, it is now admitted, generally, that science must not only participate in the development of these questions but that it alone can point the way to the solutions of many of them. But there is no halting ground here. Science must likewise enter and explore the domain of manners and morals; and these, though already largely modified unconsciously, must now be modified consciously to a still greater extent by the advance of science. Only within quite recent times have we come to realize an approximation to the real meaning of the trite saying that the proper study of man is man. So long as the most favored individuals of his race, in accordance with the hypothesis of the first centuries, looked upon him as a fallen, if not a doomed, resident of an abandoned reservation, there could be roused little enthusiasm with respect to his present condition; all thought was concentrated on his future prospects. How incomparably different does he appear to the anthropologist and the psychologist at the beginning of the twentieth century! In the light of evolution he is seen to be a part of, and not apart from, the rest of the universe. The transcendent interest of this later view of man lies in the fact that he can not only investigate the other parts of the universe, but that he can, by means of the same methods, investigate himself.

I would be the last to look upon science as furnishing a speedy or a complete panacea for the sins and sorrows of mankind; the destiny of our race is entangled in a cosmic process whose working is thus far only dimly outlined to us; but it is nevertheless clear that there are available to us immense opportunities for the betterment of man's estate. For example, to mention only one of the lines along which improvement is

plainly practicable, what is to hinder an indefinite mitigation, if not a definite extinction, of the ravages of such dread diseases as consumption and typhoid fever? Or what, we may ask, is to hinder the application to New York, Philadelphia and Chicago of as effective health regulations as those now applied to Havana? Nothing, apparently, except vested interests and general apathy. We read, not many years ago, that a city of about one million inhabitants had, during one year, more than six thousand cases of typhoid fever. The cost to the city of a single case may be estimated as not less, on the average, than one thousand dollars, making an aggregate cost to that city, for one year, of more than six millions of dollars. Such a waste of financial resources ought to appeal to vested interests and general apathy even if they cannot be moved by any higher motives. Thanks to the penetration of the enlightenment of our times, distinct advances have already been made in the line of effective domestic and public sanitation; but the good work accomplished is infinitesimal in comparison with that which can be, and ought to be, done. It is along this and along allied lines of social and industrial economy that we should look, I think, for the alleviation of the miseries of mankind. No amount of contemplation of the beatitudes, human or divine, will prevent men from drinking contaminated water or milk; and no fear of future punishments, which may be in the meantime atoned for, will much deter men from wasting their substance in riotous living. The moral certainty of speedy and inexorable earthly annihilation is alone adequate to bring man into conformity with the cosmic rules and regulations of the drama of life.

And finally we must reckon amongst the most important of the conditions favorable to the progress of science, the unexampled activity in our times of the scientific spirit

as manifested in the work of all kinds of organizations, from the semi-religious Chautauquan assemblies up to those technical societies whose programs are Greek to all the world beside. Literature, linguistics, history, economics, law and theology are now permeated by the scientific spirit if not animated by the scientific method. Curiously enough, also, the terminology, the figures of speech and the points of view of science are now quite common in realms of thought hitherto held somewhat scornfully above the plane of materialistic phenomena. Tyndall's Belfast address, which, twenty-seven years ago, was generally anathematized, is now quoted with approval by some of the successors of those who bitterly denounced him and all his kind. Thus the mere lapse of time is working great changes and smoothing out grave differences of opinion in favor of the progress of science in all the neighboring provinces with which we have been able hitherto to maintain only rather strained diplomatic relations.

Still more immediately important to us are the evidences of progress manifested in recent years by this Association and by its affiliated societies. Our parent organization, though a half century old, is still young as regards the extent in time of the functions it has undertaken to perform. It has accomplished a great work; but in the vigor and enthusiasm of its youth a far greater work is easily attainable. Exactly how these functions are to be developed, no man can foresee. We may learn, however, in this, as in other lines of research, by methods with which we are well acquainted, namely, by the methods of carefully planned and patiently executed observation and experiment. The field for energetic and painstaking effort is wider and more attractive than ever before. Science is now truly cosmopolitan; it can be limited by no close corporations; and no domain of scientific

investigation can be advantageously fenced off, either in time or in space, from the rest. While every active worker of this or of any affiliated society is, in a sense, a specialist, there are occasions when he should unite with his colleagues for the promotion of the interests of science as a whole. The results of the specialists need to be popularized and to be disseminated among the people at large. The advance of knowledge, to be effective with the masses of our race, must be sustained on its merits by a popular verdict. To bring the diverse scientific activities of the American Continent into harmony for common needs; to secure cooperation for common purposes; and to disseminate the results of scientific investigation among our fellow-men, are not less, but rather much more, than in the past, the privilege and the duty of The American Association for the Advancement of Science.

Viewed, then, in its broader aspects, the progress of science is involved in the general progress of our race; and those who are interested in promoting the former should be equally earnest in securing the latter. However much we may be absorbed in the details of our specialties, when we stop to think of science in its entirety, we are led, in the last analysis, back to the problem of problems—the meaning of the universe. All men ‘gifted with the sad endowment of a contemplative mind’ must recur again and again to this riddle of the centuries. We are, so to speak, whatever our prepossessions, all sailing in the same boat on an unknown sea for a destination at best not fully determined. Some there are who have, or think they have, the Pole Star always in sight. Others, though less confident of their bearings, are willing to assume nothing short of second place in the conduct of the ship. Others, still less confident of their bearings, are disposed to depend chiefly on their knowledge of the compass and on their skill in dead reckoning. We of the

last class may not impugn the motives or doubt the sincerity of the first two classes. We should find it difficult, probably, to dispense with their company in so long a journey after becoming so well acquainted with them; for among them we may each recall not a few of those rarer individuals of the genus homo called angels on earth. But it must be said in all truth, to resume the figure, that they have neither improved much the means of transportation nor perfected much the art of navigation. They have been sufficiently occupied, perhaps, in allaying the fears of the timid and in restraining the follies of the mutinous. Other types of mind and other modes of thought than theirs have been essential to work out the improvements which separate the earlier from the later nautical equipments of men; such improvements, for example, as mark the distinction between the dug-out of our lately acknowledged relatives, the Moros and the Tagalogs, from the Atlantic-liner of to-day.

At any rate, we are confronted by the fact that man's conceptions of the universe have undergone slow but certain enlargement. His early anthropocentric and anthropomorphic views have been replaced, in so far as he has attained measurable advancement, by views that will bear the tests of astronomy and anthropology. He has learned, slowly and painfully, after repeated failures and many steps backward, to distinguish, in some regions of thought, the real and the permanent from the fanciful and fleeting phenomena of which he forms a part. His pursuit of knowledge, in so far as it has led him to certainty, has been chiefly a discipline of disillusionment. He has arrived at the truth not so much by the genius of direct discovery as by the laborious process of the elimination of error. Hence he who has learned wisdom from experience must look out on the problem of the universe at the beginning of the twentieth

century, with far less confidence in his ability to speedily solve it and with far less exaggerated notions of his own importance in the grand aggregate of Nature, than man entertained at the beginning of our era. But no devotee to science finds humiliation in this departure from the primitive concepts of humanity. On the contrary, he has learned that this apparent humiliation is the real source of enlightenment and encouragement; for notwithstanding the relative minuteness of the speck of cosmic dust on which we reside, and notwithstanding the relative incompetency of the mind to discover our exact relations to the rest of the universe, it has yet been possible to measure that minuteness and to determine that incompetency. These, in brief, are the elements of positive knowledge at which we have arrived through the long course of unconscious, or only half-conscious, experience of mankind. All lines of investigation converge towards or diverge from these elements. It is along such lines that progress has been attained in the past, and it is along the same lines that we may expect progress to proceed in the future.

R. S. WOODWARD.

COLUMBIA UNIVERSITY.

*ZOOLOGY OF THE TWENTIETH CENTURY.**

LOOKING over the vice-presidential addresses given before the American and British Associations during the past year or two in an eager search for suggestions, I found a prevailing tone of retrospect. The advance of science in the nineteenth century was a favorite theme, and little wonder in view of the century's marvelous events. Since by the arrangement of the council I lost my opportunity to be an end-of-the-century historian last year, I shall essay the rôle of a prophet this. On the

historical side I could have given you something very interesting, I assure you. Not I, but the council that delayed my address to the following century, must be held responsible for the poor substitute I am able to present.

We have stood in retrospect at the close of the nineteenth century and marveled at what it brought forth. Here at the threshold of the twentieth century it is natural that we should wonder what it will unfold. Will the changes be as great, and in what direction will advance chiefly be made? I am the more content to consider such questions for three reasons: First, because we can use history to formulate predictions; second, because the attempt may possibly influence to some slight degree the future development of zoology; and third, because the attempt is tolerably safe, since we shall none of us know all that the century will bring forth.

Comparing the beginning of the twentieth century with that of the nineteenth, we find the most striking advances to have taken place in our morphological knowledge. The nineteenth may indeed be designated the morphological century. The demands of systematic zoology first made anatomical studies necessary. Later, comparison came to be accepted as the fundamental zoological method, and comparative anatomy, emancipated from its servitude to systematic zoology, became an independent science. Still later embryology arose, at first as a descriptive science and then as a comparative one. Out of embryology arose modern cytology, which in turn is creating a comparative histology. Partly as a result of studying embryology as a process has arisen the modern tendency toward comparative physiology. As a result of the general acceptance of the evolution doctrine, the study of the geographical distribution of organisms and of adaptations has gained a new meaning. From the great matrix of 'gen-

* Address of the Vice-president of Section F, Zoology, American Association for the Advancement of Science, Denver Meeting, August, 1901.

eral biology' there has begun to crystallize out a number of well-defined subsciences.

Looking broadly at the progress made during the past century, we see that zoology has become immensely more complex, due to its developing in many lines, and that the new lines are largely interpolated between the old and serve to connect them. The descriptive method has developed into a higher type—the comparative; and of late years still a new method has been introduced for the study of processes—the experimental. The search for mechanisms and causes has been added to the search for the more evident phenomena. The zoologist is no longer content to collect data; he must interpret them.

In view of the past history of our science, what can we say of its probable future? We may be sure that zoology will develop in all these three directions: (1) The continued study of old subjects by old methods; (2) the introduction of new methods of studying old subjects; and (3) the development of new subjects.

I am not of those who would belittle the old subjects, even when pursued in the old way. There is only one class of zoologist that I would wish to blot out, and that is the class whose reckless naming of new 'species' and 'varieties' serves only to extend the work and the tables of the conscientious synonymy hunter. Other than this all classes will contribute to the advancement of the science. No doubt there are unlabeled species, and no doubt they must, as things are, be named. And no doubt genera and families must be 'revised' and some groups split up and others lumped. So welcome to the old-fashioned systematist, though his day be short, and may he treat established genera gently. No doubt there are types of animals of whose structure we are woefully ignorant; no doubt we need to know their internal anatomy in

great detail. So welcome to the zootomist in this new century, and may he invent fewer long names for new organs. No doubt there are groups of whose relationships we know little and which have been buffeted about from one class to another in a bewildering way. We need to have them stay fixed. So welcome to the comparative anatomist and the embryologist, and may their judgment as to the relative value of the criteria of homology grow clearer. No doubt our knowledge of inheritance and development will be immensely advanced by the further study of centrosomes, asters and chromosomes. Welcome, therefore, to the cytologist, and may he learn to distinguish coagulation products and plasmolytic changes from natural structures. All these subjects have victories in store for them in the new century. To neglect them is to neglect the foundations of zoology.

But the coming century will, I predict, see a change in the methods of studying many of these subjects. In systematic zoology fine distinctions will no longer be expressed by the rough language of adjectives, but quantitatively, as a result of measurement. There is every reason to expect, indeed, that the future systematic work will look less like a dictionary and more like a table of logarithms. Our system of nomenclature, meanwhile, will probably break down from its own weight. Now that the binomial system of nomenclature has been replaced by a trinomial, there is no reason why we should not have a quadrinomial nomenclature or even worse. It seems as if the Linnæan system of nomenclature is doomed. What will take its place can hardly be predicted. The new system should recognize the facts of place-modes and color varieties. We might establish certain categories of variation such as those of geographical regions, of habitat, of color. A decimal system of numbers might be applied to the parts of the coun-

try or the kinds of habitat, and the proper number might take the place of the varietal or subvarietal name. Thus the northeastern skunk might be designated *Mephitis mephitica* 74 and the southeastern skunk *Mephitis mephitica* 75 (adopting the Dewey system of numerals). The Maine skunk would then be 741; that of New York 747, and so on. This much for a suggestion.

So likewise for the morphologist the coming century will bring new aims and new methods. No longer will the construction of phylogenetic trees be the chief end of his studies, but a broad understanding of the form producing and the form maintaining processes. The morphologist will more and more consider experiment a legitimate method for him. The experimental method will, I take it, be extended especially to the details of cytology, and here cytology will make some of its greatest advances.

Not only will the old subjects be studied by new methods, but we have every reason to believe that new sub-sciences will arise during the twentieth century as they did during the nineteenth. Of course we cannot forecast all these unborn sciences, as cytology and neurology could hardly have been forecast at the beginning of the nineteenth century. But we can see the beginnings of what are doubtless to be distinct sciences. Thus comparative physiology is still in its infancy and is as yet hardly worthy of the name of a science; there is no question that this will develop in the coming decades. Animal behavior has long been treated in a desultory way, and many treatises on the subject are rather contributions to folk-lore than to science. But we are beginning to see a new era—an era of precise, critical and objective observation and record of the instincts and reactions of animals. One day we shall reach the stage of comparative

studies, and shall have a science of the ontogeny of animal instincts. This will have the same importance for an interpretation of human behavior that comparative anatomy and embryology have for human structure.

Prominent among the advances of the century will be the ability to control biological processes. We shall know the factors that determine the rate of growth and the size of an animal, the direction and sequence of cell-divisions, the color, sex and details of form of a species. The direction of ontogeny and of phylogeny will be to a greater or less extent under our control.

The study of animals in relation to their environment, long the pastime of country gentlemen of leisure, will become a science. Some day we shall be able to say just what conditions an animal's presence at any place; and, more than that, we shall be able to account for the fauna—the sum total of animal life of any locality—and to trace the history of that fauna. This is at least one of the aims of animal ecology. It is a reproach to zoology that the subject of animal ecology should lag so far behind that of plant ecology. When zoologists fully awaken to a realization of what a fallow field lies here this reproach will quickly be wiped out. As it is, we have a notion that the factors determining the occurrence of an animal or of a fauna are too complicated to be unraveled. As a matter of fact, the factors are often quite simple. Let me illustrate this by some studies I have made this summer on the Cold Spring Beach. This beach is a spit of sand, 2,000 feet long and 50 to 75 feet broad, running from the western mainland into the harbor and ending in a point that is being made several feet a year through the cooperation of wave, tide and a silt-transporting creek of fresh water. On the outer harbor side is a broad, gradually sloping, sandy and gravelly beach, covered

by high tide and devoid of living vegetation. Above that is a narrow zone—the middle beach—covered with débris of storms, supporting a few annual plants, and bounded above by a storm-cut bluff. Above is the upper beach, covered with a perennial, sand-loving vegetation. On the lower beach the zonal distribution of animals is striking. Just above the water are found the scavenger mud snails and, further up, a crowd of *Thysanura*—small insects that rise to the surface of the water when the tide comes in. These find a living on the finer débris or silt that settles on the pebbles during the high tides. In this zone also *Limulus* lays its eggs in the sand, and its nests are crowded with nematodes that feed on the eggs. During the breeding season scores of the female *Limulus* die here, and their carcasses determine a complex fauna. First, carrion beetles (*Necrophorus*) and the flesh fly live on the dead bodies; then the robber flies and tiger-beetles are here to feed on this fauna, and finally numerous swallows course back and forward gleaning from this rich field. At the upper edge of the lower beach is a band of débris dropped at slack water and consisting especially of shreds of *Ulva* and many drowned insects, chiefly beetles. At this zone, or just above under the drier but more abundant wreckage of the last storm, occur numerous Amphipoda of the genera *Orchestia* and *Talorchestia*. Associated with these marine creatures are numerous red ants, sand-colored spiders and rove-beetles. The amphipods feed on the decaying sea-weed. The ants are here looking chiefly for the drowned insects. Their nests are further up on the middle beach, but the workers travel to the edge of the high tide to bring away their booty. The rove-beetles are general scavengers. The spiders, which are mostly of the jumping sort (of the family *Attidae*), feed on the active insects and amphipods. At a higher zone, and above all but the storm-driven

tides, one finds the nests of the ants, especially under logs, certain predaceous beetles and the xerophilous grasshoppers and crickets. Finally, on the plant-covered upper beach one finds characteristic leaf-eating beetles, grasshoppers and carnivorous insects. Now all this seems commonplace enough and not especially instructive, and yet if you go to the shore of Lake Michigan you will find on a similar beach closely similar, if not identical, forms (excepting the beach fleas and the horseshoe crabs) you will find similar ants, spiders, rove-beetles, tiger beetles and sand-grasshoppers. This fact alone shows the greater importance of habitat over geographical region in determining the assemblage of animals that occurs in any one place. It may be predicted that studies on the relation of animals to their habitat will multiply, that they will become comparative and that the science of animal ecology will become recognized as no less worthy and no less scientific than the science of morphology.

Studies on the origin of species were far from being unknown in the nineteenth century, but they were for the most part fragmentary, or speculative, or narrow in view. The opinion that there was one method of evolution seemed to hold sway. It seems to me that the signs of the times indicate that we are about to enter upon a thorough, many-sided, inductive study of this great problem, and that there is a willingness to admit that evolution has advanced in many ways. The attempt, therefore, to explain all specific peculiarities on the ground of natural selection, or on the ground of self-adjustment, or on the ground of sport preservation through isolation, we may expect equally to prove futile. All these causes are no doubt real in some cases, but to exclude any one or to deny that new causes may be found in the future is equally dangerous and unscientific.

It is often said that the factors of evo-

lution are inheritance and variation. In the new century careful and quantitative studies will be made on these factors. We shall get at quantitative expressions of the more complicated forms of heritage in the same way as Galton has given us an expression of a simple form of inheritance. We shall hope to understand why some qualities blend and others refuse to do so. We shall learn the laws of mingling of qualities in hybrids and get an explanation of the monstrosities and the sterility which accompany hybridization. What we call reversion and prepotency will acquire a cytological explanation, and it may be that the theory of fertilization will be seriously modified thereby. When we can predict the outcome of any new combination of germ plasms then, indeed, we shall have got at the laws of inheritance.

As for the other factor, that of variation, I anticipate interesting developments in our knowledge of its laws and of its causes. The methods by which this knowledge is to be acquired are doubtless comparative observation, experimentation and a quantitative study of results. Within the last decade a profound student of variation (Bateson) has declined to discuss its causes, holding that we had no certain knowledge of them. Even the categories of variation are still unenumerated. The science of variation is therefore one of those that we may hope to see established in this century. I feel convinced that statistical studies are first of all necessary to lay the foundations of the science.

As an illustration of an application of statistics to evolution studies I will give some account of my work during the past two years on the scallop of our east coast, *Pecten irradians*.

Pecten irradians is a bivalve mollusc of flattened, lenticular form, that inhabits our coast from Cape Cod southward. The Cape Cod limit is a rather sharp one, but

southward our scallop passes gradually into the closely related forms of the South American coast. This fact would seem to indicate its southerly origin. To get light on the evolution of the group, I have studied and measured over 3,000 shells, chiefly from four localities: (1) Cold Spring Harbor, Long Island; (2) Morehead, North Carolina; (3) Tampa, Florida, and (4) the late Miocene or early Pliocene fossils of the Nansemond River. The fossil shells, to which I shall frequently refer, were found imbedded in the sand at Jack's Bank, one mile below Suffolk, Virginia. The bank rises to a height of 25 to 30 feet. Shells were obtained from three layers, respectively, one foot, six feet and 15 feet above the base of the bluff. Of course, the upper shells lived later than the lower ones and may fairly enough be assumed to be their direct descendants. The time interval between the upper and lower levels cannot be stated. As I have measured sufficient shells from the bottom and top layers only I shall consider them chiefly. I wished to get recent *Pectens* from this locality, but the nearest place where they occur in quantity is Morehead, North Carolina. These *Pectens* may therefore stand as the nearest recent descendants of the *Pectens* of the Nansemond River.

The *Pecten* shells have a characteristic appearance in each of the localities studied. After you have handled them for some time you can state in 95 per cent. of the cases the locality from which any random shell has come. First of all, the shells differ in color, especially of the lower valve. In the specimens from Cold Spring Harbor this is a dirty yellow; from Morehead, yellow to salmon; from Tampa white through clear yellow to bright salmon. Second, the antero-posterior diameter of the shell becomes relatively greater than the vertical diameter as you go north. Thus, the antero-posterior diameter exceeds, on the average, the dorso-

ventral diameter : at Tampa, by about 1.5 mm.; at Morehead, 2.5 mm.; and at Cold Spring Harbor, 6 mm. The fossil *Pectens* have an excess of about 4 mm.

Comparing the fossils with the *Pectens* of Morehead we find, as shown above, that the fossils are more elongated. Comparing the depth of the right valves having a height of 59 mm., we get :

From the lowest level, Jack's Bank	8.8 mm.
" " " " " " "	9.1 mm.
" Morehead	19.7 mm.

Hence the recent shells are much more nearly spherical than the fossils; there is a phylogenetic tendency toward increased globosity.

The average number of rays in the different localities is as follows :

Lower level, Jack's Bank	22.6
Middle " " "	22.1
Upper " " "	21.7
Morehead and Cold Spring Harbor	10.3
[Tampa	20.5]

Here it appears that there is a phylogenetic tendency toward a decrease in the number of rays of *Pecten irradians*. To summarize: The scallop is becoming, on the average, more globose, and the number of its rays is decreasing and its valves are probably becoming more exactly circular in outline. The foregoing examples illustrate the way in which quantitative studies of the individuals of a species can show the change in its average condition both at successive times and in different places.

But the quantitative method yields more than this. It is well known that if the condition of an organ is expressed quantitatively in a large number of individuals of a species the measurements or counts made will vary, *i. e.*, they will fall into a number of *classes*. The proportion of individuals falling into a class gives what is known as the 'frequency' of the class. Now it appears that in many cases the middle class has the

greatest frequency (and is consequently called the mode) and as we depart from it the frequency gradually diminishes, and diminishes equally at equal distances above and below the mode. One can plot the distribution of frequencies by laying off the successive classes at equal intervals along a base line and drawing perpendiculars at these points proportional in length to the frequency. If the tops of these perpendiculars be connected by a line there is produced a 'frequency polygon.' The shape of the frequency polygon gives much biological information. When the polygon is symmetrical about the modal ordinate we may conclude that no evolution is going on; that the species is at rest. But very often the polygon is more or less unsymmetrical or 'skew.' A skew polygon is characterized by this: that the polygon runs from the mode further on one side than on the other. This result may clearly be brought about by the addition of individuals to one side or their subtraction from the other side of the normal frequency polygon. The direction of skewness is toward the excess side. The skew frequency polygon indicates that the species is undergoing an evolutionary change. Moreover, the direction and degree of skewness may tell us something of the direction and rate of that change. There is one difficulty in interpretation, however, for a polygon that is skew may be so either from innate or from external causes. In the case of skewness by addition we may think that there is an innate tendency to produce variants of a particular sort, representing, let us say, the *atavistic* individuals. In this case skewness points to the past. The species is evolving from the direction of skewness. In the case of skewness by subtraction there are external causes annihilating some of the individuals lying at one side of the mode. Evolution is clearly occurring away from that side and *in* the direction of skewness.

Now so far as we know at the present time there is no way of distinguishing skew polygons due to atavism from such as are due to selective annihilation. But in many cases at least the skewness, especially when slight, can be shown to be due to atavism; and this is apparently the commoner cause. This conclusion is based first upon a study of races produced experimentally and whose ancestry is known, and secondly upon certain cases of compound curves. Take the case of the ray flowers of the common white daisy. A collection of such daisies gathered in the fields by DeVries gave a mode of 13 ray flowers with a positive skewness of 1.2. The 12- or 13-rayed wild plants were selected to breed from, and their descendants, while maintaining a mode at 13, had the increased positive skewness of 1.9. The descendants of the 12-rayed parents had a stronger leaning towards the high ancestral number of ray flowers than the original plants had. The 21-rayed plants were also used to breed from. Their descendants were above the ancestral condition as the descendants of the 12-rayed plants were below. The skewness — 0.13 is comparatively slight. In this case we have experimental evidence that polygons may be skew toward the original ancestral condition.

Of the compound polygons it is especially the bimodal polygon that frequently gives hint of two races arising out of one ancestral, intermediate condition. Consequently we should expect the two constituent polygons to be skew in opposite directions; and so we usually find them to be. For example, Bateson has measured the horns on the heads of 343 rhinoceros beetles and has got a bimodal polygon. The polygon with the lower mode has a skewness of + 0.48; that with the higher mode a skewness of — 0.03. One might infer that the right-hand form, the long-horned beetles, had diverged less than the

short-horned from the ancestral condition. Again, as is well known, the chinch bug occurs in two forms—the long-winged and the short-winged. Now, in a forthcoming paper my pupil, Mr. Garber, will show that the frequency polygon of the short-winged form has a skewness of + 0.44, while that of the long-winged form has a skewness of — 0.43. On our fundamental hypothesis the ancestral condition must have been midway between the modes.

Still a third class of cases that gives evidence as to the significance of skewness is that where two place modes have moved in the same direction but in different degrees. Thus the index (breadth ÷ length) of the shell of *Littorina littorea*, the shore snail, as measured by Bumpus, has at Newport a mode of 90, at Casco Bay of 93. The skewness is positive in both places and greater (+ .24) at the more southern point than at Casco Bay (+ .13). This indicates that the ancestral races had a higher index even than those of Casco Bay, probably not far from 96, and also that the *Littorina littorea* of our coast came from the northward, since the northern shells are the rounder. We have historical evidence that they did come from the northward. Likewise the *Littorinas* from South Kincardineshire, Scotland, have a modal index of 88 and a skewness of + 0.065, while those of the Humber, with a mode of 91 have a skewness of + 0.048. These figures suggest that if the mode were 97 the skewness would be 0, and this would give practically the same value to the ancestral index as arrived at for the *Littorinas* of our coast. It will be seen from these illustrations that the form of the frequency polygon may be of use in determining phylogeny.

While skewness is thus often reminiscent, we must not forget the possibility that it may be, in certain cases, prophetic. This has come out rather strongly in a piece of

work I have been engaged on during the past year. I have been counting the number of rays in recent *Pecten irradians* from various localities and have obtained in some cases evident skewness in the frequency polygons. To see what phylogenetic meaning, if any, this skewness has I sought to get a series of late fossils. After careful consideration I was led to go to the Nansemond River for the late Tertiary fossils found there and already referred to. These served my purpose admirably. We may now compare the average number of rays from the two extreme layers at Jack's Bank and at Morehead with the indices of skewness of the frequency polygons from the same localities.

Place.	Avg. No. of Rays.	Index of Skewness.	σ
Morehead, N. C.	17.3	-0.09	0.81
Upper Layer, Jack's Bank.	21.7	-0.16	1.0
Lower Layer, Jack's Bank.	22.6	-0.22	1.24

This series is instructive in that it tells us that the gradual reduction in the number of rays has been accompanied at each preceding stage by a negative skewness. This skewness was thus *prophetic* of what was to be. The skew condition of the frequency polygon we may attribute to a selection taking place at every stage, and the interesting result appears that the selection diminishes in intensity from the earliest stage onward. It is as though perfect adjustment were being acquired. If adjustment were being perfected we might expect a decrease in the *variability* in the rays at successive periods. And we do find such a decrease. This is indicated in the last column where σ stands for the index of variability. From this column it appears that the variation in the number of rays has diminished from 1.24 rays in the Miocene to 0.81 rays in recent times. This fact again points to an approach to perfection and stability on the part of the rays.

Just why or wherein the reduced number of rays is advantageous I shall not pretend to say. It is quite possible that it is not more advantageous, but that there is in the phylogeny of *Pecten irradians* an inherent tendency towards a reduction in the number of multiple parts. As a matter of fact there are other *Pectens* in which the number of rays is less even than in *irradians*.

The reduction in the variability of the rays with successive geological periods has another interest in view of the theory of Williams and of Rosa, according to which evolution and differentiation have of necessity been accompanied by a reduction in variability. Evolution consists, indeed, of a splitting off of the extremes of the range of variation, so that in place of species with a wide range of variability we have two or three species each with a slight range of variability. In the particular case in hand, however, it is not certain that the lower Jack's Bank form-unit (named *Pecten eboricus* by some one) has given rise to any other form than something of which *Pecten 'irradians'* of Morehead is a near representative. The evidence indicates that the reduced variability is solely the effect of the skewing factors.

The upshot of this whole investigation into the biological significance of skew variation is then this: Skewness is sometimes reminiscent and sometimes prophetic. In our present state of knowledge it is not possible by inspecting a single skew curve to say which of the two interpretations is correct in the given case. But by a comparison of the frequency curves of allied form-units the state of affairs can usually, as in the examples given, be inferred. A method of interpreting the single skew curve is a discovery for the future.

I realize that I have been bold, not to say rash, in this attempt to forecast the zoology of the twentieth century. I suppose,

after all, I have merely expressed my personal ideals. Let those comfort themselves, therefore, who like my picture not and let them draw one more to their taste. These matters of detail are after all less important; but the general trend of the science I believe to be determined by the great general laws that will hold, whatever the detailed lines of development. First, students of the science will cling closer to inductive methods without abandoning deduction. Speculative web-spinning will be less common, will be less attractive, and will be more avoided by naturalists of repute. Great generalizations will be made, of course, but made with caution and founded at every step on facts. Second, the science will deal more with processes and less with static phenomena, more with causes and less with the accumulation of data. The time is coming when the naturalist who merely describes what he sees in his sections will have neither more nor less claim for consideration than he who describes a new variety of animal. It is relations, not facts, that count. Third, the science will become experimental, at least in so far as it deals with processes. Nothing will be taken for granted that can be experimentally tested. Better experimental laboratories will be founded and larger experimental stations, such as Bacon foresaw in the new world, will be established. Fourth, the science will become more quantitative. This is the inexorable law of scientific progress, at least where processes are concerned. I repeat that there is no reason to expect or desire the abandoning of the lines of work already recognized and followed for a half century or more. Rather holding fast to and extending the old lines of investigation, zoology will be enriched by new fields of study lying between and uniting the old. As chemistry and physics are uniting and occupying the intervening field, as geology and botany are coming close together in

plant ecology, so will zoology and mathematics, zoology and geology, zoology and botany find untouched fields between them and common to them. Working in these new fields and by the aid of new methods, the naturalist of the future will penetrate further into the nature of processes and unravel their causes.

The zoology of the twentieth century will be what the zoologist of the twentieth century makes it. One hundred years ago the prerequisites of the naturalist were few and the opportunities of getting them were small. He must have studied with some master or have worked as an assistant under a naturalist in some museum. The places were few, the masters often difficult of approach. Now while, on the one hand, the training required in vastly more exacting, on the other hand, the opportunities are generous. Just because of the fact that zoology is spreading to and overlapping the adjacent sciences, the zoologist must have his training broadened and lengthened. A zoologist may well be expected to know the chief modern languages (let us hope this requirement may not be further extended), mathematics through analytics, laboratory methods in organic as well as inorganic chemistry, the use of the ordinary physical instruments, advanced geology and physiography, botany, especially in its ecological, physiological and cytological aspects, and animal paleontology. The list of prerequisites is appallingly long; zoologists of the future will be forced to an earlier and narrower specialization, while at the same time they must lay a broader foundation for it.

But if the prerequisites of the zoologists are to be numerous their acquisition will be easy. Even now scores of universities put the services of the best naturalists at the disposal of students and offer free tuition and living to come and study with them. Librarians, great museums, great teachers

are made available to him who would work and has the requisite capacity.

All these advantages will, however, count for nothing if zoological research does not attract the best men, and if the best men be not accorded time and means for research. Our best students slip from our grasp to go into other professions or into commerce because we can offer them no outlook but teaching, administration, and a salary regulated by the law of supply and demand. We must urge without ceasing upon college trustees and corporations the necessity of freedom for research and liberal salaries if America is to contribute her share to the advance of zoology in the twentieth century.

CHAS. B. DAVENPORT.

UNIVERSITY OF CHICAGO.

SCIENTIFIC BOOKS.

Leçons de physiologie expérimentale. By M. RAPHAEL DUBOIS, professor in the University of Lyons, with the collaboration of M. EDMOND COUVREUR. Paris, Georges Carré et C. Naud. Pp. vi + 380.

These lessons in experimental physiology constitute a course of demonstrations, or lectures illustrated by demonstrations, given successfully by Professor Dubois and his pupil and collaborator, M. Couvreur, to the students in physiology of the faculty of sciences of the University of Lyons. As the authors state in the preface, they are now published with the view "of relieving the students attending the demonstrations from the necessity of taking notes, so that they may be able to devote to what they see the greatest amount of attention possible." In addition to viewing the demonstrations, the students are expected to repeat for themselves, under the direction of a master, all the classical experiments. For those who do not possess the advantage of expert supervision it is intended that the exercises described shall serve as a guide by the aid of which they may acquire a practical knowledge of physiology.

While it is encouraging to learn that some-

thing is being done to improve the teaching of practical physiology in the countries of continental Europe, where hitherto it has in general scarcely entered as a factor of any importance into the education of the student of science and particularly of medicine, we doubt whether there is a single teacher of experience in America or England who would bestow an unqualified approval upon the method adopted in this book. At the same time we can most heartily congratulate the young gentlemen (and ladies, if such there be,) of Lyons whom it releases from the bondage of the note-book and the pencil, and whose eyes and fingers (*facile princeps* in the armamentarium of physiology) it sets free for the practical study of this fascinating science.

Two well-established methods of imparting a practical knowledge of the subject are in vogue among us in schools of good standing; demonstrations by a teacher to small classes of students and practical exercises performed by the students themselves. Each of these methods has its uses, although for most purposes, and wherever the number of students is not unmanageably large, the second is by far the most satisfactory. The French lesson in experimental physiology, as typified in the Lyons course, is neither a demonstration pure and simple nor an exercise calculated to guide the student in individual practical work. It is rather a lecture on some portion of physiology, with a certain amount of actual demonstration or of talk about instruments and methods 'shoved into the belly of it.' Not full enough for systematic lectures, not precise enough in the practical directions, nor arranged with sufficient simplicity and order to be of much use as a laboratory guide, such hybrid disquisitions are neither likely, we fear, to thoroughly instruct the learner in the facts of the science nor to introduce him to a real knowledge of the methods by which the facts have been ascertained.

But when this has been said, criticism has exhausted its quiver. Faulty as is the plan of these lessons for the purposes of the elementary student, they are capable of being used with much advantage by teachers of practical physiology whom they will supply, in a somewhat

smaller compass and at a much smaller expense, with the kind of information contained in the classical 'Methodik' of Cyon, now, we believe, out of print. The advanced student also, who is able to pick and choose and piece together the information suited for his purpose, may derive considerable benefit by using the book as a supplement to other less copious but more systematically arranged manuals of practical instruction.

Beginning with the principles and technical details of the most common graphic methods of recording, the authors describe in succession the methods of fixation and anæsthetization of the animals employed; the precautions necessary for aseptic operations; the general properties of nerves and nerve centers, including the various kinds of excitation, reflex action and the effects of lesions of the brain and bulb; the general properties of muscles, illustrated by the usual myographic experiments; the mechanical, nervous and chemical phenomena of respiration in mammals, birds, reptiles and other animal groups; the mechanical and nervous phenomena of the circulation; the chemistry of the blood, lymph, the digestive juices and urine. The last lesson is devoted to animal heat. The least successful part of the book is that occupied with the chemistry of the secretions, a subject already well treated from the practical standpoint in numerous works suitable for students. The descriptions of apparatus are clear and sufficiently full, and the illustrations are well executed. In this age of blatant 'patriotism' it would seem futile to quarrel with the almost exclusive selection of French instruments and the almost exclusive citation of French authorities. In any case, if the authors have erred in this respect, their fault will be readily condoned in view of the charming naïveté of their explanation.

In matters of detail it is, of course, always easy for the captious critic to pick holes in any book. The slips and blunders in this, apart from what we think the initial vice of its plan, are neither numerous nor serious, and some of them have been corrected in a table of errata.

In the description of the action of strychnine (p. 163) the student might easily suppose, from the context that in an animal poisoned with

this drug a single direct excitation of a muscle or nerve 'produces not a single contraction but a series of contractions more or less fused.' This is true, of course, only of a reflex excitation.

The statement (on p. 196), that "after double section of the pneumogastric death always takes place as a direct or indirect consequence of asphyxia (phénomènes asphyxiques) more or less rapid," is misleading.

On p. 231, the so-called 'total velocity of the circulation,' for which a better term is the mean circulation time, is not accurately defined. The only method of measuring it described is the antiquated one of Hering.

On p. 249, the automaticity of the heart-beat is attributed to the ganglia without qualification and without any indication that the majority of physiologists who, in recent times, have busied themselves with researches on this subject have come to the opposite conclusion.

We are entirely unaware of the existence of evidence sufficiently clear to justify the conclusions so boldly drawn from Stannius' experiment on p. 251, 'that the ganglia of Bidder constitute an insufficient excito-motor center, the ganglion of Remak a sufficient excito-motor center, and the ganglia of Ludwig (in the auricular septum) an excito inhibitory center whose tonus is by itself insufficient to counter-balance the excito-motor action of Remak's ganglion.'

On p. 267 it is stated that crystallized hæmoglobin (*i. e.*, reduced hæmoglobin) is unknown. Several competent authorities have described such crystals.

On p. 271, the band of reduced hæmoglobin is, for the English reader, rather comically disguised under the appellation, 'bande de Stokes,' meaning, of course, the 'band of Stokes.'

While the general rules laid down for operations on mammals and for the use of anæsthetics will, as a whole, commend themselves to all physiologists who have had much experience in the use of warm-blooded animals for teaching purposes, we must take exception to the advice that "in all operations, whether the animal is destined to be sacrificed at the end of the experiment or not, the vivisector should

apply as vigorously as the surgeon the rules of antiseptis and aseptis." We are convinced that while, in an experimental course carried out by students, it is perfectly feasible and of great utility to insist upon rigid antiseptic precautions in such experiments as require it, they not only introduce an unnecessary complication in cases in which the animal is to be sacrificed, but often interfere seriously with, and always distract the attention of the student from the real object of the observation. Further, most of the work on mammals which can and ought to be performed by students is of such a nature that a strict adherence to antiseptic technique throughout the whole experiment is practically impossible. If the argument that "it is a bad discipline to have two styles of operation, since certain details of the antiseptic method will be fatally neglected when one wishes in exceptional cases to apply it," be a sound one, we ought seriously to enquire whether the reckless custom of wearing one sort of dress in summer and another in winter is not very likely to result in a fatal confusion of times and seasons, muslins and mackintoshes, shirt-waists and sealskin coats, and to lead to such awful inversions as ducks in December and ulsters in July, or whether any man who respects his stomach and has a conscientious regard for the interests of his insurance company, can afford to permit his cook to dabble at the same time in the cumulative mysteries of roast and boiled.

Ind.
4 *The Home Life of Wild Birds.* A New Method of the Study and Photography of Birds. By FRANCIS HOBART HERRICK. New York and London, G. P. Putnam's Sons. 1901. Pp. xiii + 148.

In 'The Home Life of Wild Birds,' Francis Hobart Herrick has given us a most valuable treatise and one which is sure to be of the greatest assistance to those who are following the perplexing pastime of bird photography. The author states the truth when he says that animals should be studied as animals and not as if they were human beings. If some others had shared this commendable belief, an enormous amount of trash would be absent from the book shelves and consequently seekers

of truth would be saved a corresponding amount of annoyance. We have no objection to well-written fairy tales, fables, or stories of personified animals, but when an author states or implies that his human thinking and acting animals are truthfully portrayed, and the alleged facts are taken from nature, then we consider he should be most severely criticised.

Taking advantage of that force which for convenience we term parental instinct, Mr. Herrick overcomes the chief difficulty that besets the bird photographer. The method is to remove the nest from its surroundings, whether it be in the tall tree, deep wood, swamp or impenetrable brier patch, and set it up in a good light, so that the branch or other support of the nest will occupy the same relative position as in the old site. It was found that the parent birds soon got used to the new surroundings and attended the young as if nothing unusual had happened. By the aid of a green tent which concealed the operator and outfit, and when in use was open only at a point in line with the lens, the affairs of the little family could be observed with perfect ease at a distance of only a few feet. In this manner the author spent what must have been many happy days in observing the interesting movements that were taking place in and about the nests of the robin, cedarbird, kingbird, chestnut-sided warbler, bluebird, brown thrasher, red-eyed vireo, nighthawk and many other species.

The 137 pages which detail these experiments are full of valuable facts and suggestions and will surely be welcomed by those who care to learn the mysteries of bird life. The numerous photographs which enliven the book, with the exception of a few distorted on account of the nearness of the object, are admirable, and in connection with the text undoubtedly will stimulate many to seek a fascinating recreation so well described and illustrated in this volume.

WASHINGTON, D. C.

DISCUSSION AND CORRESPONDENCE.

THE COAST PRAIRIE OF TEXAS.

THIS physiographic feature, which extends for a distance of nearly four hundred miles, from

western Louisiana through Texas into Mexico, is one of the newest made and least understood of our American geographic provinces.

In topographic aspect it is apparently an almost level plain sloping at the rate of about one foot to the mile seaward, but within its area there are slight irregularities or undulations, hitherto unnoticed or at least not described, which are now attracting great attention, owing to their supposed relation to the occurrence beneath them of oil.

The Louisiana extension of the prairie is generally acknowledged to be a subsiding land as attested by actual bench marks, by the drowned character of the bayous and by the cycles of cypress growth on the swamps. I know of no actual previous observations bearing upon the isostasy of the Texas portion of the prairie, but McGee in a recent article in the *National Geographic Magazine* assumed that it was also subsiding.

I have just made some observations, however, which lead me to believe that west of the Trinity river, at least as far south as the mouth of the Colorado—beyond which we know nothing—the plain is rising.

Between the Trinity and the Colorado all the streams have new-cut channels, characteristic of rising land, while the Brazos is actually cutting down through its own alluvium at sea level and for many miles above its mouth. Not only is the coast prairie now undergoing differential movement—subsiding in one part and rising in another—but there is strong evidence that it is being wrinkled and folded, the strata so affected being so recent in age that they cannot be assigned to any other period of time than Pleistocene or recent. These folds are so slight that they could never have been detected had it not been for the discovery of oil on Spindletop Hill, four miles south of Beaumont, by Captain A. F. Lucas, in January last.

When this gentleman endeavored to point out to me this hill, my trained topographic eye could hardly detect it, for it rises by a gradual slope only ten feet above the sea of prairie plain which surrounds it. I was still more incredulous when Captain Lucas insisted that this mound, only two hundred acres in extent, was a dome, and that it had been uplifted by the

pressure of gas from the great pool of oil now proved to be coincident in extent beneath it. Captain Lucas said that I should be convinced of the uplift if I could see Damon's Mound in Brazoria County. I have just returned from Damon and a second look at Spindletop, and am convinced that if these hills are not recent quaquaversal uplifts no other hypothesis will explain their existence.

Damon's Mound is an elliptical oval hill a mile or more in greatest diameter. It rises ninety feet above the surrounding level plain. Its profile is everywhere convex instead of concave, and it is not a hill of erosion or of volcanic material. Furthermore, a bed of limestone follows the contour of its surface, showing deformation. The ascent of the plain will not carry the latter to the height of this mound for one hundred miles interiorward. The oil men have insisted on this structure and are spending \$200,000 upon Damon's Mound alone, merely upon their belief that its structure is anticlinal. Not only this, but they have seized upon every hill of this character on the coast prairie of western Louisiana and Texas, and are sinking at least 100 wells at an expense of \$10,000 a piece to demonstrate their theory.

Concerning the stratigraphy of the coastal plain, it can only be said that at Galveston it is composed of at least 3,000 feet of unconsolidated land, derived sands and clays, with occasional lignite logs and estuarine shells. All this is later than the Eocene Tertiary—the last datum point we have in the Tertiary and Pleistocene stratigraphy of Texas. Of this thickness Harris has shown 2,000 feet to be post Tertiary or not proved as old as Tertiary. Fossils from the Beaumont wells, depth 1,030 feet, have been assigned to the 'Neocene,' but as 'Neocene' means nothing—being merely a word to conceal our ignorance of all the later Tertiary strata of the United States—the position of the oil is still uncertain. It is my opinion that the oil is in strata which may as well be called Pleistocene or recent. They are certainly later than any proved Tertiary strata.

One thing is certain. This oil occurs in underground pools, and another thing is probable, that these pools underlie dome-shaped anti-

clines in the new-made recent coast prairies. Furthermore, these uplifts are most probably due to isostatic movements rather than to accumulations of gas.

Another interesting fact which is developing is that these oils are not associated with extensive beds of either plant or animal remains, but at one place, Saratoga, where they outcrop, they apparently originate in ferruginous sands, and this occurrence is strikingly suggestive of Mendeleef's theory that petroleum is formed by the action of warm waters on carbide of iron at considerable depths. But conclusions on this subject are as yet premature.

ROBERT T. HILL.

DISCORD AND BEATS.

TO THE EDITOR OF SCIENCE: In a review of books on physics in a recent issue of SCIENCE, I find on page 259 the remark that the author "has defined 'discord' more sharply than the facts warrant, by failure to recognize Mayer's law, which expresses the duration of the residual auditory sensation as a function of vibration frequency, the equation being expressible in a curve which Professor Mayer published in 1894 (*Am. Jour. Sci.*, Jan., 1894)." That authors of text-books of physics discuss *psychological* problems may be very well; for it is certainly better for the student to learn some psychological theories in the physical laboratory than to learn them not at all. But, unfortunately, it is rare to find a physicist who is sufficiently familiar with the psychological literature. Permit me to make these two statements: (1) That a 'discord' cannot be defined by 'beats,' the psychologists have some time since agreed upon. The physicists—on the authority of Helmholtz, whose 'Tonempfindungen' appeared 40 years ago—still make use of this definition. (2) Mayer's curve, as recent experiments (*Zeitschrift f. Psychol. u. Physiol. d. Sinnesorgane*, 20: 408-424; reviewed in the *Psychological Review*, 7: 88-90, 1900) prove, does not express the dependency of the duration of an after-sensation on the frequency of vibration. The duration of the after-sensation does not seem to depend upon the pitch at all.

MAX MEYER.

UNIVERSITY OF MISSOURI.

THE INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.

TO THE EDITOR OF SCIENCE: Can nothing be done even at this stage to secure a better system of classification for the international catalogue of scientific literature now under process of preparation under the general supervision of the Royal Society in London? In library management this country is, as probably every one is aware, in advance of most, if not all, countries, and the result of this is that the practical application of the science of classification to the cataloguing of books and articles has been carried farther in this country than elsewhere. Published systems of classification here are more complete, there is a larger literature on the subject, and a greater number of libraries have been catalogued on a classified system. I do not think anybody familiar with classification and its practical application will hesitate in condemning the classification which has been adopted by the Royal Society. In botany, it is ridiculously incomplete. It is impossible, as I know from experience, to classify material on this subject, in the shape of papers, without a system which is at least carried down to families; and in many cases one extended to genera is wise.

The classification in geology is equally inadequate and makes insufficient provision for the great extension which has taken place in physiographic geology in the last ten years.

If any one wishes to see what can be done in the line of careful classification for geological purposes, M. Mourlon's 'Classified Index of Geological Papers' on the Dewey Decimal System will offer a striking contrast to that presented by the meager array of classification in the Royal Society. Mnemonic aids are altogether omitted in this classification, no common system of number being used for common types of classification in different subjects. In the biological field, no effort has been made to follow a similar arrangement of homologous subjects.

In fact, I think, I speak within bounds in saying that no one versed in this subject can examine this classification without feeling that it is prepared by some one who has neglected to study what has already been done in this field.

There are two subjects which every one appears to think can be done by nature. One is editing a newspaper and the other is classifying. Any one who has had any experience in either will feel differently.

TALCOTT WILLIAMS.

SHORTER ARTICLES.

NOTES ON THE LIFE HISTORY OF ANOPHELES PUNCTIPENNIS AND ON THE EGG-LAYING OF CULEX PIPIENS.

SOME time during the latter part of May, 1901, a ditch about four feet in depth was dug for the water main to the new textile building on the campus. The ditch was dug in sections, one of which ran down a considerable slope just at the end of the photographic building. This section of the ditch soon became partly full of rain water. At the lower end the water was two and a half feet deep, but the water did not extend more than a third of the length of the ditch up the slope. At the upper and shallower end of the body of water, it soon became covered with a thin green slime, which upon examination proved to be wholly of *Protococcus*. In this shallow, slimy water on June 4 the writer discovered an abundance of larvæ of *Anopheles punctipennis*. They were recognized at a glance as larvæ of *Anopheles* from Dr. Howard's excellent drawings and descriptions of the larvæ of *Anopheles maculipennis*. Glass jars were immediately called into requisition, and many larvæ were carried to the laboratory, from a study of which the following notes were made. It might be of interest to say just here that there was also an abundance of larvæ of *Culex pipiens* in the same water in company with *Anopheles*.

Eggs.—It was with some surprise and a good deal of pleasure that a number of eggs were found on the surface of the water in the jars. Like *maculipennis*, they are laid at random on the water, but naturally run together and cohere in loose irregular groups or strings of from three to a score or more. Some were found floating on their sides, but the greater number seemed to be floating with the convex side, or 'back,' up and the concave side down. They differ somewhat from the eggs of *maculipennis* in shape. These eggs resemble an Indian canoe in shape,

hence a cross section would be more or less triangular in outline. Seen from the side they are strongly convex above and concave below. One end is larger and blunter, while the other, as seen from the side, curves strongly downward, is smaller and more pointed. Above and on the sides the eggs are marked with a reticulate hexagonal sculpturing similar to *maculipennis*. Below, on the concave side is a dark wide line or band, extending nearly the length of the egg. It widens at each end into a club-like expansion. The writer could not be sure whether this was simply a band or a groove. Near the blunt end of the egg a transparent line runs from each side of the dark band obliquely down the sides of the egg. When the egg bursts, it breaks along these lines. At each end of the band are several dark, circular spots. The eggs varied from .45 mm. to .47 mm. in length. They hatched in 24 to 48 hours after being brought in, but no record was obtained as to the actual time of hatching after being laid, as none of the females laid eggs in captivity. It is probably safe to say, however, that they accord in this particular very closely with *maculipennis*.

Larvæ.—When first hatched the larvæ present a mottled appearance, owing to alternate dark and light transverse markings on the body. This appearance certainly suggests the spotted wings of the adult, although there perhaps can be no reason for thinking that the one in any way foreshadows the other. The larvæ retain this appearance up to the last molt, although it seems to grow less distinct with age. They lie in a nearly horizontal position just beneath the surface film of water, and when only slightly disturbed wriggle in a horizontal direction across the water instead of downward as *Culex*. When violently disturbed they wriggle downward. The more mature larvæ are more inclined to wriggle downward than the young larvæ, when disturbed. The feeding habits are almost identical with those of *maculipennis*, so fully described by Dr. Howard. The same rotary motion of the head with the under side uppermost in feeding was characteristic. There were no such differences between the larvæ of *punctipennis* and *maculipennis* as there were between the eggs of the

two species. Perhaps the mottled, or more properly the streaked, appearance of the larvæ of *punctipennis* is a distinguishing feature. Dr. Howard, we believe, mentions nothing of the kind in regard to *maculipennis*.

The duration of the larval stage, under normal conditions with plenty of food, varied from twelve to fourteen days.

On June 5 three larvæ were placed in a jar containing very little food. What food there was lay among some sand at the bottom. Two of them were very young, while the third could not have been more than half grown. These larvæ remained there until June 29, when the two younger died. These two did not go to the bottom after food and probably starved. The third and more mature one did go to the bottom after food and remained alive until July 3, when it was transferred to water containing an abundance of food. In a few days it transformed to a pupa. In this case the larval stage was over a month and could doubtless have been prolonged.

Pupæ.—The pupæ of *Anopheles* are not strikingly different from those of *Culex pipiens* to the unaided eye. A close observer, however, can learn to distinguish the two with the eye by the difference in length of the respiratory siphons. Those of *Anopheles* are much shorter. Under the microscope they are also seen to be of quite a different shape from those of *Culex*. The thorax and body of *A. punctipennis* differ quite markedly in shape from those of *C. pipiens*, when seen from above. Like the larvæ, the pupæ tend to wriggle in a horizontal direction when disturbed. They are not as active as those of *C. pipiens*, which fact is brought out very forcibly when one attempts to make a camera lucida drawing of the living pupæ of both in their natural position in the water.

The pupal stage of both males and females lasted with great regularity just about two days. At least it could not have varied more than a few hours from this, as the adults were found in every case on the second morning subsequent to the morning on which the pupæ were found.

Egg-laying of Culex Pipiens.—On July 17, in the back yard of a hotel at Magnolia, Mississippi, the writer found a pig trough five feet long,

containing water to the depth of about six inches. On the surface of this water by actual count there were 257 masses of eggs of *C. pipiens*. Since there were less than five square feet of surface, one can imagine the density of egg population. It was noticed that about a dozen of the egg masses were white, or yellowish white, in appearance. This led to a more careful examination, which resulted in the discovery of a female about to finish laying a batch of eggs. Time, 6 a. m. She was so busily engaged that we could watch her with a hand lens. She rested on the surface with the abdomen at a slight angle, because the caudal end was nearly touching the surface. The mosquito stood at one end of the mass, with her head away from it. As the eggs were deposited the mass was gradually pushed away from her. The end of the abdomen was slowly carried from side to side, so that the eggs might be placed across the end and the whole mass filled out and completed as she progressed. The process may be compared with the action of the hand as a bobbin is wound with thread. The eggs always came forth with the small end first. This end, since the abdomen was held closely to the mass, would strike the other eggs and appear to be slipped along the perpendicular sides of the others, and thus be brought to an upright position. However, the tip of the abdomen was curled slightly upward, so that the egg was directed upward and very likely would have been deposited in an upright position in any case. It would have been interesting to have seen the first egg deposited. There was an appreciable interval between the deposition of each egg, perhaps two seconds, although we did not time it.

GLENN W. HERRICK.

AGRICULTURAL COLLEGE, MISSISSIPPI.

RECENT ZOO-PALEONTOLOGY.

A MARSUPIAL EVOLUTION.

IN the April *Naturalist** is an important paper by Mr. B. Arthur Bensley upon the origin of the Australian Marsupialia. The evolution of the Marsupials is compared with that of the Pla-

* 'A Theory of the Origin and Evolution of the Australian Marsupialia,' *The American Naturalist*, Vol. XXXV., No. 492, pp. 245-269, April, 1901.

centals after the later Cretaceous, and the conclusion is reached that since the Placentals have radiated from a Creodont prototype beginning in the later Cretaceous period, it is quite possible that the Marsupials have during the same time radiated from a *Didelphys* prototype; there is a striking general resemblance between the early Creodonts and the opossum which tends to support this theory. It is practically the working out of a hint by Huxley in 1880, and of a very suggestive paper by Dollo upon the arboreal ancestry of the Marsupials. The idea of *Didelphys* origin, however, is original with Mr. Bensley, and the detailed comparison of the evolution of the teeth of Marsupials with that of Placentals promises to give most important and interesting results. Mr. Bensley is enjoying the extensive collections of the British Museum.

GEOLOGY OF THE JOHN DAY BASIN.*

As a result of the explorations by the University of California, John C. Merriam contributes a valuable paper upon the geology of this important region in Oregon, as preliminary to the revision of the vertebrate fauna. Although this region was first reported in 1861 and explored by Condon, Marsh, Cope, Scott, Sternberg and Wortman, this is the first exact description of its geology, and is therefore most welcome and important. The author divides the beds into the Lower (250-300 feet), which is reported to contain *Oreodon*; Middle (500-1,000 feet), chiefly distinguished by *Diceratherium*; and Upper, which contained *Paracotylops*. The exact correlation of these beds with those of the Oligocene White River awaits the precise comparison and study of the faunæ. The mode of deposition has generally been considered entirely lacustrine, as the series are everywhere uniformly stratified and bedded, on the other hand, the author presents strong reasons for an æolian origin for the finer portions of these beds. In fact the problem is precisely similar to that which is now being discussed for the finer beds of the White River formation.

* 'A Contribution to the Geology of the John Day Basin,' *Bulletin*, Dept. of Geology, Univ. of California, Vol. II., No. 9, pp. 269-314, April, 1901.

DISCOVERIES OF PLESIOSAURUS AND OF PORTHEUS.

During the past season Mr. Charles H. Sterüberg, well known for his years of explorations in the Kansas Chalk, made two discoveries of exceptional importance. The first is of a new type of Plesiosaur, the skeleton of which is preserved in an exceptional manner; this has been purchased by the University of Kansas and will be described by Professor Williston as part of his general studies upon Plesiosaurs. The second is a remarkable skeleton of *Portheus molossus*, of the suborder Acanthopteri, family Ichthyodectidæ—the characteristic predaceous fish of the Niobrara. The specimen is sixteen feet in length and is in an exceptional state of preservation. It has been purchased by the American Museum of Natural History, and will be mounted facing the great specimen of *Tylosaurus* from the Kansas Chalk which has already been described in this Journal.

H. F. O.

BOTANICAL NOTES.

SHORT NOTES ON RECENT BOOKS.

AMONG botanical books which are likely to attract attention is Dr. Wettstein's 'Handbuch der Systematischen Botanik' of which Part 1 (including pages 1 to 202) has been brought out by the Leipzig publisher Franz Deuticke. Resembling Warming's 'Haandbog i den Systematiske Botanik' and Schumann's 'Lehrbuch der Systematischen Botanik,' it promises to be much fuller and more helpful than either, and like them is to be a general survey of the structure and classification of the Vegetable Kingdom. The attempt is made to treat the subject from the phylogenetic standpoint, and whatever of success is attained in the work is largely due to this fact. In the part now issued forty-four pages are given to a general discussion of the principles involved, followed by the special discussion of representatives of the seven phyla recognized by the author, viz.: Myxophyta (including the single class *Myxomycetes*), Schizophyta (including the classes *Schizophyceae* and *Schizomycetes*), Zygomphyta (including the classes *Peridineae*, *Bacillariaceae* and *Conjugatae*), Euthallophyta (including the classes *Chlorophyceae* and *Fungi*, the latter in-

cluding the lichens), Phaeophyta, the brown algae, Rhodophyta, the red algae, and Cormophyta (including liverworts, mosses, ferns and their allies, and the seed-bearing plants). The work is admirably illustrated.

The appearance of the first half of the second volume of the new edition of Pfeffer's 'Pflanzenphysiologie' (Engelmann, Leipzig) is gratifying to botanists who have been using the first volume. This part covers 353 pages, indicating that Volume II. will be considerably larger than Volume I. The present half-volume includes ten chapters, as follows: (1) Growth Movements, (2) Mechanics of Growth, (3) Growth and Cell-increase, (4) Elasticity and Cohesion, (5) Tissue Tensions, (6) Influence of Environment on Growth-activity, (7) Cause of Specific Form, (8) Variation and Heredity, (9) Rhythm, (10) Resistance to extreme Influences. A hasty glance through these chapters indicates that the work maintains the high standard of the preceding volume. The second part of Volume II. is in course of preparation, and will complete the work.

Of Engler's 'Pflanzenreich' (Engelmann, Leipzig) four parts have already appeared, dealing with the families *Musaceae* (by K. Schumann), *Typhaceae* and *Sparganiaceae* (by P. Graebner), *Pandanaceae* (by O. Warburg), and *Monimiaceae* (by Janet Perkins and Ernst Gilg). The illustrations continue to be more than unusually helpful, being clear, well drawn, and judiciously selected. In the part devoted to *Pandanaceae* there are, in addition to the ordinary illustrations, four full-page 'half-tone' plates from photographs showing the gross appearance of different arboreal species with their natural surroundings.

Thomas Howell's 'Flora of Northwest America' (Howell, Portland, Or.), has reached Fascicle 4 which includes *Liguliflorae* to *Boraginaceae* (pages 387 to 474). As the author follows the Benthamian sequence it is easy to estimate by comparison with Gray's 'Manual' that the work is not more than one-half completed. The work, although marred by typographical errors (incidental to unprofessional printing) and an 'inky' page now and then, will be a very important help to the northwestern botanists.

The last-named work reminds us of a local

northwestern flora, 'The Flora of the Palouse Region,' by Charles V. Piper and R. Kent Beattie (Agricultural College, Pullman, Wash.), which appeared in May of the present year. The area covered is 70 kilometers in diameter with the town of Pullman, Wash., as a center, and includes about 24 townships in eastern Washington and 11 in western Idaho. In this region the authors describe 14 Pteridophytes, 9 Gymnosperms, 114 Monocotyledons and 526 Dicotyledons. The work of compilation appears to have been well done, and it is a pleasure to observe an attempt at a somewhat modernized terminology, and the use of metric measurements throughout. Engler and Prantl's System has been followed, and in nomenclature 'the so-called Kew and Berlin rules.' It must prove very helpful to students of northwestern Idaho and eastern Washington far outside of the limits covered.

The handy little book, 'Grasses,' by Dr. H. Marshall Ward, of Cambridge University (University Press, London), shows what may be done by a competent botanist in the way of making a difficult subject somewhat plain and not too technical. In less than two hundred small octavo pages the author gives a great deal of information, valuable not only to the student of grasses, but also to the practical man whose business it is to grow grasses for forage. There are chapters on the vegetative organs, anatomy, flowers and 'seeds' of grasses, followed in each case by a classification based on these characters alone. The book must be very useful in England and it suggests the need of a similar work for the United States.

POPULARIZING THE STUDY OF FERNS.

WHATEVER tends to increase the popular interest in plants is directly contributory to the advancement of science. Every book and every organization which stimulates an admiration and consideration of plants is to be encouraged by scientific men. Such a book is Mabel Osgood Wright's 'Flowers and Ferns in their Haunts' (Macmillan, New York), with its charming text, artistic cuts, and wonderfully accurate 'half-tone' reproductions of well-taken, well-selected, gray-mounted photographs of landscapes, where plants are shown in all their

glory. A chapter on 'The Fantasies of Ferns' is unequaled anywhere in fern literature. Not only is the text suited to the person whose mind 'is of the kindergarten order, that needs nice interesting object lessons,' but it will afford real pleasure and some instruction to the professional pteridologist, unless he has lost all sentiment, and love of the beautiful. It will prove a strong corrective for the mania which uproots every pretty, green thing. After reading it none but a confirmed vandal would wantonly disturb a colony of these beautiful plants.

Mrs. Wright's book may easily prepare the amateur for a more particular study of ferns, as suggested in Willard N. Clute's 'Our Ferns in their Haunts' (Frederick A. Stokes Co., New York). This is in fact a popular manual of the ferns of North America north of the Gulf States and east of the Rocky Mountains, and by the aid of an easy non-technical text, good cuts, and many 'half-tone' and colored plates, the subject is made so plain that no one need be without some knowledge of the ferns. It should find a place in the library of every amateur botanist, and it will do no harm to the professional botanist, who may well give it room on his shelves with other helpful books.

Why should not such books as these encourage those organizations which have for their object the cultivation of a love of Nature, and the protection of the native species? The Linnaean Fern Chapter of the Agassiz Association, which has recently issued its Eighth Annual Report (Miss Margaret Slossen, Secretary, Andover, Mass.) is such an organization of mostly amateur students of ferns. What a help such a society may become to the thousands of people who, away from herbaria and museums, desire to keep in touch with the work of others with like tastes. What an inspiration must come from membership in an organization whose members are scattered over the territory from Maine to California, and Canada to Florida and Texas, with one in England and another in far-away New Zealand.

A word may be said here in praise of a new society in Boston and its suburbs, named the 'Society for the Protection of Native Plants.' Its object is 'to check the wholesale destruction to which many of our native plants are ex-

posed.' Every botanist will wish this society the greatest success. Its secretary is Miss Maria E. Carter, Curator of the Herbarium of the Boston Society of Natural History. The urgent need of such a society is apparent not only in the densely populated Eastern States, but fully as much in the western summer resorts, where the hand of the vandal has already exterminated some species.

CHARLES E. BESSEY.

UNIVERSITY OF NEBRASKA.

THE PRESERVATION OF COLORADO CLIFF DWELLINGS.

THE Colorado Cliff Dwellings Association is endeavoring without aid from the legislature to preserve the ruins which lie on the Mesa Verde, a tableland twenty miles long by eight miles wide, in the southwest corner of Colorado. There are from three hundred to four hundred cliff dwellings including the noted 'Cliff Palace' on this mesa. These are all in the Ute Indian reservation and consequently the state or national government can not control the ruins. A ten years' lease has been made by the Association direct with the Ute Chiefs, by means of which control is had of the Mesa. The Secretary of the Interior having ratified the lease, the Association is now in charge of the ruins, and will open a toll road to them. The money received as toll will, however, be only part of the sum paid to the Indians as rent. The ruins will be kept from weathering and from the depredations of 'relic hunters.'

HARLAN I. SMITH.

PRESENTATION BEFORE THE FACULTY OF CANDIDATES FOR THE DOCTORATE AT THE UNIVERSITY OF PENNSYLVANIA.

THE University of Pennsylvania inaugurated this year what seems to be in many respects an excellent method of recommending candidates for the degree of Doctor of Philosophy. The usual method, borrowed from the German universities, of examining candidates before the faculty or letting them defend their theses before the faculty is not altogether suited to existing conditions. In Germany it is chiefly a form and appears to be falling into disuse. The

plan is scarcely fair to the candidate if the conferring of the degree depends on the result of a public examination; it is scarcely fair to the faculty if it is a mere formality, and, as a matter of fact, members of the faculty often do not attend. The plan adopted by the University of Pennsylvania is to let the candidate pass a written examination and then bring him before the faculty, where he is presented by the professor under whom he has taken his major subject. The presenter reads a sketch of the candidate's academic life and an outline of the scope and contents of his thesis, after which any member of the faculty may make enquiries of the candidate or the presenter. As an example of the way in which the candidates are presented and as the biographies are themselves of interest, we reproduce the credentials of the first candidate presented in each of the sciences:

Professor Smith, Presenter.

Gilbert Hillhouse Boggs was born at Memphis, Tenn., October 2, 1875. He received his early education in the public schools of Athens, Ga., and entered the University of Georgia as a freshman in 1892, graduating with the degree of Bachelor of Science in 1896. He entered the Department of Philosophy of the University of Pennsylvania, February 25, 1897 and remained in residence until February 10, 1898. He reentered October 5, 1898, and has remained in residence for the past three years. His major has been in inorganic chemistry, his minors in organic chemistry and analytic chemistry. He was granted a university scholarship in chemistry for the years 1897-98 and 1898-99, and was appointed to a Harrison Fellowship at Large in the same subject for the years 1899-1901. He was admitted to candidacy for the degree of Doctor of Philosophy when appointed to the Fellowship.

He has completed under the jurisdiction of Group Committee XIV. thirty three standard lecture courses, exclusive of the laboratory work which has occupied the greater part of his time for four academic years. He has satisfactorily passed written examinations in inorganic, organic and analytical chemistry on May 28-30, 1901, with Professor Smith, Drs. Lorenz and Shinn.

Mr. Boggs has presented a thesis entitled 'I. The Separation of Vanadic Acid from Metals by means of Hydrochloric Acid Gas. II. The Occurrence of Molybdenum in the Mineral Endlichite,' of which the following is an abstract:

Vanadium is being frequently found present in

traces in rocks and minerals. Its separation from allied metals is extremely difficult, and in this research the purpose has been to ascertain how completely hydrochloric acid gas will eliminate the vanadium, it being well established that from the alkali metals the vanadic acid is completely removed by this reagent. This study shows that with the exception of the alkali group of metals the new reagent is inadequate. An additional point of interest is that the metal molybdenum exists in the mineral endlichite, and that its presence there accounts for the fact that the vanadic acid of endlichite is removed by hydrochloric acid gas, probably because it exists as a vanado-molybdate of lead, a form different from that in which it is observed in vanadinite.

Mr. Boggs' thesis is now in the hands of the printer, and the required number of copies will be delivered to the Dean within a few weeks. Mr. Boggs is unanimously recommended by Group Committee XIV. to the Faculty of Philosophy for the degree of Doctor of Philosophy.

Professor Macfarlane, Presenter.

Henry Shoemaker Conard was born in Philadelphia, September 12, 1874. He received his early education at the Friends' Select School and Westtown Boarding School. He entered Haverford College as a junior in 1892, and graduated with the degree of Bachelor of Science in 1894. He was a graduate student at Haverford 1894-95, receiving the degree of Master of Arts in 1895. During the four years, 1895 to 1899, he was teacher of science in the Westtown School. He entered the Department of Philosophy, of the University of Pennsylvania, September 26, 1899, as Harrison Fellow in Biology, being thereby made a candidate for the degree of Doctor of Philosophy. He elected his major in botany, his minors in botany and zoology. He has completed in this University, under the jurisdiction of Group Committee XV., twenty standard lecture courses, besides spending practically all his spare time for two years in the laboratory, and has also received credit for his work at Haverford to the extent of four standard courses, making a total of considerably more than twenty-four. He has satisfactorily passed written examinations as follows: On May 28 and 29, 1900, in zoology; on February 7 and 11, 1901, in botany as a minor, and four further examinations in botany as a major, running from May 21 to 22, 1901.

He has presented a thesis entitled 'Water Lilies: a Monograph on the Genus *Nymphaea*.' It will be published in the next volume of the Series in Botany, issued by the University of Pennsylvania. A brief abstract of this thesis is subjoined:

Mr. Conard has described about thirty natural spe-

cies. A like revision has never appeared in English, and not in any language since 1853, during which time many new facts have been brought out. The classification differs slightly from that of previous workers, in view of recently discovered facts of hybridization. An attempt is made to arrange the types as nearly as possible in their evolutionary relationships. Twelve species, representing all the natural groups from all parts of the world, and a number of hybrids and varieties, have been studied carefully in cultivation in the Botanic Garden of the University. Others also have been studied in the collection of the Henry A. Dreer Company, at Riverton, N. J., and elsewhere. Each description takes up :

1. Diagnostic characters.
2. Literature and synonymy.
3. Minute morphological, physiological and, in some critical cases, histological descriptions of flower, leaf, stem and root, and the development from seeds and tubers.
4. Habitat.
5. Remarks, historical and critical.
6. Varieties similarly described.

The results of a number of observations on the times of daily opening and closing of the flowers are incorporated in the descriptions ; these, and the developmental histories of species are, for the most part, entirely new records. The paper is illustrated with photographs and line drawings.

Mr. Conard is unanimously recommended to the Faculty of Philosophy by Group Committee XV. for the degree of Doctor of Philosophy.

Professor Crawley, Presenter.

Burton Scott Easton was born in Hartford, Conn., December 4, 1877. He received his early education at the Hamilton School, Philadelphia, and with private tutors in Germany. He entered the University of Pennsylvania as a freshman in 1894, receiving the degree of Bachelor of Science in 1898. During the year 1898-99 he was instructor in mathematics and astronomy in the State University of Iowa, and pursued graduate work in the same institution. He entered the Department of Philosophy of the University of Pennsylvania, September 27, 1899, electing his major in mathematics, one minor in mathematics, and the other minor in astronomy. He was appointed Harrison Fellow at Large in Mathematics for the year 1900-01, and was transferred to the regular fellowship in mathematics and astronomy January 11, 1901. He has received credit for the following work : (1) For graduate work in mathematics pursued before receiving his Bachelor's degree, and not credited toward that degree, four standard courses ; (2) for graduate work in mathematics at the State University

of Iowa, six courses ; (3) for graduate work in this University since 1899, sixteen courses, a total of twenty-six standard courses. He has satisfactorily passed written examinations on March 30, April 4 and May 16, 1901, in mathematics with Professor Crawley, Assistant Professors Fisher and Schwatt and Dr. Hallett ; on March 16, 1901, in astronomy with professor Doolittle and Mr. Eric Doolittle. He has presented a thesis entitled 'Substitutions and Substitution Groups.' He has deposited with the Dean a copy of this thesis and the money necessary to print it. The thesis will appear in the spring of 1902. A brief outline of its contents is as follows :

The group theory is one of the most recent developments of mathematics. It is far-reaching in its applications and is a most prolific field of research at the present day. The literature of the subject is, however, principally to be found scattered through the pages of the mathematical and scientific journals, and is therefore disjointed and fragmentary not only in form but also in the manner of its presentation. Moreover, much of importance is almost useless from the difficulty of finding it when wanted.

The primary object of the dissertation is to present the results of the most recent investigations in this subject in such a manner as to give a coherent view of what has been done. The way in which this has been accomplished by the candidate shows good mathematical judgment, and a thorough appreciation of the philosophy of recent mathematics. Only a portion of what has actually been accomplished in carrying out this work is embodied in the dissertation, which is devoted in the main to a careful consideration of transitive and intransitive groups, primitive and imprimitive groups, and the isomorphism of one group with another. The limits of *transitivity* have received special attention. A certain looseness has been found to exist in the use of some terms, notably in the expression 'permutable groups.' Mr. Easton has given precise definitions in all these cases, and the necessary modifications in the subsequent developments have been introduced.

Mr. Easton is unanimously recommended to the Faculty of Philosophy by Group Committee XI. for the degree of Doctor of Philosophy.

Professor Doolittle, Presenter.

Henry Brown Evans was born in Dayton, Ohio, July 2, 1871. He was educated in the public schools of his native town, graduating from the High School in 1889. He entered the Freshman Class of Lehigh University the same year, and received the degree of Mechanical Engineer in 1893. He was instructor in mathematics and astronomy at Lehigh, 1894-95, and has been instructor in astronomy in this University

since 1895. He entered the Department of Philosophy October 23, 1895, electing his major in astronomy, his minors in mathematics and philosophy. He was admitted to candidacy for the degree of Doctor of Philosophy October 1, 1897. He has completed twenty-seven standard courses. He has satisfactorily passed written examinations in astronomy with Professor Doolittle on May 4 and 11, 1901; in mathematics with Assistant Professors Fisher and Schwatt on March 7, 1901; in philosophy with Dr. Singer on March 25, 1901. He has presented a thesis entitled 'The Right Ascensions of One Hundred and Eighty Latitude Stars,' and has deposited with the Dean a copy of the manuscript and the money necessary to print it. The scope of this thesis may be described as follows:

The determination of the latitude of any single point of the earth's surface, by the zenith telescope method, depends ultimately on the positions of the stars observed for that purpose. The object of this thesis is the determination from all available data of definitive values of the right ascensions of one hundred and eighty stars. This material is needed for the determination of the variations of latitude at the Sayre Observatory of Lehigh University and at the Flower Observatory of the University of Pennsylvania. A definitive investigation of the right ascensions has not been undertaken before this. The necessary data were found in the star catalogues heretofore published, from 1755 to date. Altogether positions of these stars were taken from about one hundred such sources. The observed positions were then combined by the method of least squares, and the definitive values of the right ascensions of the one hundred and eighty stars in question for 1875.0 were thus determined.

Mr. Evans is unanimously recommended to the Faculty of Philosophy by Group Committee XII. for the degree of Doctor of Philosophy.

Professor Patten, Presenter.

John Paul Goode was born at High Forest, Minn., November 21, 1862. He received his early education in the public schools of Olmstead County, Minn., and in the Rochester Seminary, Rochester, Minn. He entered the University of Minnesota as a freshman in 1885, and received the degree of Bachelor of Science in 1889. From 1889 to 1898 he was professor of the natural sciences in the State Normal School, Moorhead, Minn. He spent the summer of 1894 in the Summer School of Harvard University, that of 1895 as a graduate student in geology at the University of Chicago, that of 1896 as instructor in geology in the Summer School of the University of Minnesota. During the autumn and winter quarters of the year

1897-98 he was fellow in geology at the University of Chicago, being absent on leave from his professorship. During the four summers, 1897, '98, '99 and 1900, he was instructor in physiography and meteorology at the University of Chicago. In the year 1898-99 he spent the autumn, winter and spring quarters as a graduate student of geology and economics at the University of Chicago. In 1899 he was appointed to the professorship of the physical sciences and geography in the Eastern Illinois State Normal School, Charleston, Ill., which position he still holds, having been absent on leave during the past academic year.

He entered the Department of Philosophy of the University of Pennsylvania October 1, 1900, and remained in residence until April 5, 1901. On March 8, 1901, the Executive Committee decided to consider this period of residence as satisfying the rule requiring one year of residence. Mr. Goode elected his major in economics, his minors in geology and sociology. He completed in the University of Chicago fifteen standard courses in geology, two in mineralogy, and eight in economics. In this University he has completed in economics nine standard courses, making a total of thirty-four. He has satisfactorily passed written examinations on November 16, 1900, in physiography with Assistant Professor Brown; on March 30 and April 4, 1901, in economics with Professor Patten and Assistant Professor Seager; on March 23, 1901, in economic geology with Assistant Professor Brown, and on April 1 and 3, 1901, in sociology with Assistant Professor Lindsay. He has presented a thesis entitled 'The Influence of Physiographic Factors upon the Occupations and the Economic Development of the United States.' He has deposited with the Dean a letter from Mr. E. M. Lehnerts, guaranteeing the publication of the thesis in the *Bulletin of the American Bureau of Geography*. The scope of the thesis may be briefly described as follows:

1. A study of the geographic location of the United States, showing its relation to other lands and the effects that this position has on its climate.
2. A sketch of the geographical development of North America, and its effects on the distribution of mineral wealth, drainage and the formation of soils.
3. A detailed study of the physiographic provinces of the United States, showing how the relief of the land facilitates or obstructs settlement and trade. With this is given a classification of harbors and many illustrations of how they are formed and improved or destroyed.
4. A study of climate, of ocean currents and of the distribution of the rainfall.
5. The influence of forests on man; his debt to

wood as a material in the constructive arts. Future possibilities of forests when coal is gone.

6. A study of the common cereals and the conditions of soils and climate demanded by each species.

Mr. Goode is unanimously recommended to the Faculty of Philosophy by Group Committee X. for the degree of Doctor of Philosophy.

Professor Conklin, President.

John Raymond Murlin was born in Anglaize County, Ohio, April 30, 1874. He received his early education in the public schools of Mercer County, Ohio, at the Ohio Normal University, and in the Preparatory Department of Ohio Wesleyan University. He entered the Ohio Wesleyan University as a freshman in March, 1894, and received the degree of Bachelor of Science in June, 1897. During his senior year he was instructor in physiology and histology, and the following year was instructor in physiology and zoology in the same institution. He entered the Department of Philosophy of this University, September 24, 1898, electing his major and one minor in zoology, and one minor in botany. In 1899 he was granted a Harrison Fellowship at Large in zoology, this appointment carrying with it candidacy for the degree of Doctor of Philosophy. He was reappointed to the same Fellowship for the current year.

He has completed in this University twenty and one-fourth standard courses, and has in addition devoted practically his entire time for three years to laboratory work, the summers of these years being spent in the Marine Biological Laboratory at Wood's Holl, Mass. The laboratory work which Mr. Murlin has done would probably be equivalent to sixty standard courses. He has satisfactorily passed written examinations in zoology on May 28 and June 2, 1900, with Professor Conklin and Dr. Moore; on May 28 and 29, 1901, with Professor Conklin and Assistant Professor Montgomery, and in botany on May 30, 1900, with Professor Macfarlane.

Mr. Murlin has presented a thesis entitled, 'The Digestive System of the Land Isopods, with special reference to the Morphology of Absorption and Secretion,' and has deposited with the Dean a copy of it, together with the money necessary to print it. Its scope may be outlined as follows:

Structural and functional changes in the intestine of two common genera of land Isopods have been followed during (1) growth; (2) the process of shedding the chitinous lining; and (3) the stages of food absorption. The intestine might be described as a cylindrical conduit, the wall made up of a single layer of cubical elements of the same size, and lined with a homogeneous but porous intima. These elements, the cells, are very large, being visible in adult

specimens even to the naked eye. The minute structure of both cell-body and nucleus is seen with high powers of the microscope to be alveolar, *i. e.*, the protoplasm is composed of very small semi-fluid vesicles, between which is a homogeneous interalveolar substance and supporting fibers, running from the inner to the outer side of the cells. During growth of the animal the intestine increases in size both by multiplication (direct cell-division) and by enlargement of the cells. When the lining (chitin) is shed, the fibers on the side of the cells next the lumen disappear, and in their place is seen a fluid substance, by the hardening of which the new lining is laid down.

In the digestion of proteids, as is well known, several stages intervene between the insoluble condition in which the food enters the stomach, and the readily soluble condition which it must reach before it can be assimilated. Hitherto the food has been traced to the absorbing cells, and has been identified in different form in the blood of many animals after having traversed the cells. The purpose of this study was to follow the food *through* the cells. Albumose, the first soluble stage in the digestion of albuminous foods, is recognized in the cells eight hours after feeding. The food in this form traverses the interalveolar spaces, and may accumulate in the outer side of the cell from sixteen hours after feeding, onward. The course of the food through the wall of the intestine is not visibly influenced by the cell-structure except in a purely mechanical manner. Albumose is not found in the blood of the animal, which bathes the outer side of the intestinal wall; the inverse change back to albumen must therefore be effected before the food reaches the circulation. A finely granular substance comes from the nucleus and is associated with albumose in its passage through the cell; it probably acts on the albumose either to carry the digestive process farther, or to begin the inverse process (synthesis toward albumen), or both.

Carbohydrates are readily digested in the intestine, dextrose, the soluble form of starch, being found twenty-four hours after feeding. In the absorption of fats the indications are that splitting-up by ferment action into fatty acid and glycerine takes place in the lumen of the intestine, and synthesis by ferment action takes place within the cell.

The digestive secretion is first recognized in immature cells of the 'liver' in the form of (zymogen) granules. During the growth of these cells the granules increase in size, become looser in structure, more soluble in certain reagents, and more stainable. The secretion is set free into the lumen of the gland in the form of a proteid fluid by mere evacuation of the cells, or by fragmentation and dissolution of their luminal ends. Discharging cells are found from

twelve to ninety hours after feeding with proteids. The secretion is poured into the intestine, where it acts by means of its ferments on the three classes of foods: proteids, carbohydrates and fats.

Mr. Murlin is unanimously recommended by Group Committee XV. as a candidate for the degree of Doctor of Philosophy.

Professor Crawley, Presentor.

Roxana Hayward Vivian was born at Hyde Park, Mass., December 9, 1871. She received her early education in the public schools of Hyde Park, graduating from the High School in 1890. She entered the freshman class of Wellesley College the same year, receiving the degree of Bachelor of Arts in 1894. From 1895 to 1898 she taught Greek and mathematics in a preparatory school, and from 1896 to 1898 pursued graduate work in the same subjects at Wellesley college. She entered the Department of Philosophy of this University October 10, 1898, as alumnae fellow in mathematics. This appointment carried with it candidacy for the degree of Doctor of Philosophy. She was twice reappointed to her fellowship, holding it for three successive years. She elected her major and one minor in mathematics, and the other minor in astronomy. She has completed thirty standard courses, and has satisfactorily passed written examinations in astronomy with Professor Doolittle and Mr. Eric Doolittle, February 14, 1901; in mathematics with Professor Crawley, Assistant Professors Fisher and Schwatt and Dr. Hallett, on April 4 and 13, and May 11, 1901. She has presented a thesis entitled 'The Poles of a Right Line with Respect to a Curve of Order n .' The thesis will be printed at once. Pending its appearance Miss Vivian has deposited with the Dean a copy of the manuscript and the money necessary to print it. The scope of the thesis may briefly be outlined as follows:

The general subject of poles and polars with respect to Higher Plane Curves has been studied by numerous mathematicians, notably by Steiner, Cremona and Clebsch. Steiner gave in *Crelle's Journal*, Vol. XLVII., a large number of theorems relating to this subject, but he omitted the proofs. They were all proved subsequently by Cremona. Cremona's method was peculiar to himself, that is, he adapted a somewhat more general theory, that of the loci of harmonic means, to the theory of poles and polars. In discussing these problems Miss Vivian uses the analytic method. The particular line of discussion which she has taken up is one which has not been treated in any detail by any former writer. She has handled the subject ably, and has arrived at some very interesting results. In one or two instances her results show that the statements of former writers must be

taken with certain limitations, which do not appear to have been considered. Her principal object is to establish the ways in which the poles of a line are limited when the line has certain prescribed relations to the fundamental curve of the n th order, and to its allied curves, the Hessian and Steinerian. Under particular conditions certain points in the plane will be poles for all lines in the plane, while the other poles, called by the candidate 'free poles,' vary with the line. Many writers do not class the first as poles at all, but it seems more reasonable to class them with the other poles, since they have all the required properties of such points; and, besides, it is more in keeping with the present tendency of thought on these subjects to do so. The subdivisions of the paper are as follows:

1. The pencil of curves of which the poles are base points.
2. The related curves.
3. Poles when the curve $u-o$ has no singularities.
4. The inflection locus.
5. Poles when the curve $u-o$ has double points and cusps.
6. Intersections of higher order with the Steinerian.
7. $u-o$ with triple points and higher multiple points.

Miss Vivian was unanimously recommended to the Faculty of Philosophy by Group Committee XI. for the degree of Doctor of Philosophy.

SCIENTIFIC NOTES AND NEWS.

WE publish in this issue of SCIENCE the admirable presidential address given before the American Association, at Denver, on Tuesday, by Professor Woodward, and the vice-presidential address given by Professor Davenport before the Zoological Section, which is also a model of what such an address should be. We hope to publish next week an account of the meeting and one or two further addresses by the vice-presidents.

PROFESSOR THEODORE WM. RICHARDS, of Harvard University, has been invited to fill the newly established professorship of inorganic chemistry in the University at Göttingen. The position is entirely free from routine teaching, being confined to research work with the assistance of such advanced students as may be selected. It will be remembered that Professor J. H. van't Hoff was called from Holland to fill a similar position at the University of Berlin. The fact that Germany should invite two for-

eigners to such important positions demonstrates the broad-mindedness and freedom from prejudice which in part accounts for the high positions that its universities maintain. The creation of chairs devoted to research is also a forward movement in Germany, which it will be necessary for this country to follow. It is certainly a great compliment to the United States that Germany should seek here a professor for such a chair, more especially when we remember the very great number of chemists that are being trained in Germany. We are glad to learn that the president and fellows of Harvard College have taken action leading Professor Richards to remain in this country.

THE Veitch silver medal has been awarded to Mr. Thomas Meehan, of Philadelphia, 'for distinguished services in botany and horticulture.' Mr. Meehan is the third American on whom this medal has been conferred, the others being Professor Charles S. Sargent, of the Arnold Arboretum, and Professor Liberty H. Bailey, of Cornell University.

PRESIDENT LOUBET of France has conferred upon President W. R. Harper, of the University of Chicago, the decoration of the Legion of Honor.

MR. MARSHALL H. SAVILLE had been named Officier d'Académie by the French Government in recognition of his archeological researches in Mexico for the American Museum.

ON the recommendation of the Council of the Royal College of Physicians, England, it has been unanimously resolved "that the Baly Medal be awarded to Frederick William Pavy, M.D., F.R.S., F.R.C.P., for his researches on 'The Physiology of the Carbohydrates; their Application as Food, and Relation to Diabetes,' 1894; but more especially for his original investigations on sugar formation in the liver, which he has carried on during the last forty years, and with unabated enthusiasm during the last two years."

* DR. VINCENT CZERNY, the eminent professor of surgery at the University at Heidelberg, is on his way to the United States, in order to visit our medical schools.

WE noted recently that a monument to Chevreul had been unveiled in the Court of the

Museum of Natural History, Paris. We learn from French exchanges that addresses were made on the occasion by M. Edmond Perrier, director of the Museum, by M. Armand Gautier, representing the Academy of Sciences and the Academy of Medicine, by M. Arnaud, who in 1890 succeeded Chevreul in the chair of organic chemistry at the Museum, by M. David, director of the chemical laboratory of the Gobelin's Manufactory, and by M. Puglier-Conti, vice-president of the Paris municipal council. The marble statue is by M. Fagel, and is erected on a pedestal bearing the inscription:

CHEVREUL

MICHEL-EUGÈNE

NÉ A ANGERS LE 31 AOUT 1786

MORT A PARIS LE 7 AVRIL 1889

PROFESSEUR DE CHIMIE ORGANIQUE

1830-1889

DIRECTEUR DU MUSÉUM D'HISTOIRE NATURELLE

1863-1884

IT is proposed to erect a statue of Pasteur at Marnes, near Saint Cloud, where Pasteur spent the last years of his life. M. Duparquet, mayor of Marnes, is chairman of the executive committee.

DR. HENRY BENNER, professor of mathematics at Albion College, was drowned on August 14, in Lake Orion.

The death is announced of Dr. Domenico Stefanini, professor of bacteriology at the University of Pavia, at the age of eighty years; and of General Venukoff, a Russian geographer and geodesist living at Paris, at the age of seventy-one years.

THE Vienna Academy of Sciences announces that the prize founded by Freiherr von Baumgartner, will be awarded at the end of 1903 for a research enlarging our knowledge of the invisible radiations. The value of the prize is 2,000 crowns.

AT the meeting of the International Congress of Botanists which opened at Geneva, on August 7, it was voted to establish a Société Internationale de Botanique, and a series of laws was formulated which will be sent in print to botanists interested. It was decided to purchase the *Botanisches Centralblatt*, includ-

ing all back numbers, index and *Beihefte*, of the present publishers, Gebrueder Gotthelft, of Cassel. The journal is to be registered and a limited company formed in Holland. Shares will be sold to cover the purchase. Beginning with January, 1902, it will be published by E. J. Brill, of Leyden, with Dr. Uhlworm as editor and Dr. Kohl as assistant. Annual subscribers are to have equal rights with the stockholders in conducting the business. The Société elected Professor Karl Goebel of Munich, president, Professor F. O. Bower, of Glasgow, vice-president and Dr. J. P. Lotsy, Tjébodas, Java, secretary. The next meeting is to be held in Vienna, three years hence. Switzerland and France were most largely represented among the delegates present. The United States were represented by Professor J. C. Arthur, Dr. D. S. Johnson, Dr. F. E. Lloyd, Mr. W. Murrill and Dr. H. von Schrenk as delegates. The delegates were very hospitably received in Geneva, and a banquet was given in their honor. After the meeting some of the delegates, under the direction of Professor Chodat, of Geneva, made an excursion among the Swiss Alps.

ACCORDING to a cablegram to the daily papers the most important question of the meeting of the Zoological Congress came up on August 14, in the Committee on Nomenclature. Two propositions were presented. The French delegation proposed to make the existing nomenclature conform with the classic Latin, grammatically and etymologically. The American delegates proposed to make no changes, except in the case of obvious typographical errors. The Germans made a compromise proposition, which did not find favor. After a warm discussion the French proposition was accepted, the Swiss delegates giving the deciding vote for the proposal. The Dutch delegates and part of the German delegation voted with the Americans. The British delegates voted with France.

THE French Surgical Congress will hold its fourteenth annual meeting in Paris on October 21 and following days.

WE learn from the *British Medical Journal* that an Egyptian Medical Congress is to be held under the patronage of the Khedive at

Cairo from December 10 to 14, 1902, under the presidency of Dr. Abbate Pacha. The honorary presidents are Dr. Ibrahim Pacha Hassan, Dr. Pinching, and Dr. Ruffer. The general secretary is Dr. Voronoff. The work of the Congress will be divided among three sections, as follows: (1) Medical Sciences, presided over by Dr. Comanos Pacha; (2) Surgical Sciences, presided over by Dr. H. Milton; and (3) Ophthalmology, presided over by Dr. Mohammed Bey Eloui. The program of the Congress will include discussions on affections especially rife in Egypt, such as bilharzia, ankylostomiasis, bilious fever, abscess of the liver, etc. Special attention will be given to questions relative to the epidemics which for some years past have regularly visited Egypt, and the prophylactic measures to be taken against them. The following papers among others have been promised: 'Alcoholism and its Increase in Egypt,' by Dr. de Becker; 'The Frequency of Hydrocele in Egypt and its Treatment,' by Dr. Colloridi; 'Myxœdema in Egypt,' by Dr. Brossard; 'Plague,' by Dr. Gotschlich; and 'Tuberculosis in Egypt,' by Drs. Ibrahim Pacha Hassan, Eid. and Sandwith.

THE twelfth annual general meeting of the Institution of Mining Engineers will be held at Glasgow on September 3-6, under the presidency of Sir W. T. Lewis, Bart.

FOLLOWING the Congress on Petroleum, held in Paris in 1900, a second congress will be held in Paris in 1902. A permanent committee has been formed in Paris under the presidency of M. Ed. Lippmann, the secretary of the congress, and M. Dvorkovitz has recently established in London an institute for the scientific study of petroleum.

A MEETING of the Board of Visitors of the National Bureau of Standards was called in Washington, for August 23d, for the purpose of passing on proposed sites for the laboratory of the bureau. It will be remembered that the five members of the Board of Visitors were appointed by Secretary Gage, and are as follows: Dr. H. S. Pritchett, president of the Massachusetts School of Technology; Dr. Ira Remsen, president of the Johns Hopkins University; Dr.

Elihu Thomson ; Professor Edward L. Nichols, of Cornell University, and Albert L. Colby, of Pennsylvania.

ACCORDING to *Nature* the Paris correspondent of the *Chemist and Druggist* states that with a view to giving an impetus to the study of applied chemistry in Paris, it has been decided to build additional laboratories at the Conservatoire des Arts et Métiers. The initial expense is estimated at 500,000f. (20,000*l.*), and the annual upkeep at something over 3,000*l.* The laboratories will also be used for experiments in physics and mechanics.

THE German Government has sent an expedition to German East Africa for the purpose of organizing a systematic effort for the prevention of malaria. The expedition is under the command of Dr. Ollwig, Staff-Surgeon *à la suite* serving with the Imperial forces in East Africa.

A NORTH German Lloyd steamer has been chartered to leave Sydney, N. S. W., on October 11 for Kerguelen Land, conveying provisions and dogs for the German Antarctic expedition on board the steamer *Gauss*.

THE book on 'Mosquitoes' by Dr. L. O. Howard, recently reviewed in this journal by Professor Packard, is being translated into Spanish.

THE Station of the U. S. Fish Commission on the Great Lakes, with headquarters at present at Put-in-Bay, Ohio, is collecting the literature of fresh-water fauna and flora, and Professor H. S. Jennings, who has charge of the Station, will be glad to receive from authors and others publications in these subjects.

M. MAREY, the president of the International Committee on Physiological Instruments, will be glad to have sent to him at Boulevard Delesert, No. II., Paris, new physiological apparatus for presentation at the International Congress of Physiology to be held at Turin next month.

FOR the last week for which the report is at hand, the deaths from the plague in India numbered 1,125. At the same period last year there were only 200 deaths.

WE learn from *Nature* that the annual awards of prizes by the Reale Accademia dei Lincei, of Rome, are as follows: The Royal prize for chemistry has been adjudged to the late Pro-

fessor Amerigo Andreocci for his researches on heterocyclic compounds and on the santonine group, and other papers. The Royal prize for philosophy and moral science has been adjudged to the late Professor Carlo Giussani. In political science and jurisprudence no award has been made, and the same is true of the Santoro prize relating to agricultural zoology. The two prizes instituted by the Minister of Public Instruction in favor of teachers in secondary schools for work in natural science have been divided, awards being given to Professors Liberto Fantappiè (Viterbo), Antonio Neviani (Rome), De Toni (Venice), and Giacomo Trabucco (Florence). Two 'Ministerial' prizes of a similar character for philosophical and social sciences are awarded to Professors Luigi Einaudi (Turin) and Aurelio Covotti (Palermo).

THE annual meeting of the Fellows of the Royal Botanic Society, according to the report in the *London Times*, was held on August 10, in the museum in the society's gardens at Regent's Park. Mr. C. Brinsley Marlay presided. The Duke of Teck was elected president, Mr. G. J. Marjoribanks treasurer, and the Marquis of Breadalbane, Earl Howe, the Earl of Aberdeen, Sir Henry Oakley, Sir J. Blundell Maple, M.P., Mr. J. Fletcher, Dr. R. C. A. Prior and Mr. W. Sowerby were re-elected members of the council. The 62d annual report stated that the negotiations with the Department of Woods and Forests had been concluded and a new lease of the gardens had been granted for 31 years. The accounts showed that the year's working had resulted in a profit of £285, being nearly double that of the previous year. The number of fellows on the books was 2,124, which showed a steady increase in number, 88 new fellows having joined the society during the year. The garden's club continued to form one of the attractions of the society, 41 fellows of the society having joined the club during the year; and the past season had been a very successful one. The chairman, in moving the adoption of the report, said that the prospects of the society were decidedly better than they had been for some years past. Their lease had been renewed and a large number of their debentures—viz., £5,700—had been taken up. The so-

ciety was in a transition state. Mr. Austen Chamberlain, as representing the Treasury, had insisted that the society should open its gates to the public a certain number of days in the year; in fact the public had rights there which had to be recognized. Therefore the old character of the gardens had almost completely disappeared. The Society still retained its scientific character, however, and whatever facilities they could give to promote science, particularly botany, they would give. They had been unable to obtain a grant from the Government, and the scientific part of the gardens was, therefore, carried on with great difficulty. The subscriptions of the fellows were not sufficient to keep up the gardens as they should be kept up, and the council had to rely, therefore, in some measure upon the entertainments. Towards the end of the meeting the chairman called attention to the skill and beauty of a large number of Japanese drawings of flowers and birds, of which he had a very fine collection.

AT the last meeting of the Berlin Medical Society, held on July 25, Professor Virchow is reported by the *Lancet* to have alluded to the recently-enunciated views of Professor Koch as to the non-identity of tuberculosis in cattle with that affecting the human subject. In his sarcastic style he remarked that he was happy to find that Professor Koch's views had undergone a change and were now in accordance with his own, for he had maintained that the mere presence of the Koch bacillus was not the essential thing in tuberculosis; a tubercle was, in his opinion, a growth with a distinct anatomical structure, and he had always protested against the bacteriologists terming anything a tubercle simply because a Koch bacillus happened to be present. He said that the adherents to Koch's theory had believed his view to be rather old-fashioned, but it did not annoy him to recall to mind that he had sometimes been superciliously treated by the younger bacteriologists. Professor Virchow's ironical words produced a great impression on the meeting.

ACCORDING to the *Comptes Rendus*, as translated in the *Scientific American*, H. Becquere!

has confirmed, by an unpleasant experience, the fact first noted by Walkoff and Giesel, that the rays of radium have an energetic and peculiar action on the skin. Having carried in his waistcoat pocket for several periods, equal in all to about six hours, a cardboard box enclosing a small sealed tube containing a few decigrammes of intensely active radiferous barium chloride, in ten days' time a red mark corresponding to this tube was apparent on the skin; inflammation followed, the skin peeled off and left a suppurating sore, which did not heal for a month. A second burn subsequently appeared in a place corresponding to the opposite corner of the pocket where the tube had been carried on another occasion. P. Curie has had the same experience after exposing his arm for a longer period to a less active specimen. The reddening of the skin at first apparent gradually assumed the character of a burn; after desquamation a persistent suppurating sore was left which was not healed fifty-six days after the exposure. In addition to these severe 'burns' the experimenters find that their hands, exposed to the rays in the course of their investigations, have a tendency to desquamate; the tips of the fingers which have held tubes or capsules containing very active radiferous material often become hard and painful; in one case the inflammation lasted for fifteen days and ended by the loss of the skin; and the painful sensation has not yet disappeared, after the lapse of two months.

ACCORDING to a notice in *Nature*, the annual report of the Russian Geographical Society for 1900 notes the growing activity of the young branches of the society at Vladivostok, Kiakhta, Tomsk and Orenburg—their work being not limited to pure geography, but being mainly directed to the exploration of the geology, botany, zoology and prehistoric anthropology of the respective regions. A new local museum has consequently been opened at Troitskosavsk, near Kiakhta, in addition to those of Minusinsk and Yeniseisk. The chief medal of the Geographical Society, the Constantine medal, was awarded this year to V. Obrucheff, the explorer of the Nan-shan and Mongolia, who has also explored very large portions of Transbaikalia and the Pacific littoral, and whose preliminary

reports are always of the deepest interest for both the geologist and the orographer. The Count Lütke medal was awarded to M. E. Zhdanko for his extensive geodetical and hydrographical works in the far North, the Semenov medal to J. A. Kersnovsky for work in meteorology, and the Prjevalski medal to the Tomsk professor, V. V. Sapozhnikoff, whose explorations of the Altai highlands revealed hundreds of unknown glaciers, as well as widely-spread traces of glaciation, and threw much new light on the geography of the whole region. These researches are now embodied in a work, 'The Katufi and its Sources' (with maps and a summary in French).

THE Society of Chemical Industry held its annual meeting at Glasgow at the end of July. The secretary reported that the society was in the most prosperous condition, there being now 3,632 members. The president, Mr. J. Wilson Swan, chose as the subject of his address 'Electro-chemical Industry.' According to the abstract in the *London Times* he traced the progress of this branch of applied science from the early laboratory researches of Davy and Faraday down to the position it occupied at the present time. He gave particulars of the power at present utilized and products made in the 150 works using electricity for chemical and metallurgical purposes in Europe, and described the methods employed in the several branches of manufacture. In several instances the new methods of manufacture had already supplanted the old, while in others there was keen competition between the chemical and the electrolytic processes. Turning to the future, Mr. Swan pointed out that the united kingdom was severely handicapped as regards these new developments by her lack of water-power. In spite of this, however, many of the new electro-chemical industries could be carried on profitably with steam-power. The utilization of the waste gases of blast furnaces in large gas-engines for the generation of electrical energy would also become a realized fact, and would supply large quantities of cheap power for the industries under discussion. While, therefore, admitting that the position of the staple chemical and allied industries in England had been undermined to some extent by the rapid

growth of electro-chemical industries abroad, and that protective tariffs were being employed to shut out British products, Mr. Swan believed the future might be faced with some degree of confidence and hope. Speaking in one of the lecture theaters of a great university, whose long and splendid services to education has lately been commemorated, he could not but congratulate Scotland and the Scottish section of the society on the very advantageous position it occupied in that respect. In England and Ireland they were suffering acutely from dire educational neglect and destitution. They were giving to the classes at the bottom of the industrial ladder a disjointed smattering of miscellaneous science of no great value, though probably good so far as it went, while they were neglecting to thoroughly educate those upon whose shoulders would soon rest the weight of the management of the great manufacturing industries. A scientific training of university standard for our manufacturers and for our technical chiefs was an absolute necessity. One of the most pressing requirements of the moment, demanded not only in the interest of chemical industry, but in that of the manufacturing industries generally, was the adequate endowment and encouragement of research. The advances in knowledge, and the consequent revolutionary changes that had taken place in almost every branch of chemical industry during the last 100 years were probably not greater than those further changes that would be seen at the end of the present century, for change brought about by scientific discovery grew ever swifter and more sweeping. Change was the natural order of things; but, to take advantage of it, the fullest measure of assistance was demanded that education and energy could give.

MR. W. H. MAW recently delivered his presidential address before the members of the British Institution of Mechanical Engineers. Dealing with the question of the education of young mechanical engineers, he said, according to the *London Times*, that nothing was more disheartening to a student than to find at some stage in his career that he had been devoting time to learning things which were not only useless to him, but which it was desirable he

should unlearn, while, on the other hand, he had failed to acquire knowledge of which he stood badly in need. Yet this was a far too frequent experience with boys entering technical colleges from the public schools. The remedial changes which had so far been made in this direction were limited in extent compared with those really required, and there was still left to be done at the technical college much educational work which ought to have been done at school, the result being a waste of valuable time. The matter was one which merited the most careful attention of all interested in technical education. There came a time when every engineer must specialize if he really wanted to attain anything more than a subordinate position. This specialization should be at least commenced during the college career rather than subsequently, the student devoting the latter part of his course at college to the acquirement of a knowledge of the special principles which underlay practice in the particular branch of the profession to which he was about to devote himself. This meant that the college authorities must take a wider view of their responsibilities than many of them did at present. It would also probably mean in the future that certain colleges would acquire a reputation for certain branches of work. One of the chief aims of technical college training should be to develop independent thought and action in a student. It could not be too thoroughly appreciated that the vast development of mechanical engineering work which had been going on in the past half-century, and which was still going on at an ever-increasing rate, was producing a most important change in the conditions which secured both professional and commercial success. In the old days the leading firms of mechanical engineers had comparatively few customers, and they had, as a rule, to meet the great variety of requirements of those customers to the best of their ability. Repetition work was comparatively rare, and success depended largely on resourcefulness and the power of entering thoroughly into the conditions to be fulfilled. Nowadays the successful mechanical engineer was not he who made a great variety of things for the few, but a small variety of things for the many, at the same time pro-

ducing those few things in the most perfect way. Experience showed clearly that mere lowness of price was not in itself an inducement to purchasers, and the maker of an engine of exceptional economy or of a machine too, which excelled its competitors in the quantity or quality of the work it turned out would never find difficulty in obtaining proportionately good prices for his productions.

UNIVERSITY AND EDUCATIONAL NEWS.

BEREA COLLEGE, Ky., receives \$50,000 by the will of Stephen Ballard, of Brooklyn.

THE Department of Agriculture has received a communication from the University of California announcing that a dairy school is to be established at that institution and requesting that a butter and cheese expert of the department be permitted to go to California to assist in establishing the school. Mr. W. E. Griffith, one of the experts of the department, will be assigned to this work August 20.

PRESIDENT JAMES WHITFORD BASHFORD, of Ohio Wesleyan University, has been offered the presidency of Northwestern University.

DR. T. D. WOOD, professor of hygiene and organic training at Stanford University, has accepted a similar position at Teachers College, Columbia University.

ELLIOT R. DOWNING, Ph.D. (Chicago), who has been during the summer assistant in zoology at Chicago University, will in the autumn take charge of the biological department at the Northern State Normal School at Marquette, Mich.

DR. CHARLES F. HOTTES has been appointed instructor in botany in the University of Illinois. Mr. Hottes was formerly assistant in the botanical laboratory of the University, but has spent the last three years at the University at Bonn, studying plant physiology and cytology. Mr. H. Hasselbring, of the New York Agricultural Experiment Station at Geneva, has been appointed assistant in the Agricultural Experiment Station of the same University.

DR. FLORENCE M. LYON, of Smith College, has been appointed associate in botany in the University of Chicago and dean of Beecher Hall.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE Denver meeting was notable in several particulars. It was feared that a meeting so far west would be poorly attended, but the registration reached 311, being larger than that of the second Detroit and Madison meetings, and nearly as large as that of the Columbus and fourth Buffalo meetings. The number of representative men of science was proportionally very large, so that the sectional meetings were well attended and were as full of interest as at larger meetings of the Association, more than 200 papers having been presented. In the registration Colorado led with 79 members, while the number of members residing west of the Mississippi reached 162.

The attitude of the citizens of Denver and of Colorado, as indicated by the press and by arrangements for the convenience and entertainment of members, was most happy. This is well indicated by the following extract from an editorial which appeared in the *Denver Post* of August 30 :

It is believed that the visit of the scientists has been one of pleasure, as well as profit, and that if the people of Denver have taken a thorough satisfaction in their presence, they, on the other hand, have found equal satisfaction in their sojourn here. The public is too apt to think that because men devote their lives to the pursuit of scientific inquiries they are apt to be dry, self-absorbed and technical. To such as these actual contact with the members showed them to be surprisingly genial, kindly and sympathetic, while in many of them was found a fine flow of humor flavored with a wit which was none the less attractive because it carried with it no sting. In the nature of things it will be some years before Denver may again hope to entertain them as a body, but every one concerned will feel for them a regard amounting to affection, and when their next session is held here they will get a reception such as no other city could accord them.

The Denver meeting was also notable for several important changes in policy, either adopted or presented for future action. Perhaps the most radical measure under discussion was that which contemplates a change in the time of the annual meetings. The summer meeting has become so fixed a part of the annual program of many members that a change to midwinter will call for considerable readjustment. The movement for a general convocation week following the holiday week has commended itself so generally to universities, however, that the Association has concluded that the experiment deserves a trial. Accordingly, the general committee of the Denver meeting has suggested to its successor at Pittsburg that the annual meeting of 1903 be held in Washington during the week in which January 1 falls. This action simply suggests the experiment of a winter meeting, without any recommendation as to the discontinuance of summer meetings. It may

be that the Association will conclude to hold two meetings a year, which could well be of somewhat different character.

An important amendment, which was adopted, provides for representation in the council from the affiliated societies. By this action, each affiliated society is entitled to elect one member, who is a fellow of the Association, as its representative in the council; and if the society contains more than twenty-five members who are fellows of the Association, it is entitled to two representatives in the council. It seems certain that this representation in the ruling body of the Association will lead to a more compact and efficient organization of the scientific interests of the country.

Another amendment was adopted, which provides that the council shall have power to change either the time or place of meeting. Heretofore, after the adjournment of the general committee, there has been no authority to make such changes upon any contingency. It is understood that this power will be exercised only in such extreme cases that the action will commend itself to all members. For example, the time set for the Denver meeting narrowly escaped a conflict with a national meeting of such magnitude that the Association could not have been accommodated.

Three amendments were presented to be acted upon at the Pittsburg meeting, which look to much greater efficiency in the conduct of the affairs of the Association. One provides for the election by the council each year of three councillors at large, who shall serve for a term of three years. This will add to the council nine members

who have been chosen for their experience and interest in the Association, and who will give greater permanence and efficiency to this very important body.

With the idea of increasing the efficiency of sectional organizations, another amendment proposes that secretaries of sections be elected for a term of five years. Under the present method a secretary serves only long enough to learn his duties. This makes it impossible to obtain that continuity of experienced service which is necessary to develop the interests of the sections. There is no reason why such service is not as essential to a section as it is to the Association in the person of the permanent secretary. The same desire to increase the efficiency of the sectional organizations also prompted the proposed amendment providing that each section shall elect, annually, one fellow as a member of the sectional committee and that he shall serve five years.

Several reports of committees seem to call for comment. The committee on the policy of the Association made three recommendations which were adopted. One was that Section D (Mechanical Science and Engineering) be not discontinued, as had been suggested, since the recent entrance of a large body of engineers into the Association gives promise of a strong section. A second was the organization of the new Section (K) of Physiology and Experimental Medicine, which promises to be one of the strongest sections of the Association. A third was that all abstracts be restricted to 400 words, that they be published in *SCIENCE* and that the titles only shall appear in the published volumes of the *Proceedings*.

The report of the committee on the relationship of the Association and *SCIENCE* was full of interest, since it involved the first official statement of the results of this relationship. It was reported that the fees of new members have paid the expense of sending *SCIENCE* to all members. In this connection it may be well to state that according to the contract with The Macmillan Company the Association pays two dollars a year for each member to whom *SCIENCE* is mailed. These publishers certainly deserve honorable mention for their interest in promoting this movement, for it is estimated that *SCIENCE* will not be in the same financial condition as before the arrangement until the Association contains 4,000 members. There seems to be no question in the minds of members that the relationship with *SCIENCE* has been of very great advantage to the Association.

This leads to a mention of the noteworthy increase in the number of members during the last year, an increase which bears the strongest testimony to the efficiency of the permanent secretary and his immediate associates. For a few years the published lists of members showed a gradual decrease in number, until at the beginning of the last New York meeting there were 1,721 actual members. At the close of the Denver meeting, about a year later, the number of members is approximately 2,800, over 1,150 members having joined within the last year. Such a record is remarkable, but its chief importance lies in the fact that it shows what can be done with proper effort. Conservative members are now putting the number to be expected at 5,000,

while a prominent officer at the Denver meeting thought it should be 10,000. However this may be, the work of the past year has demonstrated clearly that an effort to increase membership, when wisely directed and persistently followed up, is sure to be successful.

The financial side of the Association is also becoming impressive. The report of the permanent secretary for 1900, which does not include the still larger income accruing thus far during 1901, shows receipts amounting to \$12,321.60. Of this amount the sum of \$1,300 was paid over to the treasurer for endowment, and a balance of \$4,741.60 carried over to the next year. To meet the numerous expenses of so large an organization, and also to set aside more than \$1,000 towards the permanent endowment for grants is an achievement for which the administration of the Association is to be congratulated. The same outcome will appear in the next report, for the Council has already set aside \$1,000 from the receipts of 1901 for the permanent fund.

In regard to this permanent fund the treasurer's report showed that it now amounts to over \$11,000, having doubled in seven years. This is gratifying because the income is used for grants to special committees to aid in the prosecution of research. The reports of these committees form an interesting part of the proceedings. With an organized effort for an increase in the number of members, and with the frequent communication among members secured by the relationship with this Journal, there seems to be no reason why the Association should not include in its

membership all those who are engaged or interested in scientific work in this country and thus represent completely the organization of science in America.

The steady progress toward this end is demonstrated by the signal success of the Denver meeting. Heretofore the Association has been an organization expressing chiefly the scientific activities of the eastern states, no previous meeting having been held west of the immediate banks of the Mississippi river. Henceforth the Association is in fact as well as in name an organization expressing the scientific activities of the entire continent. This first Denver meeting, therefore, must be regarded as a noteworthy event in the history of American science.

*PROCEEDINGS OF THE FIFTIETH ANNUAL
MEETING OF THE AMERICAN ASSO-
CIATION FOR THE ADVANCE-
MENT OF SCIENCE.*

THE first general session of the Denver meeting was called to order in the auditorium of the High School Building at 10 o'clock in the morning of August 26 by the retiring president of the Association, Professor R. S. Woodward, of Columbia University, who introduced the president-elect, Professor Charles S. Minot, of Harvard University. President Minot introduced the Hon. J. B. Grant, president of the local committee, who, after some remarks welcoming the Association to Denver and to Colorado and the reading of a letter from the Governor of the State, introduced the Hon. R. R. Wright, Jr., Mayor of Denver; Mr. Charles F. Wilson, President of the Chamber of Commerce; General Irving Hale and Professor Aaron Gove, Superintendent of Schools, all of whom made addresses of welcome. To these addresses

President Minot replied in the words published below.

At the closing session the permanent secretary read the following report :

The fiftieth annual meeting of the A. A. A. S., which will be known in the future as the 'Denver Meeting,' or possibly, and let us hope, as the 'first Denver Meeting,' has been a most successful one. There have been in attendance 306 members and associates, making the meeting in this regard rank as the 22d largest meeting. What may be termed the geographic distribution of the members in attendance has been interesting. From the Atlantic Coast region there have been 92, or nearly one-third, from the Pacific Coast 11, and from foreign countries 6, leaving two-thirds from the great interior of the country.

The distribution by States has been as follows :

Colorado heads the list with	79
New York	30
District of Columbia	28
Iowa	15
Missouri	14
Massachusetts	13
Penn'a., Illinois	12 ea.
Kansas	17
California	10
Nebraska	9
Indiana	8
Wisconsin	7
Minnesota, Ohio, Connecticut, N. Mexico	5 ea.
Wyoming, Canada, Michigan	4 ea.
Texas	3
West Virginia, Montana, Arizona	2 ea.
Georgia, North Dakota, South Dakota, Oregon, Nevada, Oklahoma, New Hampshire, Tennessee, New Jersey, North Carolina, Arkansas, Louisiana, England, Ireland	1 ea.

It must be borne in mind, however, that the number registered, 306, includes only the actual members and associates of the A. A. A. S., and that the great national affiliated societies of specific aim which have met with us have drawn many more sci-

entific men and women to Denver within the past week, so that it has really been a scientific congress of much importance.

The papers which have been read before the Association proper and in joint sessions with the more closely affiliated societies have been numerous and of a high order. About 220 in all have been presented.

A number of important measures concerning the future of the Association have been considered. An amendment to the constitution providing for the representation in the Council of the affiliated societies seems one of the most important steps taken by the Association of recent years, while other amendments looking towards a more stable membership in the Council have been introduced and will be considered later.

About 50 new members have been elected during the meeting; and 186 members have been made fellows.

Denver and its vicinity have provided visiting points of great scientific interest, and the facts just stated, together with the great courtesy and warm-hearted hospitality of the citizens of Denver, have combined to make the meeting now coming to a close a memorable one in the annals of the old Association.

The members of the Council in attendance were :

Past President—R. S. Woodward, New York.

Vice-President of the Columbus Meeting—Marcus Benjamin, Washington.

Vice-Presidents of the New York Meeting—Wm. Trelease, St. Louis; Amos W. Butler, Indianapolis; Calvin M. Woodward, St. Louis.

Officers of the Denver Meeting—Charles Sedgwick Minot, Boston; James McMahon, Ithaca; D. B. Brace, Lincoln; John H. Long, Chicago; H. S. Jacoby, Ithaca; C. R. Van Hise, Madison; D. S. Jordan, Leland Stanford Jr. University; B. T. Galloway, Washington; J. Walter Fewkes, Washington; John Hyde, Washington; L. O. Howard, Washington; J. M. Coulter, Chicago; D. T. MacDougal, New York; G. A. Miller, Ithaca; John Zeleny,

Minneapolis; Wm. McPherson, Columbus; C. W. Comstock, Golden; H. B. Ward, Lincoln; Ernst Bessey, Washington; G. G. MacCurdy, New Haven; R. A. Pearson, Washington; R. S. Woodward, New York.

From the Association at Large—A fellow from each section: G. B. Halsted, Austin; E. L. Nichols, Ithaca; C. S. Palmer, Boulder; C. A. Waldo, Lafayette; T. C. Chamberlin, Chicago; F. M. Webster, Wooster; D. H. Campbell, Stanford; L. M. Underwood, New York; W. J. McGee, Washington; E. T. Peters, Washington; J. McK. Cattell, New York.

From the Affiliated Societies—American Chemical Society: F. W. Clarke, A. C. Hale. Geological Society of America: N. H. Winchell, H. L. Fairchild. Botanical Society of America: C. E. Bessey, B. D. Halsted. Society for the Promotion of Agricultural Science: W. J. Beal, Agricultural College.

The address of the retiring president was published in the last issue of this journal and the addresses of the vice-presidents and abstracts of the papers read before the sections are in course of publication. The more important business transacted by the Association was as follows:

An amendment to Article 18 of the constitution, submitted at the New York meeting in 1900, was reported at general session from the council for favorable action and adopted. The amendment is as follows:

In Art. 18, after the words 'The Treasurer of the current meeting,' omit 'with the addition,' and after the words 'by ballot on the first day of its meeting' insert 'of one fellow elected by each affiliated society and one additional fellow from each affiliated society having more than twenty-five members who are fellows of the Association.'

The following amendment to Article 20 of the Constitution was also adopted:

Add to the end of Art. 20 the words, 'But if suitable preliminary arrangements cannot be made, the council may afterward change the time and place appointed by the general committee, if such change is believed advisable by two-thirds of the members present.'

The following amendments to the constitution were read before the council and at the general session and will be acted on at the next meeting:

In Article 9, after the words 'with the exception of the Permanent Secretary' omit 'and,' and after the words 'the Treasurer' insert 'and the Secretaries of the Sections; and after the words 'The term of office of the Permanent Secretary' omit 'and,' and after the words 'the Treasurer' insert 'and of the Secretaries of the Sections.'

In Article 18, after the words 'who are fellows of the Association,' insert 'and of nine fellows elected by the Council, three being annually elected for a term of three years.'

In Article 23, after the words 'of a Section there shall be' omit 'three members or fellows' and insert 'a member or fellow,' and after the words 'Vice-President and Secretary of the preceding meeting' insert 'and the members or fellows elected by ballot at the four preceding meetings.'

Reports of standing and special committees were presented and their recommendations adopted as follows:

COMMITTEE ON THE POLICY OF THE ASSOCIATION.

The Committee on the Policy of the Association presents the following recommendations to the council in regard to certain matters which have been referred to it for consideration:

1. The Committee recommends that owing to the great increase of engineers in the membership of the Association, it would be inexpedient to consider the question of the discontinuance of Section D.

2. The Committee recommends that the proceedings of the annual meetings, including the addresses of the Vice-Presidents, the reports of committees and officers, and abstracts of all papers, be published immediately in *SCIENCE*, and further that the addresses of the Vice-Presidents, titles of all papers and reports of officers and committees, the constitution and lists of officers, members and fellows, be published by the Permanent Secretary in a volume as soon thereafter as possible. The Committee further recommends that authors wishing to make alterations in abstracts of their papers shall do so before the close of the meeting and that abstracts shall not exceed 400 words in length. It further recommends that the Secretaries of Sections shall forward these abstracts with an account of the work of the meeting to the responsible editor of *SCIENCE* within a week after the close of the meeting.

3. The Committee recommends that Section K organize at the present meeting by the formation of a Sectional Committee and that papers submitted for

this Section at this meeting be referred in accordance with their character to Sections H or F.

[Signed.] CHARLES S. MINOT.
R. S. WOODWARD.
L. O. HOWARD.

COMMITTEE ON THE RELATIONS OF THE
JOURNAL, SCIENCE, WITH THE
ASSOCIATION.*

This committee is able to report that the arrangement by which SCIENCE has this year been sent to the members of the Association has been satisfactory in every respect. It has been generally approved and has apparently strengthened the Association and the organization of science in America. The membership of the Association has greatly increased, the fees of new members sufficing to pay the entire expense of sending SCIENCE to all members of the Association. We recommend that we be authorized to renew for the year 1902 the present contract with The Macmillan Company. We also recommend that the treasurer of the Association be added to this committee.

[Signed] SIMON NEWCOMB, *Chairman*,
R. S. WOODWARD,
L. O. HOWARD,
J. MCK. CATTELL, *Secretary*.

COMMITTEE ON CONVOCATION WEEK.

The plan of setting aside the week in which New Year's Day falls as a convocation week for the meetings of scientific and learned societies has met with almost universal approval on the part both of societies and of institutions of learning. At the instance of this committee, the Association of American Universities passed unanimously a resolution recommending the establishment of a convocation week, and the thirteen universities composing the Association have with one exception either left the week entirely free from academic exercises, or will give all officers leave of absence. We have now begun correspondence with about fifty additional universities, colleges and technical schools.

In view of the favorable reception of the plan for a convocation week we recommend :

1. That this Association and its affiliated societies meet in Washington in the week in which New Year's Day of 1903 falls, without, however, committing ourselves at present to the abandonment of summer meetings.

* Mr. G. K. Gilbert, the remaining member of this committee, was absent in the field and unable to sign this report, but it is known that he concurs in its recommendations.

2. That the Council meet in Chicago during the Convocation Week of 1901-2, and that the Sectional Committees may organize meetings of their respective Sections, the expenses of each of which shall not exceed \$25, to be paid from funds in the hands of the Permanent Secretary.

3. That this Committee be continued.

[Signed] CHARLES S. MINOT,
R. S. WOODWARD,
EDW. L. NICHOLS,
L. O. HOWARD,
J. MCK. CATTELL.

NINETEENTH ANNUAL REPORT OF THE COM-
MITTEE ON INDEXING CHEMICAL
LITERATURE.

The Committee on Indexing Chemical Literature, appointed by your body in 1882, respectfully presents its Nineteenth Annual Report, embracing the fourteen months from June 1, 1900, to August 1, 1901.

WORKS PUBLISHED.

A Select Bibliography of Chemistry, 1492-1897. By HENRY CARRINGTON BOLTON. Section VIII., Academic Dissertations. City of Washington, published by the Smithsonian Institution. 1901. 8vo. Pp. vi + 534.

This forms No. 1253 of the Smithsonian Miscellaneous Collections, Vol. XLI.

This Bibliography of Academic Dissertations is a second part of the work published in 1893, and with the 'First Supplement,' issued in 1899, completes (if the term can be applied to bibliography) the undertaking begun by Dr. Bolton in 1888. The three volumes comprise about 25,000 titles. The dissertations found in the libraries of the Smithsonian Institution and of the U. S. Geological Survey are indicated by appropriate initials. There is a full subject-index.

The completed manuscript of a 'Bibliography of the Analytical Chemistry of Manganese,' by Professor Henry P. Talbot and John W. Brown, has been carefully examined by your Committee, and they have recommended it for printing to the Smithsonian Institution to which it has been presented.

WORKS IN PROGRESS.

Mr. Frank R. Fraprie reports progress on his manuscript 'Index to the Literature of Cæsium, Rubidium and Lithium,' which is to be completed within a twelve-month.

Mr. G. A. Smith, of Cornell University, reports that his 'Index to the Literature of Selenium and Tellurium' will be completed by the close of the academic year.

Dr. M. D. Sohon is preparing for the press a 'Subject-Index to the Journal of the American Chemical Society.'

Dr. H. Carrington Bolton has in preparation another 'Supplement to the Select Bibliography of Chemistry,' intended to cover the period beginning with 1897, and to include omissions.

Dr. Alfred Tuckerman has revised and prepared for the press the continuation of his 'Index to the Literature of the Spectroscope'; the MS. has been presented to the Smithsonian Institution.

NOTES.

During the last twelve months there have been published the following bibliographical works on chemical subjects:

Bibliographia Lactaria. Bibliographie générale des travaux parus sur le lait et l'allaitement jusqu'en 1899. Paris, 1900. 600 pp. 8vo.

Bulletin de la Société chimique de Paris. Tables des années 1889 à 1898, dressées par Th. Schneider. Paris, 1900. Two Parts.

Zeitschrift für physikalische Chemie, Stöchiometrie, und Verwandtschaftslehre. Namen und Sach-Register über Band I.-XXV., bearbeitet von T. Paul. Leipzig, 1900. 8vo.

And Professor A. K. Krupsky, of St. Petersburg, announces a 62-page 'Bibliography of Chemistry' in Russian, which your committee is as yet unable to describe more accurately.

Committee.

COMMITTEE ON ANTHROPOMETRIC MEASUREMENTS.

At the New York meeting of the Association physical and mental measurements were made of about forty fellows of the Association, under the auspices of this committee. The number is not sufficient to permit of the publication of the results, but some points of interest were disclosed. We are anxious to continue these measurements, but cannot do so at Denver owing to the difficulty of transporting instruments and securing skilled assistance. We hope to overcome the former difficulty in future by the construction of instruments that can be packed in a dress-suit traveling case. The sum of \$50 appropriated last year for the committee has been used in constructing instruments with this object in view, a balance and measuring rod having been made that

can be readily transported. A traveling set of instruments of this character would be of value in anthropological expeditions.

The members of the committee resident in New York have continued anthropometric work, measuring the mental and physical traits of students of Columbia and Barnard Colleges, and of children in the schools. A thesis has been accepted for the degree of doctor of philosophy in Columbia University by Mr. Clark Wissler on 'The correlation of mental and physical traits.' This thesis, which has been published as a supplement to the *Psychological Review*, is the first full treatment by quantitative methods of the interrelation of mental and physical traits. Professor E. W. Thorndike has also at Columbia University carried on experiments on the correlation of mental ability, which will shortly be published.

For the completion of the traveling set of anthropometric instruments referred to, the committee asks a further grant of fifty dollars.

[Signed] J. MCK. CATTELL,
FRANZ BOAS,
W J MCGEE.

REPORT OF THE COMMITTEE ON THE QUANTITATIVE STUDY OF VARIATION.

The grant of one hundred dollars to this Committee was used to help defray the expenses of Mr. C. C. Adams, incurred in collecting for study molluscs of the genus *Io*, found in the headwaters of the Tennessee River. A preliminary report has been made by Mr. Adams, and this was printed in the *Proceedings* of the Association for 1900. Mr. Adams submits at this time a second report covering the results of study on the material collected last summer, but prefers to postpone further publication until after his final expedition, which he is making this summer. The main results so far are that he has shown by the aid of an elaborate series of measurements that the numerous species of *Io* run into each other in a very complete way, and that the differences between the shells are associated with their position up or down stream. Nevertheless there is in most streams a more or less marked discontinuity between the smooth, globular, up-stream shells and the spiny, elongated down-stream shells. The meaning of the discontinuity (which justifies, in a way, a division of the shells into two species) is still not perfectly clear. To test certain hypotheses in respect to this discontinuity, Mr. Adams has returned to the field this summer. This piece of work is, we believe, the largest and most thoroughgoing quantitative study of the variation of a species in nature that has yet been reported upon.

The committee requests the Council to grant it one

hundred dollars additional, to aid Mr. Adams in this his final summer's work on this topic.

The Committee is glad to report an increasing interest in the quantitative study of variation, and especially the establishment by Professors Pearson and Weldon of a new journal—*Biometrika*—devoted to the results of such study.

[Signed] FRANZ BOAS, *Chairman*,
 CHARLES S. MINOT,
 J. MCK. CATTELL,
 C. H. EIGENMANN,
 C. B. DAVENPORT, *Secretary*.

REPORT OF THE COMMITTEE ON THE RELATION OF PLANTS TO CLIMATE.

The investigations conducted under the guidance of the committee have been directed toward a study of the thermal relations of vegetation; an examination of the prevailing methods of meteorological observation in obtaining thermometric data has been made, and it is found that the data so obtained are incapable of direct application in the consideration of the seasonal development and distribution of plants.

As the result of two seasons of thermographic observation in the New York Botanical Garden and in the field in Montana and Idaho, a new method of calibration of the temperature exposures of plants has been formulated. This method is based upon a proposed hour degree-unit of temperature. Such unit of temperature may be defined as consisting in a departure of one degree Centigrade above or below zero for the period of one hour. The estimation of the number of such units affecting a plant in any given locality is obtained by the measurement of the areas enclosed by the thermographic curve above and below the zero line.

The number of such units of exposure to which the plants of two localities are subjected have already been estimated, and with incidental results will be presented to this Section at an early session. Thus, for instance, a meadow carpet in the New York Botanical Garden received 78,836 hour-degrees of heat during the year ending April 1, 1901, while the carpet in an adjacent hemlock forest received 68,596 hour-degrees of heat during the same period.

It is believed that the method of procedure outlined above will afford an exact method of dealing with the relation of plants to the temperatures of their environment, but it will be necessary to extend the observations over a number of years in the same locality in order to establish its usefulness and define incidental amendments.

The work involved in such observation entails constant observation by means of thermograph and much time in the calibration of thermographic curves.

Your committee asks a further grant of \$50 for the furtherance of this work, it being proposed that the sum named should be expended in clerical and mechanical assistance. A further sum of \$10 is asked for the repair of a thermograph wrecked in some recent field work in this connection, making a request for a total grant of \$60.

The following items of expenditure are presented against the grant of \$50 made by the Association to this committee at the meeting of 1900.

To freight charges on outfit from New York to Priest River, Idaho.....	\$24.86
To hauling same to camp on Priest River, to Priest Lake and return.....	25.00
To making temporary instrument shelters (partial account).....	.14
Total	\$50.00

Committee.

REPORT OF THE COMMITTEE ON THE TEACHING OF ANTHROPOLOGY IN AMERICA.

To the Council of the A. A. A. S.: Your committee beg to report careful consideration of the matter committed to them. Two meetings have been held since the last report, and one of the committee (Dr. George Grant MacCurdy) has, by authority, prepared an account of anthropologic teaching in America during the past year to be presented as a paper before Section H. It is recommended that the committee be continued and empowered to issue circulars relating to the introduction of anthropology in American universities and colleges, *provided* such circulars have the approval of the Permanent Secretary and be issued without cost to the Association.

[Signed] W J MCGEE, *Chairman*,
 GEORGE GRANT MACCURDY,
 FRANK RUSSELL.

August 27, 1901.

COMMITTEE ON THE 'EMMONS HOUSE MEMORIAL.'

The American Association for the Advancement of Science was organized in 1847. It was the organic descendant and enlarged outgrowth from the Association of American Geologists and Naturalists. The latter body was created in 1842 by the incorporation of the Naturalists within the Association of American Geologists. The Association of American Geologists is therefore to be looked upon as the legitimate organic ancestor of the American Association for the Advancement of Science.

The circumstances which led up to the organization of the Association of American Geologists are as follows:

During the prosecution of the Geological Survey of the State of New York the need of the geologists for consultation and interchange of view with others engaged in official geologic work led to the suggestion of an organization of a body of American Geologists. It appears that Lieutenant W. W. Mather, one of the New York geologists, suggested the subject of such a meeting to the Board of Geologists in November, 1838. He wrote :

Would it not be well to suggest the propriety of a meeting of the geologists and other scientific men of our country at some central point next fall, say in New York or Philadelphia? There are many questions in our geology that will receive new light from friendly discussion and the combined observation of various individuals who have noted them in different parts of our country. Such a meeting has been suggested by Professor Hitchcock and to me it seems desirable. It would undoubtedly be an advantage not only to science, but to the several surveys that are now in progress and that may in future be organized. It would tend to make known our scientific men to each other personally, give them more confidence in each other and cause them to concentrate their observations on those questions that are of interest either in a scientific or economical point of view. More questions may be satisfactorily settled in a day by oral discussion in such a body than in a year by writing and publication. (Letter from W. W. Mather to the Geological Board of New York, dated November 9, 1838, and addressed to Professor Emmons.)

It appears herein that the suggestion of this meeting was originally made by President Edward Hitchcock, of Massachusetts, who was the first to receive the appointment as geologist of the First District of New York from Governor Marcy. President Hitchcock has said in regard to the suggestion made by Lieutenant Mather : "As to the credit he has here given me of having previously suggested the subject I can say only that I had been in the habit for several years of making this meeting of scientific men a sort of hobby in my correspondence with such." (Address of President Edward Hitchcock at the inauguration of Geological Hall, at Albany, August 27, 1856. Tenth annual report New York State Cabinet of Natural History, 1857, page 23.)

Lieutenant Mather's letter to the Board of Geologists was taken up for consideration at a meeting held November 20, 1838, at the house of Dr. Ebenezer Emmons, corner of High street and Hudson avenue, Albany. (See documents herewith appended being A, a statement dictated by Professor James Hall, August 24, 1896, and B, a statement dictated by Ebenezer Emmons, Jr., February, 1900.) The action taken by the geologists was one of unanimous approval of the proposition, and Lardner Vanuxem of the Third District was commissioned to open com-

munication with other geologists, especially with President Hitchcock, with reference to carrying this project into effect.

The undertaking was not immediately successful and at a meeting held in the autumn of 1839 the purposes of the geological board were reiterated. This meeting was also held at Dr. Emmons' house, the four geologists and the paleontologist being present, and also Ebenezer Emmons, Jr., who still survives. As a result of the second undertaking on the part of the New York geologists a meeting was called in Philadelphia for April, 1840, where and when the organization of the Association of American Geologists was carried into effect. The following year the Association again met in Philadelphia, at which time the membership of the body was largely increased, and in 1842 the place of meeting was Boston and then, as already rehearsed, the name and the scope of the Association were, at the solicitation of the naturalists, both enlarged. President Hitchcock, addressing the New York public interested in the outcome of the work of their geologists, makes the following statement in the address already quoted :

It may be thought that the New York geologists in their invitation and the members of that first Philadelphia meeting had no thought of extending their Association beyond geologists ; but Professor Mather's language just quoted speaks of 'a meeting of the geologists and other scientific men of our country,' thus showing what were his aspirations, and they were shared by all of us who had anything to do with that first meeting. But we knew that only a short time previous the American Academy of Arts and Sciences at Boston had directed a request to the American Philosophical Society as the oldest of the kind in the country, that it would invite the scientific men of the land to such a meeting as the one we are now enjoying ; but the distinguished men of that Society decline through fear that the effort would prove a failure. Surely then it did not become us to announce any such intentions or expectations ; yet we did talk of them and could not but hope that what might fail if attempted on a large scale at first might be accomplished step by step. *Had not the New York geologists issued that modest invitation and confined it at first to the State surveyors probably even yet we might have been without an Association for the Advancement of Science.* (President Hitchcock's address, ut. cit.)

The committee appointed by this Association to consider the matter of placing a memorial tablet upon the Emmons' house in Albany, N. Y., begs to submit the foregoing as evidence of the prenatal history of the American Association and to recommend that this house, the home of the late Ebenezer Emmons, a man of eminence in his profession, of untiring diligence and enduring patience, be permanently marked by a tablet setting forth the interest of that spot to the history of the Association. It is suggested that such tablet bear the following inscription :

In this house, the home of
 Dr. EBENEZER EMMONS
 the first formal efforts were made, in
 1838 and 1839, toward the organization of the
 ASSOCIATION OF AMERICAN GEOLOGISTS
 the parent body of the
 American Association for the Advancement of
 Science
 by whose authority this tablet is erected
 1901

The committee further reports that the cost of this tablet will constitute no claim upon the treasury of the Association, but will be borne individually by one of its members, Dr. T. Guilford Smith.

JOHN M. CLARKE,
 C. H. HITCHCOCK,
 J. MCK. CATTELL,
 W J MCGEE.

A. Statement dictated to John M. Clarke, by Professor James Hall, August 24, 1896.

The organization of a body of American Geologists was proposed by the four geologists at Dr. Emmons' house at the corner of Hudson avenue and High street. It was during the fall of 1838. Vanuxem was asked to see or communicate with the Rogerses concerning it, but nothing came of it that year. The next year we reiterated our purpose as the intention was to get some means of comparing our results with those of other geologists in other States, especially in Pennsylvania. This meeting was held at Dr. Emmons' house, the four geologists being present and perhaps also Conrad. Ebenezer Emmons, Jr., was also there. We then decided to communicate again with the Rogerses and others for the end already suggested and to organize a Society of Geologists for this especial purpose. We wanted to compare our results with those of others and make up our nomenclature, and we had to do it soon, as we were required to publish. As a result of this unanimously expressed purpose a meeting was called for April, 1840, in Philadelphia. I was present then but not at the second Philadelphia meeting in 1841, as that year I was off in May and June with D. D. Owen on a flat boat sailing down the Ohio, sleeping on a box and collecting fossils all along from Louisville to New Harmony. As far as Rogers was concerned the meeting came to naught. He was not ready with his results and gave them only at the third meeting at Boston in 1842. It was here that the Naturalists proposed to join us and we agreed thereto, but the Boston meeting was called as the meeting of the Association of American Geologists and in the course of that meeting the name was changed to that of Association of American Geologists and Naturalists.

B. Statement dictated to John M. Clarke by Ebenezer Emmons, Jr., February, 1900.

I was present at the meeting of the four geologists at my father's house, in 1838. I was then about 16 years old, and had assisted my father in his

field work and making drawings and sketches. Mr. Conrad, the paleontologist, was also present. I recollect that the board of geologists then authorized Mr. Vanuxem to open correspondence with others for the purpose of effecting an organization.

COMMITTEE ON GRANTS.

The following grants are recommended :

1. To Committee on Quantitative Study of Biological Variation, \$100.
2. To Committee on Relation of Plants to Climate, \$60.
3. To Committee on Anthropometric Measurements, \$50.
4. To Committee on Determination of Atomic Weight of Thorium, \$50.

[Signed] R. S. WOODWARD,
Chairman.

The report of the treasurer and the financial statement of the permanent secretary were as follows :

REPORT OF THE TREASURER.

In compliance with Article 15 of the Constitution, and by direction of the Council, I have the honor to submit the following report, showing receipts, disbursements, and disposition of funds of the Association for the year ending December 31, 1900.

Receipts have come into the keeping of the Treasurer from four sources, namely: First, from commutations of fees of life-members of the Association; secondly, from excess of receipts over expenditures of the Permanent Secretary; thirdly, from a contribution to the Association by Mrs. Phoebe Thorne, of New York City; and fourthly, from interest on funds deposited in savings banks. The aggregate of these receipts is \$1,805.07.

Disbursements made in accordance with the directions of the Council amount to \$283.00.

The total amount of funds of the Association deposited in banks and subject to the order of the Treasurer, December 31, 1900, is \$10,189.18.

The details of receipts, disbursements, and disposition of funds are shown in the following itemized statement.

Dated June 1, 1901.

THE TREASURER IN ACCOUNT WITH THE
 AMERICAN ASSOCIATION FOR THE AD-
 VANCEMENT OF SCIENCE.

1900.	Dr.	
Jan. 1, to balance from last account.....		\$ 8667.11
Oct. 20, to amount received from L. O. Howard for 5 life-membership commutations.....		250.00

Oct. 20, to amount transferred from funds of L. O. Howard, Permanent Secretary	1000.00
Dec. 14, to contribution to the Association received from Mrs. Phoebe Thorne	250.00
Dec. 31, to interest on funds of the Association deposited in Savings banks, as follows:	
From Cambridge Savings Bank, Cambridge, Mass. \$35.70	
From Emigrant Industrial Savings Bank, New York, N. Y.	82.88
From Institution for the Savings of Merchants' Clerks, New York, N. Y.	99.55
From Metropolitan Savings Bank, New York, N. Y.	86.94
	305.07
Total	\$10472.18

1900.	Cr.	
Feb. 6, by cash paid Professor C. H. Eigenmann of Committee on study of blind vertebrates.....	\$	100.00
June 29, by cash paid Dr. D. T. MacDougal of Committee on study of the relations of plants to climate.....		33.00
Aug. 6, by cash paid Professor Chas. B. Davenport of Committee on quantitative study of biological variation.....		150.00
Dec. 31, by cash on deposit in banks as follows:		
In Cambridge Savings Bank, Cambridge, Mass	\$	1047.36
In Emigrant Industrial Savings Bank, New York, N. Y.		3030.85
In Institution for the Savings of Merchants' Clerks, New York, N. Y.		2818.97
In Metropolitan Savings Bank, New York, N. Y.		2889.80
In the Fifth Avenue Bank of New York, N. Y.		402.20
		10,189.18
Total.....		\$10,472.18

I have examined the foregoing account and certify that it is correctly cast and properly vouched.

EMORY MCCLINTOCK,
Auditor.

L. O. HOWARD, PERMANENT SECRETARY, IN ACCOUNT WITH THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, FROM JANUARY 1, 1900, TO DECEMBER 31, 1900.

		<u>\$12321.60</u>

I hereby certify that I have examined this account and that it is correctly cast and properly vouched for, and that the balance was on deposit in Washington banks as follows: Citizens National (as per statement Jan. 8, 1901), \$3229.62; National Safe Deposit (incl. interest credited Jan. 1, 1901), \$519.43; American Security and Trust (incl. interest credited Jan. 7, 1901), \$1034.58; in all, \$4783.63.

G. K. GILBERT, *Auditor.*

The following is a list of the officers elected to serve at the next meeting, including also the permanent secretary and treasurer previously elected for a term of five years:

President—Asaph Hall, U. S. N., retired.

Permanent Secretary—L. O. Howard, chief entomologist, Agricultural Department, Washington.

Assistant Permanent Secretary—Richard Clifton, Agricultural Department, Washington.

General Secretary—D. T. MacDougal, director of the laboratories, New York Botanical Gardens.

Secretary of Council—Professor H. B. Ward, of the University of Nebraska.

Treasurer—Professor R. S. Woodward, Columbia University.

OFFICERS OF SECTIONS.

A (Mathematics and Astronomy)—*Vice-president*, G. W. Hough, Northwestern University; *secretary*, E. S. Crawley, University of Pennsylvania.

B (Physics)—*Vice-president*, W. S. Franklin, Lehigh University; *secretary*, E. F. Nichols, Ohio State University.

C (Chemistry)—*Vice-president*, H. A. Weber, Ohio State University; *secretary*, F. C. Phillips, Western University.

D (Mechanical Science and Engineering)—*Vice-president*, J. J. Flather, University of Minnesota; *secretary*, C. A. Waldo, Purdue University.

E. (Geology and Geography)—*Vice-president*, O. A. Derby, San Paulo, Brazil; *secretary*, F. P. Gulliver, Southboro, Mass.

F (Zoology)—*Vice-president*, C. C. Nutting, Iowa State University; *secretary*, C. W. Stiles, Department of Agriculture, Washington.

G (Botany)—*Vice-president*, D. H. Campbell, Lehigh University; *secretary*, H. Von Schrenk, Shaw School of Botany, St. Louis.

H (Anthropology)—Stewart Culin, University of Pennsylvania; *secretary*, H. I. Smith, American Museum of Natural History, New York.

I (Social and Economic Science)—Carroll D. Wright, commissioner of labor, Washington; *secretary*, W. F. Wilcox, Cornell University.

K (Experimental Medicine and Physiology)—*Vice-president*, Dr. W. H. Welch, Johns Hopkins University; *secretary*, Dr. F. S. Lee, Columbia University.

The recommendation of the general committee of last year that the Association meet at Pittsburg in the summer of 1902, was supplemented by Dr. W. J. Holland, Director of the Carnegie Institute, and it was decided to meet at Pittsburg from June 28 to July 3, inclusive, 1902.

The general committee recommended also that a meeting be held in Washington, D. C., during 'Convocation Week,' or the week in which the first of January falls, in 1903.

Professor Wm. Trelease and C. M. Woodward presented an invitation to the Association to meet in St. Louis during the time of the Louisiana Purchase Exposition in 1903. This invitation was referred, without formal recommendation, to the general committee of 1902.

JOHN M. COULTER,
General Secretary.

REMARKS OF PRESIDENT MINOT.*

I WAS impressed on my way here with the somewhat unexpected arrangements I found for securing my services as a visitor at Denver. We found it easy to get here because we paid for a night's journey upon the road and owing to the delay of the train we got two nights' journey instead of one, showing how attractive it is here and how liberally one is treated coming to Denver. But when I went to your ticket office to in-

* Made at the opening general session, and reported stenographically.

quire about going away I found we had to pay the price of two nights in order to pass one when leaving your city. So there seems to be every inducement to prolong our stay. I could not but think, as I read in the newspaper that this Association had fallen upon Denver, of an anecdote related to me a few days ago in the Yellowstone, when I was told a German visitor had been there and seen the geysers, and afterwards had gone to Niagara. When asked how he liked it, he said, "Oh, that is very fine, but you shall see the geysers, they fall oop." That is the way we have 'fallen upon' Denver. We are all wonderfully impressed by the extraordinary endowments of nature in this state. It is almost incredible to a visitor coming here for the first time that any tract of land should be so richly provided with all the raw resources which man needs for the construction of civilization. We, like you, are laboring in this process of building up civilization. As you have been working in your state, so we work in every territory of nature seeking to bring forth her hidden treasures and render them available for the service of mankind and for establishing a higher life in humanity than has yet been. It is not so in the east with us at home. There civilization has been going on longer. The resources which nature provides are known. The work of civilization proceeds there in established channels, and I felt at once in coming here that the newness and creative character of your work in Colorado made a sympathetic atmosphere for us who are striving to create what is new and get from nature her unused treasures which we can employ hereafter. Everything therefore speaks of sympathy and understanding between the practical life of Colorado and the scientific life of this Association. And we are, too, nearly co-temporaries. The Association was before Denver was, but not by many years. We have, as it were, grown

up together and have lived through the same period of our country's history. Therein, too, lies the power of appreciation—mutual, I believe—between you and us who are here playing a double rôle of both guests and, in our meetings, of your hosts—for hosts we would gladly be, inviting you to our meetings, for we are a kind of intellectual Salvation Army. We do not profess to do much for the saving of souls as our direct work, though we believe that all good work tends to that end, but we do believe that we can do a great deal to save brains, they being the only things in nature which in being used are best saved and made better. So if we stimulate you to use your brains more we shall have done some service, we shall have done something to save your intellectual life, to broaden it and make character. If as a biologist I survey the realm of nature and seek to make out what is the distinguishing characteristic of man, I have to recognize that it is the value of the individual which distinguishes the human species from every other living species in the world. Man alone is able to profit by the superiority of the individual members of his species. Animals may learn a little from one another. Man alone can learn much. It is owing to this peculiarity in nature of the human species that science exists, that civilization exists, and I believe the recognition of that fact should have a profound influence upon all our political and social questions whenever we have in mind the promotion of human welfare; because, it being a true fact in nature that the average civilization of a community is not correspondent to the average intellectual and moral calibre of its members, but very nearly to the intellectual and moral calibre of its best members, that fact imposes upon us a special duty, that of promoting the development and the education of the best members in the community. And if I were asked to say what in the west seemed to me

the very best thing you had to show, I should say without a moment's hesitation it is the high school buildings here and the high school buildings we have seen in the other cities as we have passed along—emblems, as they are, of the educational system which in the very establishment of its high schools recognizes the fact that there are superior individuals who are worthy a better education than is offered by primary and grammar schools below.

But it does not do to stop there. And I am glad to see that the State of Colorado has started already the development of a university which by its prosperity shows the earnestness with which it has been founded, the devotion which has been spent upon fostering it and which stands as one of the highest marks to the credit of the State. I believe that the very best that we could do for you would be to contribute something to the public recognition of the value of the State University. It seems to me that no citizen of Colorado who has the highest ideal for the future of the state can feel that the state has done its full duty until it has developed its university, not only as it has begun, but farther in the same direction, until it shall have become one of the great universities of the country—I would even say one of the great universities of the world. It is not enough for you to work here for the development of your material resources. It is not enough for you to apply science. We who are carrying on our investigations supply the power, we generate the steam pressure, and the practical man—if I may be pardoned for the innuendo—is the crank which transmits the power to a practical purpose. Unless a state is doing its quota towards the increase of knowledge, it is fulfilling only a part of its duty. If, therefore, our coming here can have such an influence upon any of you as to increase the belief in the value of your university and to spread

that belief among you, making it deeper rooted in the innermost convictions of your great community that the university is the greatest thing in the state, we shall have done a service to you which will show we are grateful for all the magnificent hospitality which has been proffered us, for the perfection of the arrangements made here for our comfort, and that we appreciate your words of welcome, those which have come to us from the Governor, from the Mayor of the city, from the representatives of the business interests of your community and of your educational system. All this we take to heart and we beg to thank you for it with all the sincerity with which we appreciate it. And in return we would offer you this thought which is the inspiration of the professor—that the country is governed by universities, because what is done in the country is done by the men who think, who come out into the world with thoughts which were never there before; and the men who do that, with very rare exceptions, are men who have had their minds severely disciplined by university training. If you look back through the history of the United States and recall men who as statesmen, as inventors, as authors, were creators of any kind of new intellectual product, you will find that there is but a trifling number among those great men who have not come from the universities. And, therefore, it is true as a historical fact that this country is governed by the universities, and there is not a complete government in any state, in the opinion of the members of this Association—I am sure in the opinion of all of them—until there is a great, well-equipped, richly endowed and largely attended university. It is therefore to me the greatest pleasure to say that Colorado has begun with this ambition, and I hope with all my heart that you will carry it through to a fulfilment corresponding to the extraordi-

nary fulfilment which you have achieved in all the other work you have undertaken in the development of your state, and with that wish and with thanks on behalf of our Association I would close with an invitation to you all to attend our meetings; and I would express particularly the hope that all of you who are interested in broad discussions and deep-thought views of scientific problems will take advantage of the opportunity to hear the address of our retiring President, which will be the central and most interesting event of our proceedings. With thanks, therefore, for your courtesy and kindness, and expression of pleasure on behalf of all the members of the Association who are here, I will now close my reply to the hospitable welcomes which have been made us.

*SOME POINTS IN THE EARLY HISTORY AND
PRESENT CONDITION OF THE TEACHING
OF CHEMISTRY IN THE MEDICAL
SCHOOLS OF THE UNITED
STATES.**

IN the scientific awakening of the latter part of the eighteenth century medicine was not the last of the great departments of human learning to take on new vigor. As in earlier years it drew largely from alchemical philosophy for the enrichment of its *materia medica*, and for the justification of a crude therapy, so now the great teachers of physic stood ready to accept the rapidly developing facts and generalizations of the new chemistry, and to apply them in the noble task of elevating a dogmatic empiricism to the plane of a scientific system. From the time of Paracelsus, alchemy, and its offspring, chemistry, had been but the handmaids of medicine, and much of the skill of the workers in these fields was devoted to the preparation of remedies for

various diseases. But, from the labors of Priestley, Scheele, Watt, Cavendish and Lavoisier, the relations were reversed, and the chemists and the apothecaries, the cooks in the kitchen of the doctor, seemed ready to usurp the proud positions of their former masters. The nature of oxidation and the phenomena of respiration changes explained, it was clear that medicine must now depend largely on the development of chemistry for its rational groundwork.

After the downfall of the old iatro-chemistry with its empiricism and evident hollowness, our science had fallen into disrepute in the great European centers of medical learning, and physicians were somewhat slow in taking up the new ideas. But, the way once opened, the development spread rapidly, almost too rapidly in fact, because of the danger always attending hasty generalization.

The educational influences at work in the American colonies in those days were almost wholly English, and the earliest medical schools established here were modeled after those of Great Britain. We find, therefore, that in each one of the medical schools founded in the pioneer days of attempt in professional education a chair of chemistry was provided for as furnishing a necessary part of the medical student's education. Indeed, the first chair of chemistry of any kind to be filled in this country was that in the medical school of the University of Pennsylvania, and the occupant was Dr. Benjamin Rush, a man justly famous in the early history of American medicine, but not known on account of any chemical writings. This was in 1769, and the position was held by him until 1789. In the autumn of that year Dr. Rush was transferred to another department, and Dr. James Hutchinson was elected to fill the place. The latter died in 1793, and Dr. John Carson was appointed his successor in January, 1794, but died

* Address of the Vice-president and Chairman of Section C, Chemistry, at the Denver meeting of the American Association for the Advancement of Science.

without serving. In this year Priestley came to America, and lived for a short time in Philadelphia. He was offered the chair, but after some delay declined it on account of poor health and the desire to lead a quiet life in a rural country, which he found later on the banks of the Susquehanna at Northumberland.

In July, 1795, the place was again filled by Dr. James Woodhouse, who served until 1809. His successor was John Redman Coxe, who was among the earliest writers on chemistry in this country, since he published in 1811 a small work entitled, 'Observations on Combustion and Acidification; with a Theory of these Processes founded on the Conjunction of the Phlogistic and Antiphlogistic Doctrines.' Dr. Coxe was followed by Robert Hare, who was a man of great ability and a credit to the new country. Hare made numerous discoveries himself, some of them of permanent importance, and besides rendered a service to students by bringing out an American edition of Henry's chemistry. Some years later he published a text-book on chemistry himself for the use of the medical students of the University of Pennsylvania. As Hare's position was unquestionably the most important one of the kind in the country, it may be well to give a few moments' attention to his work as typical of the best of the period.

Hare began his career at a time which, from one point of view, might be considered as very unfavorable for the development of chemistry in America. The early aspirations of the founders of the Philadelphia College had failed of realization because, as must be recognized, they were beyond the practical sympathies or comprehension of the masses. The requirements for the attainment of the degree of Doctor of Physic were relatively, and in some respects, perhaps, absolutely, far in advance of those of the present time, and this the colonies were not ready for.

Then came the Revolution, followed by a long period of political discussion and rapid internal development, and finally another bloody war. This left the country poor and yet farther behind again in the sphere of intellectual development. The great European wars of the same period had not hindered scientific discovery or cultivation in France and England, at least. Through these years of turmoil, the beginning which had been made in the few American centers where chemistry was taught had come almost to a standstill, and Hare entered upon what might appear a field of little promise. But the man was an independent thinker, and the example of Berthollet, Dalton, Davy, Berzelius, Gay Lussac, Humboldt and others was not lost on him. He began his work as a private student and partly in conjunction with the elder Silliman, who came to him before beginning at Yale, and while yet a young man attracted considerable attention by the discovery of the oxy-hydrogen blowpipe, a description of which was published in 1802. Later he constructed a new form of galvanic cell with very large plates which was known as the calorimotor or deflagrator, and this gave him no small reputation abroad as well as at home.

Hare's theoretical explanations of phenomena observed were not always correct, and in some of the many polemics in which he took part he certainly defended the weaker side of the argument, but in looking through his writings one cannot but be impressed with the ingenuity he displayed in contriving experiments to illustrate simple principles.

One of the best known works of chemistry of this time was that of Dr. Henry, of Manchester. The last American edition of this was brought out by Hare, and was used in his own classes and elsewhere in the United States. Later he brought out a book of his own with the title, 'A Com-

pendium of the Course of Chemical Instruction in the Medical Department of the University of Pennsylvania, by Robert Hare, M.D. For the use of his Pupils.' There were four editions of this. The last appeared in 1840-43. In the preface of this book I find this curious passage, which reads as if it might have been written yesterday: "A chemical class in a medical school usually consists of individuals who differ widely with respect to their taste for chemistry, and in opinion as to the extent to which it may be practicable or expedient for them to learn it," etc.

With this idea of the difficulty of the subject and of the slight inclination on the part of many medical students to master it, Hare prepared a work in simple style containing an unusually large number of experimental illustrations and practical suggestions for the pupil. How successful he was with students it is now impossible to say, but that he impressed himself as a powerful teacher I have been assured by one who remembered him in his later years. He remained with the University until 1847, and died in 1858. He continued actively engaged in scientific work to the time of his death, and contributed numerous articles to the journals. No less than 150 were published in *Silliman's Journal*. That his work was respected abroad as well as at home is shown by the fact that he maintained an active correspondence with Faraday, Liebig and other great men of the day, and that we find frequent reference to his articles in contemporary writers and in the earlier volumes of the *Jahresbericht*.

While Hare was prominent in Philadelphia, Silliman, Gorham and Mitchill were developing the departments of medical chemistry in Yale, Harvard Medical School and Columbia. In the last two medical schools chemistry was taught almost as early as in Philadelphia, but apparently with less vigor, while at Yale it was taken up later.

In 1802 Benjamin Silliman, then a young man, was appointed to the chair of chemistry at Yale, and before beginning work he visited other schools in search of ideas. Prior to 1800 there seems to have been but a single chair of chemistry in the country outside of the medical schools, and this was held by Dr. John MacLean at Princeton. Silliman went there first and profited by what he saw. Later he went to Philadelphia, where he met Woodhouse, Priestley, Hare and others. Hare seems to have made the greatest impression on him, and they worked often together. In the next few years Silliman visited Europe, and on his return to New Haven aroused much enthusiasm among the scientific and medical men. It was largely through his influence that a medical school was established at Yale, and of this he became the first professor of chemistry and pharmacy. The Medical Institution of Yale College, as it was called, was chartered October, 1810, and four professorships were provided for, 'the first of chemistry and pharmacy; the second of the theory and practice of medicine; the third of anatomy, surgery and midwifery; the fourth of materia medica and botany.' It will be noticed that the chair of chemistry is here mentioned first, doubtless a tribute to Silliman's reputation and influence. He continued to give instruction to medical as well as to general students for many years, and through his writings and the journal he established he became the best known scientific man of the day in America. Silliman's interests, however, were in lines remote from medicine, and he therefore failed to exert here the influence enjoyed by his friend Hare.

The Medical School of Harvard College was established in 1782, and in 1783 Dr. Aaron Dexter was made the professor of chemistry and materia medica, his time being devoted to teaching general and medical chemistry. It does not appear that he

published any researches or did much to advance his science, but he was a man of personal popularity, and it was through his influence that the Erving professorship was founded by Major Erving, who was one of his patients. Dexter served until 1816 and was followed by Dr. John Gorham, a man of marked ability, who published a number of researches showing skill and understanding, and who must be given credit for bringing out the first original book on chemistry published in this country. The two large volumes compare very favorably with the work of his European contemporaries. Gorham, who was recognized as a power in the medical school, now moved to Boston, and his reputation was of the first order among his colleagues. He laid the foundation for the excellence in a department which has steadily grown in importance to the present time. Gorham was followed by Dr. John White Webster in 1827, an alumnus of Harvard, and a man of promise who increased the reputation of the university, and especially of the medical school by his original scientific contributions and by editing several well-known foreign works. His text-book on chemistry on the plan of the work of Brandes has considerable merit. The fate of Webster in connection with the Webster-Parkman tragedy of 1850 is probably known to all here.

In New York the old King's College had become Columbia College, and in 1792 established its first professorship of chemistry. This was in the medical school, and Dr. Samuel Lathan Mitchill was given the chair. It was this man who introduced the Lavoisier nomenclature in the United States, and in consequence was engaged in many controversies with Priestley. In 1798 he established the *New York Medical Repository*, and managed it for many years. It was the first medical journal started in this country, and exerted no little influence,

receiving contributions in general science as well as in medicine.

In 1807 a charter was granted to the College of Physicians and Surgeons in New York, and in 1811 Dr. William James Macnevin was made professor of chemistry. He was a man of marked ability, having taken the medical degree at the age of twenty in Vienna. Several scientific contributions from his pen are found in the journals of the time, and among other things he wrote 'An Exposition of the Atomic Theory,' which attracted much attention.

It will not be necessary to trace the history of chemical teaching in the other early medical institutions, as practically nothing of consequence is found recorded. The schools referred to were far in advance of those established elsewhere, and have in a large measure maintained their superiority to the present time.

For many years chemistry was taught to medical students by lectures only, and the introduction of even simple laboratory work is of comparatively recent date. In Harvard Medical School, for example, laboratory courses were not given until 1872.

It would be a discouraging task to try to follow the development of chemical teaching in medical colleges down to the present time. Few institutions were blessed with such men as Hare, Silliman or Gorham, who exerted an influence of priceless value on medical men now rapidly passing away. Owing to peculiar causes which I need not try to explain here, medical schools multiplied very rapidly in the United States, and in most of them the chair of chemistry was considered in the light of a necessary evil. As a matter of form chemistry had to be taught, but how it was taught and how it was followed by the students, were questions of wholly secondary importance. It has long been the custom in the medical schools of this country to divide the chairs into the theoret-

ical and the practical. The American boy has been taught to hold practical things in the highest esteem, and chemistry was not practical. Professors and students alike felt it, and it is hard to tell who was the most to blame for the warped and stunted conception of chemistry held even at the present time by the great majority of medical men of this country. It is likely that much of the fault lay in the weak and wholly unsatisfactory manner in which chemistry was presented for fifty years in most of our medical schools. The professor of chemistry was usually a physician who, as a rule, was not considered sufficiently strong to fill the chair of practice, obstetrics or surgery, but who might teach acceptably the less important branch of chemistry. For the convenience of such teachers a peculiar system of chemistry called 'medical chemistry' was developed, and in some places persists to the present time. The idea that a man trained outside of a medical school could teach the kind of chemistry which medical students really needed was of slow development in the United States, and in some quarters fails yet of recognition. But, for part of the trouble we must go farther back. While students in general courses were taught the elements of the sciences, languages and mathematics by recitations and quizzes, medical students, with far weaker preliminary training, were supposed to be able to absorb the essential facts of a great department of human knowledge from lectures alone. The lecture system is responsible for much of the superficiality in the old-fashioned medical schools, and no real progress was made until it began to be recognized that a medical student must be taught as other students are. With the gradual dawn of this notion it became finally possible to introduce into medical colleges rational chemical instruction, and the laughable farce of presenting the so-called medical chemistry to students ignorant of

general chemistry will in time be a thing of the past.

This medical chemistry to which I call your attention was often a curious combination of the good and the absurd. Admitting that the student should know something about the chemistry of the blood, the bile and the urine, something about the nature of food stuffs and the processes of digestion, it was thought sufficient to present all these matters to him in condensed, so-called 'practical' form, and without first requiring a solid preliminary training in general and inorganic chemistry. It was considered the correct thing to memorize a lot of definitions, and to learn to recite in parrot fashion a number of empirical organic formulas. It must be admitted, however, that the fault was not confined to medical schools alone.

Chemistry in general may be studied from two standpoints. First, as in the college of liberal arts, as a fundamental discipline, regardless of the possible application which one may make of it. On the other hand, it may be pursued as a necessary preliminary to the understanding of something else, and in this case its mastery becomes all-important. One would naturally suppose that in the latter case the science would be much more thoroughly cultivated than in the former, but this is not always true. The discrepancy is perhaps most glaringly apparent in the chemical work of the medical schools. It cannot be expected of course that the chemistry offered to the medical student of to-day should be, as in the time of Hare, Gorham and the elder Silliman, more complete than that given to other students; this would be impossible and wholly unnecessary, as chemistry is now a great specialty with numerous departments branching in all directions and a literature as voluminous as that of scientific medicine itself. But this much should be reasonably expected, that

the medical student's elementary chemistry should be at least as thorough as that of the student in liberal arts. It seems absurd to think that a man preparing, possibly, for law or theology or commerce, or studying without thought of any specialty should be made to acquire a fuller, more accurate knowledge of chemistry than that expected of the future medical man. If chemistry is of value at all, it certainly is to the doctor, rather than to the preacher, lawyer or man of business, yet in the United States in the last fifty years, the doctor's training in chemistry has been, on the average, less exacting than that of the other classes mentioned. If any one is disposed to doubt what I say let him compare the numerous 'Essentials of chemistry for the medical student' with the text-books used in other schools in the same science. It is anomalous that the doctor's chemistry should be usually the weakest of all.

But we are gradually emerging from this discouraging situation, and the improved condition is mainly due to the recognition of this fundamental truth, that there is not one kind of elementary chemistry for the doctor, another for the lawyer and a third for the preacher. There is no royal road to the acquisition of the necessary groundwork, and the medical man's elements must be learned through the same kind of patient effort that is required of other men. In the best of the medical schools of the country to-day chemistry is no longer taught by practitioners of medicine, and an honest effort is being made to present the subject as it is presented to beginners in schools of science. Such a course of laboratory and recitation work should require at least ten hours each week through a year of eight months to cover the work preliminary to the proper study of medical or physiological chemistry in the second year.

This leads me to explain what I consider the minimum work in preparatory chem-

istry for the medical student, and the character of this work. First, he should have the usual lecture or recitation course of about seventy-five lessons in general and inorganic chemistry, with especial attention paid to the theoretical groundwork. A discussion of the common inorganic salts is of less importance. This work should be followed or accompanied by a laboratory course in experiments, including the preparation of a few pure substances. In most of our schools the value of preparation work has not been sufficiently recognized, the time which might be spent there going usually to qualitative analysis which I believe is correspondingly overestimated. Inorganic qualitative analysis for most students becomes a mechanical routine in which the important element of discipline is wanting. As in the future work of the physician this branch of analysis finds little or no application, I believe the time given to it in preparatory medical work may be greatly curtailed. During the past twenty years, in which I have given instruction to medical students, I have had abundant opportunity to observe this fact, that men who have entered with training in experiments and preparations and no qualitative analysis make as a rule far better progress than do those whose laboratory work has been wholly analytical. Many of our colleges still begin their laboratory work with qualitative analysis, which, perhaps, is a relic of concession to the old utilitarian notion, and I am convinced that for the average student the time so spent is largely wasted. On the other hand, volumetric analysis may be made a medium of imparting important knowledge in fundamental principles, and I believe it should find early presentation in all our courses, general as well as medical, that it should precede rather than follow gravimetric analysis as is customary. In the case of the medical student the im-

portance of volumetric analysis is twofold. Not only is it a valuable discipline in itself, and discipline is above all what is needed in preparatory medical training, but it also becomes an instrument of practical application in the physician's subsequent work. In his practical routine labor of a clinical nature the physician is constantly called upon to make a few qualitative tests which are soon learned and easily followed. He should be in a position to make a wider range of quantitative tests, and these, almost of necessity, must be volumetric. The preparatory medical course should provide this skill, not merely in a mechanical way, but by giving a thoroughly rigorous drill in the few fundamental principles of volumetric analysis. The statement I have just made may provoke a smile, inasmuch as I may appear to be giving advice on a matter which everyone well understands, and suggesting a course which is commonly already everywhere in practice. But it has been my experience that the matter is by no means as simple as it looks. The apparently elementary relations in volumetric analysis are not fully grasped by the general class of students, even by those who devote far more time to laboratory chemistry than is the case with the medical students of our best schools. In support of this I must state that in the last fifteen or twenty years it has been my fortune to instruct hundreds of medical students who had already had laboratory training in chemistry in excellent schools, well-known state universities among the number. While these men have often brought sufficient knowledge of facts, they have as often been very deficient in acquaintance with principles, leaving them unable to deal with cases presenting slight variation in conditions from those of their former practice. Our methods of instruction fail as long as they allow the memorization of facts and isolated methods to take the place

of a study of principles. I am often asked what the value of this or that inorganic volumetric process is to the medical student, and my answer is that it illustrates a principle not readily learned in any other way. And it is safe to say that almost any one of these illustrative methods may find practical application in the physician's own work. The titration of weak acids, for example, is now a common operation in connection with the examination of stomach contents, and the permanganate titration has come into common use in the most accurate process we have for the estimation of uric acid.

I trust that I have made myself understood in insisting that the groundwork of the medical man's education in chemistry should be in the group of topics usually classed as inorganic, and this largely because of the superior advantages of this branch of the science in the presentation of general principles. I feel, therefore, like combating strongly the notion often expressed by medical men that students in medicine should not be required to 'waste' time on inorganic chemistry.

A few words as to the place of general organic chemistry in the preparatory or first year course. The subject is one of such large proportions that at best only an outline can be attempted in the first year course, but that much should at least be given. Leaving the major portion of the discussion of the sugars and other carbohydrates, the fats and the products of fermentation to be taken up with physiological chemistry proper in the second year, I believe that a fairly satisfactory outline may be given in about thirty lessons in the first year course. Remember, I am not writing this for men who expect to be chemists, and I am describing the minimum requirement which I should insist upon. In a short course of the kind it will be necessary to omit many things often supposed to be

of prime importance in the so-called medical chemistry. I have seen text-books for medical students abounding in descriptions of processes for making many of the modern synthetic remedies along with discussions of the supposed structural formulas of these compounds. This knowledge is interesting, but it is far from essential, as few principles are cleared up by it which cannot be presented to the student in more tangible form. It should be further remembered that there is a distinction between chemistry and *materia medica*, and much matter presented to students as chemistry properly belongs in the other field. The time spent in memorizing the empirical formulas of the medicinal alkaloids and of the host of antipyretics, hypnotics, etc., might better be given to a study of principles. Of course I would not be understood as urging that the medical student need not be taught the constitution of any organic compounds, but I merely claim that there is a limit to the amount of this knowledge which may be considered practical or profitable.

I have spoken of the work just described as first year medical work, as it may be taken before entering the medical school or in the first year of the course in medicine. The time is not far distant when all the courses I have described, and doubtless more, will be required for admission to the best schools. At present Harvard Medical School has such a requirement, and other institutions have it under consideration. Many colleges of liberal arts and technical schools offer now a so-called preparatory medical year in which chemistry is the principal topic. Certificates for such a year's work admit to the second year of many of the medical schools of the country. In my experience the plan is not yet a satisfactory one, as the chemistry courses taken under these conditions seems to be lacking in rigor and discipline. They seem to be followed under the notion that medical school

chemistry is so completely lacking in thoroughness that anything may be pursued as its equivalent.

In the last few years students have begun to present high school certificates for chemistry work as equivalent to that in the first year of the medical school. The courses taken in the high school at first sight may appear to be more than equivalent to those in the beginning year of the medical course, but a careful consideration of many cases has convinced me that in general it would be very unwise to grant credit in the medical school for work apparently done in the high school in chemistry. At the age at which boys and girls now do their chemistry work in most of the high schools it is quite impossible that the subject can be properly mastered. In my opinion the superficial courses now given in science in hundreds, perhaps thousands, of high schools throughout the country constitute one of the weakest spots in our system of public education. The attempt is often made to cram more chemistry into the high school boy at sixteen than many of our smaller colleges find possible at twenty. In much of this work the glorification of the teacher, not the true edification of the pupil, seems to be the prime object in mind, and the result is deplorable. With these facts in view, I always feel justified in rejecting the application of the student for advanced standing on account of high school work in chemistry. I am therefore inclined to the opinion that under existing conditions the medical student's work in general and inorganic chemistry can be best done either as a part of a thorough and required college course, or after entering the medical school itself, and that wherever done it should be characterized by a much more systematic and painstaking drill in fundamental principles than seems now to be the case in many institutions.

It is not my intention to enter upon a

discussion of what the course in physiological chemistry should be in medical schools. At present this often consists of a laboratory course in urine analysis only, along with a few lectures on subjects belonging to *materia medica*, pathology or practice rather than to chemistry. In many of the larger and more progressive schools this work is broadened out so as to include experimental studies in the sugars, the fats, the albumins, the processes and products of digestion and the examination of milk, blood, the gastric juice, bile, etc. There is a great diversity of opinion as to how much of this work may profitably be taught in the medical school. It is my own view that it is all out of place if it is not preceded by the proper drill in general chemistry to enable the student to really understand what he is doing. Without this clear understanding the laboratory course in physiological chemistry, which looks so well on paper, and which fills a good amount of space in the college announcement, degenerates into a mere mechanical routine, and becomes as valueless from the standpoint of discipline as is the justly condemned 'test-tube drill' in qualitative analysis. If the student is so illy prepared for his work that the operation of stirring a heated mixture of alkali solution and fat means simply 'making soap,' he might just as well spend his time in turning a grind-stone, as far as intellectual benefit is concerned. Unless he can connect this operation with many similar ones, and with the other processes of splitting fats, the experiment fails of its object. I am firmly of the opinion that the explanation of the low value placed on chemistry by many medical men may be found in the fact that in their own student days they have been forced through this kind of a routine course lacking the preliminary knowledge that would enable them to comprehend it. I maintain then that unless the student has been

properly and systematically prepared in the elements of organic and inorganic chemistry, much of the matter presented to him in physiology and physiological chemistry must remain practically meaningless. As Professor Remsen well says: "It is difficult to see how, without some such general introductory study, the technical chemist and the student of medicine can comprehend what is usually put before them under the heads of applied organic chemistry and medical chemistry." (Preface to 'Organic Chemistry.') But, on the other hand, supposing that the medical student has been successfully prepared in an elementary preliminary course such as I outlined above, there is much indeed that he can really master in physiological chemistry proper. It is not necessary that he should be able to make many elaborate quantitative experiments. Most of the really important reactions in the study of the fats, the sugars and the proteids may be mastered with the aid of comparatively simple qualitative and a few volumetric tests. He will be able to demonstrate understandingly the essential facts connected with most of the digestive and other ferment changes, and to follow variations in excretion corresponding to variations in food consumption, or depending on pathological conditions. This carries the medical student as far as he is ordinarily called upon to go. Anything beyond this naturally belongs to the specialist, and besides would consume more time than can be usually spared from the medical course.

From a perusal of many of our textbooks on physiology and physiological chemistry, the student is very apt to draw erroneous conclusions as to the nature of some of the reactions in this department of science. For simplicity in didactic presentation the teacher or writer is too apt to show everything in an ideal way. A great many dogmatic assertions are made, for

example, concerning the digestion of the starches and the proteids, and the student almost expects to separate and recognize the half dozen or more beautiful products lying between corn starch and malt sugar, or the different hemis and antis, pros and paras in the still more complicated proteid family. The teacher who is not himself an investigator is but too ready to become an idealist, and to present all these intricate details in systematic tables and diagrams as he thinks they ought to be, and perhaps are, rather than as the original experimenters have actually been able to find them. The student must be warned against this, and not the least valuable function of the laboratory work in physiological chemistry in my judgment is to show him the inherent difficulties in much of our research work. An honest recognition of limitations will guard him against many future mistakes, against the preposterous analyses, for example, made by many young medical men while serving as hospital internes or in other capacity. I said a moment ago that there is much which may be easily and accurately learned in physiological chemistry by the medical student. It is evident that there is much more which in the ordinary college course cannot be mastered, and against pretended knowledge here the student cannot be too earnestly warned.

Physiological chemistry is in some institutions recognized as a distinct discipline, independent of medicine. This is true of the chair in several of the great European universities, and of at least one of the older American schools. Physiological chemistry is thus presented as is general biology or comparative anatomy. But in the great majority of cases it is looked upon as forming a part of medical rather than of general discipline, and doubtless for years to come the medical school will have many advantages in properly presenting the work.

Inasmuch as no small part of the material employed in the laboratory demonstrations in the later parts of the course must be drawn from hospitals and clinics, it would seem that the effort sometimes made by other schools to give the equivalent of the medical school's work in this field must be in part futile. I am forced to the conclusion, from several practical considerations, that the student of medicine should not as a rule attempt to take physiological chemistry as a preliminary study outside the medical college. There is generally something lacking in such courses which the student recognizes often only after it is too late to recover lost ground.

Occasionally the work in physiological chemistry is given as a part of the course in physiology, but this, I believe, is a mistake, as the study is often curtailed to a consideration of a few physiological problems instead of being treated as an independent science of broad dimensions. With the present rapid expansion of this field of effort, the work calls for the attention of the specialist in chemistry rather than in physiology. This is necessarily true with respect to research study, and it is becoming equally true as regards the matter of proper didactic presentation. Much of the valuable pioneer investigation in physiological chemistry was done by physiologists, but in its later development the chemist alone can be expected to follow the accumulating mass of detail, and to sift out that which is of permanent value. It requires often rare judgment to decide how much of the newer knowledge is suitable for laboratory or class study, for no one wants to burden the already overtaxed student with a load of premature generalizations. While much of the latest work is always interesting to the specialist, it may often be quite unimportant to the student, and where to draw the proper line of separation between the new and the old calls for the teacher's maturest

judgment. This same idea should be kept in mind in estimating the value of research work for the average professional student. The training of medical students in the United States is a vastly different thing in theory and in practice both from what it is in Germany, from which land we draw so many of our ideals. We give the title of 'Doctor' to the product of our schools, but in reality we are producing *practitioners* of medicine and in the shortest possible time. The man really learned in medicine should be able to present an original research, as the German idea assumes, but the practitioner may be just as successful in actual contact with disease without this skill. I would not be understood as underestimating the value of high scientific training for medical men. Indeed in certain specialties the medical man's success depends almost wholly on his preeminent scientific knowledge acquired by long and minute study. But there is still room for the general practitioner in medicine, and in my judgment he is, and should still remain, the most useful member of the profession. The American medical school is mainly concerned in the training of men of this class rather than of those with more special knowledge, and broad culture is of more importance here than minute acquaintance with bacteriology, physiological chemistry or histology. This is an age in which we are constantly called upon to do something new, regardless of whether the new thing is really needed or not. This criticism applies to research problems in physiological chemistry given to medical students as well as it applies in any other field. It will often be found that the teacher's interests rather than those of the student receive the first consideration, and this is certainly without justification in view of what I have said about the true field of work in American schools.

The teacher who attempts the proper

presentation of general and physiological chemistry in a medical school has indeed no easy task. His work is made doubly hard by the fact alluded to above, that chemistry among the older medical men is still looked upon as a comparatively useless study, and from his preceptor's office the embryo doctor often brings this notion to the medical school. To combat this idea honestly, and to put his science before the medical student as it would be presented in a scientific or general course to freshmen or sophomores, requires the full time and energy of any man, and often little room will be left for research investigation, or, what is to some more alluring, the emoluments of commercial or expert work. But the sacrifice, if indeed it may be called such, is worth the effort. There are about 25,000 medical students in the United States, and the number graduated each year is not far from 5,000, in all schools. The number of registered physicians is about 1 to 636 for the whole population. It is no small matter to be able to make the proper impression on the minds of these men, and positions as teachers in the growing medical schools of the country have been perhaps too long overlooked by the better class of chemical graduates in search of academic openings. There is a field here which is worthy of fuller cultivation.

While I have intimated above that the possibilities for research work in chemistry for the average medical student or teacher are limited, and necessarily so, I am far from underestimating such work. While it is indeed true that in many quarters a trifling research on some trivial point of wholly artificial interest may be more highly prized than is the most painstaking and successful effort in class-work, and while it is also true that the layman, or professional man of little experience as well, may often be deceived as to the real value of such efforts, it is likewise a fact

that there is always a proper appreciation of original investigation in lines of human interest. There is no more inviting field for labor of this kind than is found in the chemistry of life. The greatest problems in the scientific medicine of the future are undoubtedly chemical problems. Indeed there are no more important or inviting problems to be found in any line of study than are here presented, and the investigator will find in them enough to tax the skill and ingenuity of the most learned for years to come. This work naturally and properly belongs to the physiological chemist, and that it must be done before much further advance can be made in scientific medicine is already recognized by leading medical men. The idea was clearly presented by the Dean of the Northwestern University Medical School in the address on Medicine at the recent meeting of the American Medical Association at St. Paul, and we find it brought forward more or less emphatically elsewhere.

The chemical difference between certain of the tissues in health and disease may be very minute in some instances, but in other cases it is certainly more pronounced and capable of demonstration. This problem will unquestionably prove one of the most interesting for future investigators. We have long had considerable acquaintance with the products of renal excretion, somewhat less with the products formed or active in the stomach, and very much less with the complex reactions taking place in the lower stretches of the intestines. Investigation here is probably fully as important as in either of the other cases, but from its inherent difficulties has been but little developed. As the analysis of the urine gives us our most certain data for the diagnosis of diabetes and various renal disorders, so, it may be expected, will the rational chemical examination of the intestinal excretion prove of equal value in the exact diagnosis of other bodily ail-

ments. There is certainly as close a connection in the one case as in the other. These questions are purely practical, and will some day claim the attention of skilled and accurate analysts.

In the field of theoretical investigations the possibilities are even greater. Almost nothing, for example, is known of the steps in nitrogenous metabolism. Between the ingested albumin and the excreted urea and uric acid is a long distance yet to be traveled by the chemical investigator; a few of the possible resting places on the way are known, but the relations of one to the other are yet extremely obscure.

Scarcely less obscure in its fundamental bearings, although seemingly less intricate, is the question of the nature and mode of action of the soluble ferments or enzymes. This is the problem of chemistry rather than of biology, as the question of the production of these substances is merely an incidental one. The epoch-marking work of Buchner in separating the active enzyme from the cells of yeast has gone far to break down the old and artificial distinction between the soluble and insoluble ferments, and to show that all these so-called vital processes are accomplished through what are essentially chemical means. It has long been supposed that in their mode of action the work of the enzyme is purely analytical, but since the interesting observations of Croft Hill on the formation of maltose from dextrose have been confirmed by O. Emmerling, who found, however, that it was isomaltose that was produced, we have opened up a new line of possible investigation which may throw light on some of the processes taking place within the animal body, where it was assumed by Liebig and others that *syntheses* do not take place.

Lately a fruitful line of investigation has been suggested by Bredig in his work on the 'inorganic ferments,' where he shows that colloidal platinum in its oxidation-

assisting behavior presents the closest analogy to some of the common organic enzymes. The colloidal metallic solutions seem to be affected by the same kinds of poisons which are known to impede the action of the soluble ferments, and to recover finally in about the same way. All these matters become of the greatest interest to the physiological chemist when we recollect that nearly all the body processes are doubtless enzymic in their character, and that the toxins or disease producers are probably chemical agents of the same class.

But it was not my intention to discuss new discoveries in chemistry. I merely wished to emphasize the fact that the fields of physical chemistry and synthetic organic chemistry are not the only ones to claim the serious thought of active investigators. I wished to suggest that the chemistry bearing on the problems of life itself presents no less interesting possibilities, and that it is worthy of more enthusiastic cultivation in our American schools. While it is doubtless true that the elementary practical instruction given in chemistry to American medical students is now equal to or possibly more systematic and thorough than that given in the majority of European schools, I wish to express the hope that in the further development of our medical colleges research work may find fuller recognition, and that in the solution of the great problems hinted at our American scholars may contribute their rightful share of effort, and in the end reap the corresponding measure of reward.

NORTHWESTERN UNIVERSITY. J. H. LONG.

SCIENTIFIC BOOKS. *Jnd.*

+ *Research Papers from the Kent Chemical Laboratory of Yale University.* Vols. I. and II. Edited by PROFESSOR FRANK AUSTIN GOOCH. New York, Charles Scribner & Sons.

The present occasion of the collected publication of these valuable papers is the coming

of the two-hundredth anniversary of the founding of Yale University. The two volumes under consideration, containing an aggregate of 108 papers and 804 pages, form part of a series of Yale Bicentennial Publications. They form also a highly creditable evidence of the chemical activity in Yale College and a worthy tribute to the memory of Albert Emmet Kent, who endowed the laboratory. They cover a period of only thirteen years, the time which has elapsed since the completion of the building.

All except three of the papers included in the volume have already appeared elsewhere, chiefly in the *American Journal of Science* and the *American Chemical Journal*; and many of them have been translated into German and have been published in the *Zeitschrift für anorganische Chemie*. Hence the contents of the volume will be no surprise to chemists; the papers consist primarily either of proposals of new analytical methods or else of careful amplifications and revisions of old methods. In every case series of test-analyses are given, performed under varying conditions; hence a clear idea is afforded of the chemical error of each process. The papers cover too wide a variety of subjects to admit of detailed mention here; iodometry receives more extensive treatment than any other one subject. The value of the collection is much increased by admirably copious classified indexes.

Besides the names of the eminent director, Dr. Gooch, and his chief assistant, Dr. Browning, those of students too numerous to mention, including four ladies, are to be found at the headings of the separate papers.

The chief lack which some will feel on studying this work is the absence of frequent appeal to modern theory for assistance. As Dr. van't Hoff has pointed out, inorganic chemistry attains its greatest significance when viewed from the standpoint of modern physical chemistry. But in spite of this lack, the careful empirical investigations are so full of essential facts that no student of analytical chemistry can afford to be unfamiliar with them. The present bringing together of the scattered articles will facilitate access to these facts.

THEODORE WM. RICHARDS.

HARVARD UNIVERSITY.

The Insect Book. A popular account of the bees, wasps, ants, grasshoppers, flies and other North American insects, exclusive of the butterflies, moths and beetles, with full life histories, tables and bibliographies. By LELAND O. HOWARD, Ph.D., Chief of the Division of Entomology, U. S. Department of Agriculture. New York, Doubleday, Page & Company. 1901.

The very complete subtitle indicates the scope of the work, and if we add that 'where possible a typical life history has been given in each family treated,' we have the leading characteristic which distinguishes it from other American works which are nominally 'popular.' Another feature of importance is that these life histories, while interestingly and entertainingly presented, are nevertheless strictly correct and scientifically accurate, in strong contrast to some other 'popular' works where vague and extravagant statements to attract the wonder-loving are relied upon to win public favor.

Dr. Howard's book, then, in its plan and in its performance stands by itself in that it makes interesting reading for him who reads merely for general information, and helps the amateur who wishes to go a little further and learn something of the classification.

But it is in this latter feature that the only notable defect in the work is found; there is no introductory chapter that familiarizes the young student with the characters referred to in the tables, nor is there any explanation of how the tables are to be used. At the bottom of page 2 the last two lines read:

"1.—Pronotum not extending back to the tegulæ
2

Pronotum extending back to tegulæ, or the latter are absent.....3"

But what a pronotum is, or what are tegulæ, has not been previously indicated and is nowhere clearly explained.

Of course there are other books that explain all this; but it is a question whether in a book of this expressed scope these tables in such form are of any real assistance to the owner. They could have been omitted without any loss whatever.

On the other hand, the chapter on collecting

and preserving insects is in all respects admirable and exactly what is needed by the tyro whom the book may interest in the subject. The ground covered by the book is so great and the general treatment is so concise and to the point that, aside from the statement that it could scarcely be better done, little remains to be said.

A book of this kind, put out in attractive form, liberally illustrated and at a really low price (\$3), will do much to create an interest in a series of insects concerning which little is generally known.

The illustrations are deserving of separate commendation. There are 264 text figures and almost without exception these are admirable. There are 48 half-tone plates, of which a fair proportion are colored, and these illustrate interestingly the limitations of this process where detail is required for identification. Nothing better has ever been done by this process and perhaps nothing better can be done. Some plates, like I. and II., are eminently satisfactory; in others, like XIV. in the same order, the majority of figures are useless for specific identification.

The book is well printed, small 4to, with xxvi + 429 pages. It contains a very complete index and a well-arranged bibliography covering the orders treated.

JOHN B SMITH.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *Journal of Comparative Neurology* for September (Vol. XI., No. 2) contains, in addition to the usual reviews of literature, but one paper, entitled, 'The Neurones and Supporting Elements of the Brain of a Selachian,' by Dr. Gilbert L. Houser, of the University of Iowa, a monograph of 110 pages, with eight plates. The entire central nervous system of the common dog shark, *Mustelus*, has been examined by a variety of the best neurological methods, both new and old, and the attempt is made to give a picture of the *complete* neurones characteristic of each important region of the brain. So far as this can be attained by the methods of Weigert, Golgi, Nissl and Haidenhain, among others, it has been quite successfully accomplished, and thus an important ad-

dition is made to our knowledge of a critical phylogenetic stage of the vertebrate nervous system. The supporting elements have been subjected to the same careful study. The phylogenetic point of view has been before the author throughout, and interesting general conclusions are suggested in connection with the various encephalic regions, notably, the problems of nerve components, the phylogeny of the cerebellum, Reissner's fiber and its associated mechanism for direct motor reflexes between the optic tectum and the body musculature, and the forebrain.

The Popular Science Monthly for September has for frontispiece a portrait of Charles Sedgwick Minot, President of the American Association, and a brief sketch of his life is to be found in 'The Progress of Science.' In the first article, 'The Greatest Biological Station in the World,' W. A. Herdman describes the Naples Station and its work in a most interesting manner, and no one could be found better capable of speaking authoritatively on the subject of zoological stations. C. K. Edmunds gives a sketch of 'Henry Cavendish,' that remarkable character known as the Newton of Chemistry, and Havelock Ellis gives the summary and conclusions of the 'Study of British Genius,' leaning towards Aristotle's dictum that 'no great genius is without some mixture of insanity.' C. B. Davenport presents a paper on the 'Statistical Study of Evolution,' the quantitative method in scientific study being one to which he has given marked attention. Robert Koch's address before the British Congress on Tuberculosis on 'The Combating of Tuberculosis' is not only very interesting but very encouraging in exhibiting the methods by which consumption may be checked. John T. Duffield describes the various steps in 'The Discovery of the Law of Gravitation,' and Byron D. Halstead discusses 'Plants as Water Carriers' and, after noting the mechanism by which this is performed, concludes that back of this is a vital force that has not been reduced to a physical or chemical basis. Edwin O. Jordan considers 'The Soluble Ferments or Enzymes,' stating that they simply influence the rate of change in any substance and do not cause the change itself. In

'The Progress of Science' is a most interesting note on Vitrified Silica.

The American Naturalist for August begins with a detailed description of 'The Texan *Kœnenia*,' by Augusta Rucker, who shows this peculiar arachnid to be distinct from the Sicilian species and names it *K. wheeleri*. Outram Bangs gives an account of 'Mammals Collected in San Miguel Island, Panama, by W. W. Brown, Jr.,' giving a list of twelve species, six of which are new and here named and described. Gary N. Calkins tells of 'Some Protozoa of especial Interest from Van Cortlandt Park,' giving a considerable amount of information regarding their habits, and Frank C. Baker discusses 'The Molluscan Fauna of the Genesee River,' showing the influence upon this of the falls of the Genesee at Rochester. Harold S. Conant describes 'The Conchometer,' a simple instrument for measuring the apical angle and length of gasteropod shells. The sixteenth part of 'Synopsis of North American Invertebrates' treats of the Phalangidæ and is by Nathan Banks, and H. L. Osborn presents some 'Variation Notes.'

The Plant World for July contains, besides a number of notes and short articles, 'The Dragon Tree of Orotava,' by Alice Carter Cook, with a fine plate of one of these curious trees, supposed to be 4,000 years old, at Teneriffe; 'Our Puffballs,' by C. L. Shear; 'A March Day's Flowers,' by Charles E. Jenney, and a biographical sketch of 'Thomas Conrad Porter,' by A. A. Heller. The supplement, 'The Families of Flowering Plants,' by Charles Louis Pollard, discusses various families of the Germinales.

The Museum Journal (of Great Britain) for August contains a report of the Edinburgh meeting of the Museums Association and prints one of the papers read there, on 'The Smallest Museum,' by Kate M. Hall. The other papers presented will appear later. The announcement is made of 'The Gift of the Horniman Museum to the London County Council.' The balance of the number is occupied with notes from various museums.

A NEW journal, entitled *Beiträge zur Chemischen Physiologie u. Pathologie*, has been estab-

lished in Strassburg under the editorship of Professor F. Hofmeister. It is to be published by F. Vieweg & Son, of Braunschweig. Twelve numbers will form a volume, to cost fifteen marks.

ACADEMIES AND SOCIETIES.

THE SUMMER MEETING AND COLLOQUIUM OF THE AMERICAN MATHEMATICAL SOCIETY.

THE Eighth Summer Meeting of the American Mathematical Society was held at Cornell University, Ithaca, N. Y., on Monday and Tuesday, August 19-20, 1901. The Third Colloquium of the Society opened on Wednesday, August 20, and extended through the remainder of the week.

About sixty persons, including forty-five members of the Society, were in attendance during the four sessions of the summer meeting. The president of the society, Professor Eliakim Hastings Moore, occupied the chair. An address of welcome by Professor L. A. Wait, representing the University, was the forerunner of a most generous hospitality extended by the University and its individual officers. Formal resolutions adopted by the Society at the close of the meeting express in part its sense of appreciation of this cordial reception.

At the meeting of the council, Dr. E. R. Hedrick, of Yale University, and Mr. S. W. Reaves, of Michigan Military Academy, were elected to membership in the Society. Twelve applications for membership were received. A committee was appointed to prepare a list of nominations of officers for the coming year.

The entire time of the four sessions barely sufficed for the presentation and brief discussion of the long list of papers. Owing to various circumstances, only two days could be devoted to the meeting, while three would not have been excessive. At future summer meetings more time must be provided. Probably the annual meeting in December will also be extended to cover two days.

The following papers were presented :

1. PROFESSOR MAXIME BÔCHER : 'On certain pairs of transcendental functions whose roots separate each other.'
2. DR. J. I. HUTCHINSON : 'On a class of automorphic functions.'

3. PROFESSOR A. PRINGSHEIM : 'Ueber den Gour-sat'schen Beweis des Cauchy'schen Integralsatzes.'
4. PROFESSOR A. PRINGSHEIM : 'Ueber die Anwendung der Cauchy'schen Multiplicationsregel auf bedingt convergente oder divergente Reihen.'
5. MR. W. B. FORD : 'On the expression of Bessel functions in terms of the trigonometric functions.'
6. PROFESSOR E. H. MOORE : 'On the theory of improper definite integrals.'
7. PROFESSOR OSKAR BOLZA : 'New proof of a theorem of Osgood in the calculus of variations.'
8. DR. G. A. BLISS : 'The problem of the calculus of variations when the end point is variable.'
9. DR. J. C. FIELDS : 'On certain relations existing between the branch points and the double points of an algebraic curve.'
10. DR. J. C. FIELDS : 'The Riemann-Roch theorem, and the independence of the conditions of adjointness in the case of a curve for which the tangents at the multiple points are distinct from one another.'
11. PROFESSOR E. B. VAN VLECK : 'A proof of the convergence of the Gaussian continued fraction

$$\frac{F(a, \beta + 1, \gamma + 1, x)'}{F(a, \beta, \gamma, X)}$$

12. PROFESSOR T. E. MCKINNEY : 'Some new kinds of continued fractions.'
13. PROFESSOR E. D. ROE : 'Note on symmetric functions.'
14. DR. G. A. MILLER : 'Groups defined by the orders of two generators and the order of their product.'
15. DR. H. F. STECKER : 'On the determination of surfaces capable of conformal representation upon the plane so that the geodetic lines shall be represented by a prescribed system of plane curves.'
16. MR. C. N. HASKINS : 'On the invariants of quadratic differential forms.'
17. DR. EDWARD KASNER : 'The cogredient and digredient theories of double binary forms.'
18. PROFESSOR MAXIME BÔCHER : 'On Wronskians of functions of a real variable.'
19. MR. F. G. RADELINGER : 'The analytical representation of a multiform function in the domain of an isolated singular point.'
20. DR. VIRGIL SNYDER : 'On the forms of unicursal sextic scrolls with a multiple linear directrix and one double line.'
21. DR. H. F. STECKER : 'Concerning the osculating plane of m -fold space filling curves of the Hilbert-Moore type.'
22. DR. H. F. STECKER : 'On non-euclidean properties of plane cubics and of their first and second polars.'
23. PROFESSOR L. E. DICKSON : 'Theory of linear groups in an arbitrary field.'

24. MR. H. L. RIETZ : 'On primitive groups of odd composite order.'

25. MISS I. M. SCHOTTENFELS : 'On the non-isomorphism of two simple groups of order $8! / 2$.'

26. PROFESSOR L. W. DOWLING : 'On the generation of plane curves, of any order higher than four, with four double points.'

27. PROFESSOR L. E. DICKSON : 'The configuration of the 27 lines on a cubic surface and the 28 bitangents to a quartic curve.'

28. PROFESSOR E. H. MOORE : 'Concerning the second mean value theorem of the integral calculus.'

29. DR. I. E. RABINOVITSCH : 'The application of circulants to the solution of algebraic equations.'

30. M. EMILE LEMOINE : 'Note sur la construction approchée de π de Mr. George Peirce.'

31. DR. C. W. MCG. BLACK :

32. PROFESSOR ALEXANDER PELL : 'Some remarks on surfaces where first and second fundamental forms are the second and first respectively of another surface.'

At the Colloquium, which was attended by twenty-three persons, two courses of four lectures each were presented :

PROFESSOR OSKAR BOLZA : 'The simplest types of problems in the calculus of variations.'

PROFESSOR E. W. BROWN : 'Modern methods of treating dynamical problems, and in particular the problem of three bodies.'

It is hoped that these lectures may be published in complete form. A summary of them will appear in the *Bulletin*.

The next meeting of the Society will be held in New York, on Saturday, October 26.

F. N. COLE,
Secretary.

PALEONTOLOGICAL NOTES.

VERTEBRATES FROM THE TRIAS OF ARIZONA.

As recently noted in SCIENCE, Mr. Barnum Brown was engaged during May and June of this year in making collections for the U. S. National Museum from the Trias of Arizona. The exploration was undertaken in the hope of obtaining ancestral forms of the Stegosaurus, and while unfortunately this hope was not realized much interesting material was obtained, although, like most Triassic specimens, in a very fragmentary condition. A large share of this represents the large Belodont from the Trias of Utah, described by the writer under the name of *Heterodontosuchus ganei*, and comprises frag-

ments of the skull, numerous dermal plates, many vertebræ, all badly broken, and portions of the pelvis and limbs, besides an absolutely complete humerus, ulna and scapula. That this last bone should have escaped destruction, while others far more solid were shattered and scattered beyond redemption, is one of the many puzzling facts that come under the notice of paleontologists. Associated with the Belodont are some bones of a Dinosaur, and as a few teeth referable to the genus *Palæoctonus* of Cope are present they also probably belong to that genus. A humerus has the deltoid and other muscular ridges remarkably well developed, indicating a reptile of the strength and agility that one might expect from the owner of such teeth; it is nearly solid and smaller than might have been expected from the size of the teeth.

In a bed of conglomerate Mr. Brown obtained a number of more or less fragmentary bones, which from the shape of some associated scutes apparently belong to Cope's *Episcopsaurus*. These specimens, and the clayey matrix containing them, are unluckily thoroughly permeated with alkali, which will make their preparation, or even preservation, a matter of difficulty.

Perhaps the most interesting of the specimens are the deeply sculptured ventral plates of some extremely large Labyrinthodont. The interclavicle, which is complete, is 40 cm. long, and 30 cm. broad, 16 by 12 inches, about the size of the corresponding bone in the European *Mastodonsaurus*. It may be of interest to note that when in Washington this spring Dr. Eberhard Fraas identified a fragment of a cranial plate from the same locality as the above as belonging to this genus.

It will be seen that all the species obtained are typically Triassic, the Belodont and *Mastodonsaurus* preeminently so.

F. A. LUCAS.

THE APPROACHING MEETING OF THE BRITISH ASSOCIATION.

THE British Association—for so it is universally called in Great Britain without any further specification, a testimony to its supremacy among associations—meets at Glasgow on Sep-

tember 11, and a comparison of its work with that of our own Association may be of use. As a rule the addresses of the president and of the presidents of the sections are better suited to their purpose than those of our own officers, although this year there is no reason to avoid a comparison. Indeed it seems evident that in recent years the general addresses before our Association have improved both in substance and in form, being addressed to a wide audience rather than to a few specialists. In regard to the proceedings of the sections, the American Association is on the whole the leader. There are usually at the British Association several eminent men of science, who take a prominent part in the proceedings, but the average number and average importance of the papers presented are probably less than in the case of the American Association. Thus at Denver over two hundred papers were presented; and their quality will compare favorably with those that will be presented at Glasgow. The social entertainments and excursions of the British Association are usually superior to ours. Owing to the interest taken in science by the upper classes in Great Britain, it receives a more marked social recognition than is the case in this country. This, however, is not a matter of great importance; and the British Association has doubtless never been entertained more generously than was the American Association at Denver. The British Association is certainly fortunate in securing the support of a large body of members, especially of annual members. Thus three previous meetings have been held at Glasgow. In 1840, there were in attendance 1,393 members; in 1855, 2,159, and in 1876, 2,800. These members were, however, chiefly local citizens who took an interest in science, attended the meetings and subscribed \$5 to support the Association. On the other hand, the American Association has a much larger proportion of scientific men in attendance; and the British Association has certainly never had an accession of nearly 1,200 permanent members, chiefly scientific men, in the course of a year, as has occurred with the American Association during the past year.

At the meeting of the British Association that opens next week, Professor A. W. Rücker,

the eminent physicist, recently elected to the presidency of the University of London, will preside and will deliver the inaugural address. The public lectures will be by Professor W. Ramsay, who has chosen as his subject 'The Inert Constituents of the Atmosphere,' and by Professor Francis Darwin on the 'Movements of Plants.'

The addresses of the presidents of the sections, for the preliminary announcement of which we are indebted to a forecast printed in the *London Times*, are as follows: In Section A (Mathematical and Physical Science), the president, Major P. A. MacMahon, will first give an account of the Mathematical Society of Spitalfields, 1717-1845; and, after some remarks upon the present state of mathematics and physics in Great Britain and the teaching of those subjects, will conclude by considering the work of a specialist in science and especially of a mathematical specialist, in relation to the general advance of scientific knowledge. The title of the address which will be delivered by Professor Percy Frankland, F.R.S., president of Section B (Chemistry), is 'The position of British chemistry at the dawn of the twentieth century.' He proposes drawing attention to the factors which have been instrumental in promoting the growing activity in original investigation during the past 20 years. Coming to the present time he will point out the disadvantages under which students of chemistry labor at the universities, and will indicate some of the more important reforms which he considers desirable in the immediate future. The president of Section C (Geology) is Mr. John Horne, of the Geological Survey Office, Edinburgh, who has chosen as the subject of his address, 'Recent advances in Scottish geology.' He proposes to review the progress of Scottish geological work since the last meeting of the Association in Glasgow. In Section D (Zoology), Professor J. Cossar Ewart will probably take the opportunity afforded him in his presidential address of summarizing the results of the long series of experiments he has been carrying out at Pennycuik in connection with the subject of inheritance and telegony. Dr. Hugh Robert Mill is the president of Section E (Geography), and in his address will deal

with research in geographic science. He will argue that geography deals with the forms of the crust of the earth and the influence which these forms exert on everything free to move on the surface. In his presidential address to Section F (Economic Science and Statistics) Sir Robert Giffen proposes to discuss the increase in population during the last 100 years in the chief European countries, in the United States, and in the English-speaking colonies. Among the topics referred to will be the changes in the relative position of European States to each other and to the United States in consequence of the differences in the increase of their population; the increasing dependence of other European countries besides the United Kingdom on supplies of food imported over sea, and the question whether changes in the rate of growth of population in recent years are likely to modify in a material degree the present relative development of the countries in question. Section G (Engineering) will be presided over by Colonel R. E. Crompton, who will first deal with the probable future development of passenger and goods transport as affecting railways, tramways and ordinary roads, and will then touch on the standardizing of parts of machines to facilitate manufacture, concluding with a consideration of the National Physical Laboratory.

In Section H (Anthropology) Professor D. J. Cunningham, F.R.S., of Trinity College, Dublin, will devote his address to a consideration of the part which the brain has played in the evolution of man, especially the structural changes in the brain which have rendered the associated movements required for articulate speech possible, and to arguing that the acquisition of speech has afforded the chief stimulus to the general development of the brain. In his presidential address to Section I (Physiology), Professor McKendrick will briefly pass in review the advance in our knowledge in this branch of science during the past quarter of a century; and he then proposes to discuss some of the problems of what may be called molecular physiology, more especially the question of how many organic molecules may be contained in the smallest particle of living matter, and whether in the ovum, for example, there

is a sufficient number of molecules to account for the facts of hereditary transmission. Professor I. Bayley Balfour is president of Section K (Botany). He will deal in his address with the construction of flowering plants, with the intention of showing that they owe their position as the dominant vegetation of the present epoch to their having solved best the problem of adequate water-carriage. The new Section L (Educational Science) is under the presidency of Sir John Gorst. The subject of his address has not been announced.

SCIENTIFIC NOTES AND NEWS.

THE Reale Accademia de Lincei of Rome has elected the following foreign members: Emile Picard, professor of higher algebra at the Sorbonne; Edward C. Pickering, director of the Harvard College Observatory; Samuel P. Langley, secretary of the Smithsonian Institution; J. H. Van't Hoff, professor of general chemistry in the University of Berlin; Heinrich Karl Rosenbusch, director of the Mineralogical and Geological Institute of the University of Heidelberg; Charles D. Walcott, director of the U. S. Geological Survey; Theodor Engelmann, of the Imperial Board of Health at Berlin; and Charles Richet, professor of physiology at the University of Paris.

ON the application of the Government of Victoria, Australia, for a director of agriculture, officers of the U. S. Department of Agriculture have recommended Professor B. T. Galloway, chief of the Bureau of Plant Industry, and Professor Willett M. Hays, agriculturist of the Minnesota Experiment Station.

DR. SANTOS FERNANDEZ, president of the third Pan-American Congress held recently at Havana, has been presented by the members of the medical profession in that city with a gold medal in recognition of his efforts to advance medical science in Cuba.

THE Alverenga prize of the College of Physicians and Surgeons of Philadelphia has been awarded to Dr. George W. Crile, of Cleveland, Ohio, for his essay entitled 'an experimental and clinical research into certain problems relating to surgical operations.'

THE Belgian government has awarded its an-

nual prize of 5,000 francs for the best work in the province of medical research to Dr. A. van Gehuchten, professor of systematic anatomy in the University of Löwen, for his researches on the human brain and spinal cord.

DR. WILLIAM HUNTER has been appointed assistant director of the Pathological Institute of the London Hospital.

As we have already announced Dr. David Starr Jordan, president of Stanford University, Dr. Barton W. Evermann, ichthyologist of the U. S. Fish Commission, and Dr. W. H. Ashmead, of the U. S. National Museum, who spent the summer in the Hawaiian Islands investigating on behalf of the U. S. Government the fishes and other aquatic resources of the Islands, returned to the United States early in August. The other members of the party will return in September, except Messrs. L. E. Goldsborough and George Sindo, who will go to Pago Pago in the Samoan Islands to make a collection of the fishes found there. The investigations proved very successful. The fishery methods, laws and statistics were carefully studied and large and important collections of the fishes were made. Upwards of 300 species were obtained, among which are many species new to science. Drs. Jordan and Evermann will soon submit a preliminary report to the Commissioner of Fish and Fisheries. The final report will not be made until more deep-sea work has been done about the islands.

MR. JOHN HYDE, statistician of the Department of Agriculture, has returned from Europe where he went to arrange with the agricultural bureaus of the leading countries for an interchange of crop reports by cable. His negotiations were successful and the plan will be in working order next year. He also investigated European methods of crop reporting, but found that they were less advanced than our own.

MR. PERCY WILSON, attached to Professor Todd's Eclipse Expedition to the East Indies, returned to the New York Botanical Garden on August 18, bringing a large collection of vegetable products for permanent exhibition from Singkep, Riouw, Malacca, Siam, Batavia, and the botanical gardens of Buitenzorg and

Singapore. Mr. Wilson has been absent with the expedition since March 2.

REUTER'S Agency states that a cablegram has been received by the Liverpool School of Tropical Medicine from Sierra Leone announcing that Major Ronald Ross is returning to England by the steamship *Phillippeville*, which was due to leave Sierra Leone on August 18. He is returning temporarily for the purpose of arranging for the despatch of an expedition, similar to that now under his charge, to the Gambia and the Gold Coast. In Major Ross's absence the work of the expedition in Sierra Leone is proceeding under the charge of the other medical men. During his present visit to the West Coast, Major Ross has been to the Gambia, Sierra Leone, the Gold Coast and Lagos.

M. A. TOURNOÛER has undertaken an expedition to Patagonia, under the auspices of the French minister of public instruction, with the purpose of continuing his researches on the tertiary mammals of South America.

A MEETING in memory of the late Professor Joseph Le Conte was held by the faculty and students of the University of California on August 21. The exercises were opened by President Wheeler, and speeches were made on behalf of the alumni by Dr. William E. Ritter, professor of zoology, and on behalf of the students by Ralph T. Fisher, former president of the Associated Students of the University of California. The College of Social Science was represented by Professor Irving Stringham, and Professor J. M. Stillman, of Stanford University, spoke as a former pupil of Professor Le Conte's. The closing address was by the Hon. Horace Davis, former president of the University of California, whose concluding words were:

The power of such a life is hard to estimate. For thirty years his name has been a tower of strength to the University, not simply for his scientific fame and intellectual attainments, but even more for his moral strength and beauty. His life has been woven into thousands of young expanding lives in this western commonwealth, and his cheerful hopes have lighted up their homes. The power of such a life cannot be estimated. You have felt it. I have felt it, and the world is better that he has lived.

Professor Edward R. Taylor then read an original sonnet entitled 'Le Conte and the Yosemite,' and the proceedings were brought to a close with selections of instrumental and choral music.

THE bust of Dr. G. Armauer Hansen, the discoverer of the bacillus of leprosy, was unveiled by Professor Visdal in the garden of the Museum at Bergen on August 10. The chief address was made by Professor Oskar Lassar, of the University of Berlin. Congratulatory addresses were received from all parts of the world, and the decoration of Commander of the Order of Ola was conferred on Dr. Hansen by the king of Norway. Dr. Hansen celebrated his sixtieth birthday on July 29.

It is announced in *Nature* that it has been decided to erect in Leoben, Austria, a statue of Peter Ritter von Tunner, who died on June 8, 1897, to commemorate his great services to the metallurgy of iron. A committee has been formed, with Mr. Ignaz Prandstetter as president, Professor J. G. von Ehrenwerth as vice-president and Professor Carl Fritz as honorary secretary, to collect subscriptions. At a recent meeting of the council of the British Iron and Steel Institute the matter was considered. As a contribution to the memorial could not be voted from the funds of the Institute, the members of council present decided to contribute two guineas each, and Mr. Bennett H. Brough, the secretary, has forwarded to the committee in Leoben contributions amounting to about \$230.

The British Medical Journal states that for the celebration of the eightieth birthday of Professor Virchow on October 13, a committee has been chosen for Switzerland, consisting of Professor Kocher, of Berne, representing the Swiss medical commission, Professor von Carenville, of Lausanne, who represents the Medical Society of French Switzerland, Dr. Haffter, of Frauenfeld, representing the Central Medical Society, and Dr. Reali, of Lugano, representing the Medical Society of Italian Switzerland. Professor Sklifasowski having been incapacitated by illness, Professor Tarantzi, head of the Medical Academy of St. Petersburg, has been chosen president of the Russian committee in his place.

AMONG the numerous greetings from all parts of the world addressed to Professor Süss, the eminent Australian geologist, paleontologist, and politician, on the occasion of his seventieth birthday, says the London *Times*, is one from the Geological Society in London. He was elected a foreign correspondent of the Society in 1863 and foreign member in 1876, while 20 years later it bestowed upon him its highest geological distinction, the Wollaston medal. The telegraphic congratulation of the Society concludes as follows: "Universally regarded here as the greatest living geologist, whose epoch-making work will bear fruit in the field of science for generations to come. Warmest congratulations and best wishes from British colleagues." To his own countrymen Professor Süss has been not only a distinguished pioneer in science. He has been an example of enlightened patriotism and devotion to the public welfare and an indefatigable reformer, whose works will remain a monument to his memory.

DR. THOMAS MASTERS MARKOE, the eminent surgeon, died on August 27, aged eighty-two years. Since 1860, Dr. Markoe had been connected with the College of Physicians and Surgeons of Columbia University as adjunct professor and professor of surgery and later as professor of the principles of surgery.

MR. ALBERT NELSON CHENEY, fish culturist of New York State, died at his home in Glen's Falls, N. Y., on August 18, aged about fifty years. He was the author of many contributions on pisciculture.

THE death is announced of Dr. Leroy Méricourt at the age of seventy-five years. Dr. Méricourt is known as one of the reorganizers of the French naval medical service and for his writings upon tropical medicine and hygiene. He was a chevalier of the Legion of Honor, a member of the Academy of Medicine and one of the founders of the *Archives de médecine navale*.

MR. ANDREW CARNEGIE has given £7,500 to Rutherglen, Lanarkshire, Scotland, for a public library and £10,000 to Motherwell, Lanarkshire, for a town hall. Gifts for libraries, under the usual conditions, of \$25,000 and \$37,000 are reported from Beloit, Wis., and Moline, Ill., respectively.

ACCORDING to the *N. Y. Medical News* a systematic plan for the extermination of mosquitoes has been inaugurated by the residents on the north shore of Long Island from Roslyn to Huntington. The immediate work to be undertaken will be in charge of Messrs. A. C. Weeks and F. E. Lutz, of the University of Chicago, who will work in conjunction with Dr. Chas. B. Davenport, director of the Biological Laboratory of Cold Spring Harbor.

It has been decided that the commission to be sent out by the Liverpool, Manchester and London Chambers of Commerce to investigate the conditions of health and sanitation in West Africa shall consist of one member from each of the three chambers of commerce and of a sanitary engineer. In addition, Major Ronald Ross has been requested to attach himself to the commission as expert in tropical medicine.

WE learn from the *Lancet* that legal authority has been given for the creation of a fund for scientific research in France. It is divided into two sections, and its object is the promotion of purely scientific work relative (1) to the discovery of new methods of treatment of the diseases which attack man, domestic animals, and cultivated plants; and (2) to the discovery, apart from the medical sciences, of the laws which govern natural phenomena (mechanics, astronomy, natural history, physics and chemistry). The income of the fund will be derived from the following sources: (1) Grants made by the government, by the departments, by the communes, by the colonies, and by other sections of the population. (2) Gifts and bequests. (3) Individual or collective subscriptions. (4) Grants deducted from the proceeds of the *pari-mutuel* assigned to philanthropic or charitable purposes locally; the annual amounts of these grants, which will not be less than 125,000 francs, will be fixed each year on the application of the council of management by the special commission held at the Ministry of Agriculture. (5) Interest of money invested in government securities or deposited with the treasury. The fund is subject to the authority of Ministry of Public Instruction, and is managed by a council assisted by a technical commission concerned with the grants.

Nature states that a committee has been appointed by the president of the Board of Trade to inquire and report as to the best means by which the state or local authorities can assist scientific research as applied to problems affecting the fisheries of Great Britain and Ireland. The members of the committee are as follows: The Right Hon. Sir Herbert Maxwell, Bart.; Mr. Walter E. Archer, Mr. Donald Crawford, Rev. William Spotswood Green, Professor William Abbott Herdman, the Hon. Thomas H. W. Pelham, Mr. Stephen E. Spring-Rice, C.B., and Professor J. Arthur Thomson.

THE daily papers report the death from yellow fever of two men and one woman who permitted themselves to be bitten by infected mosquitoes in order to become immune. It should be understood that the trials were not made in order to test the communication of yellow fever by mosquitoes, but they are certainly very convincing evidence. It is further reported that the yellow fever commission regards the experiments with the Caldas serum as having demonstrated its uselessness and will not supervise any further experiments conducted by Dr. Caldas.

THE *Lancet* states that the proposal to establish a central pathological laboratory in connection with the lunatic asylums of Ireland has taken practical shape by the insertion of a permissive clause in the lunacy bill which has just passed. According to it the committees of any two or more district asylums may, with the consent of the county council, agree to unite 'in providing and maintaining a laboratory for pathological research in connection with insanity and nervous diseases,' and the committees of those institutions may defray the expenses incurred.

A GOVERNMENT laboratory for experimenting with explosives is to be built at Sandy Hook at a cost of \$10,000.

REUTER'S Agency announces that the expedition under Captain Stoekken arrived at Christiania on August 17, after having explored the south coast of Franz Josef Land. The expedition found no trace of the three lost members of the Duke of the Abruzzi's expedition. The memorial presented by the Duke was erected on Cape Flora.

ACCORDING to the daily papers the steamer *Frithjof* arrived at Hammerfest on August 29 and reported that the Baldwin-Ziegler arctic expedition had been landed at Camp Ziegler, in latitude 90.24° north and longitude 55.52° east, on Alger Island. All the members of the expedition were in good health. Mr. Baldwin intended to start northward on August 24, by the interchannel route, across Markham Sound. We record the movements of this arctic expedition with some hesitation, as it has but little claim to be called scientific. Mr. Baldwin contributes to the last number of *McClure's Magazine* what is said to be the only authorized account of the aims of the expedition. He enlarges on his intention to reach the pole and describes in detail the number of tons of provisions of different kinds provided by the liberality of Mr. Ziegler, but does not mention the names of the members of the scientific staff. Still valuable scientific knowledge may be secured, and even voyages of adventure have some relation to the advancement of science.

THE Italian government has established laboratories of micrography and bacteriology and chemistry as dependencies of the Sanitary Bureau. According to the *British Medical Journal* a department of the bacteriological laboratory is to be devoted to the preparation and control of serums and similar products. The professional staff of the bacteriological laboratory consists of a director, with a salary of \$1,200; a coadjutor, with \$800; and two assistants, with \$500 each. For the serum department there are medical and veterinary coadjutors, each with a salary of \$800 and three assistants at \$500 each. The staff of the chemical laboratory is paid on the same scale.

THE National Good Roads Association of the United States has called an International Congress of Good Roads, to be held in Buffalo, September 16-21. All sessions of the congress will be held during the Pan-American Exposition. It is designed to devote a portion of the time included in the dates above named to demonstrate the scientific methods of modern road construction by building sections of the various classes of roads, including earth, oil, gravel, stone, tar-macadam, vitrified brick, etc.

A railroad train equipped with modern road-making machinery will be on exhibition, and practical road experts and engineers will have charge of the work. The scope of the deliberations of the congress will include general discussion and exemplification of the science of road construction and maintenance, together with experimental tests and experience of the several countries of the world and the states of the Union. Addresses will be made by prominent statesmen and officials, competent engineers, and scientific road experts from various nations.

According to the *Medical News* several members of the Chicago Sanitary District Board are said to have suppressed the reports showing the self-purification of running streams. After having appropriated \$2,500 for the preparation of the report and after having authorized its publication, they are said to have taken steps to keep it from being made public. The circumstance was brought to the surface when President Alexander J. Jones was asked to permit access to the report by several expert chemists who spent months making an examination of the waters of the drainage canal and the Illinois river. The experts are Professor E. O. Jordan, of the University of Chicago, Professors Palmer and Burrill, of the University of Illinois, and Professor Adolph Gehrmann, of the city laboratory. Political jealousy, lest the publication should reflect too much credit upon city officials, is alleged to have been the chief motive which actuated the suppression. The suggestion as to this motive comes from officials of the City Health Department. President Jones declares that the report was suppressed so that the material in it could be used by the sanitary district in its defense against the attempts of the city of St. Louis to have the drainage canal closed by the courts. Should the report become public, says President Jones, its value as a defense would be injured. The suppressed report is said to show that the waters of the drainage canal are not polluting the waters of the Illinois River and that the alarm of St. Louis is unfounded. Before the waters of the river reach Peoria they are said to be absolutely pure. At that point they are contaminated by the Peoria distilleries. The river again becomes perfectly pure many miles

north of the junction with the Mississippi River. Trustees of the sanitary district are pleased with the action of the War Department in issuing orders to allow a swift flow of water through the canal during eight hours of the day. The hours specified are between 4 p. m. and midnight, and the flow allowed is 300,000 cubic feet a minute, instead of 200,000 cubic feet, as is allowed during the remainder of the day.

THE Report on the Observatory Department of the National Physical Laboratory for the year 1900 has been published in the *Proceedings* of the Royal Society. According to an abstract in *Nature* the magnetographs have been in constant operation throughout the year, but the curves have been quite free from any large fluctuations. The mean westerly declination for the entire year was $16^{\circ} 52'.7$. The automatic and tabulated records of the various meteorological instruments have been transmitted, as usual, to the Meteorological Office, to be dealt with in its publications, and special cloud observations have been made each month in connection with the international scheme of balloon ascents. Seismological observations have been regularly made; two noticeable disturbances occurred during the year, on January 20 and October 29. A detailed list of the movements of the seismograph will be published in the Report of the British Association for the present year. As regards experimental work, the observation of distant objects during mist and fog and researches upon atmospheric electricity, referred to in previous reports, have been regularly continued. The list of the various instruments tested is a very long one. Some of the cases in which a considerable increase has occurred are: Aneroids and marine barometers (number tested in year 1900), 336 (increase 69); compasses, 963 (increase 559); rain gauges, 1,345 (increase 784); clinical thermometers, 20,476 (increase 4,456); total number of instruments tested, 27,569 (increase 5,518). The principal addition to the staff during the year has been the appointment of Dr. J. A. Harker as an assistant in the laboratory.

In an interview with a representative of the *London Times*, Professor Otto Nordenskjöld, who is at present staying at Malmö in order to

make arrangements for his antarctic expedition, made the following statement: "As soon as the *Antarctic* returns from the expedition which she has made to Spitzbergen for meridian measurements—and it is calculated that she must be on her homeward journey by September 15—we start from Göteborg. The time of our departure cannot, of course, be definitely fixed, for unforeseen hindrances may arise; but we shall certainly be able to weigh anchor by about October 1. From Göteborg we shall proceed to England, and thence to Buenos Ayres and Tierra del Fuego, whence we shall make our way to the antarctic regions. We shall endeavor to push as far south as possible with the *Antarctic*; and, when winter comes on, we shall send a party on shore to winter. That party will probably consist of six persons, of whom I shall be one. We shall build a small hut for ourselves, and engage in meteorological, magnetic, hydrographic and other scientific observations. As soon as we have landed, the *Antarctic* will return to Tierra del Fuego; and a scientist, who will sail with her, will conduct the researches in that hitherto little explored country. In this way we shall be able to work in two detachments, and make as much use of our time as possible. As is well known, an English and a German South Polar expedition are also being sent out at the same time. In order to avoid clashing with one another, these three expeditions have come to an agreement whereby we explore the region south of the Atlantic Ocean, the Germans that south of the Indian Ocean, and the British that south of the Pacific Ocean. Naturally we cannot advance so far towards the South as towards the North Pole, but the scientific results must be great, and we are well equipped for scientific research. I shall have some able scientists with me. Professor Ohlin, of Lund, the well-known explorer, and M. K. A. Andersson will accompany me as zoologists. Dr. Bodman will come as hydrographer and magnetician, M. Skottoberg as botanist, and Dr. E. Ekolof as medical officer. The Norwegian, Captain Larsin, who has already made several voyages to South Polar regions, will be in charge of the *Antarctic*."

A CORRESPONDENT of the *London Times* reports that a discovery of flint implements has lately

been made on the estate of the Marquis of Ailesbury at Knowle Farm, on the borders of Savernake Forest. A gravel pit was opened a short time ago close to the farm buildings, and the implements have been found at various depths, some embedded in coarse gravel and silt and others in dark red clay, at a depth in some instances of 8 feet to 10 feet from the surface. The ground is at least 450 feet above sea-level, and it would seem that at the particular place where the gravel occurs two or three streams must have met which had had their courses through the forest and were making their way to the valley of the Kennet, some three or four miles to the southeast. There is now no stream of water in any part of the forest, and besides this there is nothing to indicate in the present configuration of the ground the source from whence the water by means of which the valleys were eroded could have come. It is only by imagining an entirely different face to the country (such as might have been if the valleys had been eroded before the formation of the Pewsey Vale, some three or four miles to the southwest) that an origin for the streams in these forest valleys can be conceived. Between 200 and 300 implements have already been found, many of them of beautiful workmanship, while others are very rude and apparently unfinished. Whether these latter belong to the earlier 'Eolithic' period and have been washed out of earlier beds of gravel and deposited with implements of a later date (as appears to have taken place on the plateaus in Kent) is a point to be decided hereafter; but it is very difficult to imagine those rude implements to have been manufactured by the same race of people as have made and finished with so much care those apparently lying by their side. Most of the implements are of very superior flint, extremely hard in texture; one or two may be of chert, and one appears to be of 'Sarsen' stone, and they bear a marked similitude to those found at St. Acheul in the valley of the Somme. Many have been rolled and have lost all their sharp edges, while others appear to have been made on the spot and to have had but little use before they were embedded in the stiff clay where they are now found. Some are

very finely polished, as if from the constant rubbing of blown sand, and have an appearance as if coated with glass. They are of all sizes and shapes, some from 5 in. to 6 in. long, generally of a rough, unfinished type; others 3 in. to 4 in. long, of the common spear-shaped form; others of the well-known ovoid form; and others pointed as if to be used as drills. One or two paleolithic implements have been previously found in the locality; but the occurrence of them in such large numbers as these at Knowle is quite new to the district.

UNIVERSITY AND EDUCATIONAL NEWS.

THE University of Edinburgh receives £5,000 by the will of the late Miss Eleanor Omerod, the entomologist.

THE *Educational Review*, which each year carefully compiles a black list of the institutions that offer the degree of Ph.D. *honora causa*, finds this year only two such institutions—Bethany College and Dickinson College.

DR. J. W. BASHFORD, president of the Ohio Wesleyan University, who, as we reported last week, has been offered the presidency of the Northwestern University, has decided to remain with the former institution at the urgent request of the trustees.

DR. A. W. HARRIS, president of the University of Maine, has resigned in order to accept the position of director of the Jacob Tome Institute at Fort Deposit, Md.

DR. A. P. OHLMACHER, director of the pathological laboratory of the Ohio Hospital for Epileptics at Gallipolis, Ohio, has been appointed professor of pathology in the Medical School of Northwestern University.

ALBERT HENRY YODER, A.B. (Indiana), has been appointed professor of pedagogy at Washington University.

MR. R. K. McCLUNG has been awarded an exhibition scholarship of 1851 by McGill University. He will go to Cambridge University to study under Professor J. J. Thomson.

AT Hartley College, Southampton, Dr. J. T. Jenkins has been appointed lecturer in biology and geology, and Mr. J. D. Coates assistant lecturer in physics and electrical engineering.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

THE CARNEGIE TECHNICAL SCHOOL.*

It was the intention of your vice-president to prepare an address on the Evolution of the Mechanics of the Telescope for pre-

*Address of the vice-president and chairman of Section D, Mechanical Science and Engineering, of the American Association for the Advancement of Science, Denver meeting, August, 1901.

sentation before Section D of this Association, but a new and important theme has been brought before me by reason of intimate association therewith, and to which a number of the members of this Section have contributed most valuable data. I therefore beg to present to you a few notes upon this subject, namely, the technical school for which Mr. Andrew Carnegie has most generously proposed to furnish the means to build, equip and endow in the city of Pittsburg. When Mr. Carnegie gave to the city its library, its art gallery, its temple of music and its museum, neither the donor nor the citizens had the remotest dream of what they would develop into, nor how far their influence would reach and be felt. I need not tell you what potent factors these institutions have been as educators in the realms of art, science and literature. Suffice it to say, that every department of the great institute has proved itself worthy of its name and is doing marvelous work for the betterment of the people. So marked has been this development during the six years of the existence of the Pittsburg Institute that Mr. Carnegie has given over three million dollars to enlarge its boundaries and increase its influence.

But Mr. Carnegie had promised even greater things for the city of his adoption. He knew as well as any man the need, the great value of a school of technology in

Pennsylvania's great hive of industry ; and with but little preliminary discussion of the subject, with full confidence in the commission that had been entrusted with the building, care and development of the Pittsburgh Institute, he proposed to furnish the means to build, equip and endow a school of technology on the broadest possible basis, whose doors should be open not only to students from western Pennsylvania, but eventually to students from any part of the world.

President Frew of the Carnegie Commission appointed two committees : (A) A committee to confer with the city officials in reference to a site for the building, etc. (B) A committee on 'Plan and Scope' of the proposed technical school. On this latter committee President Frew appointed the following gentlemen :

President Wm. McConway, of the McConway, Torley Manufacturing Co. ; Chas. M. Schwab, president Carnegie Steel Co. ; Wm. A. Magee, 'Times Publishing Co.' ; Hon. Wm. A. Diehl, Mayor of Pittsburgh, and John A. Brashear.

After a series of important meetings in which the best plan of procedure was carefully discussed, Mr. Schwab found it necessary to resign as a member of the committee, as he had been called to the position of president of the United States Steel Co. The resignation of Mr. Schwab was greatly regretted, as he has had large personal experience in technical and manual training schools, having built and endowed a splendid school in Homestead, Pennsylvania, in the very center of the great steel industries. Mr. W. Lucien Scaife was appointed to fill the place made vacant by the resignation of Mr. Schwab. He is a graduate of the Sheffield Scientific School and has studied in the technical schools of France and Germany, and his technical and practical knowledge has proved of great value in the deliberations of the committee.

After a careful discussion of the plan of procedure it was decided to call to our assistance a number of the best men on technical lines in the country, rather than one man, no matter how thoroughly he might be posted in technical school matters, for the one man might have a bias, either of education or environment, which, while it possibly would be in the direction of the very best plan and scope for the new school, might be detrimental to its highest development ; and in this important matter it was concluded that in the 'multitude of counselors' there ought to be wisdom. The committee therefore called to its assistance, Dr. Robert H. Thurston, Professor J. B. Johnson, Dr. Thomas Gray (all members of Section D of the Association) and Dr. Victor Alderson, acting president of the Armour Institute of Chicago. These gentlemen were to come to Pittsburgh last spring to study the conditions and environment which would necessarily be important factors in formulating the plan and scope of the new school and, after several pleasant meetings with our own committee, arranged to return to Pittsburgh on the 24th of June to make at least a preliminary, if not comprehensive and final report. In the meantime the original committee found much work to do, for communications were coming from eminent technologists, technological societies, domestic art associations, educators in manual training schools and mechanical engineers, all of which contained much good grain, with here and there a hobbyist whose theories were mixed with a good deal of chaff ; but on the whole we found a widespread interest in the development of what, let us hope, will eventually become one of the best institutions for technical instruction in this good land of ours. It is for the purpose of leading the members of this Section of the American Association to take an interest in the new school, that this paper is written. It contains no new

thought, no new theories, but calls for your help in a project which we believe will be for the betterment of a large class of students, whose means are necessarily limited, but who will be, let us profoundly hope, mighty factors in the future development of American technological and allied industries.

If we are to keep fast hold of the prestige we have gained in the industrial world by hard work and persistent effort, we must open the storehouse of knowledge to our future mechanics, engineers, etc., give them an opportunity to partake of the treasures stored therein, and we shall have no fear of the position we are to occupy in the coming years.

Our advisory committee, having studied the problem from many points of view, met with us in Pittsburg on the twenty-fourth of Junelast, each member having formulated his plans without consultation with other members of the committee, yet it is a matter of interest to know that the expressed views of the advisory board as individual members were so nearly in accord on the general principles formulated for the great school of technology. Of course with such a field to work upon, there were a number of most valuable suggestions made by the individual members of the board, all of which will be of use to our committee in making up its report to the commission.

With your permission, and I am sure with that of the several members of the advisory board, I will give as briefly as possible an outline of the scheme for the new technical school.

First, as to site. The Carnegie Institute is situated in Schenley Park; and it was thought desirable by Mr. Carnegie and members of the commission to secure, if possible, enough ground near the Institute for the technical school. A tract of eleven acres was the only available land in the Park, but this was at once pronounced far

too limited in extent for the new school; indeed the first plan of buildings, campus, etc., submitted by Mr. Emil Swensson, of the Carnegie Steel Co., covered 40 acres and this for not more than one thousand students. The advisory board suggested that not less than 50 acres be secured, and as a tract of 65 acres is available not far distant from the Carnegie Institute, the board strongly recommended its purchase, or a similar piece of land as near by as it is possible to obtain it. A potent reason for placing the technical school near the Carnegie Institute is the fact that its library is rich in technical and other valuable works, which need not be duplicated in the technical school library; indeed the association of the school with the great and increasingly valuable library, museum, art gallery and Academy of Science and Art is certainly to be desired. In this connection it may be well to state that it was the intention of the donor that the city should furnish the land upon which the school of technology should be built, but it is the unanimous opinion of the advisory board that, as Mr. Carnegie not only proposes to build and equip but fully to endow it, it would be far better to purchase the land and thus, while bringing to the city of Pittsburg all the honor such a school of technology would bring, keep it forever free from baneful political influences. Dr. Gray says in summing up his report: "Such an institution properly managed, could in my opinion do much more to advance the science which underlies our industries than any national or State institution is ever likely to do, hampered as all of them are by political association. I may in conclusion express the opinion that for the best work, independence of city or other politics should if possible be insured by avoiding all kinds of public financial support."

As to the buildings for the technical school but little has been suggested; indeed,

this part of the problem, important as it is, may well be left open until the 'scope' of the great work to be done is well in hand. Dr. Thurston in his report has given an interesting résumé of the space occupied by the student in the various German technical schools, remarking that the German motto 'Viel Platz, Viel Licht, Viel Luft,' would be an excellent guide in determining this question. He says: "Ample space, good light and plenty of fresh air are essential, although the architect who should be the most earnest and intelligent of them all is often woefully deficient in appreciation of their importance when brain work is going on." Dr. Thurston further states that taking figures from the best German technical schools, which are based on the largest experience, the school of architecture at Berlin has 150 feet floor space per student, the engineering school 35 feet, but this latter school is so much over-crowded that arrangements are being made to give the student in this department at least 75 feet of floor space. In marine engineering 111 feet are provided and in metallurgy and the chemical departments each student has 426 square feet of space. Professor Thurston advises not less than 30 square feet per student in class rooms, in drawing rooms about 100 and in laboratories from 150 to 500 feet, according to character of the work to be done and magnitude of the space required for machinery and apparatus.

The Brunswick school has 410 feet floor space per student in all departments. At Karlsruhe 450 square feet is provided in the department of electrotechnics. The cost of the Berlin building is placed at \$1,000 per student, of the Brunswick buildings \$2,000 per student. From this data it can be seen that an institution which may be called upon to provide for a thousand students at once, and perhaps three or four times that number in the near future, must be planned upon a most liberal scale to

meet the demands which will be made upon it, and here we shall be confronted with the cost of such buildings. With the knowledge that Mr. Carnegie would not be satisfied with buildings devoid of architectural beauty, I feel morally certain that he would not be willing to invest his millions in buildings not properly constructed for the specific purpose for which they are intended, and with all regard to the society of architects, it is to be hoped that utility will be the first question solved in this important undertaking.

In a recent communication from Dr. Barker, of the University of Pennsylvania, upon this subject he says: "I hope the mistake will not be made of spending too much money upon buildings. The order of expenditure should be as follows: (a) Instruction; (b) endowment; (c) equipment; (d) building; by this I mean that the securing of the very best ability in the men in all the departments is an absolute desideratum, not only as teachers but investigators, for technical science is advancing so rapidly that abstract research in pure science cannot keep up with it and so applied science has to enter upon research work to supply the data it needs.

"Next comes endowment. In far too many cases, all the money given has been expended upon building and equipment, leaving nothing for maintenance." Dr. Barker then refers to a number of our noted American universities which have splendid buildings and some of them fine equipment, but with little or no funds to carry on research work. The members of this Association know this fact too well, many of them from unpleasant personal experience. Shall we steer clear of these shoals in the new technical schools?

Brainy men do not need a palace in which to make discoveries. Place a Newton, a Napier, a Faraday or an Edison, a Watt or an Ericson in a hovel and the discoveries

will come whether we will or not. Fortunately we are assured that the man who has given this great technical school for the glorious purpose it is sure to subserve will see to it that the endowment does not suffer, even if the buildings are constructed on a generous scale, but I know it to be his desire that the best technological knowledge shall be united with architectural design, so that the buildings may combine utility with beauty and reflect honor on all associated with the work.

And now as to the scope of the new school. That American schools of technology have done magnificent work for two or three decades goes without saying. Shall the new schools follow in the footsteps of the best of them, shall it unite the best features of one school with the best of another, or shall it venture upon entirely new fields to push outward the borders of human knowledge? The American, German, English, French and Swiss schools have been studied by the members of the advisory board (as well as by some members of our committee), and we have been greatly helped in formulating our plans of what the new school should be, by the generous data given in their report.

A summary of Professor Johnson's proposed scheme for the Carnegie School of Technology is as follows:

A. Colleges. Courses of four years with a high school preparation.

1. College of Science.
2. College of Engineering.
3. College of Commerce.

All the above of university grade, with degrees conferred at graduation.

B. Schools. Courses three years with a grammar school preparation.

1. Manual Training School.
2. Domestic Science School.
3. School of Industrial Design.
4. School of Commerce.

All the above of high school grade. Diplomas given at graduation.

C. Artisan Day School. Courses of three years with a preparation in reading, writing and arithmetic.

To include courses of instruction in subjects of essential importance in the practice of the various trades.

D. Night School for day workers. Preparation same as C.

Regular courses, and also special instructions of practical value to day workers of all sorts and all employments.

Professor Johnson, Dr. Alderson and Dr. Gray studied a number of the industries of our city, and in all their reports they emphasized the value of the secondary schools. The question of monotechnic or trade schools, *i. e.*, where a young man or woman can learn at least the rudiments of the trade by which they propose to make their living, was also discussed by Professor Johnson and Dr. Alderson with the writer, and it is the opinion of both committee and advisory board that in due time this part of the problem should be given earnest consideration. A summary of Dr. Alderson's recommendations as to the various departments that could advantageously be established in the school are:

First—Department of Engineering, comprising

- (a) Mechanical Engineering.
- (b) Electrical Engineering.
- (c) Civil Engineering.
- (d) Chemical Engineering.
- (e) Electro-chemical Engineering.
- (f) Foundry Practice.
- (g) Metallurgy (iron and steel).

Second—Department of Secondary Education.

1. Work preparatory to the College of Engineering.
2. Secondary Technical Education.

Courses in

- (a) Machine Tool Work.
- (b) Stationary Engineering.
- (c) Elementary Electrical Engineering.
- (d) Elementary Mechanical Engineering.
- (e) Foundry Practice.
- (f) Surveying.
- (g) Drafting.
- (h) Machine Design.
- (i) Glass Making.
- (j) Blacksmithing.
- (k) Pattern Making.

- (1) Brass Making.
- 3. Department of Library Economy.
- 4. Department of Domestic Arts and Sciences.
- (a) Normal Course.
- (b) Courses in cooking, sewing, dressmaking, millinery and household economy.
- 5. Department of Art.
- 6. Department of Evening Instruction.

Dr. Alderson closes his summary with these words of sterling advice: "The Carnegie School of Technology should be a protest against *surface education*; it should educate the hand and eye as well as the mind; it should emphasize the *doing* element in education; it should be essentially a school of applied sciences; and finally it should enter the broad field of technical education, supplying useful knowledge to boys and girls, young men and young women. The Carnegie School of Technology, located in a center of industrial activity, on grounds naturally beautiful and attractive, carefully planned and thoughtfully administered, can be made to bear the same relation to the great work of technical education that Columbia College does to university education, and thus become a technical school second to none.

Dr. Gray recommends that the institute should offer a course of instruction covering the whole nine years of study; that it be divided into two distinct schools, a secondary and upper secondary, and a higher college or professional school. He advises that the secondary school commence above the grade schools with a minimum age limit of 14 years, and that the course of instruction should include all the subjects commonly given in the best high schools, with the possible exception of Latin and Greek, and in addition the subjects more commonly given in business schools or colleges; along with this course of classroom instruction, provision should be made for practical instruction, either manual or otherwise, bearing upon the particular branch of industry which the scholar in-

tends to enter. The duration of this course should be about four years, as at present in city schools, but should be freed from a number of subjects that are of little use to the ordinary artisan class. Dr. Gray recommends a good sound course in English for students of the secondary school, but does not recommend a study of foreign languages.

One of the most important, if not the most important, recommendations made by Dr. Gray is that in regard to the upper school. I quote his language:

"This school can be made to fill the place which the present technical colleges have failed to do, namely, provide a college education for men of the rank of shop foremen, superintendents, etc. In this course, which should be of two years' duration, instruction can be given in such subjects as the design of structures and machinery, the properties of materials and machines, the design and management of power stations, telegraphy, and train signal systems, the surveying and construction of railway beds, civil engineer's and architect's office work, finer kinds of machine work and a host of other subjects, the understanding being that these subjects be treated in such a manner that *practical* information shall be the object rather than fundamental mathematical principles."

Other matters of importance are suggested in this part of Dr. Gray's report, one of which is that as there would probably be those in this course who would find it impossible to take the higher or technical college education, this upper secondary school would serve as a most excellent preparation for the same.

Dr. Gray recommends that the technical college or professional school be open only to a selected small number of students who have shown special fitness for the work, and that the entrance requirements should be considerably higher than is usual in existing

technical colleges. For this department extensive laboratory practice is recommended and thorough drill in the methods of testing properties of matter and in investigational work. Dr. Gray—as indeed every member of the advisory board—thoroughly agrees with Dr. Barker that apparatus should not be merely toys, that they must subserve some real purpose in the activities of life. As Dr. Barker puts it: “Where shall we draw the line between a testing machine and a cohesion apparatus—between a calorimeter of a pint capacity (an apparatus) and one of 100 gallons (a machine),” etc.

Dr. Gray suggests that this course might be of three years' duration and that fees be charged. Deserving students unable to bear the expense could possibly be provided with scholarships. Original research should be a prominent feature in this higher college.

Dr. Thurston's report to the committee is an exhaustive one, covering every phase of technical education, and as the commission will have it printed in full with the reports of other members of the board, I shall only give a few of the salient points in his paper.

Dr. Thurston assumes that the purpose of the institute will be primarily the useful education and technical training of the young people of Pittsburg, and especially of those belonging to the great body of wage earners, and that both sexes are, if practicable, to be equally well cared for. He divides these into two classes: (*a*) Those who can come to the instructor and give their time as required to study, to lectures and to recitations, and (*b*) those who are compelled to work during the working hours of the establishments in which they are employed and can only be given instruction outside during the evening hours, usually in evening classes.

Dr. Thurston asks: “Is it practicable to carry into effect that ambition of every tech-

nical education, so admirably pictured by Scott Russell, ‘the Technical University on the lines of which Ezra Cornell would have approved, where any man could secure instruction in any study in such departments as are capable of being utilized practicably in the sequel of life. It is obvious that could such an institution be founded, and thus the noble example be furnished in full perfection, and a standard thus provided by which to measure, the establishment of this complete and perfect model would, very probably, advance the cause of useful education of the people, for the life and work of the people for many years. It is possible that the opportunity is here and now presented, and that, lost, it may not recur again.’”

The opportunity is one not simply to provide education of the most imperatively needed sort for the youth of Pittsburg, but it is an opportunity to establish a model of the most perfect and most widely useful institution of learning that has been conceived, and that shall, by force of example establish a standard and promote the most complete and perfect system of technical and liberal education anywhere.

The general scheme laid out for the great technical school by Dr. Thurston is as follows:

(*a*) The college of mechanical engineering and the mechanic arts, with eight different departments of mechanical engineering.

(*b*) The college of civil engineering—with six departments.

(*c*) The college of architecture with three departments.

(*d*) The college of mines and metallurgy with two departments.

(*e*) The college of agriculture with six departments.

(*f*) The college of applied chemistry with four departments.

(*g*) The college of physics with two departments.

(*h*) The college of fine arts with three departments.

(*i*) The college of the business man with four departments.

(j) The college of navigation and marine transportation with two departments.

(k) The college of mathematics with two departments.

(l) The college of politics and economics with four departments.

(m) The college of languages and literature with four departments.

(n) The college of philosophical science and ethics.

(o) The college of biology.

(p) The preparatory college (standard curriculum).

"This scheme appears an ambitious one, but it so appears simply because we are in the very inception of educational work, and few persons have the slightest idea of the need or the opportunity for promoting the highest interests of the nation through a thoroughly systematized education."

Dr. Thurston refers with just pride to the Massachusetts Institute of Technology, the Armour Institute, the Pratt and Drexel institutes, as well as to others of a similar character, giving the curriculum of that sterling school of technology, the Massachusetts Institute, as well as much valuable data regarding the faculty, equipments and graduate students, all of which is compared with the Royal Technical College at Berlin. Dr. Thurston, with every other member of the commission, lays particular stress upon the value of the secondary school which he chooses to call the technical high school and which it is evident will meet the needs of the largest number of people. He chooses for a typical illustration of this division of the scheme the splendid work of the Pratt Institute of Brooklyn. Dr. Thurston also emphasizes the great value of such a secondary school to the young men and women of Pittsburg particularly, and believes it is only carrying out Mr. Carnegie's wishes to develop this department to its fullest extent.

As to the higher departments of the new school he expresses himself most charmingly in the language of John Russell on the occasion of the latter's visit to a German

technical university: "A technical university abroad was to me a surprise, a profound lesson, a delight. It was a dream of my youth suddenly embodied in living substance, and, unlike other realized dreams, the reality excelled the fiction. It was one of my early dreams that highly educated men should engage in teaching skilled workmen the profound philosophical principles which underlie all material work, and I hoped so to make their work their pleasure, excellence their ultimate aim and truth of execution and perfection of finish their highest ambition."

Dr. Thurston proceeds to discuss the higher branch of technical education with special reference to the needs of Pittsburg, then gives us some valuable information as to the status of the faculty of the great school, quoting precedents in home and foreign institutions. Endowments are also discussed with a freedom that has opened our eyes to the vital importance of this part of the scheme, and to which I have already referred in this paper. Summarizing, Dr. Thurston says:

"The first step considered advisable in preparing to supply Pittsburg and its environs with an institution of high efficiency for technical instruction should be to make a plan of that final educational structure which is taken to represent the limit toward which progress is expected to advance. The actual construction of the scheme should be commenced with the most essential elements; the less immediately and imperatively needed parts should be arranged for later. In the present case it would probably be justifiable to assume that the aim of the school should be, first, to provide for the young people of Pittsburg needing elementary technical educational instruction, and to organize for this purpose a technical high school with evening classes for pupils unable to attend regularly the day classes. This foundation being laid,

the various developments which have been considered in the preceding pages may be added, each as the preceding element is completed, working continually toward the technical university and the highest ultimate divisions of the scheme, the department of experimental engineering and research.

"The method of organization would be that which best insures the management of the whole of the great scheme and of each of its subdivisions by men expert each in his own field, whether that of director of the technical university, principal of one of its schools, or professor or instructor, or workman in shop, drawing-room or laboratory. Such an organization of a staff of experts being provided, the administration will be certain to work smoothly and efficiently, without special attention to detail on the part of the trustees. Their largest problem will be the matter of securing the endowment and its income from deterioration in later years and consequent impediment or interruption of the enterprise.

"Every division of the institution, from lowest to highest and first to last, should be so planned as to work in concert with the public schools of similar grade as far as practicable. The technical high school might accept certificates from the academic high schools of the city and from other academies of similar rank; the pupils of the city schools might be given admission to the classes of the technical school in the shops and technical departments; a half-time school, as advocated by Professor Higgins, of Worcester, might possibly come of such mutual aid of city and technical schools. The technical school would be able, in some cases probably, to promote the initiation of special instruction in manual training and in the kindergarten forms of technical work in the public schools. Every possible means of allying the technical and the common school work should

be availed of, and the cardinal principle should be constantly proclaimed and enforced: the purpose of the whole movement is to advance the best interests of the people of Pittsburg and its vicinity. It should be made distinctly understood that it is desired to make use of all possible ways to that end and to cooperate with every other educational movement."

In closing this far too lengthy paper I must acknowledge the great interest taken in the development of the scheme for the new technical school by the Engineers' Society of Western Pennsylvania, by the Women's Domestic Arts Association and by a number of eminent engineers, physicists and technologists at home and abroad; and the sole purpose of my paper is to ask the further cooperation and kindly advice of the members of this Association in formulating our plans, in steering clear of 'derelects' and in making the Pittsburg Carnegie School of Technology what its generous patron wishes it to be and what the demands of this great industrial nation require it to be. Any communication sent Mr. Wm. McConway, chairman of our committee, Pittsburg, Pa., will be received and acknowledged with great pleasure.

J. A. BRASHEAR.

SECTION A (MATHEMATICS AND ASTRONOMY) OF THE AMERICAN ASSOCIATION.

THE officers of this section were: vice-president, James McMahan; secretary, G. A. Miller; councilor, G. B. Halsted; sectional committee, James McMahan, G. A. Miller, H. A. Howe, Florian Cajori, F. H. Loud; member of the general committee, C. A. Waldo. The meetings of the section were well attended and most of the papers aroused discussion. With the exception of the anniversary meeting at Boston, the program was the most extensive in the recent history of this section. It consisted of the following twenty-five papers. As

the last six are of special interest to section B, they were presented at a joint session of sections A and B.

'Supplementary Report on Non-Euclidean Geometry': Professor G. B. HALSTED, University of Texas.

This is a supplement to the report read at the Columbus meeting. It will be published in SCIENCE.

'Kepler's Problem for High Planetary Eccentricities': Professor H. A. HOWE, University of Denver.

The solution of the equation $M = E - e \sin E$ is commonly called Kepler's problem. The known quantities e and M are respectively the eccentricity and the mean anomaly. E is to be found.

The purpose of this paper is to develop a direct method of solving Kepler's problem for planetary orbits of high eccentricity, which shall be more expeditious than any heretofore discovered, and shall be sufficiently accurate to meet the most exacting requirements of astronomers. This method is an outgrowth of one published by the author several years ago.

Let E' be an approximate value of E found by the well-known equation

$$\tan(E' - \frac{1}{2}M) = \frac{1+e}{1-e} \tan \frac{1}{2}M. \quad (1)$$

Let $2\eta = E' - M - \sin(E' - M)$, and

$$2\epsilon = \frac{1}{2}(E' - E) - \sin \frac{1}{2}(E' - E).$$

Then

$$E' - E = \frac{2\eta}{1 - e \cos \frac{1}{2}(E' + E)} - \frac{e \cos \frac{1}{2}(E' + E)}{1 - e \cos \frac{1}{2}(E' + E)} 4\epsilon. \quad (2)$$

But the unknowns, E and 4ϵ , are in equation (2), and must be made to disappear. In the most eccentric of the asteroid-orbits the value of the last term of equation (2) does not reach 0."0006; this term is therefore rejected, and we write with sufficient accuracy

$$E' - E = \frac{2\eta}{1 - e \cos \left\{ E' - \frac{\eta}{1 - e \cos(E' - \eta)} \right\}}. \quad (3)$$

E' may be found from (1), and $E' - E$ from (3); then $E' - (E' - E) = E$, the quantity desired. The paper was illustrated by large charts and will be published in the *Astronomical Journal*.

'The Great Fireball of December 7, 1900': Professor H. A. HOWE and Miss L. L. STINGLEY.

On December 7, 1900, at about 3:20 p.m., mountain time, there passed over the north-western quarter of Colorado a magnificent fireball, which exploded with startling detonations in the vicinity of the Bow Range near the north boundary-line of the state. The director of the Chamberlin Observatory prepared circulars of inquiry, containing a number of questions, which were lavishly distributed over the region from which the meteor was visible. The local press was also largely utilized for a dissemination of the queries. About 150 letters came in reply. Miss Stingley, of the class of 1903 in the College of Liberal Arts of the University of Denver, made a digest of these letters, and determined the meteor's path across the state. It passed nearly through the zenith of La Salle, and the main body came to earth in the vicinity of the town of Pearl. Its distance from the earth's surface, when near La Salle, was about 25 miles, and about 12 miles at the time of bursting. When the fireball was near Pearl an observation made by Mr. Thomas, of Manassa, a civil engineer, who was 250 miles away, gave it a height of 7 miles. Mr. Godshall, manager of a copper mining company, who was in Wyoming, about 40 miles beyond Pearl, saw the body come down in a curve somewhere in the general direction of Pearl.

Several observers thought that they saw fragments fall before the meteor reached Pearl, but on account of the wildness of the country none of the pieces have yet been found, though they have been searched for. The orbit has been computed on the

usual hypothesis that the path is a parabola. The body was moving nearly in the plane of the ecliptic, and caught up with the earth, which was traveling less rapidly in the same general direction. The search for fragments will continue. The paper will be illustrated by a large map showing the meteor's path across the country, and by a drawing exhibiting the relation of its orbit to that of the earth. It will be published in *Popular Astronomy*.

'Divergent and Conditionally Convergent Series whose Product is Absolutely Convergent': Professor F. CAJORI, Colorado College.

In an article on 'Divergent and Conditionally Convergent Series whose Product is Absolutely Convergent,' in the *Trans. of the Am. Math. Soc.*, Vol. II., pp. 25-36, were given special cases in which an absolutely convergent series is obtained as a result of multiplying two conditionally convergent series together, or one conditionally convergent series by a divergent series. But the sum of one of the two factor-series of each pair given in that article is zero. In the present paper it is shown that this is not a necessary property of conditionally convergent series whose product is absolutely convergent, and that the n th sum of such series may be of the degree $-r$, with respect to n , where $\frac{1}{2} < r \leq 1$.

'The Application of the Fundamental Laws of Algebra to the Multiplication of Infinite Series': F. CAJORI.

The behavior of infinite series with respect to the laws of algebra may be considered under two heads: An inquiry into the validity of the laws; (1) when applied to the terms of an infinite series; (2) when applied to the infinite series themselves.

The second inquiry, when made for the multiplication of series, leads to the conclusion that in this operation (assuming Cauchy's definition for the product of two infinite series), the asso-

ciative, commutative, and distributive laws are obeyed.

The two series obtained by removing the parentheses from the series,

$$S_1 \equiv \sum_{p=0}^{p=\infty} \left(\frac{1}{4p^r + 1} - \frac{1}{4p^r + 4} + \frac{1}{4p^r + 1} - \frac{1}{4p^r + 4} \right),$$

$$S_2 \equiv \sum_{p=0}^{p=\infty} \left(\frac{1}{4p^r + 4} + \frac{1}{4p^r + 4} - \frac{1}{4p^r + 1} - \frac{1}{4p^r + 1} \right),$$

where $\frac{1}{2} < r \leq 1$, are conditionally convergent, but their product is absolutely convergent.

Hence,

$$(S_1 S_2)(S_1 S_2)(S_1 S_2) \text{ is abs. convergent.}$$

But

$$(S_1 S_2)(S_1 S_2)(S_1 S_2) = S_1^3 \cdot S_2^3, \text{ and}$$

S_1^3 and S_2^3 are each divergent when $r < \frac{2}{3}$. Hence, when $\frac{1}{2} < r < \frac{2}{3}$, S_1^3 and S_2^3 are two divergent series whose product is absolutely convergent.

'On Systems of Isothermal Curves': Professor L. E. DICKSON, University of Chicago.

The object of this paper is to give an elementary geometrical definition of a system of isothermal curves in the plane. The definition is readily extended to families of curves on any algebraic surface. Two families of curves are discussed at length. From these the general definition is apparent.

'The Plane Geometry of the Point in Space of Four Dimensions': C. J. KEYSER, Columbia University.

The space under investigation is the point (in 4-space) regarded as the assemblage of all the lineoids (*i. e.*, ordinary 3-fold spaces), planes and lines containing it. This space is 3-dimensional in lineoids and in lines, the lineoid and the line being reciprocal elements; it is 4-dimensional in planes, the plane being *self-reciprocal*. The plane being

taken as element, a theory results which is in its analytical aspect identical with the Plücker line theory of the lineoid, while the two theories are geometrically disparate. It is seen that, while neither of these geometries has a correlate in its own domain, each is in the domain of 4-space the perfect correlative of the other. Naturally, therefore, in the geometry of 4-space, whether it be the point-lineoid theory or the line-plane theory, the two doctrines in question play indispensable and precisely coordinate rôles. The subject is treated under the following six headings: Introductory considerations, concerning certain metric relationships, homogeneous coordinates of the plane, the linear complex plane, linear congruences of planes, projective transformations by means of complexes.

'The Next Opposition of Eros': Professor H. A. HOWE and Miss M. C. TRAYLOR.

The planet Eros, to which astronomers have recently given so much attention, is now too near the sun for observation. As it is evident that the observatories near the equator will have a better chance to rediscover the planet than those in the United States, computations have been made for Manila, where the Jesuit Fathers have a large telescope, and for Arequipa, Peru, where the Bruce 24-inch star camera is stationed. To represent the United States Denver has been chosen, its latitude being $39^{\circ} 41'$. For each of the three dates, May 1, June 1 and July 1 of 1902 have been computed the times of sunrise, of the beginning of the morning twilight, and of the rising of Eros. From these computations it appears that the conditions for early rediscovery are most favorable at Arequipa, excellent at Manila, and unpropitious at Denver. But before July 1 it should certainly have been observed in the United States.

In order to have a secure basis for a theory about the causes of the planet's

variability, it is suggested that a table of standard magnitudes be computed for the entire period of visibility (May, 1902–October, 1903), on the assumption that the changes of brightness depend only on the relative positions of the sun, the earth and Eros. A comparison of the measured magnitudes with these will give data for theorizing.

A chart giving the path of Eros through the sky was exhibited, and also a pasteboard model of the orbits of the earth and the planet, showing their positions at favorable oppositions. This paper will appear in *Popular Astronomy*.

'On the Dimensions, Masses and Densities of the Satellites': Professor T. J. J. SEE, U. S. Naval Observatory.

The author points out the difficulty of measuring the angular diameters of very small bodies, on account of the tremors of the atmosphere, and then takes up the densities of the great planets as found in his recent investigations. He concludes that the average density of the four inner planets is 4.25, that of the outer planets 1.50. It is mentioned that the smaller inner planets have less density than the larger because the matter is less compressed by the action of gravity.

He then considers the diameters of the four large satellities of Jupiter; and, after analyzing the masses found by various investigators since the days of Laplace, adopts finally the masses used by Professor J. C. Adams. These masses, with the author's diameters, lead to the following densities for the several satellites:

Satellite I.	2.80	(Water = 1.)
Satellite II.	3.57	
Satellite III.	2.62	
Satellite IV.	0.76	

An investigation of Titan, the largest satellite of Saturn, shows its probable mass to be $\frac{1}{4700}$ that of Saturn, and the density 2.03. Thus Titan appears to be solid, and

less dense than the planet Mercury (3.00), which is the rarest of the inner planets. Professor See concludes that on the average the satellites are of the density 2.36, about the same as the matter which compresses the crust of the earth (2.55); and that the small satellites which cannot be measured are of about the same density as those which can be investigated, such as the four satellites of Jupiter, and Titan, the largest satellite of Saturn.

'Photometric Observations of Eros': HENRY M. PARKHURST, New York City.

These observations, extending from September 13 to March 22, comprised 382 double extinctions, in comparison with a large number of standard stars, including four other asteroids. From these observations the constant of brightness, reducing the distances to unity, was ascertained to be 9.78 mag., and the constant factor for phase angle .037. The phase correction, additional to the correction for defect of illuminated surface, was found to be uniform through the whole variation up to 58°. The observations confirm the discovery of the rapid change of brightness, undoubtedly due to rotation. The author's conclusion is that this change is probably due to the spheroidal form of Eros, the amount of the change depending upon the direction of the axis of rotation with regard to the earth.

'On the History of Several Fundamental Theorems in the Theory of Groups of Finite Order': Dr. G. A. MILLER, Cornell University.

This paper will appear in a future number of SCIENCE.

'On Certain Methods in the Geometry of Position': Professor ARNOLD EMCH, University of Colorado.

In this paper the author attempts to outline those methods which seem to be best adapted for an introductory study of projective geometry. Particular stress is laid upon the study of homology in advanced

plane geometry and descriptive geometry. It is shown that the principles of homology result naturally from the orthographic and also central projection, and that their application is conversely the best means for the construction of projective figures.

'The Parallaxes of 54 Piscium and Weisse 17^h, 322': Professor F. L. CHASE, Yale Observatory.

This paper was supplementary to a paper read by the same author before this section a year ago under the title, 'The Series of Parallaxes of Large Proper Motion Stars made with the Yale Heliometer,' a research begun in 1892, the observational part of which was finished the present year. In that paper the author had stated that the results of a preliminary solution indicated two of the 97 stars under investigation to possess a parallax of nearly 0''.25, which values, if confirmed by further observation, would place them among the first ten or twelve nearest stars so far as at present known. These two stars have been further investigated, two additional pairs of comparison stars being selected for each of them, and the observations with the original pairs repeated at the same time.

Altogether there were 56 observations on 54 Piscium and 54 on Weisse 17^h, 322, distributed as follows:

54 Piscium, Mag. 6.2.

Series I. 12 obs. with a & b Mags. 7.5 & 7.3 (orig.)
 Series II. 12 obs. with a & b (rep.)
 Series III. 16 obs. with c & d Mags. 8.7 & 8.7
 Series IV. 16 obs. with e & f Mags. 7.5 & 5.5

Weisse 17, 322 Mag. 8.0.

Series I. 10 obs. with a & b Mags. 7.0 & 8.0 (orig.)
 Series II. 12 obs. with a & b (rep.)
 Series III. 16 obs. with c & d Mags. 7.2 & 5.5
 Series IV. 16 obs. with e & f Mags. 8.6 & 7.2

The observations treated in the customary way and the equations derived therefrom being solved, the following results were obtained:

for 54 Piscium from

Series I.	$\pi = + 0''.241 \pm 0''.026$	Wt. 36.10
Series II.	$\pi = + 0.081 \pm 0.017$	Wt. 42.26
Series III.	$\pi = + 0.183 \pm 0.035$	Wt. 59.53
Series IV.	$\pi = + 0.055 \pm 0.023$	Wt. 51.40

for Weisse 17, 322,

Series I.	$\pi = + 0''.218 \quad 0''.030$	Wt. 33.60
Series II.	$\pi = + 0.189 \quad 0.034$	Wt. 35.08
Series III.	$\pi = + 0.198 \quad 0.022$	Wt. 45.87
Series IV.	$\pi = - 0.047 \quad 0.031$	Wt. 38.92

The author then goes on to discuss the disparity between some of the results, which are rather amazing in view of the size of the probable errors found. He investigates the question of a possible large systematic error and concludes that any such error, if it exists, must arise from the employment of different comparison stars, and is not due to changes dependent on the time. He finds only one of the comparison stars to possess any appreciable proper motion, viz., star *c* in the first table, which amounts to $- 0''.01$ in R.A. and $0''.3$ in Decl. the proper motion of 54 Piscium, according to Porter, being $- 0''.034$ in R.A. and $- 0''.38$ in Decl., and of Weisse 17^a, 322, $- 0''.040$ in R.A. and $- 1''.22$ in Decl.

He finally concludes by combining the various solutions, first, by their weights, and second, by the magnitude of the probable errors, and finds the following values :

for 54 Piscium,

I.	$\pi = + 0''.137 \pm 0''.014$	Prob. error 1 Ob. = $\pm 0''.193$
II.	$\pi = + 0.117 \pm 0.011$	

for Weisse 17, 322,

I.	$\pi = + 0''.132 \pm 0''.013$	Prob. error 1 Ob. = $\pm 0''.166$
II.	$\pi = + 0.140 \pm 0.014$	

But the author remarks that it has been considered worth while to make still another series on Weisse 17^a, 322, with the third set of comparison stars *e. f.* where there is a great difference in brightness, using screens in various ways to see if difference of brightness could account for the anomalous results obtained. Meanwhile the results above

given must be considered as only provisional.

'The Distance of the New Star in Perseus': Professor F. L. CHASE.

When the new star in Perseus first appeared last February it at once became the great desire of the author to determine, if possible, the parallax of this most remarkable object. So far as is known to the author, no one has as yet succeeded in determining the distance of one of these new stars. In 1892 he began a series of observations on Nova Aurigæ for the same purpose, but it will be remembered this star rapidly diminished in brilliancy, though with several fluctuations, and was not observable with the Yale heliometer for more than two or three months, which would not give a very sensible parallax factor. With Nova Persei conditions have been much more favorable, and even now the star is conspicuously brighter than the brightest comparison star employed, which was, according to Argelander, of the 7.4 magnitude.

There was but a single pair of comparison stars suitable for the purpose, viz., B.D. + 43°, 720 Mag. 7.4 and B.D. + 43°, 766 Mag. 8.0. Calling the first *a* and the second *b*, the position angles were respectively about 252° and 94°, and the distances, 2900" and 2700" from the Nova.

The plan was to make the observations in the usual symmetrical order *Na, Nb, Nb, Na*, so as to eliminate, as far as possible, the effect of refraction and other effects which may vary with the time. Since the distance, *ab*, was not beyond the range of the heliometer it was thought expedient to measure this distance also each night, and thus have besides the sums of the distances, an independent basis for correcting the changes in the scale value from night to night. Each night's work, then, consists of six observations of distance each of four pointings in reversed positions of the instrument, as follows: *Na, Nb, ab, ab, Nb,*

Na. Such observations were secured on five nights from February 26 to March 18, and seven from July 19 to August 4. These treated in the usual manner by the differences *Na* — *Nb*, corrected for scale value furnish seven equations of condition of the form :

$$+ 1.0x - 1.88y + 0.15z = -0.003 \text{ or } -0.004,$$

the equation derived from the observations of February 26, where *x* = the correction to the scale value, *y* = the parallax, and *z* = the proper motion.

A solution of the normals derived from these equations gives :

$$y = -0.0003 \pm 0.0013 = -0.003 \pm 0.017 \text{ Wt. } 38.85$$

or,

$$-0.0002 \pm 0.0013 \quad -0.003 \quad 0.017 \quad \text{“} \quad \text{“}$$

But since the distance *ab* furnishes an independent scale value, it was thought in the beginning that with this independent value we might solve the parallax from each comparison star separately, and thus see if there is any marked difference in the parallaxes of the comparison stars themselves. A closer investigation later, however, showed that this method would involve the parallaxes of the comparison stars in precisely the same manner as before, and hence would furnish nothing further than another value of the parallax relative to that of the mean parallax of the two comparison stars, differing from that already found simply by the difference in the scale value used.

The value found by this method was :

$$\pi = -0.006 \pm 0.022$$

as compared with

$$\pi = -0.003 \pm 0.017$$

given above ; which agrees with the uncertainty of the computations.

The author was able to find only one of the comparison stars in any other catalogues than the A. G. Zone Catalogue for 1875,

and this one shows no appreciable proper motion.

Of course the result here given must be considered as only provisional, inasmuch as nothing is known as to the proper motion of the Nova and it is barely possible that this may be such as to have just neutralized the effect of parallax. Should the star remain sufficiently bright for another six months, however, it will then be possible to determine the effect of proper motion and hence give a definitive result.

‘Hyperbolic Curves of the *n*th Order’ : Mr. A. C. SMITH, University of Colorado.

In a plane are given *n* straight lines with Cartesian equations. Any point in the plane is taken as origin and through this a line is drawn intersecting the *n* lines in *n* points. In this manner *n* segments, measured from the origin, are obtained on the line through the origin. The algebraic sum of these segments taken on this same line will determine a point, *P*, which will describe a curve of the *n*th order as the ray through the origin rotates through 360°. It was shown how the general equation of the locus could be obtained and some linear transformations were considered.

‘A Uniform Method of determining the Elements of Orbits of all Eccentricities from three Observations of Apparent Position’ : Dr. F. R. MOULTON, University of Chicago.

The methods of determining orbits which are in most general use were devised by Gauss one hundred years ago. They are different for orbits in which the eccentricities are less than, equal to, and greater than, unity, although there is no singularity, which is essential to the problem, for the eccentricity equal to one. The method of this paper is uniform for all orbits, it is considerably more convenient than that of Gauss, and the radius of convergence of the series employed is examined in each case.

The longitude of the node and the inclination are computed by the usual methods,

which are satisfactory, and the heliocentric distances and the arguments of the latitude at the epochs of the three observations are computed as in the method of Gauss.

Let $u_1, u_2, u_3, r_1, r_2, r_3$ represent the arguments of the latitude and the heliocentric distances at the epochs of the three observations. Then the parameter, p , is defined by the equation

$$k \sqrt{p}(t_3 - t_1) = \int_{u_1}^{u_3} r^2 du,$$

where r^2 is expressed as a series in u whose radius of convergence is determined as a function of u_2 and e . It is shown how the coefficients are to be found. The eccentricity, e , and the longitude of the perihelion from the node, ω , are given by

$$\left\{ \begin{array}{l} e \sin (u_1 - \omega) = \left\{ \begin{array}{l} \frac{p - r_1}{r_1} \cos (u_3 - u_1) \\ - \frac{p - r_3}{r_3} \end{array} \right\} \operatorname{cosec} (u_3 - u_1), \\ e \cos (u_1 - \omega) = \frac{p - r_1}{r_1}. \end{array} \right.$$

The time of perihelion passage is determined from the law of areas.

'On the Modular Functions associated with the Riemann Surface

$$s^3 = z(z - 1)(z - x)(z - y)';$$

Dr. J. I. HUTCHINSON, Cornell University.

The object of the present paper is to extend the results obtained by Picard in his memoir 'Sur des fonctions de deux variables independantes analogues aux fonctions modulaires' (Acta Math., II., p. 114). Picard considers in the first place the integrals of the first kind, and in particular the moduli of periodicity of the normal integrals. By changing the values of x, y in a continuous manner so as to return finally to their initial values, the moduli undergo a linear transformation, which can be represented by a linear transformation on two parameters, u, v , in terms of

which all the moduli are rationally expressible.

These transformations forming an infinite group G can be generated by five special ones $S_1 S_2 \dots S_5$, the explicit equations for which were given by Picard in a subsequent paper (Acta Math., V.).

The two variables x, y are then automorphic functions of u, v , and all functions belonging to the group can be rationally expressed in terms of these.

According to theorems previously obtained by Picard, there exist functions possessing a pseudo-automorphic character, exactly analogous to the fuchsian theta functions which Poincaré uses in connection with the automorphic functions of a single variable.

These functions can be constructed out of the theta constants. In order to do this it is necessary to determine the effect of the transformations of the group G on the latter, which is accomplished by means of the transformation theory of the theta functions. A table is constructed by means of which pseudo-automorphic functions can readily be constructed.

'Some Future Solar Eclipses, in particular that of June 8, 1918, total at Denver': Professor F. H. LOUD and Mr. L. R. INGER-SOLL, Colorado College.

The tables used in computing the circumstances of the eclipses herein discussed are those 'On the Recurrence of Solar Eclipses' published by Professor Simon Newcomb in 1879. After some remarks upon the limits within which the errors of such a computation may be expected to fall, the results of what seems the preferable combination of Professor Newcomb's tabulated data are stated as follows:

On June 8, 1918, the moon's shadow passes across the United States from northwest to southeast, covering Denver from 4^h 22^m 59^s P.M. to 4^h 24^m 23^s—a period of 1^m 24^s; while on the central line the duration is 1^m 33^s.

The width of the shadow-path is about 59.3^m and the velocity of the shadow 2900^m an hour. The eclipse will be visible from Chamberlin Observatory, Denver, and Mt. Arapahoe, Grand Co.

Sept. 10, 1923. An eclipse of duration $3^m 24^s$ is total from San Diego, Cal., eastward along a line near the United States and Mexican boundary. Width of shadow-path 102 miles.

Jan. 24, 1925. An eclipse visible (as total) from northern Michigan to New Haven, Ct., reaching the latter point at $9^h 5^m$ A.M., and lasting $2^m 8^s$.

Two maps of the Denver eclipse were shown.

'Bibliography of Quaternions and Allied Systems of Mathematics': Professor ALEXANDER MACFARLANE, Lehigh University.

The association for the promotion of quaternions and allied mathematics has in preparation a bibliography of all the literature of the subject. The field embraces all that has been written on what is called geometric algebra, or space analysis, and its three main subdivisions are quaternions, Ausdehnungslehre, and geometric algebra previous to Hamilton and Grassmann. The extent of this literature is not so small as is commonly supposed. As regards the first branch, the papers of Hamilton himself are numerous, and he has been followed by about one hundred writers. The writings of Grassmann are also numerous, and he has been followed by about the same number of writers.

It is desired to make the bibliography as complete as possible, and the writer desires mathematicians to cooperate by sending to him the necessary data about their own writings, or any rare writings in their possession.

'The Bruce Micrometer': Professor C. J. LING, Denver Manual Training High School.

The filar micrometer attached to the

telescope at the Chamberlin Observatory at University Park, Colorado, is the gift of the late Miss Caroline W. Bruce. It is especially adapted to rapid work and work on faint objects. Instead of being screwed to the tail piece of the telescope, it is so attached that it slides off, thus leaving the zero of the position circle unchanged. The position circle is furnished with a system of solid stops which enable it to be turned exactly 90° when micrometric measures of both $\Delta\alpha$ and $\Delta\delta$ are being made. These stops can be rapidly thrown back, enabling the circle to be turned any desired angle, and so rapidly thrown exactly to their former position. The circle can also be clamped at any position and adjusted by the use of a tangent screw.

The eye piece can be moved rapidly in both R. A. and Decl., admitting of the use of exceptionally long and a large number of spider webs. It is possible to observe objects differing in declination by more than $30'$, and this with a comparatively small motion of the micrometer. A micrometer screw of 20 threads to the inch makes rapid work possible. This is provided with three heads which are graduated so as to be read rapidly, two of which may be clamped in position.

The field is illuminated by two pairs of two candle power electric lamps whose intensities are regulated by a rheostat and mechanical shades, making it possible to rapidly adjust the illumination or to throw it off entirely. The observer can also illuminate at will either or both of the verniers of the position circle.

The results obtained from many hundreds of observations demonstrate that the micrometer is admirably adapted to combine rapidity and accuracy, making it an extremely efficient instrument, and this is all the more worthy of mention since it is accomplished without undue haste on part of the observer.

'The Metric System in the United States': Mr. JESSE PAWLING, Jr., Central High School, Philadelphia.

A brief history of the action of Congress in the subject of weights and measures is given. This includes the passage by the House and failure to pass by the Senate of the bill of 1796; the petitions urging legislation in uniformity of weights and measures from various states; the bills of 1866 to legalize the metric system and to allow it for the use of the post-offices; the failure to consider the bills of 1892 for the adoption of the metric system for the exclusive use in the customs service, though urged by 150 petitions; the passage of the bill of 1896 and its reconsideration, which referred it back to the committee from which it was not reported, and the bills following this for the same purpose, the adoption of the metric system for the use of the Departments of the Government, none of which were considered.

The work of the English Decimal Association has advanced the interests of the metric system. The association has among its members, members of Parliament and business people of England. It has secured the pledges of members of Parliament to vote for the metric system. It has secured the teaching of the metric system in the schools. It circulates literature and has a lecturer who addresses audiences wherever a meeting can be secured in England. It circulates reports of consuls on the metric system in other countries. It has secured the cooperation of the labor organizations, Chamber of Commerce, and National Union of Teachers: It has no dues and any one can become a member.

A similar organization may do good work in this country for the interests of the metric system. It could secure the cooperation of Congressmen. It might aim at having the metric system taught in the schools. It could educate the people by literature and

lectures like the English Decimal Association. It might secure advertisements of foreign goods in the metric system and in many other ways popularize the metric system with nominal or no dues.

'The New National Bureau of Standards': Mr. JESSE PAWLING, Jr.

The new Bureau is to be located in the suburbs of Washington, where it is free from disturbance. It has an appropriation of \$300,000 and a laboratory costing about \$200,000 is to be erected. Great care is to be exercised in selecting the personnel, and none but those trained for the work will be employed, as it is under civil service laws. Members of the Bureau are traveling to inspect laboratories of Europe. When established the Bureau will employ a number of young men just graduated from universities, giving them opportunities to develop along the lines which they wish to follow. It will invite specialists to do work in their line.

The Bureau standardizes three grades of weights and measures:

1. Those for commercial use.
2. Those for manufacturing and technical processes and professions; and
3. Those for extreme accuracy for scientific purposes.

'A Summary of the Salient Effects due to Secular Cooling of the Earth': Professor R. S. WOODWARD, Columbia University.

The effects summarized in this paper are:

(a) The slow process of heat conduction in the earth's crust, leading to the conclusion that nothing less than a million years is a suitable time unit for recording the historical succession of events.

(b) The insignificant modification of the process of conduction arising from the hydrosphere, leading to the conclusion that secular cooling goes on substantially as if the earth had neither atmosphere nor ocean.

(c) The resultant effect on the litho-

sphere of secular contraction and the process of isostasy.

(d) The effects of secular contraction on the length of the sidereal day.

'The Energy of Condensation of Stellar Bodies': Professor R. S. WOODWARD.

The problem considered in this paper is that of the energy due to the gravitational condensation of gaseous matter from a state of infinite diffusion to a finite spherical mass in which Laplace's law of density holds. The problem is worked out in its generality, formulas specifying the distribution of density, pressure, and potential in the mass being given. Special attention is given to the probable case of the fixed stars of a vanishing surface density.

'The Physical Basis of Long Range Weather Forecasts': Professor CLEVELAND ABBE, U. S. Weather Bureau.

In the absence of the author and of the member who was to present it this paper was read by title. The papers by Professor See and Dr. Moulton were presented by Professor Howe. Those by Professor Dickson, Mr. Keyser, Mr. Parkhurst, Dr. Hutchinson and Professor Macfarlane were read by the secretary. All the other papers were presented by their authors. Several other papers were read before the joint session of Sections A and B. These will be included in the report of Section B.

G. A. MILLER,
Secretary of Section A.

ON THE STABILITY OF VIBRATIONS.

Observations.—The following experiment seems to me to be an interesting illustration of the equation of the damped harmonic oscillation. It also presents a striking illustration of the stability of a given type of vibration.

The necessary apparatus is very simple, consisting of an ordinary open organ pipe (say c'' of the one foot octave) and a cylindrical tin box, 4–5 cms. in diameter and 5–6

cms. long, with a central hole at one end about 1 cm. in diameter. This is adjusted so as to be of the same period as the organ pipe. A König's resonator will do equally well, but if the box has a slightly loose lid, it brings out other phenomena also deserving notice.

The experiment is as follows: Using a resonator giving b' to e'' , depending on the intensity of the blast and with a loose (not sealed) lid, let it be placed symmetrically to the slit of the pipe at a distance, x , from it, as shown in the figure. Then as x decreases from a large distance, to say 3 cms., the resonator trembles violently (felt with the finger), but neither raises nor depresses the note. As x decreases further to 1.7 cms., no marked effect occurs, but pressure in the influx of the organ pipe will force out the octave, which it did not do before. Between $x = 1.7$ and $= 1.5$ there is destructive interference; a mere whiffing is heard from the combined instrument, but an impure octave may be forced out by pressure. Finally, when x decreases further to say 1.1 cms., a clear d'' suddenly breaks forth and is the chief feature of the experiment. For smaller distances (1.1 to .7 cms.) the d'' flattens again to e'' .

The same sharpening is produced when the resonator is placed on top of the open organ pipe, mouth inward. If two resonators are used, one as in figure, the other on top, the sharpened note of the one is further sharpened by the other.

When the so-called destructive interference occurs there is no vibration in the resonator; but on pressing the finger against its bottom, the c'' may again be heard.

If the lid of the resonator be cemented on with wax, or if a round König resonator be used, there is no whiffing. The interval, x , of instability is then very small (about .2 cm.) so that the note passes very suddenly from c'' to d'' . Too loose a lid merely depresses the tone at short distances.

The rise of the sharpened note will naturally depend on the pitch of the resonator. For a shorter one giving d'' to e'' with increasing blast, the above effect on the organ pipe is an e'' flat. A resonator of pitch d''

to f'' raises the organ pipe to e'' or depresses it to b' , as follows: c'' at long ranges, b' at $x = 1.2$, about; b' flat at $x = 1.0$ cm., then suddenly e'' at $x = .9$ cm. Here I thought I had detected two modes of vibration of a system of two degrees of freedom; yet as the butt end of the resonator produced like depressions of tone, this is probably referable to increased friction.

A resonator of pitch $a'-c''$, definitely below that of the pipe, depressed the tone from c'' to c'' flat. With the butt end the depression was a whole tone. The same resonator on top of the pipe showed just perceptible sharpening. The effect seemed to be the same whether the pitch of the resonator was depressed by lengthening or by reducing the size of the mouth.

Remarks in Explanation.—As the note of the organ pipe is always depressed when the butt end of the resonator or any other

obstacle is brought up to the lip, I think that a rough explanation in terms of a system of one degree of freedom will be admissible. Thus the organ pipe is vibrating throughout under more or less resistance. Its period may therefore be given by $T = 2\pi m / \sqrt{ma - b^2}$, where m is the inertia of the vibrating body, a is Hooke's constant and $2b$ the coefficient of friction. From another point of view, $T = 2\lambda m / b$, if $\lambda = Tb / 2m$ is the logarithmic decrement.

If the friction is increased by presenting an obstacle at the lip, b is increased and therefore T is increased or the tone is depressed. If, however, the friction is decreased by presenting a negative obstacle—i. e., the mouth of a resonator—near the lip, which initially tugs and pushes synchronously with the vibration of the lamina of air from the lip, then b is decreased and T is decreased. In other words, the tone is sharpened. It is in this way that I have presented this very striking phenomenon as an illustration of the given equation, though the full explanation cannot of course stop with a single degree of freedom.

As to the reasons for the absorption of the organ-pipe note in the resonator, if its lid is somewhat loose, it is clear that this cannot be a case of ordinary interference; for in such a case there should be vibration in the resonator, whereas none is manifest to the touch at least. In other words, each successive vibration of the organ pipe is quenched in the resonator, being completely damped out. Hence the effective friction in the resonator considered alone for the given conditions is so large as to change the harmonic type of decay in the exponential type, the period becoming imaginary. Now it is interesting to note that this takes place at a particular distance, x , from the lip within narrow limits, the resonator responding strongly to c'' for larger values of x , and to d'' for smaller values. The whiffing suggests the impure octave b'' , while

increased pressure at the organ pipe brings out the strong octave c'' .

Stability of vibration. Vibrational hysteresis.— Finally, the peculiar phenomenon observed in connection with the stability of vibration deserves special mention. A König resonator mounted on a graduated slide, x , is convenient for the purpose. If the mouth of this apparatus is approached slowly from a large distance, x , to within 2.2 cm. of the lip, c'' is strongly resounded. On passing these limits, d'' breaks forth almost suddenly. With this d'' sounding from the combined system, withdraw the resonator slowly again; d'' will be retained until x has increased to 2.8 cm., about. Hence, within 6 mm. of approach, the note is either c'' or d'' , depending upon whether the position has been reached from large or from small values of x , within the limits given. See figure. With a carefully regulated slow influx, 9 or even 10 mm. of range were attained with a sharp clicklike breakdown at each end. The change from c'' to d'' is usually more sudden, that from d'' to c'' more gradual, perhaps, but the *hysteresis-like* character of the phenomenon is unmistakable. As I have recently been studying hysteresis* from different points of view (cf. forthcoming paper in the *Physical Review*, on temporary set), the present purely vibrational case of it is to me strikingly interesting.

CARL BARUS.

BROWN UNIVERSITY.

THE FIFTH INTERNATIONAL ZOOLOGICAL CONGRESS.

THE Fifth International Zoological Congress held its sessions in Berlin from August 12 to August 16, under the gracious protection of His Highness the Crown Prince of Germany and the presidency of Professor K. Möbius, and, so far as concerns the attendance, was the most successful of

all that have so far been held. Most of the countries of Europe were well represented, delegates were present from Canada, Brazil, Mexico and the United States, the total number of those present being considerably over six hundred. The members in attendance from the United States were: Professors E. B. Wilson, of Columbia University, and Patten, of Dartmouth College; Dr. Stejneger, of the Smithsonian Institution; Dr. C. W. Stiles, of the National Museum; Mr. W. A. Murrell, of Cornell University; Mr. J. Hunter, of St. Louis, and Professor J. Playfair McMurrich, of the University of Michigan. Owing to the large number of papers to be presented, seven sections were established, namely, general zoology, experimental zoology, vertebrata (biology and systematic), vertebrates (anatomy and embryology), evertabrata (exclusive of arthropoda), arthropoda and nomenclature; and while such a separation of subjects was undoubtedly necessary and the grouping as satisfactory as might be, it made it impossible to attend the reading of many of the papers in which one might be interested.

The papers read were very varied in character, some being on special subjects, some, indeed, altogether too special for such a meeting, and others on the more general problems of zoology. If a single subject is to be selected as that which awakened the greatest interest, the new or rather the rekindled struggle between vitalism and mechanism must be the one chosen. Driesch, who has precipitated the renewal of the struggle, presented his views to a well-attended meeting of the section of experimental zoology, upholding, in a forcible and clearly stated argument, the vitalistic side of the question, while, in the discussion which followed, Ziegler, Roux and Rhumbler took the opposite side, maintaining that it is too early yet to admit the existence of vitalism or to postulate an active purpose-

* *American Journal of Science*, XI., 1901, p. 97.

fulness for the vital processes. That we cannot explain certain phenomena exhibited by living organisms on the mechanical or better the physical, hypothesis does not necessarily require the postulation of a vital force; it may rather be due to our ignorance of the physico-chemical and mechanical factors at work, and the progress of modern investigation has steadily tended towards the elucidation of more and more of the vital phenomena as chemico-physical or mechanical processes. In one of the general sessions of the Congress the same problem was the topic of a lecture by Bütschli, of Heidelberg, whose work on the structure of protoplasm necessarily inclines him towards the mechanical side. The problem, of course, cannot as yet be settled, but the opinion of the majority who took part in the discussion seemed to be in favor of the physical theory, holding that the neo-vitalists had not demonstrated the existence of a special life force or a necessity for such a force.

One of the most interesting and instructive of the lectures before the entire Congress was that given by Professor Poulton, of Oxford, on 'Mimicry and Natural Selection.' His thesis was the defense of Darwin's theory of mimicry, and in a clear and convincing manner he showed that many of the peculiarities exhibited by mimicking animals can be explained plausibly and satisfactorily on no other hypothesis. His lecture was illustrated by lantern slides, photographed in colors, showing numerous cases of mimicry in insects collected, with a special view to the study of this question, in Mashonaland, South Africa. Other lectures in the general sessions were given by Professor Grassi of Rome on 'The Malaria Problem from the Zoological Standpoint'; Professor Delage, of Paris, on 'The Theories of Fertilization'; Professor Forel, of Morges, on 'The Psychic Peculiarities of Ants'; Professor Branco, of Berlin,

on 'The Fossil Remains of Man,' the last named making the rather startling suggestion that *Pithecanthropus* may have been neither man nor ape nor yet a connecting link between the two, but a cross between pliocene man and an ape!

Of the papers read before the various sections there were but few which call for special notice. One of the most important was the announcement by Professor Patten that he had been able to detect the existence of a series of three-jointed appendages in specimens of *Cephalaspis* preserved in the British Museum, a fact which, taken along with the structure of the shell and the arrangement of organs which may be identified with median and lateral eyes, seems to indicate a close affinity of these supposed fishes with the merostomatous crustacea. In the section for vertebrate anatomy and embryology, Hubrecht presented the results of his studies of the development of *Tarsius*, which seem to explain the significance of the belly-stalk of the higher mammals, and Kopsch demonstrated by interesting experiments upon the blastoderm of the chick that Balfour's view that the primitive streak lay entirely posterior to the body of the embryo required considerable modification. Papers were also presented by Schauinsland on the development of the skull of *Hatteria* and of *Callorhynchus* and by Mitrophanow in the early development of the ostrich.

In the section for experimental zoology in addition to the paper by Driesch already mentioned, Herbst contributed an interesting communication on the influence of the nervous system on regenerated parts, having found that the regeneration of the eye-stalk of a crab resulted in the formation of an antennule, provided the optic ganglion had been destroyed by the operation. Other interesting papers presented to this section were by Spemann, of Würzburg, on the formation of double embryos by constricting

the eggs of *Triton* in the two-celled stage, his method permitting of different degrees of constriction and of constriction in different planes, as well as a thorough study of the resulting abnormalities; and by E. B. Wilson, who gave the results of his studies on the cytological changes in the eggs of *Toxopneustes* developing parthenogenetically by the Loeb method.

In the section for systematic zoology of the vertebrates one of the most interesting exhibits was that by Sclater of the skull and a portion of the skin of the newly discovered *Okapia*, a giraffine animal closely related to the extinct *Helladotherium* and obtained in the Uganda district by Sir Harry Johnston. The papers and demonstrations in the section for invertebrata were numerous, and it is impossible to refer to more than a few of them. Most noteworthy was perhaps a magnificent collection of Hexactinellid sponges obtained from the Japanese seas and exhibited by Professor Iijima, of Tokyo, while other papers of interest were by McBride on the development of *Echinus esculentus*, Apathy on the visual cells of the Herudinea (both these with demonstrations), Hoyle on intrapallial luminous organs in the Cephalopoda and Simroth on the digestive canal of the Mollusca. The section on nomenclature devoted a considerable portion of its time to a consideration of the report of the commission proposed at the last Congress and appointed a committee to codify the rules as they now exist.

The arrangements for the meeting were admirably carried out. Through the courtesy of the president of the Reichstag the sessions of the Congress were held in the Reichstag building and everything was done to make the meeting enjoyable in every way. The death of the Empress Frederick naturally cast a gloom over the city and entailed considerable alterations in the program of excursions and festivities which had been planned by the com-

mittee, but withal they were fully successful in their efforts to make the meeting both intellectually and socially enjoyable for all those in attendance.

The next Congress will be held in Berne, Switzerland, in 1904, and Professor Studer, of Basel, was unanimously chosen as president-elect.

SCIENTIFIC BOOKS.

Annals of the Astrophysical Observatory of the Smithsonian Institution. Vol. I. By S. P. LANGLEY, Director, aided by C. G. ABBOT. Washington, Government Printing Office.

During the ten years of its existence the Smithsonian Astrophysical Observatory has been almost entirely devoted to the prosecution of a single research—a continuation of one begun some years ago by Professor Langley at Allegheny—namely, the production of a map of the absorption lines in the infra-red solar spectrum which would be in some measure comparable as regards completeness and precision with those of the visible region produced photographically with the aid of the grating. Besides this main research—and carried out largely since its completion—several subsidiary researches have been undertaken, one of which, to be mentioned later, is of particular importance.

If we represent the solar radiation by an energy curve, in the usual manner, in which ordinates are proportional to radiant energy, and abscissæ to wave-lengths, the selective absorption of the solar and terrestrial atmospheres will be indicated by depressions in the curve, whose depth and width will show the intensity of the absorption and the extent of the spectral region affected by it. In the visible region, of course, the absorption will be indicated by a great number of more or less sharp, close-packed depressions, corresponding to the great number of visible 'lines.' It has been found that, besides broad regions of general absorption previously noted by Langley and others, the infra-red spectrum is also affected by similarly sharp selective absorption, producing 'lines,' and as has been said, this main research is devoted to the mapping of

these 'lines'—that is, to the accurate determination of the details of the infra-red energy curve. It is noticeable that most of the effort has been put upon the measurement of the abscissæ of the curve (*i. e.*, wave-lengths), the ordinates being considered for the present of secondary importance; and no determination of the radiant energy in absolute measure has been attempted.

The problem can be considered as made up of two distinct parts: first, the production of a sufficiently intense, pure and well-defined solar spectrum by means which permit of the direct or indirect measurement of wave lengths; second, the detection of absorption lines in a region of this spectrum quite beyond the range of visual or even special photographic processes, and in a manner which will result in the precise location of these lines in the spectrum and in the approximate determination of their intensity and character. As a means of producing the spectrum the grating, on account of loss of energy, was necessarily discarded in favor of the prism; of glass for the shorter wave lengths, of rock salt for the longer. The observatory possesses undoubtedly the finest specimens known of the latter substance; one in particular, from the salt mines of Russia, in the form of a 60° prism with faces 13 cm. wide and 19 cm. high, having been used in the present research. The spectroscope as finally used was of the extremely convenient fixed-arm type described by Wadsworth (*Phil. Mag.*, '94) combined with a very ingenious collimating system of cylindrical mirrors, due to Mr. Abbot, which enabled a slit of sufficiently small angular width to be used, while at the same time the linear width could be so great (over 0.2 mm.) that the loss of energy by diffraction at the slit was avoided. The refinement of the apparatus is shown by the fact that in the region of wave-lengths $\lambda < 2.5\mu$, a slit image of angular width 1''.5 could be used with a bolometer of angular width 1''.2, while for longer wave-length the values 4''.5 or 9'' and 3''.4 respectively were necessary to obtain proper deflections. The Rayleigh formula for visual spectroscopic resolving power indicates that with the prism used some 1,300 lines might be detected in the region between $\lambda = .76\mu$ and $\lambda = 5.3\mu$. It is here shown that by

the use of instruments of detection other than the eye the resolving power might be different and possibly greater than that given by Rayleigh's formula; and apparently this limit has been exceeded in practice. With the prism spectroscope, in order that the wave-length corresponding to a particular position in the spectrum may be known, the angle of the prism and its dispersion curve must be known; the former was determined with great care from time to time during the progress of this work, and a full discussion is given of the methods used, and of the precautions necessary when—as seems usually to be the case with rock-salt—the prism faces are curved; while the determination of the dispersion curve formed the principal subsidiary research.

As regards the method of detecting the lines, the instrument chosen was, naturally, the bolometer which for such purposes, where a linear form is essential, possesses decided advantages over any other form of radiation measurer yet devised. Instead of the usual visual observation of the motion of the spot of light reflected from the galvanometer mirror, produced by changes in the radiant energy falling on the exposed bolometer strip, a method of photographic registration was used. The spot of light fell upon a vertical photographic plate which was given vertical motion so connected mechanically with the motion of the spectrometer that each position of the plate corresponded to a definite position of the bolometer in the spectrum. The spot of light therefore occupied at any instant a position on the plate such that its one coordinate was proportional to the radiation striking the bolometer, and its other to the position of the bolometer in the spectrum; it therefore traced out the energy curve above referred to, except that the abscissæ were proportional not to the wave-length, but to the deviation produced by the particular prism used. In the form of fixed-arm spectroscope here used, the only moving part is the central table carrying the prism and a pane mirror suitably placed; if the table is given a uniform rotation, the angular motion of the spectrum past the fixed bolometer strip will be uniform also, and twice as rapid, and the particular wave-length in focus on the bolometer at any instant will have

passed through the prism at minimum deviation. The rotation of the prism corresponding to the entire range of wave-lengths here studied is less than 1° with the rock-salt prism—and hence it is necessary to be able to determine the angular position of the prism with rather unusual accuracy if the position of the bolometer in the spectrum (*i. e.*, the wave-length) is to be accurately known. The aim has been to have the maximum error in a single determination of the position of the bolometer in the spectrum not greater than $0''.6$, corresponding in the usual case to 0.1 mm. on the photographic plate. The critical part of the mechanical connection between the spectrometer and plate is a worm and wheel-segment by Warner and Swasey, which is so good that the above rigorous conditions can probably be nearly satisfied. When in use the spectrometer and plate are moved uniformly by clockwork which is, however, quite independent of the accurate mechanical connection between them, so that its errors do not enter. The photographic energy curve thus obtained by the motion of the spectrum past the bolometer strip will show besides the depressions due to the absorption lines sought, many other depressions and irregularities due to disturbances of a mechanical, electrical, magnetic or thermal nature, and a large part of the work has been an attempt to reduce to a minimum these accidental disturbances in order that the depressions in the curve due to real lines might be more clearly identified. It is impossible to consider here the causes of these irregularities—some coming from the bolometer circuit, some from the galvanometer, some from the battery, or the steps which have led to the gradual reduction of them, though these fill what is in some ways the most interesting chapter. Suffice it to say that careful comparison of a number of the best curves, or bolographs as they are called, has resulted in the more or less certain identification of over 700 lines in the region from $\lambda = 0.76\mu$ to $\lambda = 5.3\mu$ whose wave-lengths are determined with a mean probable error of two or three Ångstrom units, the results being given in tables, containing also indications as to the character and grouping of the lines. A graphic representation is also given in the form of line spectrum maps, both

normal and prismatic, either drawn by hand from the tabulated results, or transformed in a semi-automatic way from some of the curves themselves. This process seems of doubtful value, however, as the line-spectrum conveys in reality less information than the curves themselves, while it is apt to produce a false impression of authenticity. Curves and tables are also given illustrating the changes which occur, seasonal and otherwise, in the intensity of many infra red absorption lines; changes whose existence is here definitely fixed, but which will have to be further investigated before their cause can be assigned.

The most important subsidiary research has been the determination of the dispersion curves of rock-salt and fluorite; the former by direct comparison (so to speak) with a grating, the latter by comparison of fluorite bolographs with rock-salt bolographs of the solar spectrum, and measurements of the deviation of the same lines in both. Langley's early method was substantially repeated here in the work with rock-salt, and is briefly as follows:

Radiation from whatever source is used falls first upon the slit of a Rowland concave grating spectroscope, the eyepiece of which is replaced by a second slit; the radiation passing this second slit, from the grating, goes through the optical train of the prism spectroscope and is brought to focus at the proper place in the dispersion spectrum of the particular prism used. If the grating is set so as to let through the second slit light of a known (visible) wave-length in (say) the 3d order spectrum, waves of $\frac{2}{3}$ and 3 times this length will also pass through, belonging to the 2d and 1st order spectra. Hence in the dispersion spectrum of the prism there will be three distributions of energy, more or less sharp according to the widths of the two slits; and if a bolograph of this spectrum is taken in the usual way, three maxima will appear, separated by regions indicating no radiation. If on the same plate a record of the 'A' line is made, the relative deviation of the maxima (due to known wave-lengths) with respect to the 'A' line, can be determined by measurement of the plates. Such records, combined with the determination of the absolute deviation of the 'A' line, and of the angle

of the prism, gave the data for plotting the dispersion curve of rock-salt. The results, exceeding in accuracy any heretofore obtained, and which will be of the greatest value to other investigators using rock-salt dispersion for infrared work—are given in several convenient forms, most conveniently, perhaps, in the shape of a very large scale curve, extending between the limits $\lambda = 0.5 \mu$ and $\lambda = 6.5 \mu$, from which indices of refraction can be read off to 0.000002, and for which the probable error lies usually between 0.000009 and .000018. The dispersion curve of fluorite is given on the same scale between the limits $\lambda = .75 \mu$ and $\lambda = 3.5 \mu$. From the data for rock-salt have been calculated the five constants of the Ketteler dispersion formula, which differ quite noticeably from those calculated by Rubens and Trowbridge for a longer wave-length interval; but the differences between the observed and computed values of index of refraction are hardly greater than the probable errors of deviation, except for the longest wave-lengths. Accurate comparisons have also been made of the dispersion of three rock salt prisms which confirm the view that rock-salt as found in nature is in one respect of great optical uniformity, so that accurate determinations of indices of refraction for one prism can be safely applied to another for the purpose of determining wave-lengths; an extremely fortunate circumstance.

It is impossible to do more than mention some of the lesser pieces of work here recorded—such as the determination of the energy curves of various incandescent mantles; tests of the accuracy or constancy of the bolometer, which unfortunately do not touch the most difficult point, *i. e.*, constancy as regards sensibility for long time intervals; and a study of the minute structure of the infra red absorption band ' ω_1 .' A considerable space is, appropriately, devoted to the discussion of errors, and to methods for overcoming difficulties inherent in bolometric work; of which the most troublesome are undoubtedly 'drift,' or the continuous change in the zero position of the galvanometer spot of light, and the more or less rapid periodic changes of zero, or 'wiggle.' The various precautions taken, which have finally almost eliminated the drift and greatly reduced

the 'wiggle,' are dealt with in full; few of them altogether new perhaps, but certainly applied here with greater completeness and care than has been done elsewhere. The detailed consideration of manipulation and construction will be of great value to others engaged in similar work. In particular should be mentioned the study of the behavior of rock-salt prisms under conditions of rising temperature; the question of the construction of linear bolometers, in which such skill has been attained, and of the design of balancing bridges; and the full discussion of the adjustments of the fixed-arm spectroscope. In the chapter on the galvanometer will be found a useful table of the computed axial magnetic force produced by galvanometer coils of various resistances, wound either with a single size of wire or with different combinations of three sizes, which not only shows clearly the advantage of sectional winding, but will be a valuable aid in the design of galvanometers. The use of the Ayrton-Mather scale for expressing galvanometer sensibilities, now so generally adopted, would have rendered easier the comparison of the observatory instrument with others.

The valuable and interesting material, which it has been here attempted briefly to summarize, is the result of about nine years of work, involving the labors, successively, of Dr. Hallock, Mr. Wadsworth, Mr. Child and, for a longer time, of Mr. Abbot and Mr. Fowle, all under the direction of Professor Langley. From time to time statements of the progress of the work have been made by Professor Langley, and some special points considered in papers of Mr. Wadsworth, Mr. Abbot and Mr. Fowle, but the results now made public are so interesting and so important to all engaged in similar work that it is to be hoped that in the future conditions affecting publication by the government may allow more frequent and less delayed reports from this observatory, which is unique in its possibilities for the highest class of work with radiant energy.

C. E. MENDENHALL.

Dynamo Electric Machinery. Its construction, design, and operation. Direct current machines. By SAMUEL SHELDON, A.M., Ph.D.

Assisted by HOBART MASON, B.S. 12 mo. Pp. 281. Price, \$2.50, net.

The appearance of a promising new text-book on a subject relating to electrical engineering in any of its phases is a matter of much interest in the engineering schools; but Dr. Sheldon's book on 'Dynamo Electric Machinery' may justly receive special attention on account of the author's experience as a teacher and writer, his reputation for vigor, and the evident care with which he has constructed the book. Covering a field in which there are many books, the new comer finds an ample demand which is unfulfilled; for none of the older books are completely satisfactory as text-books and few are more successful as reference books. The demand for a really successful college text-book on applied electromagnetism and the construction of dynamos is therefore large and crying, and the new comer was assured of a certain effusiveness of welcome from technical college circles.

It then becomes a matter of interest to scrutinize the book and learn whether it fulfills those important requirements that are yet unfulfilled by existing literature; and it is a satisfaction to say that in many respects it bears the scrutiny well. In order of treatment and clearness of exposition the book is admirable, as it also is in typography and in much of the illustrative matter. The book has characteristics which are excellent in one designed for classes of trained mechanics, and perhaps the shorter and in some respects more superficial 'information courses' of instruction, which are given in our engineering schools to classes of men who are not following the professional course in electrical engineering and for whom the allotment of time to the subject of dynamos is insufficient for the most approved scientific instruction.

Dr. Sheldon's book was thus used during the past year in the University of Wisconsin as the text-book for a short course of study in dynamos required of mechanical engineering students. In this place the book proved successful, though several predecessors that presumably occupy a similar field had failed to give satisfaction. It is also expected that Dr. Sheldon's book will give good results in the

better classes of the Summer School for Apprentices and Artisans which has just completed its first session at the University of Wisconsin.

For the longer course in applied electromagnetism and the construction of dynamos that should be presented to the men pursuing a college course in electrical engineering, this book does not appear to be so well adapted. Such a course should deal in principles, principles, principles; and it should be remembered that good results involve much labor on the part of the student, however much interested he may be. In the small compass of Dr. Sheldon's book, so much space is occupied by descriptions and illustrations of the commercial apparatus of the day that the principles of electromagnetism and the modes of their application cannot be adequately treated.

We have no text-book on this subject which satisfactorily meets the requirements of a thorough treatise for the 'electrical engineering students' of our colleges, and we may justly say that it is better to use as a syllabus for these classes some book which deals sensibly and with reasonable adequacy in the theory of electromagnetism, than to use a book like Dr. Sheldon's which is of the so-called 'more practical' character. This choice of the preferable plan casts much labor on the teacher; but where the best teaching is the object, labor cannot be shirked.

To meet the requirements of the college classes to which I refer, a book is required of much greater scope than Sheldon's and much greater volume. One may doubt whether Sheldon's book was seriously planned for such classes, as the author's intention is stated in his preface to be to write a book 'to be used primarily in connection with instruction on courses of electrical engineering in institutions for technical education'; and also to meet the wants of '*the general reader, who is seriously looking for information concerning dynamo electric machinery of the types discussed, * * **' The object which I have set forth in italics has been well attained. It is obviously impossible to attain this object, and also to meet the requirements of extended scientific instruction, in the subject of this book, all within the covers of a duodecimo volume of 281 pages.

One object well attained is success, and it is to be hoped that the book will reach sufficient sales through the reasonable accomplishment of this object, so that the author may be encouraged to write another and more extended volume which may meet the needs of the electrical engineering students.

The author is to be congratulated upon the remarkable freedom of his first edition from typographical errors. In other respects he is perhaps not always so fortunate, as in some of his definitions, which are not always adapted to give a proper physical conception to the student. Also, in certain parts of the book, the descriptive matter is inexact or inadequate—especially is this true in the chapter on armature windings, where no attempt is made to present the rational laws of windings, and the short descriptions are inadequate and the diagrams too small to be thoroughly serviceable. Such faults, however, may be readily corrected in another edition, the compliment of an early demand for which we cordially wish for the author.

All in all, we heartily welcome the book to a useful sphere and compliment the author on his success. But we must regret that he did not make a book which might occupy the more important place of a scientific college textbook on applied electromagnetism and the construction of dynamos.

DUGALD C. JACKSON.

DISCUSSION AND CORRESPONDENCE.

A NEW FIELD FOR KITES IN METEOROLOGY.

TO THE EDITOR OF SCIENCE: Although kites carrying recording instruments to a height exceeding three miles have rendered great services to meteorology at Blue Hill and elsewhere, they have been subject to the limitation of requiring a wind that blows at least twelve miles an hour. In certain types of weather—notably anti-cyclones—the winds are light and consequently observations with kites can rarely be obtained at these times. It also happens frequently that, while the wind at the ground is sufficient to raise the kites, it fails completely above the cumulus clouds so that the kites are unable to penetrate this calm zone.

By installing the kites and apparatus on a steamship, not only can kites be flown in calm weather, but observations may be made above the oceans where little is known about the conditions of the upper air. It is evident that a vessel steaming twelve knots an hour through a calm atmosphere will raise the kites to the height they would attain in a favorable natural wind, while the force of strong winds can be moderated by steaming with the wind. In this way, kites can be flown on board a steamer, under almost all conditions and probably more easily than on land, since the steadier winds at sea facilitate launching them. Wherever these observations in the upper air may be made, there is always a station at sea-level and not far distant horizontally with which to compare them.

To test the practicability of this method of flying kites, experiments were undertaken on August 22, 1901, with the aid of my assistants, Messrs. Fergusson and Sweetland, upon a tow-boat chartered for this purpose to cruise in Massachusetts Bay. Anti-cyclonic weather conditions prevailed, and a southeast wind blew from 6 to 10 miles an hour, but at no time with sufficient velocity to elevate the kites, either from sea-level or from the summit of Blue Hill. With the boat moving 10 miles an hour toward the wind, and within an angle of forty-five degrees on either side of its mean direction, the resultant wind easily lifted the kites and meteorograph with 3,600 feet of wire to the height of half a mile.

While it is desirable to have a vessel that can be started, stopped and turned at the will of the meteorologist, as was the case in the experiments described, it is nevertheless probable that soundings of the atmosphere can often be made from a steamship pursuing its regular course, and such are about to be attempted by me on a steamer eastward bound across the North Atlantic. Although observations above all the oceans are valuable, the exploration of the equatorial region is the most important, since, with the exception of a few observations on the Andes and on mountains in central Africa, we know nothing of the conditions existing a mile or two above the equator. The need of such data to complete our theories of the thermo-

dynamics and circulation of the atmosphere was urged by the Russian meteorologist, Woeirof, at the Meteorological Congress in Paris last year. North and south of the equator, within the trade-wind belts, kites might be employed to determine the height to which the trades extend, and also the direction and strength of the upper winds, concerning which the high clouds, rarely seen in those latitudes, furnish our only information. In order to deduce the velocity of the upper current from the resultant velocity recorded at the kite, it is necessary to ascertain the direction of this latter force, which could be done from the orientation of the kite.

A. LAWRENCE ROTCH.

BLUE HILL METEOROLOGICAL OBSERVATORY, August 24, 1901.

GRADUATE COURSES IN SCIENCE.

At the request of the editor, I have drawn up a list of the graduate courses in pure science offered by several of our leading universities during the academic year 1901-1902. Chicago, Columbia, Cornell, Harvard, Johns Hopkins, Pennsylvania and Yale have been chosen because during the past four years each of these universities has almost invariably conferred from 20 to 40 doctorates of philosophy, whereas no other university in our country has on the average conferred more than eight.

This information has been collected from the most recently issued announcements of graduate courses to be given by the respective universities during the ensuing academic year, and has been made as complete as the material at command will permit. In some instances the announcements of courses fail to distinguish clearly between primarily undergraduate courses and purely graduate courses, and the compiler has in such cases endeavored to discriminate as carefully as possible. Wherever the information has been obtainable, there is added in parenthesis to the announcement of each course the number of hours a week for which that course is scheduled. Unless otherwise stated, the common denominator employed is the unit hour per week during the entire academic year. Laboratory hours are distinguished by italics. The graduate courses given at the University of Chicago during the summer quarter of 1901

have been omitted, as also the graduate courses given at the recent summer sessions of several of the universities.

ANATOMY.

(Consult also Zoology.)

Chicago.

Professor Barker: Seminar; Advanced work and original research.

Columbia.

Professor Huntington: Laboratory courses in animal morphology.

Harvard.

Professors Dwight and Dexter: Research course in anatomy.

Johns Hopkins.

Professors Mall, Harrison and Bardeen: Advanced work and original investigation (daily).

Professors Mall, Harrison, Drs. Sudler, Lewis: Systematic instruction in gross human anatomy (afternoons).

Professor Bardeen, Drs. Knower, MacCallum: Systematic instruction in histology, microscopic anatomy, neurology, and embryology (mornings).

Pennsylvania.

Professor Jayne: Research in human anatomy.

Yale (see Zoology).

ANTHROPOLOGY.

Chicago.

Professor Starr: Physical anthropology, lab. (4); Laboratory work in anthropology (4); Japan (4, 6 wks.); Pueblo Indians of New Mexico (4, 1 qr.).

Columbia.

Professor Boas: Ethnography of America (2); Statistical study of variation (2); Physical anthropology (2); American languages (2).

Professor Farrand: General introductory course (2); Ethnology, primitive culture (2).

Professors Boas and Farrand: Research work in physical anthropology, ethnology and North American languages (daily).

Harvard.

Professor Putnam: American archeology and ethnology (research).

Drs. Woods, Dixon: General anthropology (3).

Dr. Dixon: Primitive religions (1½); Special ethnology (1½).

Yale.

Professor Sneath: Philosophical anthropology (2).

Dr. Harshberger: Comparative taxonomy of plants (1+2); Comparative morphology of the myxomycetes and fungi (1+4).

Yale.

Professor Evans: Botany of the flowering plants (1½); General morphology of plants (4); Advanced morphology and taxonomy of plants.

Dr. Coe: Cytology and general embryology (2).

CHEMISTRY.

Chicago.

Professor Nef: Organic chemistry (4); Organic preparations (10 or 20); Research in organic chemistry (30 to 40); Special chapters of organic chemistry (4 hrs., 6 wks.); Journal meetings.

Professor Smith: Advanced general chemistry (4 hrs., 1 qr.); Research in general chemistry (30 to 40).

Professor Lengfeld: Inorganic preparations (10 or 20); Research in inorganic chemistry (30 to 40); Advanced inorganic chemistry (2 hrs., 1 qr.); Physico-chemical methods (5 hrs., 6 wks.).

Professor Stieglitz: Advanced qualitative analysis (10 or 20); Advanced quantitative analysis (10 or 20); Special methods in quantitative analysis; Research in organic chemistry (30 to 40); The aromatic series (2).

Dr. Jones: Elementary spectrum analysis (qualitative) (2 hrs., 1 qr.).

Columbia.

Professor Pellew: Industrial chemistry, special applications, laboratory (3½); Industrial chemistry, preparation of chemicals (1); Industrial chemistry, advanced course.

Professor Bogert: Advanced organic chemistry, laboratory (12); *ditto*, research.

Professor Bogert and Dr. Caspari: Chemistry of methane and its derivatives (3); Chemistry of the carbocyclic and heterocyclic compounds (3); Organic chemistry, general laboratory course.

Professor Miller: Quantitative analysis, special methods (16); Advanced inorganic analysis (2+lab.); Assaying, ores and metallurgical products (2); Special methods of assaying ores, alloys and furnace products (4).

Professor Morgan: Physical chemistry (3+lab.); Physical chemistry, advanced (2+12).

Dr. Wells: The spectroscopy as applied to qualitative and quantitative analysis (20).

Dr. Jouët: Quantitative analysis.

Dr. Sherman: Proximate organic and sanitary analysis, quantitative (4+12 or 18); Advanced proximate organic analysis (2+lab.).

Cornell.

Professor Caldwell: Agricultural qualitative and quantitative analysis, advanced course; Beverages and foods (1).

Professor Dennis: General inorganic and ultimate organic analysis, advanced; Spectroscopic chemical

analysis and colorimetry (1½); Qualitative and quantitative gas analysis (½); Technical gas analysis; Inorganic chemistry, advanced (3); *ditto* (laboratory); Inorganic chemistry, seminar (1).

Professor Trevor: Mathematical chemistry (3); Advanced mathematical chemistry (1).

Professor Bancroft: Physicochemical methods (3); Advanced physical chemistry (3); Advanced laboratory work, physical chemistry.

Professor Orndorff: Organic chemistry (3+3); Special chapters in organic chemistry (2); Advanced organic chemistry, laboratory; The coal tar dye-stuffs (½); Stereochemistry (½); Seminar in organic chemistry (1).

Dr. Chamot: Food and water analysis (3); Microchemical analysis (3); Potable water (1); Toxicology (1); Toxicological chemistry (½).

Dr. Carveth: Introductory physical chemistry (2).

Mr. Cushman: Technical and engineering analysis; Assaying (3).

Harvard.

Professor Hill: Carbon compounds (3); Organic chemistry (research).

Professor Jackson: Organic chemistry (research).

Professor Richards: Historical development of chemical theory (1); Advanced quantitative analysis (1½); Gas analysis (1½); Physical chemistry, (3); Inorganic chemistry, including determination of atomic weights (research); Physical chemistry (research).

Professor Sanger: Applied chemistry (research).
 _____: Electrochemistry (1½.)

Johns Hopkins.

Professor Remsen: Compounds of carbon (3); Historical topics in chemistry (12 lectures).

Professor Morse: Advanced inorganic chemistry (2).

Professor Jones: Physical chemistry (3); Elements of physical chemistry (1).

Pennsylvania.

Professor Smith: Advanced inorganic chemistry (2); History of chemistry (½); Electrochemistry (1); Mineral analysis (½); Analytical chemistry (½); Seminary (1).

Dr. Lorenz: Organic chemistry (2); Gas analysis (lab.); Physical chemistry (lab.).

Dr. Shinn: Industrial chemistry (1).

Yale.

Professor Mixer: Chemical physics.

Professor Wells: Qualitative analysis (1+lab.); Quantitative analysis; Inorganic preparations; Advanced quantitative analysis; Metallurgy and assaying; Technical gas analysis; Investigations in inorganic chemistry.

Professor Gooch: Quantitative analysis (6); Chemical theory (1); Special methods; Research in inorganic chemistry.

Professor Wheeler: Advanced organic chemistry; Organic preparations.

Professor Browning: The rare elements (1); Inorganic preparations (2).

Dr. Locke: Systematization of inorganic compounds; Advanced inorganic chemistry; Application of the ionic theory to analytical chemistry; Constitution of chemical compounds.

Dr. Foote: Physical and electro chemistry (1); Physico chemical measurements (lab.); Electro-chemistry (lab.).

Dr. Phelps: The carbon compounds (2); Organic synthesis (lab.).

Mr. Comstock: Elementary organic chemistry; Organic chemistry (1).

GEOLOGY (INCLUDING GEOGRAPHY).

Chicago.

Professor Chamberlin: Principles and theories of geology (6).

Professors Chamberlin and Salisbury: Special geology, selected themes.

Professor Iddings: Petrology (4 or 8); Special petrology (4 or 8).

Professor Weller: Special paleontologic geology (4 or 8).

Columbia.

Professor Kemp: Economic geology ($1\frac{1}{2}$); Petrology (2 + 4); Geological examinations and surveys (1).

Professor Dodge: Elementary physical geography, and geography of the United States (3).

Dr. Hollick: Paleobotany (1 + 4).

Dr. Jubin: Geology of building-stones (1); Metamorphism (1).

Dr. Grabau: Invertebrate paleontology (2 + 4).

Cornell.

Professor Tarr and assistants: Dynamic, structural and physiographic geology (2 + $2\frac{1}{2}$); Physical geography (3 +); Elementary meteorology (1); Glacial geology (3); Geological investigation; Seminar (2).

Professor Harris: Geological research in America (2); Conchology (2); Paleontological illustration ($\frac{1}{2}$); Field and laboratory work.

Dr. Ries: General economic geology (3); Clay investigation; Advanced economic geology.

Harvard.

Professors Shaler, Davis, Wolff, Smyth, Woodworth, Dr. Jaggard: Geological investigation in the field and laboratory.

Professors Shaler and Jackson: General paleontology (3); Historical geology (1); Advanced paleontology.

Professor Davis: Physiography of Europe ($1\frac{1}{2}$); Physiography, advanced (2).

Professor Smyth: Mining geology (3); Economic geology ($1\frac{1}{2}$); Mining geology, advanced (2).

Professor Jackson: General paleontology (1 + 4).

Professor Woodworth: General critical geology (3); Glacial geology ($1\frac{1}{2}$).

Professor Ward: General climatology ($1\frac{1}{2}$); Climatology of the United States ($1\frac{1}{2}$).

Dr. Jaggard: Advanced geological field work (2); Structural and dynamical geology of the United States (1).

Johns Hopkins.

Professor Clark and assistants: General geology (4); Paleontology (2); Historical geology (2).

Professor Reid: Experimental geology (1); Geological physics (1); Exploratory surveying (1).

Professor Abbe: Meteorology.

Dr. Shattuck: Physiographic geology (1).

Dr. Fassig: Climatology (1).

Mr. Willis: Stratigraphic and structural geology (1).
Dr. Bauer: Terrestrial magnetism.

Pennsylvania.

Professor Brown: Historical geology (1 + 4); Petrography (1 + 4); Chemical geology (1 + 4).

Dr. Ehrenfeld: Physical geology and physiography (1 + 3).

Professor Brown and Dr. Ehrenfeld: Paleontology of the invertebrates (5).

Yale.

Professor Williams: Historical geology (4); Evolution theories (2); Geological surveys; Practical geology.

Professor Beecher: General invertebrate paleontology (1); Invertebrate paleontology, faunal; Invertebrate paleontology, special; Research in invertebrate paleontology; Organic evolution; Taxology; Historical geology.

Professor Pirsson: Petrology; Elementary petrology ($\frac{1}{2}$); Elementary structural and dynamical geology ($1\frac{1}{2}$).

Dr. Gregory: Physiography.

MATHEMATICS.

Chicago.

Professors Moore, Bolza, Maschke: Mathematical reading and research.

Professor Moore: Theory of functions of real variables (4, 1 qr.); General arithmetic (4, 2 qr.); Seminar, Theory of functions of real variables (4, 2 qr.).

Professor Bolza: Abelian functions (4, 1 qr.); Seminar, Theory of abelian functions (4, 1 qr.).

Professor Maschke: Twisted curves and surfaces (4, 1 qr.); Theory of invariants (4, 1 qr.); Theory of functions (4, 2 qrs.); Seminar, differential geometry (4, 1 qr.).

Professor Dickson: Theory of numbers (4, 1 qr.).

Columbia.

Professor Fiske: Advanced calculus (3); Functions defined by linear differential equations (3).

Professor Cole: Theory of groups (3).

Professor Maclay: Theory of functions of a complex variable (3).

Mr. Keyser: Modern theories of geometry (3).

Cornell.

Professor Wait: Advanced analytic geometry (1); Advanced calculus, differential (3).

Professor Jones: Higher algebra and trigonometry (3); Theory of probabilities and least squares (2).

Professor Tanner: German mathematical reading (2); Algebraic invariants (2).

Professor McMahon: Quaternions and vector analysis (2).

Dr. Snyder: Projective geometry (3); General theory of algebraic curves and surfaces (3); Theory of functions (3).

Dr. Hutchinson: Advanced integral calculus (2); Theory of function (3).

Mr. Fite: Theory of groups (3); Theory of numbers (3).

—: Differential equations, advanced (3).

Harvard.

Professor J. M. Peirce: Calculus of quaternions (3); Theory of triangular coordinates and algebraic

plane curves (3); Application of quaternions to the theory of curves and surfaces ($1\frac{1}{2}$); Selected topics in quaternions ($1\frac{1}{2}$).

Professor Byerly: Advanced differential and integral calculus (3); Trigonometric series, spherical harmonics, potential function (3); Research, Picard's *Traité d'Analyse*, Vol. I.

Professor B. O. Peirce: Trigonometric series, spherical harmonics, potential function (3).

Professor Osgood: Infinite series and products ($1\frac{1}{2}$); Theory of functions (3); Research, calculus of variations.

Professor Bôcher: Higher algebra, polynomials and invariants ($1\frac{1}{2}$); Partial differential equations ($1\frac{1}{2}$); Linear differential equations of the second order (3).

Dr. Bouton: Theory of numbers ($1\frac{1}{2}$); Elementary theory of differential equations ($1\frac{1}{2}$).

Mr. Coolidge: Theory of equations, invariants ($1\frac{1}{2}$); Non-Euclidean geometry (3); Research, projective geometry.

Mr. Whittemore: Modern methods in geometry, determinants (3).

Johns Hopkins.

Professor Morley: Advanced geometry (3); The differential equations of physics (1); Mathematical seminar (1).

Dr. Cohen: Advanced differential equations (2); Theory of algebraic numbers (2); Elementary theory of functions (2).

Dr. Franklin: Probability.

Pennsylvania.

Professor Crawley: Plane analytic geometry (2); Higher plane curves (3).

Professor Fisher: Differential equations (2); Invariants and covariants (3); Theory of functions of a real variable ($1\frac{1}{2}$); Theory of functions of a complex variable ($1\frac{1}{2}$).

Professor Schwatt: Infinite series and products (3); Definite integrals and the functions of Bessel, Laplace and Lamé (3).

Dr. Hallett: Theory of substitutions (2); Theory of groups (2).

Department officers: Mathematical seminar.

Yale.

Professor Clark: Determinants (1); Differential equations (1).

Professor Gibbs: Vector analysis ($1\frac{1}{2}$); Advanced vector analysis ($1\frac{1}{2}$).

Professor Pierpont: Higher algebra ($1\frac{1}{2}$); Differential equations and function theory (3); Theory of functions (3).

Professor Smith: Advanced differential geometry (2); Foundations of geometry (1).

Dr. Porter: Advanced calculus (3); selected topics in differential equations ($1\frac{1}{2}$).

Dr. Granville: Differential geometry ($1\frac{1}{2}$).

Mr. Wilson: Projective geometry ($1\frac{1}{2}$).

MECHANICS.

Chicago. (Consult also Physics.)

Professor Maschke: Theory of the potential (4, 2 qr.).

Dr. Gale: Dynamics (4, 1 qr.).

Columbia.

Professor Woodward: Analytical mechanics (3); Advanced theoretical mechanics (2); Theory of the

potential function (2); Geodynamics (2); Mathematical theory of elasticity (2); Theory of the conduction of heat in solids (2).

Professor Pupin: Thermodynamics ($1\frac{1}{2}$); Theory of dynamo and motor ($1\frac{1}{2}$); Theory of direct-current dynamo ($1\frac{1}{2}$); Theory of alternators and transformers ($1\frac{1}{2}$); Theory of variable currents ($1\frac{1}{2}$); Maxwell's theory of electricity and magnetism (2); Theory of Bessel's functions and spherical harmonics (1); Electro-magnetic theory of light ($1\frac{1}{2}$); Advanced thermodynamics (2); Theory of oscillations (2).

Mr. Pfister: Theoretical mechanics (2).

Cornell.

Professor Trevor: Mathematical theory of thermodynamics (2).

Professor McMahon: Theoretical mechanics (2); Potential function, Fourier's series and spherical harmonics (2); Mathematical theory of sound (2).

Professor Merritt: Electricity and magnetism; Theoretical physics, mechanics and thermodynamics (4).

—————: Mathematical theory of fluid motion; Mathematical theory of electricity and magnetism.

Harvard.

Professor Hall: Elements of thermodynamics ($1\frac{1}{2}$); Modern developments and applications of thermodynamics ($1\frac{1}{2}$).

Professors Byerly and B. O. Peirce: The potential function (3).

Professor Byerly: Dynamics of a rigid body (3).

Professor B. O. Peirce: Mathematical theory of electricity and magnetism (3).

Mr. Whittemore: Hydrostatics and hydrokinematics (3).

Johns Hopkins.

Professor Morley: Kinematics (1).

Pennsylvania.

Professor Goodspeed: Theory of the potential (1); Analytic statics (1); Rigid dynamics (2); Thermodynamics (1); Dynamics of a particle (1).

Dr. Richards: Application of harmonic series to physical problems.

Yale.

Professor Clark: Electricity and magnetism (1); Thermodynamics and properties of matter (2).

Professor Beebe: Celestial mechanics (3).

Professor Bumstead: Problems in mathematical physics (2).

Mr. Wilson: Analytical mechanics ($1\frac{1}{2}$).

MINERALOGY.

Chicago.

Professor Iddings: Advanced petrology (4 or 8); Special petrology (4 or 8).

Columbia.

Professor Moses: Descriptive and determinative mineralogy (2 + 3); Physical crystallography (1 + 4); Physical crystallography, advanced (6); Mineralogy, special (research).

Dr. Luquer: The minerals of building-stones (2); Optical mineralogy (2 + 3, 2 mos.); Optical mineralogy, advanced (12).

Cornell.

Professor Gill: Physical crystallography (1½); Petrography (1½); Seminar (1); Research work in mineralogy and petrography.

Harvard.

Professor Wolf: Petrography (3).
Professor Wolf and Dr. Palache: Physical crystallography; Mineralogical and petrographical research.
Dr. Palache: Crystallography.

Johns Hopkins.

Professor Mathews: General mineralogy (4); Advanced mineralogy (3); Petrography (3).

Pennsylvania.

Professor Brown: Mathematical and physical crystallography (1 + 4); Systematic mineralogy (1 + 4); Chemical and synthetic mineralogy (1 + 3); Determination of minerals (4).

Yale.

Professor Penfield: Determinative mineralogy (3); Crystallography (1); Descriptive mineralogy (1½); Descriptive mineralogy, advanced (1); Experimental work in crystallography and mineralogy; Research courses.

PHYSICS.

(Consult also Mechanics.)

Chicago.

Professor Michelson: Theoretical physics (4, 1½ qr.); Experimental physics, advanced (10); Research course (20); Spectrum analysis (4, 6 wks.); Interference methods and their application (4, 6 wks.).

Dr. Mann: Development of physical ideas (4, 1 qr.).

Columbia.

Professor Rood: Magnetism and electricity, sound (2 + 2 or 6); Light, heat (3 + 2 or 4).

Professor Hallock: Units and measurements, exact electrical measurement (2 + 2 to 3).

Professors Rood, Hallock, Dr. Tufts, Mr. Trowbridge: Laboratory courses in physics.

Cornell.

Professor Nichols: Physical seminar (2).

Professor Merritt: Theoretical physics (4); Recent advances in experimental physics (1).

Professors Nichols and Merritt: Advanced laboratory practice in general physics (research).

Professor Moler: Advanced photography (2).

Mr. Shearer: Theory of light (4); Wave motion (2).

Mr. Ambler: Theory of alternating currents (1).

Harvard.

Professor B. O. Peirce: Electrostatics, electrokinematics, electromagnetism (1, 6 to 8); Electricity and magnetism (research).

Professor Hall: Heat and electricity (research).

Professor Trowbridge: Electrodynamics (2); Light and electricity (research).

Professors Trowbridge and Sabine: Electrodynamics, magnetism, electromagnetism (2 + lab.).

Professor Sabine: The theory of the microscope (1½); Light and heat (2 + 6 to 8); Research courses in light and heat.

Johns Hopkins.

Professor Ames: General physics (3).

Professor Wood: Physical optics (1½); Recent progress in physics (3).

Mr. Whitehead: Applied electricity.

Pennsylvania.

Professor Goodspeed (see Mechanics).

Professor Goodspeed and Dr. Richards: Absolute physical measurements (3 to 9); Theory and practice of spectroscopy (3); Seminary (1).

Dr. Richards: Electricity and magnetism (2); Theory of sound (1); Radiation, electromagnetic theory (2).

Yale.

Professor A. W. Wright: Physics [heat, light, electricity, magnetism] (2); Advanced physics (2).

Professor Hastings: Theory of observation, method of least squares, theory of electricity, electrical measurements (3 + 6).

PHYSIOLOGICAL CHEMISTRY.

Chicago.

Professor Mathews: Physiological chemistry (4 or 6, 1 qr.).

Columbia.

Professor Chittenden, Dr. Gies, Messrs. Richards and Cutter: General physiological chemistry (2 + 6).

Dr. Gies, Mr. Cutter: Advanced physiological chemistry, laboratory (6).

Dr. Gies, Mr. Richards: Special physiological chemistry, laboratory (12).

Cornell.

Professor Orndorff, Mr. Teeple: Physiological chemistry (2 + 2).

Professor Orndorff: Advanced physiological chemistry (laboratory).

Harvard.

Dr. Koch: Chemical physiology (1½).

Yale.

Professor Chittenden: Physiological chemistry (2).

Professors Chittenden and Mendel: Physiological chemistry (4 + 4).

PHYSIOLOGY.

Chicago.

Professor Loeb: The physiological effects of ions (4, 1 qr.); Physiology of space sensations (4, 1 qr.); Physiological morphology and theory of tropisms (4, 1 qr.); Seminar (1); Research work (8).

Columbia.

Professor Curtis: Laboratory course in special physiology (3).

Professors Curtis, Lee, Dr. Green: The physiology of man as related to that of other mammals and of lower vertebrates (4).

Professor Lee: General physiology (1).

Professor Lee, Mr. Budington: Laboratory course in general physiology (5).

Cornell.

Professor Wilder, Dr. Stroud, Mr. Reed: Research in physiology (daily); Fortnightly conference.

Harvard.

Professor Bowditch : Experimental physiology (research).

Johns Hopkins.

Professor Howell : Research courses ; Physiological journal club (1) ; Physiological seminar (1).

Professor Howell, Drs. Dawson, Erlanger, Mr. Stiles : Advanced research ; Regular medical course ($1\frac{1}{2} + 3$) ; Special course (3).

Yale.

Professor Chittenden : Elementary physiology (1) ; Experimental toxicology (1) ; Physiology of nutrition (1).

Professors Chittenden, Mendel : Experimental physiology (3) ; Seminary (2).

PSYCHOLOGY.

Chicago.

Professor Dewey : Seminar, mental development (4, 2 qr.).

Professor Angell, Dr. Fite : Experimental psychology, training course (4, 3 qr.) ; Experimental psychology, research (4, 3 qr.).

(See also Sociology and Statistics.)

Columbia.

Professor Cattell : Experimental psychology, introductory (2) ; Problems in experimental psychology (2) ; Research in experimental psychology (daily).

Professor Cattell, Mr. Davis : Experimental psychology, laboratory (2 or 4).

Professor Starr : Diseases of the mind and nervous system (1).

Professor Farrand : Physiological psychology (3) ; Abnormal and pathological psychology (1) ; Research in physiological and abnormal psychology.

Professor Thorndike : Genetic psychology, advanced (2) ; Research in genetic and comparative psychology.

Mr. Strong : Analytic psychology (1) ; Philosophy of mind (1) ; Research in analytic psychology and the philosophy of mind.

Cornell.

Professor Titchener, Drs. Bentley, Whipple, Mr. Baird : Systematic psychology (3) ; Laboratory exercises in psychology ; Seminar in psychology, and advanced laboratory work.

Dr. Bentley : History of psychophysics ($\frac{1}{2}$).

Dr. Washburn : Social psychology.

Harvard.

Professor James : The psychological elements of religious life ($\frac{1}{2}$).

Professor Münsterberg : Psychological seminar, The theory of the will (2).

Professor Münsterberg, Dr. MacDougall : Experimental psychology, advanced research.

Dr. MacDougall : Advanced psychology ($1\frac{1}{2}$) ; Experimental psychology, elementary (5).

Pennsylvania.

Professor Witmer : Fundamental processes (1) ; Physiological psychology (1) ; Complex mental processes (1) ; Experimental psychology (1) ; Modern psychological theory ($1\frac{1}{2}$) ; Seminar in child psychology ($1\frac{1}{2}$) ; Research.

Yale.

Professor Duncan : General psychology, advanced (2).

Professor Scripture : Physiological and experimental psychology (2) ; Experimental psychology, elementary (2) ; Experimental phonetics (1) ; Theory of statistics and measurements (1) ; Technical course in experimental psychology (1) ; Research.

SOCIOLOGY AND STATISTICS.

Chicago.

Professor Small : The ethics of sociology (4, 1 qr.) ; Seminar, Problems in methodology and classification (4) ; The premises of general sociology (4, 1 qr.) ; An outline of general sociology (4, 1 qr.).

Professor Henderson : The group of industrials (4, 1 qr.) ; Seminar, Methods of social amelioration (4) ; Urban communities (4, 1 qr.) ; Philanthropy in its historical development (4, 1 qr.).

Professor Talbot : Seminar in sanitary science (4).

Professor Thomas : Art and the artist class (4, 2 qrs.) ; Development of mind in the race (4, 1 qr.) ; Primitive social control (4, 1 qr.).

Professor Vincent : Public opinion (4, 1 qr.) ; Education as a social function (4, 1 qr.).

Dr. Mitchell : Training course in statistics (4, 1 qr.).

Columbia.

Professor Giddings : Principles of sociology (2) ; Social evolution (1) ; Progress and democracy (1) ; Pauperism, poor laws and charities (1) ; Crime and penology (1) ; Seminar in sociology (1).

Professor Mayo-Smith : Statistics and sociology (1) ; Statistics and economics (1) ; Theory of statistics (1) ; Laboratory work in statistics.

Dr. Ripley : Racial demography.

Dr. Bayles : The civil aspect of ecclesiastical organizations (1).

Cornell.

Professor Willcox : Elementary social economics (2) ; Elementary statistics (2 + 2) ; Advanced statistics (2).

Professor Fetter : Methods of modern philanthropy (2).

Professor Powers : The modern régime (2) ; Social interpretation of art (1) ; Seminar, The evolution of society (2).

Harvard.

Professor Ashley : Statistics (1).

Professor Carver : Principles of sociology (3) ; Socialism and communism (1).

——— : Seminar (1).

Johns Hopkins.

Dr. Brackett : Public aid, charity and correction (1, 3 mos.) ; Conferences on charitable legislation and custom in England and the United States (1).

Pennsylvania.

Professor Lindsay : Structure of modern society (2) ; Social-debtor classes (2) ; Seminar in sociology.

Yale.

Professor Sumner : The mental reactions (2) ; The beginnings of industrial organization (2) ; The science of society, elementary (2) ; The science of society, advanced (2).

ZOOLOGY (INCLUDING NEUROLOGY).

Chicago.

Professors Whitman, Lillie, Dr. Child : Zoological problems, research (1 + 18).

Professor Davenport : Experimental and statistical zoology (8).

Professors Whitman, Davenport, Lillie, Dr. Child : Seminar in zoology (2).

Professor Donaldson : The growth of the brain and its physical characters as related to intelligence (2 + 4, 1 qr.); Seminar in neurology (2); Research, the study of neurological problems (8).

Professor Donaldson, Dr. Hardesty : The architecture of the central nervous system (2 + 4, 1 qr.); Gross and microscopic anatomy of the human central nervous system and sense organs (3 + 6, 1 qr.).

Dr. Hardesty : The architecture of the central nervous system (2 + 10, 6 wks.); Comparative histology of the central nervous system and sense organs (2 + 9).

Columbia.

Professor Wilson : Comparative embryology (1 + lab.); Cellular biology (3).

Professor Osborn : Mammals, living and fossil (6). Professors Wilson, Osborn : Comparative zoology, advanced (10).

Professor Dean : Classification and comparative anatomy of the vertebrates (1 + 2); Embryology of fishes (1), Embryology of vertebrates ($\frac{1}{2}$ + 1).

Professor Crampton : Experimental embryology ($\frac{1}{2}$).

Dr. Calkins : General zoology of invertebrates, advanced (1 $\frac{1}{2}$ + 3); The protozoa ($\frac{1}{2}$ + 1); Sanitary biology (1 $\frac{1}{2}$).

Dr. Strong : Comparative neurology (1 + 4); The human brain and spinal cord (1 + 4).

Dr. McGregor : Mammalian dissection.

Professor Osborn, Dr. McGregor : Readings and conferences in Gegenbaur's *Vergleichende Anatomie* (1).

_____ : Practical histology; Practical embryology; Seminar; Journal Club.

Cornell.

Professor Wilder, Dr. Stroud, Mr. Read : Research in vertebrate zoology and neurology (daily); Department conference.

Professor Comstock : Research in entomology (daily); Morphology and development of insects (2).

Professor Gage : Research in histology and embryology (8); Advanced microscopy (2 $\frac{1}{2}$); Seminar in microscopy, histology and embryology.

Harvard.

Professor Mark : Anatomy and development of vertebrates and invertebrates (research).

Professor Mark, Dr. Rand : Microscopical anatomy (1 $\frac{1}{2}$); Embryology of vertebrates (1 $\frac{1}{2}$).

Professor Jackson : Fossil invertebrates (1 $\frac{1}{2}$); Fossil invertebrates, special groups (1 $\frac{1}{2}$).

Professor Parker : Introduction to the study of the nervous system (1 $\frac{1}{2}$); The nervous system and its terminal organs (1 $\frac{1}{2}$).

Dr. Rand, Mr. Carpenter : Comparative anatomy of vertebrates (3).

Dr. Castle : Experimental morphology, phylogenesis (2).

Johns Hopkins.

Professor Brooks, Drs. Andrews, Johnson : Advanced laboratory work (daily); Journal club (1); Seminar (1).

Pennsylvania.

Professor Jayne : Human anatomy (research); Mammalian osteology (research).

Professors Conklin, Montgomery, Dr. Calvert : Comparative anatomy and embryology of the invertebrata (1 + 5); Zoological seminar (1).

Dr. Moore : Recent and fossil vertebrata (2 + 2).

Yale.

Professor Verrill : Zoology, comparative anatomy, morphology, histology, systematic zoology.

Professor Smith, Dr. Coe : Elementary anatomy and histology (2); Comparative anatomy and general biology (3); Advanced comparative anatomy and general biology (daily).

Professor Ferris : Comparative morphology of the vertebrate brain (1).

Dr. Coe : Cytology and general embryology (2).

GEO. B. GERMANN.

PRIZE-SUBJECTS IN APPLIED SCIENCE.*

THE program of subjects for which prizes will be awarded by the Société industrielle de Mulhouse next year has been issued, and copies can be obtained upon application to the secretary of the Society. In general chemistry, medals will be awarded for the best memoirs or works on the theory of the manufacture of alizarin reds; the synthesis of the coloring matters of cochineal; theoretical and practical study of the carmine of cochineal; study of the coloring matter of cotton; the composition of aniline blacks; physical and chemical modifications which occur when cotton fiber is transformed into oxycellulose; action of chlorine and its oxygen compounds upon wool; constitution of coloring matters employed in linen fabrics; synthesis of a natural coloring matter used in industries; and theory of the natural formation of an organic substance and preparation of the substance by synthesis.

In connection with dyeing, medals will be awarded for the best works presented on the following subjects: A new mordant which admits of practical use; metallic solutions which give up their bases to textile fibers, and the conditions in which they are most effective; iron mordants and the part they play in dyeing according to their condition of oxidation and hydration; an aniline black which will not de-

* From *Nature*.

teriorate in the presence of other colors or affect these colors, especially those of albumin; a soluble black for dyeing, which will resist the action of light and soap as much as aniline black; a light blue cheap enough to be used to dye wools and not affected by boiling or by light; a blue similar to ultramarine which can be fixed upon cotton by a chemical process; a pure yellow which behaves like alizarin as regards its dyeing properties; a lake-red; a purple; a coloring matter to supersede logwood in its various applications; an assistant especially applicable to wool, capable of being cleared by simple washing, and composed of substances other than tin salts, hydrosulphites, sulphites, and bisulphites; new method of fixing aniline colors; a means of making colors resist the action of soap or of prolonged boiling; a means of producing the sheen of gold and silver upon materials by metallic powders; a manual containing tables showing the densities of as many inorganic and organic compounds as possible, in the crystallized state and in cold saturated solution; the synthesis of a substance having the essential properties of Senegal gum; a substance to supersede egg-white in the dyeing of linen; a colorless blood albumin which can be used instead of egg-white; a manual on the analysis of compounds employed in fabric printing and in dyeing; an indelible ink for marking cotton and similar materials; a practical method of removing grease spots from materials; a memoir on the use of resins in bleaching cotton fiber; a memoir on the bleaching and dyeing of various kinds of cotton; also memoirs dealing similarly with wool and silk; use of hydrogen peroxide for bleaching; improvements in the bleaching of wool and silk; and manuals on the bleaching of cotton, wool, silk, hemp and other fibers.

In connection with fabric printing, medals are offered for an alloy or other substance which has both the elasticity and durability of steel and also the property of not causing any chemical action in the presence of acid colors and colors containing certain metallic salts; a new cylinder machine capable of printing at least eight colors at once; and an application of electricity to bleaching, dyeing or fabric printing.

Among the prize subjects in mechanical arts are: A means of recording by a graphical method the work done by steam engines in a given period (ordinary indicator diagrams do not fulfil the conditions); memoir on the spinning of combed wool; on the force required to start spinning machines; a motor for driving machines used in printing fabrics.

In electricity medals will be awarded for an electric motor the power and driving rate of which can be easily varied; a memoir on the comparative cost of electricity and gas for lighting a town having a population of at least 30,000; and comparative costs of electricity, gas, acetylene and water-gas for lighting an industrial establishment.

Money prizes as well as medals are awarded for some of the subjects, and all the competitions are open to every one, irrespective of nationality. The memoirs, designs or models submitted for the awards should be sent to the president of the Société industrielle de Mulhouse before February 15, 1902.

SCIENTIFIC NOTES AND NEWS.

A ROYAL commission has been appointed in Great Britain to study the relation of bovine and human tuberculosis, consisting of Sir Michael Foster, Dr. Sims Woodhead, Dr. Harris Cox Martin, Professor J. McFadyean and Professor R. W. Boyce.

DR. W. J. MCGEE and Dr. W. H. Holmes were at St. Louis recently to advise in regard to the exhibit of anthropology and ethnology at the exposition in 1903. Very comprehensive exhibits were recommended, of which we hope to give later a detailed account.

PROFESSOR WILLIS L. MOORE, chief of the Weather Bureau, visited the Yellowstone Park last week, with a view to studying the desirability of establishing there a weather station.

MR. H. D. HUBBARD, private secretary to President Harper, of the University of Chicago, has been appointed, as the result of a civil service examination, secretary of the National Bureau of Standards, at a salary of \$2,000 a year.

THE Dutch Academy of Sciences at Harlem has elected to membership H. Haga, professor

of physics at Gröningen; Ed. Verschaefelt, professor of botany and pharmacognosy at Amsterdam, and S. G. De Vries, of Leiden. Foreign members have been elected as follows: H. Becquerel, professor of physics at the *École Polytechnique*, Paris; Max Planck, professor of mathematical physics and director of the Institute for Theoretical Physics at the University of Berlin, and Heinrich Dubois, associate professor of physics at the same university.

JOSEPH Y. BERGEN, the author of well-known text-books on botany, has resigned his position in the English High School of Boston. With his family he sailed on September 3 for Naples, Italy, where for the future he will make his home.

THE officers of the Society for the Promotion of Agricultural Science elected at the recent Denver meeting, to serve for next year, are:

President, W. H. Jordon, director of the New York State Experiment Station, Geneva.

Secretary-Treasurer, F. M. Webster, Wooster Ohio.

Members of the Executive Committee, to serve with the president and secretary, W. J. Beal, Agricultural College, Mich.; W. R. Lazenby, Columbus, Ohio; C. S. Plumb, Lafayette, Indiana.

DR. ADOLF FICK, the eminent physiologist, died on August 21, at the age of seventy-one years. He was born at Cassell, and after studying at Zurich became professor at that University in 1876. In 1868 he removed to Würzburg, where he made the laboratory of physiology one of the most important in Germany. He published a well-known compendium of physiology, the third edition of which appeared in 1882, and was also the author of books on the physiology of the senses and on muscular contraction, to which subjects his researches contributed in an important degree.

THE death is announced of Admiral Jonquières, the well-known French geometer.

PROFESSOR SAMUEL PORTER, a widely known teacher of the deaf and dumb, died at his home in Farmington, Conn., on September 2, at the age of ninety-one. He was a son of President Noah Porter, of Yale College, and graduated from that institution. He began the instruction of the deaf and dumb at Hartford, where he

remained till 1836. In 1846 he went to New York and in 1866 was made professor of mental science and English philology at Gallaudet College, Washington. He became professor emeritus in 1884.

DURING the present season the biological laboratory of the United States Fish Commission at Wood's Holl, Massachusetts, has been under the personal direction of Dr. H. M. Smith, of the Commission staff. The former director, Dr. H. C. Bumpus, owing to his new duties at the American Museum of Natural History, was unable to continue his services, much to the regret of Commissioner Bowers. Among those who have occupied tables and pursued investigations during the summer are Dr. Robert P. Bigelow, Massachusetts Institute of Technology; Dr. Gary N. Calkins, Columbia University; Dr. Otto Folin, McLean Hospital (Waverly, Mass.); Dr. Caswell Grave, Johns Hopkins University; Mr. Karl Kellerman, U. S. Department of Agriculture; Dr. F. T. Lewis, Harvard Medical School; Dr. H. R. Linville, DeWitt Clinton High School; Professor W. J. Moenkhaus, Indiana University; Professor George H. Parker, Harvard University; Dr. H. W. Rand, Harvard University; Dr. R. M. Strong, Harvard University; Dr. F. B. Sumner, College of the City of New York; Dr. W. T. Swingle, U. S. Department of Agriculture, and Professor R. W. Tower, Brown University.

Two vacancies in the position of assistant computer in the Nautical Almanac Office will be filled by civil service examination on October 8 and 9.

A NEW YORK State civil service examination will be held on or about September 28, to fill certain positions, including that of electrical engineer, at a salary of \$900, and of instructor in various manual arts in the State reformatories and institutions.

AT the approaching annual reception and opening of the American Museum of Natural History, New York, the Tiffany collection of gems, recently presented to the museum by Mr. J. Pierpont Morgan, will be on exhibition; part of the Bement collection of minerals will also be exhibited.

THE library of natural history, which the Park Department has fitted up in the Swedish schoolhouse on the West Drive near the Metropolitan Museum, is used by fifty to one hundred people daily. It will be kept open during the winter, and it is expected that it will be used by children from the schools. The library is dependent on gifts, and books or journals bearing on natural history will be gladly received.

MR. ANDREW CARNEGIE has offered \$20,000 and \$15,000, respectively, to Riverside, Cal., and Chatham, N. Y., for public libraries.

THE New York City Board of Health has adopted resolutions requiring public institutions to report cases of malaria and requesting physicians to do the same.

IN harmony with the vote of the executive committee, the eighteenth annual meeting of the Association of Official Agricultural Chemists will be held in Washington, D. C., beginning Thursday, November 14, and continuing over Friday and Saturday, 15 and 16, or until the business of the Association is completed. The authorities of the Columbian University have extended the courtesy of the use of the University lecture hall for the various sessions. The following order of business will be observed: The president's address; reports of the referees on nitrogen, on potash, on phosphoric acid, on soils, on ash, on foods and feeding stuffs, on liquor and food adulteration, on dairy products, on sugar, on tannin, on insecticides; reports of special committees (abstract committee, food standards, fertilizer legislation, volumetric standards).

THE following preliminary program of subjects for the proposed International Conference on Plant Breeding and Hybridization, to be held in the fall of 1902, is announced by the Horticultural Society of New York. The exact dates for the meetings are not yet decided upon, and the program as given is subject to alteration:

Results of Hybridization and Plant Breeding in Canada. (Illustrated by specimens.) William Saunders, director of the Central Experimental Farm, Ottawa, Canada.

Notes on Plant Breeding in California. E. J. Wick-

son, horticulturist, Agricultural Experiment Station, University of California.

Plant Breeding in New Jersey. (Illustrated by specimens.) B. D. Halsted, professor of botany in Rutgers College, New Brunswick, N. J.

Hybrid Plums. F. A. Waugh, horticulturist, Vermont Agricultural Experiment Station.

Variations in Hybrids not appearing in the First Generation, but Later. E. S. Goff, horticulturist, Agricultural Experiment Station, University of Wisconsin.

Results in the breeding of Species of Ricinus. E. Mead Milcox, botanist, Oklahoma Agricultural Experiment Station.

On Orchid Hybrids. (Illustrated by specimens of the parents and progeny.) Oakes Ames, Ames Botanical Laboratory, North Easton, Mass.

The Wild Hybrids of the North American Flora. (Illustrated by specimens of the parents and progeny.) David George, museum aid, New York Botanical Garden.

Hybrid Beans. R. A. Emerson, horticulturist, Agricultural Experiment Station, University of Nebraska.

Cytological Aspects of Hybrids. W. A. Cannon, Columbia University, New York City.

Correlation between the Fruit and other Parts of the Plant in Form, Color and other Characteristics. (Illustrated by specimens.) S. A. Beach, horticulturist, New York State Experiment Station, Geneva, N. Y. Other papers, the titles of which have not yet been communicated, are also promised from the following: Delegates representing the Royal Horticultural Society of England; Luther Burbank, Santa Rosa, Cal.; J. Craig, Cornell University, Ithaca, N. Y.; K. C. Davis, West Virginia Agricultural Experiment Station; S. B. Green, Agricultural Experiment Station, University of Minnesota; H. C. Price, Iowa Agricultural Experiment Station; W. van Fleet, M. D., Little Silver, N. J.; J. C. Whitten, Agricultural Experiment Station, Columbia, Mo.; C. W. Ward, Queens, N. Y.; H. J. Webber and others representing the United States Department of Agriculture.

THERE was held at Glasgow last week an international engineering congress under the auspices of the leading British engineering societies. Lord Kelvin was the honorary president and Mr. James Mansergh the president. The sections in which the congress met were as follows:

Section I.—Railways. Chairman, Sir Benjamin Baker.

Section II.—Waterways and Maritime Works. Chairman, Sir John Wolfe Barry, K.C.B., F.R.S.

Section III.—Mechanical Engineering (Institution of Mechanical Engineers). Chairman, Mr. W. H. Maw.

Section IV.—Naval Architecture and Marine Engineering (Institution of Naval Architects). Chairman, the Right Hon. the Earl of Glasgow.

Section V.—Iron and Steel (Iron and Steel Institute). Chairman, Mr. William Whitwell.

Section VI.—Mining (Institution of Mining Engineers). Chairman, Mr. James S. Dixon.

Section VII.—Municipal Engineering (Association of Municipal and County Engineers). Chairman, Mr. E. George Mawbey.

Section VIII.—Gas Engineering (Institution of Gas Engineers). Chairman, Mr. George Livesey.

Section IX.—Electrical (Institution of Electrical Engineers). Chairman, Mr. W. E. Langdon.

THE Department of State has received from the Russian Embassy, Washington, under date of August 12, 1901, notice of the International Exposition and Congress of Fisheries, to be held in St. Petersburg in 1902. An invitation is extended to the United States to participate in the exposition and to send official delegates and experts to the congress. The exhibition is open to Russian and foreign exhibitors. Its objects consist in: (a) Determining the actual condition of sea and fresh-water fisheries, and of other similar pursuits; (b) acquainting producers and consumers with the various products of fisheries and with methods of preparing and preserving the same; (c) exhibiting the gradual development and actual state of artificial fish breeding, as likewise the various aspects of amateur fishing and angling; (d) promoting scientific research pursued in the interests of fisheries.

DR. CALMETTE, the director of the Pasteur Institute at Lille, and the discoverer of a curative serum for the effect of snake-bite, was, as a correspondent to the *Lancet* reports, recently severely bitten on the hand by a trigonoccephalus. Dr. Calmette without delay gave himself an injection of his anti-venomous serum, but nevertheless the hand swelled up and acute fever set in; but by the afternoon of the same day Dr. Calmette was sufficiently recovered to attend a sitting of the Conseil-Général of the

Department, at which he argued in favor of a grant in aid of the sanatorium which he has undertaken to found at Lille. On the following day he was perfectly well, having thus afforded in his own person, albeit unwillingly, a convincing proof of the efficacy of his excellent remedy.

UNIVERSITY AND EDUCATIONAL NEWS.

IT appears that German soldiers are still occupying the buildings of the University at Tien-Tsin, and the question has been brought to the attention of our Department of State, the institution being conducted under American auspices.

THOMAS L. WATSON, Ph.D. (Cornell), assistant state geologist of Georgia for the past four years, has been elected professor of geology and botany at Denison University, Granville, Ohio.

PROFESSOR F. C. VAN DYCK, who holds the chair of electricity and mechanics at Rutgers College, has been made dean of the faculty.

E. B. HOLT, M.A. (Columbia), Ph.D. (Harvard), has been appointed instructor in psychology in Harvard University, succeeding Dr. Robert MacDougall, recently called to the chair of psychology in the School of Pedagogy, New York University.

MR. FRANK NICHOLAS SPINDLER has been elected professor of psychology and pedagogy in the State Normal College, at Stevens Point, Wisconsin.

MR. A. H. YODER, of the University of Indiana, has been appointed professor of pedagogy at the University of Washington.

A. L. KROEBER, Ph.D. (Columbia), has been appointed instructor in Indian anthropology in the University of California.

AT Brown University, Mr. G. F. Parmenter and Dr. N. A. Dubois have been appointed instructors in chemistry.

MR. S. Y. WARA has been awarded a teaching fellowship in chemistry in the University of Missouri.

DR. RUDOLPH ZUBER has been promoted to a full professorship of geology at the University at Lemberg.

WILLIAM MCKINLEY, twenty-fifth President of the United States, universally beloved and honored by a Nation whose greatness he maintained and advanced, died on September 14, 1901.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE: S. NEWCOMB, Mathematics; R. S. WOODWARD, Mechanics; E. C. PICKERING, Astronomy; T. C. MENDENHALL, Physics; R. H. THURSTON, Engineering; IRA REMSEN, Chemistry; CHARLES D. WALCOTT, Geology; W. M. DAVIS, Physiography; HENRY F. OSBORN, Paleontology; W. K. BROOKS, C. HART MERRIAM, Zoology; S. H. SCUDDER, Entomology; C. E. BESSEY, N. L. BRITTON, Botany; C. S. MINOT, Embryology, Histology; H. P. BOWDITCH, Physiology; J. S. BILLINGS, Hygiene; WILLIAM H. WELCH, Pathology; J. MCKEEN CATTELL, Psychology; J. W. POWELL, Anthropology.

the great Queen, in whose reign nearly all the meetings of the British Association have been held, has passed to her rest.

To sovereigns most honors and dignities come as of right; but for some of them is reserved the supreme honor of an old age softened by the love and benedictions of millions; of a path to the grave, not only magnificent, but watered by the tears both of their nearest and dearest, and of those who, at the most, have only seen them from afar.

This honor Queen Victoria won. All the world knows by what great abilities, by what patient labor, by what infinite tact and kindness, the late Queen gained both the respect of the rulers of nations and the affection of her own subjects.

Her reign, glorious in many respects, was remarkable, outside these islands, for the growth of the Empire; within and without them, for the drawing nearer of the Crown and the people in mutual trust; while, during her lifetime, the developments of science and of scientific industry have altered the habits and the thoughts of the whole civilized world.

The representatives of science have already expressed in more formal ways their sorrow at the death of Queen Victoria, and the loyalty and confident hope for the future with which they welcome the accession of King Edward. But none the less, I feel

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

ADDRESS OF THE PRESIDENT OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.*

THE first thought in the minds of all of us to-night is that since we met last year

* Glasgow meeting, 1901.

sure that at this, the first meeting of the British Association held in his reign, I am only expressing the universal opinion of all our members when I say that no group of the King's subjects trusts more implicitly than we do in the ability, skill and judgment which His Majesty has already shown in the exercise of the powers and duties of his august office; that none sympathize more deeply with the sorrows which two great nations have shared with their sovereigns; and that none cry with more fervor, 'Long live the King!'

But this meeting of the British Association is not only remarkable as being the first in a new reign. It is also the first in the new century. It is held in Glasgow at a time when your International Exhibition has in a special sense attracted the attention of the world to your city, and when the recent celebration of the ninth jubilee of your University has shown how deeply the prosperity of the present is rooted in the past. What wonder, then, if I take the chair to which you have called me with some misgivings? Born and bred in the south, I am to preside over a meeting held in the largest city of Scotland. As your chosen mouthpiece I am to speak to you of science when we stand at the parting of the centuries, and when the achievements of the past and present, and the promise of the future, demand an interpreter with gifts of knowledge and divination to which I cannot pretend. Lastly, I am president of the British Association as a disciple in the home of the master, as a physicist in a city which a physicist has made forever famous. Whatever the future may have in store for Glasgow, whether your enterprise is still to add wharf to wharf, factory to factory and street to street, or whether some unforeseen 'tide in the affairs of men' is to sweep energy and success elsewhere, fifty-three years in the history of your city will never be forgotten while civilization lasts.

More than half a century ago, a mere lad was the first to compel the British Association to listen to the teaching Joule, and to accept the law of the conservation of energy. Now, alike in the most difficult mathematics and in the conception of the most ingenious apparatus, in the daring of his speculations and in the soundness of his engineering, William Thomson, Lord Kelvin, is regarded as a leader by the science and industry of the whole world.

It is the less necessary to dwell at length upon all that he has done, for Lord Kelvin has not been without honor in his own country. Many of us, who meet here to-night, met last in Glasgow when the University and city had invited representatives of all nations to celebrate the jubilee of his professorship. For those two or three days learning was surrounded with a pomp seldom to be seen outside a palace. The strange middle-age costumes of all the chief universities of the world were jostling here, the outward signs that those who were themselves distinguished in the study of Nature had gathered to do honor to one of the most distinguished of them all.

Lord Kelvin's achievements were then described in addresses in every tongue, and therefore I will only remind you that we, assembled here to-night, owe him a heavy debt of gratitude; for the fact that the British Association enters on the twentieth century conscious of a work to do and of the vigor to do it is largely due to his constant presence at its meetings and to the support he has so ungrudgingly given. We have learned to know not only the work of our great leader, but the man himself; and I count myself happy because in his lifelong home, under the walls of the university he served so well, and at a meeting of the Association which his genius has so often illuminated, I am allowed, as your President, to assure him in your name of the

admiration, respect, nay, of the affection, in which we all hold him.

I have already mentioned a number of circumstances which make our meeting this year noteworthy; to these I must add that for the first time we have a Section for Education, and the importance of this new departure, due largely to the energy of Professor Armstrong, is emphasized by the fact that the Chair of that Section will be occupied by the Vice-President of the Committee of Council on Education—Sir John Gorst. I will not attempt to forecast the proceedings of the new Section. Education is passing through a transitional stage. The recent debates in Parliament; the great gifts of Mr. Carnegie; the discussion as to university organization in the north of England; the reconstitution of the University of London; the increasing importance attached to the application of knowledge both to the investigation of nature and to the purposes of industry, are all evidence of the growing conviction that without advance in education we cannot retain our position among the nations of the world. If the British Association can provide a platform on which these matters may be discussed in a scientific but practical spirit, free from the misrepresentations of the hustings and the exaggerations of the partisan, it will contribute in no slight measure to the national welfare.

But amid the old and new activities of our meeting the undertone of sadness, which is never absent from such gatherings, will be painfully apparent to many of us at Glasgow. The life-work of Professor Tait has ended amid the gloom of the war-cloud. A bullet, fired thousands of miles away, struck him to the heart, so that in their deaths the father and the brave son, whom he loved so well, were not long divided. Within the last year, too, America has lost Rowland; Viriamu Jones, who did yeoman's service for education and for sci-

ence, has succumbed to a long and painful illness; and one who last year at Bradford seconded the proposal that I should be your president at Glasgow, and who would unquestionably have occupied this chair before long had he been spared to do so, has unexpectedly been called away. A few months ago we had no reason to doubt that George Francis FitzGerald had many years of health and work before him. He had gained in a remarkable way not only the admiration of the scientific world, but the affection of his friends, and we shall miss sadly one whom we all cared for, and who, we hoped, might yet add largely to the achievements which had made him famous.

THE SCIENCE OF THE NINETEENTH CENTURY.

Turning from these sad thoughts to the retrospect of the century which has so lately ended, I have found it to be impossible to free myself from the influence of the moment and to avoid, even if it were desirable to avoid, the inclination to look backward from the standpoint of to-day.

Two years ago Sir Michael Foster dealt with the work of the century as a whole. Last year Sir William Turner discussed in greater detail the growth of a single branch of science. A third and humbler task remains, *viz.*, to fix our attention on some of the hypotheses and assumptions on which the fabric of modern theoretical science has been built, and to inquire whether the foundations have been so 'well and truly' laid that they may be trusted to sustain the mighty superstructure which is being raised upon them.

The moment is opportune. The three chief conceptions which for many years have dominated physical as distinct from biological science have been the theories of the existence of atoms, of the mechanical nature of heat, and of the existence of the ether.

Dalton's atomic theory was first given to the world by a Glasgow professor—Thomas Thomson—in the year 1807, Dalton having communicated it to him in 1804. Rumford's and Davy's experiments on the nature of heat were published in 1798 and 1799 respectively; and the celebrated Bakerian Lecture, in which Thomas Young established the undulatory theory by explaining the interference of light, appeared in the *Philosophical Transactions* in 1801. The keynotes of the physical science of the nineteenth century were thus struck, as the century began, by four of our fellow-countrymen, one of whom—Sir Benjamin Thompson, Count Rumford—preferred exile from the land of his birth to the loss of his birthright as a British citizen.

DOUBTS AS TO SCIENTIFIC THEORIES.

It is well known that of late doubts have arisen as to whether the atomic theory, with which the mechanical theory of heat is closely bound up, and the theory of the existence of an ether have not served their purpose, and whether the time has not come to reconsider them.

The facts that Professor Poincaré, addressing a congress of physicists in Paris, and Professor Poynting, addressing the Physical Section of the Association, have recently discussed the true meaning of our scientific methods of interpretation; that Dr. James Ward has lately delivered an attack of great power on many positions which eminent scientific men have occupied; and that the approaching end of the nineteenth century led Professor Hæckel to define in a more popular manner his own very definite views as to the solution of the 'Riddle of the Universe,' are perhaps a sufficient justification of an attempt to lay before you the difficulties which surround some of these questions.

To keep the discussion within reasonable limits I shall illustrate the principles under

review by means of the atomic theory, with comparatively little reference to the ether, and we may also at first confine our attention to inanimate objects.

THE CONSTRUCTION OF A MODEL OF NATURE.

A natural philosopher, to use the old phrase, even if only possessed of a most superficial knowledge, would attempt to bring some order into the results of his observation of nature by grouping together statements with regard to phenomena which are obviously related. The aim of modern science goes far beyond this. It not only shows that many phenomena are related which at first sight have little or nothing in common, but, in so doing, also attempts to explain the relationship.

Without spending time on a discussion of the meaning of the word 'explanation,' it is sufficient to say that our efforts to establish relationships between phenomena often take the form of attempting to prove that, if a limited number of assumptions are granted as to the constitution of matter, or as to the existence of quasi material entities, such as caloric, electricity and the ether, a wide range of observed facts falls into order as a necessary consequence of the assumptions. The question at issue is whether the hypotheses which are at the base of the scientific theories now most generally accepted are to be regarded as accurate descriptions of the constitution of the universe around us, or merely as convenient fictions.

Convenient fictions be it observed, for even if they are fictions they are not useless. From the practical point of view it is a matter of secondary importance whether our theories and assumptions are correct, if only they guide us to results which are in accord with facts. The whole fabric of scientific theory may be regarded merely as a gigantic 'aid to memory'; as a means for producing apparent order out of dis-

order by codifying the observed facts and laws in accordance with an artificial system, and thus arranging our knowledge under a comparatively small number of heads. The simplification introduced by a scheme which, however imperfect it may be, enables us to argue from a few first principles, makes theories of practical use. By means of them we can foresee the results of combinations of causes which would otherwise elude us. We can predict future events, and can even attempt to argue back from the present to the unknown past.

But it is possible that these advantages might be attained by means of axioms, assumptions and theories based on very false ideas. A person who thought that a river was really a streak of blue paint might learn as much about its direction from a map as one who knew it as it is. It is thus conceivable that we might be able, not indeed to construct, but to imagine, something more than a mere map or diagram, something which might even be called a working model of inanimate objects, which was nevertheless very unlike the realities of nature. Of course, the agreement between the action of the model and the behavior of the things it was designed to represent would probably be imperfect, unless the one were a facsimile of the other; but it is conceivable that the correlation of natural phenomena could be imitated, with a large measure of success, by means of an imaginary machine which shared with a map or diagram the characteristic that it was in many ways unlike the things it represented, but might be compared to a model in that the behavior of the things represented could be predicted from that of the corresponding parts of the machine.

We might even go a step further. If the laws of the working of the model could be expressed by abstractions, as, for example, by mathematical formulæ, then, when the formulæ were obtained, the model might be

discarded, as probably unlike that which it was made to imitate, as a mere aid in the construction of equations, to be thrown aside when the perfect structure of mathematical symbols was erected.

If this course were adopted we should have given up the attempt to know more of the nature of the objects which surround us than can be gained by direct observation, but might nevertheless have learned how these objects would behave under given circumstances.

We should have abandoned the hope of a physical explanation of the properties of inanimate nature, but should have secured a mathematical description of her operations.

There is no doubt that this is the easiest path to follow. Criticism is avoided if we admit from the first that we cannot go below the surface; cannot know anything about the constitution of material bodies; but must be content with formulating a description of their behavior by means of laws of nature expressed by equations.

But if this is to be the end of the study of nature, it is evident that the construction of the model is not an essential part of the process. The model is used merely as an aid to thinking; and if the relations of phenomena can be investigated without it, so much the better. The highest form of theory—it may be said—the widest kind of generalization, is that which has given up the attempt to form clear mental pictures of the constitution of matter, which expresses the facts and the laws by language and symbols which lead to results that are true, whatever be our view as to the real nature of the objects with which we deal. From this point of view the atomic theory becomes not so much false as unnecessary; it may be regarded as an attempt to give an unnatural precision to ideas which are and must be vague.

Thus, when Rumford found that the

mere friction of metals produced heat in unlimited quantity, and argued that heat was therefore a mode of motion, he formed a clear mental picture of what he believed to be occurring. But his experiments may be quoted as proving only that energy can be supplied to a body in indefinite quantity, and when supplied by doing work against friction it appears in the form of heat.

By using this phraseology we exchange a vivid conception of moving atoms for a colorless statement as to heat energy, the real nature of which we do not attempt to define; and methods which thus evade the problem of the nature of the things which the symbols in our equations represent have been prosecuted with striking success, at all events within the range of a limited class of phenomena. A great school of chemists, building upon the thermodynamics of Willard Gibbs and the intuition of Van't Hoff, have shown with wonderful skill that, if a sufficient number of the data of experiment are assumed, it is possible, by the aid of thermodynamics, to trace the form of the relations between many physical and chemical phenomena without the help of the atomic theory.

But this method deals only with matter as our coarse senses know it; it does not pretend to penetrate beneath the surface.

It is therefore with the greatest respect for its authors, and with a full recognition of the enormous power of the weapons employed, that I venture to assert that the exposition of such a system of tactics cannot be regarded as the last word of science in the struggle for the truth.

Whether we grapple with them, or whether we shirk them; however much or however little we can accomplish without answering them, the questions still force themselves upon us: Is matter what it seems to be? Is interplanetary space full or empty? Can we argue back from the

direct impressions of our senses to things which we cannot directly perceive; from the phenomena displayed by matter to the constitution of matter itself?

It is these questions which we are discussing to-night, and we may therefore, as far as the present address is concerned, put aside, once for all, methods of scientific exposition in which an attempt to form a mental picture of the constitution of matter is practically abandoned, and devote ourselves to the inquiries whether the effort to form such a picture is legitimate, and whether we have any reason to believe that the sketch which science has already drawn is to some extent a copy, and not a mere diagram, of the truth.

SUCCESSIVE STEPS IN THE ANALYSIS OF MATTER.

In dealing, then, with the question of the constitution of matter and the possibility of representing it accurately, we may grant at once that the ultimate nature of things is, and must remain, unknown; but it does not follow that immediately below the complexities of the superficial phenomena which affect our senses there may not be a simpler machinery of the existence of which we can obtain evidence, indirect indeed but conclusive.

The fact that the apparent unity which we call the atmosphere can be resolved into a number of different gases is admitted; though the ultimate nature of oxygen, nitrogen, argon, carbonic acid and water vapor is as unintelligible as that of air as a whole, so that the analysis of air may be said to have substituted many incomprehensibles for one.

Nobody, however, looks at the question from this point of view. It is recognized that an investigation into the proximate constitution of things may be useful and successful, even if their ultimate nature is beyond our ken.

Nor need the analysis stop at the first step. Water vapor and carbonic acid, themselves constituents of the atmosphere, are in turn resolved into their elements, hydrogen, oxygen and carbon, which, without a formal discussion of the criteria of reality, we may safely say are as real as air itself.

Now at what point must this analysis stop if we are to avoid crossing the boundary between fact and fiction? Is there any fundamental difference between resolving air into a mixture of gases and resolving an elementary gas into a mixture of atoms and ether?

There are those who cry halt at the point at which we divide a gas into molecules, and their first objection seems to be that molecules and atoms cannot be directly perceived, cannot be seen or handled, and are mere conceptions, which have their uses, but cannot be regarded as realities.

It is easiest to reply to this objection by an illustration.

The rings of Saturn appear to be continuous masses separated by circular rifts. This is the phenomenon which is observed through a telescope. By no known means can we ever approach or handle the rings; yet everybody who understands the evidence now believes that they are not what they appear to be, but consist of minute moonlets, closely packed indeed, but separate the one from the other.

In the first place Maxwell proved mathematically that if a Saturnian ring were a continuous solid or fluid mass it would be unstable and would necessarily break into fragments. In the next place, if it were possible for the ring to revolve like a solid body, the inmost parts would move slowest, while a satellite moves faster the nearer it is to a planet. Now spectroscopic observation, based on the beautiful method of Sir W. Huggins, shows not only that the inner portions of the ring move the more

rapidly, but that the actual velocities of the outer and inner edges are in close accord with the theoretical velocities of satellites at like distances from the planet.

This and a hundred similar cases prove that it is possible to obtain convincing evidence of the constitution of bodies between whose separate parts we cannot directly distinguish, and I take it that a physicist who believes in the reality of atoms thinks that he has as good reason for dividing an apparently continuous gas into molecules as he has for dividing the apparently continuous Saturnian rings into satellites. If he is wrong it is not the fact that molecules and satellites alike cannot be handled and cannot be seen as individuals that constitutes the difference between the two cases.

It may, however, be urged that atoms and the ether are alleged to have properties different from those of matter in bulk, of which alone our senses take direct cognizance, and that therefore it is impossible to prove their existence by evidence of the same cogency as that which may prove the existence of a newly discovered variety of matter or of a portion of matter too small or too distant to be seen.

This point is so important that it requires full discussion, but in dealing with it, it is necessary to distinguish carefully between the validity of the arguments which support the earlier and more fundamental propositions of the theory; and the evidence brought forward to justify mere speculative applications of its doctrines which might be abandoned without discarding the theory itself. The proof of the theory must be carried out step by step.

The first step is concerned wholly with some of the most general properties of matter, and consists in the proof that those properties are either absolutely unintelligible, or that, in the case of matter of all kinds, we are subject to an illusion similar to that, the results of which we admit in the

case of Saturn's rings, clouds, smoke, and a number of similar instances. The believer in the atomic theory asserts that matter exists in a particular state; that it consists of parts which are separate and distinct the one from the other, and as such are capable of independent movements.

Up to this point no question arises as to whether the separate parts are, like grains of sand, mere fragments of matter; or whether, though they are the bricks of which matter is built, they have, as individuals, properties different from those of masses of matter large enough to be directly perceived. If they are mere fragments of ordinary matter, they cannot be used as aids in explaining those qualities of matter which they themselves share.

We cannot explain things by things themselves. If it be true that the properties of matter are the product of an underlying machinery, that machinery cannot itself have the properties which it produces, and must, to that extent at all events, differ from matter in bulk as it is directly presented to the senses.

If, however, we can succeed in showing that if the separate parts have a limited number of properties (different, it may be, from those of matter in bulk), the many and complicated properties of matter can, to a considerable extent, be explained as consequences of the constitution of these separate parts; we shall have succeeded in establishing, with regard to quantitative properties, a simplification similar to that which the chemist has established with regard to varieties of matter. The many will have been reduced to the few.

The proofs of the physical reality of the entities discovered by means of the two analyses must necessarily be different. The chemist can actually produce the elementary constituents into which he has resolved a compound mass. No physicist or chemist can produce a single atom separated

from all its fellows, and show that it possesses the elementary qualities he assigns to it. The cogency of the evidence for any suggested constitution of atoms must vary with the number of facts which the hypothesis that they possess that constitution explains.

Let us take, then, two steps in their proper order, and inquire, first, whether there is valid ground for believing that all matter is made up of discrete parts; and secondly, whether we can have any knowledge of the constitution or properties which those parts possess.

THE COARSE-GRAINEDNESS OF MATTER.

Matter in bulk appears to be continuous. Such substances as water or air appear to the ordinary observer to be perfectly uniform in all their properties and qualities, in all their parts.

The hasty conclusion that these bodies are really uniform is, nevertheless, unthinkable.

In the first place the phenomena of diffusion afford conclusive proof that matter when apparently quiescent is in fact in a state of internal commotion. I need not recapitulate the familiar evidence to prove that gases and many liquids when placed in communication interpenetrate or diffuse into each other; or that air, in contact with a surface of water, gradually becomes laden with water vapor, while the atmospheric gases in turn mingle with the water. Such phenomena are not exhibited by liquids and gases alone, nor by solids at high temperatures only. Sir W. Roberts-Austen has placed pieces of gold and lead in contact at a temperature of 18° C. After four years the gold had traveled into the lead to such an extent that not only were the two metals united, but, on analysis, appreciable quantities of the gold were detected even at a distance of more than 5 millimeters from the common surface, while within a distance of three-quarters of a millimeter from the

surface gold had penetrated into the lead to the extent of 1 oz. 6 dwts. per ton, an amount which could have been profitably extracted.

Whether it is or is not possible to devise any other intelligible account of the cause of such phenomena, it is certain that a simple and adequate explanation is found in the hypothesis that matter consists of discrete parts in a state of motion, which can penetrate into the spaces between the corresponding parts of the surrounding bodies.

The hypothesis thus framed is also the one which affords a rational explanation of other simple and well-known facts. If matter is regarded as a continuous medium the phenomena of expansion are unintelligible. There is, apparently, no limit to the expansion of matter, or, to fix our attention on one kind of matter, let us say to the expansion of a gas; but it is inconceivable that a continuous material which fills or is present in every part of a given space could also be present in every part of a space a million times as great. Such a statement might be made of a mathematical abstraction; it cannot be true of any real substance or thing. If, however, matter consists of discrete particles, separated from each other either by empty space or by something different from themselves, we can at once understand that expansion and contraction may be nothing more than the mutual separation or approach of these particles.

Again, no clear mental picture can be formed of the phenomena of heat unless we suppose that heat is a mode of motion. In the words of Rumford, "it is extremely difficult, if not quite impossible, to form any distinct idea of anything capable of being excited and communicated in the manner the heat was excited and communicated in [his] experiment [on friction] except it be motion."* And if heat be mo-

tion, there can be no doubt that it is the fundamental particles of matter which are moving. For the motion is not visible, is not motion of the body as a whole, while diffusion, which is a movement of matter, goes on more quickly as the temperature rises, thereby proving that the internal motions have become more rapid, which is exactly the result which would follow if these were the movements which constitute sensible heat.

Combining, then, the phenomena of diffusion, expansion and heat, it is not too much to say that no hypotheses which make them intelligible have ever been framed other than those which are at the basis of the atomic theory.

Many other considerations also point to the same conclusion. Many years ago Lord Kelvin gave independent arguments, based on the properties of gases, on the constitutions of the surfaces of liquids, and on the electric properties of metals, all of which indicate that matter is, to use his own phrase, coarse-grained—that it is not identical in constitution throughout, but that adjacent minute parts are distinguishable from each other by being either of different natures or in different states.

And here it is necessary to insist that all these fundamental proofs are independent of the nature of the particles or granules into which matter must be divided.

The particles, for instance, need not be different in kind from the medium which surrounds and separates them. It would suffice if they were what may be called singular parts of the medium itself, differing from the rest only in some peculiar state of internal motion or of distortion, or by being in some other way earmarked as distinct individuals. The view that the constitution of matter is atomic may and does receive support from theories in which definite assumptions are made as to the constitution of the atoms; but when, as is

* *Phil. Trans.*, 1798, p. 99.

often the case, these assumptions introduce new and more recondite difficulties, it must be remembered that the fundamental hypothesis—that matter consists of discrete parts, capable of independent motions—is forced upon us by facts and arguments which are altogether independent of what the nature and properties of these separate parts may be.

As a matter of history the two theories, which are not by any means mutually exclusive, that atoms are particles which can be treated as distinct in kind from the medium which surrounds them, and that they are parts of that medium existing in a special state, have both played a large part in the theoretical development of the atomic hypothesis. The atoms of Waterston, Clausius and Maxwell were particles. The vortex-atoms of Lord Kelvin, and the strain-atoms (if I may call them so) suggested by Mr. Larmor, are states of a primary medium which constitutes a physical connection between them, and through which their mutual actions arise and are transmitted.

PROPERTIES OF THE BASIS OF MATTER.

It is easy to show that, whichever alternative be adopted, we are dealing with something, whether we consider it under the guise of separate particles or of differentiated portions of the medium, which has properties different from those of matter in bulk.

For if the basis of matter had the same constitution as matter, the irregular heat movements could hardly be maintained either against the viscosity of the medium or the frittering away of energy of motion which would occur during the collisions between the particles. Thus, even in the case in which a hot body is prevented from losing heat to surrounding objects, its sensible heat should spontaneously decay by a process of self-cooling. No such phenomenon

is known, and though on this, as on all other points, the limits of our knowledge are fixed by the uncertainty of experiment, we are compelled to admit that, to all appearance, the fundamental medium, if it exists, is unlike a material medium, in that it is non-viscous; and that the particles, if they exist, are so constituted that energy is not frittered away when they collide. In either case we are dealing with something different from matter itself in the sense that, though it is the basis of matter, it is not identical in all its properties with matter.

The idea therefore that entities exist possessing properties different from those of matter in bulk is not introduced at the end of a long and recondite investigation to explain facts with which none but experts are acquainted. It is forced upon us at the very threshold of our study of nature. Either the properties of matter in bulk cannot be referred to any simpler structure, or that simpler structure must have properties different from those of matter in bulk as we directly knew it—properties which can only be inferred from the results which they produce.

No *à priori* argument against the possibility of our discovering the existence of quasi-material substances, which are nevertheless different from matter, can prove the negative proposition that such substances cannot exist. It is not a self-evident truth that no substance other than ordinary matter can have an existence as real as that of matter itself. It is not axiomatic that matter cannot be composed of parts whose properties are different from those of the whole. To assert that even if such substances and such parts exist no evidence, however cogent, could convince us of their existence is to beg the whole question at issue; to decide the cause before it has been heard.

We must therefore adhere to the stand-

point adopted by most scientific men, *viz.*, that the question of the existence of ultra-physical entities, such as atoms and the ether, is to be settled by the evidence, and must not be ruled out as inadmissible on *à priori* grounds.

On the other hand, it is impossible to deny that, if the mere entry on the search for the concealed causes of physical phenomena is not a trespass on ground we have no right to explore, it is at all events the beginning of a dangerous journey.

The wraiths of phlogiston, caloric, luminiferous corpuscles and a crowd of other phantoms haunt the investigator, and as the grim host vanishes into nothingness he cannot but wonder if his own conceptions of atoms and of the ether

‘shall dissolve,

And, like this insubstantial pageant faded,

Leave not a wrack behind.’

But though science, like Bunyan’s hero, has sometimes had to pass through the ‘Valley of Humiliation,’ the spectres which meet it there are not really dangerous if they are boldly faced. The facts that mistakes have been made, that theories have been propounded, and for a time accepted, which later investigations have disproved, do not necessarily discredit the method adopted. In scientific theories, as in the world around us, there is a survival of the fittest, and Dr. James Ward’s unsympathetic account of the blunders of those whose work, after all, has shed glory on the nineteenth century, might *mutatis mutandis* stand for a description of the history of the advance of civilization. “The story of the progress so far,” he tells us, “is briefly this: Divergence between theory and fact one part of the way, the wreckage of abandoned fictions for the rest, with an unattainable goal of phenomenal nihilism and ultra-physical mechanism beyond.”*

* James Ward, ‘Naturalism and Agnosticism,’ Vol. I., p. 153.

“The path of progress,” says Professor Karl Pearson, “is strewn with the wreck of nations. Traces are everywhere to be seen of the hecatombs of inferior races, and of victims who found not the narrow way to the greater perfection. Yet these dead peoples are, in very truth, the stepping-stones on which mankind has arisen to the higher intellectual and deeper emotional life of to-day.”*

It is only necessary to add that the progress of society is directed towards an unattainable goal of universal contentment, to make the parallel complete.

And so, in the one case as in the other, we may leave ‘the dead to bury their dead.’ The question before us is not whether we too may not be trusting to false ideas, erroneous experiments, evanescent theories. No doubt we are; but, without making an insolent claim to be better than our fathers, we may fairly contend that, amid much that is uncertain and temporary, some of the fundamental conceptions, the root-ideas of science are so grounded on reason and fact that we cannot but regard them as an aspect of the very truth.

Enough has, perhaps, now been said on this point for my immediate purpose. The argument as to the constitution of matter could be developed further in the manner I have hitherto adopted, *viz.*, by series of propositions, the proof of each of which is based upon a few crucial phenomena. In particular, if matter is divided into moving granules or particles, the phenomenon of cohesion proves that there must be mutual actions between them analogous to those which take place between large masses of matter, and which we ascribe to force, thereby indicating the regular, unvarying operation of active machinery which we have not yet the means of adequately understanding. For the moment, I do not wish

* Karl Pearson, ‘National Life from the Standpoint of Science,’ p. 62.

to extend the line of reasoning that has been followed. My main object is to show that the notion of the existence of ultra-physical entities and the leading outlines of the atomic theory are forced upon us at the beginning of our study of nature, not only by *à priori* considerations, but in the attempt to comprehend the results of even the simplest observation. These outlines cannot be effaced by the difficulties which undoubtedly arise in filling up the picture. The cogency of the proof that matter is coarse-grained is in no way affected by the fact that we may have grave doubts as to the nature of the granules. Nay, it is of the first importance to recognize that, though the fundamental assumptions of the atomic theory receive overwhelming support from a number of more detailed arguments, they are themselves almost of the nature of axioms, in that the simplest phenomena are unintelligible if they are abandoned.

THE RANGE OF THE ATOMIC THEORY.

It would be most unfair, however, to the atomic theory to represent it as depending on one line of reasoning only, or to treat its evidence as bounded by the very general propositions I have discussed.

It is true that as the range of the theory is extended the fundamental conception that matter is granular must be expanded and filled in by supplementary hypotheses as to the constitution of the granules. It may also be admitted that no complete or wholly satisfactory description of that constitution can as yet be given; that perfection has not yet been attained here or in any other branch of science; but the number of facts which can be accounted for by the theory is very large compared with the number of additional hypotheses which are introduced; and the cumulative weight of the additional evidence obtained by the study of details is such as to add greatly

to the strength of the conviction that, in its leading outlines, the theory is true.

It was originally suggested by the facts of chemistry, and though, as we have seen, a school of chemists now thrusts it into the background, it is none the less true, in the words of Dr. Thorpe, that 'every great advance in chemical knowledge during the last ninety years finds its interpretation in [Dalton's] theory.'*

The principal mechanical and thermal properties of gases have been explained, and in a large part discovered, by the aid of the atomic theory; and, though there are outstanding difficulties, they are, for the most part, related to the nature of the atoms and molecules, and do not affect the question as to whether they exist.

The fact that different kinds of light all travel at the same speed in interplanetary space, while they move at different rates in matter, is explained if matter is coarse-grained. But to attempt to sum up all this evidence would be to recite a text-book on physics. It must suffice to say that it is enormous in extent and varied in character, and that the atomic theory imparts a unity to all the physical sciences which has been attained in no other way.

I must, however, give a couple of instances of the wonderful success which has been achieved in the explanation of physical phenomena by the theory we are considering, and I select them because they are in harmony with the line of argument I have been pursuing.

When a piece of iron is magnetized its behavior is different according as the magnetic force applied to it is weak, moderate or strong. When a certain limit is passed the iron behaves as a non-magnetic substance to all further additions on magnetic force. With strong forces it does and with very weak forces it does not remain mag-

* Thorpe, 'Essays on Historical Chemistry,' 1849, p. 368.

netized when the force ceases to act. Professor Ewing has imitated all the minute details of these complicated properties by an arrangement of small isolated compass needles to represent the molecules. It may fairly be said that as far as this particular set of phenomena is concerned a most instructive working model based on the molecular theory has not only been imagined but constructed.

The next illustration is no less striking. We may liken a crowd of molecules to a fog; but while the fog is admitted by everybody to be made up of separate globules of water, the critics of scientific method are sometimes apt to regard the molecules as mere fictions of the imagination. If, however, we could throw the molecules of a highly rarefied gas into such a state that vapor condensed on them, so that each became the center of a water-drop, till the host of invisible molecules was, as it were, magnified by accretion into a visible mist, surely no stronger proof of their reality could be desired. Yet there is every reason to believe that something very like this has been accomplished by Mr. C. T. R. Wilson and Professor J. J. Thomson.

It is known that it is comparatively difficult to produce a fog in damp air if the mixture consists of air and water-vapor alone. The presence of particles of very fine dust facilitates the process. It is evident that the vapor condenses on the dust particles and that a nucleus of some kind is necessary on which each drop may form. But electrified particles also act as nuclei; for if a highly charged body from which electricity is escaping be placed near a steam jet, the steam condenses; and a cloud is also formed in dust-free air more easily than would otherwise be the case if electricity is discharged into it.

Again, according to accepted theory, when a current of electricity flows through a gas some of the atoms are divided into

parts which carry positive and negative charges as they move in opposite directions, and unless this breaking-up occurs a gas does not conduct electricity. But a gas can be made a conductor merely by allowing the Röntgen rays or the radiation given off by uranium to fall upon it. A careful study of the facts shows that it is probable that some of the atoms have been broken up by the radiation, and that their oppositely electrified parts are scattered among their unaltered fellows. Such a gas is said to be ionized.

Thus by these two distinct lines of argument we come to the conclusions: 1st, that the presence of electrified particles promotes the formation of mist, and 2d, that in an ionized gas such electrified particles are provided by the breaking-up of atoms.

The two conclusions will mutually support each other if it can be shown that a mist is easily formed in ionized air. This was tested by Mr. Wilson, who showed that in such air mist is formed as though nuclei were present, and thus in the cloud we have visible evidence of the presence of the divided atoms. If then we cannot handle the individual molecules we have at least some reason to believe that a method is known of seizing individuals, or parts of individuals, which are in a special state, and of wrapping other matter round them till each one is the center of a discrete particle of a visible fog.

I have purposely chosen this illustration, because the explanation is based on a theory—that of ionization—which is at present subjected to hostile criticism. It assumes that an electrical current is nothing more than the movement of charges of electricity. But magnets placed near to an electric current tend to set themselves at right angles to its direction; a fact on which the construction of telegraphic instruments is based. Hence if the theory be true, a similar effect ought to be produced by a

moving charge of electricity. This experiment was tried many years ago in the laboratory of Helmholtz by Rowland, who caused a charged disc to spin rapidly near a magnet. The result was in accord with the theory; the magnet moved as though acted upon by an electric current. Of late, however, M. Crémieu has investigated the matter afresh, and has obtained results which, according to his interpretation, were inconsistent with that of Rowland.

M. Crémieu's results are already the subject of controversy,* and are, I believe, likely to be discussed in the Section of Physics. This is not the occasion to enter upon a critical discussion of the question at issue, and I refer to it only to point out that though, if M. Crémieu's result were upheld, our views as to electricity would have to be modified, the foundations of the atomic theory would not be shaken.

It is, however, from the theory of ions that the most far-reaching speculations of science have recently received unexpected support. The dream that matter of all kinds will some day be proved to be fundamentally the same has survived many shocks. The opinion is consistent with the great generalization that the properties of elements are a periodic function of their atomic weights. Sir Norman Lockyer has long been a prominent exponent of the view that the spectra of the stars indicate the reduction of our so-called elements to simpler forms, and now Professor J. J. Thomson believes that we can break off from an atom a part, the mass of which is not more than one-thousandth of the whole, and that these corpuscles, as he has named them, are the carriers of the negative charge in an electric current. If atoms are thus complex, not only is the *à priori* probability increased that the different structures which

we call elements may all be built of similar bricks, but the discovery by Lenard that the ease with which the corpuscles penetrate different bodies depends only on the density of the obstacles, and not on their chemical constitution, is held by Professor Thomson to be 'a strong confirmation of the view that the atoms of the elementary substances are made up of simpler parts, all of which are alike.'* On the present occasion, however, we are occupied rather with the foundations than with these ultimate ramifications of the atomic theory; and having shown how wide its range is, I must, to a certain extent, retrace my steps and return to the main line of my argument.

THE PROPERTIES OF ATOMS AND MOLECULES.

For if it be granted that the evidence that matter is coarse-grained and is formed of separate atoms and molecules is too strong to be resisted, it may still be contended that we can know little or nothing of the sizes and properties of the molecules.

It must be admitted that though the fundamental postulates are always the same, different aspects of the theory, which have not in all cases been successfully combined, have to be developed when it is applied to different problems; but in spite of this there is little doubt that we have some fairly accurate knowledge of molecular motions and magnitudes.

If a liquid is stretched into a very thin film, such as a soap bubble, we should expect indications of a change in its properties when the thickness of the film is not a very large multiple of the average distance between two neighboring molecules. In 1890 Sohncke † detected evidence of such a

* For the most recent account of this subject see an article on 'Bodies Smaller than Atoms,' by Professor J. J. Thomson in the *Popular Science Monthly* (The Science Press), August, 1901.

† *Wied. Ann.*, 1890, XL., pp. 345-355.

* See *Phil. Mag.*, July, 1901, p. 144; and *Johns Hopkins University Circulars*, XX., No. 152, May-June, 1901, p. 78.

change in films of average thickness of 106 millionths of a millimeter ($\mu\mu$), and quite recently Rudolph Weber found it in an oil-film when the thickness was 115 $\mu\mu$.*

Taking the mean of these numbers and combining the results of different variants of the theory we may conclude that a film should become unstable and tend to rupture spontaneously somewhere between the thicknesses of 110 and 55 $\mu\mu$, and Professor Reinold and I found by experiment that this instability is actually exhibited between the thicknesses of 96 and 45 $\mu\mu$.† There can therefore be little doubt that the first approach to molecular magnitude is signalled when the thickness of a film is somewhat less than 100 $\mu\mu$, or 4 millionths of an inch.

Thirteen years ago I had the honor of laying before the Chemical Society a résumé of what was then known on these subjects,‡ and I must refer to that lecture or to the most recent edition of O. E. Meyer's work on the kinetic theory of gases§ for the evidence that various independent lines of argument enable us to estimate quantities very much less than 4 millionths of an inch, which is perhaps from 500 to 1,000 times greater than the magnitude which, in the present state of our knowledge, we can best describe as the diameter of a molecule.

Confining our attention, however, to the larger quantities, I will give one example to show how strong is the cumulative force of the evidence as to our knowledge of the magnitudes of molecular quantities.

We have every reason to believe that though the molecules in a gas frequently collide with each other, yet in the case of the more perfect gases the time occupied in

collisions is small compared with that in which each molecule travels undisturbed by its fellows. The average distance traveled between two successive encounters is called the mean free path, and, for the reason just given, the question of the magnitude of this distance can be attacked without any precise knowledge of what a molecule is, or of what happens during an encounter.

Thus the mean free path can be determined, by the aid of the theory, either from the viscosity of the gas or from the thermal conductivity. Using figures given in the latest work on the subject,* and dealing with one gas only, as a fair sample of the rest, the lengths of the mean free path of hydrogen as determined by these two independent methods differ only by about 3 per cent. Further, the mean of the values which I gave in the lecture already referred to differed only by about 6 per cent. from the best modern result, so that no great change has been introduced during the last thirteen years.

It may, however, be argued that these concordant values are all obtained by means of the same theory, and that a common error may affect them all. In particular, some critics have of late been inclined to discredit the atomic theory by pointing out that the strong statements which have sometimes been made as to the equality, among themselves, of atoms or molecules of the same kind may not be justified, as the equality may be that of averages only, and be consistent with a considerable variation in the sizes of individuals.

Allowing this argument more weight than it perhaps deserves, it is easy to show that it cannot affect seriously our knowledge of the length of the mean free path.

Professor George Darwin † has handled the problem of a mixture of unequal spher-

§ 'Kinetic Theory of Gases,' O. E. Meyer, 1899. Translated by R. E. Baynes.

* Meyer's 'Kinetic Theory of Gases' (see above).

† *Phil. Trans.*, 180.

ical bodies in the particular case in which the sizes are distributed according to the law of errors, which would involve far greater inequalities than can occur among atoms. Without discussing the precise details of his problem it is sufficient to say that in the case considered by him the length of the mean free path is $\frac{7}{11}$ of what it would be if the particles were equal. Hence were the inequalities of atoms as great as in this extreme case, the reduction of the mean free path in hydrogen could only be from 185 to 119 $\mu\mu$; but they must be far less, and therefore the error, if any, due to this cause could not approach this amount. It is probably inappreciable.

Such examples might be multiplied but the one I have selected is perhaps sufficient to illustrate my point, *viz.*, that considerable and fairly accurate knowledge can be obtained as to molecular quantities by the aid of theories the details of which are provisional, and are admittedly capable of improvement.

IS THE MODEL UNIQUE?

But the argument that a correct result may sometimes be obtained by reasoning on imperfect hypotheses raises the question as to whether another danger may not be imminent. To be satisfactory our model of nature must be unique, and it must be impossible to imagine any other which agrees equally well with the facts of experiment. If a large number of hypotheses could be framed with equal claims to validity, that fact would alone raise grave doubts as to whether it were possible to distinguish between the true and the false. Thus Professor Poincaré has shown that an infinite number of dynamical explanations can be found for any phenomenon which satisfies certain conditions. But though this consideration warns us against the too ready acceptance of explanations of isolated phenomena, it has no weight

against a theory which embraces so vast a number of facts as those included by the atomic theory. It does not follow that, because a number of solutions are all formally dynamical, they are therefore all equally admissible. The pressure of a gas may be explained as the result of a shower of blows delivered by molecules, or by a repulsion between the various parts of a continuous medium. Both solutions are expressed in dynamical language; but one is, and the other is not, compatible with the observed phenomena of expansion. The atomic theory must hold the field until another can be found which is not inferior as an explanation of the fundamental difficulties as to the constitution of matter, and is, at the same time, not less comprehensive.

On the whole, then, the question as to whether we are attempting to solve a problem which has an infinite number of solutions may be put aside until one solution has been found which is satisfactory in all its details. We are in a sufficient difficulty about that to make the rivalry of a second of the same type very improbable.

THE PHENOMENA OF LIFE.

But it may be asked—nay, it has been asked—may not the type of our theories be radically changed? If this question does not merely imply a certain distrust in our own powers of reasoning, it should be supported by some indication of the kind of change which is conceivable.

Perhaps the chief objection which can be brought against physical theories is that they deal only with the inanimate side of nature, and largely ignore the phenomena of life. It is therefore in this direction, if in any, that a change of type may be expected. I do not propose to enter at length upon so difficult a question, but, however we may explain or explain away the characteristics of life, the argument for the truth of the atomic theory would only be

affected if it could be shown that living matter does not possess the thermal and mechanical properties, to explain which the atomic theory has been framed. This is so notoriously not the case that there is the gravest doubt whether life can in any way interfere with the action within the organism of the laws of matter in bulk belonging to the domain of mechanics, physics, and chemistry.

Probably the most cautious opinion that could now be expressed on this question is that, in spite of some outstanding difficulties which have recently given rise to what is called Neovitalism, there is no conclusive evidence that living matter can suspend or modify any of the natural laws which would affect it if it were to cease to live. It is possible that though subject to these laws the organism while living may be able to employ, or even to direct, their action within itself for its own benefit, just as it unquestionably does make use of the processes of external nature for its own purposes; but if this be so, the seat of the controlling influence is so withdrawn from view that on the one hand its very existence may be denied, while, on the other hand, Professor Haeckel, following Vogt, has recently asserted that "matter and ether are not dead, and only moved by extrinsic force; but they are endowed with sensation and will; they experience an inclination for condensation, a dislike for strain; they strive after the one and struggle against the other."*

But neither unproved assertions of this kind nor the more refined attempts that have been made by others to bring the phenomena of life and of dead matter under a common formula touch the evidence for the atomic theory. The question as to whether matter consists of elements capable of independent motion is prior to

and independent of the further questions as to what these elements are, and whether they are alive or dead.

The physicist, if he keeps to his business, asserts, as the bases of the atomic theory, nothing more than that he who declines to admit that matter consists of separate moving parts must regard many of the simplest phenomena as irreconcilable and unintelligible, in spite of the fact that means of reconciling them are known to everybody, in spite of the fact that the reconciling theory gives a general correlation of an enormous number of phenomena in every branch of science, and that the outstanding difficulties are connected, not so much with the fundamental hypotheses that matter is composed of distinguishable entities which are capable of separate motions as with the much more difficult problem of what these entities are.

On these grounds the physicist may believe that, though he cannot handle or see them, the atoms and molecules are as real as the ice crystals in a cirrus cloud which he cannot reach; as real as the unseen members of a meteoric swarm whose death-glow is lost in the sunshine, or which sweep past us, unentangled, in the night.

If the confidence that his methods are weapons with which he can fight his way to the truth were taken from the scientific explorer, the paralysis which overcomes those who believe that they are engaged in a hopeless task would fall upon him.

Physiology has specially flourished since physiologists have believed that it is possible to master the physics and chemistry of the framework of living things, and since they have abandoned the attitude of those who placed in the foreground the doctrine of the vital force. To supporters of that doctrine the principle of life was not a hidden directing power which could perhaps whisper an order that the flood-gates of reservoirs of energy should now be opened

* 'Riddle of the Universe' (English translation), 1900, p. 380.

and now closed, and could, at the most, work only under immutable conditions to which the living and dead must alike submit. On the contrary, their vital force pervaded the organism in all its parts. It was an active and energetic opponent of the laws of physics and chemistry. It maintained its own existence not by obeying but by defying them; and though destined to be finally overcome in the separate campaigns of which each individual living creature is the scene, yet like some guerilla chieftain it was defeated here only to reappear there with unabated confidence and apparently undiminished force.

This attitude of mind checked the advance of knowledge. Difficulty could be evaded by a verbal formula of explanation which in fact explained nothing. If the mechanical, or physical, or chemical causes of a phenomenon did not lie obviously upon the surface, the investigator was tempted to forego the toil of searching for them below; it was easier to say that the vital force was the cause of the discrepancy, and that it was hopeless to attempt to account for the action of a principle which was incomprehensible in its nature.

For the physicist the danger is no less serious though it lies in a somewhat different direction. At present he is checked in his theories by the necessity of making them agree with a comparatively small number of fundamental hypotheses. If this check were removed his fancy might run riot in the wildest speculations, which would be held to be legitimate if only they led to formulæ in harmony with facts. But the very habit of regarding the end as everything, and the means by which it was attained as unimportant, would prevent the discovery of those fragments of truth which can only be uncovered by the painful process of trying to make inconsistent theories agree, and using all facts, however remote, as the tests of our central generalization.

"Science," said Helmholtz, "Science, whose very object it is to comprehend Nature, must start with the assumption that Nature is comprehensible." And again: "The first principle of the investigator of Nature is to assume that Nature is intelligible to us, since otherwise it would be foolish to attempt the investigation at all." These axioms do not assume that all the secrets of the universe will ultimately be laid bare, but that a search for them is hopeless if we undertake the quest with the conviction that it will be in vain. As applied to life they do not deny that in living matter something may be hidden which neither physics nor chemistry can explain, but they assert that the action of physical and chemical forces in living bodies can never be understood, if at every difficulty and at every check in our investigations we desist from further attempts in the belief that the laws of physics and chemistry have been interfered with by an incomprehensible vital force. As applied to physics and chemistry they do not mean that all the phenomena of life and death will ultimately be included in some simple and self-sufficing mechanical theory; they do mean that we are not to sit down contented with paradoxes such as that the same thing can fill both a large space and a little one; that matter can act where it is not, and the like, if by some reasonable hypothesis, capable of being tested by experiment, we can avoid the acceptance of these absurdities. Something will have been gained if the more obvious difficulties are removed, even if we have to admit that in the background there is much that we cannot grasp.

THE LIMITS OF PHYSICAL THEORIES.

And this brings me to my last point. It is a mistake to treat physical theories in general, and the atomic theory in particular, as though they were parts of a scheme

which has failed if it leaves anything unexplained, which must be carried on indefinitely on exactly the same principles, whether the ultimate results are, or are not, repugnant to common sense.

Physical theories begin at the surface with phenomena which directly affect our senses. When they are used in the attempt to penetrate deeper into the secrets of nature it is more than probable that they will meet with insuperable barriers, but this fact does not demonstrate that the fundamental assumptions are false, and the question as to whether any particular obstacle will be forever insuperable can rarely be answered with certainty.

Those who belittle the ideas which have of late governed the advance of scientific theory too often assume that there is no alternative between the opposing assertions that atoms and the ether are mere figments of the scientific imagination, or that, on the other hand, a mechanical theory of the atoms and of the ether, which is now confessedly imperfect, would, if it could be perfected, give us a full and adequate representation of the underlying realities.

For my own part I believe that there is a *via media*.

A man peering into a darkened room, and describing what he thinks he sees, may be right as to the general outline of the objects he discerns, wrong as to their nature and their precise forms. In his description fact and fancy may be blended, and it may be difficult to say where the one ends and the other begins; but even the fancies will not be worthless if they are based on a fragment of truth, which will prevent the explorer from walking into a looking-glass or stumbling over the furniture. He who saw 'men as trees walking' had at least a perception of the fundamental fact that something was in motion around him.

And so, at the beginning of the twentieth century, we are neither forced to abandon

the claim to have penetrated below the surface of nature, nor have we, with all our searching, torn the veil of mystery from the world around us.

The range of our speculations is limited both in space and time: in space, for we have no right to claim, as is sometimes done, a knowledge of the 'infinite universe'; in time, for the cumulative effects of actions which might pass undetected in the short span of years of which we have knowledge, may, if continued long enough, modify our most profound generalizations. If some such theory as the vortex-atom theory were true, the faintest trace of viscosity in the primordial medium would ultimately destroy matter of every kind. It is thus a duty to state what we believe we know in the most cautious terms, but it is equally a duty not to yield to mere vague doubts as to whether we can know anything.

If no other conception of matter is possible than that it consists of distinct physical units—and no other conception has been formulated which does not blur what are otherwise clear and definite outlines—if it is certain, as it is, that vibrations travel through space which cannot be propagated by matter, the two foundations of physical theory are well and truly laid. It may be granted that we have not yet framed a consistent image either of the nature of the atoms or of the ether in which they exist; but I have tried to show that in spite of the tentative nature of some of our theories, in spite of many outstanding difficulties, the atomic theory unifies so many facts, simplifies so much that is complicated, that we have a right to insist—at all events till an equally intelligible rival hypothesis is produced—that the main structure of our theory is true; that atoms are not merely helps to puzzled mathematicians, but physical realities.

ARTHUR W. RÜCKER.

UNIVERSITY OF LONDON.

*A NOTABLE FACTOR OF SOCIAL DEGENERATION.**

THE subject to which I propose to call your attention cannot be said to be a new one, though I do not think that it has ever been presented before this Section. I wish to speak for a short time on one of the phases of social anthropology, in which I am very greatly interested. My theme is the problem of the feeble-minded. This term is now generally used to include all persons from those with weak minds to the most abject idiot. Perhaps most of us have met with a few individuals of this class. Almost every community contains one or more of these degenerates. The aggregate for our country, however, makes a mighty host. We do not know how many feeble-minded persons there are in the United States. The census of 1890 gives 95,571 individuals of that kind. From Pennsylvania there were reported that year 8,753; Ohio, 8,035; Indiana, 5,568; Iowa, 3,319; Kansas, 2,039; Colorado, 192. What the increase since then has been we do not know. The present census does not give any figures on this point; therefore any effort to ascertain the number can be but an estimate. These feeble-minded persons are distributed throughout our land, not in the same proportion everywhere. They are not so notable in some localities as in others. In some places they are so few or inconspicuous as scarcely to be recognized. On the contrary, elsewhere their presence is strikingly manifest, and they, in one way or another, make a deep impression upon society that must endure through succeeding generations. The feeble-minded are found under many conditions. There are children and men and women. It is as children and as adults in their more active years that most of us

know them best. Our social organization is made up of many factors. Some are constructive, some destructive. The feeble-minded are a disturbing element. Their life is a degenerating social force.

Some of the children with stronger mental powers enter the public schools. They may make some progress for a time, but whether they do or not, they must soon drop behind because they are unable to keep up with the work. Others roam the streets; the boys become the butt of the neighborhood, they are led into pranks, too often into vices, and seem to possess a peculiar tendency to immorality. The girls, many of them strong, well-appearing, with no one to teach them aright, and without strength of mind to protect themselves against the temptations which surround them, too early and too often fall into vice. "It is impossible to think of the evil of feeble-mindedness without heeding the curse of vice and illegitimacy which are its inevitable accompaniments. In the feeble-minded person the animal passions are usually present and are often abnormally developed, while will and reason, which should control and repress them, are absent. The feeble-minded woman, thus lacking the protection which should be her birthright, falls easily into vice. She cannot in her weakness resist the persuasions and temptations which beset her. When her baser passions are strong, she must oppose not only the influences from without but her own dominating desires. She is not to be condemned and punished, but rather to be pitied and helped in every possible manner." (Bicknell, Proc. Fourth Indiana State Conf. of Char. & Corr., 1895, p. 64.) Many of these poor creatures are easily attracted by an immoral life. Once begun, the pace is rapid, the course is always the same. It is impossible to tell or even to conceive of the depths of degradation to which they go. Dr. Kerlin, in

* Address of the Vice-President and Chairman of Section H, Anthropology, of the American Association for the Advancement of Science, Denver meeting, August, 1901.

1884, in his report to the National Conference of Charities and Correction speaks of moral imbecility, showing its blighting and demoralizing effects. He shows how crime, vice and depravity are spread by neglected feeble-minded or imbecile persons. He says, "There is no field in political economy which can be worked to better advantage for the diminution of crime, pauperism and insanity than that of idiocy." (Proc. Nat. Conf. of Char. and Cor., 1884, pp. 257 and 258.)

One perverted feeble-minded woman can spread throughout a community an immoral pestilence which will affect the homes of all classes, even the most intelligent and refined. The sight of such conditions or a knowledge of them must have a deadening effect upon the finer sensibilities of all.

These defectives usually also become dependents for a part of, if not all, the time. They may depend upon private charities or, when possible, upon the overseer of the poor. They frequently live in the poorest quarters of our towns and cities amid squalor and dirt, or occupy miserable huts in the least desirable localities of rural communities. It is not unusual for two or more families to live near each other or associate together. Marital ties are often lightly regarded. Frequently such bonds have not been entered into.

When these feeble-minded persons become helpless or learn the habit of regular public dependence, they find their way to poor asylums, the children being placed in such orphans' homes as will accept them. To one who visits the poor asylums and orphans' homes where they are received, the idiotic and feeble-minded are striking objects. In every one of the ninety-two poor asylums in my own State, Indiana, there are to be found inmates of this class, the greatest number in any one institution being 25; the lowest, 2. In

many, their presence is emphasized by pitiable cases, individuals who are almost uncontrollable, or by infants, the offspring—in most cases the illegitimate offspring—of parents, one or both of whom are feeble-minded. The records at hand show that there are 970 feeble-minded persons in the Indiana poor asylums. (Rept. Board of State Char. of Indiana, 1900, p. 73.) Almost all these are adults. Many are in some degree helpless and all require more or less care. They have grown up without discipline; they lack such training as is possible with their dwarfed minds or strong hands; they are not only incapable of earning their own support, but, in a large number of instances, are the objects of continual anxiety to those in charge. This is particularly the case with feeble-minded women. Four hundred and eighty unfortunates of this sex are to be found in our county asylums, comprising 49.5 of their total feeble-minded population. Under our system of care it is only by the utmost watchfulness that the sexes are kept apart. Where proper facilities for sex separation are wanting, or the overwatch is not strict, there is to be found a continual increase of feeble-mindedness. This brings an increasing burden of expense upon the tax-payers in such counties.

I am compelled to speak specifically of Indiana, because we know more of the facts concerning conditions that exist there than we do of those elsewhere.

From information received, however, it is believed that they are not materially different from those existing in other States similarly situated. Perhaps in a general way the conditions there may be said to be the average of what is true of all our States.

To quite a large number of our poor asylums the inmates often come and go at will. The absence of the feeble-minded is especially noted during the summer season. They then go to visit friends or wander

about the country. Any kind of shelter will answer their purpose and food is easily obtained. Quite a number of the women return to the poor asylum to become mothers.

In a certain county in the southern part of the State is a family of sixteen persons, representing three generations. Twelve of its members are the direct descendants of a feeble-minded blind man and his feeble-minded, partially blind, wife. The husband and wife have been inmates of the poor asylum off and on for thirty-five years. Generally wintering in the institution, they spend the summer roaming about the country, living in the woods. In unfavorable weather they seek an old hut or rail pen for shelter. They are said to make a bed of leaves or straw and live on what they can beg, supplemented by wild fruits and nuts. They have a feeble-minded daughter who is also partially blind. She has been twice married and has borne two feeble-minded daughters and three feeble-minded sons. Another feeble-minded and partially blind daughter has spent the greater part of the last twenty-two years in the poor asylum of an adjacent county and has been the mother of four illegitimate children. In this family of sixteen persons, nine are feeble-minded (three of these being also partially blind) and four are known to be illegitimate.

In an adjoining county are a husband and wife, both degenerates, who make the poor asylum their home in winter and live elsewhere in summer. It is no uncommon thing, in the spring following these wanderings, to have the family increased by a little mite of humanity which does not seem as if it could live. Many such children do live, however. This woman has borne eleven children and six of them are alive. One summer the family lived in a little shed built of short boards obtained from dry-goods boxes, old tin and carpets, along the railroad right-of-way, and obtained its liv-

ing principally from begging. This family has just made a beginning. How extensive it may become depends upon what measures are taken. It has probably been an expense of \$1,000 per year to the county.

Occasionally the children of normal parents are feeble-minded. As Mr. Bicknell has well said, there is no method of diverting the course. While it is easily possible for parents of normal faculties through dissipation, vice or disease to produce feeble-minded offspring, there seems to be no method by which the tendency can be reversed and the degeneration, thus easily accomplished, displaced by regeneration and restoration in succeeding generations. (Fifth Rept. of Indiana Board of State Charities, 1894, page 51.)

Usually, and in a large number of cases, feeble-minded children are the offspring of feeble-minded parents. It is equally true that in the majority of cases the children of feeble-minded parents are feeble-minded.

From what has been said may be gathered that the question before us presents two notable evils:

- (a) The increasing number of illegitimate children of feeble-minded parents.
- (b) The inheritance of feeble-mindedness.

In the office of the Board of State Charities of Indiana there has been collected, from every reliable source, during the past twelve years, a great mass of material relating to this group of defectives. It embraces much that has been gathered by the Indiana School for Feeble-minded Youth especially through the efforts of Mr. Alexander Johnson, its able superintendent. In addition, it contains such information as could be obtained from the Poor Asylum and Orphans' Home records and from the township trustees who are *ex-officio* overseers of the poor. I know of no such a series of records nor one so conveniently arranged. Mr. Ernest P. Bicknell, formerly the Secre-

tary of the Board of State Charities, some years ago prepared two papers based upon a part of this material. (Proc. Indiana State Conf. of Char. and Cor., 1895, p. 60. Proc. National Conf. of Char. and Cor., 1887, p. 219.)

With the fuller amount of data from these records at hand I have thought to present some illustrations obtained from it at this time.

Perhaps I may say a word as to the method of registration used in this work. From all our institutions regular reports are required. Some of these are made monthly, others quarterly. They are arranged with headings for all the principal facts in the individual and family history of each inmate. It is desired to have them filled as fully as the information obtained will permit. In addition to the regular institution records, information is sought as to the age, nativity, sex, color, mental and physical condition, and whether illegitimate. If parents are known we ask for their names and specific information as to whether either is affected with insanity, feeble-mindedness, deafness, blindness, paralysis, or whether either was a pauper, criminal or drunkard. This information, when obtained, is transferred to a card registration, where the cards are kept in duplicate; one series arranged alphabetically, the other by institutions. To the information at hand every fragment that is learned is added.

I have taken from these records some information concerning 511 families in which there is known to be feeble-mindedness. If there was any question regarding any family it was omitted. No such collection of these families has heretofore been reported upon. The number of persons known to be represented in them is 1,924. This is an average of 3.76 persons in each family. 1,343 of these persons are supported in public institutions. It is known, how-

ever, that these are not all the family representatives. They are the family members of whom we have accurate information. In it are included not only direct descendants, but those related by marriage.

Of this number of persons, 889, 46.2 per cent., were men; 1,035, 53.7 per cent., were women. 1,249—64.9 per cent., 532 men and 717 women, were feeble-minded; 54, 21 men and 33 women, were insane; 44, 25 men and 19 women, were otherwise defective. These last include blind, deaf, paralytics and epileptics. 577, 311 men and 268 women, were normal or their defectiveness was unknown. Every person known concerning whom positive information was not included in this latter group. In a number of cases there are combinations of defectiveness. One was insane and deaf, another feeble-minded, deaf and epileptic. Consequently, if we undertake to separate them we find there are 79 epileptics, 31 men and 48 women; 35 blind, 17 men and 18 women; 21 deaf, 6 men and 15 women; 19 paralytics, 8 men and 11 women; with combined mental and physical defects 101, 34 men and 67 women. Of these family members, 267, 13.8 per cent., 141 men and 126 women, are known to have been illegitimate.

What about the parentage of these individuals? In a large number of cases the characteristics are unknown. It is a matter of record that in 1,042 cases (over 54 per cent. of the whole) either one or both parents were defective. Of these in the cases of 666—348 males and 318 females, the mother was defective. In the case of 151, 83 males and 68 females, the father was defective, the mother unknown or normal. Both parents were defective in 225 instances, 122 males and 103 females. It will be seen that the records show the mother defective in 34.6 per cent. of the total number of cases noted herein, while only 7.8 per cent. of the fathers were defective, and both parents were defective

A TABLE OF 511 FEEBLE-MINDED FAMILIES CONTAINING 1,924 PERSONS.

in 11.6 per cent. instances. One cause of this difference, perhaps the chief one, is that the mothers, for various reasons which will occur to you, are often known when the fathers are not. The parents of 860 of the 1,924 children, 326 men and 534 women, an aggregate of 44.6 per cent., were either unknown or were known to be normal. In but 22 instances (1.1 per cent.) were the parents reported to be relatives. This was true in the case of 10 men and 12 women.

The physical and mental condition of the parents of these 889 males is more specifically given as follows :

Mother defective, father unknown or normal.....	348 or 39.1%
Father defective, mother unknown or normal.....	83 or 9.3%
Both parents defective.....	122 or 13.7%
Parents unknown or normal.....	326 or 36.6%
Parents related.....	10 or 1.1%
	889 99.8%

141, or 15.8 per cent., of the males are illegitimate.

The physical and mental condition of the parents of these 1,035 females more particularly stated is as follows :

Mother defective, father normal or unknown.....	318 or 30.7%
Father defective, mother normal or unknown.....	68 or 6.5%
Both parents defective.....	103 or 9.9%
Parents unknown or normal.....	534 or 51.5%
Parents related.....	12 or 1.1%
	1,035 99.7%

(' Defective ' in the above means either mentally or physically defective.)

Of the 717 feeble-minded women, 163, or 22 per cent., have had illegitimate children. These 163 women have had 248 children, an average of 1.52 each. They range in number from 1 to 8 to the mother.

Perhaps it is well to refer to a few illustrations of the ancestors of the persons whom we have been discussing.

In one of the county poor asylums of Indiana, years ago, were a man and his

wife, who are reported to have been of a low grade of intelligence, if not actually feeble-minded. The direct descendants of this couple, with those who entered the family through marriage, number 67, comprising three generations. One of the men, who is fairly bright, has raised a good family; another is an intelligent barber; two men have served in the army, but the majority of the family are feeble-minded, illiterate and of low morals, and their history is one of drunkenness, prostitution and crime. The marriage relation has been lightly regarded, and doubtless many of the unions were those of common law. Some of these persons are self-supporting, but a much larger number of them are or have been supported by the public in county or state institutions.

One woman I recall is the mother of eleven children, ten of them by one husband, one by another. A feeble-minded man whose history is known to us, was father of twenty children but was married several times.

Another group of 241 families in which there are two or more generations of feeble-mindedness has 970 persons who are blood relations, that is an average of 4.02 to each family. Of these families, 221 have two generations of feeble-mindedness, sixteen have three generations, three have four generations and one has five generations. The number of direct descendants who are feeble-minded is known to be 726. That is to say, 74.8 per cent. are feeble-minded. Does anything else reproduce itself so surely? In addition to this there are 25 who show other evidences of defectiveness. But 197 are normal or their mental and physical condition is unknown.

In the first generation 103 men and 203 women (306) were the parents of 248 children. Of these 84 were males and 164 were females. It is observed that almost twice as many women as men were known

as parents in the first generation. The reason is the women were principally poor asylum inmates who were permitted to leave the institution and either live among relatives of a similar stage of mentality or roam the country. They returned to the poor asylum as a maternity house and nothing was learned or recorded of the paternity of many of the children.

persons, 304 males and 224 females. Of these, 26 were parents of the third generation. Of the latter seven were parents of the fourth generation. From it came the single parent of the fifth generation. In the first generation there were 267 individuals of 306, or 87 per cent., who were feeble-minded; in the second generation 386 of 548, or 70 per cent., were so recorded; in the

Most of the families obviously are of two generations. The child and parent are reported, and often nothing has been learned of an earlier ancestor. Where there are three or four generations some of the older members are dead, so that the amount of information concerning them is scant. On the other hand the later generation is represented by one or more children, many of them so young that their mental state cannot be determined.

In the second generation there were 548

third generation 59 of 95, or 62 per cent., were so noted; in the fourth generation 13 of 20 cases, or 65 per cent., were given as feeble-minded. In the fifth generation the single representative is reported as feeble-minded. The aggregate showing, as noted, is that 74.8 per cent. of the descendants of these feeble-minded ancestors are feeble-minded. Other defects among the children are noted as follows: insane, 3.4 per cent.; epileptic, 3.8 per cent.; blind, 2 per cent.; deaf, 8 per cent.; paralysis, 9 per cent.;

both mentally and physically defective, 5.5 per cent. 107 or 11 per cent. were reported as illegitimate.

It will be observed that the feeble-minded and blind are more common than any other combination in the first generation, while in the second and third generations there are more feeble-minded and epileptics.

In one neighboring county a feeble-minded woman, who, according to the records in our office, has been in the poor asylum over twenty years, was the mother of two daughters, to whom she transmitted her mental defect. One of these feeble-minded daughters, Rachel, has been twice married, and has borne eleven children, three of whom are now dead. Her second union was with a negro. Her children are very ignorant, but so far our records do not show that they have been inmates of any public institution, with the exception of one son, who has been in prison. The other daughter,

sons have been the result of this marriage. One of the daughters is feeble-minded. One of the sons, also feeble-minded, is a natural criminal. The direct descendants of the feeble-minded woman first mentioned number twenty-nine, and in the past ten years twelve of these persons have spent an aggregate of twenty-two years in the poor asylum and orphans' home of the county. The total family members reported number forty-seven and extend over five generations.

One group of 13 feeble-minded families is recorded containing 68 individuals. Of these there were 18 in the first generation; 26 in the second; 24 in the third. With these degenerates it is not always true that when there is a little child there are three persons in a family. The paternity is not always known and in many cases we are compelled to count two persons, the mother and child. All the members of the first generation were feeble-minded; twenty

Kate, had four children, all girls, two feeble-minded and two illegitimate. The two feeble-minded daughters have spent much of their lives in the county poor asylum. One of them, Nancy, became the third wife of a feeble-minded, paralytic man, and one son and three feeble-minded daughters were born to her. Her husband's second wife had a feeble-minded daughter, who married an insane man, and they have one child, a son. Nancy's feeble-minded sister, Lou, married a feeble-minded man, and three daughters and two

of the second generation showed the same defect. The mental condition of the third generation is not given. The reason is that they were reported when they were at an age at which it could not be determined. Eleven of its members, however, are reported as illegitimate. The 11 women in the first generation were the mothers of 26 children. The 24 members of the third generation are the children of 12 of these. It will be noted that when the younger members of a generation are born in an institution, or become inmates very young, their mental condition cannot be reported and often is not known unless they are readmitted when

*No. of persons in 2d generation who had children = 12.

they become older and the psychosis can be determined. Neither the husbands nor the wives of the members of this group are counted in this table. Those enumerated are the direct descendants of the persons in the preceding generation.

It is not unusual to find in a poor asylum three generations of feeble-mindedness. Not long since, the speaker had grouped before him, at a poor asylum in the southern part of the State, four generations of feeble-minded persons—father born in 1817, daughter, granddaughter and great-grandson. There are nineteen members of this family; nine are feeble-minded and four are illegitimate. Most of them have been inmates of the institution where they were seen. Some of them recur to it from time to time yet. This is not a single instance, for in other poor asylums an equal number of generations, similarly afflicted, can be found, and in fact there are instances where five generations have at one time or another been inmates of such a county institution.

Years and years ago a single man here and there—a prophet in a strange land—began to call attention to the condition of the idiot. They were treated as animals in confinement. At the beginning of the present century the first institution was built for their care.

Dr. Walter E. Fernald tells us that the first recorded attempt to educate an idiot was made about the year 1800 by Itard, the celebrated physician-in-chief to the National Institution for the Deaf and Dumb at Paris, upon a boy found wild in a forest in the center of France, and known as the 'Savage of Aveyron.' This boy could not speak any human tongue, and was devoid of all understanding and knowledge. Believing him to be a savage, for five years Itard endeavored with great skill and perseverance to develop at the same time the intelligence of his pupil and the theories of the materialistic school of philosophy.

Itard finally became convinced that this boy was an idiot, and abandoned the attempt to educate him. (Proc. Nat. Conf. Char. and Cor., 1893, page 203.)

In 1818 the American Asylum for the Deaf and Dumb, at Hartford, Conn., the first institution of its kind in this country, gave the first instruction offered in the United States to idiotic children. Following this several attempts were made in teaching such children in France, Switzerland and Germany. But a few could be cared for. Slowly the thought of the possibility of their improvement spread. The progress of the work was slow. Individuals were interested and pressed into it. Finally a state took some interest.

In 1846 the first effort was made for legal provision for the instruction of idiots in this country in New York. This was unsuccessful; but a few days later in the same year action looking to similar results was begun in Massachusetts. This culminated in legislation in 1848, providing for the education of 'ten indigent idiots.' Thus began our public institutions for idiotic or feeble-minded children. In New York efforts providing for such a school were repeatedly made, but it was not until 1851 that they were entirely successful and the act passed in that State. Pennsylvania was the third State to begin the work in 1852. It was followed by Ohio in 1857. One after another of our States has recognized the duty of providing education, training and care for these unfortunates. In a number of States institutions of the highest standing have been developed. Dr. Fernald tells us the early history of these pioneer State institutions in many respects was very similar. They were practically all begun as tentative experiments in the face of great public distrust and doubt as to the value of the results to be obtained.

At last it became recognized that those who had given years of study to the idiot

had a right to have an opinion and to express it. Then it came to be believed and advocated that in this class of defectives were many who were amenable to instruction if it were only of the right kind and taught in the right way. The children might be reached and helped.

First it was thought that many of these children could be educated to make their own way in the world. Finally it was decided that while many of them could be taught to be self-supporting under direction, but very few could ever leave the fostering care of the institution. Children they are and children they will be as long as they live. For, though they become old in years, mentally they will still be children.

More and more came the conviction that there should be custodial institutions. These were especially advocated for feeble-minded women under forty-five years of age. They would be safe and with no prospect of reproducing their kind. Now it has come to be regarded as the proper right and duty to retain control over these grown-up children during life. Some states have made a beginning for this purpose.

Never did we appreciate so strongly as we do to-day the untold misery and accumulating expense caused by the lack of control of our feeble-minded population. Their fecundity and animal instincts make them fit subjects for consideration, both on financial and moral grounds, to say nothing of the dangers that beset those of strong minds who have weaker bodies.

The problem presented to us is the manner in which these conditions shall be met. Its solution lies in an intelligent and general knowledge of the subject by the public, preventive measures by legal marriage restrictions and other means, the education of feeble-minded children and the custodial care of feeble-minded women.

AMOS W. BUTLER.

INDIANAPOLIS, IND.

SCIENTIFIC BOOKS.

Anatomy of the Cat. By JACOB REIGHARD, Professor of Zoology in the University of Michigan, and H. S. JENNINGS, Instructor in Zoology in the University of Michigan. 173 original figures by LOUISA BURRIDGE JENNINGS. Henry Holt & Co. 1901. 8vo. Pp. ix+498.

Teachers and students alike will welcome the appearance of this admirable text-book because it is practically the only work which treats of the entire macroscopic anatomy of the cat, the mammal most generally available for class-room study. Of the books on the cat hitherto published none unites in itself all the requirements of a satisfactory text-book; they are either inaccurate and diffuse or accurate and meager, while another class which covers parts of the subject exhaustively is not available because incomplete. We believe that, with the aid of this present work, a teacher will find no difficulty in conducting a thorough laboratory course and can cover the entire ground in a college year. The authors are to be congratulated, not only upon producing a book which will secure a higher grade of class-room work, but also upon the completion of an important scientific contribution which cannot fail to stimulate and encourage a wider teaching of elementary anatomy. In one sense this is not an elementary work; the descriptions are scientific and concise, without attempt at popular writing. Moreover, it presupposes a knowledge on the part of the student of such general matters as the nature of tissues, the functions of organs and the meanings of scientific terms. Hence its use would seem to call for accompanying lectures or for previous preparation in courses on histology and general biology.

We are glad to see that the authors have not cast the book in the form of a laboratory guide; structures are described in their proper order and relation, the amount of space devoted to the different systems of organs being determined not only by their relative importance, but also by the amount of work on each which can be expected from the average student. Thus, for example, almost one-half of the entire work is devoted to a description of the bones and muscles, and but one-eighth to the viscera.

The descriptive portion of the book is followed by an appendix of practical directions, covering forty-three pages. Herein are given general directions for study and for the preparation of material, together with special directions for the dissection of each group of organs—as they present themselves to the student and not in the order in which they are studied in the descriptive portion of the work. The separation of these notes from the body of the book of course preserves continuity to the descriptions and enhances the value of the book as a work of reference; on the other hand, it necessitates such an amount of turning of pages by the student that it would have been wiser to have brought the practical directions into closer relation with the text—at the beginning or at the end of each section or chapter.

In the matter of nomenclature, as the authors maintain, and properly, that the primary purpose of such a work is not to illustrate or defend any particular system of nomenclature, but to aid in obtaining a knowledge of the structures themselves, and as they hold that the time has not come for an absolutely uniform nomenclature, they have adopted such terms as they judge likely to be measurably permanent. As a basis, therefore, they use, as far as possible, the Latin terms (and their English equivalents) proposed by the German Anatomical Society, but freely substitute for these other terms, either when those proposed are not appropriate for the cat, as, for example, the names for the cerebral sulci or gyri, or when the substitutes are better known to English anatomists and are not likely to be given up, as, for example, *trapezoid* for *os multangulum minus*. In cases of substitution the Latin name proposed by the German Society is given as a synonym. Whenever a structure has two names, equally well-known, both names are given. It is certainly most desirable that each structure should have a single name; if however, there be two, the student should learn them.

As terms of direction the authors properly use, almost exclusively, such intrinsic terms as *dorsal* and *ventral*; *cranial* and *caudal*; *proximal* and *distal*; *medial* and *lateral*, and they discard the older extrinsic terms *anterior* and *posterior*; *superior* and *inferior*; *inner* and *outer*. *Dorsal*

and *ventral* are also applied, less happily we think, to surfaces of the limbs; the dorsal side being indicated by the convexity of the joint, elbow or knee, the ventral side by the concavity of the joint. The constant use of adverbial forms such as *dorsad*, *cranialad*, *proximalad*, etc., certainly gives brevity and directness to the text; they do not add, however, to its elegance—nor does the use of *onto* for *on*.

We have examined the greater part of the book with care and find it to be well planned, clearly written and based on accurate original study. Some things are omitted which, from the general thoroughness of the work, one would have expected to find, as, for example, an account of the interesting arrangement of the tendons and ligaments attached to the terminal phalanges. To reduce the book to a convenient size, omissions, of course, are necessary; what shall be omitted must remain a matter of personal opinion. The drawings by Mrs. Jennings which illustrate the work are excellent; they show clearly what the student is expected to see and are not burdened with unnecessary detail. A few diagrams from frozen sections to show the relations of organs would have been instructive. The book is well made; type, paper, printing and binding are all good; and there is a capital index.

HORACE JAYNE.

Zell- und Protoplasmastudien. By F. DOFLEIN. 1900.

Under the above title Dr. F. Doflein publishes in brochure form a reprint of his paper in Spengel's 'Zoolog. Jahrbücher,' XIV. This contribution is the first Heft of the author's studies on the morphology and physiology of nuclear and cell-division. It deals, in the main, with the process of nuclear division in *Noctiluca miliaris*. The author gives a very detailed account of his work on preserved material. He differs in several particulars from the results of previous writers, the most important differences being his failure to identify the centrosome in any part of the astrophere, and his denial of a longitudinal splitting of the chromosomes as described by Calkins. The latter author has shown, from the arrangement of the chromatin threads at a certain phase in the division that

it is probable that a longitudinal splitting of the chromosomes takes place. Doflein does not find any evidence of such in process. In the absence of conclusive proof it is impossible to decide which of these two accounts is correct.

SCIENTIFIC JOURNALS AND ARTICLES.

The Plant World for August contains, besides short articles, notes and reviews, 'August Days,' by John Burroughs; 'Notes from Western Kentucky,' by Sallie F. Price, and, under the caption 'A Scanty Flora, a description of that of Bird Rock, Gulf of St. Lawrence,' by Henry E. Baum. But three species of plants are found on this islet: *Poa compressa*, *Achillea borealis* and *Plantago maritima*. Pauline Kaufman continues 'Orchids in Central Park,' and John Gifford describes 'The Dwarf Mistletoe, *Razoumofskya Prusilla*.' L. H. Pammel discusses 'Rare Plants and their Disappearance,' the drying up of sloughs and the overpasturing of the woodlot being accountable for the small numbers of the plants mentioned. In the supplement devoted to 'The Families of Flowering Plants,' Charles Louis Pollard describes the Trigoniaceæ and other families of the Germinales and begins the description of the Sapindales.

The News Bulletin of the Zoological Society of New York appeared in new form with its last (July) issue, having been reduced to a small quarto about the size of *SCIENCE*. Besides a number of views of animals living in the park, there is a cut showing the state of the monkey house in June. The completion of a restaurant and of the Service Building is announced, and many improvements in the buildings and grounds are noted. Six species of mammals, twelve of birds and eight of reptiles were born in the park this present season. A special feature of the New York Zoo is its collection of reptiles, and the additions to this have been numerous during the first six months of the year.

The Osprey for July brings this periodical nearly down to date, and the August number is promised at an early day. The present issue contains besides shorter articles 'Camping on the Old Camp Grounds,' by Paul Bartsch;

'Stephen's Whip-poor-will,' by J. H. Riley; 'The Malar Stripe of Young Flickers and the Moults,' by William Palmer; 'The Blue Grosbeak in Eastern Kansas,' by Walter S. Colvin, and the sixth instalment of 'The Osprey or Fish-hawk; its Characteristics and Habits,' by Theodore Gill.

SCIENTIFIC journals are not often sold, and it is consequently a matter of interest that the market value of a special journal has been ascertained by the sale of the *Botanisches Centralblatt* to the International Association of Botanists. According to the *Compte Rendu* of the recent congress the price was 37,500 Marks, and the present editor, Dr. Uhlworm retains his position for five years, and if subsequently superseded receives an indemnity. About half the amount has been subscribed, and the balance has been advanced by the publisher, J. E. Brille, of Leipzig, who is to be paid 4 per cent. interest.

DISCUSSION AND CORRESPONDENCE.

DISCORD AND PSYCHOLOGY.

TO THE EDITOR OF *SCIENCE*: In the issue of *SCIENCE* for August 30 Mr. Max Meyer calls attention, in a discussion of 'Discords and Beats,' to a supposed error in my review of a recent book on physics, where I referred to Mayer's law expressing the duration of the residual auditory sensation as a function of vibration frequency. He is right in thinking it rare to find physicists well up with current psychological literature, a fact necessitated by the immense mass of literature now in all departments. This fact excuses Mr. Meyer for having apparently failed to read the investigations of Professor Mayer on this subject, which were published in the *American Journal of Science* (Oct., 1874, April, 1875, and Jan., 1894). This physicist did not assume that discord was necessarily due exclusively to beats. His own conclusions were tested in 1875 by a trained musician whose deliverances were given without considering anything else than the perception of discord. This was a purely psychological investigation, therefore, so far as musical sensation was concerned. If the psychologists have some time since agreed that discord cannot be defined by beats, this negative conclusion does not estab-

lish the proposition that all discord is wholly independent of beats. Whether it be due wholly or partly to beats or to something else quite unknown as yet, Mayer's curve is sufficient to disprove the statement that the maximum of discord is due to always the same number of beats, whatever may be the pitch.

It was not my intention to publish any detailed criticism of the point to which I took exception in my review of the book of physics under examination. But Mr. Meyer will probably agree with me in objecting to the following sentences, which may now be quoted: "One cause of discord is the presence of beats between the two notes, and the greatest discord results when the beats are about 32 per second. If the number of beats is fewer than 10 per second, they are not agreeable, but do not produce discord. Discord is caused by sounding together notes that give more than 10 and less than 70 beats per second." Whatever may be the cause of discord now agreed upon among psychologists, Mayer's law comes nearer to being a statement of the truth than the sentences just quoted. The author is creditably cautious in assigning the presence of beats as 'one cause.' Presumably it may not be the only cause. But his quantitative statements warranted my criticism that he had "defined 'discord' more sharply than the facts warrant by failure to recognize Mayer's law."

If Mr. Meyer will criticise the quoted sentences from the standpoint of the psychologist he will doubtless confer a favor upon physicists who have not kept up with recent advances in psychology.

W. LE CONTE STEVENS.

WASHINGTON AND LEE UNIVERSITY,
August 31, 1901.

MAGAZINE ENTOMOLOGY.

It has been the habit to charge newspapers with the dissemination of scientific misinformation, and undoubtedly with considerable justice. But they are not the sole sinners. In the September number of *McClure's Magazine* there is a paper entitled 'Next to the Ground; Stories and Scenes of Farm Life,' by Martha McCulloch Williams. The amount of misinformation it conveys cannot be equalled by any bit of

newspaper writing, and for ignorance on the part of the author it is certainly entitled to the palm. First, we have information about the dragon fly, and the superstition concerning snakes that is connected with it; that is all right; but we are immediately afterward informed that it begins its early life as a fat white grub, variously known as Hellgrammite, dobson, etc. Now, in the first place, the hellgrammite is neither white, nor fat, nor is it a grub; and in the second place, it has absolutely no connection with the dragon fly.

From any elementary work on entomology, national or foreign, the writer could have obtained an accurate life history of the dragon fly, and also information as to the adult stages of the hellgrammite. She may have seen a dragon fly; she certainly never saw a hellgrammite to know it. Then we learn something about the locusts, and most interesting, we are told that the eggs are laid in the pith of dying twigs. So much has been written about these insects that it does seem as if the authoress might have known better than to make an assertion of this kind. Pithy stems are rarely used by locusts, if at all, and dying twigs are never attacked. The eggs are always laid in growing shoots, and in the wood itself. I wonder where she saw the black beetles or 'Betty bugs' that were three inches long? She speaks of them as 'Scarabs,' and the largest of these, occurring in the United States entitled to that name, are not more than one inch in length.

More marvelous than anything else is the description of the change from the tumble bug, black and loutish, into a 'June bug,' green all over, with copper yellow tints on the legs, etc. Where in the world this information came from, if it was not the product of overstrained imagination, seems incomprehensible. In fact, reading the entire paper, which covers eight pages, there is more dense ignorance and absolute misinformation crowded into it than I have seen anywhere on a similar subject within the last decade. And what there was in it anywhere, to recommend to the editor its publication, seems almost beyond finding out. There has been of late years a great revival of interest in natural history. We have had many useful and accurate books, including the topics on which Martha

McCulloch Williams writes. It would seem as if anyone intending to publish concerning natural history would at least familiarize himself or herself with the subject. It is discouraging to find a magazine like *McClure's* accepting and printing an article of this character.

JOHN B. SMITH.

NEW BRUNSWICK, September 12, 1901.

CURRENT NOTES ON PHYSIOGRAPHY.

THE RANGES OF THE GREAT BASIN.

THE mountain ranges of the Great basin in Utah and Nevada have been explained, chiefly by Gilbert and Russell, as due to block faulting, but without sufficient statement concerning the form of the region before faulting or of the amount of erosion since faulting. Hence the ranges have sometimes been imagined as presenting long, gentle back slopes where the pre-faulting surface has been tilted up, and abrupt frontal cliffs where the fault scarp is revealed; and in the absence of statement to the contrary it has been sometimes supposed that the faults by which the blocks are limited were determined by ordinary stratigraphic evidence.

Spurr now offers a new interpretation of these ranges ('Origin and Structure of the Basin Ranges,' *Bull. Geol. Soc. Amer.*, XII., 1901, 217-270, pl. 20-25). Finding monoclinical structure not persistent, finding much dissection on both slopes of the ranges, and finding no stratigraphic evidence of faulting along the base of the ranges, he discards the theory of block faulting and explains the mountains as residuals of a disordered and greatly denuded mass, the intermont depressions being regarded as valleys of erosion produced under a former greater rainfall and now clogged with waste since a drier climate has set in.

Attention is here called to the different values given by Spurr to the stratigraphic evidence of faults where both members of the faulted series are seen, and to the physiographic evidence where only one member is visible. Faults determined by ordinary stratigraphic evidence are spoken of as 'actually observed' (266), while faults announced by previous observers on physiographic evidence are altogether rejected, apparently because they are not confirmed by

stratigraphic proof. As a matter of fact, no faults (meaning thereby surfaces of fracture on which movements of dislocation have taken place) have been actually observed as such in the Great basin; faulting is there as elsewhere a matter of inference. In the case of faults proved by stratigraphy, the termination of one series of strata against another may be more or less closely observed; and then instead of believing that both sets of strata were 'made so' in the beginning, it is reasonably inferred that they both originally had greater extension, that they were brought into their present relations by dislocation, and that the dislocated mass has been carved into its present form by greater or less erosion. This demonstration is commonly accepted as so compulsory and all other explanations seem so infinitely improbable, that faulting proved by stratigraphic evidence is often treated as if it were a matter of first-hand observation, and given an equal order of verity with the plain facts of strike and dip.

In the case of faults proved by physiographic evidence, the outcrops of a series of strata in an escarpment or on a mountain side are directly observed; and then instead of believing that they were made so, it is inferred that the invisible parts of the series have been in some way removed. On finding that their removal cannot be reasonably accounted for by erosion alone, the aid of faulting is invoked, a greater or less amount of erosion being supposed to precede and to follow. This argument of course involves such a knowledge of the observable facts of structure and form, and such an understanding of the processes of erosion and of the forms resulting therefrom, that, while certain forms (such as the Appalachian ridges of Pennsylvania) may be reasonably ascribed to erosion alone acting on a deformed structure, certain other forms (such as the Basin ranges) may as reasonably be held to be beyond production by erosion, without relatively recent faulting. This demonstration of faulting may be just as logical as that based on stratigraphy alone, but it is somewhat more complicated and it is much less commonly employed.

Now inasmuch as the block faulting of the Basin ranges has been determined in nearly every case by the physiographic method alone,

it is certainly desirable that discussions of the Basin range structure should include a consideration of the criteria for the demonstration of faults by this means, when only one member of the faulted series is visible. Yet no such consideration of the problem is given by Spurr. He confirms earlier work by finding that marginal faults are not to be determined along the base of the ranges (except in rare instances) by ordinary stratigraphic evidence. He reiterates the undisputed fact that great erosion has occurred since the ancient folding and faulting within the body of the ranges, and he illogically infers from this that recent faulting, marginal to the ranges, has not taken place. Instead of dealing with the problem at issue—the sufficiency of physiographic evidence to prove block faulting—he asserts without adequate discussion the sufficiency of erosion to produce

upon it to attest its elevation. The block faulting of the Basin ranges may perhaps be some day disproved, but not until the evidence of faulting accepted by Gilbert and Russell has been shown to be valueless.

PHYSIOGRAPHIC EVIDENCE OF FAULTING.

The essential elements in the physiographic evidence of faulting in the Great basin are the impossibility of accounting for the presence of the mountain ranges if the intermont depressions have been produced by erosion alone, and the ease of accounting for them if the rough form of the region has been blocked out by faulting, leaving erosive processes only the smaller work of trimming the mountains into their present shape. The difficulty of dispensing with faulting is both qualitative and quantitative. In the first place, the structure of the

FIG. 1. Diagram of a mountain carved on a faulted block of previously deformed and denuded strata.

existing forms, and after the briefest consideration he denies the peculiar faulting that has been reasonably inferred on physiographic grounds to be essential for the production of the ranges. This is very much as if one should deny the modern uplift of the Appalachian Piedmont district after its broad denudation, because no strata containing marine fossils lie

ranges is commonly oblique to their border, so that the faulted margin passes indifferently from one structure to another, as in the accompanying figure; if the ranges were the residuals of a long period of undisturbed erosion, such a lack of correlation between border and structure would not be looked for; but if the ranges are limited by faults at one side or both, the

indifference of border to structure is natural enough. In the second place, the body of each range is usually continuous, although it may be incised by sharp-cut valleys; if the ranges were the residuals of a period of undisturbed erosion long enough to have permitted the excavation of broad intermont valley-lowlands, each range should be divided into isolated mountain groups by the opening of wide branch-valleys in its mass; but if the depressions and the ranges are blocked out by recent faulting, the continuity of the ranges is to be expected.

Both these tests are best met in southern Oregon, where the ranges as described by Russell are very little affected by erosion after faulting. Neither test is well met by certain ranges in southeastern California described by Fairbanks as almost worn down to grade. In Utah and Nevada both tests are well borne; but no definite statement has yet been published concerning the amount of erosion that has taken place in this district since the block faulting; nor has any careful inference been made as to the form that the region had before faulting, some remnants of which may perhaps still be detected on the lower back slope of the ranges. The absence of steep scarps along the faulted border of a range does not bear closely on the problem, although Spurr attaches much importance to it. Recent and rapid faulting would produce a scarp; but similar scarps produced less recently would now be more or less completely dissected and destroyed. Gradual faulting, even if continued into the historic period, would produce only a low basal scarp; the upper part of the fault face would be battered back and ravined. The truncated ends of certain spurs of the Wahsatch range near Prevo, Utah, seem to result from faulting of this kind, the fresh scarp that follows the base of the range being the product of the most recent episode of faulting.

No features due to recent faulting are seen in the Appalachians. The ridges there are intimately dependent upon the harder strata, the base of a ridge always follows the strike of the individual ridgemaker, and the lowlands between the ridges are demonstrably excavated by erosion on weak rocks. All these are conditions which no one has shown to obtain in

the Great basin; yet Spurr says: "Suppose the Appalachians, which likewise consist of parallel ridges eroded along lines of folding, should become arid, so that the rivers were unable to remove the detritus and the valleys become choked. There would develop in the course of time exactly what exists in the Basin region, namely, a nearly level desert, containing a series of parallel, synclinal, and anticlinal ranges" (p. 255). The strongest dissent from this unwarrantable comparison must be expressed.

THE KENTUCKY MOUNTAINEERS.

AN article that might serve as the type of many more is a description of the Kentucky mountaineers by Ellen C. Semple ('The Anglo-Saxons of the Kentucky Mountains: a Study in Anthropogeography,' *Geogr. Journ.*, XVII., 1901, 588-623). The dissected Alleghany plateau, which is of mountainous ruggedness in Kentucky and West Virginia, shares with the mountains of North Carolina the unenviable distinction of being less affected by civilization than any equal area east of the Rockies. So many old customs are there preserved that the people have been well named 'our contemporary ancestors.' Miss Semple's account of these primitive Americans is based on personal observation and affords many excellent illustrations of the consequences of living in a region too rough for easy movement and too poor to attract immigrants.

W. M. DAVIS.

THE UNIVERSITY OF CHICAGO'S FIELD WORK IN BOTANY, GEOLOGY AND ZOOLOGY.

PRESIDENT HARPER, of the University of Chicago, in his last quarterly statement gives the following details in regard to field work:

The work in biology at the Marine Biological Station at Wood's Holl, Mass., is largely in charge of University of Chicago men, the director and the majority of the staff being from this institution. The director of the Laboratory of the Brooklyn Institute at Cold Spring Harbor, Long Island, and one of the botanical staff this summer were members of this faculty. The work at both these

laboratories may be looked upon as field work of a somewhat permanent type. The courses are credited at the University of Chicago, although not formally under its charge.

Besides the local field work in connection with residence courses in botany, zoology and geology, field work during the past summer has been conducted at a distance from the University by the departments of geology and botany.

I. GEOLOGY.

1. A course in elementary field geology was given by Mr. R. D. George for four weeks of the second term of the summer quarter, the remainder of the term being devoted to the preparation of a report on the field work. A party of eleven traversed a region in the Mississippi valley between Prairie du Chien, Wis., and Muscatine, Ia. They devoted themselves to a study of (a) Paleozoic strata and fossils, (b) the topographic features of the driftless area in Iowa and Wisconsin, (c) the stratified drift of the valleys, (d) the loess, and (e) the lead and zinc deposits of the Dubuque region.

2. Professor R. D. Salisbury is in charge of several parties in Montana, Idaho and Utah. These parties consist of advanced students and are working somewhat independently, Professor Salisbury visiting the different parties at intervals and making suggestions regarding the work. A party of two is at Kipp, Mont., a second party of two at Kalispell, Mont. These two parties are investigating the phenomena of local glaciation in the Rocky mountains. Another party of two is at work in the Santa Fé mountains of New Mexico, studying their structural and stratigraphic features. A party of six, under the immediate direction of Mr. W. W. Atwood, is at work on the Wahsatch mountains, studying similar problems.

BOTANY.

1. A party of eight, under the direction of Mr. S. M. Coulter, of Washington University, spent the first part of the second term of the summer quarter at North Manitou Island, passing over later to the mainland in the vicinity of Petoskey and Charlevoix, studying the ecological relations of the flora in these regions. This work is essentially an examination of the way

in which plants associate themselves and an investigation of the determining factors of environment for each society.

2. Similar but more extended work has been undertaken by a party of eighteen in charge of Dr. H. C. Cowles. This party has a car on the Great Northern Railroad, and is stopping at various favorable localities through Montana and Washington. Two weeks were spent at Flat Head Lake, Montana, the site of the biological station of the University of Montana, whose facilities were put at the disposal of the party; another week was spent at Belton, Mont.; and other stops were made at Leavenworth and Seattle, Wash. This is the most extended field trip yet offered in the department of botany and has certainly presented unusual advantages to the students for a study of widely different floras under most varied climatic conditions.

NEW YORK BOTANICAL GARDEN.

THE Misses Olivia E. Phelps Stokes and Caroline Phelps Stokes have recently contributed the sum of \$3,200 to the Garden, of which \$200 is to be added to the Special Book Fund, the remainder is to constitute a fund, the income of which is to be devoted to the protection and preservation of native wild flowers. This will increase the effectiveness of the Garden in a very desirable direction, and enable it to do much in the promotion of a healthy public sentiment in the matter.

Dr. M. A. Howe, assistant curator, accompanied by Mr. William Lange, museum aid, and Mr. Clifton D. Howe, of the University of Chicago, made an exploration of Nova Scotia. Special attention was paid to the collection of marine algæ, of which several thousand specimens, preserved in fluid and dried condition were secured. About 8,000 sheets of herbarium specimens of land plants were secured. The exploration reached New York on September 9. The expenses of the expedition were chiefly defrayed from funds contributed by Mr. George W. Perkins, of the Board of Managers.

Dr. D. T. MacDougal, first assistant, spent a portion of the summer in Montana in cooperation with the biological expedition of the State University. Dr. MacDougal was accom-

panied by Mr. Wilson P. Harris, as voluntary assistant, and secured a large number of plants for the outdoor plantations, many kinds of seed for growing additional species and over 900 numbers of herbarium and museum specimens, collectively including more than 3,000 specimens. In addition to these, all the duplicates of the collections of the University of Montana were obtained. Attention was also given to climatological observations. Mr. Harris devoted his attention chiefly to lichens. The exploration extended along the Mission range of mountains and into the southern Kootenais, and regions were reached which had never been touched by such an expedition. The expenses of this work were paid from funds contributed by Mr. W. E. Dodge, of the Board of Managers.

Dr. MacDougal is acting director-in-chief during the absence of Dr. Britton.

Professor L. M. Underwood, of the scientific directors, recently returned from a tour of Porto Rico, bringing with him a nice collection of cacti from the arid southern part of the island, some 75 species of seeds, many of which have already germinated in the propagating houses, a number of museum specimens and about 1,000 specimens for the herbarium. He will spend a month now in the Rocky Mountains of Colorado, continuing the exploration begun by Dr. P. A. Rydberg. A recent gift from Mr. Adrian Iselin has made the extension of the important work possible.

Professor N. L. Britton, director-in-chief, left for St. Kitts, and other of the Windward Islands, on August 30, accompanied by Mr. John H. Cowell, director of the Buffalo Botanic Gardens. The object of their expedition is to obtain living tropical plants and seeds for the conservatory collections, specimens for the public museums, and as complete a collection of herbarium specimens of these islands as can be obtained during a month or six weeks' residence there. This work is in continuation of the botanical exploration of the West Indies and Central America instituted in 1899, when Mr. A. A. Heller and Mr. Samuel Henshaw were sent to Porto Rico by means of funds contributed by Mr. Cornelius Vanderbilt, and of Professor Underwood's recent work in Porto

Rico made possible by funds contributed by Mr. W. E. Dodge.

Mr. Percy Wilson, museum aid, who was sent to the East Indies in March, accompanying Professor Todd, of Amherst College, on the total eclipse of the sun expedition, has returned, bringing with him ten large cases of museum specimens illustrating economic products, a number of living orchids, a collection of seeds for growing in the propagating houses, and a valuable set of books and pamphlets treating of the botany and agriculture of that region. He visited the botanical gardens at Singapore and at Buitenzorg, Java, where he was most kindly received, and arranged with these institutions for important exchanges of plants, books and specimens.

SCIENTIFIC NOTES AND NEWS.

THE French Institute will make the first award of the Osiris prize in 1903. It is of the value of 100,000 francs, and is awarded to the one who in the preceding three years accomplishes the most important work for science, industry or literature.

THE city of Berlin will contribute \$25,000 toward the Virchow foundation for research, now being enlarged in honor of Professor Virchow's eightieth birthday.

THE Austrian Emperor has addressed an appreciative autograph letter to Professor Ed. Suess, the eminent geologist, on the occasion of his retirement from the University at Vienna.

As the newspapers fully report, the steamship *Erik* reached North Sydney, Cape Breton, on August 14, with news from Lieutenant Peary. During the eighteen months in which no news had been received from him, he had succeeded in rounding the northern limit of the Greenland Archipelago, and in reaching the highest latitude gained by an American, 83° 50'' north. Lieutenant Peary remains at Payer Harbor, and will attempt to reach the most northerly point possible in the spring of next year. Messrs. Stein and Warmbath are returning on the *Windward*, but no news is brought of Captain Sverdrup on the *Fram*.

MEMBERS of the British Geological Association visited France last month. They were

met at Clermont by MM. Glangeaud and Giraud, and after visiting the department of Puy de Dôme explored Le Cantal under the guidance of M. Boule.

DR. A. W. NIEUWENHUIS has returned from a two years' expedition across the unexplored regions of Borneo, made under the auspices of the Dutch government. Dr. Nieuwenhuis's previous expeditions to Borneo have yielded results of much zoological, geographical and ethnographic interest.

DR. H. F. KNOWLTON, of the U. S. Geological Survey, has just returned from a trip, made in company with Dr. John C. Merriam, of the University of California, through the John Day Basin, Oregon. The special object of the investigation was to secure collections of fossil plants from the rich beds of the region, and also of the vertebrate fauna of the recently differentiated rattlesnake beds. Much valuable material was secured.

DR. GEORGE A. DORSEY, curator of the department of anthropology at the Field Columbian Museum, Chicago, has returned from a trip among the Hopi Indians of Arizona.

PROFESSOR F. W. PUTNAM, professor of American archeology and ethnology in Harvard University, is at present in California, where, as last summer, he is looking into the case of the Cavalaras skull.

DR. E. W. ALLEN, of the Office of Experiment Stations, Department of Agriculture, has recently returned from an extended tour of the agricultural experiment stations in the Northwest and Alaska. He finds that the Alaska stations are meeting with encouraging success in demonstrating the entire feasibility of growing the vegetables necessary to supply the needs of the local population, and in maturing the cereal grains. He will recommend the taking up of experiments in raising and feeding farm animals to determine the extent to which this is practicable with Alaska-grown products.

REPORTS received from Professor C. C. Georgeson, the officer in charge of the Alaska experiment stations, who has just returned from a trip to the interior and down the Yukon, are exceedingly encouraging. New potatoes, cab-

bage, cauliflower and other vegetables were ready for the table early in August, and gardens planted with a variety of annual flowers were in full bloom. Rye and barley were ripened this year at the station at Rampart on the Yukon, with a fair prospect for oats and wheat. Extensive tracts of land were found on the lower Yukon which were covered with a luxuriant growth of grasses, often six feet in height, and apparently well suited to agriculture.

PROFESSOR JOHN B. SMITH, of Rutgers College, is devoting a good portion of the present season to the study of the mosquito question in New Jersey. The occurrence of these insects in great swarms along the coast, lessens the value of shore property by many millions of dollars, and some localities farther inland are rendered almost uninhabitable. The object of the present inquiry is chiefly to establish the distribution of the various species that occur in the state, their relative abundance and the general character of the breeding places. It is intended to make the facts so ascertained the basis of the report to go to the Legislature, which will probably be asked to make a substantial appropriation to carry on the work in a more thorough and comprehensive manner. It seems probable that by cooperation of the state and municipal authorities, aided by individual effort in some cases, the pest can be very materially reduced. It will require, however, a very careful study of the problem before a comprehensive plan of campaign can be formulated.

MR. WILLIAM CAMPBELL, B.Sc., F.G.S., a graduate of and former instructor in metallurgy and geology in Durham College of Science, England, has been honored for the third time by the award of an 1851 Exhibition Research Scholarship. For the past two years Mr. Campbell has been engaged in researches upon the constitution of alloys, working in the laboratories of Sir William Roberts-Austen, at the Royal School of Mines (London University), and at the Royal Mint. Mr. Campbell, at the request of the commissioners by whom the award is made, proposes to continue his researches at Columbia University in Professor Henry M. Howe's laboratory.

IN view of the resignation of Dr. Thomas L. Watson, assistant geologist of the Survey of Georgia, to accept a chair at Denison University, the State Geologist, Dr. W. S. Yeates, Atlanta, will be glad to enter into correspondence with geologists seeking such a position.

DR. EIJI AOYAGI, of the University of Kioto, is at present in the United States investigating methods for the application of electricity.

PROFESSOR A. C. HADDON, of Cambridge University, is to visit the United States, reaching New York on the steamship *Campania* of the Cunard Line about September 28 and remaining in this city until about October 7. While in this country he will deliver lectures, illustrated by excellent stereopticon views, at various educational institutions upon some of the following subjects:

The House and Family Life of the Natives of Sarawak.

Ceremonial and Secular Dances of the Papuans.

A Trip into the Interior of Borneo.

The Papuans.

Evolution in Art.

The Descriptive Art of Primitive Peoples.

The Life of a Torres Straits Islander.

As is well known, Professor Haddon is an authority on 'The Evolution of Art' and kindred subjects. He has worked for many years among the tribes of New Guinea, Borneo, Torres Straits and the adjacent territory, conducting the recent Cambridge expedition to that region.

MR. WALDRON SHAPLEIGH, a well-known industrial chemist of Philadelphia, died in Maine on August 30. He was born in Philadelphia in 1848, and was assistant professor of chemistry at Lehigh University from 1868 to 1872. He then studied abroad, and was connected first with the King's County Sugar Refinery and later with the Welsbach Company. He was an authority on the rare earths.

DR. CHARLES MELDRUM, F.R.S., formerly director of the observatory in Mauritius, died on August 28, at the age of eighty years.

THE Rev. Moses Harvey died at St. Johns, Newfoundland, on September 3, at the age of eighty-two years. He retired from active work

in the Presbyterian church in 1878, and has since been engaged in literary and scientific work.

THE death is also announced of Professor Alwin von Coler, surgeon-general of the Prussian medical service, at the age of seventy years.

THE German Geological Society will hold its forty-sixth meeting at Halle during the first week in October.

THE astronomical instruments 'conveyed' by the German soldiers from the Pekin Observatory have reached Germany, and it is said will be placed in the park of Sans Souci. Many of the German newspapers protest against the detention of these instruments.

THE director of the Paris Jardin des Plantes, M. Perrier, has asked the French government for the sum of \$2,000,000, which he claims is required for the buildings and collections.

A MAGNETIC observatory is being constructed by the government at Sitka, Alaska, under the direction of Dr. H. W. M. Edmonds, of the U. S. Coast and Geodetic Survey.

AN interesting and useful pamphlet, says *Nature*, has recently been issued by Mr. A. Hilger, containing full description and details of manipulation of the Michelson Echelon grating. Many of the principal universities of Europe have been provided with this very powerful means of spectroscopic determination, and the experience gained has been sufficient to permit the designing of a standard type of instrument. In this the thickness of each plate is 10 mm., and the width of each step 1 mm. The progressive precision in the working of the plates has enabled Mr. Hilger to avoid the considerable loss of light which was caused in the original instruments by the plates not being mechanically clamped together. They are now held in position by a screwed frame, which can be so adjusted that no distortion is perceptible, while the increase in brilliancy of the spectra is very noticeable.

MAJOR RONALD ROSS, Royal Army Medical Corps, landed at Plymouth on September 2 on his return from West Africa. He gave a press

representative an account of the work which is being done in Freetown and Lagos under his direction as leader of the expedition sent out by the Liverpool School of Tropical Medicine, in the course of which he said it was too early to speak of the sanitary work at Freetown, but the number of the mosquitoes in the center of the town had certainly been largely reduced. There were hardly any to be found in Dr. Logan Taylor's house, where formerly they used to swarm, and the same state of affairs prevailed at Government House, where Major Ross stayed with the Governor. Dr. McKendrick, of the Indian Medical Service, who had been deputed to watch over the operations of the expedition on behalf of the Government of India, was not bitten once during a whole month. In former days he would certainly have been bitten at least five or six times a day. Major Ross said he had no doubt that the expeditions would be successful and that they would be continued as long as necessary. At Lagos the measures adopted by Sir William Macgregor were admirable and he was confident of success. The Governor of Accra, Major Nathan, was anxious to start similar work there at once, and doubtless experts would be sent out immediately by the Liverpool School of Tropical Medicine. On the whole, Major Ross expressed himself as being well satisfied with his tour. Personally he did not think the health of the Coast was as bad as was painted. He believed that by minute attention to details the place would be made as healthy as India for Europeans. Old West Africans are sober and careful and generally live in very good health. It was the improvident newcomer who generally seemed to suffer. He had been informed that there was a high rate of mortality amongst such on the Cape Coast.

UNIVERSITY AND EDUCATIONAL NEWS.

MRS. PHOEBE HEARST has agreed to pay all the expenses of a department of anthropology at the University of California, which will be devoted especially to the study of Indians of the Pacific coast.

MR. AARON FRENCH, the Pittsburg manufacturer, who has made large gifts to the

Georgia School of Technology, has established a third scholarship in that institution.

SYRACUSE UNIVERSITY receives about \$40,000 by the will of the late Justice George N. Kennedy.

By the death of Mrs. Henrietta Cramp, Wesleyan College, at Bloomington, Ill., has received \$50,000, bequeathed to it by the late Rev. Samuel Cramp.

WE recently had occasion to call attention to the great development of the universities of the Central and Western States during the past ten years. There is every reason to suppose that in the course of the next ten years a great advance will be made in the Southern States. Tulane University has recently made great progress, and the University of South Carolina, under the presidency of Dr. F. P. Venable, will have this year about 600 students. This university should be included among those competent to carry on advanced work, though it was omitted from our summary of the universities awarding the degree of Doctor of Philosophy. There were, as a matter of fact, two doctorates of philosophy awarded last year, as follows :

Archibald Henderson, Mathematics : 'The Cone of the Normals and an Allied Cone for Central Surfaces of the Second Degree.'

James E. Mills, Chemistry : 'Some Molecular Changes caused by Rise in Temperature.'

As a result of the recent troubles in the Storrs Agricultural College, Mr. George W. Flint has been dismissed from the presidency. Professor R. W. Stimson, who holds the chair of English at the College, has been appointed acting president.

PROFESSOR E. M. WOOD, of Baker University, at Baldwin, Kansas, is to succeed the late Professor Henry Benner, as professor of mathematics and astronomy in Albion (Mich.) College.

PROFESSOR THOMAS C. ESTY, of Amherst, has succeeded Professor Baker in the chair of mathematics at the University of Rochester.

PAUL ARNOLD, M.A., of Los Angeles, has been appointed professor of mathematics in the University of Southern California.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THESE annual summer meetings of our Society, occurring as they do between the close of one year's academic activity and the beginning of the next, offer an excellent opportunity not merely for profitable retrospects, but for such interchange of ideas as may stimulate renewed effort. The summary of results achieved, although a natural and desirable part in the proceedings of an assembly of this sort, is subject to a growing difficulty from the ever-increasing technicality of modern research. We live in an age of great detail and at a time when our subject has branched into many narrowing paths of investigation. Thus, even at a meeting of highly trained botanists, there is less common ground than we could wish, and it is scarcely possible, without the certain ennui of most of our colleagues, to present the finer results in those particular researches which may have stirred us individually to great enthusiasm. On the other hand, the aims and methods in our varying lines are by no means so unlike, and afford an ever-fertile field for discussion and comparison. It may be further maintained, in defiance of any suspicion of prejudice, that the aims and methods of systematic botany should command an especial and very gen-

* Delivered at Denver, August 28, as an address by the retiring President of the Botanical Society of America.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

eral interest. No department of our subject is more intimately associated with every other. No other branch of botany so completely underlies all phases of botanical work. For what botanical investigation does not depend for its value upon a correct identification of the plants with which it deals? An accurate, lucid and complete classification of plants is thus the only secure basis upon which botany as a whole can rest. What is the present strength of this all-important foundation? Is it built upon rational principles? Should we build on or tear down and reconstruct? Is it nearing completion or does it represent as yet only the earliest stages of the desired structure? These are questions scarcely less significant to the physiologist, ecologist, pathologist, horticulturist or pharmacist than to the systematic botanist.

In surveying the taxonomic work of the last decade we see on every hand evidences of great and increasing activity. Small genera have become large; easy groups have become intricate. Thin periodicals have grown marvelously fat—in pages, not, alas! in pecuniary receipts. The number of regular and irregular publications has vastly increased. Species have been made by the thousand. No previous period of similar length has turned out such a bulk of systematic literature. It is true that this copious and now decentralized publication is of all degrees of merit, yet no one would wish to deny to it a reasonably high average of excellence. I speak, of course, of those papers which aim at the record of serious research. From these considerations and in the presence of this extraordinary activity there can be no doubt that systematists are making flattering progress in at least one direction; they are, namely, recording a huge number of facts.

Facts, however, can be accumulated much faster than they can be sorted and arranged. They are, to carry out our figure, only the

bricks for the structure, and to be effective building material must be laid in a firm mortar of law, organization and proper association. The chief difficulty which now besets our subject is the overwhelming accumulation of uncorrelated facts, unmonographed species, disjointed observations, preliminary and fragmentary records. The summit of our structure, instead of presenting a fairly clear and firm surface for further construction, seems to be buried at many points mountain-deep by disorderly heaps of loose bricks, in their way excellent building material, but so carelessly piled together as to impede rather than assist those who are earnestly endeavoring to bring order into this threatened chaos. Let no one understand me as discouraging the accumulation of facts—even very small facts—relating to the classification of plants. We do not know half enough even about the commoner species. I would merely urge that those who publish should take far greater pains to present their facts in an orderly and lucid way, with reasonable terseness and in such a manner as to show clearly their relation to preceding observations in the same field. This is the first possibility for advance in systematic botany and, if I mistake not, many other branches of research are in like case.

In this matter of presentation the natural sciences seem to be at a peculiar disadvantage. In belles-lettres a work of crude literary form is damned. Authors, if they would be read, must cultivate a good style. But in the natural sciences, if a work only presents some new and valuable facts it must, in spite of the crudest form, be purchased, read, reviewed, quoted, and the author is often flattered by the seeming success of a paper which may have been little better than an imposition upon his colleagues. Some improvement may undoubtedly be accomplished if the scientific public, especially editors and reviewers, can be

stirred to a more critical attitude toward work defective in form. But important advance can only emanate from the authors themselves. They should take a greater pride in the style of their publications, should realize that lucidity of exposition goes far to carry conviction, while obscurity is positive injustice to their coworkers.

Let us take, for instance, the publication of a new species. The requisites of a good description are generally known. There should be the habitual picture, giving in a few words an idea of the general form, size and nature of the plant as a whole; then a considerable number of features should be tersely described; special care should be taken to point out the differential characteristics by which the plant is distinguished from its nearest relatives; and finally full information should be given with regard to the occurrence of the species, its type, locality, collector, date and exsiccation-number of the type-specimen, with a mention of the herbarium in which it is to be found. These are usually simple matters, and their business-like statement in relation to every new species is a generally-recognized obligation of its author to his colleagues, yet it is safe to say that not one-half of the species published during the last year have received descriptions which fulfilled these simple conditions.

On the one hand insufficient characterizations still occur. A well-known botanist has recently described a new leafy-stemmed phanerogam, without mentioning root, stem, branches, leaves, pubescence, calyx or fruit. However, this sort of insufficient description is becoming rare. The need of fullness is widely recognized, and great improvement in this regard has been manifested in recent years. *Enough* is generally said. Quantity in the description is no longer such a desideratum as proper arrangement, judicious selection, and especially some form of emphasis by which the really im-

portant, invariable, and therefore diagnostic, features may stand out in high relief. As I have said, the author of a new species owes clarity to his colleagues. This obligation is not fulfilled by a page and a half of description in which, without particular emphasis, all manner of characteristics are given, ranging from those which concern a group or even family down to others so detailed as to apply only to the single specimen in hand. Here is another possibility for advance, namely, the discrimination and proper emphasis of differential characteristics in description.

Here authors can bring to bear all the keenness of insight which they possess. To estimate correctly the value of plant differences is by no means easy. To a great extent their permanence and consequent taxonomic significance can only be a matter of inference based upon a knowledge of similar differences in other groups. This fact seems to have discouraged some of our systematists to such an extent that they wish to escape all responsibility in relation to the matter. They give what is called a good full description without the slightest effort to show the relative importance of the points they mention. They trust that a future monographer will somehow extract from their miscellaneous statements or find upon their so-called types certain significant differences which will serve to distinguish their plants from all others.

It may be doubted, however, whether a writer is justified in publishing a species until he sees with clearness its differential characteristics, and certainly when he sees them he has no right to hide them without any mark of distinction in a mass of other details of little or no taxonomic significance. Let us hope that, in this regard, the coming decade may see the same improvement which the last has witnessed in the increased fullness of descriptions, and that a systematist's work may be estimated, not by the

number of plants he publishes nor by the pages of descriptions he writes, but by the clearness with which he ascribes true differential characters and the actuality of his species in nature.

Regarding the citation of the type, there is in some quarters still a carelessness or indifference which is little short of astonishing. Species are still, in some cases, and even by persons prominent in systematic botany, published with no more definite information as to habitat, collector or type than the bald statement that the plant appears to be common from Vermont to Michigan and southward to Virginia.

I have heard certain attempts to justify this sort of thing. It is said, for instance, that the citation of a type-number is likely to mislead; that even the best collectors occasionally distribute unlike plants under the same number; that Pringle's 1507 at the Philadelphia Academy of Natural Sciences may not be just the 1507 at the Arnold Arboretum; that a species is more than an individual, and if a single type is cited there will be danger that some will narrow the interpretation of the species until it is artificially confined by those individual characteristics which the type-specimen chances to exhibit. But these are weak excuses. The probability is that Pringle's 1507 will be the same species wherever found, and if by any chance this is not the case a well-drawn description will go far to remove the danger of error. It is, furthermore, always possible, indeed desirable, to state the particular herbarium in which the type is preserved and thus remove all ambiguity. The other objection to the citation of type-specimens has quite as little force, for persons given to such fine-haired discriminations that they separate so-called species on individual traits are bound to interpret a described species in the light of some supposed representative of it, and in the interests of accuracy it is

much better that this individual should be the type rather than some specimen which from its characters or presence in the author's herbarium is merely assumed to represent the species in question. It would seem, then, that an author who does not cite his types is careless or unduly timid, and it is to be hoped that negligence in this matter, of which drastic examples might be given, may be regarded with increasing disfavor. Happily, here, as in the other matters mentioned, there are hopeful signs of improvement, and some of our most important botanical establishments, for instance the United States Department of Agriculture under its present direction, have been exemplary in this regard.

On many accounts it is to be regretted that the commendable custom of describing new species in Latin has been so generally abandoned in America. Still common in England, it is almost universal in continental Europe, and as a means of uniformity it is a source of much convenience. The Latin language by its high inflection and wealth of terse adjectival expressions lends itself exceptionally to the clear and compact presentation of details, and the formal description in Latin undoubtedly requires added attention to subject matter as well as form, while the running characterization, so easily dashed off in the vernacular, is to some extent a temptation to verbosity and hasty publication. The habit of writing descriptions in Latin would also exercise a chastening influence upon nomenclature. An author who could produce an intelligible Latin characterization would scarcely name his plant *pseudolongifolia* or *pulcherrima* or *nationalparkensis*, and these are scarcely overdrawn illustrations of the crudities into which some fall who have utterly abandoned Latin in the presentation of systematic botany. In regard to this matter of names, it may not be remarkable that there are some beginners whose enthu-

siasm in publication far outstrips their general scholarship; but one may express genuine surprise that the heads of important botanical departments and editors of prominent journals let these nomenclatorial solecisms see light in print. Here is another opportunity for easy improvement in the methods of systematic botany.

To this point I have dealt chiefly with the form of presentation. Let us now consider the subject matter. Here the difficulties of improvement are naturally greater.

The first feature of this subject which demands attention is the artificiality which still lingers in our so-called natural system. It is true that the natural arrangement of orders and families has been much improved in recent years. The clues derived from the varying degrees of adnation, conation and zygomorphy of floral parts in the dicotyledons have suggested the first system in which groups of such obvious affinity as the *Caryophyllaceae*, *Aizoaceae*, *Scleranthaceae* and *Amaranthaceae* are found in natural proximity. But much artificiality still remains in the details of modern classification. For instance, we are commonly treating as equivalents in our system things which in nature have widely different values.

There is an old question always coming up, ever fresh for discussion, never very clearly settled, regarding the objectivity of species. Do they exist in nature or are they artificial categories? Much may be said on both sides. It takes, however, no very profound study of plants and their descriptions to reveal the fact that so-called species are of both kinds. Many thousands exist as well-marked entities in nature, but, alas! there are many hundreds more which scarcely extend beyond the subjective. They represent not permanent lines of more or less independent development in nature, but chance combinations of inconstant characters analogous to cross-sections

through some plastic and still unsolidified material.

The cause of this lies partly in the author of the species and is partly inherent in nature. On the one hand, such so-called species may result from the hasty description of plants whose differences, observed in a few herbarium specimens, have not been sufficiently verified in the field. On the other hand, they may come from the simple fact that there are no formed or settled species in the group concerned. The forms of that particular affinity are still in a state of free intergradation and the species *im Werden begriffen*.

There seems to be a wish upon the part of many systematists to ignore this fact; to maintain that this or that form is, in hackneyed phrase, a 'perfectly good species' because it shows certain differences from its slightly removed although copiously intergrading neighbors; in fact, to asseverate that all plants which show differences worthy of remark should, irrespective of their constancy, be classed as species. But notwithstanding these unhappy ideas, nothing can be more certain than that fortuitous cross-sections in the nebulous places of nature are not species in the sense that *Ranunculus pennsylvanicus*, *Juncus trifidus*, *Malva rotundifolia* or *Potentilla tridentata* are. Nor can we hope to escape great artificiality in any system which assigns to like rank and groups in the same category things of such diverse nature and significance.

Species as now recognized are not equivalent things. The category, called specific, is itself a complex, in the same need of critical study, of subdivision, of segregation, as many of its elements. There are species marked by pronounced morphological features, which they never lose and which may always serve to identify them. There are others with characters subject to concomitant variations, in which if one feature varies in a particular direction the change

is regularly accompanied by certain other modifications affecting other members. Such species may be subdivided, and have good subspecies or varieties. On the other hand, there is a totally different type of species in which variation is not concomitant, in which one feature changes without apparent connection with any other, in which, for instance, thorns may be developed or be absent, while leaflets may be few or many irrespective of the presence or absence of thorns, and again, the inflorescence may show further variation quite independent of leaflets and thorns. Such species, exhibiting what Dr. Gray called promiscuous variation, are well illustrated by *Acacia filicina*, *Mimosa asperata*, certain *Aquilegias*, *Delphiniums* and *Lupines*. In these cases segregation or even varietal subdivision, although often attempted, has little or no significance, for the segregates exhibit only kaleidoscopic combinations of ever-changing characters. There are, on the other hand, especially as the result of preponderating close fertilization or vegetative reproduction, species which exhibit a wonderful constancy of small characters, a remarkable fidelity in transmitting from one generation to the next the most obscure traits. Such are the segregates of *Draba verna*, elaborated by Jordan, studied with such keen interest by de Bary during the last months of his life and critically reviewed in the later work of Rosen. Such are also the newly recognized *Alchemillas* of the Alps and our own *Antennarias*.

From these illustrations it is easy to see that species as now recorded in literature are by no means alike and that they cannot be regarded as equivalents in any complete or logical system of classification. Curiously enough, however, the term 'species' seems to be growing more and more popular as it means less and less. Often and on all sides we hear lengthy arguments, and emphatic asseverations to

the effect that this or that plant is a 'perfectly good species'; and if in the course of monographic work a so-called species is let down to varietal rank it rarely fails to find somewhere its ardent defenders, who appear to hold the curious view that the monographer has not merely expressed a scientific opinion, but has somehow perpetrated an injustice upon the plant or its describer. How anxious most discoverers of new forms are that their plants may prove species, not mere varieties, and finally what a fascination the mere binomial appears to exert upon certain minds! Is it any wonder under these circumstances that the specific category has been overcrowded and made to include such widely different elements that the word species has lost nearly all its taxonomic significance?

However, no thoughtful botanist who can rise above a merely subjective attitude toward the few species in which he chances to be particularly interested and take a broader, more objective survey of the whole field, will be satisfied that the present hodgepodge of non-equivalent forms in the specific category represents the finished result of a natural system of classification.

Species must be subjected to a gradual reclassification along more definite lines. Overwhelming as the task may at first appear, it is fortunately one which can be taken up little by little, a work in which every systematist, every collector, every amateur, who will, may take part. The first step is evident enough. Each species must be examined in the light of vastly more copious material than at present exists even in our largest herbaria. Has there ever been a conscientious monographer who has not seen the pressing need of further material in his group, who has not felt that ten or even a hundred times as many specimens would have been necessary to yield a satisfactory knowledge of the directions and limits of variation? Let

us, then, proceed with the accumulation of material, with the collection of specimens which may illustrate each species at every stage of development, in every part of its range, in every environment in which it occurs. In this matter we are much behind zoologists. They often work with hundreds or even thousands of specimens while we try to draw like inferences from dozens. An entomologist recently told me, quite as a matter of course, that he had just completed a monographic examination of more than fifteen hundred specimens representing a single species of orthopterous insect, together with three or four of its varieties. When may we expect that botanists will take similar pains in the interpretation of the limits and variations of a single species?

While on this subject of collection I may be permitted to emphasize an often neglected obligation of the collector to the monographer—that of reasonably full field notes. I realize that this is a wearisome subject, well known and thoroughly appreciated by many conscientious botanists and as persistently disregarded by others. I am acquainted, for instance, with several expert systematists, most scrupulous in all other ways, who appear on this subject of labels to have a curious mental defect. They never seem to have grasped the art of writing them, nor realized in this matter any obligation whatever toward their colleagues. From one of them I recently received some excellent specimens with no data but ‘White Mountains.’ Repeatedly, when working upon a particular species at the Gray Herbarium, I have examined dozens of specimens from many different collectors in the vain hope of learning from the field notes upon the labels such simple facts as the color of the corolla, height of the plant, or nature of the soil where it grows. Here is another opportunity for advance in which nearly every one con-

nected with systematic botany can cooperate.

We have seen, then, that the first requisite for a more thorough proving of species is a much greater and more representative accumulation of material and data. Then, of course, will come the difficult task of interpreting this material and especially of determining for general guidance more definite standards of variation. Regarding this latter possibility I have heard some scepticism expressed; but it seems to offer no greater difficulty than many other problems which have been successfully settled in the natural sciences. It must be admitted, of course, that while our knowledge of particular species is derived from a dozen, or in some instances from only one or two, specimens, no satisfactory standards of variation can be devised or applied. But were we to work with a hundred times this amount of material, it is more than probable that the degrees of natural intergradation could be fairly approximated. It would at least become evident which lines of specific development had attained what may be called a normal distinctness, a condition in which intergrades would be so exceptional as to suggest atavistic reversions, while, on the other hand, many of our so-called species would doubtless be found to be connected by regular, normal and fairly numerous natural intergrades, their lines of development would still be in a state of anastomosis, not having attained habitual distinctness. The interesting question would then arise whether the intergradation were geographically general or local, whether it were morphologically concomitant or promiscuous.

To interpret these matters satisfactorily will require not only the vast accumulation of material the need of which has just been emphasized, but a cautious and judicial attitude of mind, great impartiality, and an

unswerving desire to find out and record the exact truth. I do not mean to imply that systematists to-day have not this desire. Unfortunately, however, many of them, perhaps all, seem never to escape a certain hypnotism caused by particular interests. Trifling matters assume undue importance. Little differences seem so great as to obscure the preponderating similarities, or, on the other hand, superficial likeness blinds the observer to every differing detail. An opinion is quickly formed and perhaps hastily published. It then becomes a matter of personal pride to maintain it, and if any one expresses a doubt concerning its accuracy he is promptly called out to a controversial duel.

Now these things have their bright side and are in their milder form diverting, for somehow after the scrimmage which follows, truth, for the time hidden by the dust of combat, usually shines forth in victory, or more often becomes evident as the result of compromise. Indeed controversy is perhaps the only means which will successfully dispel the narrowing and perverting influence proceeding from the intensive examination of small details, and so often blinding the systematist to the real perspective of his own observations.

If we now turn from the matter of variation to that of distribution, it is equally evident that only a beginning has been made, that inferences are drawn from very insufficient material and that a vast accumulation of further data is requisite to accurate results. Let any one who doubts try to bound the range of some common species, to draw upon a map the sinuous line connecting the outermost recorded stations. The gaps are astonishing. Great lacunæ quickly appear in our knowledge of plant distribution.

No one can doubt the value of much fuller records in this department of our subject, nor maintain that our knowledge

of any plant is satisfactory until the limits of its natural occurrence are accurately determined. While plant distribution, studied from the ecological side, has become a popular subject, comprising many useful observations and theories both valuable and fascinating, the actual record of plant-ranges is on the whole regarded as rather dry business and is a field of investigation in which laborers are few. Mention should be made, however, of Professor A. S. Hitchcock's admirable work in this direction upon the flora of Kansas. What notable advance might be made if each State of our Union could have an equally well-trained systematist similarly interested in this matter of plant distribution!

Could we but know the actual curving boundaries of a few hundreds of our best-defined species, what a wealth of new generalizations could be drawn from them, and how much new information they would yield concerning the factors which govern distribution in general! For, irregular as these lines would be, I can but think that they would in many cases stand in definite relation to lines of other kinds, to isothermals, to altitudinal contours, to degrees of humidity, to the boundaries of geological formations, the limits of glaciation, the ranges of animals, especially pollen-bearing insects, to the paths of bird-migration, and finally, to the course of human traffic. What a field for further investigation is thus suggested by our still very imperfect knowledge of plant boundaries! It is a field, too, which the careful amateur can cultivate almost as easily and as well as the professional botanist. Every one lives near the assumed limits of some plants and might, by directing his attention to the subject, do much to change these as yet vague and hypothetical boundaries into accurately determined and carefully recorded lines.

Not only would these lines be likely to

disclose new and as yet unsuspected relations to forces controlling distribution in general, but they would give us our first accurate landmarks for the observation of plant migration, thus greatly facilitating a study of progressive changes in our flora.

While the accurate determination of plant boundaries has thus great interest it may be remarked that research in this field, as in others, to be successful, must be conducted with care. Reports of occurrence, especially extra-limital stations, should be taken with much caution. In this as in many other matters of science it is impossible to make too sharp a distinction between facts actually observed and those taken on hearsay. In mapping a plant the recorder will do well to indicate this difference. If, for instance, he shows by an umbra the range which rests upon specimens personally examined, let him record unverified reports only by a penumbra. Furthermore, any work of this kind to be of permanent value must rest, at least in great part, upon specimens which are carefully preserved, for segregation is progressing rapidly and no one can foresee its subjects. A plant of supposedly uniform character may at any time prove, upon more critical observation, to be two or more distinguishable species. In such a case it is easy to see that any previous study or records of the composite plant must lose nearly all their value unless specimens have been preserved so that a re-examination will show to which of the segregates the records applied. Similarly, the disappearance of a plant from a given region may lead to a justifiable scepticism as to the accuracy of the records relating to its occurrence in that place. In this case, practically the only valid proof is a preserved specimen accompanied by the original data of collection.

In interpreting and recording this matter of plant boundaries opinions will doubtless differ as to what may be called continuous

range and what is to be regarded as an extra-limital station, or, so to speak, an island in a sea of non-occurrence. This is, of course, all a matter of degree, since in reality no plant has a continuous range, for it is represented by more or less isolated individuals. Yet this offers no serious obstacle. The meteorologist maps the analogous course and limits of a rain-storm composed of separate drops, and the biologist has long recognized the practical continuity of plant and animal ranges which, in a generalized form, are the basis of his so-called 'life-zones.'

Turning now to quite a different field which seems to offer great possibilities, I would call attention to recent researches in plant ontogeny: the investigation of embryonic development, the comparative study of seedlings, and such observations as have been recently made by Professor R. T. Jackson upon the reappearance of juvenile and ancestral traits in offsets and runners. Systematic zoologists have long made use of ontogeny in determining group affinities, but botanical taxonomists have been much less successful in drawing from the early stages of plants like inferences. There are several reasons for this. In the first place, there can be no doubt that plants in their early development do not exhibit such a continuous and complete series of phylogenetic stages as many animals do. In plants some stages seem to have dropped out by a sort of morphological and physiological elision or ellipsis. Again, while the classification of animals rests upon general morphology often well suggested even in very early stages of development, the classification of plants is based chiefly upon the mode of reproduction—that is to say, upon a series of structures produced so late in the life of the individual that no suggestion of their character is afforded by embryo or seedling.

But, after all, there can be no doubt that

ontogeny has for the plant taxonomist a wealth of information as yet unrevealed regarding the affinities of genera within the family and species within the genus. In these matters of more intimate relationship, the form, position and venation of leaves, the nature of the petioles, stipules, pubescence and glandularity, all shown in the seedling, are significant.

Here, however, as in the other subjects of which I have spoken, the real obstacle to further inference at present is an astonishing lack of material and data. It is safe to say that of the one hundred and fifty thousand flowering plants recorded in the recently issued *Index Kewensis* not one fiftieth part has been carefully traced through the earlier stages of development. Enough is known, however, to show that species even of the same genus often possess striking differences, and in other cases remarkable similarities, in the seedling stages, that these particular differences and similarities often become lost or obscured as the plants advance to maturity, and the conclusion is unavoidable that these juvenile characteristics must, at least in many cases, show ancestral traits, and, if properly studied, yield even better clues to real affinities than any which we now possess.

By way of summary, it may be said that systematic botany is very far from being a completed subject, that from our present standpoint we can see in various directions long vistas of further possibilities for fascinating exploration and profitable discovery, that among the subjects which seem to invite immediate attention the most important are: (1) The determination of the modes and degrees of variation, an investigation which alone can yield data for a more critical discrimination of plant categories; (2) far more complete study of plant ranges, which can scarcely fail to throw much new light upon the forces controlling distribution; and (3) a further examination of plant

ontogeny as the most hopeful source of information regarding the more intimate affinities and proper arrangement of plants.

B. L. ROBINSON.

HARVARD UNIVERSITY.

*THE CHANGE OF FRONT IN EDUCATION.**

DR. SAMUEL JOHNSON considered education as useful to the 'embellishments of life.' In his day very few were educated at all, and those few for society or public service. The toiling masses had no education, were supposed to need no education, and while discussing details educators and scholars took no thought of what we call the common people.

Said Johnson (in his 'Life of Milton'):

"The truth is, that a knowledge of external nature, and the sciences which that knowledge requires or includes, are not the great or the frequent business of the human mind. Whether we provide for action or conversation, whether we wish to be useful or pleasing, the first requisite is the religious and moral knowledge of right and wrong; the next is an acquaintance with the history of mankind, and with those examples which may be said to embody truth, and prove by events the reasonableness of opinions. Prudence and justice are virtues and excellences of all times and of all places. We are perpetually moralists, but we are geometricians only by chance. Our intercourse with intellectual nature is necessary; our speculations upon matter are voluntary and at leisure. Physiological learning [by which he means a knowledge of the laws and phenomena of the external world] is of such rare emergency, that one may know another half his life without being able to estimate his skill in hydrostatics or astronomy; but his moral and prudential character immediately appears.

* Address of the Vice-President and Chairman of Section I, Social Science and Statistics, of the American Association for the Advancement of Science, Denver meeting, August, 1901.

“Those authors, therefore, are to be read at schools that supply most axioms of prudence, most principles of moral truth, and most materials for conversation; and those purposes are best served by poets, orators and historians.”

This statement was, no doubt, entirely adequate to the demands of Johnson's time. Polite conversation and elegant manners were the chief characteristics of an age in which Chesterfield was a bright and shining light. With the dull, hard-working, unlettered crowds, that plodded on in the steps of their grandfathers, educators had nothing to do; for such they had no educational theories.

How wonderfully conditions have changed, both as to the curriculum and as to the constituency of education. It is interesting to picture, in fancy, the bewilderment of a Sam Johnson in the learned circles of this scientific and industrial age. Imagine him attempting to join in the discussions of our British and American Associations for the Advancement of Science, in our educational conferences, or in the halls of exchange, where the active minds of our generation do mostly congregate. He would find it difficult, in spite of the wonderful vigor of his intellect, to be either useful or ornamental, though he could easily be amusing.

From the days of John Milton, in 1608, to the end of the eighteenth century, university training culminated in a preparation for the professions of law, medicine and theology, and in the training of the nobility for the duties and responsibilities of government and elegant society.

But when alchemy developed into chemistry; when physics became an experimental science; when Leibnitz and Newton elaborated the infinitesimal calculus; when Watts invented an efficient steam engine; when Fulton built a successful steamboat; when Stephenson devised the locomotive and constructed a road with smooth rails;

and finally when Siemens and Gramme produced the electric motor—vast fields of fascinating and useful material were opened for study and research. Mathematical analysis and the principle of mechanics, which had previously been devoted to the problems of physical astronomy, were now directed to the study of the transformation and transmission of energy, the theory of structures, and the phenomena of electricity. The theory of evolution gave a new meaning to all vital phenomena; and the doctrine of the conservation of energy permeated all study of motion and force.

In the earlier days, Alexander Pope voiced the popular notion that ‘the proper study of mankind is man.’ ‘Nature Study,’ which to-day is the bright, attractive feature of the primary school, and equally the inspiring field of the savant, was not countenanced by polite society. For centuries it was held to be little short of blasphemy to wound the earth by digging for ores which were intended to be hidden away from our sight and touch, or to attempt in any way to improve upon God's workmanship. When in 1680 a Spanish engineer proposed to deepen the channels of certain rivers and to restrain their overflows in the interest of navigation, the Spanish Council decreed as follows: “If it had pleased God that those rivers should have been navigable, He would not have needed human assistance to make them so; but as He has not done it, it is plain that He does not want it done”; and the improvements were forbidden. This decree reminds me of a bit of Mrs. Eddy's logic which you may remember in substance as follows: Had the Almighty intended that drugs should be used in treating sick people, He would have placed drugs in the hands of Jesus and his disciples; Jesus and his disciples used no drugs; it is therefore evident that the Almighty does not wish drugs to be used upon people who are sick.

But, putting aside pseudo science, the modern thought of the creation is that it was and is a part of the all-wise plan to fill the earth with unsolved problems, the study and solution of which should develop our best powers, and at the same time cultivate our highest instincts of reverence for the Creator and of love and devotion for His creatures.

It has taken many centuries for the world to discover that the great forces of nature are neither sacred nor profane, neither kind nor cruel, that they neither love nor hate, and that they are more unchangeable than the stars; that shrines and temples, priests and priestesses, tripods and oracles, have been in vain, except so far as they reacted upon the human heart and satisfied its natural craving for the worship of the Superior Being. Instead of building a temple to the far-darting Apollo or to Zeus, the Thunderer, we now stretch over our cities a network for artificial lighting; and all the winds that blow and all the waters that flow are made to furnish their tribute to our comfort and pleasure. We tap the sources of endless energy and transmit it through all the ramifications of our social order, relieving mankind from heavy burdens and creating hundreds of occupations hitherto unknown.

Out of this vast extension of the horizon of human activities, and a corresponding multiplication of occupations, has come an imperative demand for more education and for technically educated men. In our industrial system the crying want has been and is for men who can both plan and execute. The secret of our unparalleled commercial and industrial success lies in the fact that we have put educated brains into our work. Hence a score of professions unthought of 100 years ago have been called into being, and the standards of these new professions are of the highest order.

It is this grand movement towards a

study of the materials and the forces of nature and the problems of modern life, sociological, commercial and industrial, that constitutes the change of front in education. This does not mean that we must abandon altogether the old education. We must preserve all that is permanently fine and essential to high thinking and well doing. The great epics of Homer, like the book of Job and the Psalms of David, will live forever, imperishable monuments of the youth of the world, but we shall not perpetually care for Aristotle's speculations about the origin of matter, or the conceited discussions of Cicero at Tusculum. Modern life in all its details has so far departed from the ancient that neither the moralizings nor the tragedies have a lively and sustained interest for us. We are deeply interested in the affairs of to-day, in a civilization not based upon human slavery, nor upon a blooded aristocracy buttressed and supported by millions of laborers ground down in ignorance, poverty and superstition, but based upon the principle of human equality before the law, and of equal rights to life, liberty and the pursuit of happiness.

In turning from an inherited scheme of education which faced backward, which concerned itself largely with the thought, the deeds and the theories of the past, and in proclaiming the universal need, as well as the universal opportunity, of education, we must not fail to preserve the dignity and the nobility of our educational standards. In spite of frequent assumptions to the contrary, modern education is becoming more and more 'liberal.' The defenders of the Johnsonian programs delight in the use of unworthy epithets with which to characterize the tendency of modern education; they plead for 'humanities' as though anything human was foreign to our curriculum. What can be more human than human life as we see it

and as we share in it? What problems can be more human than those which face nine out of ten of the people who reach the age of individual responsibility?

More and more we are considering the many and not the few, when we draw up our schemes of study and training. As wealth increases, as the hours of labor become shorter, as luxuries multiply, and a taste for literature and art and science becomes general, the number of students entering upon some form of higher education greatly increases. The number of such students to-day per million of people has doubled several times in fifty years.

It is, therefore, not surprising that there should arise, in the minds of many less familiar with the content and the method of a modern technical university, a fear that the standards of character as well as the standards of scholarship should suffer, and, in being less 'select,' that the content of education should be at the same time less fine. Whether this fear be well grounded or not, we must all sympathize with its spirit. We can have no quarrel with those who wish the first fruit of education to be character. I cannot forbear quoting a few sentences from the late president of the Massachusetts Institute of Technology, Gen. Francis A. Walker, upon the tendencies of modern technical education, in reply to certain strictures as to its dignity and unselfishness. In his remarks at the dedication of new science and engineering buildings at McGill University, Montreal, General Walker said:

"The notion that scientific work was something essentially less fine and high and noble than the pursuit of rhetoric and philosophy, Latin and Greek, was deeply seated in the minds of the leading educators of America a generation ago. And it has not even yet wholly yielded to the demonstration offered by the admirable effects of the new education in training up young

men to be as modest and earnest, as sincere, manly and pure, as broad and appreciative, as were the best products of the classical culture, and, withal, more exact and resolute and strong. We can hardly hope to see that inveterate prepossession altogether disappear from the minds of those who have entertained it. Probably these good men will have to be buried with more or less of their prejudices still wrapped about them, but from the new generation scientific and technical studies will encounter no such obstruction, will suffer no such disparagement.

"Another objection which the new education has encountered is entitled to far more of consideration. This has arisen from the sincere conviction of many distinguished and earnest educators that the pursuit of science, especially where its technical applications are brought strongly out, loses much of that disinterestedness which they claim, and rightly claim, is of the very essence of education. I differ from these honorable gentlemen. I believe that the contemplated uses of science, whether in advancing the condition of mankind, or even in promoting the ulterior usefulness, success and pecuniary profit of the student of a technical profession, do not necessarily impair that disinterestedness. These gentlemen appear to me to have an altogether unnecessary fear of the usefulness of science.

"The strong desire to become a useful man, well equipped for life, capable of doing good work, respected and entitled to respect, constitutes no breach of disinterestedness in any sense of that word."

Finally he says:

"I boldly challenge comparison between the scientific men of America, as a body, and its literary men or even its artists, in the respect of its devotion to truth, of simple confidence in the right, of delight in good work for good work's sake, of indis-

position to coin name and fame into money, of unwillingness to use one thing that is well done as a means of passing off upon the public three or four things that are ill done. I know the scientific men of America well, and I entertain a profound conviction that as regards sincerity, simplicity, fidelity and generosity of character, in nobility of aims and earnestness of effort, in everything which should be involved in the conception of disinterestedness, they are surpassed, if indeed they are approached, by no other body of men."

Of like import are these words from a recent address of Hon. F. W. Lehmann, of St. Louis. Speaking of the breadth of the modern university, he said :

"The university of to-day has abdicated none of its old functions, but it has taken on many new. Not disdaining mere scholarship, making, indeed, the standard always a higher one, it widens its domain and adapts its teachings to the after-work of life. Its graduates are not simply conventional finished gentlemen, but beginners in the serious business of life, scholars as before, but artists, engineers and artisans as well. The sciences lose nothing because they become utilities. Physics and mathematics gain in interest by application to the building of bridges, and the very sewers of a city become classic to the scholar because one of the means to the classic excellence of a sound mind in a sound body."

Perhaps the characteristic most dreaded by the opponents of the new education is usefulness. They have but to learn that a certain branch of study, course of training or line of culture is useful, and its value is at once compromised. One of the few foolish things that Lowell ever wrote or said was that, 'a university is a place where nothing useful is taught.' I will not discuss a statement which, after all, may not do justice to Lowell's thought, but I will define a university as a place where every-

thing useful in a high and broad sense may be taught. Matthew Arnold would have defined a university as a place where is taught and illustrated 'the best that has been thought and done in the world.'

Supt. Gilbert, of Rochester, N. Y., said at Buffalo last month : "The exalted character of a man's work is to be measured by its usefulness to mankind ; I believe in the universality of service."

It has often been assumed that this new education is not liberal. Liberality consists not so much in the subject as in the method of study. The liberal method is broad, deep, generous, comprehensive. It recognizes infinite uses, both far and near. It aims at the artist rather than the artisan ; the engineer, not the craftsman ; the freeman, not the slave. Liberal culture deals with fundamental principles, typical phenomena, general results, not special applications. It is liberal to study the laws of manufacture, trades, commerce, finance and social progress ; it is not liberal to seek merely the conditions of a successful business, whether it be law, medicine or manufacture. It is liberal to demand the *raison d'être* of dogma, canon, rule, dictum, formula or usage ; it is illiberal to blindly follow authority, to put facts and processes above principles and reasons, to prefer echoes to living voices.

A recent reviewer said that mathematics and electricity are becoming less valuable for general education on account of their increasing usefulness in technical pursuits. The maximum of educational value (he held) appertains to a sort of knowledge which falls short of such a mastery as makes it useful. Of course, I accept no such statements. That man's notion of a liberal education is not yours nor mine.

The list of liberal branches of study is ever increasing. For four years Harvard compelled me to give one-sixth of my time to Greek and one-fourth to Latin ; to-day

one may go through Harvard and take his degree without giving one moment to either Greek or Latin, while in Cambridge. The same thing is true at many universities. Are we, therefore, less liberal than formerly? Can we not answer that we are more liberal? People now read Demosthenes and Quintilian and Horace, analytic geometry, physics, thermodynamics and the like, because they wish to be familiar with those authors or to master those subjects, not because they are compelled to by a traditional canon. Does any one suppose that there is not a decided gain in the quality of the result?

Through the technical schools, some of the most valuable educational studies have been developed. How few people realize the surpassing mental discipline that comes from the study of descriptive geometry, laboratory physics and the mechanic arts. I knew nothing of the study of descriptive geometry till years after I left college, and yet no subject I had in college could compare with it as a mental stimulus and a cultivator of the scientific imagination. It ought to have place in every liberal course of study. Modern courses of study contain, of necessity, extensive allowances of laboratory work of one sort and another. Our idea of all such work is that the method shall be unfailingly rational; that facts, though essential, shall be rated as far less important than the principles which underlie them. Where this idea is realized, the study becomes truly liberal.

In spite of the old claim of preeminent liberality, the old college curriculum, when examined historically, is found to have been adopted for reasons of utility. People learned Latin because they wanted to use Latin. All books and state papers were written in Latin, and one needed to both read it and write it, as we must English prose. The physician must read Galen in the original; the clergyman needed the Greek Testament; the lawyers must read

the Institutes of Justinian, and the man of leisure and the orator must be able to quote Aristotle and Homer, Virgil and Horace. The first American colleges were organized for the training of clergymen. Every feature of the course was directly useful to the end in view.

It is easy to see the source of a widespread prejudice against technical training. The history of civilization has been the history of masters and slaves, of castes, of contempt for labor and for all useful arts. Every one of the technical professions had its beginning in the crafts and the present technical expert and engineer had as a prototype a man in overalls, with horny hands and a soiled face, who presided over some enginery which was not authorized by the ancients and which at best was generally regarded as ungenteeled. Milton placed Memnon, the first ante-tellurian engineer, among the fallen angels, and sent him

‘With his industrious crew to build in hell.’

The engineer is by nature an iconoclast. He has small respect for the traditions. He bows not down to the ‘tyranny of the ancients.’ His glories are in the future. He looks forward, not back. He does not hesitate to smile at the puerile fancies of people who created gods and demi-gods in order to account for phenomena which to-day submit to mathematical analysis and which bear no comparison with the exploits of modern engineering. The accomplished engineer generally reciprocates the prejudice I have mentioned, for he cannot understand how the worship of the ancients can be really serious; it seems to him three-fourths affectation. This mutual prejudice was fostered by the high wall of separation which at first kept the technical and the liberal branches of study far apart. That wall, I am happy to say, is fast tumbling down, and men are rapidly scrambling over it in both directions. It becomes us, from our various vantage grounds of influence,

to encourage this evolution of a better feeling, a more intimate acquaintance, a mutual respect, and a common zeal for whatever is broad and high and fine.

While we may for many reasons congratulate ourselves on the decided change of front we have achieved in education, we must not be blind to the fact that much remains to be done. We must still devise a scheme of secondary and higher education for a stage of progress in which secondary and higher education may become approximately universal. As Sir Walter Besant put it, the twentieth century must not only "open up all intellectual careers to lads [and lasses] who are capable, clever and ambitious, but we must have a system of education broad enough and elastic enough to include the children who are destined for crafts, industries and arts of all kinds; one that will make them good citizens, not ignorant of their civic rights, and alive to their civic duties."

I do not at all assume that we have yet discovered the true system for universal secondary education. The manual-training high school with its opportunities for training and culture along many lines, industrial, commercial, civic, artistic and literary, seems to come near the ideal, but it is by no means generally accepted, and when accepted it is at once exposed to serious dangers.

In our most advanced communities only a small minority of children enter upon the secondary stage of education. In my own city of St. Louis, only about one boy in seven takes a course in a school of high-school grade. In many communities the proportion in secondary schools is greater—in others it is less. There must be some reason for this; either the training and culture are not what they ought to be or our people are so ignorant that they do not know the value of education. I will not admit that poverty offers a sufficient explanation. In

either case, it is evident that we have much to do and much to learn.

Of the dangers to which the manual-training high school is exposed, I have spoken elsewhere at length. I will at present only refer to the strong tendencies of 'practical' people, who are more intimate with the old system of apprenticeship than they are with the art of education, to introduce the teaching of special trades. I think we shall be able to stem this unfortunate tendency, but it is well to be forewarned that we may be forearmed. The advocates of the introduction of trade work make three serious mistakes:

1. They assume that the graduate of the manual-training school is unfitted to enter an industrial shop to advantage.

2. They would begin trade work with pupils who are too young.

3. They do not realize that only about 50 boys in 100 are so constructed mentally and physically that they can and ought to learn what are known as the industrial trades.

In my paper already referred to, I have at some length defended the natural right of a boy to the privilege of choice of occupation at an age of some maturity and after a training which enables him to substitute a rational judgment for a boyish whim.

In this connection, I fail to endorse at least one feature in the Report of the Advisory Committee of the Carnegie Technical School. The full report was published in *SCIENCE* for July 12, 1901. For a variety of excellent reasons, the Committee reaches the conclusion 'that some new kind of preparation for the work of life must be introduced into the school training of both boys and girls.' It then proceeds to outline a technical college, a technical high school and an artisan day and evening school, which are to meet this demand. Here we have a clear recognition of a twentieth-century problem and an attempt to solve it.

The artisan day and evening school is somewhat on the order of German and English low-grade technical schools. I earnestly hope that the suggestion of this school may be adopted and that the experiment may be fairly tried in America. The plan for a technical college is in complete harmony with our best engineering schools, and needs no discussion here.

The scheme for a technical high school, however, seems to me faulty. This school would be of high-school grade, taking pupils from the grammar schools and covering presumably four years. The normal ages of entrance and graduation would accordingly be 14 and 18.

Three things in the Committee's outline of this technical high school deserve more attention than I can give them at this time :

1. The elective principle is to be recognized, the student selecting the required number of courses under the direction of the director of the school. Here the pupil at a tender age (only 14 or 15) is asked to surrender his birthright to the privilege of choice when he is 18.

2. The course in mathematics—which begins with elementary algebra—is to include the *elements of calculus*! Of course, it must include solid geometry, higher algebra, trigonometry and analytical geometry! One rarely meets with such an astounding proposition from engineers who are supposed to have studied mathematics and to know what they are talking about. They might as well propose that the pupils shall take thermodynamics in a short course of lectures. To be sure, similar ambitious schemes have been proposed elsewhere for boys just out of the grammar school, but they came from people who could have known very little mathematics, and nothing of the uses of the calculus. This criticism may seem trivial, but in more than one place the scheme attempts too much.

3. The technical studies suggested take the form of trade work or special employments, with well-equipped shops and experimental laboratories under the direction of expert artisans.

What Mr. Carnegie will do with this last suggestion remains to be seen, but any attempt to embody it in a real technical high school of secondary grade will be full of interest to the educational world. If any man was well prepared to give the scheme a fair trial that man is Andrew Carnegie; but it will cost a vast amount of money and its experience will teach us how not to do many things.

I have high respect for the members of the Advisory Committee, but I think a less ambitious scheme would be more successful. You cannot teach the higher mathematics in a high school, and I have no great faith in the value of attempts to teach employments, commercial or industrial, within the limits of any secondary school. Such attempts are certain to mislead and ultimately hinder those they aim to help. Any trade or special employment must be dwarfed and narrowed before it can be brought down to the grasp of an untrained boy, and its very narrowness unfits it for the best educational uses.

The school is the place where one should learn the fundamental unchanging laws and manifestations of force and materials. Special occupations, like special constructions, should be analyzed in their elements, and pupils should become expert in such analyses, in so far as they involve universal elements that pupils can comprehend. But there are many things essential to a business employment which cannot even be apprehended in school. As William Mather, M.P., says :

“There is no possibility of teaching in a school that sort of knowledge which practical work carried out on commercial principles, within restrictions as to time of

execution, etc., can alone make any one familiar with." ('*Technical Ed'n in Russia*,' p. 12.)

As to values, let us teach intrinsic values, not market values; the latter are fluctuating with time and place, the former are permanent.

No scheme of American education is complete without a careful study of the duties and responsibilities of citizenship. The tramp, like the political leech, assumes that the world owes him a living; the good citizen knows that he owes it to the state to earn his own living, to support his family and to contribute his share to the necessary expenses of the city, state and nation. Hence the youth must learn how the city, state and nation are respectively organized and what their proper functions are; and when he is a man he must to the extent of his ability see to it that those functions are placed in the hands of public servants who are both capable and honest. The corrupting influence of a politician who fosters selfishness in his neighborhood, that he and his neighbors may profit at the expense of other neighborhoods, must be counteracted by a generous education which shall cultivate a love of justice and plant the seeds of manly and noble ideals. If democratic governments are to survive, the whole people must be educated to the highest standards of citizenship, and the new education must face and solve the problem of securing those results.

CALVIN M. WOODWARD.

WASHINGTON UNIVERSITY, ST. LOUIS.

SECTION C (CHEMISTRY) OF THE AMERICAN ASSOCIATION.

In accordance with the recent custom, the meetings of Section C were held conjointly with those of the American Chemical Society, the officers of the latter presiding on Monday and Tuesday and those of the former during the remainder of the ses-

sion. The meetings proved to be of unusual interest, a large number of valuable papers being presented. Eighty persons, representing twenty-three different States, were in attendance.

The Section was first called to order Monday, August 26, at 11:30 a. m., by Vice-president, Jno. H. Long. Mr. Franklin Guiterman was introduced and welcomed the members on behalf of the chemists and metallurgists of Colorado. Brief responses were made by F. W. Clarke, President of the American Chemical Society and Vice-president Long. Section C was then organized in accordance with the provisions of the constitution. The following were the officers for the Denver meeting:

Vice-president, Jno. H. Long.

Secretary, Wm. McPherson.

Sectional Committee: J. L. Howe, Vice-president, Section C, 1900; A. A. Noyes, Secretary, Section C, 1900; Jno. H. Long, Vice-president, Section C, 1901; Wm. McPherson, Secretary, Section C, 1901; W. D. Bancroft, C. S. Palmer, A. Lachman.

Member of General Committee, H. W. Hillyer.

Member of Council, C. S. Palmer.

Press Secretary, C. L. Parsons.

After the organization of Section C, the officers of the American Chemical Society took charge of the meeting. With the exception of Wednesday afternoon, two sessions were held daily until the final adjournment on Friday. Wednesday afternoon was given up to a visit to the Denver Smelting Works, under the direction of Mr. Franklin Guiterman. A special train conveyed the visitors to the Argo, Grant and Globe Works, successively. In the evening a subscription dinner was given at the University Club by the courtesy of the House Committee. After the final adjournment on Friday a number of the chemists accepted the invitation of Mr. J. D. Hawkins to visit the works of the various smelting companies at Colorado City.

At the meeting of the General Commit-

tee on Thursday evening, Professor H. A. Weber, Ohio State University, and Professor Francis C. Phillips, University of Western Pennsylvania, were elected respectively Vice-president and Secretary of Section C for the Pittsburg meeting, 1902.

The following is a complete list of papers presented at the meeting, together with brief abstracts whenever it was possible to secure these from the authors.

1. 'Report of the Census Committee of the American Chemical Society': CHAS. BASKERVILLE, *Chairman*.

The report included a detailed résumé of improved conditions in the teaching of chemistry in the United States; of the establishment of agricultural colleges, technical institutions, standard bureaus; comparative statements of the training of chemists and chemical engineers in the United States and indications of directions for even greater improvement and extension of the work of the larger institutions; suggestions for the guidance of growth of the smaller colleges.

The complete report will be published in the memorial volume of the twenty-fifth anniversary of the American Chemical Society.

2. 'A Summary of the Analyses of some Massive and Eruptive Rocks of Boulder County, Colorado': CHAS. SKEELE PALMER.

The paper included a condensed statement of the analyses of typical or characteristic rocks of Boulder county. The work was done largely by seniors in the chemical laboratory of the University of Colorado, with the view of training the individual student in the accuracy and independence necessary for original work; also with the further view of adding to the general knowledge of the composition of the rocks of this region. The paper will be published in the *Journal of the American Chemical Society*.

3. 'Recent Developments in Physical Chemistry': WILDER D. BANCROFT.

A résumé was given of the important work done recently in physical chemistry in the various laboratories both in the United States and foreign countries.

4. 'On the Optical Rotation of Certain Tartrates in Glycerol': J. H. LONG.

The rotation of the ordinary tartrates in water is well known, and it has been shown that in dilute solutions the molecular rotations are nearly constant. In this paper the rotations of the following bodies in glycerol are discussed: Potassium sodium tartrate, ammonium tartrate, ammonium hydrogen tartrate, potassium antimonyl tartrate, ammonium antimonyl tartrate and potassium boryl tartrate.

In the cases of the antimony compounds, the molecular rotations agree very well with each other, and also with the rotations in water solution for the same salts; their molecular rotations are therefore very different from those of the simple salts of tartaric acid, which suggests, possibly, that the active acid ion here is no longer that of tartaric acid. Following the suggestion of Clarke, it may be that we have here to deal with salts of tartrantimonious acid ($C_4H_4O_6Sb$)OH, the properties of which are very different from those of the dibasic tartaric acid.

The behavior of the borotartrate in glycerol is very different from that in water, and also different from that of the antimony compound. It is likely that the assumed analogy between these bodies does not hold. There is nothing especially noteworthy in the behavior of the simpler tartrates in glycerol. For Rochelle salt the rotation is larger than that in water and in marked degree variable with the concentration.

5. 'The Atomic Volume Curve in Relation to the Periodic Sequence': CHAS. SKEELE PALMER.

The author proposes a new form of Lothar Meyer's curve which seems to indicate the form in short and long independ-

ent series as the more natural one for the periodic sequence.

The paper will be submitted to the American Chemical Society for publication.

6. 'Report on some of the Mineral Waters of the Philippine Islands': G. B. FRANKFORTER.

The author called attention to the occurrence of lithium in many of the samples. Rubidium and cæsium were also found in some cases.

7. 'Proper Methods of Teaching Physical Chemistry': WILDER D. BANCROFT.

According to the author, an introductory lecture course in physical chemistry should begin with the physics of one-component systems, the formation, separation, properties and identification of phases. Next should come the corresponding study of two-component systems, stress being laid on the variation of properties with concentration and the resulting analytical methods. With three-component and four-component systems, chemical methods of analysis become necessary. The general theory of separation by fractional crystallization and distillation comes in at this point. An outline was given of the laboratory course now offered at Cornell University, which is designed to supplement the lecture course and which calls for thirty-three afternoons' work.

8. 'Some Observations on the Teaching of Chemistry': CHAS. SKEELE PALMER.

The paper emphasized: (1) The value of the thorough study of oxidation and reduction tables as a systematic basis for general inorganic chemistry; (2) the conservative use of the periodic sequence in the form of short and long independent series; (3) the lack of an easy, natural and thoroughly satisfactory introduction to general systematic inorganic chemistry after the consideration of the typical elements and the atomic theory; (4) the use of qualitative reactions in the laboratory work of elemen-

tary organic chemistry, pending the use of the necessary but more complicated synthetic work of organic chemistry proper.

9. 'Some Suggestions for the Improvement in Instruction in Technical Chemistry': ARTHUR LACHMAN.

This paper will be published in full in SCIENCE.

10. 'Discussion of Methods used in Different Universities for giving Instruction to Large Classes in Elementary Laboratory Work': WM. MCPHERSON.

11. 'Chemistry in the High School': FREDUS N. PETERS.

12. 'Chemistry in Manual Training Schools': ARMAND R. MILLER.

In this paper the writer gave a description of the method of teaching the subject in the Manual Training High School of Kansas City, Mo. In harmony with the spirit of the school, the practical applications of the subject are prominently brought out and the facts linked, so far as possible, to the things of every-day life. With this same end in view, the pupils are shown through smelters, soap factories, acid works, gas works, etc.

In the study of the metals careful attention is given to the ways in which these occur in nature, the metallurgical processes by which the metals are obtained, and their physical properties, upon which their adaptation to various uses depend. The value of the stereopticon as an aid in arousing and holding an interest in the subject is recognized and a collection of suitable slides is being made. It is not considered wise to attempt to teach qualitative analysis in a one-year course and so all the time is devoted to the study of general chemistry. About one half the time is spent in the laboratory. Brief notes are made there and elaborated at home. A few quantitative experiments are performed in order that the pupils may get some conception of quantitative relations. A course in qualitative analysis is offered, but a second year is de-

voted to it. Pupils who show sufficient ability are encouraged to take up quantitative analysis or assaying, this work being done in the afternoons without credit, as these are not regular courses.

13. 'Notes on the Chlorides of Ruthenium': JAS. LEWIS HOWE.

Claus described double chlorids of trivalent ruthenium of the type $2XCl, Ru'''Cl_3$, and also those of what he considered to be the tetrachlorid of the type $2XCl, RuCl_4$. These last Joly showed to be nitroso-chlorids of the type $2XCl, RuCl_3NO$. Antony has recently succeeded in forming a true tetrachlorid, $2KCl, RuCl_4$, by the solution of potassium ruthenate, K_2RuO_4 in dilute hydrochloric acid.

When ruthenium tetroxid, RuO_4 , is treated in the cold with a strong solution of cesium (or rubidium) chlorid and a few drops of hydrochloric acid, it is gradually converted into a salt of a new series, cesium- (or rubidium) oxy-chlor-ruthenate, $2CsCl-RuO_2Cl_2$, which is instantly decomposed by water. On treatment with strong hydrochloric acid this is converted into the tetrachlorid (chlor-ruthenate), $2CsCl, Ru^{iv}Cl_4$. In most of its reactions it closely resembles the ordinary trichlorid.

This ordinary trichlorid has the formula $2CsCl, Ru'''Cl_3, H_2O$, but numerous other salts exist with varying proportions between the ruthenium trichlorid and the alkaline chlorid.

When the tetrachlorid is warmed in dilute acid solution with alcohol, rose prisms are formed of the same formula as the ordinary trichlorid, but this salt is very distinct in its properties and may be an aqua-trichlorid, $2CsCl, RuOH_2Cl_3$. This gives the tetrachlorid again with strong hydrochloric acid.

The blue solution produced by the action of H_2S on ruthenium solutions can also be obtained by electrolytic reduction, and is, when concentrated, precipitated by cesium

chlorid, but the precipitated salt has not yet been obtained in a state of purity. It seems to have the formula $3CsCl, 2Ru''Cl_2, - 2H_2O$, but is receiving further investigation.

After treatment with stannous chlorid, ruthenium trichlorid gives a yellow flocculent precipitate with caustic potash. This is soluble in hydrochloric acid, from which there crystallize brilliant yellow octahedra, containing tin, ruthenium and chlorin. These are being investigated.

This paper will be published in the *Journal of the American Chemical Society*.

14. 'On the Existence of a New Element associated with Thorium': CHAS. BASKERVILLE.

Pure thorium salts obtained from five sources were repurified and fractioned first by sulphur dioxide and second by variation in the solubility of the citrates. Three evidences of the complexity of thorium were offered.

1. Pure thorium dioxide has a specific gravity of 10.2. This was fractioned, giving oxides having specific gravities of 9.25 and 10.53. This corroborates Brauner's work on the hydrolysis of the heptahydrated thorium tetrammonium oxalate.

2. Thorium dioxide is slightly radioactive. Crookes has recently found by fractioning pure thorium nitrate that one fraction was three times as active as the other. The author has found the radioactivity to increase with the increase of specific gravity of the oxides. The oxide having the lower specific gravity is inactive. Description of methods of procedure were given.

3d. Pure thorium tetrachloride was prepared and the atomic weight of thorium determined. $223.25 \pm .05$ was the value found, which is given tentatively. The generally accepted atomic weight is 232.6.

These evidences prove the complexity of thorium and from some data already obtained the new body appears to have an

atomic weight between 260 and 280. As the original material came from the monazite sands of the Carolinas, the author desires, in case the element is ever separated in a pure form, and the indications are most favorable, to have it known as *Carolinium*.

This paper will be published in full in the *Journal* of the American Chemical Society.

15. 'Some New Laboratory Furniture': ARTHUR LACHMAN.

The author described a drawer for storing glass tubing (and showed a photograph). The drawer is open on one end and pivoted at the other. When closed it looks like an ordinary drawer, and does not extend beyond the drawer case. Upon opening, it swings out at an angle, the open end permits the inspection and withdrawal of any piece of tubing.

A special laboratory sink was described. It is 18 inches wide, 30 inches long and 4 inches deep. It is cast of iron, $\frac{3}{8}$ inch thick. The inner surface drains towards the center from all points. The straining plate consists of a perforated plate of lead which is hammered into a flange provided in the sink. The waste pipe is screwed on to a projecting pipe by means of a flange, the projecting pipe being cast into the sink. In this way no screws or other obstructions present themselves in the sink proper and the life of the sink is greatly prolonged. The sinks were cast to order, weigh about 100 pounds and cost about \$5.00.

A convenient and cheap air-bath was also described. This is merely an asbestos-covered oven, such as is used for gasoline stoves. Such ovens have been in use in the author's laboratories for over three years with excellent results. They measure about 20 by 14 inches on bottom and are about 20 inches high. A single Bunsen burner can heat them to 170° C. They will hold over sixty funnels for drying purposes. They cost only \$2.80 (in Chicago).

16. 'Recent Developments in Organic Chemistry': ARTHUR LACHMAN.

The following is a brief summary of some of the topics considered: The Richter system of registration; direct nitration of paraffins; graphitic acid; Friedel-Crafts reaction; diazo compounds; the uric-acid group; some curious nitrogen compounds and reactions; some artificial substitutes for cocaine; the odorous ingredients of the jasmine and the orange blossom (methyl anthranilate and indol); the odor of the mercaptans; the increasing importance of physical chemistry for the purposes of organic chemistry; catalysis in organic reactions; the two forms of acetylene di-iodide; the chemical nature of alcoholic fermentation; trivalent carbon; the commercial manufacture of artificial indigo. A number of details and calculations are given in this instance. Tautomerism is defined and illustrated in its various forms. The formation of acetoacetic ether. Molecular rearrangements. The stereochemistry of nitrogen, of sulphur, of tin and of iodine—the three first mentioned form optically active compounds. Some new mercury derivatives of organic compounds. Auto-oxidation. Some new organic derivatives of hydrogen peroxide. Quadrivalent oxygen in dimethylpyrone. Is oxygen really acid forming? Thiele's theory of unsaturated compounds and the benzene ring. Nef's methylene theory. Michael's theory of organic reactions. Conclusion: the unity of organic research work.

The complete paper will be printed in the *Journal of the American Chemical Society*.

17. 'The Electrolysis of Certain Proteids': MARY ENGLE PENNINGTON.

A solution of edestin, a globulin from hemp seed, dissolved in 0.6 per cent. orthophosphoric acid and subjected in a partitioned cell to the action of a current of $N.D._{100} = 0.2-0.4$ ampere and 6-18 volts, gives a heavy white precipitate in the cath-

ode chamber. This precipitate, purified as carefully as possible, contains about 2.8 per cent. of phosphorus and 16.41 per cent. of nitrogen. Its properties do not entirely coincide with any known class of proteids, but approach more nearly to those of the nucleo proteids. It is difficultly soluble in pure cold water, easily soluble in hot or boiling water and separates from the hot solution unchanged on cooling. By pepsin-hydrochloric acid digestion it yields a substance containing about 7 per cent. of phosphorus. Decomposition by boiling with sulphuric acid and subsequent treatment for nitrogen bases yields a white, crystalline substance containing nitrogen. The anode chamber, after electrolysis as above, gives a different substance, also containing phosphorus. Egg albumen behaves in an analogous manner. The cathode product showed about 2 per cent. of phosphorus.

This paper will be published in the *Journal of the American Chemical Society*.

18. 'The Reduction in an Alkaline Solution of 2,4,5 Trimethyl Benzalazine and the Preparation of some Derivatives of the Reduction Products': E. P. HARDING.

By reducing 2,4,5 Trimethyl benzalazine,

in an alkaline solution, two reduction products may be obtained depending upon the degree of reduction—one a 2,4,5 trimethyl benzal 2,4,5 trimethyl benzyl hydrazone,

and the other a symmetrical 2,4,5 trimethyl dibenzyl hydrazine,

The hydrazone is a weak base. With picric acid it forms the addition product 2,4,5 trimethyl benzal 2,4,5 trimethyl benzyl hydrazone picrate,

The imid hydrogen atom may be substituted by an acetyl, benzoyl or nitroso group forming the corresponding acetyl, benzoyl or nitroso derivatives, viz :

and

By the action of hydrochloric acid it hydrolyzes to 2,4,5 trimethyl benzaldehyde and to 2,4,5 trimethyl-benzyl hydrazine hydrochloride,

from which the free base may be obtained by the action of caustic potash.

2,4,5 trimethyl benzyl hydrazine

forms with benzaldehyde, benzal, 2,4,5 trimethyl benzyl hydrazone

With pyrrocemic acid, it forms 2,4,5 trimethyl benzyl hydrazine pyrrocemate,

It is also capable of forming addition products. With picric acid, it produces 2,4,5 trimethyl benzyl hydrazine picrate,

with phenyl mustard oil, it forms 2,4,5 trimethyl benzyl phenyl thio semicarbazide

and with cyanic acid, 2,4,5 trimethyl benzyl semicarbazid.

This paper will be presented in the *Journal of the American Chemical Society*.

19. 'The Identification and Properties of Alpha and Beta Eucaïne': CHAS. L. PARSONS.

Alpha and beta eucaïne are new alkaloids which quite recently have been offered to the medical profession as a substitute for cocaine. There seem to be certain advantages possessed by beta eucaïne which are leading to its quite general acceptance. Chief among these are its comparatively low toxicity, its stability when boiled, which allows the solution to be easily disinfected, and its non-excitation of the heart's action. Both of these alkaloids have been synthesized in the laboratory and so far as known are not a product of life. Beta eucaïne acts as a local anæsthetic, like cocaine. Both eucaïnes resemble cocaine structurally and in general chemical properties they react much like cocaine, being easily shaken out of alkaline solution with ether, petroleum ether, benzine, chloroform, etc. Their chief distinguishing reactions are obtained with ammonia, potassium bichromate, mercurous chloride, platinic chloride, potassium permanganate and their actions under polarized light—both in the polariscope and polarizing microscope. Beta eucaïne and its hydrochloride are also characterized by a low solubility in water and alcohol.

This paper will be published in detail in the *Journal of the American Chemical Society*.

20. 'The Alkaloids of *Isopyrum* and *Isopyroïne*': G. B. FRANKFORDER.

The *isopyrum*, so far as can be learned at present, has only once been studied chemically. Hartsen in a brief paper on *Isopyrum thalictroides*, reported the isolation of two new alkaloids. The one he named *isopyrine* and the other *pseudoisopyrine*. He obtained the *isopyrine* by extracting the tubers with water and precipitating out the alkaloid by means of ammonia. The alkaloid was obtained in the pure form by extracting this ammonia precipitate with ether.

Nothing more was done with the alkaloid. No analyses were made and none of the properties given, not even the melting point.

Pseudoisopyroïne was obtained by Hartsen by extracting the root with alcohol after extracting with water. The alcoholic extract was treated with ammonia as in the case of the water extract. On evaporating off the ether the pseudo alkaloid crystallized out in star-shaped crystals. Nothing was done with this substance, not even the melting point was given.

In beginning the work on *Isopyrum biter-natum* the method given above was tried, but with unsatisfactory results. In fact, many methods were tried, a few of which gave quantities of the alkaloid. Best results were obtained, however, by first extracting with very dilute hydrochloric acid. The hydrochloride was found to be very soluble in water, and hence readily removed from the solid matter. The alkaloid was finally obtained by extracting the residue from the dilute acid with ether or by first neutralizing with ammonia. This latter step is important unless the acid solution be evaporated cautiously. Moderately strong acid decomposes the alkaloid. By extracting the acid and alkaline residues with alcohol, the hydrochloride and the free base, respectively, were obtained. Both were purified and analyzed, giving results which correspond to the formula,

In addition to the above, other salts were formed including the platinum double salt and the methyl iodide compound.

21. 'Derivatives of Camphor Oxime': G. B. FRANKFORDER and P. M. GLASOE.

The great difficulty in the study of camphor oxime is the ease with which it loses a molecule of water and forms the so-called campho nitrile. Camphor oxime acts as both acid and base. We have found that

the basic properties predominate. So marked are its basic properties that it combines with nearly all the common acids and even with the aldehydes forming peculiar para derivatives.

Monochlorcamphor oxime $C_{10}H_{15}ClNOH$.

Until recently no real halogen derivatives of camphor oxime have been made. Free chlorine acts upon it, but forms, instead of a chloride, the common hydrochloride and the nitrile. However, if the oxime is dissolved in ether and treated with sulphur dichloride, the monochloride is formed directly in almost pure state.

Monobromcamphor oxime $C_{10}H_{15}BrNOH$.

The same difficulty in introducing chlorine was experienced in making the bromine compounds. It was finally made by treating a chloroform solution of the oxime in the dark with bromine and allowing to stand until the bromine color had disappeared. The pure substance is inactive toward polarized light, has a specified gravity of 1.48 and an index of refraction of 1.557535 at $15^{\circ} C$.

Dibromcamphor oxime $C_{10}H_{14}Br_2NOH$.

By treating a boiling dilute alcoholic solution of camphor oxime with bromine in excess an oily substance settles to the bottom. The substance was removed, purified and analyzed. The results correspond to the above formula.

Numerous attempts were made to substitute the chlorine and bromine, but as yet results are unsatisfactory. No proof has likewise been obtained of the position in which the halogens enter.

22. 'A Chemical Study of the Seed of *Rhus glabra*': G. B. FRANKFORTER and A. W. MARTIN.

The seed of the *Rhus glabra* or common sumach has been examined, but almost wholly with the idea of determining the amount of tannic acid. In the present paper we have made, so far as possible, an

exhaustive examination with special reference to the oils and to the cholesterol present.

We began by studying the seed and husk together, but soon found it advisable to separate them, as most of the oil exists in the seed and all the tannic acid in the husk. The seed contains 9.1 per cent. of oil, while the husk contains 2.5 per cent. On the contrary, the husk contains 7.32 per cent. of tannic acid and 1.35 of malic acid, while the seed contains none.

An examination of the oils showed that the one obtained from the seed resembled that from the husk, the chief difference being in the quantity of foreign substance present. The following is a brief comparison of the properties:

	Seed Oil.	Husk Oil.
Sp. gr. at $15^{\circ}C$.	.923	.933
Index of Refraction at $15^{\circ}C$.	1.48228	1.48764
Saponification Value	194.7	190.1
Iodine Value	86.4	87.2
Drying Properties	None	None
Color	Light yellow	Dark brown

An examination of both the oils showed the presence of a substance resembling cholesterol. It was obtained by the common method for the extraction of cholesterol. It is probable that the substance obtained in each oil is the same. That obtained from the seed oil was so small that it was not studied. The husk oil contained 2.26 per cent. It was readily removed from the oil by acetone. The substance was carefully purified and analyzed. Analysis gave numbers corresponding with the formula

The molecular weight determination gave numbers agreeing with the above formula.

23. 'Phenoxozone Derivatives': H. W. HILLYER.

As indicated in the paper read at the meeting of the Association in New York, when picryl chloride acts on pyrocatechin in presence of two molecules of alkali, one

molecule of hydrochloric acid and one of nitrous acid are split off and a condensation takes place with the formation of dinitro phenoxozone.

The same kind of action takes place with homopyrocatechin and qualitatively the same action results with the other ortho-dihydroxy compounds; protocatechuic ethyl ester, æsculitin, daphnetin, alizarine and nitropyrocatechin. The condensation products have been isolated but not in quantity to make satisfactory analyses. Most of them yield brilliant carmine solutions when treated with sodium ethylate. The change produced in this way is only superficial since at least in the case of the simplest one, dinitro phenoxozone, the original compound is precipitated on dilution with water.

The substance produced by action of alcoholic soda on dinitro phenoxozone has been further studied and found to be the strong acid dinitro dioxy phenoxide.

The substance formed by action of one molecule of pyrocatechin, two of picryl chloride and two of alkali is proven to be dipicryl pyrocatechin by analysis and by the fact that it splits off one molecule of picric acid and one of nitrous acid and yields dinitro phenoxozone.

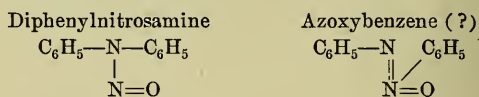

24. 'The Constitution of Azoxybenzene': ARTHUR LACHMAN.

Two formulæ have been proposed for azoxybenzene:

No positive evidence is available for either of these. The author undertakes to show, by a comparison of azoxybenzene with diphenylnitrosamine, that formula (II.) cannot represent the properties of azoxybenzene. There is considerable similarity between (II.) and the structure of diphenylnitrosamine; and since the compounds are

isomeric, similarity of reaction may also be expected:

With four different reagents (hydrochloric acid, phenyl-hydrazine, hydroxylamine, and zinc ethyl) the author obtained prompt and decisive reactions with diphenylnitrosamine under circumstances where azoxybenzene was unacted upon. From this it is concluded that only formula (I.) can be regarded as satisfactory for azoxybenzene. This conclusion is strengthened by thermochemical data; the oxidation of azobenzene to azoxybenzene gives off 257 K, whereas all other classes of nitrogen compounds have negative heats of oxidation. This shows that in azoxybenzene the nitrogen and oxygen have attained the maximum saturation of their affinities.

25. 'The Action of Zinc Ethyl on Nitro and Nitroso-Compounds, A Reply to I. Bewad': ARTHUR LACHMAN.

Bewad has recently claimed priority for the investigation of the above-named reaction. This priority is unquestioned. But Bewad is mistaken in his explanations of the various results obtained. He assumes that the nitro and nitroso groups, NO_2 and NO respectively, behave in a manner exactly analogous to the carbonyl group, CO . The author shows, on the basis of his own work, that this supposed analogy does not exist; that certain nitroso compounds show a peculiarly unique behavior with zinc ethyl; that other nitroso compounds differ from these first, as well as from carbonyl compounds; and that no reliable conclusions whatever can be drawn as yet from the behavior of nitro compounds. There is also some difference of fact to be noted in the work of Bewad and of the author, which calls for further experimentation.

26. 'Some Hydrochlorated Sulphates':

CHAS. BASKERVILLE, LIONEL WEIL and I. F. HARRIS.

The work of Ditte on $\text{HgSO}_4, \text{HCl}$ was repeated and found correct. $\text{HgSO}_4, 2\text{HCl}$ was also prepared. Hydrated cadmium sulphate ($3\text{CdSO}_4, 8\text{H}_2\text{O}$) was treated with anhydrous hydrochloric acid under different conditions of temperature, time and variation of masses and the water replaced gradually by hydrochloric acid. Eventually, under certain conditions, the sulphuric acid was entirely replaced by hydrochloric acid. E. F. Smith has made similar observations with sodium and potassium sulphates, but in no case was all the sulphuric acid replaced as observed with compounds treated of in this paper.

This paper will be published in the *Journal of the American Chemical Society*.

27. 'The Origin and Use of Natural Gas at Manitou, Colo.': WILLIAM STRIEBY.

The paper opens with a statement of the geological features of the region about Manitou in so far as they have a bearing upon the origin of the carbon dioxide, viz., the limestones at Manitou, the rock-fault following the line of the Ute Pass, the igneous rocks of the higher lands westward at Cripple Creek, etc. Analyses of waters from several springs at Manitou are given and discussed with a view of tracing the source of the mineral matters and gas contained in them. Some theories of the origin of carbon dioxide are briefly summarized and dismissed as inapplicable to this locality. A short discussion of chemical reactions occurring in rocks due to permeating solutions gives a basis for the theory adopted in this paper, and finally a few confirmatory facts are cited and a reference made to the gas springs at Saratoga, New York, and Cañon City, Colorado.

The latter part of the paper details the work done under the direction of the writer in the measurement of the gas given off at some of the springs at Manitou, the calcu-

lation of the quantity of carbonated water to be obtained, the design of suitable apparatus for catching the gas and the choice of compression and carbonating machines to produce the gassed mineral water.

The following papers were read by title. With few exceptions, they will be published in the *Journal of the American Chemical Society*.

'Analysis of a Few Southwestern Coals': HERMAN POOLE.

'Copper—Its Scientific and Commercial Value': W. S. EBERMAN.

MEMBERSHIP OF THE AMERICAN ASSOCIATION.

THE following have completed their membership in the American Association for the Advancement of Science during the month of August:

Frank L. Abbott, Professor of Physical Sciences, State Normal School, Greeley, Colo.

Geo. E. Alexander, Chemist and Mining Engineer, 1736 Champa St., Denver, Colo.

Dr. John E. Almy, Instructor in Physics, University of Nebraska, Lincoln, Nebr.

Miss Theodosia G. Ammons, Professor of Domestic Science, State Agricultural College, Ft. Collins, Colo.

John B. Annear, Chemist, Boulder, Colo.

Geo. F. Archer, 31 Burling Slip, New York, N. Y.

Robert Armstrong, M.D., Boulder, Colo.

Barton O. Aylesworth, President State Agricultural College, Ft. Collins, Colo.

Francis N. Balch, Lawyer, 23 Court St., Boston, Mass.

George Bell, Mineralogist, 200 S. Washington Ave., Denver, Colo.

Edgar H. Berry, Draftsman, 72 E. 87th St., New York, N. Y.

Frank W. Blackmar, Professor of Sociology and Economics, University of Kansas, Lawrence, Kansas.

Fred C. Blake, Boulder, Colo.

Newton A. Bolles, Chemist, 1457 Ogden St., Denver, Colo.

Fred Bond, State Engineer, Cheyenne, Wyoming.

Joseph H. Bowman, Electrical Engineer, Apartado 21, Cordoba, Mexico.

Frank P. Brackett, Professor of Mathematics, Pomona College, Claremont, Cal.

David W. Brunton, Mining Engineer, 865 Grant Ave., Denver, Colo.

Mrs. Emma F. J. Bullene, 1431 Court Place, Denver, Colo.

Virgil M. Came, 315 Quincy Bldg., Denver, Colo.

James Carter, M.D., Carbon, Wyoming.

Rollin T. Chamberlin, Hyde Park Hotel, Chicago, Ill.

Ellery C. Chilcott, Professor Geology and Agronomy, Agricultural College, Brookings, S. D.

Arthur Cobb, Architect, 600 Equitable Bldg., Louisville, Ky.

Thomas H. Conorroe, M.D., Lecturer on Biology, Hahnemann Medical College, 833 N. 26th St., Philadelphia, Pa.

Samuel R. Cook, Professor Physics and Chemistry, Washburn College, Topeka, Kansas.

Clifford E. Corwin, Teacher of Science, High School, 508 5th St., Marietta, Ohio.

Mattoon M. Curtis, Professor of Philosophy, Western Reserve University, 43 Adelbert Ave., Cleveland, Ohio.

Alvin S. Daggette, M.D., 400 S. Craig St., Pittsburg, Pa.

A. H. Danielson, Assistant Agriculturist, Agricultural College, Ft. Collins, Colo.

Edward E. Davis, 157 N. 20th St., Philadelphia, Pa.

Manning W. Doherty, Associate Professor of Biology, Ontario Agricultural College, Guelph, Canada.

Charles R. Dryer, Professor of Geography, State Normal School, Terre Haute, Ind.

Philip K. Dumaresq, Sears Building, Boston, Mass.

George M. Duncan, Professor of Philosophy, Yale University, 299 Edwards St., New Haven, Conn.

Miss Alice Eastwood, Curator of Herbarium, Academy of Sciences, San Francisco, Cal.

David C. Eccles, Pharmacist and Chemist, 191 Dean St., Brooklyn, N. Y.

Isaac R. Edmands, Electrical Engineer, Union Carbide Co., 315 Buffalo Ave., Niagara Falls, N. Y.

E. Waite Elder, Instructor in Physics, High School No. 1, Denver, Colo.

Dr. Arthur H. Elftman, Mining Engineer, 706 Globe Building, Minneapolis, Minn.

Wilbur D. Engle, Professor of Chemistry, Univ. of Denver, University Park, Colo.

Philo J. Farnsworth, M.D., Clinton, Iowa.

Professor Wm. C. Ferril, Curator, State Historical and Natural History Soc., 2123 Downing Ave., Denver, Colo.

Dexter M. Ferry, Jr., Seedsman, 1040 Woodward Ave., Detroit, Mich.

Francis A. J. FitzGerald, P. O. Box 118, Niagara Falls, N. Y.

Robert H. Forbes, Professor of Chemistry and Dir. Agr. Exper. Sta., Territorial Univ., Tucson, Arizona.

Floyd C. Furlow, Professor Experimental Engineering, Ga. School of Technology, Atlanta, Ga.

John B. Garvin, Instructor in Chemistry, Denver High School, 2536 W. 34th Ave., Denver, Colo.

H. Allan Gleason, Asst. in Botany, Univ. of Illinois, John St., Champaign, Ill.

Gustavus E. Gordon, Scientific Director, Walker-Gordon Laboratory Co., 1120 Conn. Ave. N. W., Washington, D. C.

Professor H. A. Gossard, Professor of Entomology, Agric. Coll., Lake City, Fla.

H. P. Grabill, Student of Chemistry, Drake University, 1004 Anas Ave., Des Moines, Iowa.

U. S. Grant, Northwestern University, Evanston, Ill.

Willis H. Grant, Teacher of Chemistry and Geology, Academic High School, Pittsburg, Pa.

Clarence S. Hammatt, Electrical and Mechanical Engineer, Jacksonville, Fla.

Everhart P. Harding, Asst. in Chemistry, Univ. of Minnesota, Minneapolis, Minn.

R. H. Harper, M.D., Practicing Physician, Afton, Indian Territory.

J. Campbell Harris, 119 S. 16th St., Philadelphia, Pa.

Samuel T. Hensel, Chemist, 801 East Colfax Ave., Denver, Colo.

John W. Heston, Pres. S. D. Agri. College, Brookings, S. D.

Charles N. Hewitt, M.D., Secy. State Board of Health, Red Wing, Minn.

Geo. M. Holferty, Instructor in Botany, Univ. of Ill., 931 W. Green St., Urbana, Ill.

A. M. Holmes, M.D., Jackson Block, Denver, Colo.

Samuel J. Holsinger, Special Agt. Interior Dept., Tucson, Arizona.

Walter D. Hunter, Entomologist, Victoria, Texas.

Elsworth B. Knerr, Midland College, Atchison, Kansas.

Andrew C. Lawson, Prof. of Geology and Mineralogy, Univ. of California, Berkeley, Cal.

Henry C. Lay, Mining Engineer and Geologist, Telluride, Colo.

William G. Lee, 7 Littles, Cambridge, Mass.

Mrs. Julia A. Lender, 2201 Lincoln Ave., Denver, Colo.

Percy A. Leonard, Editor and Manager *Ores and Metals*, P. O. Box 364, Denver, Colo.

Edwin H. Lockwood, Assistant Professor Mechanical Engineering, Yale University, New Haven, Conn.

Geo. D. Louderback, Professor of Geology, Nevada State University, Reno, Nevada.

J. R. Lovejoy, Electrician, 811 Union St., Schenectady, N. Y.

Otto J. J. Luebker, Bureau of Forestry, Dept. Agriculture, Washington, D. C.

D. W. McGee, Farley, Iowa.

Howard L. McLaury, Professor of Mathematics and Physics, South Dakota School of Mines, Rapid City, S. D.

John W. Mahin, Teacher in Manual Training High School, 1411 16th Ave., Denver, Colo.

Fredrick Wm. Mally, Entomologist, Orchardist and Nurseryman, College Station, Texas.

Amos L. Mason, M.D., Physician to Boston City Hospital, York Harbor, Maine.

Dr. J. A. Mathews, Chemist and Metallurgist, 4 First Place, Brooklyn, N. Y.

Elmer D. Merrill, Assistant Agrostologist, U. S. Dept. Agriculture, Washington, D. C.

Ralph D. Mershon, Consulting Engineer, 621 Broadway, New York, N. Y.

Mrs. Cornelia Miles, Principal Broadway School, 1544 Franklin St., Denver, Colo.

Armand R. Miller, Professor of Chemistry, Manual Training High School, Kansas City, Mo.

E. J. Molera, Civil Engineer, 606 Clay St., San Francisco, California.

Hart Momsen, Chief Clerk, Division of Agriculture, Census Office, Washington, D. C.

Stanley H. Moore, Director Manual Training Dept., Manual Training High School, Kansas City, Mo.

Horatio N. Parker, Biologist to Metropolitan Water Board, 24 Wendell St., Cambridge, Mass.

Arthur L. Patton, Instructor in Physics and Chemistry, State Preparatory School, Boulder, Colo.

Jesse Pawling, Jr., Instructor in Physics, Central High School, Philadelphia, Pa.

Mrs. Lucy E. Peabody, 1430 Corona St., Denver, Colo.

Harold Priestman, Electrician, care of Westinghouse Elec. Co., Pittsburg, Pa.

Mrs. Mary I. D. Putnam, President Davenport Academy of Sciences, 2013 Brady St., Davenport, Ia.

T. A. Rickard, Mining Engineer and Geologist, University Club, Denver, Colo.

John M. Roberts, Principal High School, Marshall, Mo.

E. Dwight Sanderson, Entomologist, Agr. Exp. Sta., Newark, Del.

W. M. Scott, State Entomologist, Atlanta, Ga.

James F. Sellers, Professor of Chemistry, Mercer University, Macon, Ga.

Gustavus Sessinghaus, Mining Engineer, Alma, Colo.

Homer LeRoy Shantz, Instructor in Biology, Colorado College, Colorado Springs, Colo.

John C. Shedd, Professor of Physics, Colorado College, Colorado Springs, Colo.

James D. Skinner, 823 E. 14th Ave., Denver, Colo.

H. Clyde Snook, Professor of Physics and Chemistry, Allegheny College, Meadville, Pa.

Nathaniel M. Snyder, Electrical Engineer, Gering, Neb.

Zachariah X. Snyder, President State Normal School, Greeley, Colo.

Elmer G. Starr, M.D., Clinical Professor Ophthalmology, University of Buffalo, 523 Delaware Ave., Buffalo, N. Y.

Thomas B. Stearns, Mining and Mechanical Engineer, Denver, Colo.

Robert Stevenson, Consulting, Civil and Mining Engineer, P. O. Box 2214, San Francisco, Cal.

James H. Stewart, Director W. Va. Agr. Exp. Sta., Morgantown, W. Va.

George A. Still, Student, Drake University, 1428 Locust St., Des Moines, Iowa.

Miss Lela Lorena Stingley, Astronomical Student, University Park, Colo.

Goodwin D. Swezey, Professor of Astronomy and Meteorology, University of Nebraska, Lincoln, Nebr.

Harry Stanley Thayer, Chemist, Greeley, Colo.

Miss Mary Clark Trayler, Astronomical Student, 653 S. Grant Ave., Denver, Colo.

George B. Upton, Milton, Mass.

Rudolph J. Walter, Mining Engineer and Metallurgist, 1452 Blake St., Denver, Colo.

C. E. Wantland, Land Agent, Union Pacific R. R. Co., 1025 17th St., Denver, Colo.

Milan L. Ward, Professor Mathematics and Astronomy, Ottawa University, Ottawa, Kan.

David Wesson, Mgr. and Treas. of Wesson Process Co., 204 Bay St., Savannah, Ga.

Rev. Henry White Warren, Bishop M. E. Church, University Park, Colo.

Thomas B. Whitted, Electrical Engineer, General Elec. Co., Denver, Colo.

Merle J. Wightman, Electrical Engineer, 150 Nassau St., New York, N. Y.

Edwin M. Wilcox, Botanist and Entomologist, A. and M. College, Stillwater, Oklahoma.

Arthur Williams, with N. Y. Edison Co., 261 Linden Boulevard, Brooklyn, N. Y.

Wm. H. Wilson, Professor of Mathematics, University of Wooster, 141 Beall Ave., Wooster, Ohio.

Alexander N. Winchell, Professor of Geology, Montana School of Mines, Butte, Montana.

Byron C. Wolverton, Engineer, New York and Pennsylvania Telephone and Telegraph Company, P. O. Box 43, Elmira, N. Y.

William S. Yeates, State Geologist, Atlanta, Ga.

SCIENTIFIC BOOKS.

A Laboratory Course in Plant Physiology, especially as a basis for ecology. By WILLIAM F. GANONG, Ph.D., Professor of Botany in Smith College. New York, Henry Holt and Company. 1901. Octavo, cloth. Pp. vi + 147.

Practical Text-book of Plant Physiology. By DANIEL TREMBLY MACDOUGAL, Ph.D., Director of the Laboratories of the New York Botanical Garden. With one hundred and fifty illustrations. New York, Longmans, Green and Co. 1901. Octavo, cloth. Pp. xiv + 352.

Professor Ganong's little book is a product of his laboratory, and therefore has the merit of practicality. The illustrations of apparatus (about thirty) are from photographs of the appliances actually used, and the text consists of descriptions of experiments which the author has repeatedly made. The book is in two parts, in the first of which the author discusses methods of study and the necessary equipment, while in the second is given an outline of a course of experiments in the laboratory on protoplasm, nutrition, growth, reproduction and irritability. The author says (p. 23), 'It goes without saying that a greenhouse and a laboratory are indispensable for a course in physiology,' and naturally gives a good deal of attention to the plans and equipment of both. These sections of the book will prove very helpful to those who are building up their facilities for physiological work. The experiments, of which nearly one hundred are specifically indicated, are selected with reference to their availability and practicability in an elementary course. The treatment here is such as to make investigators. The author does not ask numberless leading questions of the 'kindergarten order,' nor does he leave the student without any guide, but wisely follows a middle

path suggested no doubt by his long and successful experience as a teacher.

We would call especial attention to the fact that the author has planned this course 'especially as a basis for ecology.' In some quarters there is a feeling that ecology should be one of the first things brought to the young student's attention, and so we have a swarm of elementary books for secondary school children in which 'ecology' figures prominently. We are in full sympathy with the author when he says, "More than one recent writer has described ecology as at present mostly a series of guesses; and so will much of it continue to be until given logical precision and a firm foundation in exact physiology." Evidently ecology must come *after* the student has prepared himself for it, and *not* as an introduction to botany.

Dr. MacDougal's work is the first American text-book of plant physiology of advanced grade to be published. It is intended for and adapted to the demands of such students as have already made considerable progress in the study of plant activities. In fact, we apprehend that to a large extent it will be the hand-book for the teacher, rather than for the student. However used, it must do much to stimulate physiological inquiry in colleges and universities. The aim of the work is thus defined in the preface, "The chief purpose of the author is to present practical directions for the demonstration of the principal phenomena of the physiology of the plant, and also details of experimental methods suitable for the exact analyses requisite in research work."

The sequence of topics is considerably different from that usual in works on the physiology of plants. Thus the author takes up in order, 'The Nature and Relations of an Organism,' 'Relations of Plants to Mechanical Forces,' 'Influence of Chemicals upon Plants,' 'Relations of Plants to Water,' 'Relations of Plants to Gravitation,' 'Relations of Plants to Temperature,' 'Relations of Plants to Electricity,' and other forms of energy, 'Relations of Plants to Light,' 'Composition of the Body,' 'Exchanges and Movements of Fluids,' 'Nutritive Metabolism,' 'Respiration,' 'Fermentation and Digestion,' 'Growth,' 'Reproduction.' It

is difficult to specify chapters in a work in which there is so much to commend, but to us the most interesting is that on the 'Composition of the Body' (IX.), in which the treatment, though not extended, is especially satisfactory. Here the principal topics are 'Substances found in Plants,' 'Carbohydrates,' 'Fractional Extractions,' 'Estimation of Tannins and Glucosides,' 'Determination of Sugars and Dextrins,' 'Starch,' 'Cellulose,' 'Proteids,' 'The Fats,' 'Determination of Organic and Inorganic Matter,' 'Enzymes.' We venture to say that the general introduction of the matter of this chapter into plant physiology will revolutionize much of the teaching of this subject in this country. There has been too little of the study of what plants actually are in the physiology of the past, so far as this country is concerned, and it is just here that American botanists have been weakest. This book will serve as a corrective, and it is to be hoped that it will turn the attention of students in physiological laboratories to this much-neglected aspect of their work.

CHARLES E. BESSEY.

NOTES.

THE American Institute of Mining Engineers will, as we learn from the *Railway and Engineering Review*, publish two volumes as follows:

1. 'The Genesis of Ore-Deposits,' comprising the famous treatise of the late Professor Franz Posepny, with the successive discussions thereof by Le Conte, Blake, Winchell, Church, Emmons, Becker, Cazin, Rickard and Raymond (all of which were published in Volumes XXIII. and XXIV. of the *Transactions* of the Institute, and subsequently in the special 'Posepny Volume,' issued by the Institute); also, later, papers by Van Hise, Emmons, Weed, Lindgren, Vogt, Kemp, Blake, Rickard and others, and the discussion of these papers by De Launay, Beck and many others (all of which will be published in Volumes XXX. and XXXI.); also a complete bibliography of the Institute papers and discussions on this subject from 1871 to the present time. The volume now in press will be an octavo of about 825 pages, bound in 'book-linen.' This book will be sent, postpaid,

for \$5 to members or others who subscribe for it before its issue.

2. 'The Evolution of Mine-Surveying Instruments.' This will be a volume of about 400 pages, issued in the same style as the foregoing, and containing the original paper of Mr. Dunbar D. Scott on that subject (*Transactions*, XXVIII.), first published in 1898, together with later papers continuing the same subject, and discussions thereof, by Hoskold, Lyman, Davis and many others. Subscriptions will be received for this volume in advance of its issue at \$3, under the conditions already stated above.

DISCUSSION AND CORRESPONDENCE.

WEATHER CONTROL.

A CHARACTERISTIC of storms which meteorologists do not perhaps sufficiently consider is that they are the falling down or collapsing of unstable states of the atmosphere. Such phenomena in thermodynamics are called reversible processes; let us call them *sweeping processes* or simply *sweeps*. The trend of a sweeping process may be affected to any extent, however great, by a cause, however insignificant, provided the cause acts at the critical initial stage of the sweep. For example, a mere breath may determine whether a brick chimney shall fall harmlessly into a vacant lot or with unmeasured calamity into an adjacent factory, or, to take an example from meteorology, an unstable state of the atmosphere over the United States may lead to a cyclonic movement the effects of which may differ enormously according to the time and place that the unstable state begins to break, and in the limiting case the flight of a grasshopper in Colorado or Montana may be the determining factor.

If the cyclonic movements of the atmosphere which have so much to do with the distribution of rainfall are ever to be controlled by the infinitesimal means at the disposal of man it must be by the proper application of these means during the early and exceedingly sensitive stages of these vast sweeping processes. How, when and where to apply our puny power is a matter of detail, of experiment and study.

We must study the initial phases of cyclonic

movements in their relations to subsequent trend and character, and we must devise means for inaugurating these initial phases in a way which will lead to desired results. This study has been pursued by the scientists of the Weather Bureau for many years and is the basis of the weather forecasts issued daily by this great scientific department of the government. As to the means for inaugurating at will the storm movements of the atmosphere the smoke-ring cannon of Burgomaster Stiger is the most rational that has yet been suggested, as will be explained later.

Weather control is, however, not so simple a matter as would appear from the above statement. It is a well-known fact that two cyclonic movements initially alike may have very great differences of trend and character. The explanation of this fact will be made clear by considering a simple mechanical analogy. Imagine a great number of dominoes to be stood on end not in a simple row but in a very complicated network of rows and imagine slight disturbances to be produced over the entire system; for example, a number of grasshoppers might be turned loose into the dominoe enclosure! Now there might be one particular region where the dominoes are more sensitive than elsewhere so that collapse would usually start in this region and spread over the system, but the ultimate trend and character of the collapse would depend not only upon its initial phases but quite as much upon whether a particularly vigorous grasshopper had happened to kick over a dominoe or two in regions remote from the starting point of the main collapse. The driving energy of the dominoe storm at any given place is derived from the falling of the dominoes at that place and not at all from the remote source of the storm, and if we could imagine the spreading dominoe storm to gradually make the dominoes just ahead of it taller and taller then there would be local displays of excessive violence as these tall dominoes fall. It is scarcely necessary to alter the wording of the above statement, so evident is its application to a vast stretch of atmosphere over a sun-heated continent. The dry arid regions where the sun beats down without hindrance are the regions in which the atmosphere

most quickly reaches a very sensitive state of instability and perhaps the sun-heated air on the rising slope of a mountain may determine the start of the atmospheric overturn. As the atmospheric collapse spreads over the continent its character may be greatly influenced by the degree of instability existing in the regions over which it passes and by the existence of independent storm movements. Furthermore it is known to be the case that a typical cyclone in the United States causes a great mass of warm air to be gathered near the earth's surface on its southeast front and when this mass of warm air and the overlying cold air make a summersault a tornado (cyclone, popularly called) or severe local disturbance is the result.

Our dominoe storm, to carry our analogy further, might be inaugurated with indefinitely small effort at a time when the system is ready for a more or less complete collapse, and the trend of the collapse could be controlled not only by choice of time and place of starting the collapse, but also by starting independent collapses at other times and places, and the control of weather must likewise consist of proper starting of storm movements and of their proper modification by independently inaugurated movements.

Reports are coming to us from southern Europe of the control of hail storms by means of a special form of cannon which throws a large vortex ring at high velocity into the upper atmosphere. In many details these reports are absurd, while in other details they are by no means absurd, although it must be admitted, if we credit the reports, to be a very remarkable fact that this first crude trial to control the weather—for it is the first that conforms at all to the physical requirements of the case—should be in so large a measure successful.

The problem is to upset the increasing instability of the atmosphere on a hot summer's afternoon before the beginning of that particular type of collapse, whatever it may be, that constitutes a hail storm, to set the sky off half-cocked as it were, and it is hard to think of a better means for starting a collapse of an unstable atmosphere than the smoke-ring cannon of Burgomaster Stiger. A simple concussion or

loud sound is not at all effective. The thing that is necessary is not a momentary to and fro motion of air such as accompanies a sound wave and which is very slight even in a sound wave of exceedingly great intensity, but an actual transfer of air from one place to another, such as is produced near the muzzle of a gun in what is called the blast, or such as is produced by a vortex ring.

It seems to be within the range of possibility that Stiger's cannon may be a means for controlling all kinds of storm movements.

W. S. FRANKLIN.

REVIEW OF TWO RECENT PAPERS ON BAHAMAN CORALS.

TO THE EDITOR OF SCIENCE: It was my pleasure to visit the American Museum of Natural History in New York during the first week of September, and through the courtesy of Professor Whitfield to examine the recent species of West Indian corals in that institution.

I saw two specimens that have recently been described by Professor Whitfield, and after having received copies of his papers, desire to make some remarks on them.

The first paper is entitled, 'Notice of a Remarkable Case of Combination between Two Different Genera of Living Corals,' *Bull. Amer. Mus. Nat. Hist.*, Vol. XIV., Art. XVII., pp. 221, 222, pls. XXXI., XXXII. (date, July 29, 1901). Professor Whitfield considers his specimen a combination of *Meandrina labyrinthica* and a *Ctenophyllia* which he says is perhaps nearest to *Ctenophyllia quadrata* Dana.

Are two genera represented? Most emphatically no! The *Meandrina* of Milne-Edwards and Haime (not Lamarck, 1801) is characterized by possessing distinctly toothed septa and a spongy columella, in which may be a lamellar element connecting one calicial center with the next; the series are variable in length, often very long, and usually sinuous. The wall between adjoining series is simple (not double as in *Diploria*). The septa and wall are imperforate. Pali may or may not be present; they are not of specific value in this genus. An examination of plate XXXII. will show that there are no generic differences in the specimen figured.

The genus *Ctenophyllia* Dana (= *Meandrina* Lamarck, 1801, + *Pectinia* (pars) Oken, 1815, + *Meandrina* (pars) Lamarck, 1816, + *Ctenophyllia* Milne-Edwards & Haime, 1848, + *Pectinia* Milne-Edwards & Haime, 1851 and 1857) was proposed for four species, *C. pectinata*, *C. quadrata*, *C. pachyphylla* and *C. profunda*. Dana explicitly states that the septa are 'entire or nearly so.' He also says, "This group appears to be related to the Euphyllia and has been placed in the same subfamily with them." Dana was absolutely correct in his characterization and in his understanding of the systematic relations of the genus. The *Ctenophyllia*, perhaps *quadrata*, of Whitfield differs utterly from Dana's genus *Ctenophyllia*, and according to nearly every modern student of zoophytes it would not be placed in the same family.

It can be seen, by examining the plates, that the valleys and collines of the central portion of the colony are directly continuous with those of the surrounding portion. The differences consist in the absence of pali, and in the larger collines and larger valleys in the central portion. The specimen merely shows the variation which may take place within a single colony.

The second paper is entitled, 'Some Observations on Corals from the Bahamas, with a Description of a New Species,' *Bull. Amer. Mus. Nat. Hist.*, Vol. XIV., Art. XVIII., pp. 223, 224, pls. XXXIII., XXXIV. (date, July 29, 1901).

The 'new species' described is named *Diploria geographica*. It is merely a form of the very abundant *Diploria labyrinthiformis* (Linn.) emend. Esper (= *Diploria cerebriformis* (Lamarck)). The only difference is in its possessing more angular gyrations than are common in *D. labyrinthiformis*.

These two papers are reviewed because, in my opinion, such errors should be corrected as soon as possible.

T. WAYLAND VAUGHAN.

SMITHSONIAN INSTITUTION,
WASHINGTON, D. C., Sept. 11, 1901.

TWO UNKNOWN WORKS OF RAFINESQUE.

BIBLIOGRAPHY does not indicate that Rafinesque ever published a work entitled 'Florula Lexingtoniensis,' or, in fact, it does not seem known that such a work was even contem-

plated by him. There has been discovered in the herbarium of the Academy of Natural Sciences of Philadelphia a single signature of a work with the above title, consisting of pages 73-80 inclusive, and marked K. As the number of pages would indicate, it is a quarto, though of small size.

Perhaps this intended work met the fate of the 'Western Minerva,' another of Rafinesque's Lexington attempts in literature, which, with the exception of three copies, was suppressed by the printer, because, it is said, the amount of his bill was not forthcoming. It is odd, in any event, that no mention of a 'Florula Lexingtoniensis' was made in Rafinesque's other writings.

Another of Rafinesque's works of which no record seems to have been made is the 'American Florist,' of which at least two parts appeared, as there are two copies of the second part in the library of the above-mentioned institution. This 'Second Series' is also entitled 'Eighteen Figures of Handsome American and Garden Flowers. By C. S. Rafinesque, Philadelphia, 1832.' It is a large sheet, measuring from border to border 21½ by 17½ inches, bearing illustrations of *Arctium latifolium*, *Poteria sanguisorba*, *Betonica officinalis*, *Pyrus malus*, *Bryonia alba*, *Barbarea alliaria*, *Clinopodium vulgare*, *Chrysanthemum leucanthemum*, *Fraxinus quadrangularis*, *Agrostema githago*, *Melissa officinalis*, *Saxifraga granulata*, *Spartium scoparium*, *Bupleurum rotundifolium*, *Primula farinosa*, *Alchemilla alpina*, *Hedera helix*, *Cardamine pratensis*. The illustrations are much like those in his 'Medical Botany,' but are printed in black ink. They bear numbers 19-36, the first series, no doubt, holding numbers 1-18.

WILLIAM J. FOX.

ACADEMY OF NATURAL SCIENCES,
PHILADELPHIA, PA.

RECENT ZOO-PALEONTOLOGY.

THE present summer has been rich in paleontological discoveries. The most notable event is the discovery of the body of a frozen mammoth which is now being conveyed to St. Petersburg. Expeditions in this country have been sent out from many of the larger museums, and Professor Von Zittel has sent one of

his assistants, Dr. Broili, with Mr. Charles H. Sternberg, the well-known collector, into the Permian of Texas. The Natural History Museums of London have conducted explorations both in Egypt and in Greece. In the latter country Dr. A. Smith Woodward has been working in the Lower Pliocene of Pikermi, and has secured 47 boxes of valuable fossils, including horses, rhinoceroses and, of still greater rarity, another specimen of the hyracoid, *Pliohyrax*.

Mr. Charles W. Andrews, of the British Museum of Natural History, went on several expeditions into the Nile desert, accompanying the geological survey of Egypt. A year previous he had reported the existence of fossil mammals of undoubted Oligocene age; during the present expedition he made the most important discovery of early and generalized Proboscidea, especially of a small mastodon-like animal, with both premolar and molar teeth in place. Older beds were found to contain a primitive *Dinotherium*. Since the oldest *Dinotherium* and *Mastodon* of Europe are of Miocene age, this discovery not only carries the proboscidean phylum further back, but is strongly in favor of the theory of the African origin of this order. Africa has long been the dark continent of paleontology, and one of the results of English occupation will undoubtedly be a succession of paleontological discoveries of the greatest interest.

The special explorations for fossil horses by the American Museum have been completely successful. The Texas expedition in July secured eight skulls of *Protohippus* with portions of the skeletons associated. They are all in a hard matrix and somewhat crushed. The Colorado expedition has secured a complete skeleton, in a perfect state of preservation, of the large Upper Miocene or Loup Fork horse. This *Anchitherium* is the first complete skeleton of a horse of this period which has been found in this country. The explorations in the same region seem to demonstrate that there were four distinct types of horses, almost contemporaneous. It has been reported also that the Carnegie Museum secured some very complete horse skeletons, but these prove to belong to *Merycochoerus*, an oreodont.

Another discovery of importance, by the Texas party of the American Museum, is the nearly complete shell of the armored edentate *Glyptodon*, four feet in length, together with two feet of the armored tail and parts of the skeleton within the shell. Hitherto *Glyptodon* has only been known from teeth, recorded by Cope from southern Texas, in 1888, and by Leidy from Florida in 1889. The present specimen is almost identical in its elaborate shell-pattern with the Pampean glyptodons.

The explorations for Dinosaurs in the Jurassic have also been very successful. Several discoveries have been reported by the Field Columbian Museum party in western Colorado. A Carnegie Museum party has been working in the sandstone of Marsh's old quarry near Cañon City, and has secured parts of the skeleton of *Morosaurus*, and a skull of *Stegosaurus*. The American Museum has continued its exploration of the Bone Cabin Quarry, in central Wyoming, resulting in the discovery of the skull of one of the large Sauropoda, also the skull of a large carnivorous Dinosaur, and parts of the skulls of two other Dinosaurs, besides a quantity of skeletal material.

The Triassic is still the least known period. Reports from Professor Lester F. Ward of the existence of vertebrate fossils in Arizona led to a party being sent out by the National Museum under the leadership of Professor Ward, assisted by Mr. Brown, of the American Museum, resulting in the discovery of remains both of Dinosaurs and of the primitive crocodile-like Belodons. The Dinosaurs appear to be related to the Stegosaurian division, according to the preliminary examination made by Mr. F. A. Lucas, and there is also a new genus of Belodon in the collection.

September 9, 1901.

REPORTS OF FOREIGN MUSEUMS.

THE report of the Australian Museum, Sydney, N. S. Wales, for 1899, shows that institution to be doing good work, although hampered by the smallness of its appropriation. Owing to what the curator terms a 'miserable appropriation' for the purchase of specimens, the growth of the collections has been principally

through donations from individuals, 317 donors having presented some 6,000 specimens. This and the attendance speak well for the popularity of the Museum. The government did, however, provide \$67,500 for an addition to the Museum building which was already a much finer structure than the National Museum of the United States. The most important accessions were an oar-fish, *Regalecus gese*, the third of the species known, and an oil-fish, or 'palu,' *Ruvettus pretiosus*; the remainder of the important additions were ethnological. In the exhibition series special attention seems to be given to groups of birds, and fifteen new 'nest groups' were added, besides an additional example of the interesting nest of the bower bird, *Chlamydodera maculata*; this was elaborately decorated at both ends with bones of mammals and birds, shells, pebbles, bits of glass and other objects. It is announced that the manuscript and illustrations for the 'Catalog of the Nests and Eggs of Birds found breeding in Australia' is well advanced. The work will comprise some three hundred pages of text, about one hundred text figures, thirty plates of eggs and forty of nests, and its publication will extend over a period of three years.

The Manchester Museum, Owens College, in its Reports for the year 1900-1901 also makes a good showing for a small expenditure. The principal increase in the collections has been in lepidoptera, plants and mollusks, among the last being an example of the very rare *Pleurotomaria adansoniana*. A specialty of this Museum appears to be the preparation of exhibits of an educational value, and among them is a series of moths selected to represent the families given in the Cambridge Natural History, dissections of Mollusca to illustrate the system of classification based on the gills, and a series of skulls to illustrate dental anatomy and arranged and labeled for the advantage of students.

A series of excellent lectures, addresses and demonstrations was, as usual, given during the year by members of the Museum staff and, as in the past, one is a little surprised at the small attendance on some of these in a city of half a million inhabitants. For example, an address by Boyd Dawkins on 'Our Neolithic Ancestors'

drew an audience of only ninety-five. The Sunday lectures, however, were better attended, the most popular being 'The Arrival of Man.' An attractive series is announced for the coming fall and winter.

SCIENTIFIC NOTES AND NEWS.

THE fourth Glasgow meeting of the British Association opened its sessions on September 11. The address of the president, Professor A. W. Rücker, printed in the last issue of SCIENCE from a copy sent in advance of its delivery, was given at the inaugural meeting in the evening. Professor Rücker was introduced by the retiring president, Sir William Turner, and the usual vote of thanks was proposed by the Lord Provost of Glasgow and seconded by Lord Kelvin. The general committee held its first meeting on the 11th, when on the proposal of Sir Michael Foster, a cablegram with expressions of sympathy was sent to President McKinley. At the second meeting of the general committee Professor James Dewar was elected president for next year's meeting at Belfast, and the date of the opening of the meeting was set for Wednesday, September 10. It was decided to hold the meeting of 1903 in Southport, where the Association met twenty years previously. Sir W. Roberts-Austen and Dr. D. H. Scott were reappointed as general secretaries, Mr. G. Griffith as assistant general secretary and Professor Carey Foster as general treasurer. The following were appointed vice-presidents for the Belfast meeting: The Marquis of Dufferin, the Marquis of Londonderry, the Earl of Shaftesbury, Sir F. Macnaghten, and the Earl of Rosse, Lord Mayor of Belfast, the president of Queen's College and Professor Ray Lankester.

THE University of Adelaide, Australia, will be represented at the Yale bi-centennial by Dr. Edward C. Stirling, professor of surgery.

MR. F. J. V. SKIFF, director of the Field Columbian Museum, has been appointed director of exhibits for the St. Louis Exposition. Mr. Skiff was deputy director-general of the Columbian Exposition, and was director in chief of the United States Commission to the Paris Exposition.

THE gold medal of the Italian Science Society has been presented to Mr. Marconi for his services in the invention of wireless telegraphy.

THE Röntgen Society has awarded a gold medal to Mr. C. H. F. Müller, of Germany, for the most practical X-ray tube for general purposes. There were in all twenty-eight entries.

DR. WILLIAM PATTEN, professor of zoology at Dartmouth College, has leave of absence for the present term and is engaged in zoological work in Russia.

MR. JOHN A. FLEMING, of the U. S. Coast and Geodetic Survey, has arrived in Honolulu for the purpose of erecting and conducting a station for the study of terrestrial magnetism.

DR. CARL LUMHOLTZ, of the American Museum of Natural History, lectured on the Indians of Mexico before the Royal Geographical Society on September 14.

ON the occasion of the seventieth birthday of the great zoologist Leuckart, a portrait-bust was made by the sculptor, Seffner. He has undertaken to supply Professor Charles L. Edwards, of Trinity College, with a plaster cast. If others wish to secure copies of the bust, Professor Edwards is willing to forward the orders. The cost in Leipzig would be from 40 to 50 Marks.

THE death is announced of Dr. Philip S. Baker, who for many years held the chair of chemistry in the medical department of De Pauw University.

THE death is announced at the age of seventy-three years of Dr. Ferdinand Arnold, a German botanist, known for his researches on lichens.

DR. J. L. W. THUDICHUM died in London on September 7. He was born in Germany and graduated from the University of Giessen about fifty years ago, but soon came to London and engaged in medical practice. He conducted researches on physiological chemistry and was also the author of a volume on the 'Chemistry of Wine Production.'

THE Tufts College laboratory of biology, at South Harpswell, Maine, was closed for the

year on September 6. During the summer every table was occupied. Among those who availed themselves of its facilities for varying lengths of time were Professor Alvin Davison, of Lafayette College, Dr. Emily Ray Gregory, of Wells College, Professor Albert F. Matthews, of the University of Chicago, Professor M. A. Wilcox, of Wellesley College, Dr. C. B. Wilson, of the Westfield Normal School and Dr. F. A. Woods, of Harvard University. During the winter the laboratory will be enlarged, providing a number of private rooms for investigators.

AN International Office of Weights and Measures is to be established in Sèvres for the preservation of standards and the supplying of copies.

AN annex to the Astronomical Observatory, at Cambridge, England, is being constructed on the north side of the dome to be used as a laboratory.

THE daily papers report that Mr. S. J. Holsinger, a special agent of the Department of the Interior, has presented a report stating that pottery and other remains have been taken in an unauthorized manner from the ruins in Arizona and New Mexico, and that the government may claim the collections deposited in several museums.

THE Vallauri Prize, of the value of about \$6,000, will be awarded in 1903 for the most important scientific work accomplished whether by a foreigner or an Italian during the preceding four years.

WE learn from the London *Times* that, following their acceptance of the proposal of the British Association for an ethnographic survey of India, Lord Curzon's Government has adopted the suggestion of the Royal Society for the carrying out of a magnetic survey. Sun spots are believed to be closely connected with the perturbations of the magnetic needle, and, as Sir Norman Lockyer's inquiries are held by him to establish some association between sun spots and Indian droughts, the survey, besides subserving the cause of science, may prove to be of some practical utility from the administrative standpoint. The existing magnetic observatories at Bombay and Calcutta being

inadequate as base stations for the vast area the survey will cover, similar observatories are in course of construction at Dehra Dun, below the Himalayas, at Kodaikanal, in the Madras Presidency, and at Rangoon. The Dehra Dun observatory will be under the supervision of Colonel Gore, R.E., the Surveyor-General of the Indian Survey (whose headquarters are located there); but the other four will be in charge of Mr. John Eliot, the meteorological reporter to the Government. The Survey and Meteorological Departments will, in fact, be jointly responsible for the investigations. The field observations will be carried out by six or seven detachments of the Survey Department, and these will be controlled by Captain Fraser, R.E., who has recently been arranging in England for the purchase of the necessary instruments. Sind and the Punjab will first be taken in hand; and, as the country is now intersected with railways in all directions, enabling field detachments to quickly cover the distances from one observing station to another, it is anticipated that five years will suffice to complete the field work of the preliminary magnetic survey.

THE representatives of the newly-established Australasian confederation have appointed a commission to consider the adoption of the metric system, and it is reported that with the approval of the authorities in Great Britain, the system will be adopted in Australasia.

A NEW steamship for the U. S. Coast and Geodetic Survey, being constructed by the Townsend and Bowney Shipbuilding Company, was launched in Newark Bay on September 21. The steamship, which has been called *The Bache* in honor of the former eminent superintendent of the Coast Survey, is 136 feet in length, with a steel frame, and is to be fitted with engines developing 125 horse power.

A COMMITTEE of the Chemical Section of the British Association has been appointed to urge upon the Government the desirability of remitting the duty on alcohol used for chemical research.

It is officially estimated that the deaths from the plague in India during the past five years

exceed 600,000. Unfortunately there is no abatement. For the last week for which details are at hand there were 2,816 deaths as compared with 2,003 in the preceding week, and only 285 in the corresponding week of last year. The Bombay districts are at present suffering the most severely.

THE correspondent of the *Lancet* in India reports that bacteriological work is being started at several new places. The Port Commissioners at Rangoon propose building and equipping a laboratory chiefly at first for the examination of suspected plague. The Government of the Malay States has recently established a Research Institute open to all workers irrespective of nationality. Pathological work and chemical research, as well as bacteriological investigations, will be open to all.

THE corporation of the City of Hull has made itself responsible for the conduct of the museum of the Literary and Historical Society.

THE executive committee of the National Educational Association will meet early in October to determine the place of meeting of the next convention.

THE International Congress of Physiology opened its sessions at Turin on September 17.

An International Congress of Archeologists will be held in Greece in April, 1903. Meetings will be held at Athens, Olympia, Delphi and other points of interest.

THE International Engineering Congress, the general program of which we have already published, opened in Glasgow on September 3, with about 3,000 members in attendance.

THE eighty-first meeting of the American Institute of Mining Engineers will be held in Mexico in the first week of November. Sessions will be held in the cities of Mexico, Pachuca and Monterey, and stops will be made at various points of interest. Two special trains have been chartered, one of which will leave New York on November 1, by the Pennsylvania Railroad, and the other will be run as a second section, starting from Chicago at 10 p. m., on November 2, by the Atchison, Topeka & Santa

Fe Railway. The cost of the trip from Chicago, lasting about thirty days, including berth and meals will be \$250.

THE Dutch Society of Sciences at Harlem announces a series of subjects for the prizes to be conferred during the next three years, the details of which can be obtained from the Secretary, Professor J. Bosscha, Harlem. The prize in each case is a gold medal or 500 florins at the option of the author and the papers may be written in English.

THE *British Medical Journal* gave in a recent issue the prizes offered by the Paris Academy of Medicine, about thirty of which are open to foreigners. The François-Joseph Audiffred Prize is of the value of £1,000, and is offered to any person who is adjudged to have discovered a preventive or cure of tuberculosis. The following are also among the more important offered for the year ending with the end of February, 1902; the sum specified in each case does not necessarily go to one candidate, but may be divided. The Academy Prize, awarded annually, worth about £40, is this year for a research on the rôle of toxins in pathology; the Baillarger Prize of about £80 (biennial) is for the best work on the treatment of mental diseases and the organization of asylums; and the Charles Boullard Prize, also biennial, of £50, is for a similar subject. The Barbier Prize of £80 (biennial), is for the discovery of a cure for such 'incurable' maladies as hydrophobia, cancer, epilepsy, typhoid and cholera. The Mathieu Bourceret Prize of £50 (annual) is for work on the circulation of the blood. The Campbell Dupierris Prize (biennial), of the value of £96, is for the best work on anæsthesia or the diseases of the urinary passages. The Chevillon Prize (annual) of £65, is for the best work on the treatment of cancer. The Desportes Prize of £55 (annual), will be awarded for the best work on practical medical therapeutics. The Herpin (of Metz) Prize (quadrennial) of £50, is offered for a research on the abortive treatment of tetanus. The Theodore Herpin (of Geneva) Prize of £125 (annual), is for a research on epilepsy and nervous diseases. The Laborie Prize of £210 (annual), is given for the greatest advancement in surgical science during

the year. The Lefèvre prize (triennial) of £75, is for a research on melancholia. The Meynot Prize (annual), of £108 is for the best work on ear disease; and the Saintour Prize (biennial) of £166, for the best work on any subject in medicine.

WE learn from the *Astronomical Journal* that the council of the *Astronomische Gesellschaft* has undertaken the preparation of a new Catalogue of Variable Stars and has delegated the conduct of the work to a committee consisting of Professors Dunér, Hartwig, Müller and Oudemans. The committee request* observers of variable stars who have considerable unprinted series of observations, which would be useful in the correction of elements, either to publish them soon or to communicate them to the member of the committee in charge, Professor G. Müller, Potsdam Observatory. The Committee also announces that it will from the present time undertake the definitive notation of newly discovered variables as soon as their light-fluctuations are certainly ascertained. A list will shortly be published of the names of variables found in recent years which have heretofore remained unnamed.
