THE *New York Sun*, whose astronomical news is unusually full and accurate, notes that the foreign associates of the Royal Astronomical Society are distributed as follows: Argentine Republic, 1; Austria, 1; France, 9; Germany, 8; Holland, 3; Italy, 2; Russia, 4; Sweden, 1; United States, 14. It is to be noted that the associate from the Argentine is himself an American. The American members are: Dr. E. E. Barnard, Yerkes Observatory, Chicago; Professor L. Boss, Dudley Observatory, Albany; Professor S. W. Burnham, Yerkes Observatory, Chicago; Dr. S. C. Chandler, Cambridge; Dr. W. L. Elkin, Yale University; Professor G. E. Hale, Yerkes Observatory, Chicago; Professor A. Hall, U. S. N., retired; Dr. E. S. Holden, New York; Dr. S. P. Langley, Smithsonian Institution; Professor A. A. Michelson, University of Chicago; Professor S. Newcomb, Washington; Professor E. C. Pickering, Harvard College Observatory; Professor C. A. Young, Princeton University, and Dr. J. M. Thome, National Observatory, Argentine.

UNIVERSITY AND EDUCATIONAL NOTES.

THE construction of a new science building, costing \$300,000, has been begun at Colorado College. Towards this building Dr. D. K. Pearsons gave \$50,000 and an anonymous donor has recently given \$100,000.

THE equipment of the Whitin Observatory of Wellesley College has received the addition of a sidereal clock, built by the E. Howard Clock Company of Boston.

MR. JAMES S. DICKSON, of Glasgow, has given £10,000 to the University of that city for the endowment of a lectureship of mining.

LORD KELVIN delivered the inaugural address on the occasion of the formal opening of the James Watt Laboratory of Engineering at Glasgow University on September 3. The cost of the laboratory has been about \$200,000, toward which sum about \$125,000 has been subscribed.

WE learn from the London *Times* that the new technical school with museum extension in William Brown street and Byrom street, Liverpool, the foundation-stone of which was laid on July 1, 1898, by Sir William Forwood, chairman of the Library, Museum and Arts Committee of the Liverpool Corporation, is now practically completed, and its doors will in a few days be opened to students in general. The new building, designed by Mr. E. W. Mountford, is of the modern nineteenth-century classic style, and built of Stancliffe stone, from the same quarry whence was obtained the material for St. George's Hall. It extends from the Brown Public Museum to Byrom street, where there is an imposing curved front, and the seven windows of the lower art gallery are separated by couples of Ionic columns, over thirty feet in height. The technical school occupies three lower floors of the building as well as some galleries at the very top, and is entered from Byrom street, while the two upper floors form an extension of the Brown Museum, and are entered only from that building. Notable features of the William Brown street frontage are two bold, projecting bays, with deep vaulted arches enriched with simple decoration, while emblematic statuary fills in the pediment, all the statuary being from the studio of Mr. T. W. Pomeroy. In the basement,

which is very little below the street level, are many rooms and laboratories intended for various handicrafts, with up-to-date apparatus. In a cross-gallery on the top floor of the building is a chemical laboratory where about threescore students can work, while above all is an observatory with a large equatorial telescope. Altogether the school has accommodation for 1,300 students at one time, and the electric lighting and 'Plenum' ventilation are excellent in all departments. In the chemical and nautical rooms students are already at work.

DR. E. E. SCHIEB, of the University of South Carolina, has been appointed professor of philosophy and pedagogy in Tulane University.

DR. T. H. HAINES, has been appointed assistant professor of philosophy in Ohio State University.

DR. L. W. LADD, who is a son of Dr. George T. Ladd, professor of philosophy at Yale University, has been appointed to the newly established Hanna chair in the Medical College of Western Reserve University.

DR. EMILY RAY GREGORY has been appointed professor of biology, Wells College, Aurora, N. Y.

AT Dartmouth College Mr. George H. Lyman, of Beloit College, has been called as successor to Dr. George T. Moore, professor of botany, who has accepted a government position at Washington. Charles E. Bolser, A.B. (Dartmouth), Ph.D. (Göttingen), has been appointed instructor in chemistry.

PROFESSOR JOSEPH FRENCH JOHNSON has resigned the chair of finance in the University of Pennsylvania and accepted the chair of political economy and banking in the New York University school of commerce, accounts and finance.

DR. A. STANSFIELD, instructor in assaying under Sir W. C. Roberts-Austen, at the Royal College of Science, London, has been appointed to the newly-established chair of metallurgy in McGill University.

DR. KASNER has qualified as docent in meteorology in the Polytechnic Institute at Berlin; Dr. Weinhold for mathematics at Kiel; Dr. G. Rost for mathematics at Würzburg, and Dr. E. Haunig for botany at Strasburg.

THE PROPOSED NATIONAL UNIVERSITY.*

THE paper by Hon. Chas. D. Walcott, Director of the U. S. Geological Survey, published in SCIENCE for June 28, 1901, then issued in a separate pamphlet, and now kindly brought to my notice by the author, disposes of the National University movement in the following summary manner:

But Congress has always looked on the scheme with suspicion, and not one of the various bills offered was ever acted upon by the Senate and House of Representatives. The trend of opinion has been and is that the Government should not found a National University in the sense suggested by Washington and his followers.

At first I thought to let these statements pass without notice, believing that in course of time they would correct themselves. But on reflection I conclude to make a comprehensive review of them, as also some comments on the 'Memorial' scheme so fully set forth in connection therewith, and finally to point out some of the special functions of the proposed National University which so deeply concerned Washington, but which seem never to have been duly considered by those now engaged in promoting an enterprise which its projectors intend shall defeat the establishment of such university altogether.

* A review of Hon. Chas. D. Walcott's paper on 'Relations of the General Government to Higher Education and Research.'

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

ATTITUDE OF CONGRESS.

Of the non-passage of bills I will speak further on. Let us, first of all, see how far this declaration concerning the attitude of Congress accords with the real facts in the case.

To begin with the House, the only action ever taken by that body on the subject of a national university was affirmative and unanimous. The National Educational Association, having first by a unanimous vote, at Trenton, N. J., in 1869, declared a great American university to be 'a leading want of American education,' and appointed a 'committee consisting of one member from each of the States * * * to take the whole matter under consideration,' and to report thereon, and having twice unanimously adopted the affirmative reports of said committee (at Cleveland, in 1870, and at St. Louis, in 1871), then by unanimous vote created a permanent committee to prepare and offer to Congress a bill to establish a national university.

The committee embraced, besides the chairman, Ex-President Thomas Hill, of Harvard; Editor Godkin, of *The Nation*; State Superintendent Wickersham, of Pennsylvania; Dr. Barnas Sears, of Virginia; Col. D. F. Boyd, President of the University of Louisiana; President Daniel Read, of the University of Missouri; Dr. W. F. Phelps, President State Normal School, Winona, Minnesota; Ex-Governor A. C. Gibbs, of Oregon; Hon. Newton Bateman, Superintendent of Public Instruction of Illinois; Superintendent Emerson E. White, President-elect of the National Educational Association; General John Eaton, U. S. Commissioner of Education; Dr. Joseph Henry, Secretary of the Smithsonian Institution and President of the National Academy of Sciences; Dr. J. Lawrence Smith, of Kentucky, President of the American Association for the Advancement of Science; and Dr. Samuel Elliot, of Connecticut,

President of the American Social Science Association.

The bill prepared by these men was introduced in the House during the last session of the 42nd Congress and referred to the Committee on Education, of which Chairman Perce, of Mississippi, and Mr. Hoar, of Massachusetts, were prominent members, and near the end of the said session was unanimously returned to the House with a strong report, of which the following is the closing passage:

If, then, it be true, as the committee has briefly endeavored to show, that our country is at present wanting in the facilities essential to the highest culture in many departments of learning; and if it be true that a central university, besides meeting this demand, would quicken, strengthen and systematize the schools of the country from the lowest to the highest; that it would increase the amount and the love of pure learning, now so little appreciated by our people, and so improve the intellectual and social status of the nation; that it would tend to homogeneity of sentiment, and thus strengthen the unity and patriotism of the people; that by gathering at its seat distinguished savants, not only of our own but of other lands, it would eventually make our national capital the intellectual center of the world, and so help the United States to rank first and highest among the enlightened nations of the earth—then is it manifestly the duty of Congress to establish and amply endow such a university at the earliest possible day.

The committee, therefore, affirm their approval of the bill, and recommend its passage by the House.

It is believed that the success of the university measure in some proper form then required only that uninterrupted attention which, unhappily, a change of circumstances rendered it impossible for its friends to give. The opinion of the National Educational Association, in favor of the establishment of a national university, was reaffirmed by unanimous vote at its annual meeting, held in Detroit, on August 6, 1874, and, as seen by its recent declarations, in the same place, has endured with the years.

2. In 1890, when Senator Geo. F. Ed-

munds introduced his 'Bill to establish the University of the United States,' and moved its reference to a special committee, no opposition was made. Had he retained his physical vigor, he would doubtless have made his chairmanship of the committee effective.

3. At the Senate's session of August 3, 1892, when Senator Proctor presented the 'Memorial in regard to a National University' by John W. Hoyt, and moved that it be printed and referred, Senator Sherman moved the further printing of 5,000 extra copies, which was ordered unanimously; also, that at a subsequent session other thousands of extra copies were ordered printed without objection.

4. Although at the opening of the 52nd Congress, Senator Proctor, whose interest was very positive, assumed the chairmanship, by request, he was occupied with important measures already in hand, and submitted his sterling and unanimous report so late in the Congress that other matters prevented its consideration. The committee was a strong one and would have been potential, could they early have taken it in hand, as they would have done a question of commerce, finance or war. The Senate was ready.

5. When the Senate 'Committee to establish the University of the United States' was made a 'standing' committee, there was no opposition to the change.

6. In the 53rd Congress, when Senator Hunton was chairman of the committee, he was so circumstanced that his able report (also unanimous) could not be prepared, submitted and supported, as it was, by his own and other able speeches, until the time had come when appropriation bills had the right of way, and a single negative vote could again prevent action by the Senate.

7. It was not until during the first session of the 54th Congress, when the determination of the executive council of

the National University Committee had met with assurances of cooperation from all parts of the country, and the council, with the Chief Justice of the United States presiding and but one of its fifteen members absent, gave three protracted sessions to the framing of a new bill, that there appeared the first sign of opposition, either in or out of Congress.

The members of the executive council at that time were these:

The Honorable Melville W. Fuller, Chief Justice of the United States; Ex-U. S. Senator Geo. F. Edmunds, of Vermont; Dr. William Pepper, Ex-Provost of the University of Pennsylvania; Hon. Andrew D. White, Ex-President of Cornell University, Ambassador to Germany; Ex-Governor John Lee Carroll, of Maryland, General-President Society of Sons of the Revolution; General Horace Porter, President-General Society of Sons of the American Revolution, Ambassador to France; Ex-U. S. Senator Eppa Hunton, of Virginia; Ex-U. S. Senator A. H. Garland, late Attorney-General of U. S.; Ex-U. S. Senator J. B. Henderson; Col. Wilbur R. Smith, of Kentucky University; Gen. John Eaton, Ex-U. S. Commissioner of Education; Hon. Gardiner G. Hubbard, President National Geographic Society; Professor Simon Newcomb, Director of the Nautical Almanac, U. S. N.; Hon. John A. Kasson, Ex-U. S. Minister to Austria and Germany; Hon. Oscar S. Strauss, Ex-U. S. Minister to Turkey; G. Brown Goode, Assistant-Secretary Smithsonian Institution; Ex-Gov. John W. Hoyt, Chairman National University Committee. (In the places of Messrs. Pepper, Hubbard, Garland and Goode, since deceased, there are now: Hon. H. A. Herbert, Ex-Secretary of the Navy; Dr. S. P. Langley, Secretary of the Smithsonian Institution; Lieutenant-General Nelson A. Miles, commanding the Army.)

The bill was unanimously approved by

the other distinguished members of the National University Committee, and gave promise of early success. President David Starr Jordan, of Leland Stanford University, wrote, 'Put it through without the change of a punctuation point.' Its passage was advocated in person, before the Senate university committee, by ex-Senator Geo. F. Edmunds, ex-Provost William Pepper, of the University of Pennsylvania, Professor Simon Newcomb, General John Eaton, Hon. Gardiner G. Hubbard, Hon. John A. Kasson, ex-Gov. John Lee Carroll, Hon. Andrew D. White and John W. Hoyt; and on March 10, 1896, Senator Kyle, chairman, submitted an affirmative report, with the said supporting arguments, and with over three hundred letters from members of the National University Committee, and other papers supporting the university proposition. It was an eminently satisfactory report of 156 printed pages, and for a time was supposed to be without dissent from any member. Adverse influences from denominational and other sources had been at work, however, so that a month later a brief minority report was submitted, with opposing letters from the presidents of Harvard, Yale, Columbia, and the University of Pennsylvania, and five or six small colleges, all denominational. Even with their friends it was beyond comprehension how the minority were willing to appear with so weak a showing.

For the rest, it is sufficient to say that the rule of courtesy which allowed the minority time to get ready, the printing of affirmative reports, and other causes, resulted in a postponement of action by the chairman of the Senate committee until the following session of Congress.

8. The 'Reply to Views of the Minority,' by the chairman of the National University Committee, when submitted to the Senate by Chairman Kyle, with many additional letters of indorsement from distinguished

friends of the measure, was promptly received by the Senate and ordered printed.

9. At the opening of the second session of the 54th Congress, papers in support of the National University proposition, by Professor William H. H. Phillips, of South Dakota, and President David Starr Jordan, of Leland Stanford University, were, upon motion of Senator Kyle, ordered printed by the Senate, without dissent.

10. Before the Senate committee's report could be conveniently called up in the second session of the 54th Congress, Chairman Kyle was called to his distant home, and, although confidently expected from week to week, so that neither Senator Sherman, who was next on the committee list, nor any other member thought it fit to act in his stead, he did not actually return until within three days of the end of that Congress.

11. Upon the opening of the 55th Congress, the appointment of Senator Wellington, of Maryland, to the chairmanship was a surprise to the National University Committee, because of assurances touching the continuous and earnest work of Senator Kyle. It also proved to be without result; for, notwithstanding assurances from Chairman Wellington of his deep interest in the university cause and his purpose to do everything possible to further it, not even a meeting of his committee could be secured during the said Congress.

12. Notwithstanding these facts, coupled with the readiness of Senator Chauncey M. Depew, always a warm friend of the national university idea, to take the lead and carry the measure forward, Chairman Wellington (still in possession, under Senatorial usage), because of assurances of action, held over. And there was at last a meeting of the committee, during the first session of the 56th Congress, and an agreement, without dissent, upon the new bill offered by Senator Depew with the approval

of the National University Committee. A report was also made ready and, with one hundred additional letters (including those from Ex-President Benjamin Harrison, from ex-senators, heads of national organizations, and the presidents of sixty additional colleges and universities, beginning with the University of Virginia and embracing ten of the leading Methodist institutions), was at one time on Chairman Wellington's desk, in the Senate, for presentation. They were never submitted, however. And of course there were requests many, appeals many and promises many.

Such is a brief history of both Senatorial and committee action on the subject of a national university during the past few years. It proves unmistakably that the talk of 'suspicion' on the part of Congress is without so much as the shadow of a foundation—that there has been none but affirmative action from first to last; that Congress has in fact done everything that was ever asked of it or of either House; and that in nearly, if not in every, case such affirmative action has been prompt and unanimous. There have been trying delays, but those of the last decade are not chargeable to the Senate, but to individual members of its university committee. And it may not be improper to add that there were Senators not a few, and among the most active and influential, who were as emphatic in their expressions of disappointment at the obstructive course of a chairman chosen because of his declared friendly attitude, as were the members of the National Committee themselves.

'THE TREND OF OPINION.'

After the showing thus made of the friendly attitude of Congress, first, last and always; of the views of leading men of the nation in all the great pursuits, including the heads of all but five or six of the colleges and universities appealed to; and,

last of all, the marked demonstration again made by the National Educational Association at Detroit, it is hardly worth while to spend a moment discussing the 'trend of public opinion.' Dr. Walcott should know that it 'has been and is, that the Government' *should* 'found a national university,' and that, too, 'in the sense suggested by Washington and his followers.' I mean in the broad sense, and for the accomplishment of the great ends he had in view. There have been such advances in science and such development of educational institutions since his day as he could not foresee, and as would necessitate a different sort of university work, in some respects, from that of his day, and yet not different in that it was to be, and is to be, the highest possible—and that, too, with help rather than hindrance of all other institutions, and with a fulfilment of special offices to which it alone would be competent, as I shall show at the end of this review. The Depew bill (last before the Senate), like its forerunners, makes sure of the national university's limitation to this high field.

OPPOSITION BECAUSE OF MISCONCEPTIONS.

There were, in 1896, a few opposing senators, but, since none of them have offered valid reasons for negative action (see 'Reply'), we are not without hope that they will yet concur. If they are endowers, graduates or patrons of some half-dozen leading universities, it is difficult to believe that on this account, and right here, in the midst of unparalleled facilities for a true university—facilities provided at a cost of some \$40,000,000 to the whole people of the country, and maintained and utilized at a cost of several millions annually—they would be glad to prevent the establishment of an institution which would at once do honor to the nation and be a practical friend of their favorites. Surely any such senators will upon reflection come to agree

with the multitude of statesmen and scholars of a hundred years, the views of whom are so emphatically reaffirmed by Ambassador Andrew D. White, who just now again says, from Berlin: "It would, in many ways make itself helpful to every school, college and university in the land"; and by President Harper, of the University of Chicago, when he wrote me not very long ago: "I have always believed in such an institution and will continue to believe in it. There is everything to be gained and nothing to be lost." They will see with Dr. Cattell, the able editor of *SCIENCE*, that "all the arguments which have been urged against the establishment of a national university turn out to be in its favor." Nay, more, it is hard to believe that any right-minded, unbiased senator or representative will fail at length to see that such an institution as is planned by the National University Committee would also serve to give the United States a new dignity and importance among the nations.

Under this head should also be embraced all friends of the national university movement who, whether they have done aught to advance it or not, or have inquired into the causes of delay, are now tired of waiting for the grand result, and have been induced to lend their influence to a scheme whose origination and inauguration have been with those who intend that it shall prevent the establishment of the university. They, too, will surely right themselves, when rightly informed.

Of course the hindrances common to great movements for intellectual advancement have not been wanting in this one; such as the extent to which legislators accounted the best are often absorbed in questions that concern industrial development, commerce, finance and international differences involving war—matters all of them so related, moreover, to the ascendancy of

political parties as at times to fill the whole field of vision; causes such as the growing passion for increase of wealth and power as means of supremacy among the nations, and which leave out of consideration the no less necessary and still higher conditions of a superior civilization; such, indeed, as lie in a spirit of denominational ambition, which in some of the churches is stronger than the spirit of religious freedom or anything else. And last of all, possibly in this case more serious than all others, there is the very nobleness of the national university idea, on account of which so many eminent and influential citizens, who should make themselves felt in every practicable manner, rest in the hope that every other friend of the pending measure will do his full duty, and themselves do little or nothing—in other words shift the responsibility on Providence, forgetting that Providence helps those who first help themselves, and that no great end is realized except through sacrifice.

OTHER OPPOSING FORCES.

Lastly, there are others, the grounds of whose opposition I will not even make a subject of conjecture, confining myself to a statement of facts of interest and to the pointing out of a few faults and the total insufficiency of the 'Memorial Institution.' The author of the paper under review was himself but lately interested in the national university, as will appear from his letter of December 20, 1894, which reads as follows:

"I fully believe in establishing such a university in the interest of higher education, and I cordially indorse the statements made by the late President James C. Welling, printed on pages 95-7 of your Memorial on the subject. The statements and views expressed in the Memorial are so exhaustive and comprehensive that I do not know that I could add to them, except to record my personal approval of the movement."

The following is an extract from President Welling's letter to which Dr. Walcott here refers :

"Such a university as I here prefigure would come into no rivalry with any existing institution under the control of any denomination. It would aim to be the crown and culmination of our State institutions, borrowing graduates from them and repaying its debt by contributing in turn the inspiration of high educational standards, and helping also in its measure to train the experts, * * * who should elsewhere strive to keep alive the traditions of a progressive scholarship. * * * It is not enough that our colleges should perpetuate and transmit the existing sum of human knowledge. We must have our workers on the boundaries of a progressive knowledge if we are to establish our hold on the directive forces of modern society."

It may be added that, within a very few months, Dr. Walcott, who is still a member of the National University Committee, avowedly shared the writer's indignation on account of delays, and expressed regret that he could not contribute more to the progress of the national university movement.

FAULTS OF THE 'MEMORIAL' SCHEME.

Now, while I have neither plan nor purpose to make war upon the 'Washington Memorial Institution,' and might never have said a word concerning it but for this strange attempt upon the life of the national university movement, it seems my duty, as the matter stands, to point out some reasons why the said 'Memorial Institution,' if established exactly as its friends would have it, is not likely to meet their expectations. I do so for the benefit in particular of such of its patriotic members as, being without time for a careful study of the whole subject, may have thought of it as a possible practical begin-

ning of the national university in which they have believed.

In the first place it is to be regretted that, as devised and constituted, it is not better calculated to represent the ideas of him whom it affects to honor—that it is fragmentary and does not contemplate a final national university.

The friends and promoters of the national university movement had duly considered the question of making the best practicable beginning they could, on the scientific side, without waiting for direct Congressional authority, but soon concluded that it would be wiser to go forward and secure the desired Congressional action. The country had waited a hundred years and could wait a little longer. A proper charter then seemed within easy reach. A liberal charter is still bound to come, and at no distant day, now that the schemers have boldly thrown off the mask, on the one hand, and that the National Educational Association has again, for the fifth time, by an overwhelming vote, declared for a national university of the highest rank.

Secondly, Washington wanted a true university, for supreme work only, and for reasons first national, then universal, located at the national capital, and sustaining such relations to all other institutions and educational agencies of the country and to the government itself as would make it in a superior sense a stimulating and guiding, as well as elevating, force and influence for the universal good.

It is also such an institution as this that the truly patriotic people of the United States want to-day. Nothing less will ever satisfy, as the able advocacy of earnest men in all the past, the persistent efforts of the National University Committee, the liberal action of the U. S. Senate and the recent renewal of supporting declarations of the country's educators plainly show.

Passing these two considerations, ethical and patriotic, the scheme of the Memorial Institution is itself of a character to challenge serious criticism, as its originators will find when they come to a practical test.

According to Dr. Walcott, it is to be a private foundation, without Government support or control. But he also tells us: "The policy of the Government, as expressed, is to aid in higher education by granting [to the Washington Memorial Institution] the use of such facilities as are at its command in the District of Columbia"; and again, "The Government's part in the work of the Washington Memorial Institution, when once under successful headway, will be to enlarge the quarters of the various bureaus concerned." To be sure, he hastens to add: "This will be necessary eventually, even if no student assistants are provided for." But it is apparent that if the Memorial Institution is to utilize the Government's collections and facilities for scientific research at Washington, such collections and facilities, now inadequate to such utilization, must exceed the Government's own demands, and exceed them in proportion to the utilization by the Memorial Institution; in other words, that Congress must make constantly increasing appropriations for the benefit of the Memorial Institution. Indeed, this enlargement of Governmental collections and facilities at Washington is the very *sine qua non* of the Memorial Institution. Yet we are told the Memorial Institution is to be without Government support.

This is not all. The Memorial Institution is to be also independent of Government control, says Dr. Walcott. But he then goes on to inform us that the Cabinet and various other Government officials are largely to constitute the advisory board of the Memorial Institution, and that the character and extent of the student-assistants'

work in the various departments of the Government is to be defined by the heads thereof, so that the same may be without detriment to the public service. And so, after all, there will be considerable opportunity and indeed necessity for Government control.

It thus appears that the Memorial Institution is to avail itself of the very assistance, and is to be subject to the same influence which its promoters condemn when proposed, to a less extent, in connection with a national university.

Other difficulties will present themselves after a little careful reflection; such as these, for example:

1. The three particular functions of the Memorial Institution—to ascertain and publish the opportunities for students in the Government Departments at Washington; to receive, enroll and direct such students to the places awaiting them; and to record their work and certify it, when requested, to any institution of learning—require no such widely scattered board of trustees as is provided, but could be as well, and indeed more effectively, performed by a small local committee. Unlike a national university, with plans and policies to be developed, the Memorial Institution begins with a fixed plan, whose operation will be largely subject to the dictation of the men whom the fortuities of politics have placed in charge of the Government Departments. The number and distribution of the board in question seem but a vain pretension to the nationality to which they are confessedly opposed.

2. The number of students of the Memorial Institution being limited (very limited, in the absence of Congressional appropriations), what is to prevent the institution in whose interest the Memorial Institutions was primarily worked up from having an undue share of student-assistant places? What is to safeguard the interests

of the four hundred or more colleges and universities of the country, by insuring them equitable representation in the opportunities which the Government provides and which the Memorial Institution proposes to dispense?

3. The Departments will not readily cooperate with a non-Governmental agency calculated to interfere with its own work.

4. If the Memorial Institution claims to provide opportunities for original research and investigation, it will sadly fail, for the Government does not carry on general scientific investigations, but confines itself to certain lines of work, which are not only special, but routine. If the Government expert himself cannot be an original, independent investigator, much less can the student-assistant.

5. The Memorial Institution repudiates the idea of instruction. Yet how will the investigations by its student-assistants, in scientific work, be carried on without instruction, and pretty systematic instruction, at that, to say nothing of any work it may attempt on lines not strictly scientific?

6. Even on the very limited lines proposed by the Memorial Institution, more money will be needed than such a concern is calculated to obtain from private sources. And how is the Memorial Institution to placate its Congressional patrons, when every student-assistant, especially if he becomes a Government fixture (and the Memorial Institution anticipates that a majority of them will remain in the Government service), closes the door to just so much Congressional patronage?

7. What shall be said of the ethics of an institution which encourages scientific work by students in the Departments at Washington as a means to the attainment of degrees at certain universities whose equipments are insufficient to such degrees? It has decidedly the appearance of giving credit where credit is not due, and will

eventually discredit the Institutions it favors by such means.

8. It is said that the *esprit du corps* so desirable in every student-body could not be developed by Congressional action, in connection with scientific investigations at Washington, because it would be 'a violent departure from all precedent,' and in the next breath we are told that this happy result has been obtained by the legislation of March 3, 1901, which nominally extended the utilization of the Government's scientific equipment at Washington to all the educational institutions of the country.

9. In view of the land-grant colleges and the U. S. military and naval academies, what sense is there in the talk of 'a violent departure from all precedent' involved in a provision for a crowning university of the United States?

10. What argument that justifies a State university would not justify a national university?

11. Contrary to the views of the Memorial Institution's advocates, no university is national, whatever its 'constituency,' 'support,' 'policies' and 'sympathies,' which is not vitally and distinctively of and by the Government of the United States.

12. People are most interested in that to which they contribute, and they cannot be so easily interested in a private institution as in an institution to which they have in some form contributed, which they may justly claim to be their own, and in which alone they could have a national pride.

13. The plan of the Memorial Institution necessitates practical duplication of Government experts and scientific apparatus, a thing which the Government could properly effect only in the interest of an institution of its own creation and in due measure subject to its control.

14. If there should be a measure of competition between a national university and a few other universities, that would by no

means be a serious matter. Among existing institutions competition even proves a means of rapid growth. Neither Harvard nor Columbia collapsed when the Johns Hopkins and Chicago Universities were established. Moreover, on the national side there would be the least possible of this element, for two important reasons, namely: First, because the purpose to do a work for the most part beyond existing institutions—that is, to occupy a field especially its own—would be both controlling and constant; and, secondly, because, by reason of its origin, aims and connection with the Government, there would not only be no room for a spirit of competition with the other institutions of the country, but rather, on account of direct relations with them, a sincere and never-failing desire to promote their advancement.

15. If the existing institutions already 'far more than supply the needed opportunities for higher study and research in the United States,' why do the richest of them strive for greater facilities; why do thousands go abroad annually for facilities which cannot be obtained in this country; and what is the need of the 'Memorial Institution'?

16. If the national opportunities sought to be utilized through the Memorial Institution are of a 'genuine university character,' why not have a genuine national university to utilize them?

It thus appears that while, on the one hand, the Memorial Institution contemplates no sort of advantage which in due measure the friends of a national university have not considered and set forth, on the other it has agreed on and published certain definite and independent plans for use of the Government Departments and bureaus such as no private institution but this would be likely to venture, and which the National University Committee has not felt warranted in planning for the University of the United States.

OVER-ESTIMATES OF EXTENT OF OPPOSITION.

Citizens here and there, with a supreme interest in certain institutions, cannot immediately subordinate all personal, local, and denominational ambitions, so as to take the national and world view of this matter. Or, if seeing rightly, as it is believed some of them do, they have not yet made up their minds to suffer the temporary losses and reproaches liable to follow a patriotic declaration of independence. If, therefore, I have at any time spoken of the half-dozen institutions whose present executive heads do not concur, as opposing the national university idea, the remark was too sweeping, for I am now satisfied that many of the broadest of the men thus embraced are in heart with us, that the opponents in these institutions constitute a minority only, and that of these many will be found on the affirmative side when fully informed concerning the national university proposed.

SPECIAL OFFICES OF A NATIONAL UNIVERSITY.

Neither the above mentioned nor the unenlisted of whatever class or quarter have yet realized that the efforts made for a national university are not so much because we are still without a single exclusively post-graduate university in America, and are therefore properly regarded by the foreign world as in the second rank, with thousands of our graduates annually going abroad for the facilities we do not furnish, but rather because the national university we seek to have established at Washington would fulfill special offices of national importance which none other, whether private, denominational, or state, much less this Memorial Institution, could by any possibility fulfill—among them these:

1. It would serve to supplement, coordinate, guide, inspire and finally perfect the whole series of public educational agencies in the United States and thus entitle us to speak of 'The American System

of Education '—a system such as this great republic certainly should have without further delay.

In the words of the editor of SCIENCE, issue of February 5, 1897, "A great national university would be the head of our educational system. It would not interfere with existing universities any more than these interfere with our colleges, or our colleges with our schools. Our present universities consist chiefly of professional schools, on the one hand, and of colleges for the instruction of boys on the other. They are indeed developing toward true universities, but nothing could better hasten and direct this development than a national university."

2. A national university could more properly than other institutions, with less embarrassment to the Government, and with great common advantage, still further utilize the resources already at Washington in the form of libraries, museums, gardens, laboratories and observatories, at a cost of \$40,000,000 to the whole people, and all of which, together with the \$7,000,000 a year for maintenance and utilization, and the possible help of scientific and practical experts, are, in some part, as I have said before, an enormous capital running to waste.

3. A national university would powerfully influence ambitious students in the public schools of whatever grade, even though purposing to make their college studies, or even a measure of post-graduate study, in denominational institutions of their preference. They would keep it in view as the final goal, the place of final preparation for special spheres of activity in life.

4. Moreover, a national university would at the same time in many ways help, and in nowise hinder, all the other institutions of the country; for in the first place, being without general academic courses of study, like a college, it would receive college and

university graduates for special studies only, leaving the general work looking to purely academic degrees (certainly those below the doctorate) to existing colleges and universities; and, secondly, being free from both local and denominational ambitions, it would naturally deal with all institutions of high rank and doing any work supremely well, in a most liberal manner, and in harmony with the best system of cooperation that could be devised.

5. When in full operation the national university would be more effective than all other institutions in keeping at home the three to five thousand of our graduates who now annually go abroad for the completion of their studies. The honor of its approval would soon come to be esteemed before any that could be offered by the foreign world.

6. A national university would at length attract thousands of students of high character and attainments from other lands, whose return, after years of contact with a prosperous, cultured and happy people living under free institutions, would tend to promote the cause of liberal government everywhere.

7. A national university would be able, as would none other, to attract to its own service, as lecturers, expert workers, guides, and directors, many of the most gifted and best qualified of those in the Government service at Washington, with the triple advantage of economy to the university, of increase of revenue to those so employed, and of an improved service in the Government through the added attraction thus furnished to superior men and women who now hesitate and oftentimes refuse to enter the service because of insufficient salaries and the less than satisfying dignity of many positions on this very account. In other words, men of genius and rare acquirements would accept places in the Government, and of lower grade than otherwise,

because of promised or probable connection with the world's leading university.

8. As could none other, a national university would attract men of genius and distinction from every quarter of the world to its professorships, lectureships and fellowships, thus increasing the cultured intellectual forces of both university and country.

9. A national university, to an important extent, and as could no other institution, whatever its rank, would make itself a co-worker with the Government in the several Departments; meeting their demands with the least possible delay; making trustworthy answers (as in the military and naval Academies) to important questions; taking up, on request, the solution of difficult problems of every sort; and supplying the Government with experts of supreme ability in greater number because drawn from the field of the world.

10. A national university would create an atmosphere at the national capital that would be influential for good in all departments of the Government, and so increase the demand for public men of character and culture as to furnish a new guaranty of wise legislation, and justice of judgment, as well as of faithfulness and efficiency of administration.

11. A national university, thus honored and encouraged, would powerfully stimulate and strengthen the patriotic sentiment of the country. The people universally would come to feel a pride in it as a sign of intellectual supremacy and of exalted aims, while to students in the schools and colleges of the States it would furnish a juster conception of what is meant by the field of learning, as well as new incentives to higher, and the highest possible, attainments; thus contributing in a degree beyond calculation to make us an educated people, and filling us with the determination to become the most cultured of all peoples.

12. Having duly established a university of the United States and made it capable of fulfilling all these offices, so important, shall we not have gained for our country that rank and influence among the nations to which not all our vast and varied material resources, the genius and wonderful energy of our people, and all our conquests in war are alone equal? Heirs to the better part of this great continent, with its vast resources of every sort, we have indeed made a wonderful growth in area, population, wealth and power; and meanwhile there has been a corresponding development in the boundless realm of the sciences, so that the national university we should now establish must differ in some respects (those of extent and greatness) from that which would have been founded in the days of Washington. Nevertheless, the special reasons which he so clearly had in mind have not only remained, as they ever must, but have strengthened with the years. They inhere in the nature of the case and should be regarded as conditions of a real supremacy of the American republic and of its becoming the world's most effective promoter of human advancement.

Other offices to be fulfilled by a national university will suggest themselves; but are not these enough to satisfy and forever silence the query, "Do we really need another and national university?"

The establishment by Congress of a national university is an undertaking of so great importance, of such origin, and of such advocacy throughout the whole period of the nation's life as to have gained an abiding place in the hearts of the people. It is an undertaking, the necessity for whose success is a firm conviction among the men most worthy to be heard in the interest of American education, and one the leadership in which, from first to last, has been as purely patriotic as any that was ever known, in peace or war. Such an

undertaking will surely triumph. Schemes skilfully devised may delay, but they cannot prevent, the establishment of a University of the United States.

JOHN W. HOYT,

Chairman National University Committee.

ADDRESS OF THE PRESIDENT OF THE
PHYSIOLOGICAL SECTION OF THE BRITISH
ASSOCIATION FOR THE ADVANCE-
MENT OF SCIENCE.*

WHEN the British Association met in Glasgow twenty-five years ago I had the honor of presiding over Physiology, which was then only a subsection of Section D. The progress of the science during the quarter of a century has been such as to entitle it to the dignity of a section of its own, and I feel it to be a great honor to be again put in charge of the subject. While twenty-five years form a considerable portion of the life of a man, from some points of view they constitute only a short period in the life of a science. But just as the growth of an organism does not always proceed at the same rate, so is it with the growth of a science. There are times when the application of new methods or the promulgation of a new theory causes rapid development, and there are other times when progress seems to be slow. But even in these quiet periods there may be steady progress in the accumulation of facts, and in the critical survey of old questions from newer points of view. So far as physiology is concerned, the last quarter of a century has been singularly fruitful, not merely in the gathering in of accurate data by scientific methods of research, but in the way of getting a deeper insight into many of the problems of life. Thus our knowledge of the phenomena of muscular contraction, of the changes in the secreting cell, of the interdependence of organs illustrated by what we now speak of as internal secretion, of the events that

occur in the fecundated ovum and in the actively growing cell, of the remarkable processes connected with the activity of an electrical organ, and of the physiological anatomy of the central nervous organs, is very different from what it was twenty-five years ago. Our knowledge is now more accurate, it goes deeper into the subject and it has more of the character of scientific truth. For a long period the generalizations of physiology were so vague, and apparently so much of the nature of more or less happy guesses, that our brethren, the physicists and chemists, scarcely admitted the subject into the circle of the sciences. Even now we are sometimes reproached with our inability to give a complete solution of a physiological problem, such as, for example, what happens in a muscle when it contracts; and not long ago physiologists were taunted by the remark that the average duration of a physiological theory was about three years. But this view of the matter can only be entertained by those who know very little about the science. They do not form a just conception of the difficulties that surround all physiological investigation, difficulties far transcending those relating to research in dead matter; nor do they recollect that many of the more common phenomena of dead matter are still inadequately explained. What, for example, is the real nature of elasticity; what occurs in dissolving a little sugar or common salt in water; what is electrical conductivity? In no domain of science, except in mathematics, is our knowledge absolute; and physiology shares with the other sciences the possession of problems that, if I may use a paradox, seem to be more insoluble the nearer we approach their solution.

The body of one of the higher animals—say that of man—is a highly complex mechanism, consisting of systems of organs, of individual organs and of tissues. Physi-

* Glasgow meeting, 1901.

ologists have been able to give an explanation of the more obvious phenomena. Thus locomotion, the circulation of the blood, respiration, digestion, the mechanism of the senses and the general phenomena of the nervous system have all been investigated, and in a general way they are understood. The same statement may be made as to the majority of individual organs. It is when we come to the phenomena in the living tissues that we find ourselves in difficulties. The changes happening in any living cell, let it be a connective tissue corpuscle or a secreting cell or a nerve-cell, are still imperfectly understood; and yet it is upon these changes that the phenomena of life depend. This has led the more thoughtful physiologists in recent years back again to the study of the cell and of the simple tissues that are formed from cells. Further, it is now recognized that if we are to give an adequate explanation of the phenomena of life, we should study these, not in the body of one of the lower organisms, as was at one time the fashion, where there is little if any differentiation of function—the whole body of an amœboid organism showing capacities for locomotion, respiration, digestion, etc.—but in the specialized tissue of one of the higher animals. Thus the muscle-cell is specialized for contraction, and varieties of epithelium have highly specialized functions.

But when cells are examined with the highest microscopic powers, and with the aid of the highly elaborated methods of modern histology, we do not seem to have advanced very far towards an explanation of the ultimate phenomena. There is the same feeling in the mind of the physiologist when he attacks the cell from the chemical side. By using large numbers of cellular elements, or by the more modern and fruitful methods of micro-chemistry, he resolves the cell-substance into proteids, carbohydrates, fats, saline matter and water,

with possibly other substances derived from the chemical changes happening in the cell while it was alive; but he obtains little information as to how these proximate constituents, as they are called, are built up into the living substance of the cell. But if we consider the matter it will be evident that the phenomena of life depend on changes occurring in the interactions of particles of matter far too small even to be seen by the microscope. The physicist and the chemist have not been content with the investigation of large masses of dead matter, but to explain many phenomena they have had recourse to the conceptions of molecules and atoms and of the dynamical laws that regulate their movements. Thus the conception of a gas as consisting of molecules having a to-and-fro motion, first advanced by Krönig in 1856 and by Clausius in 1857, has enabled physicists to explain in a satisfactory manner the general phenomena of gases, such as pressure, viscosity, diffusion, etc. In physiology few attempts have been made in this direction, probably because it was felt that data had not been collected in sufficient numbers and with sufficient accuracy to warrant any hypothesis of the molecular structure of living matter, and physiologists have been content with the microscopic and chemical examination of cells, of protoplasm and of the simpler tissues formed from cells. An exception to this general remark is the well-known hypothesis of Du Bois-Reymond as to the existence in muscle of molecules having certain electrical properties, by which he endeavored to explain the more obvious electrical phenomena of muscle and nerve. The conception of gemmules by Darwin and of biophors by Weismann are examples also of a hypothetical method of discussing certain vital phenomena.

The conception, however, of the existence in living matter of molecules has not escaped some astute physicists. The sub-

ject is discussed with his usual suggestiveness by Clerk Maxwell in the article 'Atom' in the 'Encyclopædia Britannica' in the volume published in 1875, and he places before the physiologist a curious dilemma. After referring to estimates of the diameter of a molecule made by Loschmidt in 1865, by Stoney in 1868, and by Lord Kelvin (then Sir W. Thomson) in 1870, Clerk Maxwell writes:

"The diameter and the mass of a molecule, as estimated by these methods, are, of course, very small, but by no means infinitely so. About two millions of the molecules of hydrogen in a row would occupy a millimeter, and about two hundred million million million of them would weigh a milligram. These numbers must be considered as exceedingly rough guesses; they must be corrected by more extensive and accurate experiments as science advances; but the main result, which appears to be well established, is that the determination of the mass of a molecule is a legitimate object of scientific research, and that this mass is by no means immeasurably small.

"Loschmidt illustrates these molecular measurements by a comparison with the smallest magnitudes visible by means of a microscope. Nobert, he tells us, can draw 4,000 lines in the breadth of a millimeter. The intervals between these lines can be observed with a good microscope. A cube, whose side is the 4,000th of a millimeter, may be taken as the *minimum visible* for the observers of the present day. Such a cube would contain from 60 to 100 million molecules of oxygen or of nitrogen; but since the molecules of organized substances contain on an average about fifty of the more elementary atoms, we may assume that the smallest organized particle visible under the microscope contains about two million molecules of organic matter. At least half of every living organism consists of water, so that the smallest living

being visible under the microscope does not contain more than about a million organic molecules. Some exceedingly simple organism may be supposed built up of not more than a million similar molecules. It is impossible, however, to conceive so small a number sufficient to form a being furnished with a whole system of specialized organs.

"Thus molecular science sets us face to face with physiological theories. It forbids the physiologist from imagining that structural details of infinitely small dimensions can furnish an explanation of the infinite variety which exists in the properties and functions of the most minute organisms.

"A microscopic germ is, we know, capable of development into a highly organized animal. Another germ, equally microscopic, becomes when developed an animal of a totally different kind. Do all the differences, infinite in number, which distinguish the one animal from the other arise each from some difference in the structure of the respective germs? Even if we admit this as possible, we shall be called upon by the advocates of pangenesis to admit still greater marvels. For the microscopic germ, according to this theory, is no mere individual but a representative body, containing members collected from every rank of the long-drawn ramification of the ancestral tree, the number of these members being amply sufficient not only to furnish the hereditary characteristics of every organ of the body and every habit of the animal from birth to death, but also to afford a stock of latent gemmules to be passed on in an inactive state from germ to germ, till at last the ancestral peculiarity which it represents is revived in some remote descendant.

"Some of the exponents of this theory of heredity have attempted to elude the difficulty of placing a whole world of wonders within a body so small and so devoid of

visible structure as a germ by using the phrase structureless germs. Now one material system can differ from another only in the configuration and motion which it has at a given instant. To explain differences of function and development of a germ without assuming differences of structure is, therefore, to admit that the properties of a germ are not those of a purely material system."

The dilemma thus put by Clerk Maxwell is (first) that the germ cannot be structureless, otherwise it could not develop into a future being, with its thousands of characteristics; or (second) if it is structural it is too small to contain a sufficient number of molecules to account for all the characteristics that are transmitted. A third alternative might be suggested, namely, that the germ is not a purely material system, an alternative that is tantamount to abandoning all attempts to solve the problem by the methods of science.

It is interesting to inquire how far the argument of Clerk Maxwell holds good in the light of the knowledge we now possess. First, as regards the *minimum visible*. The smallest particle of matter that can now be seen with the powerful objective and compensating eyepieces of the present day is between the $\frac{1}{400000}$ and the $\frac{1}{500000}$ of an inch, or $\frac{1}{200000}$ of a millimeter in diameter, that is to say, five times smaller than the estimate of Helmholtz of $\frac{1}{40000}$ of a millimeter. The diffraction of light in the microscope forbids the possibility of seeing still smaller objects, and when we are informed by the physicists that the thickness of an atom or molecule of the substances investigated is not much less than a millionth of a millimeter, we see how far short the limits of visibility fall of the ultimate structure of matter.

Suppose, then, we can see with the highest powers of the microscope a minute particle having a diameter of $\frac{1}{200000}$ of a

millimeter, it is possible to conceive that some of the phenomena of vitality may be exhibited by a body even of such small dimensions. The spores of some of the minute objects now studied by the bacteriologist are probably of this minute size, and it is possible that some may be so minute that they can never be seen. It has been observed that certain fluids derived from the culture of microorganisms may be filtered through thick asbestos filters, so that no particles are seen with the highest powers, and yet those fluids have properties that cannot be explained by supposing that they contain toxic substances in solution, but rather by the assumption that they contain a greater or less number of organic particles so small as to be microscopically invisible. I am of opinion, therefore, that it is quite justifiable to assume that vitality may be associated with such small particles, and that we have by no means reached what may be called the vital unit when we examine either the most minute cell or even the smallest particle of protoplasm that can be seen. This supposition may ultimately be of service in the framing of a theory of vital action.

Weismann in his ingenious speculations has imagined such a vital unit to which he gives the name of a biophor, and he has even attempted numerical estimates. Before giving his figures let us look at the matter in another way. Take the average diameter of a molecule as the millionth of a millimeter, and the smallest particle visible as the $\frac{1}{200000}$ of a millimeter. Imagine this small particle to be in the form of a cube. Then there would be in the side of the cube, in a row, fifty such molecules, or in the cube $50 \times 50 \times 50 = 125,000$ molecules. But a molecule of organized matter contains about fifty elementary atoms. So that the 125,000 molecules in groups of about fifty would number $\frac{125000}{50} = 2,500$ organic particles. Suppose, as was done

by Clerk Maxwell, one-half to be water; there would remain 1,250 organic particles. The smallest particle that can be seen by the microscope may thus contain as many as 1,250 molecules of such a substance as a proteid.

Weismann's estimates as to the dimensions of the vital unit to which he gives the name of biophor may be shortly stated. He takes the diameter of a molecule at $\frac{1}{20000000}$ of a millimeter (instead of the one millionth) and he assumes that the biophor contains 1,000 molecules. Suppose the biophor to be cubical, it would contain ten in a row, or $10 \times 10 \times 10 = 1,000$. Then the diameter of the biophor would be the sum of ten molecules, or $\frac{1}{20000000} \times 10 = \frac{1}{2000000}$ or $\frac{1}{2000000}$ of a millimeter. Two hundred biophors would therefore measure $\frac{200}{2000000}$ or $\frac{1}{10000}$ mm. or 1μ (micron = $\frac{1}{10000}$ mm.). Thus a cube one side of which was 1μ would contain $200 \times 200 \times 200 = 8,000,000$ biophors. A human red blood corpuscle measures about 7.7μ ; suppose it to be cubed, it would contain as many as 3,652,264,000 biophors.

Now if the smallest particle that can be seen ($\frac{1}{2000000}$ mm.) may contain 1,250 molecules, let us consider how many exist in a biophor, which we may imagine as a little cube, each side of which is $\frac{1}{2000000}$ mm. There would then be five in a row of such molecules, or in the cube $5 \times 5 \times 5 = 125$ molecules; and if the half consisted of water about sixty molecules.

Let us apply these figures to the minute particles of matter connected with the hereditary transmission of qualities. The diameter of the germinal vesicle of the ovum is $\frac{1}{2}$ of a millimeter. Imagine this a little cube. Taking the diameter of an atom at $\frac{1}{100000000}$ of a millimeter, and assuming that about fifty exist in each organic molecule (proteid, etc.), the cube

would contain at least 25,000,000,000,000 organic molecules. Again, the head of the spermatozoid, which is all that is needed for the fecundation of an ovum, has a diameter of about $\frac{1}{2000}$ mm. Imagine it to be cubed; it would then contain 25,000,000,000,000 organic molecules. When the two are fused together, as in fecundation, the ovum starts on its life with over 25,000,000,000,000,000 organic molecules. If we assume that one-half consists of water, then we may say that the fecundated ovum may contain as many as about 12,000,000,000,000 organic molecules. Clerk Maxwell's argument that there were too few organic molecules in an ovum to account for the transmission of hereditary peculiarities does not apparently hold good. Instead of the number of organic molecules in the germinal vesicle of an ovum numbering something like a million, the fecundated ovum probably contains millions of millions. Thus the imagination can conceive of complicated arrangements of these molecules suitable for the development of all the parts of a highly complicated organism, and a sufficient number, in my opinion, to satisfy all demands of a theory of heredity. Such a thing as a structureless germ cannot exist. Each germ must contain peculiarities of structure sufficient to account for the evolution of the new being, and the germ must therefore be considered as a material system.

Further, the conception of the physicist is that molecules are more or less in a state of movement, and the most advanced thinkers are striving towards a kinetic theory of molecules and of atoms of solid matter which will be as fruitful as the kinetic theory of gases. The ultimate elements of bodies are not freely movable each by itself; the elements are bound together by mutual forces, so that atoms are combined to form molecules. Thus there may be two kinds of motion, atomic and molecular.

By molecular motion is meant, "the translatory motion of the centroid of the atoms that form the molecule, while as atomic motion we count all the motions which the atoms can individually execute without breaking up the molecule. Atomic motion includes, therefore, not only the oscillations that take place within the molecule, but also the rotation of the atoms about the centroid of the molecule." *

Thus it is conceivable that vital activities may also be determined by the *kind* of motion that takes place in the molecules of what we speak of as living matter. It may be different in kind from some of the motions known to physicists, and it is conceivable that life may be the transmission to dead matter, the molecules of which have already a special kind of motion, of a form of motion *sui generis*.

I offer these remarks with much diffidence, and I am well aware that much that I have said may be regarded as purely speculative. They may, however, stimulate thought, and if they do so they will have served a good purpose, although they may afterwards be assigned to the dust-heap of effete speculations. Meyer writes as follows in the introduction to his great work on 'The Kinetic Theory of Gases,' p. 4: "It would, however, be a considerable restriction of investigation to follow out only those laws of nature which have a general application and are free from hypothesis; for mathematical physics has won most of its successes in the opposite way, namely, by starting from an unproved and unprovable, but probable, hypothesis, analytically following out its consequences in every direction, and determining its value by comparison of these conclusions with the result of experiment."

JOHN G. MCKENDRICK.

DATA ON SONG IN BIRDS. OBSERVATIONS
ON THE SONG OF BALTIMORE ORIOLES
IN CAPTIVITY.

MUCH has been written in regard to the songs of birds, and no small part of the literature of the subject has dealt with the problem of the way in which many kinds of birds have acquired the distinctive song that characterizes each different species.

In the eastern United States many of us recognize, without seeing, the singer, on hearing the song of one of our commoner native birds. We say, 'A robin is singing,' 'Listen to the bobolink,' 'That is a song sparrow.'

Some who pay close and particular attention realize that individuals of a given kind have sometimes slight, though marked, variations in the method of song that distinguish them from the mass of their kind and characterize them as individuals which are readily known by their *peculiar personal song*. So we say, 'This robin is a good singer,' 'The note of that thrush is particularly pleasing,' 'That oriole has some harsh notes.' Such comments are indicative of the taste or appreciation of the listener and are only introduced here to emphasize two facts. First, that the song of all the individuals of a given kind of bird, as the robins, is so characteristic that we call it the robin's song, readily recognize it, and know that, in the main, all the robins of a given region have a common song, so much alike that we do not individualize the singer. Second, that now and again individual birds of a given kind, robins again for example, are readily distinguishable as individuals by some turn or phrasing of the notes that gives to the individual singer an identity as a particular robin, with an individual song, different, to a greater or less degree, from the mass of robins in the same region.

The question at once suggests itself: How is this characteristic song acquired?

Is it a matter of inheritance? Or does each robin learn to sing? Is it inherent in the species or is this song of the robin a matter of education?

A. R. Wallace and Lloyd Morgan especially have advanced hypotheses to account for the matter of call notes and song, and Mr. Morgan's work is based on many careful experiments that are set forth in his book, 'Habit and Instinct.' But, so far, I am not aware of any prolonged or detailed account of the study of this factor, as it develops with, and extends through, the life of a given individual, nor has a second generation been carefully watched.

The following experiment, though imperfect and by no means as exhaustive as could be desired, seems, however, worthy of record, as from it certain conclusions may be drawn. The notes accumulated extend over a period of nearly five years and are briefly as follows:

On July 7, 1895, I took from a maple tree at Annisquam, Massachusetts, a nest of the Baltimore oriole. (*Icterus galbula*), which contained three very young birds. They were quite naked and showed no signs of wing or tail feathers. They appeared to be about five days old. As a record to refer to, one was killed and preserved in alcohol. The other two were carefully reared by hand and thrived well.

So far as I know, they did not hear, after coming into my possession, any birds sing, nor did any person whistle or sing to them.

At the age of between three and four weeks they were able to feed and care for themselves. They began then to fly from place to place about the room, and it became necessary to confine them in a cage. However, they were allowed the larger liberty of the sitting room for a portion of each day and were very tame and familiar, for a long period calling for food in the characteristic oriole way and begging with drooping

fluttering wings of any one who came into the room.

By August 1 they were fully fledged and the downy first plumage of the head and body began to be replaced by the compact and finished plumage of the first autumn. The wing and tail feathers were, however, not moulted at this time.

During the first week in October, the birds were taken by me to Boston. Here I lived in rooms on the upper floor of a four-story house where there were no other birds in confinement, so that no song of any kind was heard by the birds while at this place.

Now I began to appreciate that both were female birds and also noted great temperamental differences in the two. One was timid, and the other taking advantage of this characteristic, scolded and chased the timid bird both in the cage and when at large in the room. So by name I began to distinguish them as Driver and Timid, which last soon became Timmy, a name always associated in my mind with Baltimore orioles.

At this time they had a single call note very like that of wild birds, but with a slightly different quality difficult to define, more abrupt, musical and much louder. They also had the peculiar rattling chatter associated with orioles. These were all their notes and were uttered rarely, the infant appeal so prevalent during the first four weeks of their lives having disappeared with their babyhood.

During the next few months their lives had no marked events. Each day they spent much time out of the cage at large in the room. Threads interested them, and hours were spent by the two birds in sewing, for I can use no other word, threads and strings into the wire bars of the cage they lived in. Without any semblance of weaving a nest or attempting to shape one, the birds simply tied and wove the threads

into the wire until there were no loose ends. Ultimately thick bunches of thread and string on the bars characterized the cage.

I have told all this detail, really foreign to my thesis, because it seems important to record an inheritance so marked. The birds never learned to do more with threads than is here described, though they were ultimately allowed a room to live in with branches of trees to alight on, etc., and at least one of them laid eggs in an artificial nest.

On February 16, 1896, I took the birds by train from Boston to New York, where they spent the succeeding months until May 6 in a room in a large hotel. I wish to emphasize again two facts: both birds were females though I was not absolutely sure of it at this period, and, so far as I am aware, they heard no birds sing after I took them from their parents when about five days old, until after I took them to the country again on May 6, as will presently be related.

After reaching New York it was found expedient to keep them in separate cages when confined, though they were daily allowed much liberty at large in the room. During the last of February a partial moult occurred in both birds. This was chiefly the feathers of the head, throat and back. The wing and tail feathers were not shed.

Till now the two birds had looked so much alike, that in order to readily distinguish them I had early in October clipped the tips of the secondary feathers in one of Timmy's wings. This was a distinct mark even with the wings closed. But with the moult I am about to discuss, the birds ceased to be alike in appearance and were readily recognized.

Timmy in this moult acquired a distinct black throat patch, some black arrow-shaped marks in the feathers of the top of the head and decidedly dusky patches about

the region of the ears. The throat patch extended over the throat proper. The entire period taken in completing this moult was about three weeks.

The other bird, Driver, did not acquire any decided black marking about the head, throat or ears, and only showed a few scattered tiny black feathers.

Before this moult was quite completed, during the latter part of February, the birds began to sing. The interval between the singing was sometimes several days, and only a very few minutes in each day were devoted to song. This song was very low and soft, and more or less broken, reminding one of the song of the white-throated sparrow (*Z. albicollis*) as it is heard during the fall and in the early spring migrations.

Timmy was the first to sing in this way, and the period of song when noticed was brief, not lasting more than about one minute. The song was not heard again for several days. Then it became of daily occurrence, and was gradually more prolonged and better sustained. About five days after Timmy began to sing, Driver sang also. Driver soon became the chief singer, so that Timmy's weaker song was not so noticeable. But both increased in volume, and frequency all through the month of March, and during April and the first half of May while daylight lasted, the song was incessant in both birds. It was now a loud clear series of notes of great brilliancy, and poured forth in such rapid succession as to be like that of the house wren (*T. ædon*) in the intervals, and lasting about as long as the warble of that bird. Except for the 'rattle' which was now and then a part of the repertoire, this song had nothing in it that reminded one of the song of the Baltimore oriole as heard in New York, Massachusetts or at any point where the birds occur. Through the second week in May, the song of both birds gradually diminished.

I could generally, during the height of the song season, start the birds to sing by going to their cages, speaking to them and whistling a few notes. Here it seems essential to emphasize the fact that I in no way trained them to sing and made no effort to start them in song till long after their method of singing was established. In fact, the quality and phrasing of their singing was of such a character that none save an expert whistler could reproduce it.

Early in May of 1896 I took the birds to the country near New York, where we remained until July 20, 1897, a period of some fourteen months; then I moved to Princeton, New Jersey, where the remainder of their lives was passed. Both birds died during the winter of 1899-1900, apparently of old age.

To go back to the time of departure from New York in the spring of 1896. As has been stated, the birds' song became less frequent by the first week in May, and by the twentieth of that month they had ceased to sing. On June 6 I noticed the first signs of the summer moult and in a very few days it was in full progress.

It may be well to indicate some of the details of the change, though this is a divergence from the chief subject. Also, it should be borne in mind that native birds kept in confinement are generally about a month earlier in moulting and also in the song season, than are the representatives of the same species at liberty out of doors. This applies to all the species I have kept in confinement and when the birds are perfectly normal and healthy—so sound in health as to *breed in captivity*, which seems a good criterion. As examples, I may mention the bluebird (*S. sialis*), robin (*M. migratoria*), wood thrush (*H. mustelina*), catbird (*G. carolinensis*), brown thrasher (*H. rufus*), and the orchard oriole (*I. spurius*), all of which I have had live and breed and

go through the song and moult seasons year after year in captivity.

The moulting period of the two orioles occupied a month, and early in July both were in most exquisite fall plumage. The deeper orange and rusty tint that is so characteristic of the species, and the suffusion of the black areas on the throat, were as marked and fine in detail as in wild birds. At this moult for the first time the larger wing and all the tail feathers were shed and replaced. The two birds were marvels of beauty at all times, but just after the full summer moult they filled those who saw them with admiration and wonder. After the moult there was a secondary song season of short duration. The song was of the same character, but not so prolonged or elaborate.

So I have endeavored to give an idea of a year, or rather more, of these birds' lives, and the succeeding years to the end were but repetitions with but slight variation.

Each year the wearing of the tips of the feathers was apparent in January, and a partial moult such as I have described took place late in that month or in February. Then began again the peculiar low soft song at infrequent intervals, presently becoming noticeable in volume and occurrence, till the song wave reached its height and died away. Each early June found the birds putting on an entirely new garment of feathers.

I have spoken before in this paper of the observations of a second generation. I find that this perhaps conveys a wrong impression. Let me say at once that the second generation consisted of a brood of young orioles in no way related to Timmy or Driver. However, for the purpose of my subject, really these were a second generation, of birds of a given kind, subject to the influence of older birds of their own species.

On June 15, 1897, when Timmy and

Driver had passed through the song seasons and had a well-established song formula of their own, I obtained a brood of Baltimore orioles which I believed to be about six days old. The birds were secured at South Orange, N. J., a point several hundreds of miles from the birthplace of my original birds, Timmy and Driver. I shall distinguish these birds, when speaking of them, as the brood of 1897. They were reared in the same way that the other orioles had been, except that they had the *society of, and were closely associated during their early lives with,* the two older orioles.

The moults occurred at the same intervals that I have indicated, and by the winter of 1897-1898 I was able to distinguish the sexes of my four new birds by the characteristics that correlate with sex. Three were males and assumed full nuptial plumage by a partial moult in late January and part of February. The fourth bird was a female.

On my coming to live in Princeton when these 1897 orioles were about seven weeks old, they, as well as Timmy and Driver, had an especial room given over to their use, and from that time on the birds knew little or nothing of cage life.

After the spring or, rather, late winter moult of 1898, Timmy and Driver began to sing as they had done in the two previous years. At this time friends, good field ornithologists, familiar with the conventional song of the Baltimore oriole, heard them both sing, and not having up to that time seen the birds, were at a loss to identify the song as being like anything they had ever heard.

Soon after Timmy and Driver began to sing, the 1897 birds one by one joined, and in a month all were singing a song not to be distinguished from that of the two older birds. They outlived Timmy and Driver a year or more and always sang as I believe they had been taught by older birds of their

own kind. In short, only six orioles have ever sung this song, for I pursued the experiment no farther, other matters interfering.

My conclusion is that two birds, *isolated from their own kind and from all birds*, but with a strong inherited tendency to sing, originated a novel method of song, and that four birds, *isolated from wild representatives of their own kind, and associated with these two who had invented the new song*, learned it from them and never sang in any other way.

WILLIAM E. D. SCOTT,
Curator of Ornithology.

PRINCETON UNIVERSITY.

THE BOTANICAL SOCIETY OF AMERICA.

THE Botanical Society of America met in business sessions in Room 4 of the High School Building, Denver, Col., August 27 and 28, 1901, and presented its scientific program in joint session with Section G of the A. A. A. S. in the same place on August 28. The Presidential address on 'The Problems and Possibilities of Systematic Botany,' by Professor B. L. Robinson, was read by Dr. J. M. Coulter. The following program was presented:

'The Fundamental Phenomena of Vegetation': F. E. CLEMENTS.

'The Physical Basis of Ecology'; F. E. CLEMENTS.

'A System of Nomenclature for Phytogeography': F. E. CLEMENTS.

'The Plant Formations of the Rocky Mountains': F. E. CLEMENTS.

'Early Winter Color of the Plant Formations of the Great Plains': C. E. BESSEY.

'The Anatomy of the Embryo and Seedling of *Tsuga Canadensis* Carr' (by invitation): W. A. MURRILL.

'Clues to Relationships among Heterœcious Plants': J. C. ARTHUR.

'The Thermal Relations of Vegetation': D. T. MACDOUGAL.

'The Application of Ecology in Taxonomy': F. E. CLEMENTS.

'Some of the Changes now taking place in a Forest of Oak Openings': W. J. BEAL.

'The Life-History of *Vittaria Lineata*': E. G. BRITTON and A. TAYLOR.

In accordance with the adoption of an amendment to the Constitution of the A. A. S., Drs. Bessey and Halsted were chosen to represent the Society on the Council of the Association at the sessions just finished.

A committee consisting of Drs. Wm. Trelease, N. L. Britton and B. L. Robinson was appointed to report upon the condition of the National Herbarium, and to recommend changes for its improvement.

As a result of consideration of the report of the committee on the policy of the Society appointed a year ago, it was resolved "That it is the present policy of the Society to accumulate invested funds until the annual income, interest and dues, is at least \$500, and then to use such income yearly, or at greater or less intervals, as circumstance may dictate, for the best advancement of botanical knowledge."

The address of the retiring President at the next annual meeting will be delivered by Professor B. D. Halsted, who presided over the session, and whose term of office has just expired.

The officers for the ensuing year are :

President, J. C. Arthur.

Vice-President, B. T. Galloway.

Treasurer, C. A. Hollick.

Secretary, D. T. MacDougal.

Councillors, C. E. Bessey and Wm. Trelease.

D. T. MACDOUGAL,

Secretary.

NEW YORK BOTANICAL GARDEN,
BRONX PARK, N. Y. CITY.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FELLOWS ELECTED AT THE DENVER MEETING.

John Almy, Instructor in Physics, University of Nebraska, Lincoln, Nebr. (B).

J. H. Appleton, Professor of Chemistry, Brown University, Providence, R. I. (C).

Howard Ayers, President, University of Cincinnati, Cincinnati, Ohio (F).

Solon I. Bailey, Associate Professor of Astronomy, Harvard University, Cambridge, Mass. (A).

Simeon E. Baldwin, Associate Judge of Supreme Court of Errors, New Haven, Conn. (I).

W. D. Bancroft, Professor of Physical Chemistry, Cornell University, Ithaca, N. Y. (C).

C. R. Bardeen, Anatomical Laboratory, Wolfe and Monument Sts., Baltimore, Md. (F, K).

A. E. Beardsley, Professor of Biology, State Normal School, Greeley, Colo. (F).

John Andrew Bergström, Associate Professor of Psychology and Pedagogy, Indiana University, Bloomington, Ind. (K).

Ernst A. Bessey, Department of Agriculture, Washington, D. C. (G).

Frank W. Blackmar, Professor of Sociology and Economics, University of Kansas, Lawrence, Kansas, (I).

E. M. Blake, University of California, Berkeley, Cal. (A).

Thaddeus L. Bolton, Department Philosophy, University of Nebraska, Lincoln, Nebr. (K).

Louis F. G. Bouscaren, Chief Engineer, Water Works Commission, Cincinnati, Ohio (D).

Charles L. Bouton, Instructor in Mathematics, Harvard University, Cambridge, Mass. (A).

Wm. L. Bray, Professor of Botany, University of Texas, Austin, Texas (G).

Lyman J. Briggs, U. S. Dept. of Agriculture, Washington, D. C. (B).

S. J. Brown, U. S. N., U. S. Naval Academy, Annapolis, Md. (A).

Lawrence Bruner, Professor of Entomology, University of Nebraska, Lincoln, Nebr. (F).

Edward F. Buchner, New York, N. Y. (H, K).

Luther Burbank, Horticulturist, Santa Rosa, Cal. (G).

E. S. Burgess, Botanist, 11 W. 88th St., New York, N. Y. (G).

E. A. Burt, Professor of Natural History, Middlebury College, Middlebury, Vt. (G).

William Cain, Professor of Mathematics, University of North Carolina, Chapel Hill, N. C. (A, D).

Florian Cajori, Professor of Mathematics, Colorado College, Colorado Springs, Colo. (A).

C. N. Calkins, Instructor in Zoology, Columbia University, New York, N. Y. (F).

F. K. Cameron, Bureau of Soils, U. S. Department of Agriculture, Washington, D. C. (C).

W. W. Campbell, Director, Lick Observatory, Mt. Hamilton, Cal. (A).

George L. Cannon, Instructor in Geology, Denver High School (No. 1), Denver, Col. (E).

H. W. Cattell, Pathologist, 3709 Spruce St., Philadelphia, Pa. (K).

Wm. M. Chauvenet, Mining Engineer, 620 Chestnut St., St. Louis, Mo. (C).

- T. M. Cheesman, Pathologist, Garrison-on-Hudson, N. Y. (K).
- C. M. Child, Instructor in Zoology, University of Chicago, Chicago, Ill. (F).
- Frank Hurlbut Chittenden, Assistant Entomologist, U. S. Dept. Agriculture, Washington, D. C. (F).
- Russell H. Chittenden, Dean Sheffield Scientific School, Yale University, New Haven, Conn. (C, K).
- Frank H. Cilley, Mass. Inst. Technology, Boston, Mass. (A, B, D).
- Gaylord Parsons Clark, Professor of Physiology, Syracuse University, Syracuse, N. Y. (F, K).
- John S. Clark, 110 Boylston St., Boston, Mass. (I).
- S. F. Clarke, Professor of Biology, Williams College, Williamstown, Mass. (F).
- T. D. A. Cockerell, Entomologist, Las Vegas, N. M. (F).

Diplodocus Marsh. *Its Osteology, Taxonomy and Probable Habits, with a Restoration of the Skeleton. Memoirs of the Carnegie Museum*, Vol. I., pp. 1-63, pl. I.-XIII.

The *Memoirs of the Carnegie Museum* open auspiciously with this valuable contribution by Mr. J. B. Hatcher, curator of the department of vertebrate paleontology and associate editor of the publications of the Museum. The subject is the description of two remarkable skeletons of the great sauropodous dinosaur *Diplodocus* discovered by the Museum expeditions of 1899 and 1900 on Sheep Creek, Albany County, Wyoming. The first specimen consists of forty-one vertebrae, which form an unbroken series from the second or axis vertebra to the twelfth vertebra of the tail, besides extensive parts of the appendicular skeleton, all in a remarkable

state of preservation. The fourteen cervicals alone measure 21 feet and the author estimates a total length of 68 feet for the vertebral column and skull. The second skeleton belongs to a smaller animal in which one of the hind limbs is perfectly preserved, and with the aid of a fore limb and of some characters taken from the tail of a specimen in the American Museum collection, Mr. Hatcher gives (Plate XIII.) by far the most perfect restoration of a *Sauropod* which has yet been published. The neck is extraordinarily long and slender, increasing in power and in the length of the centra near the chest. The back, including only eleven vertebrae with short centra is extremely short; while the long and heavy tail evidently balances the anterior portion of the column, and the sacrum forms the center of the body. The marvelously light and yet strong structure of the vertebrae is well brought out in the pen drawings by Mr. Weber, and the author adds a number of most useful new terms for the future description of these elaborate structures. Of the animal as a whole he observes:

The restoration at once reveals the unusual proportions of *Diplodocus*. The remarkable long neck and tail contrast strikingly with the short body. The hind limbs are longer than the fore limbs, and this fact, together with the enormous elevation of the spines of the sacra and posterior dorsals, fixes the sacral region as the highest in the vertebral column, a determination first made by Osborn. The powerful ilia, firmly united to the rigidly coossified sacra with lofty coalesced spines, together with the other pelvic elements proportionately well developed, at once emphasizes the paramount importance of the pelvic region and fixes it as the center of power and motion.

Among the new important points brought out in this Memoir are the following: First, the gradual transition from the paired spines of the neck to the highest single spines of the back; the clear description and definition of the remarkable cavities surrounding the vertebrae, intramural or inside of the bones as well as around the centra and neural arches; the modification of the first two dorsals especially for the support of the scapula; the presence of four true sacra and of one dorso-sacral or pelvic vertebra, strengthening the support of

the ilium; the fact that the posterior sacral is larger than the anterior, showing the enormous power exerted by the tail; the coossification of the 17th and 18th caudal vertebræ, indicating that this was a fixed point when the animal stood upon its hind feet and partly supported itself upon the tail in the tripod condition; the excessively small neural canal throughout, the probable presence of a pair of clavicles, not hitherto observed in the Sauropoda; the hollow character of the large limb bones.

These skeletons are referred to a new species, *D. carnegiei*, in honor of the founder of the Pittsburgh Museum.

As regards the habits of these animals Mr. Hatcher speaks as follows:

From the above consideration I am inclined toward the opinion that *Diplodocus* was essentially an aquatic animal, but quite capable of locomotion on land. Though living for the most part in the more important rivers and fresh-water lakes, it may not infrequently have left the water and taken temporarily to the land, either in quest of food or in migration from one to another of adjacent bodies of water.

It is not improbable that during the period when these huge dinosaurs lived and flourished over what is now New Mexico, Colorado, Wyoming, Montana and the Dakotas, there prevailed throughout this region physical conditions somewhat similar to those which exist to-day in tropical America and more especially over the coastal plain of the lower Amazon with its numerous bayous and islands, or the more elevated valleys of the anterior in the Brazilian provinces of Amazonas and Matto Grosso with their numerous lakes and large rivers surrounded by a dense tropical vegetation with broad, level valleys subject to periodical inundations.

With the beginning of the Cretaceous there began a subsidence over this region, and a great inland sea was formed which gradually encroached upon the habitat of these animals, more and more restricting the area adapted to them, so that at about the commencement of the Upper Cretaceous the entire region formerly occupied by them had become a shallow sea save only certain islands of limited extent, and perhaps otherwise poorly adapted as the homes of such animals as were the *Sauropoda*.

A few years more of such efficient exploration as this and of such remarkably careful field and preparation work promises to give us a knowledge of the osteology of these great Sauropods almost as complete as our knowledge of the

skeleton of the recent horse, for example. The author of the present work and Dr. J. L. Wortman, who found the type skeleton, have led the way in these methods of field work.

HENRY F. OSBORN.

An Introduction to Physiology. By WILLIAM TOWNSEND PORTER, M.D., Associate Professor of Physiology in the Harvard Medical School. Cambridge, Mass., The University Press. Pp. 314.

This small volume contains in a convenient form what is apparently the course of practical physiology given for the past two or three years at the Harvard Medical School. To those who are not conversant with the difficulties that beset the practical teaching of the subject to large classes it may appear surprising that in this matter the large American medical schools should have lagged behind the smaller, in some of which courses of a considerably wider scope than that under review have not only, for the best part of a decade, been available for the advanced student of medicine, but have taken their place among the compulsory subjects of the ordinary curriculum. He, however, who knows how much wise planning and laborious organization—what material, intellectual and even moral resources—are required for the successful conduct of a practical class for a couple of hundred students will be much more ready to congratulate Dr. Porter and the Harvard Medical School on the satisfactory results of their efforts than to criticise them as belated laborers in the vineyard of practical physiology. Nor will the experienced teacher whose circumstances enable him to make free use of mammals as well as frogs seriously blame, however much he may regret, the entire omission of mammalian experiments, except those performed on the students themselves. He will nevertheless note that the lack of this element, so valuable, under proper conditions, in the training of the medical students, renders the book less suited to the requirements of schools of moderate size than would otherwise be the case. On the other hand, for those who are so situated that they can only use frogs, the work may be recommended as a sound guide to the performance of the fundamental experiments in the general physiology

of muscle and nerve. The mechanical phenomena of the circulation are also adequately treated in a series of exercises on an ingeniously constructed artificial scheme.

It would have been better, we think, to omit much of the elementary physics which bulks so largely in some of the chapters. The simple experiments on magnetic induction, lines of force and electromagnetic induction, given in Chapter II., would be in their proper place in a manual of practical physics. We doubt the wisdom of encouraging the medical student to neglect his physics, as he so often does at the period of his preliminary scientific studies, in the sure and certain hope that 'all he really requires,' the titbits of that severe and repellent science—will be served up to him later on in semi-digested form in the course of physiology.

The proofs have been read with commendable care, and few actual errors have escaped detection. On page 188, however, it is wrongly stated that 'in muscle the electrotonic currents are much stronger than in nerve.' The assertion, on page 189, that 'the electrotonic currents are absent in nerves which lack a myelin sheath' seems a little too absolute, although everybody admits that they are weaker than in medullated nerves. On page 250 one is rather staggered by the argument that 'were the slow passage of the blood in the capillaries due simply to friction, the blood would move still more slowly in the veins because the retarding influence of the friction in the veins would be added to that of the capillaries.' This would hold true if the blood possessed only kinetic energy. But since the blood in the capillaries is under a higher pressure than in the veins, there is a surplus of potential energy which is capable of being converted into kinetic.

It is a good idea to encourage the learner to discuss his results by setting him here and there a definite question for consideration. A critical comparison of the isotonic and isometric causes of contraction (pp. 221, 229) affords a valuable mental gymnastic to the student who has just been exercising his manual dexterity in obtaining them. And if Swift could extract an elegant meditation (according to the style and manner of the Hon. Robert Boyle) from so dry a piece of timber as a broomstick, the ingenuous

reader will waste no sympathy on the twentieth-century medical student, even when he is requested to tackle a somewhat unpromising theme, to write, for example (according to his own style and manner) 'a critical account of the muscle-lever in his laboratory note-book.'

G. N. I. S.

Theory of Functions of a Complex Variable. By A. R. FORSYTH, Sc.D., F.R.S., Fellow of Trinity College, Cambridge, Sadlerian Professor of Pure Mathematics. Second Edition. Cambridge, at the University Press. 1900. 8vo. Pp. xxiv + 782.

The publication of a second edition of Professor Forsyth's very valuable and comprehensive work on the theory of functions is a matter of no little interest and importance to the mathematical world. The first edition, which appeared in the spring of 1893, was the first extended systematic presentation in English of a field of modern mathematics now generally recognized as the most useful as well as the most fascinating. Furthermore it was the most comprehensive treatise on the subject in any language, treating a greater number of departments, exhibiting a greater variety of methods, and giving more references to important original contributions than any previous work. Its position in all these respects has been modified since only by a single work, the elaborate historical and bibliographical report of Professors Brill and Noether published in the third volume of the 'Jahresbericht der deutschen Mathematiker-Vereinigung.'

The new edition has been enlarged by about one hundred pages. By means of these additional pages and also by omitting about twenty pages devoted in the earlier edition to binomial differential equations, the author has been enabled to introduce an elementary discussion of the birational transformations and to give some account of Abel's theorem and its applications.

In the work of revision many improvements in the details of presentation have been introduced. The author has altered the wording of a considerable number of theorems and demonstrations which before contained slips of one sort or another. The work has thereby gained

on the side of scientific precision without becoming less agreeable to read or less easy to understand.

It would, of course, be absurd to expect a work of the magnitude and scope of the present one to be free from errors of both omission and commission.* The present writer may be permitted to point out one of the former sort which seems particularly serious, viz: the omission of the fundamental proof of Cauchy relative to the continuity of the roots of an algebraic equation. On page 181 of the new edition, as on page 162 of the old edition, the author simply takes it for granted that when the independent variable changes continuously, so will every root of the algebraic equation.

DISCUSSION AND CORRESPONDENCE.

PREGLACIAL DRAINAGE IN SOUTHWESTERN OHIO.

TO THE EDITOR OF SCIENCE: In SCIENCE for August 9, reference is made, in a review of Professor W. M. Davis, to recent papers by Tight, Bownocker, Todd and Fowke upon the subject of 'Preglacial Drainage of Ohio.' In particular Mr. Fowke is represented as advocating for the Licking and Kentucky rivers a continuance of their courses northward by way of a reversed Miami river or some of its tributaries. There seems to me to be an objection to this theory, which will become apparent to any one who will study the relation of the channels of the Miami river and its principal tributaries to the boundary outcrop of the lower and upper Silurian formations in that region. In a district where the dip of the rocks is very slight, not over four feet to the mile to the northward, all the reentrant angles, formed in a retreating Clinton limestone escarpment, look as if they had been formed by up-stream cutting action of southward-flowing streams. Note on the accompanying map not only the major northeastern reentrant

* For a careful analysis of the first edition see Professor Osgood's review published in the *Bulletin of the American Mathematical Society*, Vol. I. (1894-5), pp. 142-154. Some of the criticisms which appear there apply equally to the present edition.

of the Big and Little Miami rivers combined, but also the minor reentrants of the tributaries to the Big Miami from the northwest—those of Four Mile, Seven Mile, Twin and Stillwater Creeks, and that of the upper Miami itself. This Clinton escarpment only here and there peeps out from under its heavy mantle of glacial drift. Evidently there has been no retreat of these escarpments since the glaciers themselves retreated. The veneering of glacial drift has stereotyped this preglacial topography. It is true that geological boundary reentrants

Map
of a District in South Western Ohio
Showing sinuosity of Clinton Escarpment
in relation to southward flowing streams

Scale ——— = 2 miles

may point down stream. South of the Ohio, one is seen in the lower course of the Kentucky River—the Trenton—Hudson boundary reentrant. This is accounted for by the average dip of the rocks to the northwest on this slope of the Lexington uplift being 12 feet to the mile, while the fall of the river in the same is only 1.2 feet per mile. In order that the reentrants northwest of the Miami River should have been made by streams in that region having a reversed drainage, the average gradients of these streams could not have been greater than four feet to the mile. Four feet to the mile is about the present southwest fall of the Miami River itself, a much steeper gradient

than the preglacial Miami had, but hardly steeper than the gradients of streams occupying the channels of its present tributaries, whether they flowed north or south.

The accompanying map only shows a portion of the Silurian drainage areas to the north of the Ohio. It might have added force to the above argument, to have shown the drainage from the south as well. It would have been found to present an appearance symmetrical with that from the north. In spite of arguments derived from width-of-channel comparisons, etc., it still looks as if the Ohio River were the parent stream and that its present tributaries, the Miami, the Licking, the Kentucky have never been tributary to anything else, but represent normal lateral stream development.

ARTHUR M. MILLER.

STATE COLLEGE OF KENTUCKY.

A POST-GRADUATE SCHOOL OF BIBLIOGRAPHY.

TO THE EDITOR OF SCIENCE: It will not be difficult for any one familiar with the development of libraries and librarianships in this country to see that we have arrived at a turning-point in their history. The large and even moderate sized libraries are developing and will continue to develop special departments in which acquisition is done by collecting rather than selecting. These departments will need for their care and utilization librarians with special knowledge. The largest libraries will specialize in several departments and consequently will need a staff of reference librarians each a specialist—a 'faculty,' as Mr. Melvil Devey calls it in a very suggestive article in the July number of *The Library*. Lastly, highly specialized libraries, each devoted to some special science or group of sciences, will grow up.

This development will necessitate some very radical changes in the class of men who will take up library work, and consequently in the provision for the education of librarians. We shall see men with university education taking responsible positions in libraries instead of seeking university professorships, and the demands of such men for opportunities to prepare themselves for their life-work without having to go back to the college or even high-school grade must be met. It cannot be met by the pres-

ent library schools as now constituted. The work these schools are doing in preparing young men and women for subordinate positions in popular libraries is an absolutely necessary one and one that must not be slighted. In addition to these we need special schools for the education of scientific librarians and bibliographers. Perhaps one or the other of the library schools can develop a school of this grade. However that may be, there should be established at the large universities special schools of bibliography of the same rank as the schools of engineering, commerce and history.

The present writer had occasion to bring this question to the attention of the librarians at the conference of the American Library Association in July of this year, as has already been noticed in SCIENCE. The question is certainly of great importance, not only to librarians, but to the scientific and educational world at large, and the purpose of these lines is to invite a discussion of the ways and means for the establishment of such schools. I hope that SCIENCE will open its columns for this discussion and that educators and scientific men and librarians, too, will take part in it.

A school such as here proposed would naturally be open to any one who would take up the study of bibliography or any of its branches, and not exclusively to prospective librarians. These studies have a fascination of their own, just as literary history, philosophy or mathematics, and are just as capable as any of these sciences of inspiring with enthusiasm the searcher after truth.

The curriculum of a school of bibliography should include the following subjects:

1. The literature of bibliography, with practical exercises in the handling of bibliographical repertories and indexes and in bibliographical compilation.

2. History and methodology of the sciences, and comparative history of literature (literature taken in its broadest sense), including the study of the systems of classification of knowledge and their relations to the schemes for classification of books.

3. History of printing and bookselling, with special emphasis on the invention of printing, and exercises in the cataloguing of incunabula.

4. History of libraries and library administration.

5. Paleography, classical and mediæval; diplomatics; administration of archives.

The studies in the schools of bibliography should lead up to the degree of Doctor of Philosophy as the studies in any other school. To create a special degree in 'library science,' as has been done in the library schools, seems unnecessary.

THE JOHN CRERAR LIBRARY,
CHICAGO, Sept. 7, 1901.

NOTES ON INORGANIC CHEMISTRY.

It has been often claimed that the presence of nickel in dust is a sufficient criterion to distinguish it as being cosmic rather than terrestrial in its origin. Hartley and Ramage have, however, shown in a paper recently read before the Royal Society that nickel is found in soot, and hence that nickeliferous dust may be of terrestrial origin. They also called attention to the wide distribution of gallium in small traces, being found in all aluminous minerals, in many flue dusts, in many iron ores, and in soot and atmospheric dust. A dust is described which is probably of cosmic origin. It fell on a calm night in November, 1897, was magnetic and very uniform in composition, and unlike volcanic dust or the dust of any known terrestrial source.

A CONTINUATION of Gautier's work on the rare elements in the crystalline rocks reveals not only the presence of nitrogen and argon, but also iodine and arsenic. Helium was not found. The gases of mineral waters and the gases issuing from the earth's crust into the atmosphere seemed to be formed by the action of water at high temperature upon the nitrides, argonides, carbides, sulphides, arsenides and other accessory constituents of the igneous rocks.

THE action of manganese dioxide and other finely-divided substances in facilitating the liberation of oxygen from potassium chlorate at a low temperature, is considered by some to be merely mechanical. After a series of experiments at the Explosives Committee's laboratory at the Royal Arsenal, Woolwich, Sodeau comes to the conclusion "that the supposed ability of

chemically inert solid particles to facilitate the decomposition of potassium chlorate is unsupported by experimental evidence, and, if existing, is inadequate to explain even a small fraction of the great facilitation produced by the oxides of manganese, iron, cobalt, nickel, and copper. The action of the latter substances would therefore appear to be entirely chemical."

THE discovery, or rather the isolation, of a new element has been announced by M. Demarçay, in the *Comptes Rendus*. Some fifteen years ago Sir William Crookes called attention to an anomalous band in the spectrum of samarium, which he attributed to a hypothetical meta-element which he called S^d . A few years later De Boisbaudran described a series of lines in the spark spectrum of samarium, and called the element which he supposed their cause Z' . The element causing the band and the lines has now been isolated by Demarçay and named *Europium*. It has an atomic weight of about 151, and in its properties lies between gadolinium and samarium.

A NEW and interesting case of isomorphism is noted by Guthrie in the *Berichte*, between one of the modifications of potassium tellurate, $K_2TeO_4 \cdot 2H_2O$, and potassium osmate $K_2OsO_4 \cdot 2H_2O$. Mixed solutions of these two salts crystallize out together. This is one of the very few instances in which tellurium shows an analogy with the metals of the eighth group of the periodic system.

A PAPER has recently appeared in the *Journal de Pharmacie et de Chimie*, by E. Jungfleisch, on the 'Sulfur Industry in Sicily.' The output has increased from 150,000 tons in 1860 to 447,000 tons in 1898. The world's production at these two dates was 157,000 and 488,000 tons, Sicily thus furnishing about 90 per cent. The price during this period has not varied very largely, having been 120 francs in 1860, 142 in 1875, 100 in 1880 and 92 francs a ton in 1898. The amount of sulfur in the ore varies from the very rare richness of 75 per cent. to 20 or 25 per cent. of sulfur in the ordinary ore. A 30-per cent. ore is considered rich, while ores are worked with as little as 10 or even 8 per cent. Poorer ores than this cannot be worked profit-

ably. The older methods of obtaining sulfur from its ore by setting fire to it in covered heaps or in kilns, where the sulfur itself served as fuel, have been discarded both on account of the waste and because of the intolerable nuisance to which the fumes of the burning sulfur gave rise. Coal is in general used as fuel, although very expensive. Extraction of the sulfur with carbon bisulfid or with a concentrated solution of calcium chlorid is in many cases used, but the only method in which no noxious fumes are generated is the extraction with steam under pressure. The extent of the industry is rapidly increasing and Sicily will long continue to supply the major part of the world's production.

The use of sulfur as a fungicide is rapidly increasing in the continental vineyards, and for this purpose it is necessary that the sulfur shall be in the most finely divided condition possible. Flowers of sulfur were at first used, and then ground and sifted refined sulfur, but a large portion of even this was wasted on account of the size of the particles. 'Blown' sulfur (*zolfo ventilato*) has lately come into extensive use. The finely ground sulfur is carried by an endless chain into a strong current of air, or for the purpose of avoiding explosions, of gases as free as possible from oxygen. The sulfur dust is carried into large settling chambers where all the larger particles are separated by their more rapid deposition. The sulfur dust thus obtained is pale yellow, resembling precipitated sulfur, and is found to be very satisfactory for fungicidal purposes.

J. L. H.

CURRENT NOTES ON PHYSIOGRAPHY.

PHYSIOGRAPHIC GEOLOGY.

^{coll} THE increasing recognition of physiography as related to geology is illustrated in Brigham's excellent contribution to the Twentieth Century series ('A Text-book of Geology,' New York, Appleton, 1901, pp. 477, many illustrations). A chapter of forty pages in the middle of the book, devoted to 'Physiographic Structures,' presents a compact epitome of the subject, including a consideration of forms as the result of processes, with a brief exposition of the cycle of erosion and development of drainage. On

the other hand, physiographic discipline is not likely to be gained in forty pages, as appears from the scanty treatment of so important a matter as the adjustment of drainage (284-), the explanation of which, as here given, can hardly be appreciated by those who do not already understand it. It may be questioned whether the categorical method of separating folded structures (223-) from the origin and form of folded mountains (256-) is as effective a method of presenting the real earth to beginners as would be found in a closer connection of these naturally associated facts. The same may be said of volcanic processes (135-) and volcanic topography (262-), and of glacial processes (91-) and glacial topography (266-). There may be abundant precedent for the categorical arrangement, and some justification for it in teaching; but a more natural method would bring process and form closer together.

GLACIAL LAKES IN MINNESOTA.

WINCHELL summarizes the history of twenty-six 'Glacial Lakes in Minnesota' (*Bull. Geol. Soc. Amer.*, XII., 1901, 109-128, map), whose geographical consequences are seen in gravel and silt deposits, shore lines and especially in outlet channels. The lake waters were held up by the retreating ice lobes of the Superior and Red river troughs. The most famous of them is Lake Agassiz, so fully described by Upham (*Monogr. XXV.*, U. S. Geol. Surv.). The others were much smaller, and their outlines are at present but imperfectly traced. The outlet channels are of moderate depths, but are usually well defined by banks carved in till; the channel floors are sometimes without streams, sometimes occupied by small streams, sometimes partly covered with shallow ponds or sloughs. The fuller details of this complicated lake system will afford material for local studies for years to come.

ESKER LAKES IN INDIANA.

DRYER, who has already described the 'morainic lakes of Indiana' ('Studies in Indiana Geography,' *Terre Haute*, 1897, 53-60), now gives an account of 'certain peculiar eskers and esker lakes of northeastern Indiana,' (*Journ. Geol.*, IX., 1901, 123-129, 2 maps). The region concerned is traversed by a series of massive

moraines, the joint product of the Erie and Saginaw lobes of the Laurentide ice sheet. Unusual features abound. "Half-filled valleys and abnormal drainage lines, isolated knobs and morainic outliers, clusters and chains of lakes, kettles and kames conspire with esker-like ridges to produce a type of topography and scenery which seems artificial and almost bizarre." Two of these lakes, High and Gordy's, owe their existence and outline to the presence of eskers, whose origin is ascribed to deposition in tunnels or crevasses in the wasting ice sheet.

THE ONTARIO COAST.

THE Ontario coast between Fairhaven and Sodus bays (near Oswego, N. Y.) is described by J. O. Martin, of Cornell (*Amer. Geol.*, XXVII., 1901, 331-334), as consisting of truncated drumlins connected by stony beaches which enclose bays and marshes. Active 'long-shore movement was noted when waves came obliquely on the shore; a cobble weighing seven ounces was moved sixteen yards in ten minutes by waves whose breaking height was a foot. The recession of the shore line is rapid, in some cases several feet a year. The farmers know this, as they have to set back their shore fences from time to time. Several submerged boulder pavements, having the outline of drumlins but standing at a considerable distance off shore, seem to indicate former drumlins now swept away.

GLACIAL CORRIES IN THE CARPATHIANS.

RECALLING a recent note on corries in the Bighorn Mountains of Wyoming, reference may be made to de Martonne's studies of similar forms in the Carpathians ('*Sur la Formation des Cirques*, *Ann. de Géogr.*, X., 1901, 10-16. See also *Bull. Soc. Géol. France*, XXVIII., 1900, 275-319, and *Bull. Soc. Sci. Bucharest-Roumanie*, IX., 1900, No. 4). After a careful study of several examples, this author concludes not only that cirques or corries are certainly of glacial origin, but that they are as safe indication of glacial action as moraines, striations and rounded rocks; that they are of longer duration than the latter, and hence of greater value for the detection of somewhat remote glacial periods; and that they give definite indications of the character of the glaciation by

which they were produced, being due to glaciers of the Pyrenean type, and not to a general nor to a local ice sheet. High mountains may thus owe a significant share of their form to glaciation, although whether de Martonne would go as far in this direction as Richter has (see *SCIENCE*, April 5, 1901) does not appear.

W. M. DAVIS.

SHORTER ARTICLES.

DEFINITIONS OF PHYSICAL QUANTITIES.

THE standards of 'scholarship' must be essentially alike in all branches of knowledge, although differences in detail will show themselves according to the subject. I suppose that the attainment of these standards in the physics of to-day must include accuracy in conceiving fundamental quantities and their connection with each other. Within the past half century much careful thought has been devoted to gaining such clear conceptions and constructing a framework of relation among them. In proportion as the younger physicists inherit the results of that thought undiminished, they will themselves be trained for discriminating and exact thinking. It is therefore a matter of regret that some of our leading authorities are habitually lax in presenting certain definitions that are built into the foundations of mathematical physics. I refer particularly to deliberate statements found in text-books of great general excellence. These are fair marks for criticism, because they must aim at consistent and systematic exposition, and because they influence strongly minds that are in the formative stage. Their example should not encourage a student to confound ideas that are really distinct, nor to tolerate inaccuracy in himself. This can be said without implying a demand for pedantic nicety in writing for experts, who are able to catch the right cue, even from an elliptical expression. I shall illustrate my meaning with a few quotations from Professor Thomson's '*Elements of the Mathematical Theory of Electricity*,' and from Professor Webster's '*Theory of Electricity and Magnetism*.' These are chosen because they are books of acknowledged value; at the present time each may be taken to register high-water mark within its own range. Since they are representative, we are

all concerned that they should everywhere furnish good models.

Let us first take the general law of inverse square, on account of its widespread application. We find the definition of 'Newtonian Forces, the most familiar examples of which are the mutual attractions of the sun and the planets' (Webster, p. 113), followed by the general expression for potential energy in such cases (p. 114). The latter contains no indication of the factor which becomes gravitation constant, or dielectric constant, or permeability factor; yet it has been stated previously (p. 111) that "Potential energy is defined as work. The unit of energy is, therefore, the *erg*." The medium-factors for electric and magnetic phenomena are introduced later (p. 354), but the gravitation constant is nowhere restored in the developments, so far as I am aware.

The potential function, or potential, is very commonly defined as representing so much work. Thus, "The potential at *P* is the work done by the electric forces when the unit charge is taken from *P* to an infinite distance" (Thomson, p. 27). Or we are told that the potential function is obtained as a particular value of the potential energy, when one mass-factor is unity (Webster, p. 144). This is inconsistent with the dimensions of potential as generally accepted, and as given by the authors themselves (Thomson, p. 449; Webster, p. 559). It is consistent, however, with their definition of field as a force. The negative vector-parameter of the potential function is "The strength of the field, that is, the force experienced by a unit of mass, concentrated at the point in question" (Webster, p. 144). "The electric intensity [field] is the force acting on a small body charged with unit positive charge, when placed at this point" (Thomson, p. 13). But the dimensions of field are not those of force. Electromotive force, as difference of potential, is then of course work also; we find this explicitly stated (Thomson, p. 282; Webster, p. 333). Current, again, is work as well. " $W = 4\pi i$. Thus the work [*W*] done on unit pole, when it travels round a closed curve, * * * is equal to $4\pi i$, if *i* is the strength of the current" (Thomson, p. 325). Professor Webster gives this in the form $\Omega = I\omega$

(p. 413). Here Ω is magnetic potential, *I* current and ω solid angle.

The clue to all these confusions (except the first) is the same elementary consideration. There is a failure to distinguish, in the context and in set terms, between a numerical equality, and a 'physical equation' in which the quantities equated are of the same dimensions. But a sense of such differences must be cultivated, as a part of correct physical thought; although they may be ignored sometimes for the immediate purposes of the mathematician or of numerical determinations in the laboratory. It is probable that repeated contact with statements like those cited dulls our first impression of the contradictions in them. In order to restore its vividness, we need only to construct parallel instances, with which custom has not familiarized us. Thus, density is mass; that is, the mass of a unit volume. In a similar (numerical) sense, force, or momentum, or kinetic energy is mass in special cases. I have pointed out elsewhere ('Principles of Mechanics,' p. 242) that the true dimensional relations for the electrical quantities can be preserved very simply by defining field and potential, respectively, as force and work *per unit* (in the body affected) of the measured quality that is subject to the influences of the particular field. There is no unclearness if the (dimensional) division is indicated by this verbal device or its equivalent.

F. SLATE.

UNIVERSITY OF CALIFORNIA.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THERE is not much to add to the information we gave last week in regard to the Glasgow meeting of the British Association. The president of the Association was directed to write a letter to the American embassy in the name of the Association, containing expressions of regret on the death of President McKinley.

The attendance was 1,912, distributed among the different classes as follows: 310 old life members, 37 new life members, 374 old annual members, 131 new annual members, 794 associates, 246 ladies and 20 foreign members. This is a smaller attendance than at the previous

Glasgow meetings of 1855 and 1876, the Glasgow Exposition and the previous meeting of the International Engineering Congress having apparently interfered with the number of new annual members and associates.

The following grants for scientific purposes amounting to £1,000 were made :

Mathematics and Physics.—Electrical standards, £40 ; seismological observations, £35 ; investigation of the upper atmosphere by means of kites, £75 ; magnetic observations at Falmouth, £80.

Chemistry.—Relation between absorption spectra and constitution of organic substances, £20 ; wave length tables, £5 ; properties of metals and alloys affected by dissolved gases, £40.

Geology.—Photographs of geological interest, £5 ; life zones in British carboniferous rocks, £10 ; exploration of Irish caves, £45.

Zoology.—Table at the Zoological Station, Naples, £100 ; index generum et specierum animalium, £100 ; migration of birds, £15 ; structure of coral reefs of Indian region, £50 ; compound sascidians of the Clyde area, £25.

Geography.—Terrestrial surface waves, £15.

Economic Science and Statistics.—Legislation regulating women's labor, £30.

Mechanical Science.—Small screw-gauge, £20 ; resistance of road vehicles to traction, £50.

Anthropology.—Silchester excavation, £5 ; ethnological survey of Canada, £15 ; age of stone circles, £30 ; anthropological teaching, £3 ; exploration in Crete, £100 ; anthropometric investigations of native Egyptian soldiers, £15 ; excavations on the Roman site at Gelligaer, £5.

Physiology.—Changes in hæmoglobin, £15 ; work of mammalian heart under influence of drugs, £20.

Botany.—Investigations of the cyanophycene, £10 ; the respiration of plants, £15.

Educational Science.—Reciprocal influence of universities and schools, £5 ; conditions of health essential to carrying on work in schools, £2.

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

INFORMATION in regard to the annual meetings of the French Association for the Advancement of Science is not easy to obtain. The secretaries do not answer letters addressed to them, and the French journals contain very inadequate reports of the proceedings. The *Revue Scientifique* does indeed publish annually the address of the president and the reports of the secretary and treasurer. None of the

French journals, however, gives the programs and officers, or similar information.

The meeting this year was held at Ajaccio, in the Island of Corsica—the date is not given in any of the French journals at hand—and the president was M. E. T. Hamy, whose address was on 'The Beginnings of Anthropology in France.' The report of the secretary contains practically nothing but a list of the more eminent members who have died during the year, and a list of those on whom prizes and honors have been conferred. The report of the treasurer is the only document that gives us information in regard to the workings of the Association. This bears witness to transactions of considerable magnitude. The permanent funds of the Association amount to about \$270,000. They were increased last year by three legacies amounting to \$6,500, and two legacies have already been received this year, one of which amounts to \$6,000. It seems strange that in France, where comparatively so little is given or bequeathed for public purposes, the French Association has been given a considerable endowment which is continually increased, whereas the American Association receives practically no part of the large sums that are annually given or bequeathed for educational and scientific purposes. It seems almost certain that if those who give money understand the needs of our Association, and the fact that the French Association from the income of its invested funds is able to support over fifty researches, the American Association will soon be placed in the same condition. As regards current income from the members and its relation to the expenses, the American Association compares favorably with that of France. Though the French Association carries on its books a very large number of members, many of them apparently do not pay the annual fees, for the total receipts are only \$9,000, whereas the expenses of administration and publication are over \$10,000, and the cost of the meeting last year was \$3,000. For this meeting the City of Paris made a special subsidy.

Among the researches for which the largest appropriations have been made are: M. Turpan, for work on Hertzian waves ; M. Cheval-

lier, for the publication of his botanical researches in Africa; M. Turquan, for the publication of his work on statistics; Abbe Breuil, for paleontological researches in l'Aisne; M. Cartailhac, for prehistoric researches in Sardinia; M. Chantre, towards the publication of his work on quaternary man in the Valley of the Upper Rhône; the Paris School of Anthropology, for researches on the antiquity of man; MM. Fournier and Repelin, towards the publication of their explorations in Provence; M. Gentil, for excavations in Algeria; and M. Rivière, for researches in the caves of Mouthe.

SCIENTIFIC NOTES AND NEWS.

PROFESSOR WOLCOTT GIBBS has been appointed one of the five official representatives of Harvard University at the bi-centennial exercises of Yale University.

DR. CARROLL D. WRIGHT, U. S. Commissioner of Labor, has been elected a member of the Paris Institute of Sociology.

WILLIAM JAMES, professor of philosophy, George Lincoln Goodale, professor of natural history and director of the Botanical Garden, and Maxime Bôcher, assistant professor of mathematics, have returned to their work at Harvard after a year's leave of absence spent abroad. We regret to learn that the health of Dr. B. O. Peirce, professor of mathematics and natural philosophy, is such that it has been necessary to extend his leave of absence.

MR. FRANK B. LITTELL, of the U. S. Naval Observatory, has been appointed a professor of mathematics in the navy.

PROFESSOR H. W. CONN, of Wesleyan University, has been appointed lecturer on agricultural bacteriology at the Connecticut Agricultural College, and has been put in charge of dairy experimentation at the Storrs Experiment Station. The experimental work is to be done partly at Storrs and partly in the biological laboratory at Wesleyan University.

DR. DAVID T. DAY, chief of the department of mines and metallurgy in the St. Louis Exposition, has added these experts to the department: Professor J. A. Holmes, state geologist of North Carolina; George F. Kunz, gem expert, with Tiffany & Co., New York City; John

Birkinbine, president of the Franklin Institute, Philadelphia; E. W. Parker, editor of the *Engineering and Mining Journal*, New York City; Jefferson Middleton, geological survey, Washington, D. C., clay expert; and Charles C. Yale, Mint Bureau, San Francisco.

WE learn from *Nature* that owing to losses in the staff by death and retirement, the following appointments have been made on the Geological Survey of the United Kingdom: Dr. J. S. Flett has been selected to assist in the petrographical work of the Survey, Mr. J. Allen Howe and Mr. H. H. Thomas have been appointed geologists on the English staff, Mr. H. B. Muff on the Scottish staff and Mr. W. B. Wright on the Irish staff.

PROFESSOR W. H. HOLMES, of the U. S. National Museum, has gone to Indian Territory to make collections of Indian remains.

MR. CLOUD RUTTER, scientific assistant of the U. S. Fish Commission, is on the Pacific Coast for the purpose of gathering salmon statistics, with headquarters on the Sacramento River near Rio Vista.

MR. S. W. LOPER, curator of the museum of Wesleyan University, spent the greater part of the summer in the study of the Cambrian formation of Cape Breton Island for the United States Geological Survey. Mr. Loper made a large collection of fossils.

It is reported that Mr. H. DeWindt and Mr. George Harding will make a third attempt to accomplish an overland journey via Bering Straits between Europe and America.

THE steamship *Windward* has arrived at Newfoundland bringing Mr. Robert Stein, of Washington, and Mr. Samuel Warmbath, of Boston. The *Windward* will return next summer for Lieutenant Peary.

A TELEGRAPH from Alice Springs on July 19 states that Professor Baldwin Spencer's expedition had finished its work at Barrow Creek, where six weeks had been spent among the Kaitish and Ummatjera tribes. The next main camp was to be formed at Tennant's Creek, about 150 miles further north.

A GRANITE monument in memory of James Bowman Lindsay, an investigator and an in-

ventor who fifty years ago made experiments in connection with wireless telegraphy, was unveiled on, September 14, at Dundee, Scotland, by Sir William Preece.

WE regret to learn that Edward W. Claypole, professor of geology at Throop Institute, Pasadena, Cal., died quite suddenly at Long Beach, Cal., on August 17, aged sixty-six years. Professor Claypole was an Englishman and had degrees of A.B. and Sc.D. from the University of London. He came to this country in 1872 and through the influence of Rev. Ed. Everett Hale, was appointed professor of natural science at Antioch College, Ohio, where he served until 1881. He was paleontologist to the second Geological Survey of Pennsylvania for two years and professor of geology at Buchtel College, Ohio, from 1883 to 1897, when he sought the milder climate of Southern California in the interest of his wife's frail health. Dr. Claypole was a geologist noted on two continents. He was a fellow of the Geological Societies of London, Edinburgh and America, and a fellow of the American Association, having served at different times as both section president and secretary of geology. He had published 'The Lake Age in Ohio' and was a frequent contributor to American and foreign scientific journals.

DR. ABRAM LITTON, who for fifty years filled the chair of chemistry both at Washington University and the St. Louis Medical College, died at his home in St. Louis on September 22 aged eighty-seven years.

THE position of assistant pomologist in the Bureau of Plant Industry of the Department of Agriculture will be filled as the result of a civil service examination on November 2. The examination is entirely on the subjects of the office, and applicants are not required to be present at any special place. On October 22, an examination will be held to fill the position of assistant in the Dairying Division of the Bureau of Animal Industry at a salary of \$1,200. The examination will be held in any city in the United States where rural free delivery has been established.

THE subject of the Fiske Fund Prize Essay (\$200) for the year 1902 is 'Serumtherapy in

the Light of the Most Recent Investigations.' Further information may be obtained from the secretary of the Board of Trustees of the Fiske Fund, Dr. Halsey DeWolf, 212 Benefit Street, Providence, R. I.

MR. W. C. MILLS, curator of the Ohio State Archeological and Historical Society, has returned to Columbus, Ohio, from a successful season of exploration in various part of Ohio. He excavated the noted Adena Mound, situated in sight of Chillicothe and perhaps the largest mound in the Scioto Valley, being 26 feet high and 445 feet in circumference. The mound contained about 6,000 cubic yards, all of which was turned over and examined. Thirty-two skeletons with many implements and ornaments were found. One specimen is a very fine carving about 8 in. long, representing the human figure. In execution it is not surpassed by any of the objects found in mounds in the Scioto Valley.

THE German Mathematical Society held its annual meeting from September 22d to 28th at Hamburg in affiliation with the Congress of German Men of Science and Physicians. Twenty-one papers are to be found on the program issued in advance of the meeting, and it is stated that the Society would consider the publication of a monthly journal in the place of the present *Jahresbericht*.

WE learn from the London *Times* that the Congress of the International Association for Testing Materials was held at Budapest, from September 9 to 14, under the presidency of Professor L. von Tetmajer, and was largely attended by engineers from all parts of the world. The delegates present included four from England, 41 from Austria, three from Belgium, nine from Denmark, two from the United States, 36 from France, 152 from Hungary, 70 from Germany, three from Norway, 12 from Italy, 26 from Russia, one from Roumania, three from Spain, one from Servia, ten from Switzerland and five from Sweden. After an inaugural presidential address and address of welcome from the Hungarian authorities, a representative of each country was elected an honorary president of the congress, Mr. Bennett H. Brough being chosen for England, and Professor H. M. Howe for the United States.

The other English and American members present were: Sir William H. Bailey (Manchester), Mr. Bertram Blount (London), Dr. C. J. Renshaw (Ashton-on-Mersey), and Dr. R. Moldenke (New York). In addition to the various reports of committees dealing with technical problems, the following papers dealing with metals were read and discussed: 'On the Measurement of Internal Tension,' by Mr. Mesnager (Paris); 'On the Forms of Carbon in Iron,' by Baron Jüptner (Leoben); 'On Brinell's Researches,' by Mr. A. Wahlberg (Stockholm); 'On the Testing of Metals by Means of Notched Bars,' by M. H. Le Chatelier (Paris), by M. G. Charpy (Paris), and by Professor Belebubsky (St. Petersburg); 'On Micrographical Researches on the Deformation of Metals,' by Mr. F. Osmond (Paris); 'On Metallography,' by Mr. E. Heyn (Charlottenberg); 'On the Testing of Railway Material,' by Mr. E. Vanderheyem (Lyons); and 'On the International Iron and Steel Laboratory,' by Professor H. Wedding (Berlin). Several papers dealing with stone and mortars were also read, and an interesting lecture on the iron industry of Hungary was delivered by Professor Edvilles (Budapest).

It is now said that the German government has authorized the purchase of the astronomical instruments originally taken from Peking by the German soldiers.

IN addition to the *Lucania*, three other steamships of the Cunard Line—the *Campania*, the *Umbria* and the *Etruria*—will be fitted with Marconi's system of wireless telegraphy.

CONSUL HAYNES, of Rouen, under date of August 26, 1901, says that the metric system is compulsory in twenty countries, representing more than 300,000,000 inhabitants—Germany, Austria-Hungary, Belgium, Spain, France, Greece, Italy, Netherlands, Portugal, Roumania, Servia, Norway, Sweden, Switzerland, Argentine Republic, Brazil, Chile, Mexico, Peru, and Venezuela—and advises American exporters in dealing with any of these countries to adopt the system.

WE learn from the *Electrical World* that the International Statistical Institute will hold this year in Budapest, from September 20 until

October 5, an international exhibit of all kinds of machines and instruments which facilitate work with figures. The aim of the exhibit is to furnish to the most competent representatives of scientific and practical statistics assembled from different parts of the world the opportunity of gathering personal information about this kind of technical construction. The exhibit will include all kinds of inventions, engines and apparatus which are intended to facilitate work with figures in general, and especially those which are devised to facilitate the compilation of statistical data and to perform the necessary proportional calculations, and to accelerate and render more economical statistical labor; especially machines for adding, multiplying, dividing, tabulators, accounting machines for the combined compilation of data, etc.

It is announced that a commission, to be presided over by Sir Colin Scott-Moncrieff, is being appointed to lay down rules for control of irrigation works in India. In connection with this announcement the London *Times* quotes figures given in the annual review of irrigation issued recently in India. From them it appears that 22 of the large productive works realized a net revenue amounting to 9.52 per cent. on the capital outlay, while 13 others yielded only 0.79 per cent., reducing the average return to 7 per cent. The total area of the crops irrigated or protected exceeded 18½ millions of acres, being an increase of over three quarters of a million during the year. The principal enhancements were in respect to the Punjab canals, the area irrigated there exceeding all previous records by over 300,000 acres, while the net return on capital in respect to that province was as high as 10.24 per cent. Still more gratifying results may be looked for in the current year, since the great Jehlum Canal, begun in the autumn of 1898, is to be formally opened in October, and will irrigate a vast tract of country lying between the Chenab and Jehlum rivers, a great portion of which has hitherto lain waste. Other large projects are being carried out in the Punjab, and will, when ready, be worked on the lines so successfully adopted in the case of the Chenab colonies. The total surplus revenue earned since irrigation works were undertaken by government has been nearly ten millions

sterling. This is the purely financial result of irrigation, regarded as an investment, and the figure quoted has no reference to its economic value in increasing food supplies, in preventing famine, and in strengthening the position of the owners and occupiers of the land. Neither does it take into account the increase of land revenue received by the State, as a result of bringing waste tracts under cultivation.

UNIVERSITY AND EDUCATIONAL NEWS.

THE Severance Chemical Laboratory of Oberlin College was dedicated on September 26, the address being made by President Ira Remsen, of the Johns Hopkins University. At the conclusion of the dedicatory exercises it was announced that Mr. Lewis Severance, of New York City, the donor of the laboratory, had given the sum of \$40,000 for an endowment for the chair of chemistry.

THE University of Southern California at Los Angeles has obtained the \$100,000, of which \$25,000 was offered by Mrs. Anna Hough on condition that the balance be given. Mrs. Hough has now offered \$40,000 towards a second \$100,000.

BY the will of the late Mrs. Martha Callahan, \$20,000 is bequeathed to Tuskegee Normal and Industrial Institute of Tuskegee, Ala.

PROFESSOR GOLDWIN SMITH has given \$10,000 to the library of the University of Toronto.

AT a recent meeting of the corporation of Yale University it was decided that the house which Professor O. C. Marsh bequeathed to the University and which is now occupied by the Forest School shall be known officially as Marsh Hall, and the grounds about it as the Yale Botanical Garden.

AT the spring meeting of the trustees of Colby College, Waterville, Me., the department of geology was abolished, and it was decided that henceforth the teaching of geology should be by the assistant in chemistry. The determination was taken suddenly, the reason assigned for the action being purely a financial one. The abolition of the department necessarily legislates Dr. W. S. Bayley from the position which he has held during the past twelve years.

DR. STURGIS, of the Connecticut Agricultural Experiment Station, Professor Brinton, the State entomologist, and Professor Hopkins, of West Virginia University, have been appointed special lecturers in the Yale Forest School.

MR. EUGENE L. LEHNERT, of Clinton, Mass., has been elected professor of veterinary medicine at the Agricultural College at Storrs.

AT the Western Reserve University, Dr. F. W. Reichmann, of the University of Chicago, has been appointed instructor in physics; Dr. O. F. Tower has been promoted to be associate professor of chemistry.

DR. CHARLES M. HAZEN has been appointed professor of biology in Richmond College, at Richmond, Va.

THE following appointments have been made at the Illinois College, Jacksonville, Ill.: J. Bishop Tingle, Ph.D. (Munich), instructor of chemistry at the Lewis Institute, Chicago, to be professor of chemistry. J. B. Overton, Ph.D. (Chicago), graduate assistant in botany in the University of Chicago, to be professor of biology. J. H. Hall, Ph.D. (Yale), assistant in the University of Chicago, to be assistant professor of physics.

MISS S. M. HALLOWELL, professor of botany at Wellesley College, has been given leave of absence for the year and the work of the department will be under Miss Clara E. Cummings, assistant professor of botany.

EDWARD C. SCHNEIDER, Ph.D. (Yale, 1901), has been appointed to take charge of the work in biology at Tabor College, Tabor, Iowa.

MR. R. M. FERRIER, B.Sc. (Glasgow), M.Sc. (Durham), has been appointed to the chair of engineering at University College, Bristol, in succession to Dr. Stanton, who has received the appointment of superintendent of the engineering department in the National Physical Laboratory.

DR. ROKURO NAKASEKO, who has been the recipient of a University Fellowship at Yale during the past two years, has returned to Kyoto, Japan, to take charge of the instruction in physiological chemistry in the Scientific School there.

THE FISH FAUNA OF JAPAN, WITH OBSERVATIONS ON THE GEOGRAPHICAL DISTRIBUTION OF FISHES.*

THE JAPANESE FISH FAUNA.

THE group of islands which constitute the empire of Japan is remarkable for the richness of its animal life. Its variety in climatic and other conditions, its nearness to the great continent of Asia and to the chief center of marine life, the East Indian Islands, its relation to the warm Black current or Kuro Shiwo from the south and to the cold currents from the north, all tend to give variety and richness to the fauna of its seas. Especially is this true in the group of fishes. In spite of the political isolation of the Japanese Empire, this fact has been long recognized and the characteristic types of Japanese fishes have been well known to naturalists.

NUMBERS OF SPECIES OF JAPANESE FISHES.

At present about 900 species of fishes are known from the four great islands which constitute Japan proper, Hondo, Hokkaido, Kiusiu and Shikoku. About 200 others are known from the volcanic islands to the north and south. Of these 1,100 species, about fifty belong to the fresh waters. These are all closely allied to forms found

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

* Address to the Section of Zoology, Denver Meeting, 1901.

on the mainland of Asia, from which region all of them were originally derived.

FRESH-WATER FAUNAL AREAS.

Two faunal areas of fresh waters may be fairly distinguished, although broadly overlapping. The northern region includes the island of Hokkaido and the middle and northern part of the great island of Hondo. In a rough way, its southern boundary may be defined by Fuji Yama and the Bay of Matsushima. It is characterized by the presence of salmon, trout and sculpins, and northward by sturgeon and brook-lampreys. The southern area loses by degrees the trout and other northern fishes, while in its clear waters abound various minnows, gobies and the famous ayu, or Japanese dwarf salmon, one of the most delicate of food fishes. Sculpins and lampreys give place to minnows, loaches and chubs. Two genera, a sculpin* and a perch,† are confined to this region and seem to have originated in it, but like the other species, form a Chinese stock.

ORIGIN OF JAPANESE FRESH-WATER FISHES.

The question of the origin of the Japanese river fauna seems very simple. All the types are Asiatic. While most of the Japanese species are distinct, their ancestors must have been estrays from the mainland. To what extent river fishes may be carried from place to place by currents of salt water has never been ascertained. One of the most widely distributed of Japanese river fishes is the large hakone dace or chub. ‡ This has been repeatedly taken by us in the sea at a distance from any stream. It would evidently survive a long journey in salt water. An allied species § is found in the midway island of Tsushima, between Korea and Japan.

* *Trachidermis*.

† *Bryttosus*.

‡ *Leuciscus hakuensis* Günther.

§ *Leuciscus jouyi*.

FAUNAL AREAS OF MARINE FISHES.

The distribution of the marine fishes of Japan is mainly controlled by the temperature of the waters and the motion of the ocean currents. Five faunal areas may be more or less clearly recognized, and these may receive names indicating their scope, Kurile, Hokkaido, Nippon, Kiusiu, Kuro Shiwo and Riu Kiu. The first or Kurile district is frankly sub-Arctic, containing species characteristic of the Ochotsk Sea on the one hand, and of Alaska on the other. The second or Hokkaido* district includes this northern island and that part of the shore of the main island of Hondo† which lies to the north of Matsushima and Noto. Here the cold northern currents favor the development of a northern fauna. The herring and the salmon occupy here the same economic relation as in Norway, Scotland, Newfoundland and British Columbia. Sculpins, blennies, rockfish and flounders abound off the rocky shores and are seen in all the markets.

South of Matsushima Bay and through the Inland Sea as far as Kobe, the Nippon fauna is distinctly one of the temperate zone. Most of the types characteristically Japanese belong here, abounding in the sandy bays and about the rocky islands.

About the islands of Kiusiu and Shikoku, the semi-tropical elements increase in number and the Kiusiu fauna is less characteristically Japanese, having much in common with the neighboring shores of China, while some of the species range northward from India and Java. But these faunal districts have no sharp barriers. Northern fishes,‡ unquestionably of Alaskan origin, range as far south as Nagasaki, while certain semi-

* Formerly, but no longer, called Yeso in Japan.

† Called Nippon on foreign maps, but not so in Japan. where Nippon means the whole empire.

‡ *Pleuronichthys cornutus*; *Hexagrammos otakii*; *Ozorthe hexagramma*, etc.

tropical* types extend their range northward to Hakodate and Volcano Bay. The Inland Sea, which in a sense bounds the southern fauna, serves at the same time as a means of its extension. While each species has a fairly definite northern or southern limit, the boundaries of a faunal district as a whole must be stated in the most general terms.

The well-known boundary called Blackiston's Line, which passes through the Straits of Tsugaru, between the two great islands of Hondo and Hokkaido, marks the northern boundary of monkeys, pheasants and most tropical and semi-tropical birds and mammals of Japan. But as to the fishes, either marine or fresh water, this line has no significance. The northern fresh-water species probably readily cross it; the southern rarely reach it.

We may define as a fourth faunal area that of the Kuro Shiwo district itself, which is distinctly tropical and contrasts strongly with that of the inshore bays behind it. This warm 'Black Current,' analogous to our Gulf Stream, has its origin in part from a return current from the east, which passes westward through Hawaii, in part from a current which passes between Celebes and New Guinea. It moves northward by way of Luzon and Formosa, touching the east shores of the Japanese islands Kiusiu and Shikoku, to the main island of Hondo, flooding the bays of Kagoshima and Kochi, of Waka, Suruga and Sagami. The projecting headlands reach out into it and the fauna of their rock pools is distinctly tropical, as far to the northward as Tokio.

These promontories of Hondo, Waka, Ise, Izu, Misaki and Awa have essentially the same types of fishes as are found on the reefs of tropical Polynesia. The warmth of the off-shore currents gives the fauna of

Misaki its astonishing richness, and the wealth of life is by no means confined to the fishes. Corals, crustaceans, worms and molluscs show the same generous profusion of species.

A fifth faunal area, closely related to that of the Black Current, is formed by the volcanic and coral reefs of the Riu Kiu Archipelago. This fauna, so far as known, is essentially East-Indian, the genera and most of the species being entirely identical with those of the islands about Java and Celebes.

RESEMBLANCE OF THE JAPANESE AND MEDITERRANEAN FISH FAUNAS.

It has been noted by Dr. Günther that the fish fauna of Japan bears a marked resemblance to that of the Mediterranean. This likeness is shown in the actual identity of genera and species, and in their relation to each other. This resemblance he proposes to explain by the hypothesis that, at some recent period, the two regions, Japan and the Mediterranean, have been united by a continuous shore-line. The far-reaching character of this hypothesis demands a careful examination of the data on which it rests.

The resemblance of the two faunal areas, so far as fishes are concerned, may be stated as follows: There are certain genera* of shore fishes, tropical or semi-tropical, common to the Mediterranean and Japan, and wanting to California, Panama and the West Indies, and in most cases to Polynesia also. Besides these, certain others, found in deeper water (100 to 200 fathoms) are common to the two areas,† and have been rarely taken elsewhere.

* Of these, the principal ones are *Oxystomus*, *Myrus*, *Pagrus*, *Sparus*, *Macrorhamphosus*, *Cepola*, *Callionymus*, *Zeus*, *Uranoscopus*, *Lepidotrigla*, *Chelidonichthys*.

† Among these are *Beryx*, *Helicolenus*, *Lotella*, *Nettastoma*, *Centrolophus*, *Hoplostethus*, *Aulopus*, *Chlorophthalmus*, *Lophotes*.

* As *Halichoeres*, *Tetrapturus*, *Callionymus*, *Ariscopus*, etc.

SIGNIFICANCE OF RESEMBLANCE.

The significance of these facts can be shown only by a fuller analysis of the fauna in question, and those of other tropical and semi-tropical waters. If the resemblances are merely casual, or if the resemblances are shown by other regions, the hypothesis of shore continuity would be unnecessary or untenable. It is tenable if the resemblances are so great as to be accounted for in no other way.

Of the genera regarded as common, only two* or three are represented in the two regions by identical species, and these have a very wide distribution in the warm seas. Of the others, nearly all range to India, to the Cape of Good Hope, to Australia or to Brazil. They may have ranged farther in the past; they may even range farther at present. At the most, but two † are confined to the two districts in question. As equally great resemblances exist between Japan and Australia or Japan and the West Indies, the case is not self-evident, without fuller comparison. I shall, therefore, ask your attention to a somewhat fuller analysis of the evidence bearing on this and similar problems, with a view to the conclusions which may be legitimately drawn from the facts of fish distribution.

DIFFERENCES BETWEEN JAPANESE AND
MEDITERRANEAN FISH FAUNAS.

We may first, after admitting the alleged resemblances and others, note that differences are equally marked. In each region are a certain number of genera which we may consider as autochthonous. These genera are represented by many species or by many individuals in the region of their supposed origin, but are more scantily developed elsewhere. Such genera in Mediterranean waters are *Crenilabrus*, *Labrus*, *Spicara*, *Pagellus*, *Mullus*, *Boopis*, *Spondylosoma*,

* *Beryx*, *Hoplostethus* and perhaps *Macrorhamphosus*.

† *Lepadogaster*, *Myrus*.

Oblata. None of these occurs in Japan nor have they any near relatives there. Japanese autochthonous types, as *Pseudoblennius*, *Dymæria*, *Anoplus*, *Histioplerus*, *Monocentrus*, *Oplegnathus*, *Plecoglossus*, range southward to the Indies or to Australia, but all of them are totally unknown to the Mediterranean. The multifarious genera of Gobies of Japan show very little resemblance to the Mediterranean fishes of this family, while blennies, labroids, scaroids and scorpenoids are equally diverse in their forms and alliances. To the same extent that likeness in faunæ is produced by continuity of means of dispersion, is it true that unlikeness is due to breaks in continuity. Such a break in continuity of coast-line, in the present case, is the Isthmus of Suez, and the unlikeness in the faunas is about what such a barrier should produce.

SOURCES OF FAUNAL RESEMBLANCES.

There are two main sources of faunal resemblances; first, the absence of barriers permitting the actual mingling of the species; second, the likeness of temperature and shore configuration favoring the development of the same or analogous types. If the fish faunæ of different regions have mingled in recent times, the fact would be shown by the presence of the same species in each region. If the union were of a remote date, the species would be changed, but the genera might remain identical.

In case of close physical resemblances in different regions, as in the East Indies and West Indies, like conditions would favor the lodgment of like types, but the resemblance would be general, the genera and species being unlike. Without doubt, part of the resemblance between Japan and the Mediterranean is due to similarity of temperature and shores. Is that which remains sufficient to demand the hypothesis of a former shore-line connection?

EFFECTS OF DIRECTION OF SHORE-LINE.

We may first note that a continuous shore-line produces a mingling of fish-faunas only when not interrupted by barriers due to climate. A north and south coast-line, like that of the East Pacific, however unbroken, permits great faunal differences. It is crossed by the different zones of temperature. An east and west shore-line lies in the same temperature. In all cases of the kind which now exist on the earth (the Mediterranean, the Gulf of Mexico, the Caribbean Sea, the shores of India), even species will extend their range as far as the shore-line goes. The obvious reason is because such a shore-line rarely offers any important barrier to distribution, checking dispersion of species. We may, therefore, consider the age and nature of the Isthmus of Suez and the character of the faunas it separates.

NUMBERS OF GENERA IN DIFFERENT FAUNAS.

For our purposes, the genera must be rigidly defined, a separate name being used in case of each definable difference in structure. The wide-ranging genera of the earlier systematists were practically cosmopolitan, and their distribution teaches us little. Using the modern definition of genus, we find in Japan 483 genera of marine fishes; in the Red Sea, 225; in the Mediterranean, 231. In New Zealand 150 are recorded; in Hawaii, 171; 357 from the West Indies, 187 from the Pacific coast of tropical America, 300 from India, 450 from the East-Indian islands and 427 from Australia.

Of the 483 genera ascribed to Japan, 156 are common to the Mediterranean also, 188 to the West Indies and Japan, 169 to the Pacific coast of the United States and Mexico. With Hawaii Japan shares 90 genera, with New Zealand 62; 204 are common to Japan and India, 148 to Japan and the Red Sea, most of these being found

in India also. 200 genera are common to Japan and Australia.

AFFINITIES OF JAPANESE FAUNA.

From this, it is evident that Japan and the Mediterranean have much in common, but apparently not more than Japan shares with other tropical regions. Japan naturally shows most likeness to India, and next to this to the Red Sea. Proportionately less is the resemblance to Australia, and the likeness to the Mediterranean seems much the same as that to the West Indies, or to the Pacific coast of America.

But, to make these comparisons just and effective, we should consider not the fish fauna as a whole; we should limit our discussion solely to the forms of equatorial origin. From the fauna of Japan we may eliminate all the genera of Alaskan-Aleutian origin, as these could not be found in the other regions under comparison. We should eliminate all pelagic and all deep-sea forms, for the laws which govern the distribution of these are very different from those controlling the shore fishes, and most of the genera have reached a kind of equilibrium over the world.

SIGNIFICANCE OF RARE FORMS.

We may note also, as a source of confusion in our investigation, that numerous forms found in Japan and elsewhere are very rarely taken, and their real distribution is unknown. Some of these will be found to have, in some unexpected quarter, their real center of dispersion. In fact, since these pages were written, I have taken in Hawaii representatives of three* genera which I had enumerated as belonging chiefly to Japan and the West Indies. Such species may inhabit oceanic plateaus, and find many halting places in their circuit of the tropical oceans. We have already discovered that

* *Antigonia*, *Etelis*, *Emmelichthys*.

Madeira, St. Helena, Ascension and other volcanic islands constitute such halting places. We shall find many more such, when the deeper shore regions are explored, the region between market-fishing and the deep-sea dredgings of the *Challenger* and the *Albatross*. In some cases, no doubt, these forms are verging on extinction and a former wide distribution has given place to isolated colonies.

The following table shows the contents, so far as genera are concerned, of those equatorial areas in which trustworthy catalogues of species are accessible. It includes only those fishes, of stationary habit, living in less than 200 fathoms. It goes without saying that considerable latitude must be given to these figures, to allow for errors, omissions, uncertainties and differences of opinion.

EXTENSION OF INDIAN FAUNA.

From the above tables it is evident that the warm-water fauna of Japan, as well as that of Hawaii, is derived from the great body of the fauna of the East Indies and Hindostan; that the fauna of the Red Sea is derived in the same way; that the fauna of the Mediterranean bears no especial resemblance to that of Japan, rather than to other elements of the East Asiatic fauna in similar conditions of temperature, and no greater than is borne by either to the West Indies; that the faunas of the sides of the Isthmus of Suez have relatively little in common, while those of the two sides of the Isthmus of Panama show large identity of genera, although few species are common to the two sides. Of the 255 genera recorded from the Panama region, 179, or over 70 per cent., are also in the West Indies; while 68, or more than 30 per cent. of the number, are limited to the two regions in question.

THE ISTHMUS OF SUEZ AS A BARRIER TO DISTRIBUTION.

With the aid of the above table, we may examine further the relation of the fauna

* *Holotrachys, Cirrhitops, Perkinsia.*

† *Malacanthus.*

of Japan to that of the Mediterranean. If a continuity of shore-line once existed, it would involve the obliteration of the Isthmus. With free connection across this isthmus, the fauna of the Red Sea must have been once practically the same as that of the Mediterranean. The present differences must be due to later immigrations to one or the other region, or to the extinction of species in one locality or the other, through some kind of unfitness. In neither region is there evidence of extensive immigration from the outside. The present conditions of water and temperature differ a little, but not enough to explain the difference in fauna. The Red Sea is frankly tropical and its fauna is essentially Indian, much the same, so far as genera are concerned, as that of Southern Japan. The Mediterranean is at most not more than semi-tropical and its fishes are characteristically European. Its tropical forms belong rather to Guinea than to the East Indies. With the Red Sea the Mediterranean has very little in common, not so much, for example, as has Hawaii. Forty genera of shore fishes (and only fifty of all fishes) are identical in the two regions, the Mediterranean and the Red Sea. Of those, every one is a genus of wide distribution, found in nearly all warm seas. Of shore fishes, only one genus in seven is common to the two regions. Apparently, therefore, we cannot assume a passage across the Isthmus of Suez within the lifetime of the present genera. Not one of the types alleged to be peculiar to Japan and the Mediterranean is thus far known in the Red Sea. Not one of the characteristically abundant Mediterranean types* crosses the Isthmus of Suez, and the distinctive Red Sea and Indian types† are equally

* As *Crenilabrus, Labrus, Symphodus, Pagellus, Spondyliosoma, Sparisoma.*

† As *Chætodon, Lethrinus, Sphærodon, Abudedefduf,* etc.

wanting in the Mediterranean. The only genera which could have crossed the Isthmus are certain shallow-water or brackish-water forms, sting-rays, torpedoes, sardines, eels and mullets, widely diffused through the East Indies and found also in the Mediterranean. The former channel if one ever existed, had, therefore, much the same value in distribution of species, as the present Suez Canal.

GEOLOGICAL EVIDENCE OF SUBMERSION OF THE ISTHMUS OF SUEZ.

Yet, from geological data, there is strong evidence that the Isthmus of Suez was submerged in relatively recent times. The recognized geological maps of the Isthmus show that a broad area of post-Pliocene or Pliocene deposits constitutes the Isthmus and separates the nummulitic hills of Suez from their fellows about thirty miles to the eastward. The northern part of the Isthmus is alluvium from the Nile, and its western part is covered with drifting sands. The Red Sea once extended farther north than now and the Mediterranean farther to the southeast. Assuming the maps to be correct, the Isthmus must have been open water in the late Pliocene or post-Pliocene times.

Admitting this as a fact, the difference in the fish fauna shows that the waters over the submerged area must have been so shallow that rock-loving forms did not and could not cross it. Moreover, the region must have been overspread with silt-bearing fresh waters from the Nile. To such fishes as *Chatodon*, *Holocentrus*, *Thalassoma*, of the Red Sea, or to *Crenilabrus*, *Boops* and *Zeus*, of the Mediterranean, such waters would form a barrier as effective as the sand-dunes of to-day.

CONCLUSIONS AS TO THE ISTHMUS OF SUEZ.

We are led, therefore, to these conclusions:

1. There is no evidence, derivable from the fishes, of the submergence of the Isthmus of Suez.

2. If the isthmus was submerged in Pliocene or post-Pliocene times, the resultant channel was shallow and muddy, so that ordinary marine fishes or fishes of rock bottoms, or of deep waters, did not cross it.

3. It formed an open water to brackish-water fishes only.

4. The types common to Japan and the Mediterranean did not enter either region from the other, by way of the Red Sea.

5. As most of these are found also in India or Australia or both, their dispersion was probably around the south coast of Africa or by the Cape of Good Hope.

THE CAPE OF GOOD HOPE AS A BARRIER TO FISHES.

The fishes of the Cape of Good Hope are not well enough known for close comparison with those of other regions. Enough is known of the Cape fauna to show its general relation to those of India and Australia. The Cape of Good Hope lies in the South Temperate zone. It offers no absolutely impassable barrier to the tropical fishes from either side. It bears a closer relation to either the Red Sea or the Mediterranean than they bear to each other. It is, therefore, reasonable to conclude that the transfer of tropical shore fishes of the Old World between the Atlantic and Pacific, in recent times, has taken place mainly around the southern point of Africa. To pelagic and deep-sea fishes the Cape of Good Hope has offered no barrier whatever. To ordinary fishes it is an obstacle, but not an impassable one. This the fauna itself shows. It has, however, not been passed by many tropical species, and by these only as the result of thousands of years of struggle and point-to-point migration.

RELATIONS OF JAPAN TO MEDITERRANEAN
EXPLAINABLE BY PRESENT CONDITIONS.

We may conclude that the resemblance of the Mediterranean fish fauna to that of Japan or India is no more than might be expected, the present contour of the continents being permanent for the period of duration of the present genera and species. The imagined removal of barriers on any large scale would necessitate much closer resemblances than those which actually exist.

THE ISTHMUS OF PANAMA AS A BARRIER
TO DISTRIBUTION.

Conditions in some regards parallel with those of the Isthmus of Suez exist in but one other region—the Isthmus of Panama.

IDENTITY OF GENERA ON TWO SHORES OF
THE ISTHMUS OF PANAMA.

Here the first observers were very strongly impressed by the resemblance of forms. Nearly half the genera found on the two sides of this isthmus are common to both sides. Taking those of the Pacific shore for first consideration, we find that three fourths of the genera of the Panama fauna occur in the West Indies as well.

This identity is many times greater than that existing at the Isthmus of Suez. Moreover, while the Cape of Good Hope offers no impassable barrier to distribution, the same is not true of the southern part of South America. The subarctic climate of Cape Horn has doubtless formed a complete check to the movements of tropical fishes for a vast period of geologic time.

UNLIKENESS OF SPECIES ON THE SHORES OF
THE ISTHMUS OF PANAMA.

But curiously enough, this marked resemblance is confined chiefly to the genera and does not extend to the species on the two shores.

Of 1,400 species of fishes recorded from tropical America north of the Equator, only about 70 are common to the two coasts. The number of shore fishes common is still less. In this 70 are included a certain number of cosmopolitan types which might have reached either shore from the Old World.

A few others invade brackish or fresh waters and may possibly have found their way, in one way or another, across the Isthmus of Nicaragua. Of fishes strictly marine, strictly littoral, and not known from Asia or Polynesia, scarcely any species are left as common to the two sides. This seems to show that no waterway has existed across the isthmus within the lifetime, whatever that may be, of the existing species. The close resemblance of genera shows apparently with almost equal certainty that such a waterway has existed, and within the period of existence of the groups called genera. How long a species of fish may endure unchanged no one knows, but we know that in this regard great differences must exist in different groups. Assuming that different species crossed the Isthmus of Panama in Miocene times, we should not be surprised to find that a few remain to all appearances unchanged; that a much larger number have become 'representative' species, closely related forms retaining relations to the environment to those of the parent form, and, finally, that a few species have been radically altered.

This is exactly what has taken place at the Isthmus of Panama with the marine shore fishes. Curiously enough, the movement of genera seems to have been chiefly from the Atlantic to the Pacific. Certain characteristic genera* of the Panama region have not passed over to the Pacific. On the

**Hoplopagrus*, *Xenichthys*, *Xenistius*, *Xenocypris*, *Microdesmus*, *Cerdale*, *Cratinus*, *Azevia*, *Microlepidotus*, *Orthostachus*, *Isaciella*, etc.

other hand, most of the common genera* show a much larger number of species on the Atlantic side. This may be held to show their Atlantic origin.

Of the relatively small number of genera which Panama has received from Polynesia, few † have crossed the Isthmus to appear in the West Indian fauna.

GÜNTHER ON THE ISTHMUS OF PANAMA.

The elements of the problem at Panama may be better understood by a glance at the results of previous investigations.

In 1869 Dr. Günther, after enumerating the species examined by him from Panama, reaches the conclusion that nearly one third of the marine fishes on the two shores of tropical America will be found to be identical. He enumerates 193 such species as found on the two coasts; 59 of these, or 31 per cent. of the total, being actually identical. From this he infers that there must have been, at a comparatively recent date, a depression of the Isthmus and intermingling of the two faunas.‡

OBSERVATIONS IN 1885.

In an enumeration of the fishes of the Pacific coast in 1885,§ the present writer showed that Dr. Günther's conclusions were based on inadequate data.

In my list, 407 species were recorded from the Pacific coast of tropical America—twice the number enumerated by Dr. Günther. Of these, 71 species, or 17½ per cent., were found also in the Atlantic. About 800 species are known from the Caribbean and adjacent shores, so that out of the total

* *Hæmulon*, *Anisotremus*, *Gerres*, *Centropomus*, *Galeichthys*, *Hypoplectrus*, *Mycteroperca*, *Ulaema*, *Stellifer*, *Micropogon*, *Bodianus*, *Microspathodon*.

† Among these are perhaps *Teuthis* (*Acanthurus*), *Ilisha*, *Salarias*, *Myripristis*, *Thalassoma*. Some such which have not crossed the Isthmus are *Cirrhitides*, *Secutor*, *Sebastes* and *Lophiomus*.

‡ 'Fishes of Central America,' 1869, 397.

§ *Proc. U. S. Nat. Mus.*, 1885, 393.

number of 1,136 species, but 71, or 6 per cent. of the whole, are common to the two coasts. This number does not greatly exceed that of the species common to the West Indies and the Mediterranean, or even the West Indies and Japan. It is to be noted also that the number 71 is not very definitely ascertained, as there must be considerable difference of opinion as to the boundaries of species, and the actual identity in several cases is open to doubt.

This discrepancy arises from the comparatively limited representation of the two faunæ at the disposal of Dr. Günther. He enumerates 193 marine or brackish-water species as found on the two coasts, 59 of which are regarded by him as specifically identical, this being 31 per cent. of the whole. But in 30 of these 59 cases, I regard the assumption of complete identity as erroneous; so that taking the number 193, as given, I would reduce the percentage to 15. But these 193 species form but a fragment of the total fauna, and any conclusion based on such narrow data is certain to be misleading.

Of the 71 identical species admitted in our list, several (*e. g.*, *Mola*, *Thunnus*) are pelagic fishes common to most warm seas. Still others (*e. g.*, *Trachurus*, *Carangus*, *Diodon* sp.) are cosmopolitan in the tropical waters. Most of the others (*e. g.*, *Gobius*, *Gerres*, *Centropomus*, *Galeichthys* sp., etc.) often ascend the rivers of the tropics, and we may account for their diffusion, perhaps, as we account for the dispersion of fresh-water fishes on the isthmus, on the supposition that they may have crossed from marsh to marsh at some time in the rainy season.

In very few cases are representatives of any species from opposite sides of the Isthmus exactly alike in all respects. These differences in some cases seem worthy of specific value, giving us 'representative species' on the two sides. In other cases, the distinctions are very trivial, but in

most cases they are appreciable, especially in fresh specimens.

Further, I expressed the belief that "fuller investigation will not increase the proportion of common species. If it does not, the two faunas show no greater resemblance than the similarity of physical conditions on the two sides would lead us to expect."

This conclusion must hold so far as species are concerned, but the resemblance in the list of genera is too great to be accounted for in this way.

OBSERVATIONS OF DR. GÜNTHER.

In 1880 * Dr. Günther expressed his views in still stronger language, claiming a still larger proportion of the fishes of tropical America to be identical on the two sides of the continent. He concluded that "with scarcely any exceptions the genera are identical, and of the species found on the Pacific side, nearly one half have proved to be the same as those of the Atlantic. The explanation of this fact has been found in the existence of communications between the two oceans by channels and straits which must have been open till within a recent period. The isthmus of Central America was then partially submerged, and appeared as a chain of islands similar to that of the Antilles; but as the reef-building corals flourished chiefly north and east of these islands and were absent south and west of them, reef fishes were excluded from the Pacific shores when the communications were destroyed by the upheaval of land."

CONCLUSIONS OF EVERMANN AND JENKINS.

This remark led to a further discussion of the subject on the part of Dr. B. W. Evermann and Dr. O. P. Jenkins. From their paper on the fishes of Guaymas† I make the following quotations:

* 'Introduction to the Study of Fishes,' 1880, p. 280.

† *Proc. U. S. Nat. Mus.*, 1891, pp. 124-126.

"The explorations since 1885 have resulted, (1) in an addition of about one hundred species to one or other of the two faunæ; (2) in showing that at least two species that were regarded as identical on the two shores* are probably distinct; and (3) in the addition of but two species to those common to both coasts.†

"All this reduces still further the percentage of common species.

"Of the one hundred and ten species obtained by us, 24, or less than 21 per cent., appear to be common to both coasts. Of these 24 species, at least 16, from their wide distribution, would need no hypothesis of a former waterway through the isthmus to account for their presence on both sides. They are species fully able to arrive at the Pacific shores of the Americas from the warm seas west. It thus appears that not more than eight species, less than 8 per cent. of our collection, all of which are marine species, require any such hypothesis to account for their occurrence on both coasts of America. This gives us, then, 1,307 species that should properly be taken into account when considering this question, not more than 72 of which, or 5.5 per cent., seem to be identical on the two coasts. This is very different from the figures given by Dr. Günther in his 'Study of Fishes.'

"Now, if from these 72 species, admitted to be common to both coasts, we subtract the 16 species of wide distribution—so wide as to keep them from being a factor in this problem—we have left but 56 species common to the two coasts that bear very closely upon the waterway hypothesis. *This is less than 4.3 per cent. of the whole number.*"

"But the evidence obtained from a study

* *Citharichthys spilopterus* and *C. gilberti*.

† *Hæmulon steindachneri* and *Gymnothorax castaneus* of the west coast probably being identical with *H. schranki* and *Gymnothorax funebris* of the east coast.

of other marine life of that region points to the same conclusion."

"In 1881, Dr. Paul Fischer discussed the same question in his 'Manual de Conchyliologie,' pp. 168-169, in a section on the Molluscan Fauna of the Panamic Province, and reached the same general conclusions. He says: 'Les naturalistes Américiens se sont beaucoup préoccupés des espèces de Panama qui paraissent identiques avec celles des Antilles, ou qui sont représentatives. P. Carpenter estime qu'il en existe 35. Dans la plupart des cas, l'identité absolue n'a pu être constatée et on a trouvé quelques caractères distinctifs, ce qui n'a rien d'étonnant, puisque dans l'hypothèse d'une origine commune, les deux races pacifique et atlantique sont séparées depuis la période Miocène. Voici une liste de ces espèces représentatives ou identiques.' Here follows a list of 20 species. 'Mais ces formes semblables,' he says, 'constituent une infime minorité (3 per cent.)' "

"These facts have a very important bearing upon certain geological questions, particularly upon the one concerning the cold of the Glacial period.

"In Dr. G. Frederick Wright's recent book 'The Ice Age in North America,' eight different theories as to the cause of the cold are discussed. The particular theory which seems to him quite reasonable is that one which attributes the cold as due to a change of different parts of the country, and a depression of the Isthmus of Panama is one of the important changes he considers. He says: * "Should a portion of the Gulf Stream be driven through a depression across the Isthmus of Panama into the Pacific, and an equal portion be diverted from the Atlantic coast of the United States by an elevation of the sea-bottom between Florida and Cuba, the consequences would necessarily be incalculably great, so that the mere existence of such a possible cause

* P. 409.

for great changes in the distribution of moisture over the northern hemisphere is sufficient to make one hesitate before committing himself unreservedly to any other theory; at any rate, to one which has not for itself independent and adequate proof."

"In the Appendix to the same volume Mr. Warren Upham, in discussing the probable causes of glaciation, says, 'The quaternary uplifts of the Andes and Rocky Mountains and of the West Indies make it nearly certain that the Isthmus of Panama has been similarly elevated during the recent epoch. * * * It may be true, therefore, that the submergence of this isthmus was one of the causes of the Glacial period, the continuation of the equatorial oceanic currents westward into the Pacific having greatly diminished or wholly diverted the Gulf Stream, which carries warmth from the tropics to the northern Atlantic and northwestern Europe.'"

"Any *very* recent means by which the fishes could have passed readily from one side to the other would have resulted in making the fish-faunas of the two shores practically identical; but the time that has elapsed since such a waterway could have existed has been long enough to allow the fishes of the two sides to become *practically distinct*. That the molluscs of the two shores are almost wholly distinct, as shown by Dr. Fischer, is even stronger evidence of the remoteness of the time when the means of communication between the two oceans could have existed, for 'species' among the molluscs are probably more persistent than among fishes.

"Our present knowledge, therefore, of the fishes of tropical America justifies us in regarding the fish faunas of the two coasts as being essentially distinct, and believing that there has not been, at any comparatively recent time, any waterway through the Isthmus of Panama."

It is thus shown, I think, conclusively,

that the Isthmus of Panama could not have been depressed for any great length of time in a recent geological period.

CONCLUSIONS OF DR. HILL.

These writers have not, however, considered the question of generic identity. To this we may find a clue in the geological investigations of Dr. Robert T. Hill.

In a study of 'The Geological History of the Isthmus of Panama and Portions of Costa Rica,' Dr. Hill uses the following language:

"By elimination we have concluded that the only period of time since the Mesozoic within which communication between the seas could have taken place is the Tertiary period, and this must be restricted to the Eocene and Oligocene epochs of that period. The paleontologic evidence upon which such an opening can be surmised at this period is the occurrence of a few California Eocene types in the Atlantic sides of the tropical American barrier, within the ranges of latitude between Galveston (Texas) and Colon, which are similar to others found in California. There are no known structural data upon which to locate the site of this passage, but we must bear in mind, however, that this structure has not been completely explored.

"Even though it was granted that the coincidence of the occurrence of a few identical forms on both sides of the tropical American region, out of the thousands which are not common, indicates a connection between the two seas, there is still an absence of any reason for placing this connection at the Isthmus of Panama, and we could just as well maintain that the locus thereof might have been at some other point in the Central American region.

"The reported fossil and living species common to both oceans are littoral forms, which indicate that if a passage existed, it must have been of a shallow and ephemeral character.

"There is no evidence from either a geologic or a biologic standpoint for believing that the oceans have ever communicated across the Isthmian regions since Tertiary time. In other words, there is no evidence for these later passages which have been established upon hypothetical data, especially those of Pleistocene time.

"The numerous assertions, so frequently found in literature, that the two oceans have been frequently and recently connected across the Isthmus, and that the low passes indicative of this connection still exist, may be dismissed at once and forever and relegated to the domain of the apocryphal. A few species common to the waters of both oceans in a predominantly Caribbean fauna of the age of the Claiborne epoch of the Eocene Tertiary is the only paleontologic evidence in any time upon which such a connection may be hypothesized.

"There has been a tendency in literature to underestimate the true altitude of the Isthmian passes, which, while probably not intentional, has given encouragement to those who think that this Pleistocene passage may have existed. Maack has erroneously given the pass at 186 feet. Dr. J. W. Gregory states 'that the summit of the Isthmus at one locality is 154 feet, and in another 287 feet in height.' The lowest Isthmian pass, which is not a summit, but a drainage col, is 287-295 feet above the ocean.

"If we could lower the Isthmian region 300 feet at present, the waters of the two oceans would certainly commingle through the narrow Culebra Pass. But the Culebra Pass is clearly the headwater col of two streams, the Obispo flowing into the Chagres, and the Rio Grande flowing into the Pacific, and has been cut by fluvial action, and not by marine erosion, out of a land mass which has existed since Miocene time. Those who attempt to establish Pleistocene inter-oceanic channels through this pass on

account of its present low altitude, must not omit from their calculations the restoration of former rock masses, which have been removed by the general leveling of the surface by erosion."

SUMMARY OF DR. HILL.

In conclusion, Dr. Hill asserts that "there is considerable evidence that a land barrier in the tropical region separated the two oceans as far back in geologic history as Jurassic time, and that that barrier continued throughout the Cretaceous period. The geological structure of the Isthmus and Central American regions, so far as investigated, when considered aside from the paleontology, presents no evidence by which the former existence of a free communication of oceanic waters across the present tropical land barriers can be established. The paleontologic evidence indicates the ephemeral existence of a passage at the close of the Eocene period. All lines of inquiry—geologic, paleontologic and biologic—give evidence that no connection has existed between the two oceans since the close of the Oligocene. This structural geology is decidedly opposed to any hypothesis by which the waters of the two oceans could have been connected across the regions in Miocene, Pliocene, Pleistocene, or recent times."

FINAL HYPOTHESIS AS TO PANAMA.

If we assume the correctness of Dr. Hill's conclusions, they may accord in a remarkable degree with the actual facts of the distribution of the fishes about the Isthmus. To account for the remarkable identity of genera and divergence of species I may suggest the following hypothesis:

During the lifetime of most of the present species, the Isthmus has not been depressed. It was depressed in or before Miocene time, during the lifetime of most of the present genera. The channel formed was relatively shallow, excluding forms inhabiting rocky bottoms at considerable

depths. It was wide enough to permit the infiltration from the Caribbean Sea of numerous species, especially of shore fishes of sandy bays, tide pools and brackish estuaries. The currents set chiefly to the westward, favoring the transfer of Atlantic rather than Pacific types.

Since the date of the closing of this channel, the species left on the two sides have been altered in varying degrees by the processes of natural selection and isolation. The cases of actual specific identity are few, and the date of the establishment as species, of the existing forms, is subsequent to the date of the last depression of the isthmus.

While local oscillations, involving changes in coast-lines, have doubtless frequently taken place and are still going on, our knowledge of the distribution of fishes should render impossible the speculations on the dance of continents, which certain geologists and certain biologists have, at one time or another, used as a convenient means of accounting for glacial phenomena, or for anomalies in distribution. We may be also certain that none of the common genera ever found their way around Cape Horn. Most of them disappear to the southward, along the coasts of Brazil and Peru.

Further, it goes without saying, that we have no knowledge of the period of time necessary to work specific changes in a body of species isolated in an alien sea. Nor have we any data as to the effect on a given fish fauna of the infiltration of many species and genera belonging to another. All such forces and results must be matters of inference.

LAWS GOVERNING DISTRIBUTION OF ANIMALS.

I have elsewhere* had occasion to say that the laws governing the distribution of

* 'Footnotes to Evolution.'

animals are reducible to three very simple propositions.

Each species of animal is found in every part of the earth having conditions suitable for its maintenance, unless :

(a) Its individuals have been unable to reach this region through barriers of some sort; or,

(b) Having reached it, the species is unable to maintain itself, through lack of capacity for adaptation, through severity of competition with other forms, or through destructive conditions of environment; or else,

(c) Having entered and maintained itself, it has become so altered in the process of adaptation as to become a species distinct from the original type.

SPECIES ABSENT THROUGH BARRIERS.

The absence from the Japanese fauna of most European or American species comes under the first head. The pike has never reached the Japanese lakes, though the shade of the lotus leaf in the many clear ponds would suit its habits exactly. The grunt* and porgies† of our West Indian waters and the crenilabri of the Mediterranean have failed to cross the ocean and therefore have no descendants in Japan.

SPECIES ABSENT THROUGH FAILURE TO MAINTAIN FOOTHOLD.

Of species under (b), those who have crossed the seas and not found lodgment, we have, in the nature of things, no record. Of the existence of multitudes of estrays we have abundant evidence. In the Gulf Stream off Cape Cod are every year taken many young fishes belonging to species at home in the Bahamas and which find no permanent place in the New England fauna. In like fashion, young fishes from the tropics drift northward in the Kuro Shiwo to the coasts of Japan, but never finding a

permanent breeding-place and never joining the ranks of the Japanese fishes. But to this there have been, and will be, occasional exceptions. Now and then one among thousands finds permanent lodgment, and by such means a species from another region will be added to the fauna. The rest disappear and leave no trace. A knowledge of these currents and their influence is eventual to any detailed study of the dispersion of fishes.

SPECIES CHANGED THROUGH NATURAL SELECTION.

In the third class, that of species changed in the process of adaptation, most insular forms belong. As a matter of fact, at some time or another almost every species must be in this category, for isolation is a source of the most potent elements in the initiation and intensification of the minor differences which separate related species. It is not the preservation of the most useful features, but of those which actually existed in the ancestral individuals, which distinguish such species. I have elsewhere noted that natural selection must include not only the process of the survival of the fittest, but also the results of the survival of the existing. This means the preservation through heredity of the traits not of the species alone, but those of the actual individuals set apart to be the first in the line of descent in a new environment. In hosts of cases the persistence of characters rests not on any special usefulness or fitness, but on the fact that individuals possessing these characters have, at one time or another, invaded a certain area and populated it. The principle of utility explains survivals among competing structures. It rarely accounts for qualities associated with geographical distribution.

BARRIERS CHECKING MOVEMENT OF FISHES.

The limits of the distribution of individual species or genera must be found in

* *Hæmulon*.

† *Calamus*.

some sort of barrier, past or present. The chief barriers which limit marine fishes are the presence of land, the presence of great oceans, the differences of temperature arising from differences in latitude, the nature of the sea bottom and the direction of oceanic currents. That which is a barrier to one species may be an agent in distribution to another. The common shore fishes would perish in deep waters almost as surely as on land, while the open Pacific is a broad highway to the albacore or the sword-fish.

Again, that which is a barrier to rapid distribution may become an agent in the slow extension of the range of a species. The great continent of Asia is undoubtedly one of the greatest of barriers to the wide movement of species of fish, yet its long shore-line enables species to creep, as it were, from bay to bay, or from rock to rock; till, in many cases, the same species is found in the Red Sea and in the tide-pools or sand-reaches of Japan. In the North Pacific, the presence of a range of half-submerged volcanoes, known as the Aleutian and the Kurile Islands, has greatly aided the slow movement of the fishes of the tide-pools and the kelp. To a school of mackerel or of flying fishes these rough islands would form an insuperable barrier.

TEMPERATURE THE CENTRAL FACT IN DISTRIBUTION.

It has long been recognized that the matter of temperature is the central fact in all problems of geographical distribution. Few species in any group freely cross the frost-line, and except as borne by oceanic currents, few species extend their range far into waters colder than those in which the species is distinctively at home. Knowing the average temperature of the water in a given region, we know in general the types of fishes which must inhabit it. It is the similarity in temperature and physical

conditions, not the former absence of barriers, which chiefly explains the resemblance of the Japanese fauna to that of the Mediterranean or the Antilles. This fact alone must explain the resemblance of the Arctic and Antarctic faunæ.

AGENCY OF OCEAN CURRENTS.

We may consider again for a moment the movements of the great currents in the Pacific as agencies in the distribution of species.

A great current sets to the eastward, crossing the ocean just south of the Tropic of Cancer. It extends between the Gilbert and the Marshall Islands and passes on nearly to the coast of Mexico, touching the Galapagos Islands, Clipperton Island and especially the Revillagigedos. This at once accounts for the number of Polynesian species found on these Islands, about which they are freely mixed with immigrants from the mainland of Mexico.

From the Revillagigedos* the current moves northward, passing the Hawaiian Islands and thence onward to the Ladrões. The absence in Hawaii of many of the characteristic fishes of the Society Islands and the Gilbert Islands is doubtless due to the long detour made by these currents, as the conditions of life in these groups of islands are not very different. Between the Gilbert Islands and Samoa there is also a return current to the west, and northeast of Hawaii is a great spiral current, moving with the hands of the watch, forming what is called Fleurieu's Whirlpool. This does not reach the coast of California. This fact may account for the almost complete distinction in the shore fishes of Hawaii and California.†

* Clarion Island and Socorro Island.

† A few Mexican shore fishes, *Chætodon humeralis*, *Galeichthys dasycephalus*, *Hypsoblennius parvipinnis*, have been wrongly accredited to Hawaii by some misplacement of labels.

The westward current from Hawaii reaches Luzon and Formosa. It is deflected to the northward and, joining a northward current from Celebes, it forms the Kuro Shiwo or Black Stream of Japan, which strews its tropical species in the rock pools along the Japanese promontories as far as Tokio. Then, turning into the open sea, it passes northward to the Aleutian Islands, across to Sitka. Thence it moves southward as a cold current, bearing Ochotsk-Alaskan types southward as far as the Santa Barbara Islands, to which region it is followed by species of Aleutian origin. A cold return current seems to extend southward in Japan, along the East shore perhaps as far as Matsushima. A similar current in the sea to the west of Japan extends still further to the southward, to Noto, or beyond.

It is, of course, not necessary that the movements of a species in an oceanic current should coincide with the direction of the current. Young fishes, or fresh-water fishes, would be borne along with the water. Those that dwell within floating bodies of seaweed would go whither the waters carry the drifting mass. But free-swimming fishes, as the mackerel or flying-fishes, might as readily choose the reverse direction. To a free-swimming fish, the temperature of the water would be the only consideration. It is thus evident that a current which to certain forms would prove a barrier to distribution, to others would be a mere convenience in movement.

In comparing the Japanese fauna with that of Australia, we find some trace of both these conditions. Certain forms are excluded by cross-currents, while certain others seem to have been influenced only by the warmth of the water. A few Australian types on the coast of Chili seem to have been carried over by the cross currents of the South Atlantic.

CENTERS OF DISTRIBUTION.

We may assume, in regard to any species, that it has had its origin in or near that region in which it is most abundant and characteristic. Such an assumption must involve a certain percentage of error or of doubt, but in considering the mass of species, it would represent essential truth. In the same fashion, we may regard a genus as being autochthonous or first developed in the region where it shows the greatest range or variety of species. Those regions where the greatest number of genera are thus autochthonous may be regarded as centers of distribution. So far as the marine fishes are concerned, the most important of these centers are found in the Pacific Ocean. First of these in importance is the East-Indian Archipelago, with the neighboring shores of India. Next would come the Arctic Pacific and its bounding islands, from Japan to British Columbia. Third in importance in this regard is Australia. Important centers are also found in temperate Japan, in California, the Panama region, and in New Zealand, Chili and Patagonia. The fauna of Polynesia is almost entirely derived from the Indies; and the shore-fauna of the Red Sea, the Bay of Bengal and Madagascar, so far as genera are concerned, seems to be not really separable from the Indian fauna generally.

I know of but six genera which may be regarded as autochthonous in the Red Sea, and nearly of these are of doubtful value or of uncertain relation. The many peculiar genera described by Dr. Alcock, from the dredgings of the *Investigator* in the Bay of Bengal, belong to the bathybial or deep water series, and will all, doubtless, prove to be forms of wide distribution.

In the Atlantic, the chief center of distribution is the West Indies; the second is the Mediterranean. On the shores to the northward or southward of these regions occasional genera have found their origin.

This is true especially of the New England region, the North Sea, the Gulf of Guinea and the coast of Argentina. The fish fauna of the North Atlantic is derived mainly from the North Pacific, the differences lying mainly in the lower richness of the North Atlantic. But, in certain groups common to the two regions, the migration must have been in the opposite direction; exceptions that prove the rule.

REALMS OF DISTRIBUTION OF FRESH-WATER FISHES.

If we consider the fresh-water fishes alone we may divide the land areas of the earth into districts and zones, fairly agreeing with those marked out for mammals and birds. The river-basin, bounded by its shores and the sea at its mouth, shows many resemblances, from the point of view of a fish, to an island considered as the home of an animal. The nature of the various barriers limiting species in river-basins I have elsewhere* fully discussed and need not consider it further here. It is evident that, with fishes, the differences in latitude outweigh those of continental areas, and a primary division into Old World and New World would not be tenable.

The chief areas of dispersion of fresh-water fishes we may indicate as follows, following essentially the grouping proposed by Dr. Günther: †

NORTHERN ZONE (ARCTIC AND TEMPERATE).

With Dr. Günther, we may recognize, first the *Northern Zone*, characterized familiarly by the presence of sturgeon, salmon, trout, white-fish, pike, lamprey, stickleback and other species of which the genera and often the species are identical in Europe, Siberia, Canada, Alaska and most of the United States, Japan and China.

* Science Sketches: 'The Dispersion of Fresh-water Fishes.'

† 'Introduction to the Study of Fishes.'

This is subject to cross-division into two great districts, the first Europe-Asiatic, the second North American. These two agree very closely to the northward but diverge widely to the southward, developing a variety of specialized genera and species, and both of them passing finally, by degrees, into the Equatorial Zone.

Still another line of division is made by the Ural Mountains in the Old World and by the Rocky Mountains in the New. In both cases the Eastern region is vastly richer in genera and species, as well as in autochthonous forms, than the Western. The reason for this lies in the vastly greater extent of the river basins of China and the Eastern United States, as compared with those of Europe or the Californian region.

Minor divisions are those which separate the Great Lake region from the streams tributary to the Gulf of Mexico; and in Asia, those which separate China from tributaries of the Caspian, the Black and the Mediterranean.

EQUATORIAL ZONE.

The Equatorial Zone is roughly indicated by the tropics of Cancer and Capricorn. Its essential feature is that of the temperature, and the peculiarities of its divisions are caused by barriers of sea or mountains.

Dr. Günther finds the best line of separation into two divisions to lie in the presence or absence of the great group of dace or minnows,* to which nearly half of the species of fresh-water fishes the world over belong. The entire group, now spread everywhere except in the Arctic, South America, Australia and the islands of the Pacific, had its origin in India, from which its genera have radiated in every direction.

The Cyprinoid division of the Equatorial Zone forms two districts, the Indian and the African. The Ancyprinoid division includes South America, south of Mexico, and

* Cyprinidæ.

all the islands of the tropical Pacific lying to the east of Wallace's line. This line, separating Borneo from Celebes and Bali from Lompoe, marks in the Pacific the western limit of Cyprinoid fishes, as well as that of monkeys and other important groups of land animals. This line, recognized as very important in the distribution of land animals, coincides in general with the ocean current between Celebes and Papua, which is one of the sources of the Kuro Shiwo.

In Australia, Hawaii and Polynesia generally, the fresh-water fishes are derived from marine types by modification of one sort or another. In no case, so far as I know, in any island to the eastward of Borneo, is found any species derived from fresh-water families of either the Eastern or the Western Continent. Of course, minor subdivisions in these districts are formed by the contour lines of river basins. The fishes of the Nile differ from those of the Niger or the Congo, or of the streams of Madagascar or Cape Colony, but in all these regions the essential character of the fish fauna remains the same.

SOUTHERN ZONE.

The third great region, the Southern Zone, is scantily supplied with fresh-water fishes, and the few it possesses are chiefly derived from modifications of the marine fauna or from the Equatorial Zone to the north. Three districts are recognized, Tasmanian, the New Zealand and the Patagonian. The fact that certain peculiar groups are common to these three regions has attracted the notice of naturalists.

ORIGIN OF NEW ZEALAND FAUNA.

In a critical study of the fish fauna of New Zealand,* Dr. Gill discusses the origin of the four genera and seven species of fresh-water fishes found in these islands, the principal of these genera (*Galaxias*) being repre-

sented by nearly related species in South Australia and in Patagonia.*

According to Dr. Gill, we can account for this anomaly of distribution only by supposing, on the one hand, that their ancestors were carried for long distances in some unnatural manner, as (a) having been carried across entombed in ice, or (b) being swept by ocean currents, surviving their long stay in salt water, or else that they were derived (c) from some widely distributed marine type now extinct, its descendants restricted to fresh water.

On the other hand, Dr. Gill suggests that as 'community of type must be the expression of community of origin,' the presence of fishes of long-established fresh-water types must imply continuity or at least contiguity of land. The objections raised by geologists to the supposed land connection of New Zealand and Tasmania do not appear to Dr. Gill insuperable. It is well known, he says, "that the highest mountain chains are of comparatively recent geological age. It remains, then, to consider which is the more probable, (1) that the types now common in distant regions were distributed in some unnatural manner, by the means referred to; or (2) that they are descendants of forms once wide-ranging over lands now submerged." After considering questions as to change of type in other groups, Dr. Gill is inclined to postulate, from the occurrence of species of the trout-like genus *Galaxias*, in New Zealand, South Australia and South America, that "there existed some terrestrial passage-way between the several regions at a time as late as the close of the Mesozoic period. The evidence of such a connection afforded by congeneric fishes is fortified by analogous representatives among insects, mollusca and even amphibians. The separation of the several areas must have occurred little later than the late Tertiary, inasmuch as the salt-

* 'A Comparison of Antipodal Faunæ,' 1887.

* *Galaxias*, *Neochanna*, *Prototroctes* and *Retropinna*.

water fishes of corresponding isotherms found along the coast of the now widely separated lands are to such a large extent specifically different. In general, change seems to have taken place more rapidly among marine animals than fresh-water representatives of the same class."

It is not often that I have occasion to differ from Dr. Gill on a question in ichthyology; but, in this case, when one guess is set against another, it seems to me that the hypothesis first suggested, rather than the other, lies in the line of least logical resistance. I think it better to adopt provisionally some theory not involving the existence of a South Pacific Antarctic Continent, to account for the distribution of *Galaxias*. For this view I may give five reasons:

1. There are many other cases of the sort equally remarkable and equally hard to explain. Among these is the presence of species of paddle-fish and shovel-nosed sturgeon,* types characteristic of the Mississippi Valley, in Central Asia. The presence of one and only one of the five or six American species of pike † in Europe; of one of the three species of mud-minnow in Austria, ‡ the others being American. Such cases occur all over the globe and must be explained, if at all, on some hypothesis other than that of former land connection.

2. The supposed continental extension should show permanent traces in greater similarity in the present fauna, both of rivers and of sea. The other fresh-water genera of the regions in question are different, and the marine fishes are more different than they could be if we imagine an ancient shore connection. If New Zealand and Patagonia were once united other genera than *Galaxias* would be left to show it.

* *Scaphirynchus* (the shovel-nosed sturgeon) and the paddle-fish (*Polyodon* and *Psephurus*).

† *Esox lucius*.

‡ *Umbra*, the mud-minnow.

3. We know nothing of the power of *Galaxias* to survive submergence in salt water, if carried in a marine current. As already noticed, I have found young and old in abundance of the commonest of Japanese fresh-water fishes in the open sea, at a distance from any river. Thus far this species, the hakone* dace, has not been recorded outside of Japan, but it might well be swept to Korea or China. Two fresh-water fishes of Japanese origin now inhabit the island of Tsushima in the Straits of Korea.

4. The fresh-water fishes of Polynesia show a remarkably wide distribution and are doubtless carried alive in currents. One river-goby † ranges from Hawaii to the Riu Kiu Islands. Another species, ‡ originally perhaps from Brazil through Mexico, shows an equally broad distribution.

5. We know that *Galaxias* with its relatives must have been derived from a marine type. It has no affinity with any of the fresh-water families of either continent, unless it be with the Salmonidæ. The original type of this group was marine, and most of the larger species still live in the sea, ascending streams only to spawn.

When the investigations of geologists show reason for believing in radical changes in the forms of continents, we may accept their conclusions. Meanwhile, almost every case of anomalies in the distribution of fishes admits of a possible explanation through 'the slow action of existing causes.' Geologists will attach more weight to biological data, if biologists refrain from insisting on theories which at the best are mere possible explanations, in the incomplete state of our knowledge.

Finally, I may repeat that real causes are always simple when they are once known. All anomalies in distribution

* *Leuciscus hakuensis*.

† *Eleotris fusca*.

‡ *Awaous crassilabris*.

cease to be such when the facts necessary to understand them are at our hand.

DISTRIBUTING MARINE FISHES.

The distribution of marine fishes must be indicated in a different way from that of the fresh-water forms. The barriers which limit their range furnish also their means of dispersion. In some cases proximity overbalances the influence of temperature; with other forms, questions of temperature are all-important.

PELAGIC FISHES.

Before consideration of the coast lines, we may glance at the differences in vertical distribution. Many species, especially those in groups allied to the mackerel family, are pelagic—that is, inhabiting the open sea, and ranging widely within limits of temperature. In this series, some species are practically cosmopolitan. In other cases the genera are so. Each school or group of individuals has its breeding place, and from the isolation of breeding districts new species may be conceived to arise. The pelagic types have reached a species of equilibrium in distribution. Each type may be found where suitable conditions exist, and the distribution of species throws little light on questions of distribution of shore fishes. Yet, among these species are all degrees of localization. The pelagic fishes shade into the shore fishes on the one hand and into the deep-sea fishes on the other.

BASSALIAN FISHES.

The vast group of bassalian or deep-sea fishes includes those forms which live below the line of adequate light. These, too, are localized in their distribution, and to a much greater extent than was formerly supposed. Yet, as they dwell below the influence of the sun's rays, zones and surface temperatures are nearly alike to them, and the same forms may be found in the arctic or under the equator. Their differences in distribution are largely vertical, some liv-

ing at greater depths than others, and they shade off by degrees from bathybial into semi-bathybial, and finally into ordinary pelagic and ordinary shore types.

The fishes of the great depths are soft in substance, some of them blind, some of them with very large eyes, all black in color, and very many are provided with luminous spots or areas. A large body of species of fishes are semi-bathybial, inhabiting depths of 200 or 300 fathoms, showing many of the characters of shore fishes, but far more widely distributed. Many of the remarkable cases of wide distribution of type belong to this class. At such depths, red colors are almost universal, corresponding to the zone of red algæ, and the colors in both cases are perhaps determined from the fact that the red rays of light are the least refrangible.

A certain number of species are both marine and fresh water, inhabiting estuaries and brackish waters, while some more strictly marine ascend the rivers to spawn. In none of these cases can any hard and fast line be drawn, and some groups which are shore fishes of one region will be represented by semi-bathybial or fluviatile forms in another.*

LITTORAL FISHES.

The shore fishes are in general the most highly specialized in their respective groups, because exposed to the greatest variety of selecting conditions and of competition. Their distribution in space is more definite than that of the pelagic and bassalian types, and they may be more definitely assigned to geographical areas.

* The dragonets, *Callionymus*, are shore fishes of the shallowest waters in Europe and Asia, but inhabit considerable depths in tropical America. The sea-robins (*Prionotus*) are shore fishes in Massachusetts, semi-bathybial fishes at Panama. Often, arctic shore fishes become semi-bathybial in the temperate zone, living in water of a given temperature. A long period of cold weather will sometimes bring such to the surface.

DISTRIBUTION OF LITTORAL FISHES BY COAST-LINES.

Their distribution is best indicated, not by realms or areas, but as forming four parallel series, corresponding to the four great north and south continental outlines. Each of these series may be represented as beginning at the north in the Arctic fauna, practically identical in each of the four series, actually identical in the two Pacific series. Passing southward, forms are arranged according to temperature. One by one in each series, the Arctic types disappear; sub-arctic, temperate and semi-tropical types take their places, giving way in turn to south-temperate and Antarctic forms. The distribution of these is modified by barriers and by currents, yet though genera and species may be different, each isotherm is represented in each series by certain general types of fishes.

Passing southward, the two American series, the East Atlantic and the East Pacific, pass on gradually through temperate to antarctic types. These are analogous to those of the arctic, and in a few cases they are generically identical. The West Pacific* (East Asian) series is very much broken

*The minor faunal areas of shore fishes may be grouped as follows:

EAST ATLANTIC.	EAST PACIFIC.	WEST PACIFIC.
Icelandic,	Arctic,	Arctic,
British,	Aleutian,	Aleutian,

Argentinian,		New Zealand,
Patagonian.		Antarctic.

by the presence of Australia, the East-Indies and Polynesia. The irregularities of these regions make a number of sub-series, which break up the simplicity expressed in the idea of four parallel series. Yet the fauna of Polynesia is strictly East-Indian, modified by the omission or alteration of species, and that of Australia is Indian at the north, and changes to the southward much as that of Africa does. In its marine fishes, it does not constitute a distinct 'realm.' The East Atlantic (Europe-African) series follows the same general lines of change as that of the West Atlantic. It extends, however, only to the South Temperate Zone, developing no Antarctic elements. The relative shortness of Africa explains in large degree, as already shown, the similarity between the tropical elements in the two Old World series, as the similarity in tropical elements in the two American series must be due to a former depression of the connecting Isthmus. The practical unity of the Arctic marine fauna needs no explanation in view of the present shore lines of the Arctic Ocean.

EQUATORIAL FISHES MOST SPECIALIZED.

In general, the different types are most highly specialized in equatorial waters. The processes of specific change, through natural selection or other causes, if other causes exist, take place most rapidly there and produce most far-reaching modification. As I have elsewhere stated, the coral reefs of the tropics are the centers of fish-life, the cities in fish-economy. The fresh waters, the arctic waters, the deep sea and the open sea, represent forms of ichthyic backwoods, regions where change goes on more slowly, and in them we find survivals of archaic or generalized types. For this reason, the study in detail of the distribution of marine fishes of equatorial regions is in the highest degree instructive.

The study of the origin of the fish groups of Japan affords a fascinating index to its multifarious problems.

DAVID STARR JORDAN.

STANFORD UNIVERSITY.

*THE LABORATORY TEACHING OF PHYSIOLOGY.**

THE student of physiology should perform the classical experiments upon which the science rests. The writer of these papers has for several years endeavored to place the laboratory teaching of physiology within the reach of every school. To accomplish this it is necessary that apparatus of precision be designed upon lines permitting its manufacture in large quantities at a small cost. The apparatus described below is believed to show progress in this direction.

the box admits the rays from a lantern or other source of light. This circular window may be closed by a clear glass plate or by any of the several diaphragms described below. Two pins, one at the side and one below the opening, are so placed that when the diaphragm rests against them its aperture will lie in the axis of the optical system. The lenses and mirrors employed with the box are mounted in square wooden blocks, to protect them from injury. When the side of the wooden block is placed against the 'rabbit strip' shown at the lower inside angle of the box the center of the lens or mirror mounted in the block will lie in the optical axis. The rays of light entering the box are made visible by the fumes of Japanese incense, a small stick of which is lighted and placed in a hole in a cork upon which fits a tin cylinder shown in Fig. 1.

FIG. 1. The optical lantern and artificial eye.

I. THE ARTIFICIAL EYE.

The artificial eye (shown in section in Fig. 1, one fourth the actual size) consists of a wooden box the top of which is closed by laying upon it a piece of clear plate-glass. A circular opening in the front of

* Porter, W. T.: *Boston Medical and Surgical Journal*, Dec. 29, 1898. *Philadelphia Medical Journal*, Sept. 1, 1900. 'An Introduction to Physiology,' Cambridge, 1900 and 1901. 'Experiments for Students in the Harvard Medical School,' Second Series, Cambridge, Jan., 1901. Third Series, Cambridge, May 1901.

The optical lantern consists of a sixteen-candle-power electric lamp, with small spiral filament, mounted in a wooden box pierced with holes which permit thorough ventilation but do not allow the escape of light to disturb the observer. The lantern box is provided with a condensing lens and two focusing lenses mounted in draw tubes which may be easily removed. The slot for the diaphragms is furnished with a stop so placed that when the diaphragm is shoved against it the aperture of the

diaphragm will lie in the optical axis. When the focusing tubes are removed the lantern may be mounted on a stand by means of a brass ring with set screws, and then serves admirably for ophthalmoscopic or laryngological work.

The following lenses, diaphragms, etc., are provided for the experiments in physiological optics made by first-year students in the Harvard Medical School. Convex lens, four inches focus; convex lens, twenty inches focus; concave lens, twenty inches focus; astigmatic cylinder, twenty inches focus; astigmatic cylinder, five and a half inches focus; mirror, convex on one side, concave on other, one inch focus; plain mirror; diaphragm with circular aperture two millimeters in diameter; diaphragm with vertical and horizontal slits; dia-

necessary. The light rays are very distinct in any room after sunset. A hundred or more students may work in the same laboratory. If a focusing-cloth or other screen be used, the observations may be made in daylight.

II. THE CIRCULATION SCHEME.

The artificial scheme (Fig. 2) to illustrate the mechanics of the circulation in the highest vertebrates consists of a pump, a system of elastic tubes, and a peripheral resistance. The inlet and outlet tubes of the pump are furnished with valves that permit a flow in one direction only. The peripheral resistance is the friction which the liquid undergoes in flowing through the minute channels of a piece of bamboo. To this must be added the slighter resistance

FIG. 2. The circulating scheme.

phragm with L-shaped slit; clear-glass slide; ground-glass slide; wooden screen to serve as retina; square bottle filled with eosin solution, to study refraction.

With this apparatus reflection and refraction from plain and spherical surfaces, spherical and chromatic aberration, astigmatism, myopia, and hypermetropia may be studied. A special dark room is not

due to friction in the rubber and glass tubes.

In this system the pump represents the left ventricle; the valves in the inlet and outlet tubes the mitral and aortic valves, respectively; the resistance of the channels in the bamboo the resistance of the small arteries and capillaries. The tubes between the pump and the resistance are the arte-

ries; those on the distal side of the resistance are the veins. The side branch substitutes a wide channel for the narrow ones and thus is equivalent to a dilatation of the vessels. Between the pump and the outlet valve is a side tube leading to a membrane manometer which records the changes in the pressure within the pump (the loss in conveying the pressure through the short wide connecting tubes may be neglected). A mercury manometer is placed between the pump and the capillary resistance, to measure the arterial pressure, and a second mercury manometer on the distal side of the capillary resistance to measure the venous pressure.

The device used for the aortic valve is shown in Fig. 3. A small glass tube is fastened in a larger glass tube by a collar of rubber tubing. The small glass tube is closed at one end. One side is pierced with a valve hole. The valve hole is closed by a piece of rubber tubing which is drawn over the small glass tube, and the middle portion of the rubber tubing is cut away

FIG. 3. The modified Williams' valve of the circulating scheme.

except over the hole. During the stroke of the pump the water enters the small glass tube under pressure, lifts the rubber, escapes through the valve hole, and is carried off by the large glass tube. When the pressure in the small glass tube is no longer as great as that in the surrounding large glass tube the rubber shuts the valve-hole. Backflow is thus prevented. The mitral valve is similar to the aortic, but the position of the small glass tube is reversed.

With this apparatus the physical phenomena of the circulation may be learned thoroughly. The conversion of the intermittent into a continuous flow, the relation

between rate of flow and width of bed, the relation of peripheral resistance to blood-pressure, the inhibition of the ventricle, the opening and closing of the aortic valve, the period of outflow from the ventricle, the pulse wave, the physical phenomena of the circulation in fevers and in aortic and mitral regurgitation and stenosis, may all be studied by the graphic method. Excellent pulse curves may be obtained by placing a sphygmograph upon the aortic tube.

I first described the circulation scheme in 'The Introduction to Physiology,' January, 1900. Its use during two years by large numbers of students in the Harvard Medical School has suggested certain changes which enable the apparatus to be more quickly put together. In making these changes I have been much helped by the criticism of Mr. F. H. Pratt, Dr. W. B. Cannon and others of my associates.* The accompanying figures show the most recent form of the apparatus.

III. THE MOIST CHAMBER.

The moist chamber, shown in Fig. 4, provides for the study of the electrical properties of nerve and muscle under conditions that prevent the stimulation caused by drying. It consists of a porcelain plate which bears near the margin a shallow groove. In this groove rests a glass shade which for the sake of clearness has been omitted from Fig. 4. To the porcelain plate is screwed a rod, by which the plate may be supported on a stand. Within the glass shade a right-angled rod carries a small clamp, composed of a split screw on which moves a nut, by means of which the femur of a nerve muscle preparation may be firmly grasped. The holder for the split screw is arranged to permit of motion in all directions. The right-angled rod also carries two or more unpolarizable electrodes. Each of these is

* To Mr. Pratt's skilful hand I am indebted for the drawings from which Fig. 2 and Fig. 3 were made.

borne by a spring clip. On compressing its projecting ends the clip no longer presses against the rod, but may be moved from side to side or revolved upon its axis. The electrodes are made of potter's clay, skilfully fired, and are unglazed except where they are grasped by the spring clip. They have the shape of a boot. By turning the leg of the boot in the clip the foot may be brought as near the foot of the neighboring electrode as may be desired. On placing the boot in normal saline solution the porous clay rapidly absorbs the indifferent liquid. The hollow leg of the boot is then half filled with saturated solution of zinc sulphate and

FIG. 4. The moist chamber, with spring clips and unpolarizable boot electrodes.

placed in the clip. A thick wire of amalgamated zinc, provided at one end with a hole in which a connecting wire may be fastened with a set-screw, is placed in the leg of the boot, and the other end of the connecting wire brought to one of the four binding posts shown in Fig. 4. These four posts are in electrical connection with four other posts beneath the porcelain plate. The boot electrodes are unpolarizable. They serve equally well for leading off the nerve or muscle current to the electrometer and for stimulation. They are easily cleaned and are far more convenient than the electrodes of glass and clay or plaster of Paris.

WILLIAM TOWNSEND PORTER.

HARVARD MEDICAL SCHOOL,
September 20, 1901.

ANDREW ELLICOTT DOUGLASS.

ANDREW ELLICOTT DOUGLASS died on September 30 in his eighty-second year. Anthropological science has thus lost a sincere friend. Mr. Douglass was born at West Point, New York, on November 18, 1819. He was the son of Major David Bates Douglass, and his mother was a daughter of Andrew Ellicott, professor of mathematics at West Point.

Mr. Douglass graduated from Kenyon College in 1838 and received the degree of A.M. in 1841. On completing his undergraduate course he engaged in business, being connected with the firm afterwards known as the Hazard Powder Company. In 1867 he became president of the company and retired nine years later from a successful business career.

Since 1876 Mr. Douglass devoted much of his time to the study of the Indian artifacts of the United States. He spent ten winters cruising along the Floridian coast, locating over fifty Indian mounds, many of which he excavated. For his study Mr. Douglass brought together an excellent library relating to American archeology and made a synoptical collection of over 22,000 specimens, which latter he presented to the American Museum of Natural History during the present year. This collection of implements is arranged in various special classes irrespective of geographical distribution with the purpose of solving the theory of their use. Mr. Douglass believed, however, in the geographical method of arrangement, but that both methods were necessary. A series of over a thousand hematite objects in the collection constitutes what is perhaps a unique feature. The collection is most carefully catalogued and cross-referenced as might be expected by those who knew Mr. Douglass's painstaking business method.

Mr. Douglass was a member of the Metropolitan Museum of Art and a patron of

the American Museum of Natural History. He was a fellow of the American Association for the Advancement of Science since 1885, and attended the Section of Anthropology. He was also enrolled as a member of the Linnæan Society, the Numismatic and Archeological Society, the Anthropological Society of Washington and the American Geographical Society, as well as being a life member of the Anthropological Society of Paris. At the time of his death he was the oldest living member of the American Ethnological Society.

Mr. Douglass's most recent contribution to the literature of anthropology appeared as Article X. in Vol. VIII. of the *Bulletin of the American Museum of Natural History*. This paper was entitled 'A Table of the Geographical Distribution of American Indian Relics [in a Collection exhibited in the American Museum of Natural History, New York,' with explanatory text.

Although suffering from an infirmity of old age, Mr. Douglass was enthusiastic and cheerful to the last. He was a man of great patience, charitable to those who differed from him in opinion and of a gentle and courteous nature.

HARLAN I. SMITH.

SCIENTIFIC BOOKS.

SOME RECENT WORKS ON MECHANICS.

Theoretical Mechanics. An elementary textbook. By L. M. HOSKINS, Professor of Applied Mathematics in the Leland Stanford Junior University. Published by the author, Stanford University Bookstore, agent. 1900. 8vo. Pp. ix + 436.

The Principles of Mechanics. An elementary exposition, for students of physics. By FREDERICK SLATE, Professor of Physics in the University of California. Part I. New York, The Macmillan Company; London, Macmillan and Company, Limited. 1900. 12mo. Pp. x + 299.

Theoretical Mechanics. An elementary treatise. By W. WOOLSEY JOHNSON, Professor of Mathematics, U. S. Naval Academy. New York, John Wiley and Sons; London, Chapman and Hall, Limited. 1901. 12mo. Pp. xv + 424.

Ad. Wernickes Lehrbuch der Mechanik in elementarer Darstellung mit Anwendungen und Übungen aus den Gebieten der Physik und Technik. In zwei Teilen. Erster Teil, Mechanik fester Körper, von DR. ALEX. WERNICKE. Vierte völlig umgearbeitete Auflage. Erste Abteilung, Einleitung—Phoronomie—Lehre vom materiellen Punkte. 8vo. Pp. xv + 314. Zweiter Teil, Flüssigkeiten und Gase, von RICHARD VATER. Dritte völlig umgearbeitete Auflage. 8vo. Pp. xii + 374. Braunschweig, Friedrich Vieweg und Sohn. 1900.

Of the production of books, and good books, on the science of mechanics the end is not yet in sight. The first three works on our list fall into the same class. Each of them purports to give an elementary exposition only of the science, each is a good specimen of book-making, and each is supplemented by an index. They differ from one another, however, in several important respects; and their characteristic differences reflect clearly, it would appear, the points of view of the authors. Thus, Professor Hoskins has in mind mainly the needs of the progressive and aggressive engineer, and seeks at the same time to avoid the narrower demands of specialists. Professor Slate looks at the subject as a physicist, with a keen appreciation of the broader aspects of the science and the critical examination its principles have received from recent writers like Maxwell, Mach and Love. Professor Johnson, on the other hand, with perhaps a deeper sense of the difficulties to be encountered by the student, is somewhat conservative, and follows more closely the methods which have proved so effective in the works of the great analysts.

Singularly enough, the definitions of mechanics given by these authors are very much alike, and all of them are somewhat old-fashioned. Hoskins says, "*Mechanics* is the science which treats of the motions of material bodies"; Slate says, "The science of Mechanics

is concerned with the physical phenomena involved in motion"; while Johnson says, "Mechanics is the science which treats of the motions of *material bodies*, and the causes of these motions." Definitions of the science, however, are not very important to the elementary student. He must know the subject pretty well before he can appreciate a definition of it. All such definitions as those just cited, need, as their authors doubtless anticipated, much supplementary explanation in the light of the student's enlarged experience.

Professor Hoskins follows the historical development of the subject and gives to statics first place, passing on thence to kinematics and kinetics. Professor Slate adopts the modern, more logical, order of presentation beginning with kinematics. Professor Johnson follows more closely the Newtonian method, starting with dynamics and passing on to statics and kinetics, kinematical principles being explained as needed chiefly. There is much to be said in favor of each of these methods; and for the beginner either method is effective with the aid of a good teacher; but with proper preliminary training the modern method, introduced by Kelvin and Tait, would seem to be most advantageous.

The theory of dimensions, which helps more than anything else to give clearness to ideas in mechanics, is explained and freely used in the works of Professors Hoskins and Slate, but it is unfortunately omitted from the work of Professor Johnson. The need of this theory is shown at several points in the latter work; for example, on p. 126, where the phrase 'intensity of pressure' occurs, and on p. 268, where the equally cumbersome phrase 'intensity of force' occurs. Both of these phrases, which are now happily obsolescent, are here used by the author in a very puzzling way. Commonly 'intensity of pressure' means force divided by area, or stress in the more recent use of the latter term. Commonly, also, 'intensity of force' means force divided by mass, or acceleration. But these are not the senses in which Professor Johnson has used these phrases.

Without constant appeal to the theory of dimensions it is very difficult for the most careful

authors to avoid ambiguity of language. Thus, to cite an illustration from the work of Professor Hoskins, take his equation (1), p. 194, specifying simple harmonic motion, namely,

$$\ddot{x} = -kx,$$

wherein the first member means acceleration and x is a distance. The constant k , then, must be the reciprocal of the square of a time. But Professor Hoskins says that k is 'written for the attractive force *per unit mass* at unit distance from 0' (the origin); a statement immediately contradicted and corrected by the theory of dimensions. There is a more refined obscurity in Professor Hoskins' articles 177, 178, wherein the gravitation constant is involved. It appears from these articles that the force of gravitation, like 'electric force' and 'electromotive force,' may be different from the force considered elsewhere in the book.

Nearly all the older works on mechanics are marred by such obscurities as those noted above. The gravitation constant has been erroneously defined by many eminent authors, and some of our best works, in the French and German languages especially, are disfigured by the introduction of forces of more than one species. It is high time that all such obscurities and ambiguities, so easily detected by the theory of dimensions, were banished from mechanics.

In connection with this subject of clear and definite terminology attention should be called to Professor Johnson's revival of the use of the term 'force of inertia' and to Professor Hoskins' use of the term 'effective forces.' These are properly going, if not wellnigh gone, out of fashion. They seem doomed to be replaced by the more suggestive term 'kinetic reaction,' or 'mass reaction.' The word 'inertia' is responsible for a deal of difficulty in mechanics, and it seems well to follow the example set by Maxwell in his *Matter and Motion*, and use inertia very sparingly, if at all, except in the set phrase 'moment of inertia.' It appears worth while also to note that all the works in question define the term 'stress' in its earlier sense, assigned to it by Rankine. The more recent sense of the word, especially appropriate and useful in elasticity and hydromechanics, is force per unit area; that is, force divided by

area. This rather than the original meaning of the term seems destined to persist.

The work of Wernicke is likewise intended for elementary students, and was evidently prepared for home use especially, since it is printed in German type. It is far too detailed a work, as may be inferred from the title page, not all of which is quoted above, to meet with favor, except in reference libraries on this side of the Atlantic. The authors leave little room for play of the student's imagination and less room for the development of his originality. Everything is explained in extenso, and often in a provokingly complicated or inelegant fashion. The beautifully drawn diagrams convey too much information; and the many numerical examples seem well calculated to obscure rather than to illustrate salient principles. The work is one of the happily passing texts that try to present mechanics with little or no use of the calculus, and thus waste a deal of the student's time. There is much useful information in the volumes, however, and they may prove handy for those who cannot bring an adequate preparation to the subject.

The first volume is devoted to mechanics proper and gives an elementary view of the principles applicable to rigid bodies, with many applications to machinery. The second volume treats of gases and liquids, with applications to pumps, injectors, water motors, ventilators, etc. The second volume is supplied with a good index, but the first volume has none. R. S. W.

Water Filtration Works. By JAMES H. FUERTES, M. Am. Soc. C. E. New York, John Wiley & Sons; London, Chapman & Hall, limited. Cloth, 5 × 8 in. 19 plates and 45 figures in the text. 1901. Price, \$2.50.

In this work the author has discussed in a clear and very readable form the theory and practice of water filtration as it stands to-day. As preliminary to the subject proper the author devotes a short chapter to a brief statement of the relation of typhoid fever to polluted water supplies, and discusses the various processes of natural purification and the means of protecting surface waters from pollution. The great value of filtration as a means of purification is also here set forth. Chapter II. deals with intakes and sedimentation basins. The former subject

is treated very briefly and mainly with reference to questions pertaining to quality; the latter subject is treated quite fully, as is quite proper in a work on filtration, since clarification by sedimentation is very frequently an important part of the purification process.

Following these two chapters is a full discussion of the subjects of slow sand-filtration and rapid or mechanical filtration, in each case the underlying theory being first set forth and then matters pertaining to the design, construction and operation of works. In Chapter VII. are given the author's conclusions as to the relative advantages of the two systems, together with suggestions as to possible combinations. A few pages are also devoted to a very brief consideration of minor processes of filtration. It was doubtless proper to omit any consideration of household filters, but in a special work of this kind it would seem that a fuller treatment of the use of filters in the removal of color and of iron in solution might have been desirable. A brief chapter on filtered-water reservoirs completes the volume.

A noteworthy feature of the work is the full and valuable data relating to the operation of filter plants and settling basins. The designing engineer will also find convenient the numerous conversion tables and diagrams contained therein. The book is well illustrated by half tones showing interesting phases of construction and operation, and by well-executed cuts of details, particularly of filter-regulating devices. As a whole, the work places before the engineer a good summary of the latest information on this important subject, and at the same time presents the matter in a way to be of interest to the general reader.

F. E. TURNEAURE.

DISCUSSION AND CORRESPONDENCE.

IS IT NOT TIME THAT THE TITLE 'PROFESSOR OF AGRICULTURE' SHOULD GO OUT OF USE?

In most of our State institutions, known generally as Agricultural and Mechanical Colleges or Land Grant Colleges, we have what is known as the Agricultural Department, together with other Departments of the College, as, for example, the Mechanical, Civil and Electrical Engineering Departments, the Chemical, Bio-

logical Departments, etc. In some states where these institutions have merged into or connected themselves with State Universities, many more departments are present. The institutions there have a larger significance, and instead of terming the various lines of work as departments, they are designated as Colleges. Cornell University, for example, is made up of the Colleges of Agriculture, Law, Medicine, Engineering, etc. Each college goes to make up the university and each department goes to make up a college.

There seems to have been a tendency in the evolution of the Colleges of Law, Medicine, Engineering, etc., to recognize the fact that to have just one chair, designated as that of law, medicine or engineering, was to all purposes of reasoning ambiguous. The titles of professor of law, professor of medicine or professor of engineering therefore are not commonly used. In most cases the title designates explicitly the particular department, as, in law, professor of equity jurisprudence and law of real property, professor of commercial law, etc., in medicine, professor of clinical medicine, professor of dermatology, etc., in engineering, professor of mechanical, electrical, civil, marine, mining, etc., engineering.

The School or College of Agriculture seems to be alone in not having abandoned a custom long since recognized by others as obsolete. The title of 'professor of agriculture' is not explicit enough. Where in years past one man taught everything of economic importance in regard to plants and animals, to-day there are a number of well-defined departments. Instead of the professor of agriculture, we have the professor of agronomy, soil physics, animal industry, horticulture, forestry, etc.

In the modern institution, as in the University of Illinois, we find no professor of agriculture and it is readily seen that there is little need for such. It is believed that, in the future, when the fact of its misapplication is thoroughly understood, this custom, now so common, will go out of use.

FRANK WM. RANE.

THE NEW HAMPSHIRE COLLEGE,

AND FORESTRY.

THE WASHINGTON MEMORIAL INSTITUTION AND
A NATIONAL UNIVERSITY.

THE article by the Hon. John W. Hoyt, chairman of the National University Committee, published in the issue of SCIENCE for last week, may properly be the subject of a few words of comment from one who would welcome the establishment of a University of the United States and who at the same time regards the Washington Memorial Institution as the most important movement in this direction that is feasible at the present time. I am the more inclined to make these comments because Dr. Hoyt quotes from an article written by me four or five years ago without, as it seems to me, giving its full intention. I am quoted, for example, as remarking that 'all the arguments which have been urged against the establishment of a national university turn out to be in its favor.' The passage from which these words are taken reads as follows:

From a theoretical point of view it would seem that all the arguments which have been urged against the establishment of a national university turn out to be in its favor. The cost, the incompetence of government and the claim that existing universities suffice are, however, practical difficulties which we do not underestimate. Indeed, these are so evident that we should regard it as useless to advocate the immediate establishment of a great national university. We rather hope for a gradual growth from the national institutions already existing at Washington. We have there great libraries, museums and laboratories, able investigators engaged in advancing pure and applied science, and younger men learning from them the methods of research. These are the essentials of a university.

The establishment of the Washington Memorial Institution seems to be a most happy compromise between those who oppose and those who advocate the immediate establishment of a national university. Dr. Hoyt in criticising this institution probably does not represent the majority of the committee of which he is chairman. President Harper was chairman of the committee of the National Council of Education which endorsed the institution, and he doubtless regards it as the beginning of a national university. Other members of the committee may wish to confine the functions of the institution to those at present outlined, but time and the course of events will, in my opinion, prove irresistible forces. The best and

most stable results are usually secured through gradual evolution, and the Washington Memorial Institution can grow as rapidly as circumstances permit. Should there be a congressional cataclysm in favor of a national university, a foundation will be at hand which will obviate the necessity of erecting castles in the air.

The action of the National Council of Education in somewhat brusquely setting aside the report of its committee, and that of the National Educational Association in affirming its position in favor of a national university, certainly represent a strong trend of opinion. More especially are the representatives of the great State universities in favor of a national university, and these universities are the allies of the future. We are in the midst of conditions that have not existed elsewhere or heretofore. Our privately endowed colleges and universities originated largely in sectarian enthusiasm, and are still in large measure supported by adherents of special religious denominations. The unexampled gifts of rich men for public education have undoubtedly tended to maintain the stability of society and have bridged over the interval required for the people to learn the importance of higher education for the common good. But we shall not always depend on the charity of the rich, nor will our universities always be administered by business men. Pennsylvania, Johns Hopkins and Cornell are turning to the State for help; Harvard, Yale and Columbia must do the same if their prestige is to be maintained.

The obvious outcome of democratic institutions is the support of education by the people. We have district schools, city colleges and state universities. We shall have a University of the United States. It may come suddenly, but it is far more likely to result from the gradual development of the Washington Memorial Institution.

J. MCKEEN CATTELL.

SHORTER ARTICLES.

SOME OBSERVATIONS BEARING ON THE PROBABLE SUBSIDENCE DURING RECENT GEOLOGICAL TIMES OF THE ISLAND OF SANTA CATALINA OFF THE COAST OF SOUTHERN CALIFORNIA.

IN the course of the dredging operations carried on along the coast of southern California

by the Zoological Department of the University of California, during the past summer, observations were made incidentally of such obvious geological interest that I feel justified in going outside my own province to record them.

While dredging in forty-five fathoms about three-quarters of a mile off Long Point, on the north side of Santa Catalina Island, the dredge brought up large numbers of cobble stones varying in size from a sparrow's egg to a man's head. Most of them were very smooth and round, though they were covered by a thick coating of encrusting bryozoa, worm tubes, ascidians, chitens, sponges, etc., showing them to have remained undisturbed for a long period.

They were entirely similar in material and shape and size to the cobbles composing the shingle of many of the little beaches on different parts of the island, *e. g.*, that at Avalon near by.

That they came from a submerged beach was a suggestion so obvious as not to escape any of those on board the launch, in spite of the fact that there was not a geologist among us, and hence no one greatly familiar with the geological history of the region, and consequently prepared to put such an interpretation on what we saw.

When, however, we came to consider the matter in the light of facts of a wholly different character well known to geologists, and understood by them to testify that the island has been sinking beneath the waters of the Pacific in recent geological time, there would seem to be little doubt that at no very remote date in the past, geologically speaking, the *shore line of the island at the point from which these stones were taken was from three-quarters of a mile to a mile out to sea from its present position.*

The subject is so interesting as to make it worth while to present in outline the evidence from other sources tending to show that a subsidence of the island *has* taken place even if it is not still in progress.

It is now generally admitted among geologists, I believe, that San Pedro Hill on the mainland has emerged from the sea and been elevated to its present height, 1475 feet, since Post-Pliocene times. The hill, particularly on its seaward slope, is laid off into a succession

of remarkably clear-cut steps, or benches, one above another, to the number of ten in all, according to Professor Lawson. On approaching it from the sea one's imagination easily makes it the terraced grounds ages ago deserted and fallen into ruins, of one of Cronus' country seats before that crafty monarch was overthrown by all-powerful Zeus.

Professor A. C. Lawson* has brought forward arguments that are, I should think, conclusive, in support of the view that these steps are marine wave-cut terraces; that they mark the position of the ocean strand at successive periods during the elevation of the hill.

The island of San Clemente, 1,964 feet high, lying sixty miles to the southwest of San Pedro Hill, is very similar to it in topographical features, particularly as regards the terraces, the chief difference being that the terraces of the island are more sharply defined and more numerous than those of the Hill. The evidence is, then, that both the mainland of the coast, and San Clemente island emerged simultaneously from the sea.

Now the island of Santa Catalina, lying midway between the two, is wholly different from either of them topographically. It is a mountain mass as bold and jagged as one often sees, and terraces are entirely wanting. The same sally of the imagination that makes San Pedro Hill the country seat of King Cronus makes Santa Catalina Island the site of his castle; for not only have we here the rock upon which the castle stood, but in San Pedro channel, a hundred fathoms deep at not much beyond an arrow's flight from the rocky walls, we have also the moat of the castle.

The contrast between Catalina and the two land masses between which it is situated cannot be better brought out than by Professor Lawson's own words: "In all the physiographic wonderland of Southern California," he writes, "there is probably nothing more surprising than the contrast which the topography of Santa Catalina presents to that of both San Pedro Hill and San Clemente. Lying

* 'The Post-Pliocene Diastrophism of the coast of Southern California,' *Bulletin of the Department of Geology*, University of California, Vol. I., No. 4, 1893.'

midway between the two latter insular masses, in the same physiographic province, and affected by the same climatic conditions, Santa Catalina might, *à priori*, be supposed to differ from these but little in the character of its land sculpture. This supposition proves, however, to be fallacious. The difference between the aspect of the island and that of the two other neighboring insular masses is amazing, and the hypothesis which we are forced to entertain to account for it, is correspondingly startling."

The writer then proceeds to bring forward cogent arguments in support of the proposition that "*Santa Catalina was a land-mass, subject to the forces of subaerial degradation, at the time when San Pedro Hill and San Clemente began to emerge from the waters of the Pacific, in Post-Pliocene time.*"

But not only this. He finds further strong evidence, on physiographic grounds alone, that not only was the island full-born when the neighboring land masses began to emerge from the sea, but that while the latter have been undergoing elevation *Catalina itself has been subject to a process of submergence.*

In this latter view the author is defending a suggestion made by Dr. J. G. Cooper, the pioneer California naturalist who explored the island in 1863 as geologist of the California State Geological Survey.

With the addition of the evidence produced by our dredgings this summer to that brought forward by Professor Lawson, it would seem that the subsidence hypothesis reaches well nigh a demonstration.

It should be said that some of the fishermen at Avalon have known for a number of years of the existence of this particular bed of cobble stones, and it is asserted by them that the bed extends out to seventy-five fathoms.

Time would not permit us to trace out the full extent of bed. Similar cobbles were brought up at other points around the island, though not so abundantly as here; but it should be stated that most of our work here was done with the beam trawl, as this was found better adapted to our biological work. It is, however, much less likely to pick up such stones than is the dredge.

It is highly probable that careful dredging

with this as the primary object will discover similar evidence of submerged shingle beaches at many other points around the island.

WM. E. RITTER.

UNIVERSITY OF CALIFORNIA,
Sept. 7, 1901.

ZONE OF MAXIMUM RICHNESS IN ORE BODIES.

FOR a long time, and among many mining people, the theory has prevailed that ore deposits have been derived from the interior of the earth, the mineral materials being carried upward to the surface by means of heated solutions. As a result, a maxim has been established that ore bodies necessarily get richer as depth increases. The fact that many exceptions have been found to this rule is ascribed to peculiar local conditions.

Aside from the bare statement of the general rule, no limitations have been formulated by the mining men. It has remained for the geologists to reach measurable results regarding the relative richness of ore bodies at varying depths. The results are not only very satisfactory, but they are totally at variance with the commonly assumed formulæ. Late investigations demonstrate, both theoretically and practically, that the problem has been wholly misunderstood by miners; and that the so-called empirical rule has very decided limitations.

Contrary to opinions heretofore generally held, many, if not most, ore bodies are believed not to be formed by the materials coming up in a superheated condition from great depths to the surface of the earth. Revolutionary as it may seem to many who have not followed carefully the trend of recent investigation, it appears to be a fact, nevertheless, that ore bodies are to be regarded as deposits formed very near the surface of the earth's crust; or, to be more precise, formed only in that thin outer part of the zone of the lithosphere which geologists are pleased to call the zone of fracture. Unusual richness which many ore deposits show at very shallow depths has come to be looked upon as due to local enrichment long after the first concentration has taken place.

Careful study of important ore bodies indi-

cates that after a certain depth is reached, there is frequently a very marked decrease in the amount of ore material, until finally in some cases the ores become too lean to work. From the point of view of origin, diminution in richness with depth is not, then, to be regarded as an actual depreciation in grade of the ore. The real status of the case is that the original deposition of the ore has, in the upper zone undergone a greater or less augmentation in metallic content since the ore bodies first began to form.

As distinct processes, the rival theories of ascending solutions, descending solutions and laterally moving solutions no longer find countenance among those who have given the subject of ore genesis most attention, and especially among those who have approached the subject from the geological side. Ore deposition may take place through all three means, which may have equal importance. After an ore deposit has once formed under special geological conditions, the secondary enrichment which it may undergo is believed to take place largely under the influence of the descending solutions. Therefore, in the exploitation of ore bodies, everything goes to show how vitally important is a full consideration of the geological structures presented, both at the time of the first concentration and as subsequently assumed.

Under the title of 'Enrichment of Mineral Veins by Later Metallic Sulphides,' in the recently issued Volume XI. of the *Bulletin* of the Geological Society of America, Mr. W. H. Weed gives the results of his investigations concerning the zones of maximum richness in ore bodies. Briefly stated, the attempt is made to prove: (1) that the leaching of a relatively lean primary ore, commonly by surface waters, will supply the material in solution for such enrichment; (2) that the unaltered sulphides, especially pyrite, will induce precipitation, that the material precipitated is crystalline, and that a number of mineral species are commonly formed, and are now forming, in veins by such reactions; and (3) that such minerals deposited in quantity may form ore bodies of considerable size (bonanzas), or may be disseminated through the lean primary ore in strings and patches, thus enriching the ore body as a whole and

even making a former low-grade body of sufficient value to work.

It may be concluded that later enrichment of mineral veins is as important as the formation of the veins themselves, particularly from an economic standpoint. In many cases the enrichment proceeds along barren fractures and makes bonanzas. The enrichment is usually due to downward-moving surface waters, leaching the upper part of the vein and precipitating copper, silver, etc., by reaction with the unaltered ore below. As a consequence of this, veins do not increase in richness in depths below the zone of enrichment.

In the *Transactions* of the American Institute of Mining Engineers, Volume XXX., which is just being distributed, Mr. S. F. Emmons has a paper bearing upon this same subject of 'Secondary Enrichment of Ore Deposits.' The author draws upon his wide experience in calling attention to the many cases of secondary enrichment. The main theme discussed is summed up in the opening paragraphs, when he says that, 'admitting fully the general truth of the statement that the descending surface waters exert an oxidizing action, and hence that oxidation products within reach of the surface waters are the result of alteration by the latter, I have been led to believe, by observations now extending over a considerable number of years, that, under favorable conditions, the oxidation products may be changed back again into sulphides and redeposited as such, thus producing what may be called a sulphide enrichment of the original deposits. * * * Being rather a searcher after facts than a theorist, I am not deterred from accepting what may appear to me the correct reading of observed facts because it seems to contradict generally accepted theories.'

The same volume of the *Transactions* contains a practical application of Mr. Weed's theory to Montana deposits, under the title of the 'Enrichment of Gold and Silver Veins.' Attention is especially called to the dependence of such enrichments upon the presence of iron sulphide in the primary ore, and to the structural features which control the circulation of the enriching solutions below water-level. The process may be briefly described as follows. Leaching out of the metals from the portion of

the vein lying above ground-water level is to be considered as the main source of the enriching materials. The leaching is due to superficial alteration, and leaves the iron as a gossan, while the waters carrying the gold, silver, copper and other metals in solution trickle downward through the partially altered ores into cracks and water-courses which penetrate the ore body below the water-level. In weathering, the sulphides oxidize according to their relative affinity for oxygen and inversely as their affinity for sulphur. It is inferred from the evidence that ore bodies lacking in iron pyrite will not show enrichment, thus explaining the absence of any such phenomena in the pure silver-lead bodies of the Coeur d'Alene district and elsewhere.

CHARLES R. KEYES.

RECENT ZOO-PALEONTOLOGY.

VERTEBRATE PALEONTOLOGY AT THE CARNEGIE MUSEUM.

DURING the past summer three parties from the Department of Vertebrate Paleontology of the Carnegie Museum have been operating in our western fossil fields under the direction of Mr. J. B. Hatcher, the Museum's curator of vertebrate paleontology. One of these parties, in charge of Mr. O. A. Peterson, was sent to northwestern Nebraska to examine the Oligocene and Miocene deposits of that region. The work carried on by this party has been quite successful,—as might be expected from any party in charge of so experienced and skilled a collector of vertebrate fossils as is Mr. Peterson. Among other material secured may be mentioned as of especial value, skeletons of *Hoplophoneus*, *Daphænus*, *Oreodon*, *Procamelus* and *Merycochærus*, all, it is believed, sufficiently perfect to admit of mounting as complete skeletons. A second party, in charge of Mr. C. W. Gilmore, was despatched to southern Wyoming to continue the work which has been carried on by the Museum for the past two years in the Jurassic deposits at Camp Carnegie, on Sheep Creek, in Albany Co., Wyoming. This party has met with the usual success attending the two previous expeditions

to this locality, and owing to the skill and energy of Mr. Gilmore the value of the Museum's already important collections of Jurassic dinosaurs has been greatly enhanced. The third party has been in charge of Mr. W. H. Utterback, who has been engaged since November last in reopening the old quarry near Canyon City, Colorado, so long worked by the late Professor Marsh. From this quarry Professor Marsh obtained much of his best material of Jurassic dinosaurs. The bones at this quarry are imbedded in a very hard sandstone, which renders the work of securing them exceedingly difficult and tedious. Already a considerable portion of the skeletons of *Morosaurus* and *Stegosaurus* has been secured, along with other valuable material. Within the last month the work of reopening the quarries near Canyon City, which were operated for a number of years by the late Professor Cope, has been commenced by Mr. G. F. Axtell, also of the staff of this Museum.

DISCOVERIES IN NORTHERN AFRICA.

In the September number of the *Geological Magazine* Dr. Chas. W. Andrews* publishes details of his discoveries in the Western Desert of Egypt which mark the beginning of a new epoch in mammalian paleontology. The first visit to beds of upper Eocene and Oligocene age resulted in the discovery of a Sirenian (probably *Eotherium*), of *Zeuglodon*, a primitive Cetacean, and of Crocodilia, Chelonia and Amphibia. In later visits still more important fossils were secured, which Dr. Andrews has made the types of three new genera. *Palæomastodon* is a trilophodont proboscidean with five grinding teeth in the lower jaw, therefore much more primitive than the oldest Miocene mastodons of Europe. *Mærittherium*, found in older beds of supposed Upper Eocene age, is bilophodont and is probably correctly regarded by Dr. Andrews 'as a generalized forerunner of the mastodon type of proboscidean'; the upper and lower incisors are in pairs, the outer being tusk-like, as we should anticipate. A third, more aberrant type is *Braditherium* 'which in many respects resembles

Dinotherium, but in others reminds one of some of the gigantic Amblypoda of North America.' The resemblance to the Amblypoda is in our opinion unreal because all amblypods have triangular teeth, whereas this animal has quadrate bilophodont teeth and reminds us truly of *Dinotherium* as the author suggests. A strong resemblance is also seen to the great gravigrade sloths such as *Megatherium* or more correctly to their American Eocene ancestors with incisors and enameled teeth such as *Psittacotherium*; the depth of the jaw, the early wearing of the enamel, the position of the coronoid process on the outside of the lower molars, all tend to support this likeness. We shall therefore eagerly await the determination of the actual affinities of this animal. The epoch-making character of these discoveries consists in the promise they afford that Africa will prove to be the home of all those families of mammals such as the elephants, hippopotami, giraffes and antelopes, as well as of earlier types, which suddenly appeared in Europe without known ancestry. This would accord with an hypothesis independently advanced by Rüttimeyer and Osborn that Africa was an isolated center of mammalian evolution and radiation in the early tertiary, and subsequently contributed great migrations of its fauna to Europe and America.

NOTES ON PRIMITIVE AND FOSSIL BIRDS.

PYCRAFT's fourth paper in his 'Contributions to the Osteology of Birds,'* treats of the grebes and divers or Pygopodes. As regards the affinity of the Cretaceous toothed bird *Hesperornis* to this order (rather than to the separate order Odontornithes) he believes with D'Arcy Thompson that there can no longer be any doubt (p. 1041). The paper is supplemented by an excellent key to the comparative osteology of this group, a plan also followed in his extensive memoir † on the morphology and phylogeny of the *Palæognathæ* (*Ratitæ* and *Crypturi*) and *Neognathæ* (*Carinatæ*). In this memoir the pterylography, osteology and soft anatomy of the Tinamous (*Crypturi*) and of the various stru-

* 'Extinct Egyptian Vertebrates,' *Geol. Mag.*, p. 400, Sept., 1901.

* *Proc. Zool. Soc.*, London, Dec. 19, 1901.

† *Trans. Zool. Soc.*, London, Dec., 1900.

thious forms (ostrich, rhea, dinornis, aepyornis, emeu, cassowary, kiwi or apteryx) are thoroughly examined and lead the author to unite these two groups into a new division *Palæognathæ*, differing from all the remaining orders (*Neognathæ* equals *Carinatae* minus *Crypturi*) especially in skull structure.

His conclusion is that the various 'struthious' forms are widely separate in origin; the emeus and cassowaries are on the whole the most primitive, the true ostriches being a later branch from the same stem; the moas are distantly related to the aepyornithes; the kiwis (*Apteryges*) are highly aberrant. The inter-relationships of the higher birds are not discussed, but an appended phyletic tree represents *Hesperornis* as one of the *Pygopodes* and *Ichthyornis* as related to the *Steganopodes* (pelicans, tropic birds, cormorants, etc.).

H. F. O.

*THE BRITISH ASSOCIATION AND THE DEATH
OF PRESIDENT MCKINLEY.*

WE reproduce the letter addressed by the President of the British Association for the Advancement of Science to the United States Ambassador to Great Britain and the latter's reply :

BRITISH ASSOCIATION FOR THE ADVANCEMENT
OF SCIENCE.

BURLINGTON HOUSE,
LONDON, W., Sept. 19, 1901.

To his Excellency, The Hon. J. H. CHOATE, Ambassador of the United States of America.

Sir, The General Committee of the British Association for the Advancement of Science, assembled this year in Glasgow, desire me to express to you the horror with which they heard of the attack upon the late President of the United States, and their deep sorrow at his death. On the first day of the meeting in Glasgow the Association telegraphed to Mr. McKinley the assurance of their sympathy and of their earnest hopes for his recovery.

These hopes have not been fulfilled; and it is now my sad duty to inform you that the tragic fate of the President of the United States has cast a deep shadow over our meeting. Together with all our fellow-countrymen we share in the sorrow of the great sister nation which you represent; and we desire, through you, to inform the men of science of America that the members of the British Association are bound to them not only by ties of blood, not only by the links

which unite all students of nature, but by the deeper feelings which draw together those who are partners in a common sorrow, and mourn one of the leaders of our common race.

I am, sir,

Your obedient servant,

A. W. RÜCKER,

President.

AMERICAN EMBASSY,

LONDON, Sept. 23, 1901.

Sir,

I have received with heartfelt gratitude the kind expression of condolence and sympathy at the death of President McKinley which you have forwarded to me on behalf of the General Committee of the British Association for the Advancement of Science.

I shall duly advise my government of its receipt, and it will be highly appreciated by them and by Mrs. McKinley. Your kind message and hundreds of other similar communications from all parts of the British Dominions, carry an assurance of national friendship and goodwill which will be most welcome to the American people.

Yours sincerely,

JOSEPH H. CHOATE.

A. W. RÜCKER, ESQ.,

President.

SCIENTIFIC NOTES AND NEWS.

AMONG the scientific men who have expressed their intention of being present at the Yale bicentennial exercises are Professor Simon Newcomb and Professor Charles S. Minot.

PROFESSOR BASHFORD DEAN, of Columbia University, has returned from his sabbatical year, spent in studying the marine zoology of Japan, and in visiting China and the Philippines. He has sent to the American Museum of Natural History a fine collection of Ainu materials, also a series of glass sponges and of the Japanese long-tailed fowls. For the Zoological Department of Columbia he brings back extensive research and exhibition collections.

WE regret to learn that Dr. J. H. Hyslop, professor of logic and ethics in Columbia University, is ill, and has been given leave of absence for a sabbatical year which he will spend in the Adirondacks. Dr. A. L. Jones, as lecturer, will take his courses.

PROFESSORS MITSURU KUHARA and Hanichi Muraoka, occupying respectively the chairs of

chemistry and physics in the Imperial University of Kyoto, Japan, who have been spending a few weeks in this country, sailed from New York City, on October 8, for Europe, in continuation of their eastward trip around the world. They expect to reach Japan in February, in time to resume their duties at the beginning of the second half-year.

THE Hon. Andrew D. White, United States Ambassador to Germany, arrived in New York on October 5. He will return to his post in Berlin shortly.

THERE was a meeting of the students of the graduate school of Harvard University on October 3, at which Professor E. C. Pickering, director of Harvard College Observatory, made an address.

MR. S. P. JONES, of Atlanta, Ga., has been appointed assistant State Geologist of Georgia, vice Dr. Thomas L. Watson, resigned. Mr. Jones, after five years' work at the University of Georgia, practiced law a year or more, and then pursued a course of geological study with Professors Le Conte, Lawson and Merriam at the University of California. A year or two was spent in teaching, and in 1900 he refused an appointment on the Alabama Geological Survey to accept a fellowship at Vanderbilt University.

DR. ARTHUR WILLEY has resigned the post of curator to the museum at Demarara, to which he was recently appointed, and the place will be filled by Mr. R. Evans, of Oxford.

THE Swiney lectures on geology, in connection with the British Museum (Natural History), will this year be given by Mr. John S. Flett. The subject of the course of twelve lectures is 'The Geological Evidences of Former Geographical Conditions.' The first lecture will be given on October 7.

IN the death of Frederick Fraley, born on May 18, 1804, Philadelphia has lost one of its most honored citizens. Mr. Fraley was always ready to assist scientific work. He was one of the original trustees of Girard College, since 1847 trustee of the University of Pennsylvania, and since 1880 president of the American Philosophical Society.

DR. A. F. W. SCHIMPER, professor of botany at Basle, died on September 9, at the age of forty-five years.

THE London *Times* announces the death of Mr. Martin Fountain Woodward, demonstrator in biology at the Royal College of Science, South Kensington. He was the younger son of Dr. Henry Woodward, F.R.S., keeper of the department of geology in the British Museum, and was drowned on the night of September 15, by the capsizing of a boat on the Irish coast. Mr. Woodward was in temporary charge of the marine biological laboratory of the Fisheries Board for Ireland. He and his friend, Mr. W. Watson, F.R.S., assistant professor to Professor Rücker, at the Royal College of Science, were crossing from Innisbofin, when, about a mile from the shore, the boat was caught by a sudden squall and capsized. Mr. Watson and the fisherman who was with them reached the shore with the aid of an oar, but their companion was not seen again after the boat turned over. Mr. Woodward entered the Royal School of Mines and Normal College of Science in 1883, where he obtained the Murchison Prize and Medal. He was appointed demonstrator in biology in 1885 by Professor Huxley, and had since acted in that capacity to Professor Howes. He was the author of various papers on mollusca and on the dentition of mammalia. In 1898-1900 he edited an English edition of Korschelt and Heider's 'Text-book of Embryology of Invertebrates.' He was secretary of the Malacological Society of London, and was specially devoted to marine zoology, having on several occasions dredged the British and French coasts.

WE learn from *Nature* that the Reale Istituto Veneto announces nine prizes for competition in the faculties of science, letters and arts, for which essays have to be sent in at the close of the years 1901, 1902, 1903. The subjects in science include the projective properties of the two-dimensional algebraic surfaces of n -dimensional space, the geophysical and biological characters of the lakes of the Venetian district excluding the Lago di Garda, and the development of the respiratory apparatus of the pulmonate vertebrata.

THE estate of the late Jacob S. Rogers has been appraised at over \$5,600,000. It will be remembered that the greater part of the estate was bequeathed to the Metropolitan Museum of Art.

THE Paris Academy of Medicine will occupy its new building on the rue Bonaparte at the beginning of next year. It is reported that the Paris Municipal Council will secure the present building on the rue des Saints-Pères, for the Charité Hospital.

AT the recent Buffalo meeting of the American Public Health Association officers were elected as follows: President, Dr. Henry D. Holton, Brattleboro, Vt.; 1st Vice-President, Dr. Walter Reed, U. S. Army; 2d Vice-President, Dr. Jesus Chico, Guanajuato, Mexico, and Treasurer, Dr. Frank W. Wright, New Haven, Conn. The next meeting will be held in New Orleans.

The British Medical Journal states that the new Anatomical Department of the University of Glasgow was formally opened by Lord Lister on the afternoon of September 12. The department had for years been hampered by an unsuitable and insufficient accommodation, and the splendid new buildings now inaugurated have been provided through the munificence of the trustees of the late Mr. J. B. Thomson, the well-known shipbuilder. The new buildings include an excellent laboratory and museum, and for this museum Professor Cleland has presented to the university his fine collection of anatomical specimens. In his address, Lord Lister dwelt on the importance of the study of anatomy, and congratulated Professor Cleland and the university on the excellent accommodation which was now set apart for that study. Amongst the others who took part in the proceedings were Principal Story, Lord Provost Chisholm, Sir William Turner, and Professor Cleland; and after the speeches the premises were inspected by the company, and afternoon tea was served.

THE new Pathological Laboratory of the University of Oxford will be opened on October 12. Sir William Church, Bart., president of the Royal College of Physicians of London, Dr. G. Sims Woodhead, professor of

pathology in the University of Cambridge, and others will take part in the proceedings.

THE plans of Dr. Walter Wyman, surgeon-general of the U. S. marine hospital service, for the establishment of an institute for the study of yellow fever have been approved by the government.

THE Brazilian government has declared that the City of Rio de Janeiro is infected with the bubonic plague. Eleven cases of bubonic plague and four deaths are reported from Naples.

THE Fifth International Congress of Physiology was opened on September 17, in the physiological laboratory of the University of Turin, under the presidency of Professor Angelo Mosso. Sir Michael Foster was elected honorary president. Professor Fano, Professor Fredericq, Professor Grützner and Professor Sherrington were appointed general secretaries. More than 200 physiologists were present, and 186 communications were announced. A reception was given by the members of the Academy of Medicine of Turin and an exhibition of physiological apparatus was opened.

THE opening meeting of the eleventh session of the British Institution of Mining and Metallurgy will be held on October 17, in the rooms of the Geological Society, Burlington House. The meetings during the session will, to suit the convenience of the members, be held from 5 to 7 p. m., and tea will be provided at 4.30. The annual dinner will be held on the same day.

THE twenty-second annual congress of the French Geographical Society was held recently at Nancy, under the presidency of M. Fournier. There were no less than twenty-two societies represented, of which nineteen were local geographical societies. The Society made a number of recommendations, including the following: That a colonial exposition be held in Algiers; that conventional signs be universally adopted in geographical and topographical work; that the metric system be introduced in those colonies where it has not been adopted; that a decimal division of the quadrant of a circle be adopted; that additional canals be constructed in France; that certain

districts be reforested; that methods be adopted for increasing the birthrate of France, and that a postal service be organized in China under French auspices.

THE biological teachers on the transport *Thomas*, who went to the Philippine Islands in the latter part of July, organized during the voyage a biological society for the investigation of the fauna and flora of the Islands. Mr. H. H. Kenagy, formerly graduate assistant in zoology, University of Nebraska, was chosen as the first president of the organization.

THE British Antarctic exploration ship, *Discovery*, arrived at Cape Town on the 3d inst.

THE committee on the Senn Medal call attention to the following conditions governing the competition for this medal for 1902: (1) A gold medal of suitable design is to be conferred upon the member of the American Medical Association who shall present the best essay upon some surgical subject. (2) This medal will be known as the Nicholas Senn Prize Medal. (3) The award will be made under the following conditions: (a) The name of the author of each competing essay shall be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device is to be read at the meeting at which the award is made, and the corresponding envelope to be then and there opened and the name of the successful author announced. (b) All successful essays become the property of the Association. (c) The medal shall be conferred and honorable mention made of the two other essays considered worthy of distinction, at a general meeting of the Association. (d) The competition is to be confined to those who at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the American Medical Association. (e) The competition for the medal will be closed three months before the next annual meeting of the American Medical Association, and no essays will be received after March 1, 1902. Communications may be addressed to any member of the committee, consisting of the following: Dr. Herbert L. Burrell, 22 Newbury street, Boston, Mass.; Dr. Edward Martin, 415

South Fifteenth street, Philadelphia, Pa.; Dr. Charles H. Mayo, Rochester, Minn.

THE U. S. Geological Survey has issued a statement concerning the value of the mineral products of the United States from which we take the following:

	1880.	1890.	1900.
Metallic products.	\$190,039,865	\$305,735,670	\$552,418,627
Nonmetallic products.	173,279,135	312,776,503	516,690,262
Unspecified.	6,000,000	1,000,000	1,000,000
Total.	\$360,319,000	\$619,512,173	\$1,070,108,889

Last year the value of the mineral products for the first time exceeded a million dollars. During the past nine years the value of the silver mined has not increased, though there has been a considerable increase in the course of the last four years. During the nine years the value of the gold has increased from 33 to 39 million dollars; of pig iron from 128 million to 129 million; of copper from 38 million to 98 million, and the value of aluminum has increased thirteenfold. The value of bituminous coal has increased from 117 million to 221 million, and the value of petroleum from 30 million to 75 million. While in the case of the metals the output has increased approximately in proportion to the value, this is not the case with petroleum. In 1891 the value of crude petroleum was about 56 cents per barrel, whereas in 1890 it was \$1.20.

UNIVERSITY AND EDUCATIONAL NEWS.

By the will of the late Susan Cabot Richardson, of Milton, Mass., Radcliffe College will ultimately receive nearly \$200,000.

SYRACUSE UNIVERSITY has received an anonymous gift for the erection of a new building to be called the Hall of Natural History.

It is said that the proposed Milliken University, at Decatur, Ill., will be opened next year, with an endowment of over \$1,000,000, of which sum Mr. James Milliken has given over \$500,000. Professor S. R. Taylor, recently president of the Kansas State Normal School, will be president. The institution is under the charge of the Cumberland Presbyterian church.

MR. ANDREW CARNEGIE has given £25,000 to the Glasgow Technical College towards the £50,000 necessary to complete the required fund, £150,000, for the improvement of that institution. Mr. Carnegie has also offered £7,500 for a library at Ilkeston.

THE attendance at Cornell University, including 850 new students, is stated by President Schurman, in his annual opening address, as about 250 in excess of that of last year, and as indicating the total registration for the year, inclusive of the medical school in New York and the summer school at Ithaca, as between 3,250 and 3,500. The registration on the campus, of students in regular courses, promises to be about 2,750. Sibley College has a total attendance of new students, in all classes and courses, of above 350, almost equal to the total of upper classmen returning to the college, making the probable total registration for 1901-'02 about 750 in all grades. The College of Civil Engineering has increased fifty per cent., and the other colleges and departments report large additions. The new building for the medical department is about half completed; that for Sibley College, the great central 'dome,' about one third.

PRESIDENT SETH LOW presented his resignation to the trustees of Columbia University on October 7. It was accepted with expressions of deep regret, and Dr. Nicholas Murray Butler, professor of philosophy and education, was made acting president.

DR. GEORGE H. DENNY, professor of Latin, has been elected president of Washington and Lee University to fill the vacancy caused by the death of William L. Wilson last October. Dr. Denny is not yet thirty-one years of age.

F. H. KING, since 1888 professor of agricultural physics in the University of Wisconsin, has accepted the position of chief of a new division, created in the Bureau of Soils, and goes to the new appointment in November next. The vacancy created at the University of Wisconsin has not yet been filled.

AT Trinity College, Professor Flavel S. Luther, of the mathematical department, has returned from Europe and will take up his work after a year's absence. Rev. Herman Lilienthal has resigned as assistant in the department

of philosophy and Rev. Charles Harris Hayes, Ph.D. (Columbia, Halle and Oxford), of Portland, Me., will take his classes.

DR. EDWIN MEAD WILCOX, M.Sc. (Ohio), and Ph.D. (Harvard), formerly professor in the Agricultural and Mechanical College of Oklahoma, has been appointed professor of biology in the Alabama Polytechnic Institute, Auburn, Ala., filling the vacancy caused by the resignation of Professor F. S. Earle, who has resigned to accept a curatorship in the botanical department of Columbia University, New York.

DR. W. M. BLANCHARD, last year instructor in chemistry at the Rose Polytechnic Institute, has been appointed instructor in charge of the department of chemistry at De Pauw University, in the room of Dr. P. S. Baker, whose death we were recently compelled to announce.

THE following changes have been made in the scientific departments of the University of Maine; Gilbert A. Boggs, Ph.D. (Pennsylvania), has been appointed instructor in chemistry; John E. Burbank, A.M. (Harvard), tutor in physics; Frank H. Mitchell, B.S., tutor in chemistry; H. W. Britcher, of Syracuse and Johns Hopkins Universities, assistant in zoology; Louis R. Cary, B.S., assistant in biology, and Geo. E. Poucher, of De Pauw University, assistant in physics.

DR. ISAMBARD OWEN having definitely declined to accept the principalship of the South Wales and Monmouthshire University College, the council at a recent meeting decided to advertise for a successor to the late principal, Viriamu Jones, at a salary of £1,000 a year.

MR. W. J. POPE has been appointed professor of chemistry and head of the chemistry department at the new Municipal School of Technology at Manchester.

DR. T. E. STANTON, professor of engineering at University College, Bristol, who recently accepted the appointment of superintendent of the Engineering Department in the National Physical Laboratory, is succeeded in his chair at Bristol by Mr. R. M. Ferrier, B.Sc. (Glasgow).

PROFESSOR MAX WOLF, of Heidelberg, has received a call to the University at Göttingen as professor of astronomy and director of the observatory.

SECTION B, PHYSICS.

THE officers of this Section were: Vice-President, D. B. Brace; Secretary, John Zeleny; Member of Council, E. L. Nichols; Sectional Committee, D. B. Brace, John Zeleny, B. W. Snow, L. B. Spinney, E. L. Nichols; Member of General Committee, L. B. Spinney.

A large number of papers of unusual importance was presented before the Section, so that a keen interest was maintained in the meetings to the very end. The authors of a number of the papers were absent but had representatives who were familiar with the subjects they presented, so that beneficial discussions were possible even in these cases.

On Thursday forenoon, August 29, the Section met with the American Physical Society, and on the afternoon of the same day there was a joint meeting of Sections A and B.

The following are the abstracts of the papers that were presented:

1. 'A Spectrophotometric Comparison of the Relative Intensity of Light from Carbon at Different Temperatures': ERNEST BLAKER.

The instrument used in this work was a Lummer-Brodhun spectrophotometer, the comparison source being an acetylene flame.

The carbon studied was that of the filament of the ordinary incandescent lamp with treated surface, on the one hand, and a similar filament with smoked surface on the other. Temperatures were computed by means of the empirical relation between them and the ratio of the resistances of the hot and cold filament, established by Chatelier.*

Isochromatic curves showing the rise in intensity with the temperature were plotted for various wave lengths of the visible spectrum. These, taken separately, exhibit the form characteristic of bodies previously investigated, such as platinum and the artificially produced 'black body.'

The temperature or its reciprocal as demanded by the received equations for radiation is nearly proportional to the logarithm of the intensity.

The corresponding isothermal curves, however, show the existence of the remarkable peculiarity noted by Nichols † in a recent paper. The selective radiation in the yellow, described by that author, is even more strikingly developed at the higher temperatures covered in these experiments. It exists alike in the case of the gray-surfaced carbon and in lamp black and would lead us to classify carbon rather with the metallic oxides than with the black bodies, as regards the laws of radiation.

2. 'The Distribution of Energy in the Spectrum of the Acetylene Flame': GEORGE W. STEWART.

The great value of acetylene not only for illuminating purposes, but also in experimental research, makes the study of the distribution of energy in its spectrum of considerable importance. In the work to be described, a mirror spectrometer and fluorite prism were used to produce the spectrum, and the radiometer of Nichols to measure the radiant energy. The mirror-

prism device of Wadsworth was utilized, the main advantage gained being that the radiometer could be kept stationary. The spectrum fell upon a slit mounted directly in front of the fluorite window of the radiometer, thus avoiding the use of any lens whatever.

The source of light used in the work upon the visible portion of the spectrum was a cylindrical acetylene flame from a single-tip burner. This type was used because the intensity per unit area was greater than in the flat flame. The results, plotted in the form of a curve, afford definite data concerning the distribution of energy in the visible spectrum of this flame.

Owing to the difference in the dispersion of the prism, a slight change in the relative positions of the spectrometer and radiometer was of greater consequence in the infrared than in the visible portion of the spectrum.

The most striking characteristic of the curve of energy distribution is the set of elevations which are due to the emission bands of the gases of the flame. If the acetylene is pure, the gases to be expected are CO_2 and H_2O . According to Paschen, the maximum points of the emission bands of these gases are as follows:

H_2O Spectrum,
1.46 μ , 1.90 μ , 2.83 μ .

CO_2 Spectrum,
2.71 μ (2.68 μ when CO_2 is not dry) and 4.40 μ .

The energy curve shows elevations whose maxima agree very closely with these values. Observations of wave lengths longer than 6 μ are useless, the error due to stray radiation being so great.

Similar measurements were made upon the flame of a bunsen burner adapted for the combustion of acetylene.

In this curve all five emission bands appear and the values of the wave length at the maximum points agree with the values

* Chatelier, *Journal de Physique* (3), I., p. 203.

† Nichols, *Physical Review*, Vol. XIII., 1901.

quoted above. If we compare the bunsen and the single tip curves, we see that they do not agree in all respects. The elevations due to the emission of the H_2O gas have not the same relative values in the two cases, but this discrepancy disappears when corrections are made for slit widths. The band at 2.3μ does not appear in the bunsen flame and this fact makes its presence in the other somewhat in doubt.

The changes produced in the correction of the curves possess several points of interest. The maximum of intensity is shifted considerably toward the violet, appearing in the corrected curve at about 0.94μ .

Using Langley's method of finding the ratio of the area in the visible portion of the spectrum, to the area of the entire curve, the radiant efficiency was calculated. The value for the cylindrical flame is 0.100 and for the flat flame 0.131. The latter value is not very reliable, but there is not much doubt but that the radiant efficiency of the flat flame is the larger. Stewart and Hoxie, using a modification of the Melloni method, found the value 0.105 for the flat flame. (To be printed in the *Physical Review*.)

3. 'Experiments on a New Form of Standard High Electrical Resistance': H. C. PARKER. (By title.)

4. 'Variation of Contact Resistance with Change of E. M. F.': H. C. PARKER. (By title.)

5. 'On Flutings in a Sound Wave and the Forces due to a Flux of a Viscous Fluid around Spheres': S. R. COOK, Washburn College.

The author shows that the forces due to a perfect fluid are not sufficient to produce the laminae and flutings in a sound wave, but that there are other forces which are probably due to the viscosity of the vibrating media. That there must be other forces was first manifest by a series of experiments with air, carbon dioxide, chlorine and

hydrogen as media, using various materials to form the laminae, including filings of coin silver and platinum.

The author also shows that flutings are not confined to a stationary sound wave but are capable of being produced by direct sound waves on an open surface.

A mica disk, threaded on a fine wire in a resonance tube, was caused to vibrate in unison with the prong of a large tuning fork, whose frequency was 32 per second. Koenig's equations for the forces due to a perfect fluid when reduced to their final form are:

$$X = \frac{3/2\pi\rho R^3 R_1^3 W_0^3}{r_0^4}$$

$$Z = -\frac{3\pi\rho R^3 R_1^3 W_0^3}{r_0^4}$$

$$M = \rho R_2^3 W_0 \sin 2\theta.$$

ρ = density of medium, R , R_1 , R_2 are the radii of the sphere or disks, W_0 the velocity of the stream. This gives repulsion parallel and attraction perpendicular to the stream lines. The forces were studied by first allowing RR_1 to vary while ρ and W_0 remained constant. Then ρ was varied while all other factors were kept constant, and it was shown that

$$\frac{X_1}{X_2} = \frac{Z_1}{Z_2} = \frac{M_1}{M_2} > \frac{\rho_1}{\rho_2}$$

when ρ_1 was the density of carbon dioxide and ρ_2 that of air.

A further study of the forces was made with sealing-wax spheres and it was found that when the spheres, whose radii were less than 1 mm. were at a greater distance than one-half their diameter apart, they followed the perfect fluid forces, but when they were less than one-half their diameter they were repelled perpendicular, and attracted parallel, to the line of flow.

The author reaches the following conclusions:

1. The conditions for the formation of laminae are found whenever there is a flux of a viscous fluid around solid particles.

2. There are forces exactly opposite to those of the perfect fluid.

3. These new forces are most probably due to the viscosity of the medium.

4. The new forces in conjunction with the forces of a perfect fluid make possible a complete and clear explanation of the laminae and flutings produced in a sound wave. (To be printed in the *Phil. Mag.*)

6. 'Interferometer Curves': J. C. SHEDD, Colorado College.

The general equation of the interference curves is found to be a conic and the conditions for obtaining the various forms are determined by considering the question of eccentricity.

The various cases are taken up in detail and the experimental manipulations necessary for obtaining them are explained.

7. 'On the Absorption Spectrum of Iodine in Solution': EDWARD L. NICHOLS and WILLIAM W. COBLENTZ.

That iodine dissolved in carbon disulphide, although opaque to the visible spectrum, transmits the infra-red rays freely, has long been known, but no systematic studies of the spectrum of such solutions appear to have been made. In the study of the visible spectrum a horizontal slit spectrophotometer was used. Quantities of iodine varying from 3.3 mg. to 0.017 mg. per cubic centimeter were dissolved and their absorption spectra measured. A single broad band was found, having its maximum at $\lambda = .52\mu$, the transmission curve being steeper on the side towards the violet. For the solution containing 0.017 mg. per cc. the transmission in the center of the band was 80 per cent. With increasing concentration the band widens and becomes more dense. Solutions containing more than .25 mg. per cc. are opaque in the center of the band, and the region of opacity extends as the amount of iodine in solution is increased until the entire visible spectrum is obscured. Observations upon

iodine dissolved in alcohol showed a very different absorption spectrum. Such solutions were opaque in the violet, the transmission increasing steadily towards the red. The form of the curves was such as to indicate an absorption band of which one side only lies in the visible spectrum, the center being in the ultra-violet. To extend these measurements to the infra-red spectrum a Nichols radiometer was employed. Readings of the transmission of various solutions were made out to 2.7μ , beyond which wave-length the solvent itself rapidly becomes opaque. It was found that all solutions rose rapidly in transmitting power with increasing wave-length and became completely transparent between 1.0μ and 1.1μ , between which region and 2.7μ , iodine appears to exert no absorbing power whatever.

7a. 'A Preliminary Communication on the Pressure of Light and Heat Radiation': E. F. NICHOLS and G. F. HULL.

The experiment consisted of two parts: (1) The determination of the light pressure by observing the deflection, either static or ballistic, of a torsion balance when one vane of the balance was exposed to light, and (2) the determination, in ergs per second, of the intensity of the light falling upon the vanes. The image of an aperture, upon which the rays from an arc lamp were concentrated by two condensing lenses, was focused in the plane of the glass vanes placed symmetrically with regard to a rotation axis held by a quartz fiber of known torsion coefficient. The torsion balance was covered by a bell jar connected to pressure gauges and a mercury pump. To eliminate the disturbing action due to the residual gas in the receiver, the following devices were used: (1) The vanes were silvered and highly polished, thus making the absorption small and the reflection percentage large. (2) The silver surface of one vane was turned towards, and of the other, from,

the light, thus making the effect of the gas action and light pressure in the same direction on one vane, and in opposite directions on the other. (3) The pressure of the air in the bell jar was varied, and the pressures were chosen in the vicinity of that pressure at which the gas action was very small. (4) The length of exposure of light on the vane in most of the observations was short. The gas action, which begins at zero and increases with the length of exposure, was thus reduced in comparison with the instantaneous action of the radiation pressure. By means of an inclined glass plate placed in front of the aperture a portion of the incident light was thrown on a thermopile. The deflection of a galvanometer connected with the latter gave the relative light intensities.

Two methods of determining radiation pressure were used:

(1) The vane was exposed continuously to the light until the turning points of the vibration of the balance showed that static conditions had been reached. The other vane was then exposed. Finally the whole suspended system was turned through 180° , and the vanes were exposed in turn. The mean of the angles of deflection, multiplied by the torsion coefficient of the fiber and divided by the lever arm, gave the force in dynes acting on the vane. (2) The vanes were exposed for a quarter of the period of the suspended system. The period, damping coefficient, torsion coefficient and lever arm being known, the value of the radiation could be found. The two methods gave practically the same result except for the air pressures for which the gas action was large.

The energy falling upon the vanes was measured by means of a bolometer consisting of a thin disc of platinum, about the size of the vanes, covered with platinum black. The bolometer, occupying exactly the position which the glass vane had pre-

viously occupied, was made one of the arms of a Wheatstone bridge. The bridge was balanced, the bolometer exposed to the light, and the throw of the bridge galvanometer read. Later the disc was heated by an electric current which entered and left at two equipotential points on the bridge current and the galvanometer throw again was read. The current strength and the resistance of the disc being known, the activity of the disc is given by $i^2R \times 10^7$ ergs per second. The readings of the thermopile before mentioned made it possible to reduce all observations to a constant light intensity. If E = energy per second falling upon a surface, a = the percentage of the radiation reflected, v = the velocity of light, then, theoretically, the value of the radiation pressure is $\frac{(i + a)E}{v}$. The experimental value of the pressure as found by the authors was about 80 per cent. of the theoretical value.

8. 'The Absorption Spectrum of Ferric Hydrate': B. E. MOORE, University of Nebraska.

The author in a recent article upon 'A Spectrophotometric Study of the Hydrolysis of Ferric Chloride,' has pointed out that the final product is colloid ferric hydrate. This product can be formed by Graham's dialytic method. It would then be inferred that identical products would have identical absorption spectra.

It was found that the absorption of the two products was quite different in character. The addition of given quantities of chlorine or of hydrochloric acid, did not effect any transformation in the dialyzed colloid, *i. e.*, crystalloids, if present, were not changed by this treatment. If dialyzed ferric hydrate, or hydrolyzed ferric chloride were added to fresh dilute ferric chloride, the hydrolysis of the latter was accelerated. The greater acceleration was caused by the hydrolyzed ferric chloride. From this it is

inferred that both solutions contain identical colloids, but that the Graham's colloid contains also considerable inactive crystalloid hydrate. The absorption curve then suggests that the crystalloid has an absorption curve lying between hydrolyzed ferric chloride and non-hydrolyzed ferric chloride. (To be printed in *Physical Review*.)

9. 'Note on the Transmission of Radiation by Thin Films of Asphalt': E. L. NICHOLS.

10. 'The Faraday Effect in Solutions of Hydrolyzed Ferric Chloride': FRED. J. BATES, University of Nebraska.

The rotation of the plane of polarization in optical transparent substances, when the light is transmitted along the lines of magnetic force, has been the subject of numerous experiments since the days of Faraday, and is known as the 'Faraday Effect.' There have been many determinations of the molecular rotation of substances in solution, but little effort to determine whether the effect in solution arises from a molecule or from an ion or from both. Observations have also frequently been limited to one color (and perhaps then a mixed color), or to a few colors. It seemed desirable to extend these observations to different parts of the spectrum. This is particularly true of colored solutions, whose colors correspond hypothetically to the free periods of their vibrations, affecting the dispersion and probably the rotation of the plane of polarization.

Ferric chloride solutions afford a good means of testing this phenomenon. Observers have noted that the molecular rotation of this substance decreases upon dilution of the solution. This suggests that the rotation arises from the molecules rather than from the ions. The writer tried a solution of sufficient concentration to give him a rather large rotation. The solution was then diluted enough to leave the effect slightly but certainly noticeable.

If the rotation was proportional to the concentration, no effect was observed, which suggests that the ions are inactive or possess very small rotary power in comparison to that of the molecules. Observations by Goodwin and Moore show that dilute solutions of ferric chloride hydrolyze and finally form a new product, colloid ferric hydrate. It was thought that by restoring an iron molecule by this process there would possibly be a small rotation where previous ionization had made it unobservable. By this test it was found that the required dilution to obtain sufficient hydrolysis made the quantity of iron too small to give any further evidence by the usual method of observation. However, the use of a sunlight spectrum showed an effect as soon as one began to pass from the transparent spectral region into the absorption region. The half-shade polariscope could be read to 0.01° , and in the red the difference between a .01 normal solution (hydrolysis forced by heating the solution) and water was not more than 0.01° . The difference between an unhydrolyzed solution of this concentration and water was also unobservable. Upon examination of the hydrolyzed solution at a point in the green where the absorption is very marked, a rotation of $.79^\circ$ was observed, while at the same point the other two solutions showed no difference. That is, we have here an anomalous rotary polarization or 'Faraday Effect,' analogous to anomalous dispersion. It is clear that in this case the anomaly arises from molecules in the region of their absorption. It remains to be seen whether such an anomaly will also arise in solution where the absorption arises from ions.

11. 'Discharge of Electricity from Glowing Platinum and the Velocity of the Ions': E. RUTHERFORD.

A rectangular platinum plate 14 cm. long, 7.5 cm. wide and .002 cm. thick, was heated to incandescence by an electric

current. The platinum plate was charged to a known potential by means of a battery and the current between the platinum plate and a parallel copper plate observed by means of a sensitive galvanometer. The rate of discharge of positive and negative electrification was examined under varying conditions of temperature, distance and P. D. between the plates, and compared with the theoretical results deduced from the ionization theory of gases.

At a temperature of a dull red heat positive ions are produced at surface of the platinum plate, which travel to the opposite plate through the gas, if the platinum is positively charged. The movement of the ions disturbs potential gradient between plates and at high temperatures the slope of potential near hot plate is extremely small.

Let i = current per sq. cm. through the gas.

n = number of ions per cc. at any point distant x from platinum plate.

V = P. D. between the plates.

K = velocity of positive ion for unit potential gradient.

e = charge on ion.

d = distance between the plates.

Assuming the potential gradient zero at the platinum surface, it can readily be shown that

$$i = \frac{9V^2K}{32\pi d^3}$$

The current is thus independent of number of ions produced, *i. e.*, the temperature of the plate, providing it exceeds a certain value. Experimentally it was found :

1. For a distance of 2 cm. and under, the current at first increased rapidly with rise of temperature up to a certain point, and then more slowly. For distances of from 3 to 8 cm. the current rose to a maximum, and then steadily decreased with rise of temperature.

2. The maximum current varied approximately as square of the P. D.

3. Current diminished more rapidly than $\frac{1}{d^3}$.

The differences observed in (1) and (3) between experiment and theory are due to (a) decrease of velocity of ions with distance from heated platinum plate, (b) presence of some very slow-moving carriers produced at platinum surface at high temperatures.

The velocity of the ions was measured by a direct method depending on the use of an alternating P. D. of known frequency. The method was similar to that used previously for determination of velocity of ions produced by ultra-violet light (*Proc. Roy. Soc.*, 1898). It was found that the velocity of ions was not a constant, but varied between wide limits.

This is probably due to difference in size of ions in consequence of their varying power of forming clusters of molecules round them.

The following table gives results obtained for different distances between plates. Under heading 'calculated velocity' are given values of K calculated from equation (1) by measuring maximum current i for given distance and voltage.

Distance between plates.	Velocity in cm. per sec. for 1 volt per cm.		
	Maximum.	Average.	Calculated.
2 cms.	13	7.8	5.5
3 "	7.9	5.8	3.2
5 "	—	4.7	2.2

12. 'On Conditions controlling the Drop of Potential at the Electrodes in Vacuum-Tube Discharge': CLARENCE A. SKINNER, University of Nebraska.

With the passage of electricity through rarefied gases, it requires, relatively, a very high P. D. to force the discharge directly across the space between the electrodes when these are brought within a certain small distance apart. To locate at what part of the path the potential increases was the primary object of this investigation.

The results led to a more general investigation of the drop of potential at the electrodes.

A cylindrical vacuum-tube, with disk electrodes (perpendicular to its axis) insulated so as to force the discharge directly across the space between them, and nitrogen were used. The potential of the gas at any position was obtained by a movable wire.

As the electrodes approach each other the drop at the anode remains constant so long as there is an extended positive column. With the anode passing through the Faraday dark space its 'drop' rises to a maximum and then falls to zero in the negative glow, but rises again *rapidly* as the anode moves into and through the cathode dark space. The cathode drop remaining constant until the anode reaches the cathode dark space begins then to increase with great rapidity. During these changes the conductivity of the gas does not vary.

These results are explained on the hypothesis that the impact velocity of the discharging ion tends to prevent charge from being transmitted to the electrode; that to give up its charge the ion must first come to rest.

Other Observations.—At the cathode the drop may be expressed by the equation

$$V = C + \frac{c}{p}(a + i)$$

where i is the current density; p , the gas pressure; C , a constant approximating in value the cathode drop, as measured by Warburg; c , a constant depending on the nature of the gas, but independent of the metal used as cathode; and a , a constant. At the anode the drop appears to vary according to a similar law, where c is about one thirty-fifth its magnitude at the cathode.

The great difference in magnitude of the drops at the two electrodes may be explained on the hypothesis that the positive ion is of much greater mass than the nega-

tive and hence (for the same impact velocity), its elastic reaction being greater, the greater resistance to its discharge.

The difference in the drop occasioned by the use of different metals may be explained by their contact-potentials. Of two metals, that possessing the greater attraction for negative electricity is found to possess the lower drop as anode, apparently by its attraction for the charge on the ion aiding in overcoming the elastic reaction of the impinging ion. The same applies to the cathode. (To be printed in the *Phil. Mag.*)

13. 'The Influence of Temperature upon the Photo-electric Effect': JOHN ZELENY, University of Minnesota.

Ultra-violet light impinging upon negatively electrified bodies dissipates their charge. The electricity is supposed to be carried away by ions which are formed at the surface of the body by the rapid absorption of certain of the waves of the incident light. A study of the influence of temperature upon the effect was made to see if it would throw any light upon the question as to the relative parts played in the phenomenon by the material of the body and by the occluded gases. The charged body which was experimented upon was a platinum wire that could be heated by sending an electric current through it. The light used was obtained from an electric spark produced between two zinc rods by an induction coil. The results obtained are somewhat complicated. As the temperature was gradually increased to about 200° C., it was found that the rate at which the negative electricity was discharged diminished, but for still higher temperatures it increased again, so that at about 700° C., it was nearly three times its value at room temperature. The rate of discharge at certain temperatures depends considerably upon the immediate previous history of the wire, being much larger for a given temper-

ature, although diminishing with time, if the wire has just been hotter than if it has just been colder. The conditions at the surface of the body at these temperatures reach their steady state but slowly, while for temperatures below 100° C. this is acquired much more rapidly. Changes in the molecular arrangement of the body, as well as the amount of the occluded gas, may play a large part in the phenomenon. From an iron wire the rate of discharge while small at the lower temperatures became many times larger at the higher temperatures. It was also found that a positively charged body does not lose any charge due to the action of the light, even when its temperature is raised to that of red heat. To get an explanation for the unipolarity of the photo-electric effect, we need but consider that the intra-molecular impulses which are produced by the light, and which give rise to the discharge, are able to throw off from the body the negative ions or corpuscles, but are not able to disengage the much larger positive ions for which the forces of restitution are correspondingly greater.

14. 'The Diminution of the Potential Difference between the Electrodes of a Vacuum Tube produced by a Magnetic Field': JOHN E. ALMY.

15. 'Note on the Discharge Current from a Surface of Large Curvature': JOHN E. ALMY, University of Nebraska.

The discharge from a wire to a surrounding concentric cylinder, with reference to discharge current, especially, is studied. The law of discharge, under the conditions given below is found, $I = aV(V - b)L/R^3$, where

I = the discharge current, passing from wire to cylinder.

V = the potential difference between wire and cylinder.

L = the length of the wire.

R = the radius of the cylinder.

b = a constant, with given apparatus and gas pressure, and is very approximately the 'minimum potential' of Röntgen.

a = a constant.

The applicability to the discharge was shown with gas pressures, from 20 to 75 cm. of mercury, with cylinders, up to 10 cm. in diameter. The proportionality of current to wire length holds so long as the wire length is greater than the radius of the cylinder used. Finally, the proportionality of current to the inverse cube of the cylinder radius does not hold accurately. More strictly speaking it may be said that $I \propto \frac{1}{R^n}$ and $3.3 > n > 2.8$, in the experiments made.

20. 'On the Calorimetric Properties of the Ferro magnetic Substances, with special reference to Nickel-steel': B. V. HILL.

It is well known that the ferro-magnetic substances when heated through a certain range of temperature, depending on the nature of the substance, absorb latent heat and pass into an allotropic modification in which they are non-magnetic. Certain alloys (*e. g.*, nickel-steel) having been transformed into this state by heating, maintain it down to comparatively low temperatures, so that there are many so-called irreversible nickel-steel alloys to be obtained in both modifications within the same range of temperature (20° to 300° C.). This allows the properties of the alloys in the two states to be compared.

The latent heat of transformation for one sample of nickel-steel was found to be 2.783; that of another, 13.45; which, according to the theory of solutions, should have been 15.9—the application of the theory being, however, questionable. The specific heat of nickel-steel is greater in the non-magnetic state than in the magnetic (from 2 to 6 per cent., depending on the temperature interval through which it is obtained).

Six samples of iron differing in permeability showed that the greater the permeability of iron the smaller its specific heat. This supports the view that the difference in permeability is caused by a difference in composition of magnetic and non-magnetic iron.

21. 'On the Demagnetizing Effect of a Discharge in Iron when Electromagnetically Compensated': ZENO CROOK.

22. 'The Absorption Spectra of Solutions of Potassium Permanganate': B. E. MOORE, University of Nebraska.

The absorption spectra of solutions of the following concentrations, $.25n$, $.025n$, $.0025n$, $.00025n$ and $.000025n$ ($n = \text{normal}$), were studied.

The observations, though they may need later some slight correction, show that upon dilution the solutions become relatively darker in the blue, *i. e.*, there is a displacement of the absorption band toward the blue upon dilution. The phenomenon is explained upon the theory of dissociation.

25. 'Accidental Double Refraction in Liquids': BRUCE V. HILL, University of Nebraska.

In a former paper upon this subject (*Phil. Mag.* (5), 48, p. 485) the writer gave results of a series of experiments upon gelatinizing solutions which became double

refracting when subjected to a strain between rotating cylinders. The results indicated that we have in such solutions quasi-solids, and that there is a difference between colloid and crystalloid solutions not to be explained upon the assumption of a large molecular weight in the former.

The present experiments consist of an examination of water solutions of gelatine when subjected to a *static* strain. They vary in concentration from .1 per cent. to .5 per cent. and were too dilute to sustain their own weight. They were accordingly placed in thin-walled brass tubes 42.55 cm. in length and 2.77 cm. in diameter. Glass caps were fastened to the ends of these tubes by slipping short pieces of rubber hose over them. The tubes were strained, so that their cross-sections were elliptical, by means of clamps. The double refraction decreases so rapidly with rise in temperature that at room temperature—about 23° C.—no effect was visible in jellies of the above concentrations. The tubes were then surrounded by ice and the formation of dew upon the glass ends was obviated by slipping over the tube a second one, also having a glass cap and containing a little phosphoric anhydride. The amount of double refraction was measured as before by means of a half-shade polariscope. The seven sets of observations show that when a stress is applied, the strain increases to a certain point beyond which no further strain is produced. Further stress ruptures the solution, and the refraction diminishes or ceases. The amount a solution can be strained without rupturing depends upon the age of the solution. This point was sufficiently studied to show that the diluter jellies required much longer time to reach the point where they would sustain a maximum strain than the stronger jellies. Along with double refraction, depolarization also appears and then diminishes after standing some time.

These solutions are as fluid as water, but still behave optically as quasi-solids, capable of sustaining a static strain without a displacement of the mobile particles. This condition is reached very slowly and the depolarization early in the formation indicates that the progress of formation of the solid structure is not homogeneous, but that it later becomes so, as indicated by the disappearance of the depolarization.

26. 'Notes on Dielectric Strain': LOUIS TRENCHARD MORE, University of Cincinnati.

This paper—'Notes on Dielectric Strain'—is an answer to a paper by Dr. Paul Sacerdote (*Philosophical Magazine*, March, 1901), criticizing an article by me which appeared in the *Philosophical Magazine* for August, 1900. In attempting to extend the work of Quinke and others who found that glass, when electrified, elongated proportionally to the square of the difference of potential and inversely as the square of the thickness of the dielectric, I noticed that after errors were eliminated the effect vanished or was at least less than $\frac{\delta l}{l} = 10^{-13}$

—a result much less than that found by former investigators. My work attracted the attention of Professor Cantone and Dr. Sacerdote, the latter of whom had recently published a theoretical discussion of the subject. This theory is based on a coefficient which expresses the relation between the potential and the elongation and so fails if the elongation is eliminated. Dr. Sacerdote's criticism showed, I thought, that he had not understood my results and had underestimated the delicacy of my apparatus which seems fully capable of recording the changes of length noticed by the most accurate of former investigators—Professor Cantone.

I have in these papers shown that my apparatus was capable of measuring the effect—that it did record an effect similar to that noted by other investigators, but

that this effect was due to bending of the glass tube by electrostatic attraction—that this error being eliminated the effect vanished.

The sources of errors of former investigators are probably the following:

1. No adequate precautions were taken against lateral bending of the tube. The changes of length produced by an extremely small deflection would account for the entire amount of the effect.

2. The elongations are too close to limit of observation to establish a law when the effect itself is still questionable.

3. Changes of length on charge and discharge are not equal. This difference sometimes equals 40 per cent. of the entire change. An extraneous effect of such magnitude casts doubt on the cause of the elongation.

4. With each investigator, using improved and more delicate apparatus, the amount of the effect steadily decreases. This points either to a partial or entire influence of extraneous causes. (To be printed in the *Philosophical Magazine*.)

27. 'The Temperature Gradient of the Atmosphere, with Formula': S. R. COOK, Washburn College.

The author calls attention to the difficulty, in discussing the escape of gases from the atmosphere, of determining the temperature of the station in the upper atmosphere under consideration.

From the kite observations of the United States Weather Bureau and the recent balloon ascensions at Paris, it was shown that the rate of decrease of temperature with altitude was not constant.

From balloon ascensions made March 24, 1899, near Paris, an experimental formula $t_x = t_0 e^{-kx}$ was obtained for the temperature gradient when t_x and t_0 are the absolute temperatures at positions whose distances from the surface are x , and at the surface respectively, and when k is a constant obtained from the balloon ascensions.

The graph of the temperature gradient is given and compared with Ferrel's graph. A density graph computed from the pressure and temperature graphs is also given and compared with Cottier's density graph computed from the formula $\frac{\rho_0}{\rho_1} = \left(\frac{p_0}{p_1}\right)^v$ where v has the experimental value 1.2.

Attention is also called to the need of more accurate and systematic data for the determination of the temperature gradient at altitudes from 5,000 to 20,000 meters.

JOHN ZELENY,
Secretary.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

SECTION G, BOTANY.

THE Section met for organization on Monday, August 26, at 11.30 a. m., with the Vice-President, Mr. B. T. Galloway, in the chair. The following were the officers for the Denver meeting:

Vice-President, B. T. Galloway.

Secretary, E. A. Bessey (in absence of A. S. Hitchcock).

Sectional Committee, Wm. Trelease, Vice-President 1900; D. T. MacDougal, Secretary 1900; B. T. Galloway, Vice-President 1901; E. A. Bessey, Secretary 1901; C. E. Bessey, C. L. Shear, Miss C. E. Cummings.

Member of General Committee, W. J. Beal.

Member of Council, D. H. Campbell and L. M. Underwood.*

On Wednesday, August 28, in accordance with the custom established at the last New York meeting, Section G held a joint session with the Botanical Society of America, the officers of the latter taking charge of the meeting.

On Thursday evening the following were chosen by the General Committee as Vice-President and Secretary, respectively, for the Pittsburg meeting, June, 1902: D. H. Campbell, Leland Stanford University, and Hermann von Schrenk, Shaw School of Botany.

*Chosen to succeed D. H. Campbell after the latter's early departure.

The following is a complete list of the papers presented. Abstracts are given where furnished by the authors, except for the papers presented at the joint meeting with the Botanical Society of America, abstracts of which will be published elsewhere by the Secretary of that Society.

1. 'Thermal Relations of Plants': D. T. MACDOUGAL. (No abstract furnished.)

2. 'Experiments with Lime and Solutions of Formaldehyde in the Prevention of Onion Smut': A. D. SELBY.

Onion Smut, *Urocystis cepulae* Frost, a soil-infesting fungus, has become introduced into soils devoted to the growing of onion sets near Chillicothe, Ohio, and into those devoted to the growing of market onions about Berea, Ohio. Certain results of experiments made in 1900 at Chillicothe were published in a bulletin (No. 122) of the Ohio Experiment Station. These showed decided advantages of quicklime applied to the soil before seeding and of dilute solutions of formaldehyde in water sprinkled upon the seeds in contact with the soil, as compared with flowers of sulphur, sulphur and lime (in small quantities), and other substances heretofore proposed for the prevention of onion smut. More extended experiments along these lines were conducted both at Chillicothe and Berea during 1901. The results from Chillicothe are now at hand and show very gratifying smut prevention and corresponding increase in the yield of onion sets. All plots herein considered are 760 square feet in area; results are stated in actual and calculated yields.

Plot.	Treatment.	Actual yield lbs. per plot.	Calculated yield per acre, bushels.
I.	Lime, 34 bu. per A.	121.6	174.
II.	" 70 " " "	152.0	217.5
III.	Formalin, .375% sol.	196.0	280.8
IV.	Nothing	92. (large sets)	131.8
V.	Formalin, .75% sol.	202.	289.4
VI.	Lime, 125 bu. per A.	203.	290.8
VII.	" 70 " " "		
	and Formalin, .375% sol.	214.	306.5

Thus lime, at the rate of 70 bushels per acre, gave an increase in yield of 65 per cent. over the untreated plot. Formalin, .375 per cent. solution, an increase of 113 per cent. and double that strength an increase of 119.6 per cent. Seventy bushels of lime per acre and the weaker solution of formalin combined gave an increase of 132.5 per cent., while lime at the rate of 125 bushels per acre gave an increase of 120.5 per cent. The lime used was purchased in the ground state and was applied with a drill before the hoes, chiefly on the surface. The formaldehyde solutions were applied by trickling down with the seeds. This paper will be printed in a bulletin of the Ohio Agricultural Experiment Station.

3. 'Comparative Climate of a Meadow and Hemlock Forest': D. T. MACDOUGAL. (No abstract furnished.)

4. 'The Tylostomaceæ of North America': V. S. WHITE, presented by L. M. Underwood.

The extensive accumulation of material bearing on the stalked puffballs in the Ellis collection, supplemented by considerable material sent in from the Southwest by Professors Wooton, Cockerell and Griffiths has led to a complete revision of the species of this family, which is now appearing in the August number of the *Bulletin of the Torrey Botanical Club*. This is illustrated by ten plates (exhibited when the paper was read). A summary of the results is as follows:

The family as represented in North America consists of—

Tylostoma—Seventeen species, of which eight are new. Of these seventeen species eight are found in Colorado, which is double the number from any other State with the single exception of Kansas, which has five species. Of the eight new species four are from Colorado.

Chlamydotopus—One species recently collected in New Mexico by Professor Cocker-

ell. The genus has hitherto been known only from South America.

Battarrea—Four species of which two are new. All from the Southwest.

Queletia—One species, possibly introduced from Europe. Found once in this country.

Dictyocephalos—A new genus from Colorado, collected by Professor Bethel, of Denver; monotypic.

Much still remains to be known of the early stages of these plants; in fact very little is known of them. Much also remains to be known of their geographic and seasonal distribution. Two-thirds of the family belong to the region of the Great Plains southwestward to Texas, Sonora and southern California.

5. 'Lantern Views of the Botanical Garden of the Agricultural College of Michigan': W. J. BEAL.

The author exhibited views showing the arrangement of the garden and gave many practical hints concerning the management of botanical gardens.

6. 'Plants of the Eastern Foothills': FRANCIS RAMALEY.

The author exhibited a number of views showing some of the more characteristic plants of the eastern foothills of the Rocky Mountains in Colorado.

7. 'Some Protective Leaf Movements induced by Winter Temperature': WM. TRELEASE.

The paper records, with lantern illustrations, observations upon the drooping and inrolling of *Rhododendron* leaves and the inrolling of leaves of *Yucca flaccida*, effected when the freezing temperature is reached, by which protection is secured against undue radiation and evaporation. Reference is made to Harsberger's paper of 1889, and Darwin and Acton's and MacDougal's text-books of plant physiology which thus far appear to refer only to *Prunus laurocerasus* and the genera named.

8. 'Germination of Seeds of some Common Cultivated Plants after prolonged Immersion in Liquid Air': A. D. SELBY.

At the suggestion of Mr. J. E. Woodland, of Wooster, Ohio, who was conducting experiments with liquid air during the winter season of 1900-1901, the writer prepared and supplied him with seeds of *Ricinus*, *Lupinus luteus*, maize, flax, wheat, rye, cucumber, Russian sunflower, *Pinus sylvestris*, *Mimosa pudica*, *Onobrychis sativus*, *Chenopodium album* and *Pinus parryana*. At first the lots of seed were immersed in the liquid air directly from the room temperature and kept submerged for six and twelve hours, respectively. Later other lots were given a gradual transition from the temperature of the room to that of the liquid air and an equally gradual withdrawal, being immersed for twenty-four and forty-eight hours, respectively. The seeds were then germinated in the usual manner, together with control lots reserved when the original packages were selected. There was practically no essential effect of the treatment noticeable upon the percentages of seeds that germinated, the control, short treated, and longer treated lots giving essentially the same percentages of germination. This paper will be printed in the *Bulletin of the Torrey Botanical Club*.

On Wednesday the following program was given in joint session of Section G and the Botanical Society of America:

Address of the Retiring President—'Problems and Possibilities of Systematic Botany': B. L. ROBINSON. Read by J. M. Coulter.

'The Fundamental Phenomena of Vegetation': F. E. CLEMENTS.

'Early Winter Colors of Plant Formations upon the Great Plains': C. E. BESSEY.

'The Plant Formations of the Rocky Mountains' (lantern lecture): F. E. CLEMENTS.

'A Suggested Hybrid Origin of *Yucca gloriosa*' (lantern lecture): WM. TRELEASE.

'The Physical Basis of Ecology': F. E. CLEMENTS. (By title only.)

'The Anatomy of the Embryo and Seedling of *Tsuga canadensis* Carr' (by invitation): W. A. MURRILL. Read by J. M. Coulter.

'Clues to Relationship among Heteroecious Plant Rusts': J. C. ARTHUR. Read by L. M. Underwood.

'Some of the Changes now taking place in a Forest of Oak Openings': W. J. BEAL.

'Preliminary Notes on the Flora of Western Iowa, especially from the Physiographical-Ecological Standpoint': L. H. PAMMEL. (By title only.)

'The Life History of *Vittaria lineata*': E. G. BRITTON and A. TAYLOR. Read by L. M. Underwood.

'A System of Nomenclature for Phytogeography': F. E. CLEMENTS.

'The Application of Ecology in Taxonomy': F. E. CLEMENTS. (By title only.)

On Thursday the regular session of Section G was resumed with the following papers:

9. 'The Location of a Tropical Research Station in Porto Rico': L. M. UNDERWOOD.

The agricultural station in Porto Rico should, if possible, be located where it will also be available as a station for general botanical research. A combination of (1) the greatest amount of agricultural production, not alone in coffee, sugar and tobacco, but also in the minor products; (2) the greatest accessibility from all portions of the island, and particularly those portions where the most important agricultural products are cultivated under most favorable conditions; and (3) the most interesting botanical portion of the island, including accessibility to a large original forest, is met with in the eastern half of the island and particularly in the region between Arecibo and Utnado. With this can be com-

bined many less prominent but important accessories, particularly access to an abundant supply of potable water.

10. 'Notes on Colors of Salsify Hybrids': BYRON D. HALSTEAD.

Hybrids between *Tragopogon porrifolius* L. (garden salsify) and the wild species, *T. pratensis* L., were reported on last year. The following paper considers only the color side of the results obtained with hybrid seedlings the present year (second generation hybrids). According to the standard color chart employed (Prang's), the cultivated salsify has for the color of its corollas a mixture of violet and red, corresponding to No. 224 (VRV/L), *i. e.*, light violet red violet—a shade of purple, in ordinary language. The other parent has a plain yellow. The direct hybrid of these two is of two distinct types, the one with the color uniform throughout the head, and the other, about equally numerous, with a yellow in the center, although here the tips of all the corollas are of the same color as the ray blossoms, namely No. 241 (RRV/DD), *i. e.*, darker red red violet. It is seen by this that the *T. porrifolius* controls the color, although the violet of this parent gives place largely to red. The crossing is reciprocal and the results are the same whichever is the seed parent. Among the hundreds of seedlings grown this season no less than 36 numbers upon the color chart are represented. Out of 200 counts the following is the record for the 13 having the largest score: Yellow, 10; light yellow, 12; lighter yellow, 6; darker orange red orange, 9; darker red orange, 6; darker red, 23; dark red, 13; light red violet, 9; lighter red violet, 7; violet red violet, 23; light violet red violet, 35; lighter violet red violet, 29; dark violet gray, 6. It is seen that in the second generation the colors are many. Both parents are now represented, and many intergrades between their respective

colors. The yellows in all the tints score 28 points to 103 by the violet reds. If all the shades obtained were enumerated under their appropriate heads the violet reds would outnumber the yellows by 41. There were no pure orange blossoms, but in combination with red there were many representatives. The yellow failed to blend with any other color. In one instance there was a plant with slate-colored blossoms, thus bringing in the blue of the chromatic scale, and several specimens had a strong tendency towards chlorosis, thus completing the series in the solar spectrum. A chart of the prismatic colors, violet, blue, green, orange, yellow and red was constructed, and the parent hybrid and its seedlings located with pasters of colored paper, while the relative amount of each of the latter was shown by the size of the paper bearing the color corresponding to that of the seedling hybrid flowers thus graphically represented. It is thus evident that with the salsify hybrid, while there is uniformity the first year, it is otherwise the second season, with a tendency to revert to the parent types. The red, present in obscure form in one parent only, becomes very prominent the first year and yields many unmixed reds the second. Out of this union by selection it is probable that many strongly contrasting types might be fixed.

11. 'Observations on *Egrecia menziesii*': FRANCIS RAMALEY.

Egrecia consists, as do the other Laminariaceæ, of hold-fast, stipe and lamina; the branching of the stipe gives rise to members (branches) each having the characters of the entire frond of *Alaria*. The multiform proliferations which occur on both stipe and lamina replace functionally the large lamina in other genera. This structure is, in *Egrecia*, greatly reduced in size and importance. On account of the great elongation of the stipe a floating ap-

paratus has become necessary, and this is provided in the vesicles developed by the swelling of the stalks of certain proliferations. The presence of vesicles gives *Egregia* a superficial resemblance to *Macrocystis*, while it is probably more nearly allied to *Alaria*. A mathematical study of variation in *Egregia menziesii* leads to the conclusion that the species is in a state of equilibrium. The curves of variation are all symmetrical and remarkably similar. *Egregia* presents some interesting anatomical features which cannot be well summarized. This paper will be printed in *Minnesota Botanical Studies*.

12. 'The Morphology of the Pine Cone': C. E. BESSEY.

Although there has been much discussion of the morphology of the 'ovuliferous scale' of the pine cone, recent summaries show that it is not yet satisfactorily settled. The author suggests an explanation which he has used in his lectures to students in the University of Nebraska for several years. Comparing the cones of Cupressineæ, Taxodiæ, Araucariæ and Abietineæ, they are found to be alike, with a similar origin for their ovules, but in the Abietineæ there is in connection with each ovule a woody scale, while in Araucariæ there is a rudimentary scale. This scale is regarded as a backward development of the ovule, and the cones are therefore strictly homologous. Concisely stated, this view may be formulated as follows: The microsporangial and megasporangial cones are strictly homologous, and in the latter the sporophyll enlarges or remains small, just as a chalazal development of the megasporangium into a scale is less or more pronounced. According to this view the Abietineæ must be given place at the summit of the Conifers. This paper will be printed in SCIENCE.

13. 'General Botanical Features of the Coast Mountains of California': ALICE EASTWOOD.

The Coast Mountains of California extend from the northern to the southern part of the State, passing through about ten degrees of latitude, and rise from the sea level to an altitude of more than 9,000 feet. Consisting of many different chains and spurs, with valleys between made up of different geological formations, a great variety characterizes their flora. Many genera are in an unsettled condition and the species are uncertain. The outer ranges may be divided into four environmental zones: (1) That along the sea coast, characterized by fleshy plants or those clothed with some form of pubescence. They do not differ much from maritime plants in other regions. (2) The forest areas, along streams where the redwoods (*Sequoia sempervirens*) find a home. This keeps quite close within the area of summer fog, and the plants are dependent upon moisture and shade. (3) The grassy uplands and valleys. Here, during the rainy season, flowers (mostly annuals) grow in great profusion and form beautiful gardens. They soon disappear and the hills become yellow, except where clumps of oaks, pines, or spruces occur. (4) The brush-covered hills, where the shrubs grow so close together that it is almost impossible to travel through them except on the trails. They hold the water by their roots and prevent evaporation by their dense growth. Most of them show characteristics belonging to desert plants rendered necessary by the long drought and the intense heat to which they are subjected in the summer. The southern coast mountains become even more desert-like in the character of their flora, and here and there will be found wanderers from the desert. The northern coast mountains in general rise to a greater elevation, and in some of the chains the character of the mountains is like that of the Sierra Nevada range and the flora similar at like elevations. A great amount of work has to be

done before many of the genera are understood and a great deal of territory must be explored before the species are approximately known. Following this work, the problems of geographical distribution can be solved and life zones satisfactorily mapped out.

14. 'The Xerophytic Vegetation of the Uintah Mountains': L. H. PAMMEL.

In the Uintah range occur types of plants from the arid regions of the Southwest, boreal types in the mountains farther northward, and many forms from the main Rocky Mountain flora. The largest xerophytic areas occur in the Colorado and Green River basins. The xerophytic vegetation of the Uintah range varies with the different physiographic conditions and geologic formations. One naturally expects to find a very different flora in passing through the Green River and lower basins up to the higher peaks such as Gilbert, La Motte and Wilson; however, at an altitude of 9,200 feet the valleys and park-like openings have many xerophytic plants common to the lower basins of the streams. The succession of plant formation in this region is fairly well marked; it is not difficult, therefore, to trace a succession of plant life on the flood plains since the quaternary. The foothill and mountain floras change successively from hydrophytic to mesophytic, then to xerophytic and finally culminate in the mesophytic of the foothills with hydrophytic basins. In the Green River basin and the tributaries of the immediate vicinity of this basin the xerophytic plants are much more pronounced than in the foothills. In the broad flood plains of Green River there occur such plants as *Distichlis spicata*, the widely distributed *Hordeum jubatum*, and the western *H. cespitosum*. The habit of growth and the manner of reproduction of *Distichlis* make it well adapted to the conditions prevailing in that arid region. Two

Capparidaceous plants, *Cleome integrifolia* and *C. lutea*, are common. A somewhat similar yellow-flowered crucifer, *Stanleya pinnatifida*, is scattered through the dry lowlands. Naturally one expects to find many chenopodiaceous plants. Their succulent leaves enable them to adapt themselves to these dry regions. *Sarcobatus vermiculatus*, *Chenopodium fremontii*, *C. rubrum*, *Eurotia lanata* and *Suaeda depressa* are common plants of the dry basins. *Artemisia tridentata* with its accompanying *Eriogonum ovalifolium* and *E. umbellatum* are common at higher altitudes along Black's Fork. The terrace formation is especially well marked from the mouth of Black's Fork up to 8,500 feet. In the lower region there are small groves of *Juniperus occidentalis* var. *monosperma*, frequently accompanied by *Picea pungens*, *Juniperus communis* and *Arctostaphylos*. At an altitude of 7,500 feet three-well-defined flood plains are recognizable. The present flood plain contains mesophytic groves, the second flood plain is dotted with small patches of trees and sage brush, the third flood plain contains no trees. *Artemisia tridentata* is the most characteristic plant. *Symphoricarpos*, *Lupinus* and *Stipa* also occur. From the third flood plain there is an abrupt rise of from three to five hundred feet. The sides are lined with *Symphoricarpos*, *Prunus*, and some sage brush. The top of the benches contains almost no trees except farther up, but sage brush, *Eurotia lanata*, *Stipa*, *Castilleja*, *Orthocarpus* and *Eriogonum* are characteristic plants.

15. 'Some Aspects of the Wyoming Desert Flora': AVEN NELSON.

South central Wyoming contains an extensive area known as the Red Desert. This has a considerable flora, the most obvious members of which belong in the genera *Artemisia*, *Atriplex*, *Chrysothamnus*, *Tetradymia*, *Sarcobatus*, and *Agropyron*. Besides this there is a very considerable fugacious vegetation. This desert flora,

while a limited one, is highly organized. It is succulent and rich in water by reason of its many contrivances for husbanding all its resources. Consolidation tends to reduce expenditure. Pleiocyclic herbs successfully maintain themselves by reason of their highly developed underground organs. The prevailing color of the flowers is yellow. Some of the vegetation is exceedingly tolerant of alkali, raising the question whether this property is due to histological peculiarities or represents a physiological difference in the protoplasm.

16. 'Effects of Salt Solutions on Seeds and Plants': E. E. SLOSSON.

Experiments have been carried on for several years on the action of the salts occurring in the soil of arid regions, as alkali, on the germination of seeds and the growth of plants. Solutions of sodium chloride, sulphate and carbonate; potassium sulphate and chloride; magnesium sulphate; and sugar; in solutions ranging in strength from 0 to 100 atmospheres osmotic pressure had been tested, the following seeds being used: corn, wheat, sunflower, peas, buckwheat, rape, beans, alfalfa, rye, clover, *Scirpus paludosus* and, for comparison, wood. It has been found that the imbibition of water is less from all solutions than from pure water. Solutions of all salts and of sugar of the same osmotic pressure retard and lessen the imbibition of water by seeds to about the same extent. Isosmotic solutions produce nearly the same effect in retarding the germination of seeds. Solutions of slight osmotic pressure stimulate germination. The same results are obtained with growing plants. Plants and seeds absorb a greater amount of potassium than of sodium salts from solutions of the same osmotic pressure, and more sulphates than chlorides. Hydroxyl ions increase the absorption of salts and of water by seeds. This paper will be printed in Bulletins of the Wyoming Experiment Station.

17. 'The Position of Protococcus and Mosses on Trees': HENRY KRAEMER. (Read by title.)

18. 'Contributions to the Knowledge of the Physiology of Karyokinesis': A. C. LEWIS. (Read by title.)

This paper will be published in the *Botanical Gazette*.

19. 'Seedlings of *Arisema dracontium*': ROSINA J. RENNERT. (Read by title.)

20. 'Some Plant Adaptations on the Tucson Plains': J. W. TOUMEX. (Read by title.)

ERNST A. BESSEY,
Secretary, Section G.

MEMBERSHIP OF THE AMERICAN ASSOCIATION.

THE following have completed their membership in the American Association for the Advancement of Science during the month of September.

Edward G. Acheson, President International Acheson Graphite Co., Niagara Falls, N. Y.

Curtis Alexander, Mining Engineer and Metallurgist, Spearfish, S. D.

J. Hartley Anderson, M.D., Physician, 4630 Fifth avenue, Pittsburg, Pa.

Bion J. Arnold, 4128 Prairie avenue, Chicago, Ill.

Andrew J. Bigney, Professor of Biology and Geology, Moores Hill College, Moores Hill, Ind.

R. I. Bond, M.D., Physician, Hartshorne, Ind. Ter.

Edwin D. Carnaghan, Mechanical Engineer, Durango, Do, Mexico.

Willard Colfax Cheney, Electrical Engineer, Portland, Ore.

Francis A. Crandall, 2219 15th street, N.W., Washington, D. C.

Col. William Crozier, U. S. A. Ordnance Office, Washington, D. C.

Dr. Kary Cadmus Davis, Professor of Horticulture and Forestry, W. Virginia State University, 628 N. High street, Morgantown, W. Va.

Wm. S. Hall, Professor of Mining and Graphics, Lafayette College, Easton, Pa.

John Hays Hammond, Mining Engineer and Geologist, Denver, Colorado.

Dr. Felix B. Herzog, Electrical Engineer, 51 West 24th street, New York, N. Y.

Julius Hortvet, State Chemist, 1521 University avenue S.E., Minneapolis, Minn.

A. E. Jenks, Bureau of Ethnology, Washington, D. C.

John A. Just, Chemist, 116 West Castle street, Syracuse, N. Y.

Wm. D. Marks, The Art Club, Philadelphia, Pa.

Lucius Herbert Merrill, Professor of Biological Chemistry, University of Maine, Orono, Maine.

Benjamin L. Miller, Johns Hopkins University, Baltimore, Md.

Robert D. Murray, M.D., Marine Hospital Service, Key West, Fla.

George J. Murdock, Mechanician and Inventor, 248 Sixth avenue, Newark, N. J.

Richard A. Parker, C.E., E.M., 4 P. O. Square, Boston, Mass.

Thomas S. Perry, 312 Marlborough street, Back Bay, Boston, Mass.

Wm. L. Prather, President of University of Texas, 1914 Nueces street, Austin, Texas.

Walter Merritt Riggs, Professor of Electrical Engineering, Clemson College, Clemson College, S. C.

Fred W. Robins, Superintendent of Schools, Bethlehem, Pa.

George St. John Sheffield, Twin Elms Farm, Attleborough, Mass.

Charles H. Shinn, Inspector of Experiment Stations, University of California, Berkeley, Cal.

Harvey F. Smith, Attorney-at-law, Clarksburg, W. Va.

Norman W. Storer, Electrical Engineer, 6109 Howe Street, Pittsburg, Pa.

W. S. Sutton, Professor of Science and Art of Education, University of Texas, 1812 Congress avenue, Austin, Texas.

E. A. H. Tays, Civil and Mining Engineer, San Jose de Gracia, Sinaloa, Mexico.

Alonzo P. Troth, Supervisor of Instruction in Science, High School, Leadville, Colo.

Andrew A. Veblen, Head of Department of Physics, State University of Iowa, Iowa City, Iowa.

Wm. A. Wadsworth, Genesee, Livingston county, N. Y.

Dr. Walter F. Willcox, Professor of Economics, Cornell University, Ithaca, N. Y.

ADDRESS OF THE PRESIDENT OF THE ANTHROPOLOGICAL SECTION OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.*

I.

TWENTY-FIVE years have passed since the British Association met in Glasgow. This is a long time to look back upon, and yet

*Glasgow meeting, 1901.

the period appears short when measured by the great advance which has taken place in almost all branches of knowledge. Anthropology has shared in the general progress. The discoveries made within its confines may not have been so startling, nor yet have had such a direct influence upon the material welfare of the people, as in the case of other fields of scientific study, but its development has been steady and continuous, and it has grown much in public estimation.

At the Glasgow meeting of the Association in 1876 anthropology held a subsidiary position. It only ranked as a department, although it gained a special prominence through having Alfred Russel Wallace as its chairman. It was not until several years later that it became one of the recognized sections of the Association, and attained the high dignity of having a letter of the alphabet allotted to it. But quite independently of its official status it has always been a branch of study which has been accorded a large amount of popular favor. The anthropological meetings have, as a rule, been well attended, and the discussions, although perhaps on certain occasions somewhat discursive, have never lacked vigor or animation. Professor Huxley, who presided over the Anthropological Department at the Dublin meeting in 1878, ascribed the popularity of the subject to the many openings which it affords for wide differences of opinion between the exponents of its numerous branches, and to the innate bellicose tendency of man. As the representative of a country in which, according to the same high authority, this tendency is less strongly marked than elsewhere, and of a race which has so frequently and pointedly exhibited its abhorrence of vigorous language, I trust that my presence here as president may not react unfavorably on the interest shown in the work of the Section.

The present occasion might appear to be peculiarly appropriate for my taking stock of our anthropological possessions and summing up the numerous additions to our knowledge of 'man and his doings' which have been made during the century which has just passed. Such a task, however, is surrounded with so much difficulty that I shrink from undertaking it. The scope of the subject is enormous, and the studies involved so diverse and so varied that I feel that it is beyond my power to give any comprehensive survey of its development in all its parts. I prefer therefore to confine my remarks to that province of anthropology within which my own work has been chiefly carried on, and from this to select a subject which has for some years held a prominent place in my thoughts. I refer to the human brain and the part which it has played in the evolution of man.

One of the most striking peculiarities of man, when regarded from the structural point of view, is the relatively great size of his brain. Although with one or two exceptions the several parts of the brain are all more or less involved in this special development, it is the cerebral hemispheres which exhibit the preponderance in the highest degree. This characteristic of the human brain is rendered all the more significant when we consider that the cerebral hemispheres cannot be looked upon as being primitive parts of the brain. In its earliest condition the brain is composed of three simple primary vesicles, and the cerebral hemispheres appear in a secondary manner in the shape of a pair of lateral offshoots or buds which grow out from the foremost of these primitive brain-vesicles.

The offshoots which form the cerebral hemispheres are found in all vertebrates. Insignificant in size and insignificant in functional value in the more lowly forms, a steady increase in their proportions is manifest as we ascend the scale, until the

imposing dimensions, the complex structure, and the marvelous functional potentialities of the human cerebral hemispheres are attained. In their development the cerebral hemispheres of man rapidly outstrip all the other parts of the brain, until they ultimately usurp to themselves by far the greater part of the cranial cavity. To the predominant growth of the cerebral hemisphere is due the lofty cranial vault of the human skull; to the different degrees of development and to the different forms which they assume are largely due the variations in cranial outline in different individuals and different races—variations in the determination of which the craniologist has labored so assiduously and patiently.

I think that it must be manifest to every one that the work of the craniologist, if it is to attain its full degree of usefulness, must be founded upon a proper recognition of the relation which exists between the cranium and the brain, or, in other words, between the envelope and its contents.

The cranium expands according to the demands made upon it by the growing brain. The initiative lies with the brain, and in normal conditions it is questionable if the envelope exercises more than a very subsidiary and limited influence upon the form assumed by the contents. The directions of growth are clearly defined by the sutural lines by which the cranial bones are knit together; but these are so arranged that they admit of the expansion of the cranial box in length, in breadth and in height, and the freedom of growth in each of these different directions has in all probability been originally determined by the requirements of the several parts of the brain.

The base or floor of the cranium, supporting as it does the brain-stem or the parts which possess the greatest phylogenetic antiquity, and which have not under-

gone so large a degree of modification in human evolution, presents a greater uniformity of type and a greater constancy of form in different individuals and different races than the cranial vault, which covers the more highly specialized and more variable cerebral hemispheres.

To what extent and in what directions modifications in the form of the cranium may be the outcome of restrictions placed on the growth of the brain it is difficult to say. But, broadly speaking, I think we may conclude that the influence which the cranium, under normal circumstances, independently exerts in determining the various head-forms is trifling.

When we speak, therefore, of brachycephalic or short heads and dolichocephalic or long heads, we are merely using terms to indicate conditions which result from individual or racial peculiarities of cerebral growth.

The brachycephalic brain is not molded into form by the brachycephalic skull; the shape of both is the result of the same hereditary influence, and in their growth they exhibit the most perfect harmony with each other.

Craniology has been called the 'spoiled child of anthropology.' It is supposed that it has absorbed more attention than it deserves, and has been cultivated with more than its share of care, while other fields of anthropology capable of yielding rich harvests have been allowed to remain fallow. This criticism conveys a very partial truth. The cranium, as we have seen, is the outward expression of the contained brain, and the brain is the most characteristic organ of man; cranial peculiarities, therefore, must always and should always claim a leading place in the mind of the anthropologist; and this is all the more imperative, seeing that the brains of different races are seldom available for investigation, whilst skulls in the different museums may literally be counted by thousands.

Meantime, however, the craniologist lies buried beneath a mighty mountain of figures, many of which have little morphological value and possess no true importance in distinguishing the finer differences of racial forms. Let us take as an example the figures upon which the cephalic or length-breadth index of the skull is based. The measurement of the long diameter of the cranium does not give the true length of the cranial cavity. It includes, in addition, the diameter of an air-chamber of very variable dimensions which is placed in front. The measurement combines in itself, therefore, two factors of very different import, and the result is thereby vitiated to a greater or less extent in different skulls. A recent memoir by Schwalbe* affords instructive reading on this matter. One case in point may be given. Measured in the usual way, the Neanderthal skull is placed in the dolichocephalic class; whereas Schwalbe has shown that if the brain-case alone be considered it is found to be on the verge of brachycephaly. Huxley, many years ago, remarked that 'until it shall become an opprobrium to an ethnological collection to possess a single skull which is not bisected longitudinally,' in order that the true proportions of its different parts may be properly determined, we shall have no 'safe basis for that ethnological craniology which aspires to give the anatomical characters of the crania of the different races of mankind.' It appears to me that the truth of this observation can hardly be disputed, and yet this method of investigation has been adopted by very few craniologists.

It has become too much the habit to measure and compare crania as if they were separate and distinct entities and without a due consideration of the evolutionary

* 'Studien über *Pithecanthropus erectus*' (Dubois). *Zeitschrift f. Morph. und Anthropol.*, Band I., Heft 1, 1899.

changes through which both the brain and its bony envelope have passed. Up to the present little or no effort has been made to contrast those parts of the cranial wall or cavity which have been specially modified by the cerebral growth-changes which are peculiar to man. It may be assumed that these changes have not taken place to an equal extent, or indeed followed identically the same lines in all races.

Unfortunately our present knowledge of cerebral growth and the value to be attached to its various manifestations is not so complete as to enable us to follow out to the full extent investigations planned on these lines. But the areas of cerebral cortex to which man owes his intellectual superiority are now roughly mapped out, and the time has come when the effect produced upon the cranial form by the marked extension of these areas in the human brain should be noted and the skulls of different races contrasted from this point of view.

To some this may seem a return to the old doctrine of phrenology, and to a certain extent it is; but it would be a phrenology based upon an entirely new foundation and elaborated out of entirely new material.

It is to certain of the growth changes in the cerebrum which I believe to be specially characteristic of man, and which unquestionably have had some influence in determining head-forms, that I wish particularly to refer in this address.

The surface of the human cerebrum is thrown into a series of tortuous folds or convolutions separated by slits or fissures, and both combine to give it an appearance of great complexity. These convolutions were long considered to present no definite arrangement, but to be thrown together in the same meaningless disorder as is exhibited in a dish of macaroni. During the latter half, or rather more, of the century which has just ended it has, however, been shown by the many eminent men who have

given their attention to this subject that the pattern which is assumed by the convolutions, while showing many subsidiary differences, not only in different races and different individuals, but also in the two hemispheres of the same person, is yet arranged on a consistent and uniform plan in every human brain, and that any decided deviation from this plan results in an imperfect carrying out of the cerebral function. In unraveling the intricacies of the human convolutionary pattern it was very early found that the simple cerebral surface of the ape's brain in many cases afforded the key to the solution of the problem. More recently the close study of the manner in which the convolutions assume shape during their growth and development has yielded evidence of a still more valuable kind. We now know that the primate cerebrum is not only distinguished from that of all lower mammals by the possession of a distinct occipital lobe, but also by having imprinted on its surface a convolutionary design which in all but a few fundamental details is different from that of any other order of mammals.

There are few matters of more interest to those anthropologists who make a study of the human skull than the relationship which exists between the cranium and the brain during the period of active growth of both. Up to the time immediately prior to the pushing out of the occipital lobe, or, in other words, the period in cerebral development which is marked by the transition from the quadrupedal type to the primate type of cerebrum, the cranial wall fits like a tight glove on the surface of the enclosed cerebrum. At this stage there would appear to be a growth antagonism between the brain and the cranial envelope which surrounds it. The cranium, it would seem, refuses to expand with a speed sufficient to meet the demands made upon it for the accommodation of the growing brain. In

making this statement it is right to add that Hochstetter, in a carefully reasoned memoir, has recently cast doubt upon the reality of the appearances which have led to this conclusion, and at the recent meeting of the Anatomische Gesellschaft, in Bonn, Professor Gustaf Retzius,* one of the numerous observers responsible for the description of the early cerebrum upon which the conclusion is based, showed some inclination to waver in his allegiance to the old doctrine. This is not the time nor the place to enter upon a discussion of so technical a kind, but I may be allowed to say that whilst I fully recognize the necessity for further and more extensive investigation into this matter I do not think that Hochstetter has satisfactorily accounted for all the circumstances of the case.

When the occipital lobe assumes shape the relationship of the cranial wall to the enclosed cerebrum undergoes a complete change. The cranium expands so rapidly that very soon a wide interval is left between the surface of the cerebrum and the deep aspect of the cranial envelope within which it lies. This space is occupied by a soft, sodden, spongy meshwork, termed the subarachnoid tissue, and it is into the yielding and pliable bed thus prepared that the convolutions grow. At first the surface of the cerebral hemisphere is smooth, but soon particular areas of the cortex begin to bulge out and foreshadow the future convolutions. These suffer no growth restriction, and they assume the form of round or elongated elevations or eminences which rise above the general surface level of the cerebral hemisphere and break up its uniform contour lines in the same manner that mountain chains protrude from the surface of the globe.

As growth goes on, and as the brain

* *Anatomische Gesellschaft*, Bonn, May 28, 1901. Gustaf Retzius, 'Transitorische Furchen des Grosshirns.'

gradually assumes a bulk more nearly in accord with the cavity of the cranium, the space for surface protrusions of this kind becomes more limited. The gyral elevations are now pressed together; they become flattened along their summits, and in course of time they acquire the ordinary convolutionary shapes. While this is going on the valleys or intervals between the primitive surface elevations become narrowed, and ultimately assume the linear slit-like form characteristic of the fissures. These changes occur shortly before birth, but are not fully completed until after the first few months of infancy. The final result of this process is that the convolutions come into intimate relation with the deep aspect of the cranial wall and stamp their imprint upon it.

It is obvious that certain of the later changes which I have endeavored to portray might be ascribed to a growth antagonism between the brain and the enclosing cranium at this period. In reality, however, it is merely a process by which the one is brought into closer adaptation to the other—a using up, as it were, of superfluous space and a closer packing together of the convolutions—after the period of active cortical growth is past. Nevertheless the convolutionary pattern is profoundly affected by it, and it seems likely that in this process we find the explanation of the different directions taken by the cerebral furrows in brachycephalic and dolichocephalic heads.

The cortical elevations which rise on the surface of the early cerebrum are due to exuberant growth in localized areas. There cannot be a doubt that the process is intimately connected with the development of function in the districts concerned. We know that functions of different kinds are localized in different parts of the cortex, and when we see an area on the surface of the early cerebrum rise up in the form of

an eminence, we may reasonably conclude that the growth in the area concerned is the structural foundation of what will become later on a center of functional activity of an acute kind.

A consideration of this matter gives the clue to the simple convolutions of the ape and the complex convolutions of man, and, further, it explains how the interrupted form of fissural development is one of the essential characteristics of the human brain as compared with the simian brain. Areas which rise up in the form of one long elevation on the surface of the ape's brain appear in the form of several eminences on the surface of the human brain, and fissures which appear in the form of long continuous slits in the simian cerebrum appear in the human cerebrum in several detached bits, which may or may not in the course of time run into each other and become confluent. All this is due to the greater definition, refinement and perfection of the functions carried on in the cerebral cortex of man. It is an index of a more complete 'physiological division of labor' in the human brain.

It is not necessary, for the purpose I have in view, to enter into any detail regarding the many points of difference which become evident when the cerebral surface of the ape is compared with that of man. It is more my purpose to indicate certain of the districts of cerebral cortex which have undergone a marked increase in the human brain—an increase which may be reasonably supposed to be associated with the high mental attributes of man. To us, at the present time, it is difficult to conceive how it was ever possible to doubt that the occipital lobe is a distinctive character of the simian brain as well as of the human brain, and yet at successive meetings of this Association (1860, 1861 and 1862) a discussion, which was probably one of the most heated in the

whole course of its history, took place on this very point. One of our greatest authorities on animal structure maintained that the occipital lobe and the hippocampus minor—an elevation in its interior—were both peculiar to man and to him alone. Every one has read in the 'Water Babies' Charles Kingsley's delightful account of this discussion. Speaking of the Professor he says: "He held very strange theories about a good many things. He had even got up at the British Association and declared that apes had hippopotamus majors in their brains just as men have. What a shocking thing to say; for if it were so, what would become of the faith, hope and charity of immortal millions? You may think that there are other more important differences between you and an ape, such as being able to speak, and make machines, and know right from wrong, and say your prayers, and other little matters of that kind; but that is a child's fancy." In the light of our present knowledge we can fully understand Professor Huxley closing the discussion by stating that the question had 'become one of personal veracity.' Indeed, the occipital lobe, so far from being absent, is developed in the ape to a relatively greater extent than in man, and this constitutes one of the leading positive distinctive characters of the simian cerebrum. Measured along the mesial border, the percentage length of the occipital lobe to the total length of the cerebrum in the baboon, orang and man is as follows:

Baboon	29.7
Orang	23.2
Man	21.2

But these figures do not convey the full extent of the predominance of the occipital lobe in the ape. The anterior border of the lobe grows forwards beyond its proper limits, and pushes its way over the parietal lobe which lies in front, so as to cover over a portion of it by an overlapping lip termed

the occipital operculum. There is not a trace of such an arrangement in the human brain, and even in the anthropoid ape the operculum has become greatly reduced. Indeed, in man there is exactly the reverse condition. The great size of the parietal lobe is a leading human character, and it has partly gained its predominance by pushing backwards so as to encroach, to some extent, upon the territory which formerly belonged to the occipital lobe.* A great authority † on the cerebral surface refers to this as a struggle between the two lobes for surface extension of their respective domains. "In the lower apes," he says, "the occipital lobe proves the victor; it bulges over the parietal lobe as far as the first annectant gyrus. Already in the orang, the occipital operculum has suffered a great reduction; and in man the victory is on the side of the parietal lobe, which presses on the occipital lobe and begins, on its part, to overlap it." Now that so much information is available in regard to the localization of function in the cerebral cortex, and Flechsig has stimulated our curiosity in regard to his great 'association areas' in which the higher intellectual powers of man are believed to reside, it is interesting to speculate upon the causes which have led to the pushing back of the scientific frontier between the occipital and parietal cerebral districts.

The parietal lobe is divided into an upper and a lower part by a fissure, which takes an oblique course across it. Rudinger, ‡ who studied the position and inclination of this fissure, came to the conclusion that it

* It is necessary to emphasize this point, because in Wiedersheim's 'Structure of Man' we are told that in man there is a preponderance of the occipital lobe, and that the parietal lobe is equally developed in man and anthropoids.

† Eberstaller, *Wiener Medizinische Blätter*, 1884, No. 19, p. 581.

‡ 'Beiträge zur Anatomie und Embryologie,' als Festgabe Jacob Henle, 1882.

presents easily determined differences in accordance with sex, race and the intellectual capacity of the individual. He had the opportunity of studying the brains of quite a number of distinguished men, amongst whom were Bischoff of Bonn, Döllinger of Munich, Tiedemann of Heidelberg, and Liebig of Munich, and he asserts that the higher the mental endowment of an individual the greater is the relative extent of the upper part of the parietal lobe.

There is absolutely no foundation for this sweeping assertion. When the evolutionary development of the parietal part of the cerebral cortex is studied exactly the reverse condition becomes manifest. It is the lower part of the parietal lobe which in man, both in its early development and in its after-growth, exhibits the greatest relative increase. Additional interest is attached to this observation by the fact that recently several independent observers have fixed upon this region as one in which they believe that a marked exuberance of cortical growth may be noted in people of undoubted genius. Thus Retzius has stated that such was the case in the brains of the astronomer Hugo Gyldén,* and the mathematician Sophie Kovalevsky; † Hansemann ‡ has described a similar condition in the brain of Helmholtz; and Guszman § in the brain of Rudolph Lenz, the musician. Some force is likewise added to this view by Flechsig, who, in a recent paper, || has called atten-

* Retzius, *Biologische Untersuchungen*, neue Folge, VII., 1898, 'Das Gehirn des Astronomen Hugo Gyldéns.'

tion to the fact that within this district there are located two of his so-called 'Terminalgebiete,' or cortical areas, which attain their functional powers at a later period than those which lie around them, and which may therefore be supposed to have specially high work to perform.

Without in any way desiring to throw doubt upon the observations of these authorities, I think that at the present moment it would be rash to accept, without further evidence, conclusions which have been drawn from the examination of the few brains of eminent men that have been described. There cannot be a doubt that the region in question is one which has extended greatly in the human brain, but the association of high intellect with a special development of the region is a matter on which I must confess I am at present somewhat sceptical.

But it is not only in a backward direction that the parietal lobe in man has extended its territory. It has likewise increased in a downward direction. There are few points more striking than this in the evolution of the cerebral cortex of man. In order that I may be able to make clear the manner in which this increase has been brought about, it will be necessary for me to enter into some detail in connection with the development of a region of cerebral surface termed the *insular district*. The back part of the frontal lobe is also involved in this downward extension of surface area, and, such being the case, it may be as well to state that the boundary which has been fixed upon as giving the line of separation between the parietal and frontal districts is purely artificial and arbitrary. It is a demarcation which has no morphological significance, whilst from a physiological point of view it is distinctly misleading.

D. J. CUNNINGHAM.

[To be concluded.]

SCIENTIFIC BOOKS.

Die Partiellen Differential-Gleichungen der Mathematischen Physik. Nach Riemann's Vorlesungen. In vierter Auflage. Neu bearbeitet von HEINRICH WEBER, Professor der Mathematik an der Universität Strassburg. Braunschweig, Druck und Verlag von Friedrich Vieweg und Sohn. 1900, 1901. Erster Band, pp. xvi + 506; Zweiter Band, pp. xi + 527.

The appearance of this new and greatly enlarged edition of the work founded on Riemann's lectures will be welcomed with delight by every student of the mathematico-physical sciences. Those acquainted with the preceding capital edition of Hattendorff do not need to be reminded of the high model of excellence in exposition he set. Professor Weber has not only amplified this model, but he has fairly canonized it, placing before the student a glorified summary of the physical concepts and the mathematical methods on which the great progress of the nineteenth century in physical science rests.

It is a good sign of the times that many eminent European mathematicians are reverting to the example set by the illustrious Gauss and followed with such signal success by Riemann, Clebsch, Kirchhoff and others. The advantages to be gained by the pure and by the applied mathematician in following such an example are mutual so far as existing science is concerned, while the better understanding of one another's work which results therefrom makes it easier to secure that sort of cooperation essential to rapid and permanent advances. The mathematical physicist is, therefore, under deep obligations to Professor Weber for the admirable presentation he has given us of the more important and more difficult branches of mathematical physics.

The reader who may be unacquainted with the earlier editions of this work should be warned against supposing it to be a treatise on any one of the subjects considered. Its great merit lies in the fact that while not a treatise, it states the salient principles and essential mathematical features of many branches of physics with a clearness and with an attractiveness rarely attained in formal treatises. No previous work, so far as we are

aware, is quite so successful in producing for the student the right combination of physical and mathematical difficulties.

The first volume is divided into three principal parts and into twenty-three sections. The first part is devoted to pure analysis, with sections in order on definite integrals, Fourier's integral, infinite series, Fourier's series, multiple integrals, functions with complex arguments, differential equations, and Bessel's functions. The second part treats of geometrical and mechanical theorems, with sections on linear infinitesimal deformation, vectors, the potential function, examples of potential function, spherical harmonics, and the fundamental principles of mechanics. The third part is devoted to applications in the fields of electricity and magnetism, with sections on electrostatics, problems in electrostatics, magnetism, electrokinetics, electrolytic conduction, steady electrical currents, flow of electricity in surfaces, flow of electricity in space and electrolytic displacements.

The second volume is divided into five parts and into twenty-three sections. The first part is concerned with the theory of linear differential equations, with sections on integration by means of hypergeometric series, integration by means of definite integrals, the P -function of Riemann, and, under the heading Oscillationstheoreme, a section treating very fully the equation $d^2y/dx^2 + \rho y = 0$, where ρ is in general a function of x . The second part is devoted to heat diffusion, with sections on the differential equation of heat diffusion, the problem when dependent on a single coordinate, and the problem of diffusion in a sphere. The third part is devoted to the theory of elasticity, with sections on the general theory of elasticity, statical problems, equilibrium and deformation of an indefinite isotropic solid, vibrations of stretched cords, Riemann's method of integration, vibration of membranes and the general theory of the differential equation of a vibrating membrane. The fourth part is occupied with electrical oscillations, with sections on electric waves, linear electric currents, and reflection of electric oscillations. The fifth part treats of hydrodynamics, with sections on general theorems, motion of rigid bodies in

fluids (two sections), discontinuous fluid motion, propagation of an impulse in a gas and aerial vibrations of finite magnitude.

When all parts of a work like this one are noteworthy for their unsurpassed excellence, it is difficult to cite parts specially commendable or to call attention to small defects. Every reader, according to his bias, will be drawn first to those sections in which he has special interest, and he must be a narrow specialist if he does not find many such sections. Generally, the work is to be praised for its admirable clearness. Some of us foreigners find the German frequently lacking in directness and perspicuity; and we are especially mystified often by the offensive use of italics so common with writers whose thoughts are unclarified. Professor Weber's style, however, is as transparent as that of the best French standards, and in this respect his work recalls the faultless exposition of such great masters as Gauss and Kirchoff.

The typography of the work is likewise unsurpassed. It, like the selection of the subject-matter and the treatment thereof, is a model for all makers of mathematical books. Book makers and publishers in America should take note of the fact that each of the volumes of this work (comprising over 500 pages per volume) 'made in Germany,' is beautifully printed, on excellent paper, and is yet less than 30 millimeters thick over all, including the rather stout half-morocco binding. To do as well in our country it will be essential to discard the miserable, thick, talc-loaded or lead-loaded paper now so commonly used here.

It would be possible to find some small faults with the presentation and treatment of the topics, here and there. 'There are spots on every sun'; but in this case, as with our orb, they do not disturb the general luminosity, and we may expect to see them disappear from future editions. In the meantime, students of mathematics and physics generally will find this work a mine of instructive and inspiring information accessible by the aid of a full table of contents and a good index. Every worker in mathematical physics should have the volumes constantly within an arm's reach.

R. S. W.

Ind.
 A *Text-book of Astronomy*. By GEORGE C. COMSTOCK, Director of the Washburn Observatory and Professor of Astronomy in the University of Wisconsin. New York, D. Appleton and Company. Cloth. Pp. 391. Price, \$1.30.

Written in simple, clear and concise language, illustrated by appropriate and well-constructed figures, made interesting by apt and homely comparisons and useful by numerous and well-chosen exercises, this book forms a welcome addition to the list of elementary text-books of astronomy. Professor Comstock has written a new book and has not merely rearranged the material of earlier ones. His purpose is clearly outlined in the first paragraph of the preface: "The present work is not a compendium of astronomy or an outline of popular reading in that science. It has been prepared as a text-book, and the author has purposely omitted from it much matter interesting as well as important to a complete view of the science, and has endeavored to concentrate attention upon those parts of the subject that possess special educational value. From this point of view, matter which permits of experimental treatment with simple apparatus is of peculiar value and is given a prominence in the text beyond its just due in a well-balanced exposition of the elements of astronomy, while topics, such as the results of spectrum analysis, which depend upon elaborate apparatus, are in the experimental part of the work accorded much less space than their intrinsic importance would justify."

Inspection of the table of contents shows that the author has departed widely from the conventional methods of treating the elements of the subject, especially in the first six and the eighth chapters. The special features of the book are numerous questions scattered throughout the text, to teach the student to think and construct as well as to read and assimilate; and many exercises, in the nature of laboratory work, all to be performed with simple apparatus, easily constructed by the students themselves. In these exercises the students obtain practice in the three fundamental processes of all practical astronomy, the measurement of time, angle and distance. Although the exer-

cises are numerous, still the author has not exhausted the list and might with profit have given more.

It would have been well, if possible, to so arrange the material that the exercises, which all fall in the first five chapters, would be more distributed. It is not necessary, of course, that the teacher present the material in just the order given, but the facts are that the large majority of teachers will present it in that way. The author has, apparently, purposely avoided all reference to the *Nautical Almanac* and *American Ephemeris*. The wisdom of this is open to question. While it is unnecessary and certainly unwise to introduce the *Ephemeris* at first and thus make the student dependent upon it, still I think it equally unwise to totally exclude it. An explanation of the *Ephemeris* and a few exercises which demand its use should, I think, be included in the most elementary course in practical astronomy. Any school in which astronomy is taught can surely afford to buy one of these books each year, and any person capable of teaching the subject should be able to use the book intelligently.

Many bits of good advice are given in connection with the exercises. On page 3, for instance, in connection with a measurement to be made, we find: "But perfection can seldom be attained, and one of the first lessons to be learned in any science which deals with measurement is that however careful we may be in our work, some minute error will cling to it and our results can be only approximately true. This, however, should not be taken as an excuse for careless work, but rather as a stimulus to extra effort in order that the unavoidable errors may be made as small as possible."

A point to be commended is the use of the metric system throughout the exercises. In the descriptive parts of the text, however, the author retains the English units. Perhaps it is best to break away gradually, but I believe no criticism would have been offered if the metric system had been used throughout.

The illustrations and figures of the book are well chosen and the student should learn something from each. Very few, if any, have been inserted for pictorial effect. Among the figures

which deserve special mention are Nos. 16 and 17, from which the position of any of the five brighter planets may be determined for a number of years; No. 23, which ingeniously illustrates the tide-raising forces; No. 54, illustrating the moon's rotation; No. 121, illustrating the determination of parallax of the fixed stars.

Of the many apt illustrations contained in the book, the following, page 121, is one of the best: "Every such timepiece, whether it be of the nutmeg variety which sells for a dollar, or whether it be the standard clock of a great national observatory, is made up of the same essential parts which fall naturally into four classes, which we may compare with the departments of a well-ordered factory: I. A time-keeping department, the pendulum or balance spring, whose oscillations must all be of equal duration. II. A power department, the weights or main spring, which, when wound, store up the power applied from outside and give it out piecemeal as required to keep the first department running. III. A publication department, the dial and hands, which give out the time furnished by department I. IV. A transportation department, the wheels, which connect the other three and serve as a means of transmitting power and time from one to the other.

"The case of either clock or watch is merely the roof which shelters it, and forms no department of its industry. Of these departments the first is by far the most important, and its good or bad performance makes or mars the credit of the clock."

The last chapter, growth and decay, deserves special mention. It is a clear, philosophic treatment of the best theories of sidereal evolution, and although not out of place in a high-school text, it might well form a part of a larger treatise.

SIDNEY D. TOWNLEY.

UNIVERSITY OF CALIFORNIA,

May 1, 1901.

SCIENTIFIC JOURNALS AND ARTICLES.

The Journal of Physical Chemistry, June, 1901.

'The Theory of Electrolytic Dissociation as viewed in the Light of Facts recently ascertained,' by Louis Kahlenberg; 'On the Gener-

alization of Clapeyron's Equation,' by Paul Sorel; 'On the Phase Rule,' by Paul Sorel. This paper by Dr. Kahlenberg demands more than passing mention. Since its enunciation by Arrhenius in 1887, the theory of electrolytic dissociation has received a recognition which has rarely been accorded a scientific theory in so short a time, and few theories have been so productive of results. Unhesitating assent has been by no means accorded it by many, especially of the older, chemists, but few attempts have been made to reveal its weaknesses experimentally. Dr. Kahlenberg, himself a pupil of Ostwald, has been one of the few who have from time to time called attention to experimental facts which were not in accord with the theory. In his present paper, the author first details a large amount of experimental work on the electrical conductivity of solutions at low and at high temperatures, and on molecular weight determinations by boiling point and cryoscopic methods, in solutions of gradually increasing strength, in which is shown often a great discrepancy between the results and those required by the dissociation theory. He then proceeds to discuss at length these and many other failures of the theory, drawing the conclusion that the theory is applicable to a decidedly limited class of solutions. The true nature of solutions must be reached by a study, not of those extremely dilute, but first of the concentrated solution, approaching the dilute solution as a limiting case. In conclusion, he says: "It must be fully and freely admitted that the dissociation theory has done much good in stimulating research in many lines. It has been fruitful in proportion to the amount of truth contained in it. Like other theories founded upon too narrow a basis of induction, it has gradually been outgrown—the facts are too much for it. It would be difficult of course to say of any theory—even of one long ago discarded—that it is entirely worthless, and so the writer has no inclination to make such a statement concerning the dissociation theory. * * * It is solely because of the rapid growth of the erroneous idea that the deductions drawn from the indiscriminate application of the simple gas equation to solutions and from the notion that all well-known facts harmonize with the theory

of electrolytic dissociation, that I have felt compelled to call attention to the real status of the experimental facts underlying these deductions."

J. L. H.

The Popular Science Monthly for October has for its opening article 'The Progress of Science,' by R. S. Woodward, being the address of the retiring president of the American Association. George Stuart Fullerton discusses 'Free-will' and the 'Credit for Good Actions' and Alexander McAdie presents some 'Fog Studies on Mount Tamalpais,' hinting at the possibility of dissipating such fogs as the one in which the steamer *Rio de Janeiro* was lost. Hugh M. Smith describes 'The French Sardine Industry' pointing out incidentally improvements that might be made in that of the United States. 'The Late Epidemic of Smallpox in the United States' is considered by James Nevins Hyde who makes a strong plea for vaccination. Edward Atkinson treats of 'Food and Land Tenure,' considering that the free land tenure of the United States is at the bottom of our great agricultural development. The final article is by W. Ramsay on 'The Inert Constituents of the Atmosphere,' describing the methods by which some of these have been discovered. The number completes Vol. LIX. and the index is appended.

The American Naturalist for September contains the third instalment of W. M. Wheeler's important and interesting description of 'The Compound and Mixed Nests of American Ants,' which includes in the present part the slave-keeping ants. The bulk of the number is taken up with the seventeenth of the 'Synopsis of North American Invertebrates,' in which H. S. Jennings treats of the Rotatoria, the paper being illustrated by nine plates comprising 171 figures.

THE Museums Journal of Great Britain for September contains a brief account of the work of 'The International Zoological Congress,' which includes some notes on the museums of Berlin and Hamburg, a paper by H. M. Platnauer, 'To Utilize Specialists,' and an account of the 'Museum of Science and Art, Edinburgh,' a very popular institution if one may

judge by the annual attendance of 350,000. A number of samples of labels used in the U. S. National Museum are given and there are notes concerning various museums and art galleries in different parts of the world.

SOCIETIES AND ACADEMIES.

NEW YORK ACADEMY OF SCIENCES, SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY.

THE section met on October 7, at the Chemist's Club. Professor Wm. Hallock reported that he had tried and failed to obtain permission of the Calumet and Hecla Company to make measurements of underground temperatures in their shaft at Keweenaw Point during the summer. He described and exhibited before the Section a new and very simple form of wind musical instrument which he found on sale at the Buffalo Exposition. The instrument was operated by blowing through the nose, the mouth cavity of the operator acting as the resonance chamber of the instrument. The tone quality was very similar to that of a flute.

Professor J. K. Rees reported that the Astronomical Department of Columbia had received from the Lick observatory a number of star photographs which were to be measured for the determination of parallax. Professor Harold Jacoby reported upon some photographs of stars near the celestial poles which had been received by the department.

Professor R. S. Woodward reported the results of an investigation he had carried on upon the effects of secular cooling and meteoric dust on the length of the terrestrial day. His investigation showed that, due to secular cooling, the length of the day will not change or has not changed, as the case may be, by so much as a half second in the first ten million years after the initial epoch, and that the total effect from secular cooling will accrue before the effect from meteoric dust will begin to be appreciable.

Professor DeRemus gave a brief account of the research laboratory in chemistry which had been lately established at Schenectady, N. Y.

F. L. TUFTS,

Secretary.

THE ELISHA MITCHELL SCIENTIFIC SOCIETY.

THE 136th meeting of the Society was held at the University of North Carolina, on Tuesday evening, October 8, when the following papers were presented :

'Interpretation of the Value $\frac{0}{0}$ ': PROFESSOR WILLIAM CAIN.

'The Work of the Beaufort Laboratory during the Season of 1901': PROFESSOR H. V. WILSON.

'Note on the Existence of a New Element associated with Thorium': PROFESSOR CHAS. BASKERVILLE.

The permanent secretary, President F. P. Venable, reported some four or five hundred exchanges as continued, and favorable progress in the cataloging and binding of the journals received in exchange.

The following officers were elected for the year: *President*, Dr. H. V. Wilson; *Vice-President*, Dr. A. S. Wheeler; *Secretary*, Dr. Chas. Baskerville.

CHARLES BASKERVILLE,
Secretary.

DISCUSSION AND CORRESPONDENCE.

AN INSTITUTE FOR BIBLIOGRAPHICAL RESEARCH.

TO THE EDITOR OF SCIENCE: In these days when large endowments are made for furthering scientific research in many directions, it is only natural that bibliographers and librarians should look forward eagerly to an endowment in the interest of that science which is the foundation of library work and, in a way, of all scientific investigation. Without bibliographies knowledge of what has been previously done in the various sciences would be wellnigh impossible; the investigator would be groping in the dark, and many a work would be written to demonstrate what had already been well demonstrated. Without bibliographies the building up of an ever so modest library would be beset with difficulties without end.

The thought that such an endowment must be made was in everybody's mind at the meeting this summer of the American Library Association. The plans for cataloging at one place books for all libraries in the country, which were discussed at the last two confer-

ences of the Association (Montreal, 1900, and Waukesha, 1901), presuppose a central bureau of some kind to organize the work and carry it out. The generous way in which the Librarian of Congress met the Publishing Board of the Association gives assurance that the cataloging of the current literature will be taken care of through the National Library. But this is only one part of the needed work. If thus the American literature of the new century will be permanently recorded (it is to be hoped that the work will be retrospective so as to cover the whole of the year 1901) we shall still lack an accurate bibliography of the American literature of past times.

There are other works of great importance that should be undertaken. Let me mention a few:

Bolton's catalogue of scientific and technical periodicals covers only one group of sciences and does not cover that one completely. A complete and accurate catalogue of serial publications of all kinds, including such as are published by societies, academies and other institutions, is a desideratum.

There is no critical and complete bibliography of bibliographies in existence. Petzholdt's monumental work does not go beyond 1866, and Henri Stein's recent volume, while bringing his predecessor's work fairly down to date, is anything but critical. It is doubtful whether a really authoritative catalogue of bibliographies can be produced without the cooperation of bibliographers and specialists in this country and Europe.

The catalogue of scientific literature undertaken under the auspices of the Royal Society of London has met with gratifying support from American libraries. But the 'Regional Bureau' for America that should do our part of the work is not yet founded. The Smithsonian Institution has provisionally undertaken to act as 'Regional Bureau,' but with all the other demands on it it is uncertain how long it can continue to cooperate in this work.

This catalogue is planned to cover only the natural and physical sciences. It is of the utmost importance that other sciences also should be covered by similar catalogues.

Furthermore, the Royal Society catalogue

covers only the current literature. The older publications should not be neglected, but should be cataloged in a series of monographs on special subjects.

The annotation of books by experts, advocated for many years with rare enthusiasm by Mr. George Iles, or at least the indexing and condensing of authoritative book reviews, is another work that would naturally come within the scope of a Central Cataloguing Bureau.

And finally, the bibliographical interests need an organ of their own where problems can be discussed and results made known.

It is clear that all these various undertakings, if carried out simultaneously, would result in a great deal of unnecessary duplication were there no central organization to guide and supervise the whole, and, if no provision were made for the utilization in many places of any title entry needed in several catalogues, without the necessity of setting up the matter anew for every time. As long ago as 1850, Professor Charles C. Jewett proposed that stereotype plates be made of the titles of all the books in American libraries, these to be kept at the Smithsonian Institution and to be utilized for the printing of catalogues of any library desiring it. The cost was too large then and the proposition too new. What was then looked upon as the visionary, though interesting, dream of an enthusiast, is now a reality, proved to be of economic value. The experience of the John Crerar Library with electrotype plates for title entries, used for printing of catalogues in book form as well as on cards, has been that the cost of making these plates and of their care and handling is less than that of printing the same matter over again from newly set type.

The purpose of these lines has been to call attention to the need of an Institute for Bibliographical Research where all the bibliographical and library interests of the country would center, and I hope that they may reach some one who might be able and willing to endow such an institute.

AKSEL G. S. JOSEPHSON.

THE JOHN CRERAR LIBRARY, CHICAGO,
Sept. 10, 1901.

DISCORD.

TO THE EDITOR OF SCIENCE: Permit me to respond briefly to Mr. W. Le Conte Stevens's remarks on 'Discord and Psychology' in the issue of SCIENCE for September 20. (1) How Mr. Stevens found out that I had not read the investigations of Professor Mayer on this subject is an enigma to me. His intimation that they were unknown to me is based solely on the fact that I do not swear by the authority of these investigations, made 25 years ago (1875). I have known them for many years. But I know also many more recent investigations which do not agree with those of Mayer. Physicists who are interested in psychological theories and discuss them in their text-books may keep up with current literature by looking once a year at the 'Psychological Index,' published annually by the *Psychological Review*, or at any other psychological bibliography. (2) With Mr. Stevens's request to criticize from the psychological standpoint the sentences quoted by him, I shall gladly comply by quoting a few sentences from a physicist who was unusually familiar with psychological literature, namely the late Professor Melde, who says (Winkelmann's 'Handbuch der Physik,' I., p. 789): 'Eine Hauptstörung eines regelmässigen Tones oder eines consonirenden Zusammenklanges bilden die Stösse oder Schwebungen. Sie können durchs Zusammenwirken der primären Töne, also durch Interferenz entstehen, oder es können auch auf rein mechanische Weise solche Stösse erzeugt werden. Ihre Wirkung muss in beiden Fällen mehr oder weniger die einer Beimischung eines Rasselgeräusches sein. Zur Erklärung des inneren Wesens einer Con- oder Dissonanz können aber nach des Verfassers Ueberzeugung auch nicht die Stösse (*viz.*, auch nicht Nebentöne) herangezogen werden, denn eine sogenannte Dissonanz besteht sicherlich auch ohne jedes Verhandensein von Stössen.'" Let me further quote from Stumpf, 'Konsonanz und Dissonanz' (1898), p. 5, where the author discusses the very investigations of Professor Mayer which I am supposed to have ignored: "Wir können Intermissionen in beliebiger Frequenz auch bei zwei konsonanten Tönen künstlich herstellen, ohne dass sie dissonant würden."

When there are beats, the psychologist speaks

of beats; when the beats are comparatively frequent, he speaks of 'roughness'; but the psychologist does not arbitrarily call roughness 'discord.' Upon the *cause* of discord the psychologists have *not* agreed; it is as yet unknown—at least to the psychologists.

MAX MEYER.

UNIVERSITY OF MISSOURI.

A CORRECTION.

IN SCIENCE for September 27, 1901, I called attention to a signature of a work entitled 'Florula Lexingtoniensis,' which I then supposed to be a work of C. S. Rafinesque. There is now no doubt that the signature in question is part of a work with the same title which appeared in the *Transylvania Journal of Medicine*, under the authorship of C. W. Short. The signature had been repaged, and does not have the appearance of a journal extract.

WILLIAM J. FOX.

ACADEMY OF NATURAL SCIENCES
OF PHILADELPHIA, PA.

CURRENT NOTES ON PHYSIOGRAPHY.

MT. KTAADN.

Two visits to Mt. Ktaadn (5,150') in northern Maine and four ascents have convinced Tarr that even the summit of the mountain has been glaciated, for fragments of schist, argillite and sandstone were found on its granite peaks ('Glaciation of Mt. Ktaadn, Maine,' *Bull. Geol. Soc. Amer.*, XI., 1900, pp. 433-448, 10 pl.). The greater part of the top is occupied by a 'tableland' surmounted by the several summits and gnawed into by huge basin headed valleys or corries, whose smooth and precipitous walls can hardly be scaled. Little talus lies in the basins, but a number of rock-basin lakes and terminal moraines were found on the valley floors. Where the basins come close together they are separated by sharp ridges, whose ruggedness Tarr accounts for by the moderate destructive action of the upper part of the ice sheet, as well as by postglacial weathering. He suggests that large local glaciers radiated from Ktaadn after the time of general glaciation.

Following the views of Richter, de Martonne and Matthes, recently noted in these columns, and the still earlier views of Johnson, the steep

walls and sharp dividing ridges between the Ktaadn corries would be ascribed to the retrogressive erosion of their local glaciers, aided by the excessive frost action of the Bergschrund belt; and the 'tableland' would be regarded as a residual of a larger preglacial dome.

NORWEGIAN FIORDS.

THE year-book of the Norwegian geological survey for 1900 ('Norges geologiske Undersøgelse,' No. 32, Aarbog for 1900, Kristiania, 1901, p. 263, many sketches and an English summary), contains an account of two important landslips in postglacial clays and a general discussion of the relief of certain typical areas. The highlands are regarded as presenting traces of two cycles of erosion; the older appears in the lofty snow-covered plateaus, more or less mountainous; the younger in the broad, open, high-level valleys among the high plateaus. The deeper valleys, whose deepest distal portions contain the fiords, are of later origin, after a great upheaval of the land, and are probably the work of water and ice in several interglacial and glacial epochs. Regarding the relative proportions of ice and water work, Reusch appeals to certain fiord valleys, in whose walls a number of ravines have been produced by ordinary subaerial erosion. In such cases, the valleys must have been, Reusch thinks, worn nearly to their present depth before the ravines could have been formed. Hence "the glaciers enlarged the main valley and partly destroyed the side valleys, but they cannot be said to have made the main valley." But this conclusion leaves the problem in a quandary; for if the ravines indicate the preglacial depth of the main valley, it is difficult to understand why certain

hanging lateral valleys, whose streams are much larger than those in the ravines, were not also

worn down in preglacial time to the great depth of the main valley. Moreover, as a rule, the fiord walls are not strongly ravined; they are generally rather smooth, as if they had been severely scoured. May it not therefore be supposed that the ravines are of late interglacial origin in rock structures that favor relatively rapid wearing; and that they have been eroded with respect to a valley floor which earlier glacial erosion had already deepened; while a minimum measure of the total glacial erosion is best given by the altitude of the large hanging valleys above the fiord bottoms, huge as the minimum may be?

THE ORIGIN OF MOELS.

'The Origin of Moels, and their Subsequent Dissection' (*Geogr. Journ.*, XVII., 1901, 63-69) is a discussion by Marr of the rounded mountains common in several parts of Great Britain, showing convex, dome-like tops and concave basal slopes, all covered with rock waste and vegetation, and not dissected by streams. Etymologically they are the Welsh equivalents of the 'balds' of our North Carolina mountains. Their form is ascribed to weathering under vegetation. The irregular forms into which a tableland is carved by streams would in time be subdued to moels, if weathering under a climate which favored the growth of a mantle of vegetation by which streams are excluded. In an arid or frigid climate, sharp peaks or ridges with even-sloping sides would, it is said, be developed, while running water would carve the well-known concave valley lines with steepening slope to their sources. The author goes on to show that if streams should gain a hold on a moel, either by climatic change destroying the plant mantle or by headward growth from the basal slopes, radial valleys would be carved by retrogressive erosion. Such valleys would in time reduce the intervening spurs into sharp ridges; notches would be worn in the narrowing ridges near the summit, where they are soonest consumed by the widening valley heads; and the peak of each ridge, just outside of the notch, would then be a 'tahoma,' as Russell has called such forms on Mt. Rainier (18th Ann. Rep. U. S. G. S., pt. II., 349). When one side of a mountain is exposed to rainy winds, while

the other side is relatively dry, the convex moel slope may be paired with the concave stream slope, as in certain parts of the English lake district.

Soil-creeping might have been given more explicit consideration than it here receives; for both the convex upper summit and the concave basal slopes of a valleyless moel may be largely produced by the slow creeping of the waste cover, as well as or better than 'partly by the action of the wind, and partly by inconstant runnels of water.' It seems unadvisable to treat moels as exhibiting 'the ultimate outlines of mountains which have been shaped by denudation'; for the ultimate outlines are level to the eye, and even the penultimate outlines have but a faint relief as the moels fade away. It is questionable whether the attainment of a convex summit outline is impossible in arid and frigid deserts; more probably it is merely delayed till the reduction of the mountain to a moderate relief in a late stage of the cycle weakens the forces of waste transportation to essential equality with forces of waste supply; a graded waste cover may then be formed all over the surface, whose outline will exhibit no sharp forms, but only gentle undulations. These undulations may be too gentle to be classed with the strong moels of Wales, but they deserve consideration in the general study of land forms.

W. M. DAVIS.

THE PHYLOGENY OF THE TOOTHED WHALES.

A RECENT issue of the *Memoirs of the Royal Museum of Natural History of Belgium* is devoted to a paper by Dr. O. Abel on the 'Longirostrine Dolphins of Bolderien,' in which the author describes and figures in detail the skulls of two remarkable extinct dolphins, *Cyrtodelphis sulcatus* and *Eurhinodelphis cocheteuxi*. The memoir is, however, a great deal more than the description of these crania, valuable though this be, for nearly one-half of it is devoted to observations on the phylogeny of the Odontoceti. We have a discussion of the evidence furnished by the dentition in general, and that of the pre-maxillaries in particular, the dermal armor and the general characters of

the cranium. Following this is a diagram showing *Zeuglodon* at the bottom and *Ziphius* as the most highly modified genus at the top, other genera, recent and fossil, being indicated in their proper positions at either side. This portion of the work is replete with information and abounds in references to other papers. There are, however, two points to which it may be well to call attention: The first of these is the assumption that *Zeuglodon* is the ancestor of the toothed whales, the other is the assumption that *Zeuglodon* had a highly developed dermal armor, amounting in fact to a carapace. Both of these conclusions should for the present be held in abeyance, as neither is as yet proven. This may perhaps be modified somewhat by saying that under the term *Zeuglodon* are included two perfectly distinct genera, *Basilosaurus* and *Dorudon*, and that while it seems very improbable that the former left any descendants, the structure of the latter is much nearer that of modern whales and these may be descended from that genus. There is, however, a large undescribed cetacean, indicated by vertebræ in the U. S. National Museum, found in the Eocene of Alabama and a knowledge of this form may throw some light on the problem of the origin of modern toothed whales. As to the defensive armor of *Zeuglodon* it may be well to discuss this at length later; for the present it may be said that the fine material collected by Mr. Schuchert for the U. S. National Museum shows nothing more than a few dermal ossicles, about the size of one's fist, of a rounded shape and slightly keeled on one edge. Had there been any extensive dermal armor it seems likely that it would have been collected, or at least seen, by Mr. Schuchert.

F. A. L.

ANTHROPOLOGY AT THE UNIVERSITY OF CALIFORNIA.

A DEPARTMENT of anthropology has, as we have already noted, been established by the regents of the University of California. The work of this department, for the present, will be anthropological research and the formation of a museum. Mrs. Phoebe A. Hearst has for several years been collecting a large amount of valuable material from the several expeditions

she has established, particularly in Egypt, in Peru and in California. These collections she gives to the University at Berkeley. The University has also a large collection from Alaska, presented by the Alaskan Commercial Company; and it is known that other collections are to become the property of the University when the museum is established. There are also now in the University many archeological specimens and human crania obtained from various parts of the state. For the storage and preservation of all this valuable material a temporary fire-proof building of brick and iron is to be erected at once. It is believed that this action will also be an incentive to the friends of the University to provide the funds for a museum building adequate for the proper exhibition of the collections in all departments.

As an encouragement to others and as an expression of her great interest in the new department, Mrs. Hearst, who is one of the regents and a most generous patron of the University, makes a gift of \$50,000 a year for five years for anthropological research. This amount will be devoted to continuation of the work in Egypt and in South America and to securing Greek and Roman antiquities; also to a thorough research of the archeology and ethnology of California, with particular reference to investigations of the deposits from the supposed Pliocene gravels to recent times, with the object of discovering when man first appeared on the Pacific Coast; also to a study of the many Indian tribes of California, their languages, myths and customs. For this work several parties are already in the field.

At present there will be no regular courses in the department, but university lectures on special topics in anthropology will be given from time to time. The first of these lectures was delivered on September 20 by Professor F. W. Putnam, who was invited to outline the purpose and scope of the new department and the methods of anthropological research. This was followed by a lecture on the study of the Indians by Miss Alice C. Fletcher; and the third lecture is to be by Mrs. Zelia Nuttall on the picture-writing of the ancient Mexicans.

Dr. A. L. Kroeber and Mr. P. E. Goddard have been appointed respectively instructor

and assistant in anthropology with assignment for field work among the Indians of California. Professor J. C. Merriam of the paleontological department has been given immediate charge of the research. Dr. P. M. Jones is engaged in archeological work with special reference to Santa Rosa Island. An honorary advisory committee has been appointed by the regents, as follows :

Dr. Benjamin I. Wheeler, President of the University.

Professor F. W. Putnam, Chairman of the Committee.

Mrs. Phoebe Hearst.

Miss Alice C. Fletcher.

Mrs. Zelia Nuttall.

Dr. Franz Boas.

Professor John C. Merriam.

Mr. J. G. M. E. d'Aquin has been appointed assistant secretary and executive officer of the department.

SCIENTIFIC NOTES AND NEWS.

THE eightieth birthday of Professor Rudolf Virchow has been celebrated in Berlin with elaborate ceremonies. The birthday actually occurred on Sunday, October 13, but the public exercises were on the previous day. There was a reception in the Pathological Institute in the afternoon and a banquet in the dining hall of the Prussian Diet in the evening, followed by an official reception in the parliament hall. Professor Waldeyer, secretary of the Berlin Academy of Sciences, presented 50,000 Marks, subscribed by medical men in Germany toward increasing the Virchow research fund. The Emperor has conferred an order and a medal, which have presumably been so long withheld owing to Professor Virchow's active participation on behalf of liberal institutions. The municipality of Berlin has resolved to call its new hospital, containing beds for 1,700 patients, the Virchowkrankenhaus. In New York City there was a banquet in honor of Virchow on October 12, when addresses were made by Drs. William Osler, W. H. Welch, A. Jacobi and A. H. Smith. Two days previously the *Geselligenschaftliche Verein* also celebrated the

event, on which occasion addresses were made by Drs. A. Jacobi, Franz Boas and J. N. Senner.

A STATUE of Pasteur was unveiled on September 9, at Arbois, where he spent his childhood and his holidays in later life. The monument, erected at a cost of over \$10,000, was designed by M. Daillon and represents Pasteur seated. On the pedestal are two bas-reliefs, one representing inoculation against rabies and the other agriculture profiting from Pasteur's discoveries. On the occasion of the unveiling addresses were made by M. Decrais, French minister of the colonies, and M. Liard, representing the Department of Public Instruction.

AMONG the scientific men who will be present as delegates at the bicentennial celebration of Yale University are : President H. S. Pritchett and Professors Wm. T. Sedgwick and George F. Swain from the Massachusetts Institute of Technology ; President Schurman from Cornell University ; Professors J. M. Van Vleck, W. N. Rice and W. O. Atwater from Wesleyan University, and Dr. H. C. Bumpus from the American Museum of Natural History.

DR. RUDOLF VON LEUTHOLD, has been appointed Staff-Surgeon-General of the German Army, in succession to the late Dr. von Coler.

SURGEON GENERAL GEORGE M. STERNBERG has returned to Washington after a tour of inspection in the Philippines.

PROFESSOR BASHFORD DEAN has returned to Columbia, after spending his sabbatical year in the east. He has brought back an almost complete series of developmental stages of the Port Jackson Shark, *Heterodontus japonicus*, a number of stages in the development of *Chlamydoselachus*, two new *Myxinoids*, a new *Chimæra*, together with a general zoological collection. During a visit to the Hokkaido (Yezo), he brought together several hundred specimens of Aino antiquities, which are now deposited in the American Museum of Natural History in New York. He also secured a collection of interesting glass sponges from the region of Misaki, which are also destined for the American Museum. Among other specimens are included a

number illustrating artificial selection; a series of the highly specialized varieties of Japanese gold fishes together with a number of the long-tailed fowls of Tosa, whose tail feathers sometimes reach the extraordinary length of fifteen feet. For the Columbia collection, he obtained during a visit in southern Negros, P. I., a series of dissections of *Nautilus*, prepared from fresh material. Dr. Dean, while in Japan, was the guest of the Imperial University of Tokyo, and spent most of his time at the zoological laboratory at Misaki.

PROFESSOR F. W. PUTNAM has recently returned from his trip through New Mexico and California. During part of the time he was engaged, in company with Professor J. C. Merriam, of the University of California, in a geological and archeological study of the gravels and other recent formations of California. For this purpose several caves in Calaveras and Tuolumne counties were explored, and human and other bones were found. Many old mining shafts and tunnels were also examined. On his way east Professor Putnam accepted an invitation to address the committee of the St. Louis World's Fair of 1903 in relation to the proposed ethnographical exhibit of the native peoples of the world.

MR. J. E. SPURR, who, as we have already noted, has been employed for geological surveys by the Sultan of Turkey, has begun his work in Macedonia and Albania.

DR. C. H. HERTY, of the University of Georgia, has during the summer been engaged in an investigation of the turpentine industry in southern Georgia. His results will appear in the bulletin of the Bureau of Forestry, for which he has acted as scientific assistant.

MR. WILLIAM L. CHERRY has returned to Chicago from a trip of several years' duration in Central Africa. He has brought with him to America a large ethnological collection.

DR. ROLAND B. DIXON has returned to Harvard University from an extended trip in Russia. Mr. W. C. Farabee, a graduate student at Harvard University, has been engaged during the summer in exploring a pueblo ruin in New Mexico, and A. M. Tozzer, a second-year graduate, has made a study of myths and

language of the Navajo Indians. William Jones, a student and fellow of Columbia University, has returned from Oklahoma, where he has been conducting linguistic researches conjointly for the American Museum of Natural History and the Bureau of American Ethnology. Henry Minor Huxley has returned from his anthropological expedition in Syria.

THE Philippine Forestry Bureau has made a veritable raid on the professionally educated foresters in this country. The New York State College of Forestry has lost two of its senior students, Messrs. Clark and Klemme, who were sufficiently advanced in their studies to pass the Civil Service examination, and also Mr. Hagger, its forest manager from the College Forest, and its first graduate, who leaves a position with the New York State Forest, Fish and Game Commission. Captain Geo. P. Ahern, the chief of the Forestry Bureau, also secured the services of two other foresters, Messrs. Griffith and Hareford, and of Mr. S. N. Neely, a civil engineer, formerly employed by the United States Forestry Division in timber and physics work, to conduct a wood-testing laboratory. The crop of foresters promises to grow more rapidly in the future, the New York State College of Forestry having, this year, inscribed 38 students, and the students in the Yale Forest School, showing an increase of 22.

THE sixtieth birthday of Professor Hermann Nothnagel, the eminent pathologist of the University of Vienna, has been celebrated with appropriate ceremonies by his former students.

A TESTIMONIAL banquet, in honor of Dr. N. S. Davis, was given at Chicago on October 5. There were about 350 physicians in attendance and addresses were made by a number of well-known medical men and by Dr. Davis, who was presented with a cup. Dr. Davis, who was born January 19, 1817, took an important part in the reform of medical education in the United States. The American Medical Association was established at his initiative, and he was the first editor of its journal.

DR. SAMUEL J. JONES, professor of ophthalmology and otology at the Northwestern University Medical School, died October 4, aged

65 years. He was for many years editor of the *Chicago Medical Journal and Examiner*.

WE regret to learn that Mr. Joseph S. Crosswell, a graduate of the Massachusetts Institute of Technology and instructor in shop work and drawing at the Missouri School of Mines, as a result of emotional insanity, shot and killed Miss M. Powell, after which he committed suicide.

THE death is announced of Major-General Alfred Wilkes Drayson, who was for many years professor of astronomy at Woolwich, England.

DR. MAX REESS, formerly professor of botany in the University at Erlangen, died on September 15, aged fifty-six years.

THE Board of Directors of the Rockefeller Institute for Medical Research held a meeting in New York City on October 12. It was decided to award nineteen fellowships, the holders of which will work in established laboratories.

THE Medical Society of the State of Pennsylvania met at Philadelphia on September 24, 25 and 26, under the presidency of Dr. Thomas D. Davis, of Pittsburg. Dr. F. P. Ball, of Lock Haven, was elected president for next year, and the meeting will be at Allentown.

THE New York State Medical Association will meet in New York City, beginning on October 22.

WE learn from the New York *Medical Record* that a conference of sanitary officers of the state of New York will be held at Albany on October 24 and 25. It will commence with an evening session on the twenty-fourth, which will be held in the Assembly Chamber of the capitol, and it is expected that the meeting will be addressed by Governor Odell. The next day there will be a morning and afternoon session, and the conference will close with a banquet in the evening at the hotel Ten Eyck. The object of this gathering is to afford an opportunity for meeting and making the personal acquaintance of the local and the central health authorities, and in a personal conference to present, by addresses and discussions, subjects and matters which are of practical and immediate interest to boards of health and their executive officers.

THE Christmas Island Phosphate Company has given £1,000 to the Liverpool School of Tropical Medicine for a scientific expedition to investigate beri-beri, and has also given free transportation to the members of the expedition who left Cardiff on October 4. Sir John Murray and the Colonial Office have each contributed £100 in aid of the expedition.

REUTER'S AGENCY reports that the Antarctic steamship, *Discovery*, on its way to Cape Town landed a party at South Trinidad, which remained six hours on the island. Messrs. Scott, Murray and Köttlitz ascended over 1,000 feet, obtaining some interesting natural history collections. Some new specimens of seaweed were obtained by towing a net while sailing, and were named after the *Discovery* and Mr. Scott.

WORD has been received by Professor Osborn of the discovery of the entire side of the shell of a fossil *Glyptodon* by an expedition from the American Museum of Natural History in Texas. This animal looks more like a turtle than a mammal, the body being encased in a dome-shaped shell of bone, ornamented with an elaborate mosaic pattern. It has hitherto been known in this country by only two teeth and a few pieces of the shell, recorded by Professors Cope and Leidy in Texas and Florida in 1888 and 1889. The great shell found by the American Museum is four feet long, accompanied by the heavily armored tail, all beautifully sculptured and in perfect preservation. It is not a true *Glyptodon*, but more like the species *Hoplophorus* described by Lund from the bone caverns of Brazil. This specimen has been shipped to the Museum. It was found by one of the expeditions sent out especially for fossil horses.

THE Peabody Museum of Harvard University has secured several large stone sculptures or old Mexican idols, stone faces, stone beads, etc., which were collected about forty years ago by a resident of Mexico.

THE London correspondent of the New York *Evening Post* cables that a second consignment containing the later collections made by Sir Harry Johnston in East Africa has been received at the Natural History Museum. It in-

cludes four specimens of the five-horned giraffe, two males and two females, obtained on Mount Elgon. Expert opinion, however, has not yet pronounced this giraffe to be distinct from the form already known to occur in East Central Africa. Dr. Oldfield Thomas, the mammalogist of the Museum, is preparing a critical statement for the Zoological Society. The Royal Gardens at Kew have received an important series of plants collected by Sir Harry Johnston on the Ruwenzori mountain range, several species being new to botanical science.

IN Forest Park, the site selected for the exposition to be held in St. Louis in 1903, is a group of six circular mounds. In order that they may remain during and after the fair, steps should be taken by the scientific men of St. Louis to preserve them from destruction during the erection of the buildings. They would certainly form an interesting addition to the archaeological exhibit of the exposition equal in value to the space they occupy and would afterwards remain objects of permanent interest.

THE Director-in-Chief and other members of the staff of the New York Botanical Garden have extended an invitation to members and their friends to be present in Bronx Park on Saturdays, October 12, 19, 26 and November 2, 9 and 26. A train leaves Grand Central station at 2:15 p. m. for Bronx Park, and returning leaves Bronx Park at 5:38 p. m. Opportunity will be given for inspection of the museums, laboratories, library and herbarium, the large conservatories, the herbaceous collection, the hemlock forest, the fruticetum and parts of the arboretum site. The walk planned will be a little over one mile. The following lectures will be given at 4:30 p. m. :

October 12. 'Sunlight and vegetation,' by DR. D. T. MACDOUGAL.

October 19. 'Botany of the West Indies,' by DR. N. L. BRITTON.

October 26. 'Habits and characteristics of some of the larger marine plants,' by DR. M. A. HOWE.

November 2. 'Ancestral history of some living trees,' by DR. C. A. HOLLIICK.

November 9. 'Production of cinchona bark and quinine in the East Indies,' by DR. H. H. RUSBY.

November 16. 'Botanical features of the mountains of Colorado,' by DR. L. M. UNDERWOOD.

UNIVERSITY AND EDUCATIONAL NEWS.

MRS. JAMES FINNEY HOW has given to Washington University the sum of \$100,000 as a memorial of her father, the late James B. Eads. It has not yet been decided in what way this sum shall be used.

THE University and Bellevue Hospital Medical School has received an anonymous gift of \$25,000.

COLUMBIA UNIVERSITY has received from Dean Lung a gift of \$12,000 to be added to the endowment of \$100,000 for the Chinese department given last June.

THE HON. OSCAR STRAUS has given to the University of Georgia a cabinet organ and several hundred dollars toward an equipment for work in experimental psychology.

MISS HELEN MILLER GOULD has given to Vassar College two scholarships of \$10,000 each, for the benefit of graduates of the Tarrytown High School and of the Washington Irving High School at Irvington, N. Y.

THE new building for the Tufts College Medical School was opened on October 3, when Dr. Elmer T. Capen, president of the college, made the inaugural address.

THE Missouri School of Mines is now putting in a new heating plant and has in process of erection a building to be known as 'Mechanical Hall.' It will have two stories, 150 x 60 feet, and will be used for shop work and dynamo, steam and hydraulic laboratories. A second story is being added to the chemical laboratory, and it is being enlarged by two wings 55 x 60 feet each. One of these will be devoted entirely to assaying. An extension, 42 x 80 feet, to the ore-dressing and metallurgical laboratory, which has a floor space of 60 x 75 feet, will also be added, and plans have been made for a new main building. It will be three stories, with a basement well above ground, and 140 x 85 feet. The new site for this building has been purchased, consisting of eight acres immediately adjacent to the present campus, which contains about 20 acres. The present floor space of the school, devoted to laboratories, lecture rooms, etc., is 45,085 square feet. It will be on completion of the new buildings 126,848 square feet.

THE registration at the summer quarter of

the University of Chicago in the different groups was as follows: Philosophical-sociological 1,169, language and literature 2,544, divinity 788, education 1,602, sciences 1,128. The number of courses offered in the sciences and the registration were as follows:

<i>Physical.</i>	
Mathematics.....	14 317
Astronomy.....	3 40
Physics.....	11 191
Chemistry.....	14 195
Geology.....	8 124
Totals.....	50 867
<i>Biological.</i>	
Zoology.....	9 72
Anatomy.....	9 70
Physiology.....	2 33
Neurology.....	4 28
Botany.....	11 158
Totals.....	35 361

It is reported that restrictions will be placed on foreign students attending the Technical Institute at Charlottenburg. In Berlin, in Munich, and in other technical schools, there has recently been much complaint in regard to the number of foreign students. The restrictions are aimed especially against Russians, Americans being less numerous than formerly.

It is expected that a professorship of pathology will be filled at the University of Sydney at the close of the present year.

DR. ROLAND THAXTER has been promoted to a professorship of cryptogamic botany at Harvard University.

GILBERT H. BOGGS, A.B. (Georgia), Ph.D. (Pennsylvania), has been appointed instructor in chemistry in the University of Maine. W. C. Ebaugh, A.B. (Pennsylvania), Ph.D. (Pennsylvania) has taken the professorship of chemistry and physics in Kenyon College, Gambier, Ohio. Lily G. Kollock, A.B. (Woman's College), Ph.D. (Pennsylvania), has received an appointment in the Girls' High School, Louisville, Kentucky, as professor of chemistry and physics. Thomas M. Taylor, S.B. (Oberlin), Ph.D. (Pennsylvania), becomes instructor in chemistry in Oberlin College. Leonard P. Morgan, S.B. (Pennsylvania) has accepted an instructorship in chemistry in the Mining and Agricultural College, Stillwater, Oklahoma.

In the Medical College of Western Reserve University, Dr. F. C. Waite, of the University of Chicago, has been appointed assistant professor of histology and embryology, Dr. H. B. Parker demonstrator in pathology, and Dr. R. G. Perkins lecturer on bacteriology.

At the University of Pennsylvania, Dr. M. Howard Fussell has been appointed assistant professor of medicine, Dr. Thomas R. Neilson assistant professor of genito-urinary diseases, and Dr. Elisha H. Gregory, Jr., demonstrator of anatomy. Dr. Frederick A. Packard will deliver the lectures upon applied therapeutics, and Dr. H. C. Wood, Jr., those on the physiological action of drugs, in the place of Dr. Horatio C. Wood, professor of therapeutics, who has been granted leave of absence for a year.

At Washington University, Mr. A. P. Winston has been appointed instructor in political economy and Mr. A. O. Lovejoy, lately of Leland Stanford Junior University, has been appointed professor of philosophy.

FRANCIS GANO BENEDICT, Ph.D., has been promoted to an associate professorship in chemistry, at Wesleyan University, Middletown, Conn.

DR. EARL BARNES has been appointed a special lecturer in pedagogy in the School of Pedagogy of New York University.

DR. A. A. LAWSON, of the botanical staff of the University of California, who has spent the past year at Chicago (as fellow in botany), has been appointed assistant in botany at Leland Stanford Junior University.

MR. H. T. A. HUS, M.S., a graduate student in botany at the University of California, has been appointed assistant in botany at the University of Amsterdam, Holland.

DR. HERMANN SIMON, docent in physics at Frankfort a/M., has been appointed associate professor of physics and electricity in the University at Göttingen, and Dr. Ernst Neumann, docent in applied mathematics and physics in the University of Halle, has been appointed to an associate professorship in the University at Breslau. Dr. Julius Precht, associate professor of physics at Heidelberg, has been called to the Technical Institute at Hanover.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE: S. NEWCOMB, Mathematics; R. S. WOODWARD, Mechanics; E. C. PICKERING, Astronomy; T. C. MENDENHALL, Physics; R. H. THURSTON, Engineering; IRA REMSEN, Chemistry; CHARLES D. WALCOTT, Geology; W. M. DAVIS, Physiography; HENRY F. OSBORN, Paleontology; W. K. BROOKS, C. HART MERRIAM, Zoology; S. H. SCUDDER, Entomology; C. E. BESSEY, N. L. BRITTON, Botany; C. S. MINOT, Embryology, Histology; H. P. BOWDITCH, Physiology; J. S. BILLINGS, Hygiene; WILLIAM H. WELCH, Pathology; J. MCKEEN CATTELL, Psychology; J. W. POWELL, Anthropology.

FRIDAY, OCTOBER 25, 1901.

THE first meeting of the Section was called to order by Vice-President David Starr Jordan, on Monday, August 26, at 11:30 a.m., when the Section was organized with the following officers:

Vice-President, David Starr Jordan.

Secretary, Henry B. Ward.

Member of Council, C. H. Eigenmann.

Member of General Committee, V. L. Kellogg.

Sectional Committee: C. B. Davenport, Vice-President, 1900; C. H. Eigenmann, Secretary, 1900; D. S. Jordan, Vice-President, 1901; H. B. Ward, Secretary, 1901; E. P. Felt, W. H. Ashmead, T. D. A. Cockerell.

The report from the Committee on Variation was read, and on motion the Section voted to recommend the granting of the funds requested for prosecuting the work. The report is as follows:

The grant of one hundred dollars to this committee was used to help defray the expenses of Mr. C. C. Adams incurred in collecting for study molluscs of the genus *Io*, found in the headwaters of the Tennessee River. A preliminary report has been made by Mr. Adams, and this was printed in the *Proceedings* of the Association for 1900. Mr. Adams submits at this time a second report covering the results of study on the material collected last summer, but prefers to postpone further publication until after his final expedition which he is

making this summer. The main results so far are that he has shown, by the aid of an elaborate series of measurements, that the numerous species of *To* run into each other in a very complete way, and that the differences between the shells are associated with their position up or down stream. Nevertheless, there is in most streams a more or less marked discontinuity between the smooth, globular, up-stream shells and the spiny, elongated down-stream shells. The meaning of the discontinuity (which justifies, in a way, a division of the shells into two species) is still not perfectly clear. To test certain hypotheses in respect to this discontinuity, Mr. Adams has returned to the field this summer. This piece of work is, we believe, the largest and most thoroughgoing quantitative study of the variation of a species in nature that has yet been reported upon.

The committee request the council to grant it one hundred dollars additional, to aid Mr. Adams in this his final summer's work on this topic.

The committee is glad to report an increasing interest in the quantitative study of variation, and especially the establishment by Professors Pearson and Weldon of a new journal, *Biometrika*, devoted to the results of such study.

Respectfully submitted,

F. BOAS,
CHAS. S. MINOT,
J. MCK. CATTELL,
CHAS. B. DAVENPORT,
C. H. EIGENMANN.

The following resolution was also passed requesting an appropriation for the Concilium Bibliographicum from the funds of the general society:

In view of the very limited sum at the command of the Committee on Grants, and recognizing also the fact that this money has hitherto been devoted only to the encouragement of research, this Section would

recall its request that a grant be made from these funds to the Concilium Bibliographicum.

As an important aid to research, already firmly established, of great assistance to investigators and capable of development so as to serve a wider usefulness, this Section regards the Concilium Bibliographicum as particularly deserving of support and encouragement, and to the end that such financial assistance as is necessary may be given, requests that a special appropriation of \$50 from the general funds of the Association be made for this purpose, and placed at the disposal of an advisory committee of three, consisting of President Minot, together with two other members or fellows appointed by him.

On Monday, at 3 p. m., the Section listened to the address of Vice President Davenport on 'The Zoology of the Twentieth Century,' which, in the absence of Mr. Davenport, was read by the secretary.

On Wednesday morning the Section adjourned to hear the address of Vice-President Jordan before Section G on 'Political and Social Conditions in the Hawaiian Islands.'

At a meeting of the General Committee on Thursday evening, Professor C. C. Nutting, of the University of Iowa, Iowa City, was elected vice-president and chairman of the Section for 1902, and Dr. Charles W. Stiles of the Bureau of Animal Industry, Washington, D. C., was elected secretary for 1902.

The following papers were presented before the Section and, so far as given by the authors, the abstracts for each are appended.

1. 'The Fish-Fauna of Japan, with Observations on the Distribution of Fishes': DAVID STARR JORDAN, President of Stanford University. Published in SCIENCE for October 11.

2. 'On the Morphology of the Pineal

Region based upon its Development in *Acanthias*': CHARLES SEDGWICK MINOT, LL.D.

The paper describes the development of the epiphysis, the posterior and superior commissures, the velum transversum and the paraphysis in the embryos of the dog-fish, of from 11.5 to 86.0 mm., studied chiefly by means of median sagittal sections. The velum transversum arises close to the epiphysis, and, unlike other known types, the dog-fish retains this relation permanently. The velum gives rise by its lateral expansion to the choroid plexus of the lateral ventricles. In front of the velum is the paraphysial arch, which is not identical with the paraphysis. This arch exists in all vertebrates, but has not hitherto been recognized as a constant morphological constituent of the brain. The true paraphysis arises as a small evagination from the paraphysial arch, and appears very late in development—in the oldest embryo examined it was not clearly present, so that it is uncertain whether it exists in the dog-fish at all. In amphibia and birds it is easily found, and there develops into a glandular organ, never, so far as known, into a sense-organ, as has been generally assumed hitherto. The single duct opens into the cavity of the brain. We may assume, in default of actual knowledge, that the gland supplies a secretion to the brain, being physiologically comparable to the infundibular gland of the lower vertebrates. In amphibians the velum transversum expands so much that it grows forward and across in front of the paraphysis; the enlarged velum is wholly transformed into the adult choroid plexus, as a part of which the paraphysial gland was long regarded erroneously. In birds and mammals the median portion of the velum is rudimentary or obliterated; the paraphysial arch is well developed and forms a large part of tela choroidea superior; the later portions, on

the contrary, are greatly developed to form the lateral plexus.

3. 'The Essential Mechanism of Hearing in Man': HOWARD AYRES.

4. 'On the Disappearance of the Vast Flocks of Wild Pigeons (*Ectopistes migratoria*) in Eastern North America': EDWARD T. KEIM, Denver, Colo.

In the memory of the middle-aged man many facts can be recalled relating to the annual flight of the myriads of wild pigeons through the Eastern, Middle and Central States of the United States of America. The newspapers of that period (1850 to 1870 and 1880) teemed with accounts of the vast numbers seen, and the superlative adjective was immoderately used to describe the great number and the indiscriminate slaughter. Certain wooded sections in the States of Kentucky, Tennessee, Missouri, Iowa, Illinois, Minnesota and Michigan, when the white settlers first came into these regions, were visited annually by the pigeons for nesting places, but owing to the almost ceaseless attacks by man, beast and bird, these localities were deserted for a year or more. Another fact also observed was that the abundance or scarcity of the 'mast' and the wild fruits and grains, which constituted their main food, determined the location of the annual nesting places. An account of a visit by the writer in company of a party of hunters, to the so-called pigeon roost near Maquoketa, Jackson county, Iowa, will be given, and a map of the United States showing approximate location of known breeding places will be exhibited. An effort will be made to secure mounted specimens of the male and female pigeon.

5. 'The Eleven Elements in the Superior Molar Teeth of Mammals' (illustrated by models): HENRY F. OSBORN.

6. 'The Homologies of the Mouth Parts of Insects with Complete Metamorphosis': VERNON L. KELLOGG.

Despite the continued attention of entomologists through nearly one hundred years to the problem of the homologies of the insect mouth parts, an agreement has not yet been reached as to the interpretation of these homologies in the Diptera and perhaps in other holometabolic groups. The extreme modification of certain parts and the reduction to mere unintelligible vestiges, or, indeed, to total disappearance, in the imaginal condition of the more specialized flies and the fact that even in the generalized flies the fully developed mouth-parts are so modified that a comparison with the typical biting or orthopterous mouth is difficult and hazardous, has determined this long-continued uncertainty in the determination of the mouth-part homologies. For the problem has been heretofore attacked exclusively, or nearly so, by the method of the comparative study of the fully-developed mouth structures. It is certain that no absolute determination of the homologies can be reached by this method alone. I have therefore made an attempt to trace the development of the imaginal mouth parts in the Diptera, Lepidoptera, Coleoptera and Neuroptera, while a student of mine, Mr. A. B. Spaulding, has undertaken similar work on the Hymenoptera. The special difficulty of the work lies of course in the remarkable histolytic and histogenetic conditions attending the post-embryonic development of the holometabolic insects.

It is perfectly feasible to trace continuously the development of mouth parts of the dipterous larvæ, from the first budding of the appendages on the successive head segments to fully developed larval condition. But the utter casting aside at pupation of these larval mouth structures and their supplanting by the radically different imaginal parts, which have developed from imaginal histoblasts (derived from the larval hypoderm) make it impossible to trace

a perfect continuity from embryonic anlagen to the definitive imaginal structures.

But we find in the advanced larva that the developing imaginal structures push out into and perfectly correspond with the larval parts, and that an interpretation of the homologies of the adult mouth parts in any of the holometabolic insects can be got at on the basis of this correspondence in position.

The value of this evidence from position is made apparent when the development of the imaginal mouth structures in holometabolic insects with biting mouths, as the Neuroptera and Coleoptera, are studied. There is no question in the minds of entomologists regarding the certainty of the homologies of imaginal mandibles, maxillæ and labium of these insects with the same parts of the imaginal orthopterous mouth. But a study of the development of the imaginal mouth parts in the Neuroptera and Coleoptera has revealed that perfect correspondence in position between the developing imaginal parts and the larval parts, as is apparent in the Diptera, Hymenoptera and Lepidoptera.

I have, therefore, been able to show that the interpretation of the homologies of the imaginal dipterous mouth parts formerly advanced by me (see papers on *Psyche*, 1900) on the basis of a comparative study of the fully-developed imaginal mouth structures, in all the generalized families and several of the specialized families is confirmed by the evidence derived from a study of the post-embryonic development of the imaginal parts. And further, this study shows that the ordinarily accepted interpretation of the homologies of the imaginal mouth parts of the other holometabolic orders of insects is confirmed by the study of their development.

7. 'On Taxonomic Relations between Scolytids and their Host Plants': A. D. HOPKINS, Entomologist, W. Va. Agric. Exp. Sta.

This paper embraces some of the results of the author's studies of the host plants of nearly all the described, and some 100 undescribed, North American Scolytidæ, which in addition to the literature containing references to the plants infested by these beetles in all countries, enables him to bring together for comparison a more comprehensive list of the insects and plants, than has ever before been possible. The species of insects with observed or recorded host plants represent some 500 species, 52 genera, 20 sub-groups, 7 groups, and 3 sub-families. All the host plants are found to belong to the Phanerogamæ. The Gymnospermæ are represented by 1 order, 13 genera and 30 species. The Angiospermæ by 1 order and 1 species in the Monocotyledons, and by 36 orders, 56 genera and 120 species in the Dicotyledons. The paper is illustrated by a chart, showing the relations of the primary and minor divisions in the classification of the insects with those of the plants. The genus of plants infested by the species of any genus or group of insects is shown in horizontal spaces, while the genera of insects, connected with any genera or group of plants, are shown in vertical spaces, crossing the horizontal ones. Thus the relations of genera to genera, and group to group, are presented in a most convenient manner for study and comparison. In the relations observed there seem to be some facts of considerable taxonomic importance which, if properly interpreted, and taken in connection with structural characters of the insects, will aid materially in determining natural affinities. When we came to consider these facts, and apply the evidence they furnish, towards the solving of some taxonomic problems, some rather striking results were obtained, which have guided us to the discovery of some valuable specific, generic and group characters in the insect, heretofore entirely overlooked. Closely

allied species and genera, which had been relegated to far corners in different groups, have been brought together, and order is being restored where there was much confusion. The evidence found in the fossils of Eocene rocks, and in amber, indicates that the Scolytidæ reached a high stage of development at the beginning of the Tertiary, and that it is not at all improbable that a maximum development was attained during the Jurassic or Cretaceous. We find the sequoia, and other survivors of ancient groups of conifers; the tulip, sassafras, oaks, elms, beeches, poplars and other survivors of primitive genera, and groups of other plants, supporting what are believed to be the oldest surviving types of groups and genera of Scolytidæ. This, together with the evidence furnished by the records of the host plants of existing species, furnishes guides and suggestions towards a clear conception of the probable lines of evolution of present forms from primitive generalized groups. They suggest that the progenitors of the Scolytidæ may have found their way into the soft bark and wood of conifer-like trees of the first true forest in the Devonian; or of the thick soft bark of the great tree ferns, *Sigillaria* and *Cicades*, of the Carboniferous, and that from these progenitors of the Gymnosperms, Monocotyledons and Dicotyledons the descendants of the insects have adapted themselves to the physiological changes in the evolution of their hosts, sharing with them the struggle for existence through the changes in surface and climate, from age to age, and from period to period, to the present.

8. 'Some Recent Observations on Culioidæ': L. O. HOWARD, chief entomologist, U. S. Department of Agriculture, Washington.

An account of some new work on the biology of *Aedes*, *Psorophora*, *Megarhinus* and *Stegomyia*.

9. 'The Larva of *Pyrrharcia isabella* as an Anatomical Subject': E. P. FELT, N. Y. State entomologist, Albany, N. Y.

The availability and desirability of this larva is shown and a few general statements made in regard to its internal anatomy. Attention is also called to an internal parasite and its relations to its host. Two small drawings illustrate the paper.

10. 'On the Development and Evolution of the Scolytid Gallery': A. D. HOPKINS.

This paper embraces some of the results of the author's special study of the galleries of the large number of described and many undescribed North American Scolytidæ, together with those figured from all countries, so far as available; representing in all some 400 species, 37 genera, 13 sub-groups, 7 groups and 3 subfamilies. Brief reference is made to the structural character, and characteristics of habit, which distinguish this family of beetles. In the galleries three fundamental forms, or types, are recognized: (1) The longitudinal, (2) the transverse, (3) the broad, irregular chambers which, modified or combined, form the specific types of all galleries, and these seem to fall naturally into eight primary groups and thirty-two divisions. The primary groups are designated as follows: (1) The primitive forms; (2) broad, irregular, branching forms; (3) the ambrosia galleries; (4) the intermediate or transverse branching forms; (5) the longitudinal, branching forms; (6) the double, transverse; (7) the double longitudinal; (8) the single longitudinal, or higher forms. The paper is illustrated by numerous lantern slides from photographs, and by drawings of typical forms of galleries; also by a chart which shows the relations of the various genera, sub-groups, groups and sub-families, to the groups of galleries, in horizontal and vertical spaces. The various forms of the galleries throughout the

family, so far as observed, range from the simplest longitudinal burrow (excavated in decaying bark or wood), as the primitive type, to the complex or composite form (with its many radiating branches from a central chamber), as the intermediate, and to the short, straight, longitudinal egg gallery (with its symmetrical radiating brood burrows in living bark), as representing the highest type. It is seen from a study of this diagram, that a group of allied forms of galleries does not necessarily represent any single group of species, but that the several groups of galleries represent parallel or periodic stages and relations in the evolutionary development of all the groups.

Thus if the characters, as expressed by the gallery, are properly interpreted as indicating a stage or period in the evolution, and are studied in connection with structural characters of the insects, it will indicate the natural position of a species, in its relation to other species in its group, and to similar stages and periods in other groups. The results of this line of study and thought, incompletely expressed as they are in this paper, may serve at least to suggest the course of evolution of the scolytid gallery within the maximum and minimum limit of an instinctive idea or tendency common to all individuals of the family, but expressed in varying degree as the different, low, intermediate and higher species and individuals are capable of expressing it. This suggests a parallel with the social development of the human species, in the evolution of the idea common to all, of constructing a habitation in which to rear and protect a family of offspring, as has been expressed in varying degree from the simplest to the highest perfection. It may suggest the importance of considering the law of parallel development of characters and characteristics, in species of remote, as well as near, affinity, and thus enable us to

eliminate some of the errors in our systems of classification, where a character, due to parallel development, has been mistaken for one of near affinity. And finally the results of this study of the gallery, together with the results of a study of the parallel relation of structural characters, indicate a law of parallel or periodical relation of groups of organisms somewhat similar to that of the chemical elements.

11. 'The Eye of the Blind Lizard *Rhineura floridana*': C. H. EIGENMANN, Bloomington, Ind.

The eye has been withdrawn from the surface; the tear glands are enormous as compared with the eyeball, which is very small, the optic fiber layer forming a central strand. The optic nerve does not extend to the eye. The layers of the retina have retained a high degree of specialization.

12. 'The Ontogenic Development and Degeneration of the Eye of the Blind Fish *Amblyopsis*': C. H. EIGENMANN, Bloomington, Ind.

The history of the eye of *Amblyopsis* may be divided into four periods: (1) The period of palingenic development ending when the fish is about 4.4 mm. long. (2) The period of direct development, during which the eye develops directly from a palingenic stage to the highest development the eye reaches—at the end of 10 mm. in length. (3) The period of progressive modification, during which the eye undergoes many changes without reaching a more perfect condition as an organ of vision. This ends when the fish has reached full maturity. (4) The period of degeneration ending with death; during this period the eye is gradually wiped out.

13. 'The Finding of the *Leptocephalus* of the American Eel': C. H. EIGENMANN, Bloomington, Ind.

Among many *Leptocephali* in the United States National Museum were found two which on account of their great resemblance

to the *Leptocephalus* of the European eel and on account of their differences from that of the European eel, which were just the differences between the adults, were considered the *Leptocephali* of the American eel. They were taken off New York.

14. 'A Gigantic Campanularian, with Observations concerning its Systematic Relations': C. C. NUTTING, Iowa City, Iowa.

15. 'The Harvard Embryological Collection': CHARLES S. MINOT, LL.D.

The collection was founded in connection with the Embryological Laboratory of the Harvard Medical School. It is intended to be used primarily for research work in the comparative embryology of vertebrata. It is proposed to have carefully graded stages of eighteen or more species, chosen as types of vertebrate classes, and to have of each stage three sets of serial sections in three planes—transverse, frontal and sagittal. The collection is to be thoroughly catalogued, every section being numbered. The paper describes the precise method used, the growth of the collection and other details.

16. 'On a New Type of Secretion by the Formation of Spherules': by CHARLES S. MINOT, LL.D.

The process here recorded was first observed in the glands of the cervix of the human uterus. The end of the epithelial cell, next the lumen of the gland, assumes a clearer appearance, becomes distended and then breaks off as a spherule, which lies in the gland cavity. The spherule breaks down, and its substance forms the secretion of the gland. Certain observations indicate that the same type of spherular secretion recurs in the mesonephros (Wolfian body of the pig, embryo, kidney of the frog). Mingazzini has described a somewhat similar spherule formation occurring on the basal ends of the epithelial cells of the intestine, during the resorption of food.

17. 'Laws of Adaptive Radiation': HENRY F. OSBORN.

18. 'Potential, Latent or Parallel Homology as distinguished from Phyletic or Derivative Homology (illustrated by Models)': HENRY F. OSBORN.

19. 'The Phylogenetic Relations of the Simple Vertebrates': HOWARD AYRES.

21. 'A Study of the Variations in *Sympetrum rubicundula* Say and *S. obtrusa* Hagen': MORTON J. ELROD, University of Montana.

These two species of Odonata are separated from each other on the relative sizes of the divisions of the bifid hamule, those having a little more than the apical third bifid being classed as *rubicundula*, those having the genital hamule with a fourth bifid being classed as *obtrusa*. The observations are based on the study of 394 specimens, from Maine to Montana, 223 being males. The aim of the author is to determine if the relative portions of the bifid hamule are a constant factor, and to determine if there are other factors that may be used for separation of the species.

Sixteen tables of figures are given, showing the variations observed in the fore and hind wings of both males and females, the length of males and females, the number of antecubitals, postcubitals and cross nervures of the fore and hind wings of the right and left sides of both males and females, the length of hamule of males, the relative widths of the bifid portions of the males, and the vulvar lamina of the females. The results of the measurements are as follows: The antecubitals and postcubitals are very irregular in number. There is a high percentage of both males and females of both species with five antecubitals on the hind wings. The antecubitals are much more constant than the postcubitals. The females show greater variation than the males. The left side shows greater variation than the right. The antecubitals on fore wings vary from six to nine, on hind wings from

four to seven. Postcubitals on fore wings vary from five to ten, and on hind wings from five to eleven. The males have more cross nervures than the females. Three-fourths of all the specimens have a less number of cross nervules on one wing than on the other. There is great variation in the length of the hamules. The comparison of the bifid portions of the hamules does not justify the separation into two species. There is no appreciable difference in the wings or length of body of the two species. No differences of consequence could be observed in the vulvar laminae of the females. The two species should be reduced to one, *S. rubicundula* Say, and a new description of the species written, which description is given in the paper. The variety *assimilata* is retained.

22. 'Further Studies in the Geographical Variation of *Io*': CHAS. C. ADAMS, Zoological Department University of Chicago, Chicago.

23. 'A Preliminary Statement of the Alkalinity of the Blood in Infections and the Infusion of Salts derived from Horses' Blood as a Therapeutic Measure': A. EMIL SCHMITT, New York City.

Based on the premises that the degree of alkalinity in the blood of certain species of lower animals, as horse, dog and cat, is greater than that in man, and that it is a causative factor in their immunity, and also that the alkalinity of the blood in man is reduced in the infections, and that by the infusion of alkaline solutions this can be increased and the infection thus overcome, the writer suggests the use of the salts derived from the horses' blood-ash and reports cases of puerperal septicæmia and cerebro-spinal meningitis thus treated. The views on the question of alkalinity are sustained by a number of authors, and the advantage accruing from the use of the salts derived from horses' blood-ash are set forth and compared with the prepared solutions of

salts composed according to analyses of blood-ash. The relationship of degree of alkalinity of blood and the incubation period of infections, as well as the immunity enjoyed by the black races, as also instances among the white race, and especially with lower animals compared with man, are hinted at.

No definite results as a therapeutic measure are claimed, but the author wishes to suggest a new trend of thought which will attack disease at its very foundations, altering the composition of the blood and body juices to make them uninhabitable for germ propagation. Introduction by means of infusion into the veins at the elbow instead of subcutaneously is resorted to on account of the pain and possible change of composition in the latter method. 500-1,000 cc. of the 1-per-cent. salt solution are infused at one time, controlled by the condition of arteries and heart. With this strength neither a dissolution nor a crenation of the corpuscles takes place, as demonstrated under the microscope, the isotonic coefficient of human blood compared with various strengths of this solution varying from .44-.58 per cent. No harmful effects have been noticed and venesection, to rid the body of some of its toxins in serious cases, is considered a valuable adjunct to the new form of treatment.

24. 'Cold as a Causal Factor in the Blood Changes due to High Altitude': JOHN WEINZIRL, Albuquerque, New Mexico.

Up to the present time no satisfactory explanation of the blood changes due to high altitude has been offered. The more commonly accepted hypothesis that the increased blood counts are due to diminished atmospheric pressure, or that] more red corpuscles are required to furnish sufficient oxygen to the tissues when the oxygen supply is diminished, has serious objections to it. In the first place, the oxygen absorption by the hemoglobin of the red

cells is a chemical phenomenon independent of the partial pressure of oxygen. Secondly, it is not at all plain why an increased number of red cells should be required to carry a given amount of oxygen, for, as Paul Bert has shown, the amount of oxygen actually used by an animal is constant even when the supply is diminished by one-half, or when pure oxygen is respired. Nor are the various other hypotheses that have been offered more satisfactory than the above. An experiment with common white rabbits, planned to test some of these hypotheses, accidentally revealed the fact that extreme temperature changes or a change from a warm to a cold temperature, produced all the phenomena of high altitude; and that when the animals were subsequently taken to a higher altitude the usual phenomena did not ensue.

That the blood counts made in winter are higher in red cells than those made in summer has been previously observed, and comparative tests by the writer confirm this fact. An important factor in altitude changes is a change in temperature, and since cold is capable of producing phenomena of the blood identical with those produced by high altitude, it would appear that cold is an important factor in accounting for the blood changes due to high altitude. That cold is the only factor the writer does not maintain.

HENRY B. WARD,
Secretary.

THE GLASGOW MEETING OF THE BRITISH
ASSOCIATION FOR THE ADVANCE-
MENT OF SCIENCE.

THE enterprise of the city of Glasgow in holding this year a large and successful industrial exposition attracted to that great commercial center a large number of congresses, and among others the British Association for the Advancement of Science, which held its sessions under the presi-

dency of Professor Arthur W. Rücker in the university building during the week beginning September 11. In attendance the meeting was not quite so successful as in previous years, the total number of members registered being 1,912. The following Americans had the honor of attending as guests of the Association: Chancellor MacCracken of the University of New York, Mr. Edward Atkinson of Boston, Professor Arthur Michael of Tufts College, Professor Edward W. Morley of Cleveland, Professor A. Lawrence Rotch of the Blue Hill Observatory and Professor J. Playfair McMurrich of the University of Michigan. The papers presented to the meeting reached the usual standard of excellence, and reports of the proceedings of the various sections will appear in later numbers of SCIENCE.

The usual public lectures were given by Professor W. Ramsay, on 'The Inert Constituents of the Atmosphere,' and by Mr. Francis Darwin on 'The Movements of Plants.' As is customary, numerous receptions were held in honor of the Association, and the majority of the members took advantage of the suspension of meetings of the sections, on the Saturday, to make excursions to various points of interest in the western Highlands or to visit some of the numerous great industrial enterprises which have made Glasgow famous.

THE GEOLOGICAL SECTION.

As might have been expected from the place of meeting of the Association, much of the material presented to the Geological Section dealt with the geology of Scotland. The president of the section, Mr. John Horne, acting director of the Geological Survey of Scotland, gave as his address a review of the progress in our knowledge of Scottish geology during the quarter-century which has elapsed since the last meeting of the Association in Glasgow, and furnished

such abundant evidence of the activity and skill of the Scotch geologists in recent years as to justify the hope which was expressed that their work might form a fitting sequel to the labors of such men as Hutton, Hall, Murchison, Lyell, Hugh Miller, Fleming, Nicol and Ramsay, all of whom claimed Scotland as the land of their birth. It would be difficult to satisfactorily abstract the address, since from the wealth of material with which it had to deal, it in itself was but an all too brief synopsis; but there may be mentioned, among the important additions to geology to which reference was made: the tabulation of the various divisions of the Torridonian sandstones by the Geological Survey and the determination of the pre-Cambrian age of that formation; the collection of evidence of post-Cambrian terrestrial movements in the northwest Highlands resulting in the production of reversed faults and thrusts for which a parallel can be found only in the Alps and Provence, the determination of the order of succession of the Silurian rocks of the south of Scotland by Professor Lapworth, the unraveling of the history of the secondary rocks by Professor Judd; and the study of the Tertiary volcanic rocks of the western coast.

In connection with this last-named topic attention was called to the recent discovery, in the island of Arran, of a volcanic vent covering an area of about eight square miles and now filled with volcanic agglomerate and large masses of sedimentary material which has yielded Rhætic and Lower Triassic fossils. And in a special paper Sir Archibald Geikie described an interesting circumstance which gave a basis for estimating the time intervals between successive lava flows in the inner Hebrides. This was the occurrence in the basalt of the west coast of Mull of a fossil tree whose roots were apparently imbedded in a lower sheet of lava, in which were signs of soil. The

tree, which was penetrated by calcite, extended to about five feet above this old soil, and above this was a hollow in the basalt about forty feet high, which evidently represented a cast of the tree. The conditions indicated an old lava flow which had later undergone a certain amount of disintegration and afforded a soil upon which the tree established itself; then a period succeeded during which the tree grew until it reached a diameter of eight feet and an estimated height of eighty feet; then an outflow of lava around the tree was followed by an interval during which the decay of the tree took place; and finally the outflow of the sheet of basalt, which covered and sealed up the top of the hollow left by the decay.

The geology of the nearly related north coast of Ireland also received its due share of attention, papers being presented by Messrs. McHenry and Kilroe, of the Geological Survey, on 'The Relations of the Old Red Sandstones of Northwest Ireland to the Adjacent Metamorphic Rocks and their Similarity to the Torridon Beds of Sutherland,' and on 'The Relation of the Silurian and Ordovician Rocks of Northwest Ireland to the Great Metamorphic Series.' This latter paper, which attempted to refer the metamorphic rocks of Mayo and Galway to the Lower Silurian period, awakened a considerable amount of discussion and some adverse criticism, since, if the views of the authors were correct, it became a difficult matter to explain the present difference between these rocks and the fossil-bearing Lower Silurian beds of adjoining areas. Papers were also read by Mr. G. H. Kinahan, entitled, 'Notes on the Irish Primary Rocks and their Associated Granite and Metamorphic Rocks,' and on 'Some Laccolites in the Irish Hills.'

Papers on the geology of foreign areas were comparatively few. Miss Raisin gave an account of a lithological study of volcanic

rocks collected on Perim Island and took occasion to refer to the geological history of the Red Sea area, inferring that this sea formed part of the Great Rift Valley, extending from Lake Tanganyika to the Jordan and displaying at many places volcanic outbursts on a large scale, at different periods. Dr. Logan Jack, formerly head of the Geological Survey of Queensland, gave an account of the 'Artesian Water in the State of Queensland.' The greater part of the western interior of Queensland is composed of soft beds of lower Cretaceous rocks so disposed as to crop out on the western flanks of the coast range where the elevation and rainfall are greater than in the downs of the west. Along the eastern margin of the Cretaceous outcrop is a porous sandstone whose outcrop forms a belt of from five to twenty-five miles in width, the strata dipping at a low angle beneath the clayey and calcareous beds which form the surface of the downs. The conditions accordingly seemed favorable for boring artesian wells, and a successful beginning of the development of a water supply of this nature was made under the supervision of Dr. Jack in 1885 and up to June, 1900, one hundred and eighty-five miles of boring had been made in the district, the majority of the borings being successful. Owing, however, to the fact that the artesian basins are imperfect, a considerable amount of leakage takes place from them, the water probably finding an outlet into the Great Australian Bight or the Gulf of Carpentaria.

In a paper on 'The Physical History of the Norwegian Fiords,' Professor Edward Hull described six important stages in the development of these characteristic features of the Norwegian coast. First there was the continental condition with archæan rocks; when the river erosion began, and this was succeeded by a second stage of partial submergence in early Silurian times. The third stage was the elevation of the land

during Mesozoic and Tertiary periods, accompanied by a deepening of the river channels; the fourth was the early glacial period, during which the elevation reached its greatest development. The fifth period was the post-glacial, characterized by subsidence and partial submergence of the land; and the sixth and recent stage was a stage of reëlevation to the present conditions, the process being accompanied by the formation of raised beaches.

On the mineralogical side papers were read on 'The Copper-bearing Rocks of South Australia,' by Mr. E. P. Manuell; on 'Scottish Ores of Copper in their Geological Relation,' by Mr. J. G. Goodchild; on 'The Occurrence of Barium Sulphate and Calcium Fluoride as Cementing Substances in the Elgin Trias,' by Dr. W. Mackie; and on 'The Source of the Alluvial Gold of the Kildonan Field, Sutherland,' by Mr. Malcolm Maclaren, who took occasion to advocate a return in certain cases to the old theory of the precipitation of gold from solution by carbonaceous matters, a theory which has been almost forgotten since Skey's demonstration of the power possessed by sulphides to produce complete precipitation.

Of paleontological papers there may be mentioned that by Professor Smith Woodward on 'The Bone Beds of Pikermi, Attica, and on Similar Deposits in Northern Eubœa,' giving an account of the excavations made by the trustees of the British Museum at the suggestion of Sir E. H. Egerton, British Minister at Athens. These researches have added but little to the list of forms already known to occur in the beds, though much important material was obtained, and excavations at Achmet Aga, northern Eubœa, revealed bone beds similar to those of Pikermi and containing similar fossils. The most plausible explanation of these bone deposits seems to be that the bodies of animals were carried by

torrential floods through tree-obstructed water courses to lakes in which they collected, the broken limbs and torn fragments of trunks affording evidence of the violence of the passage to the lakes. Mr. J. L. Beadnell of the Geological Survey of Egypt gave a preliminary notice of the discovery of a rich deposit of new Pliocene and post-Pliocene fossils in the Fayum depression, situated in the Libyan desert some fifty miles southwest of Cairo, and Mr. B. N. Peach presented a contribution to the Cambrian fossils of the northwest Highlands, in which he pointed out that the fossils in the Balnakiel group of the Durness dolomities present a remarkable American facies and suggested the existence in Cambrian times of a large continent extending from the north of Scotland to America, an idea which, as was pointed out by Professor Lapworth, was supported by the fact that the succession of beds in northern Scotland was paralleled only on the American continent.

Professor Sollas described a method by which serial sections, similar to those employed by zoologists, might be made of fossils, and exhibited a machine designed for the purpose by the Rev. G. Smith and also showed wax models reconstructed from serial sections of a Graptolite, of an Ophiuran and of *Palæospondylus*.

Finally reference may be made to a suggestive paper by Mr. J. R. Kilroe on 'Geology regarded in its Economic Application to Agriculture by means of Soil Maps,' in which he claimed that the geologist could furnish much information regarding the profitable localization of certain branches of agriculture, such as stock-breeding, dairying and tillage, and advocated the publication of maps which would give information as to the nature of the soil in different localities. The author believed that much of practical value could be done by the geologists even without an extensive

set of soil analyses, and described a scheme of coloration which might be employed to indicate different qualities of soil.

THE ZOOLOGICAL SECTION.

The address of the President of the zoological section, Professor J. Cossar Ewart, was entitled, 'The Experimental Study of Variation,' and was a consideration of the results of experimental breeding in their bearing on the causes of variation and on certain theories which have been more or less generally accepted. Especial interest was given to the address by the fact that the conclusions reached were based for the most part on the results of experiments conducted by the author at his Penycuik station, and the members of the association had the pleasure of studying for themselves three of the now celebrated zebra hybrids which Professor Ewart has bred.

In opening his address Professor Ewart assumed that the primary cause of variation is always the effect of external influences acting directly upon the germ-cells and proceeded to discuss certain influences which might be supposed to be active in the production of variability.

1. Age was found to have a decided effect upon the character of the offspring. A young blue-rock male pigeon was mated with a well-matured and vigorous black barb; the first pair of birds resulting from the mating were almost exactly like the female parent except that the beaks were rather longer; one of the second brood resembled the barb, while the other was of a grayish color with slightly mottled wings and a tail bar; in the third brood both birds were of a grayish color with indistinct wing bars as well as a tail bar; while in the fourth brood one bird resembled the birds of the third brood, while the other resembled closely its blue rock sire. Similar results were obtained by mating a young blue rock male with a white fantail, and

also by pairing young gray quarter-wild rabbits with an old white Angora buck, and Professor Ewart regards the gradual, 'almost mathematical' change in the coloration of the offspring as due to the gradual increase of vigor or prepotency of the young sires. The phenomena might possibly be explained by the doctrine of 'saturation' popular among breeders, but such an explanation is overthrown by the occurrence of the same results in the crossing of young females with old males.

2. Ripeness of the germ-cells. In studying the effect of this condition the Penycuik experiments confirmed the results obtained by Mr. H. M. Vernon from the hybridization of Echinoderm ova, 'the offspring resulting from the union of equally ripe germ-cells differing from the offspring developed from the conjugation of ripe and unripe germ-cells, and still more from the union of fresh and over-ripe germ-cells.'

3. The condition of the soma. Undoubtedly the germ-cells may be influenced by a diminution of the vitality of the soma, but there is no evidence to show that they are modified in such a way as to transmit definite modifications in the offspring.

4. Change of habitat. This factor acts by influencing the vigor of the soma, but 'there is no evidence whatever that definite changes of the soma, due to the direct action of the environment, can be imprinted on the germ-cells.'

5. Intercrossing and interbreeding. Intercrossing in general tends towards reversion and never results in the production of characters absolutely new to the species. It may, however, indirectly tend towards progressive variation by imparting additional vigor to the offspring, which when intercrossed frequently give rise to 'an almost infinite diversity of character.' Interbreeding, on the other hand, may be a cause of progressive variation. Vigor, however, plays a very important part in the de-

termination of the characters of the offspring and if interbreeding be performed with animals lacking in vigor or with too closely related individuals, it leads to what may be termed degeneration, the offspring being frequently delicate, of impaired fertility and, what is remarkable, frequently either entirely or nearly white.

In connection with the question of intercrossing Professor Ewart considered the swamping effect upon new varieties, pointing out how important the decision of this point is upon the validity of the doctrine of natural selection. Darwin himself nowhere suggests how new varieties escape swamping, although Wagner by his theory of isolation, and Romanes by that of physiological selection, have indicated special methods by which it may be avoided. It seems certain, however, that new varieties make their appearance even in the absence of such barriers to intercrossing, and Professor Ewart points out that it does not seem to have occurred to biologists that a new variety may be sufficiently vigorous or prepotent to swamp the old, since it is unquestionable that the vigor of the parents has much to do with the character of the offspring. Professor Ewart possesses a skewbald Iceland pony which produces richly striped hybrids to a zebra, but to whole-colored bay, Arab, or Shetland ponies invariably gives offspring colored exactly like herself. So too, black Galloway bulls frequently produce, through long-horned, brightly colored Highland heifers, offspring which would readily pass for pure Galloways, and it is known that the wolf is prepotent over the dog and the wild rabbit, rat and mouse over their tame relatives. Granting, therefore, a variety more vigorous than the ancestral form, intercrossing, instead of swamping it, would only increase the number of individuals representing it, even without any such barriers as are demanded by the theories of Wagner and Romanes.

6. Maternal impressions. There is no evidence to show that such impressions affect in any way the offspring.

7. Needs of the organism.

8. Direct action of the environment and use-inheritance. Neither of these causes is believed by Professor Ewart to have any action in the production of definite variations.

9. Telegony or infection. Referring to the celebrated case of supposed telegony described by Lord Morton, the author produced evidence showing that the observed case was more probably due to reversion than to infection, and furthermore he added to his original observations on the subject by stating that since 1895 twelve mares, after producing sixteen zebra hybrids, have given birth to twenty-two pure-bred foals, in none of which is there any indication of the action of telegony. It was also pointed out that the observations of Baron de Parana in Brazil upon the pure-bred offspring of mares previously mated with zebras, as well as his results obtained from several mule-breeding establishments which are in reality carrying on telegony experiments on a large scale, were entirely negative.

The address concluded with a brief appeal for the establishment of a well-equipped institute for biological experimentation on a large scale.

The address of the President was followed by the report of the special committees appointed at the last meeting of the Association. That on bird migration in Great Britain dealt with the migration of larks and swallows, while progress was reported by the committee on the Index Animalium, the Natural History and Ethnography of the Malay Peninsula, the coral reefs of the Indian regions and the Zoology of the Sandwich Islands.

Of the special papers presented it must suffice to mention but a few. Mr. J. Stan-

ley Gardiner gave an account, illustrated by excellent lantern slides, of his observations upon the coral islands of the Maldives, the evidence obtained seeming to indicate that they had been formed during a period of elevation. Dr. J. Y. Simpson gave the results of his observations on the occurrence of variation in binary fission. It has been generally accepted that this method of reproduction is merely a duplication and that variation does not occur in connection with it, but only as the result of a commingling of the chromatin of two individuals in conjugation. Testing this generalization by observation of successive generations of *Paramœcium* and *Stylonychia*, it was found that variation may accompany fission, modifications occurring in the general outline of the body, in its total length, in its greatest breadth, in the distance between the contractile vacuoles of *Paramœcium* and in the length of the median caudal bristle of *Stylonychia*. From the fact that such variations do occur and may be transmitted to the succeeding generation, it would seem that fission is the primary method of reproduction among the Ciliate Infusoria, and that conjugation is merely a method of compensating for the waste involved in that process.

The President of the Section gave some observations, additional to those contained in his address and illustrated by lantern slides, on zebras and zebra-hybrids. He pointed out that the stripes of the zebra were undoubtedly protective, causing the animal to become indistinguishable at a comparatively short distance, and he was able to render a dun-colored pony similarly indistinguishable by tying ribbons upon it so as to break up the uniform coloration. The lion is the most inveterate enemy of the zebra, which is protected by its coloration as well as by the rapidity of its movements, for there is no animal which the author knew which could turn about and break

into a trot so quickly as the zebra. As to the original nature of the coloration of the zebra, it was pointed out that although the forms such as the Chapman zebra, which were less striped, might be supposed to be most primitive, yet it was an interesting fact that zebra-donkey hybrids were more richly striped than pure-bred zebras.

Professor W. E. Hoyle described an interesting sub-pallial luminous organ in certain forms of Cephalopods, and Mr. J. Graham Kerr read a suggestive paper on the 'Origin of the Limbs of Vertebrates,' in which, after pointing out the unsatisfactory nature of the theories at present existent, he suggested the possibility of the limbs being derived for external branchiæ, such as are found in *Polypterus* and in certain Urodele amphibians. It may be stated, however, that from the discussion which followed, the new suggestion did not seem to be received with any great amount of favor. Major Ronald Ross gave an account of the experiments on the destruction of the mosquito now being carried on in Sierra Leone by the Liverpool School of Tropical Medicine, and stated that although the experiments had been in progress now for only two or three months, yet there was already an appreciable diminution in the numbers of the insects, and maintained that it is possible that even on the west coast of Africa, malaria may become a thing of the past.

Other papers presented to the Section were 'The Pelvic Cavity of the Porpoise as a Guide to the Determination of the Sacral Region in the Cetacea,' by Drs. Hepburn and Watson; 'The Relationship of the Premaxilla in Bears,' by Professor R. J. Anderson; 'A Method of Recording Local Faunas,' by Mr. E. J. Bles; 'The Fishes of the Coats Arctic Expedition,' and 'A Preliminary Notice of the Fauna of Franz Joseph Land,' by Mr. W. S. Bruce; 'The Behavior of Artifi-

cially Hatched Gulls,' and 'On Germinal Selection in Relation to Inheritance,' by Professor J. Arthur Thompson; 'The Tanganyika Problem,' by Mr. J. E. S. Moore; 'The Mechanism of the Frog's Tongue,' by Professor Marcus Hartog and Mr. Nevil Maskeleyne; 'Dimorphism in the Foraminifera,' by Mr. J. J. Lister; 'The Habits and Life Histories of some Sarawak Insects,' by Mr. R. Shelford; 'On a Large Nematode Parasite in the Sea-urchin,' by Dr. J. F. Gemmill; 'On the Youngest Known Larva of Polypterus,' by Mr. J. S. Budgett; on 'The Land Crabs of a Coral Island,' by Mr. L. A. Borradaile; and on 'The Fauna of an Atoll,' by Mr. C. F. Cooper.

A very pleasing incident of the meeting was the announcement of a generous gift, amounting to £3,500, from a donor who wished to remain anonymous, towards the equipment of the Scottish Marine Biological Station, now established at Millport on Cumbrae Island in the Firth of Clyde. The station, which was visited by a large number of the members of the Section, is admirably situated and is accomplishing most excellent work. The present gift will be devoted to an extension of the buildings so as to afford quarters for those who may be working at the station.

J. PLAYFAIR McMURRICH.

UNIVERSITY OF MICHIGAN.

ADDRESS OF THE PRESIDENT OF THE ANTHROPOLOGICAL SECTION OF THE BRITISH ASSOCIATION, II.

THE insular district in the fetal brain is a depressed area of an elongated triangular form. The general surface of the cerebrum occupies, all round about it, a more elevated plane, and thus the insula comes to be bounded by distinct walls, like the sides of a shallow pit dug out in the ground. The upper wall is formed by the lower margins of the frontal and parietal lobes, the lower wall by the upper margin of the

temporal lobe, and the front wall by the frontal lobe. From each of these bounding walls a separate portion of cerebral cortex grows, and these gradually creep over the surface of the insula so as to overlap it, and eventually completely cover it over and exclude it from the surface, in the same way that the lips overlap the teeth and gums. That which grows from above is called the *fronto-parietal operculum*, while that which grows from below is termed the *temporal operculum*. These appear very early, and are responsible for closing over more than the hinder three-fourths of the insula. The lower or temporal operculum is in the first instance more rapid in its growth than the upper or fronto-parietal operculum, and thus it comes about that when their margins meet more of the insula is covered by the former than by the latter. So far the development is apparently precisely similar to what occurs in the ape. The slit or fissure formed by the approximation of the margins of these two opercula is called the Sylvian fissure, and it constitutes a natural lower boundary for the parietal and frontal lobes which lie above it. At first, from the more energetic growth of the lower temporal operculum, this fissure slants very obliquely upward and backward, and is very similar in direction to the corresponding fissure in the brain of the ape. But in the human brain this condition is only temporary. Now begins that downward movement of the parietal lobe and back part of the frontal lobe to which reference has been made. The upper or fronto-parietal operculum, in the later stages of fetal life and the earlier months of infancy, enters into a growth antagonism with the lower or temporal operculum, and in this it proves the victor. The margins of the two opercula are tightly pressed together, and, slowly but surely, the fronto-parietal operculum gains ground, pressing down the temporal operculum, and thus extending

the territory of the frontal and parietal districts. This is a striking process in the brain development of man, and it results in a depression of the Sylvian fissure or the lower frontier line of the frontal and parietal lobes. Further, to judge from the oblique direction of the Sylvian fissure in the brain of the ape, the process is peculiar to man; in the simian brain there is no corresponding increase in the area of cerebral cortex under consideration.

I do not think that it is difficult to account for this important expansion of the cerebral surface. In the fore part of the region involved are placed the groups of motor centers which control the muscular movements of the more important parts of the body. These occupy a broad strip of the surface which stretches across the whole depth of the district concerned. Within this are the centers for the arm and hand, for the face, the mouth and the throat, and likewise, to some extent, the center for speech. In man certain of these have undoubtedly undergone marked expansion. The skilled movements of the hands, as shown in the use of tools, in writing, and so on, have not been acquired without an increase in the brain mechanism by which these are guided. So important, indeed, is the part played by the human hand as an agent of the mind, and so perfectly is it adjusted with reference to this office, that there are many who think that the first great start which man obtained on the path which has led to his higher development was given by the setting of the upper limb free from the duty of acting as an organ of support and locomotion. It is an old saying 'that man is the wisest of animals because of his hands.' Without endorsing to its full extent this view, I think that it cannot be a matter for surprise that the district of the cerebral cortex in man in which the arm-centers reside shows a manifest increase in its extent.

In the same region of cerebral cortex, but at a lower level, there are also situated the centers which are responsible for facial expression. In the ape there is a considerable degree of facial play; but this is chiefly confined to the region of the lips, and the muscles of the face, although present in greater mass, show comparatively little of the differentiation which is characteristic of the lighter and more feeble muscles in the face of man. And then as to the effect produced: These human muscles are capable of reflecting every fleeting emotion, every change of mind, and, by the lines and furrows their constant use indelibly fixes on the countenance, the character and disposition of an individual can to some extent be read. As the power of communication between primitive men became gradually established, facial movements were no doubt largely used, not only for the purpose of giving expression to simple emotions, such as anger or joy, but also for giving point and force to the faltering speech of our early progenitors by reflecting other conditions of mind. The acquisition of this power as well as the higher and more varied powers of vocalization must necessarily have been accompanied by an increase of cerebral cortex in the region under consideration. And in this connection it is a point well worthy of note that the area of cortex mapped out in the human brain,* as controlling the muscles of the face, mouth and throat, is as large if not larger than that allotted to the arm and hand,† and yet it is questionable if all the

* See diagram in Schäfer's article on the 'Cerebral Cortex' in his recent work on physiology.

† The comparison only refers to surface area, and this is not an absolutely true criterion of the relative amount of cortex in each region. The arm-center has a large amount of cortex stowed away within the fissure of Rolando, in the shape of interlocking gyri, which is not taken into account in a measurement confined to the superficial surface area. Still, this does not to any great degree detract from the argument which follows, seeing that the discrepancy is still sufficiently marked.

muscles under the sway of the former would weigh as much as one of the larger muscles (say the triceps) of the arm. This is sufficient to show that it is not muscle power which determines the extent of the motor areas in the cerebral cortex. It is the degree of refinement in the movements required, as well as the degree of variety in muscle combinations, which apparently determines the amount of ground covered by a motor center.

Still, the increase in the amount of cerebral cortex in man due to the greater refinement of movement acquired by different groups of muscles is relatively small in comparison with the increase which has occurred in other regions from which no motor fibers are sent out, and which therefore have no direct connection with muscles.

The remarkable conclusions arrived at by Flechsig, although not confirmed and accepted in all their details, have tended greatly to clear up much that was obscure in the relations of the different districts of cerebral cortex. More particularly has he been able to apportion out more accurately the different values to be attached to the several areas of the cerebral surface. He has shown that fully two thirds of the cortex in the human brain constitutes what he terms 'association centers.' Within these the higher intellectual manifestations of the brain have their origin, and judgment and memory have their seat. They are therefore to be regarded as the psychic centers of the cerebral cortex.

Now, it requires a very slight acquaintance with the cerebral surface to perceive that the great and leading peculiarity of the human brain is the wide extent of these higher association centers of Flechsig. Except in connection with new faculties, such as speech, there has been relatively no striking increase in the extent of the motor areas in man as compared with the cortex of the ape or the idiot, but the expansion of

the association areas is enormous, and the increase in the frontal region and the back part of the parietal region is particularly well marked. It is this parietal extension of surface which is chiefly responsible for the pushing down of the lower frontier of the parietal lobe and the consequent enlargement of its territory.

I have already referred to the views which have been recently urged by several independent observers, that in the men who have been distinguished during life by the possession of exceptional intellectual power this region has shown a very special development.

It is a curious circumstance, and one which is worthy of consideration, that in the left cerebral hemisphere the Sylvian fissure or the lower boundary of the parietal lobe is more depressed than in the right hemisphere, and, as a result of this, the surface area occupied by the parietal lobe is greater on the left side of the brain than on the right side. To the physiologist it is a matter of every-day knowledge that the left cerebral hemisphere shows in certain directions a marked functional preeminence. Through it the movements of the right arm and right side of the body are controlled and regulated. Within it is situated also the active speech center. This does not imply that there is no speech center on the right side, but simply that the left cerebral hemisphere has usurped the chief, if not the entire, control of this all-important function, and that from it are sent out the chief part, if not the whole, of the motor incitations which give rise to speech. The significance attached to the dominant power of the left hemisphere receives force from the now well-established fact that in left-handed individuals the speech function is also transferred over to the right side of the brain. To account for this functional preeminence of the left cerebral hemisphere numerous theories have been elaborated. The inter-

est attached to the subject is very considerable, but it is impossible on the present occasion to do more than indicate in the briefest manner the three views which have apparently had the widest influence in shaping opinion on this question. They are: (1) That the superiority of the left cerebral hemisphere is due to its greater weight and bulk; (2) that it may be accounted for by the greater complexity of the convolutions on the left brain and the fact that these make their appearance earlier on the left side than on the right side; (3) that the explanation lies in the fact that the left side of the brain enjoys greater advantages in regard to its blood supply than the right side.

Not one of these theories when closely looked into is found to possess the smallest degree of value. Braune* has shown in the most conclusive manner that if there is any difference in weight between the two hemispheres it is a difference in favor of the right and not of the left hemisphere; and I may add from my own observations that this is evident at all periods of growth and development. Equally untrustworthy are the views that have been put forward as to the superiority of the left hemisphere from the point of view of convoluntary development. I am aware that it is stated that in two or three cases where the brains of left-handed people have been examined this superiority was evident on the right hemisphere. This may have been so; I can only speak for the large percentage of those who are right-handed; and I have never been able to satisfy myself that either in the growing or fully developed brain is there any constant or marked superiority in this respect of the one side over the other; and I can corroborate Ecker† in his statement that there is no proof that the

convolutions appear earlier on the one side than on the other. The theory that an explanation is to be found in a more generous blood supply to the left hemisphere is more difficult to combat, because the amount of blood received by each side of the brain depends upon two factors, viz., the physical conditions under which the blood-stream is delivered to the two hemispheres and the caliber of the arteries or tubes of supply. Both of these conditions have been stated to be favorable to the left hemisphere. It is a matter of common anatomical knowledge that the supply pipes to the two sides of the brain are laid down somewhat differently, and that the angles of junction, etc., with the main pipe are not quite the same. Further, it is true that the blood-drains which lead away the blood from the brain are somewhat different on the two sides. Whether this would entail any marked difference in the blood-pressure on the two sides I am not prepared to say. This could only be proved experimentally; but, taking all the conditions into consideration, I am not inclined to attach much importance to the argument. It is easy to deal with the loose statements which have been made in regard to the size of leading supply pipe (viz., the internal carotid artery). It passes through a bony canal on the floor of the cranium on its way into the interior of the cranial box. Its size can therefore be accurately gauged by measuring the sectional area of this bony tunnel on each side. This I have done in twenty-three skulls chosen at random, and the result shows that considerable differences in this respect are to be found in different skulls. These discrepancies, however, are sometimes in favor of the one side and at other times in favor of the other side, and when the combined sectional area for all the skulls examined was calculated, it was, curiously enough, found to be $583\frac{1}{2}$ sq. mm. for the left side and 583 sq. mm. for the right side.

* 'Das Gewichtsverhältniss der rechten zur linken Hirnhälfte beim Menschen,' *Archiv für Anat.*

† *Archiv für Anthropologie*, 1868, Bd. CXI.

Leaving out of count the asymmetry in the arrangement of the convolutions in the two hemispheres, which cannot by any amount of ingenuity be twisted into such a form as to give a structural superiority to one side more than the other, the only marked difference which appears to possess any degree of constancy is the increase in the territory of the left parietal lobe produced by the more marked depression of its lower frontier line (Sylvian fissure). That this is in any way associated with right-handedness or with the localization of the active speech center in the left hemisphere I am not prepared to urge, because the same condition is present in the ape. It is true that some authorities* hold that the ape is right-handed as well as man, but in the gardens of the Royal Zoological Society of Ireland I have had a long and intimate experience of both anthropoid and lower apes, and I have never been able to satisfy myself that they show any decided preference for the use of one arm more than the other.

That differences do exist in the more intimate structural details of the two hemispheres, which give to the left its functional superiority, there cannot be a doubt; but these have still to be discovered. Bastian has stated that the gray cortex on the left side has a higher specific gravity, but this statement has not as yet received corroboration at the hands of other observers.

I have already mentioned that man's special endowment, the faculty of speech, is associated with striking changes in that part of the cerebral surface in which the motor center for articulate speech is located. It is questionable whether the acquisition of any other system of associated muscular movements has been accompanied by a more evident cortical change. The center in question is placed in the lower

and back part of the frontal lobe. We have seen that the insular district is covered over in the hinder three-fourths of its extent by the fronto-parietal and temporal opercula, and thus submerged below the surface and hidden from view. The brain of the ape and also of the microcephalic idiot with defective speech goes no further in its development. The front part of the insular district remains uncovered and exposed to view on the surface of the cerebrum. In man, however, two additional opercula grow out and ultimately cover over the fore part of the insula. These opercula belong to the lower and back part of the frontal lobe, and are to be looked upon as being more or less directly called into evidence in connection with the acquisition of articulate speech.

The active speech center is placed in the left cerebral hemisphere. We speak from the left side of the brain, and yet when the corresponding region* on the right side is examined it is found to go through the same developmental steps.

The stimulus which must have been given to general cerebral growth in the association areas by the gradual acquisition of speech can hardly be exaggerated.

During the whole course of his evolution there is no possession which man has contrived to acquire which has exercised a stronger influence on his higher development than the power of articulate speech. This priceless gift, 'the most human manifestation of humanity' (Huxley), was not obtained through the exertions of any one individual or group of individuals. It is the result of a slow process of natural growth, and there is no race, no matter how

* Rudinger and others have tried on very unsubstantial grounds to prove that there is a difference in this region on the two sides of the brain. There is, of course, as a rule, marked asymmetry; but I do not think that it can be said with truth that the cortical development of the region is greater on the left side than on the right.

* Ogle, 'On Dextral Preeminence,' *Trans. Med. Chirurg. Soc.*, 1871; Aimé Pèrè, 'Les Courbures latérales normales au rachis humain,' Toulouse, 1900.

low, savage or uncultured, which does not possess the power of communicating its ideas by means of speech. "If in the present state of the world," says Charma, "some philosopher were to wonder how man ever began to build those houses, palaces, and vessels which we see around us, we should answer that these were not the things that man began with. The savage who first tied the branches of shrubs to make himself a shelter was not an architect, and he who first floated on the trunk of a tree was not the creator of navigation." And so it is with speech. Rude and imperfect in its beginnings, it has gradually been elaborated by the successive generations that have practiced it.

The manner in which the faculty of speech originally assumed shape in the early progenitors of man has been much discussed by philologists and psychologists, and there is little agreement on the subject. It is obvious that all the more intelligent animals share with man the power of giving expression to certain of the simpler conditions of mind both by vocal sounds and by bodily gestures. These vocal sounds are of the interjectional order, and are expressive of emotions or sensations. Thus the dog is said, as a result of its domestication, to have acquired the power of emitting four or five different tones, each indicative of a special mental condition and each fully understood by its companions. The common barn-door fowl has also been credited with from nine to twelve distinct vocal sounds, each of which is capable of a special interpretation by its fellows or its chickens. The gestures employed by the lower animals may in certain cases be facial, as expressed by the grimaces of a monkey, or changes in bodily attitude, as we see continually in the dog.

I think that it may not be unreasonably inferred that in the distant past the remote progenitors of man relied upon equally

lowly means of communicating with their fellows, and that it was from such humble beginnings that speech has been slowly evolved.

There cannot be a doubt that this method of communicating by vocal sounds, facial expressions and bodily gestures is capable of much elaboration; and, further, it is possible, as some hold, that it may have attained a considerable degree of perfection before articulate speech began to take form and gradually replace it. Much of it indeed remains with us to the present day. A shrug of the shoulders may be more eloquent than the most carefully prepared phrase; an appropriate expression of face, accompanied by a suitable ejaculation, may be more withering than a flood of invective. Captain Burton tells us of a tribe of North American Indians whose vocabulary is so scanty that they can hardly carry on a conversation in the dark. This and other facts have led Mr. Tylor, to whom we owe so much in connection with the early history of man, to remark: "The array of evidence in favor of the existence of tribes whose language is incomplete without the help of gesture-signs, even for things of ordinary import, is very remarkable"; and, further, "that this constitutes a telling argument in favor of the theory that gesture-language is the original utterance of mankind out of which speech has developed itself more or less fully among different tribes." It is a significant fact also, as the same author points out, that gesture-language is, to a large extent, the same all the world over.

Many of the words employed in early speech were undoubtedly formed, in the first instance, through the tendency of man to imitate the natural sounds he heard around him. To these sounds, with various modifications, was assigned a special conventional value, and they were then added to the growing vocabulary. By this means a very decided forward step was taken, and

now primitive man became capable of giving utterance to his perceptions by imitative sounds.

Max Müller, although bitterly opposed to the line of thought adopted by the 'Imitative School' of philologists, has expressed their views so well that I am tempted to use the words he employed in explaining what he satirically branded as the 'Bow-wow Theory.' He says: "It is supposed that man, being yet mute, heard the voices of the birds, dogs and cows, the roaring of the sea, the rustling of the forest, the murmur of the brook and the whisper of the breeze. He tried to imitate these sounds, and finding his mimicking cries useful as signs of the object from which they proceeded, he followed up the idea and elaborated language."

Hood* humorously and unconsciously illustrates this doctrine by a verse descriptive of an Englishman, ignorant of French, endeavoring to obtain a meal in France:

'Moo!' I cried for milk;
If I wanted bread
My jaws I set agoing;
And asked for new-laid eggs
By clapping hands and crowing.

But, although much of early articulate speech may have arisen by the development of interjectional sounds and the reproduction, by the human vocal organs, of natural sounds, it is very unlikely that these afforded the only sources from which words were originally derived. Romanes insists upon this, and, in support of his argument, refers to cases where children invent a language in which apparently imitative sounds take no part. He likewise alludes to the well-known fact that deaf mutes occasionally devise definite sounds which stand for the names of friends. In the light of such evidence, he very properly asks, 'Why should it be held impossible for primitive man to have done the same?'

* Quoted from 'The Origin of Language,' by Hensleigh Wedgwood, 1866.

The value of spoken language as an instrument of thought is universally admitted, and it is a matter incapable of contradiction that the higher intellectual efforts of man would be absolutely impossible were it not for the support which is afforded by articulate speech. Darwin expresses this well when he says: "A complex train of thought can no more be carried on without the aid of words, whether spoken or silent, than a long calculation without the use of figures or symbols." Such being the case, I think that we may conclude that the acquisition of speech has been a dominant factor in determining the high development of the human brain. Speech and mental activity go hand in hand. The one has reacted on the other. The mental effort required for the coining of a new word has been immediately followed by an increased possibility of further intellectual achievement through the additional range given to the mental powers by the enlarged vocabulary. The two processes, mutually supporting each other and leading to progress in the two directions, have unquestionably yielded the chief stimulus to brain development.

More than one philologist has insisted that 'language begins where interjection ends.' For my part, I would say that the first word uttered expressive of an external object marked a new era in the history of our early progenitors. At this point the simian or brute-like stage in their developmental career came to an end and the human dynasty endowed with all its intellectual possibilities began. This is no new thought. Romanes clearly states that in the absence of articulation he considers it improbable that man would have made much psychological advance upon the anthropoid ape, and in another place he remarks that 'a manlike creature became human by the power of speech.'

The period in the evolution of man at which this important step was taken is a

vexed question, and one in the solution of which we have little solid ground to go upon beyond the material changes produced in the brain and the consideration of the time that these might reasonably be supposed to take in their development.

Darwin was inclined to believe that articulate speech came at an early period in the history of the stem-form of man. Romanes gives a realistic picture of an individual decidedly superior to the anthropoid ape, but distinctly below the existing savages. This hypothetical form, half simian, half human, was, according to his sponsor, probably erect; he had arrived at the power of shaping flints as tools, and was a great adept at communicating with his fellows by gesture, vocal tones and facial grimaces.

With this accomplished ancestor in his mental eye, it is not surprising that Romanes was inclined to consider that articulate speech may have come at a later period than is generally supposed.

At the time that Romanes gave expression to these views he was not acquainted with the very marked structural peculiarities which distinguish the human brain in the region of the speech center. I do not refer to the development of the brain in other districts, because possibly Romanes might have held that the numerous accomplishments of his speechless ancestor might be sufficient to account for this; I merely allude to changes which may reasonably be held to have taken place in direct connection with the gradual acquisition of speech.

These structural characters constitute one of the leading peculiarities of the human cerebral cortex, and are totally absent in the brain of the anthropoid ape and of the speechless microcephalic idiot.

Further, it is significant that in certain anthropoid brains a slight advance in the same direction may occasionally be faintly

traced, whilst in certain human brains a distinct backward step is sometimes noticeable. The path which has led to this special development is thus in some measure delineated.

It is certain that these structural additions to the human brain are no recent acquisition by the stem-form of man, but are the result of a slow evolutionary growth—a growth which has been stimulated by the laborious efforts of countless generations to arrive at the perfect coordination of all the muscular factors which are called into play in the production of articulate speech.

Assuming that the acquisition of speech has afforded the chief stimulus to the general development of the brain, and thereby giving it a rank high above any other factor which has operated in the evolution of man, it would be wrong to lose sight of the fact that the first step in this upward movement must have been taken by the brain itself. Some cerebral variation—probably trifling and insignificant at the start, and yet pregnant with the most far-reaching possibilities—has in the stem-form of man contributed that condition which has rendered speech possible. This variation, strengthened and fostered by natural selection, has in the end led to the great double result of a large brain with wide and extensive association areas and articulate speech, the two results being brought about by the mutual reaction of the one process upon the other.

D. J. CUNNINGHAM.

*PROFESSOR PAWLOW'S RESEARCHES ON
THE PHYSIOLOGY OF SECRETION.*

THE publication, last year, of the conditions which are to govern the award of the Nobel prizes was followed not long since by the announcement that Professor J. P. Pawlow of St. Petersburg had been designated, with Professor Niels R. Finsen of Copenhagen, as the first recipient of this honor, for the most important discovery in

the department of physiology or of medicine. To those readers of SCIENCE who are not familiar with the details of modern physiological investigation, a brief review of the more important work of this brilliant Russian investigator may be of interest.

Professor Pawlow's researches have, for the most part, been directed to the solution of problems connected with the physiology of secretion. His persistent efforts in this field have been crowned with success to an unusual degree; and physiology owes to him and his coworkers much of the progress which has been made in recent years towards a clearer understanding of the processes of digestion in the animal organism. New experimental methods have been devised, and older ones applied to new purposes.

With reference to the nitrogenous metabolism of the salivary glands, Pawlow showed (1888) by direct chemical analysis, that anabolic and katabolic processes are coincident in the secreting organ. This observation, usually overlooked by physiologists, was in itself an important contribution to the theory of secretion. The extensive series of experiments on the innervation of the gastric and pancreatic glands—researches which have had their origin in Pawlow's laboratory—have evoked the widest attention. In this study of gastric secretion the improvements in the general technique consisted primarily in the simultaneous introduction of an ordinary gastric fistula (in dogs) and a division of the œsophagus in the middle of the neck. The cut ends were attached to openings in the neck so that swallowed food passed out at one opening without reaching the stomach; and, through the other, food which it was desired should enter the stomach could be passed in. The more important facts ascertained by the use of this method were, that when food is eaten a flow of gastric juice is started; inasmuch

as under the experimental conditions referred to the ingested material fails to reach the stomach, the reflex character of the impulses which provoke the secretion can thus be demonstrated. The paths along which the reflex stimulation reaches the gastric glands were shown to be the vagus nerves; for while section of the splanchnics does not interfere with the reflex secretion, this reaction entirely disappears after division of the vagi. To make the proof complete, Pawlow showed that artificial stimulation of the peripheral end of a cut vagus will incite a flow of active gastric juice.

The possibility of obtaining pure gastric juice uncontaminated with the products of digestion was thus accomplished in a way never before equaled. It remained, however, to observe the production of the secretion and its properties during the course of actual digestion. Heidenhain had already developed a method of isolating one portion of the stomach from the rest, so that it was possible to keep animals in this condition under observation for a long period. In his operations, however, the nerve supply to the isolated portion was undoubtedly seriously interfered with. Pawlow improved the method, so that there remained an undisturbed nerve distribution, the functional importance of which he clearly showed. Secretion in the isolated portion could thus be followed while digestion was proceeding in the adjoining parts of the stomach.

Along similar lines our knowledge of the work of the pancreas and the production of the bile has been largely added to by Pawlow and his pupils. The introduction of a successful method for obtaining permanent fistulas has been followed by a study of the secretory activity of the pancreatic gland. The reflex character of the ordinary stimuli has been demonstrated, and the paths through which the impulses reach the gland ascertained. The existence of inhibitory

nerves for the secretory glands has been made more probable by Pawlow. The true significance of this discovery lies in the fact that it has enabled us to appreciate more clearly the mechanism by which the secretory glands, like other organs, adapt themselves so perfectly to the work which they have to accomplish at different times.

With pure digestive juices made thus readily available, it is not surprising to find interest in the study of their composition renewed. The way has been opened for more purely chemical investigations, such as the recent one of Professor v. Nencki—a colleague of Professor Pawlow—on the character of the enzymes of the gastric juice. From the general biological point of view, one of the most interesting aspects of the work of the St. Petersburg school is the demonstration of the purposeful character of secretion into the alimentary canal. Quantitatively and qualitatively the work of the glands varies with the character of the substances upon which they exert their action at different times. Changes in diet bring variations in the character of secretion. Pawlow has broadly expressed this view in summarizing his contributions to our knowledge of the specific excitability of the digestive glands. He writes: "Our results have, we trust, dispelled from our domain, once for all, the unfruitful idea that the alimentary canal is excitable by any agent whatsoever, mechanical, chemical or thermal, without regard to the peculiarity of each specific digestive task. At present, agencies such as these, vigorously applied, must be regarded merely as favoring or inhibitory influences, not as the normal and determining factors which excite secretory activity. In place of gross uncertainty (*Scheinwissen*) we now see the outlines of an artistic mechanism which, like everything that we understand in nature, exhibits an unusual degree of exactness and utility in her processes."

It remains to speak of Pawlow's work (in cooperation with v. Nencki and others) on the functions of the liver. Here again a brilliant operative technique—the Eck fistula, by which the portal blood is diverted directly into the vena cava without entering the hepatic capillaries—has inaugurated progress. The splendid researches on the seat of urea formation in mammals have modified and shaped the current teaching of this subject and other aspects of intermediary metabolism. What light they may throw upon the pathogeny of certain abnormal states, such as uræmia and diabetes, can scarcely be foretold.

Among the comparatively recent contributions to physiological literature no book has exerted a more stimulating influence than Pawlow's '*Die Arbeit der Verdauungsdrüsen*' (J. F. Bergmann, Wiesbaden, 1898). It summarizes in suggestive chapters the main achievements of the author in his chosen field of work. Its original treatment of the problems in this domain has aroused the interest of both physiologists and physicians; and the work has already served in fulfilment of the author's hope, to further physiological science by promoting a more active interchange of ideas between the practitioner and the laboratory worker. Pawlow's work has demonstrated what Sir Michael Foster has written in another connection: that "the heart of physiology is in the laboratory. It is this which sends the life-blood through its frame; and in respect to this, perhaps, more than anything else, has the progress of the past years been striking."

LAFAYETTE B. MENDEL.

SHEFFIELD SCIENTIFIC SCHOOL
OF YALE UNIVERSITY.

SCIENTIFIC BOOKS.

Report of the Sanitary Investigations of the Illinois River and its Tributaries. The Illinois State Board of Health, 1901.

The self-purification of streams has been for many years a perennial subject of discussion among sanitarians. Early faith in the power of running water to purify itself was severely shaken by the advent of the science of bacteriology, and the postulate that 'no river was long enough to purify itself' was accepted by many as representing the ultimate conclusion of science upon the subject. Recently data have been accumulating in the opposite direction and apparently indicate that under certain conditions streams do tend to become purer as they flow. A notable instance of this may be found in a report just issued by the Illinois State Board of Health on the Sanitary Investigations of the Illinois River and its Tributaries, with special reference to the effect of the sewage of Chicago on the Des Plaines and Illinois rivers prior to and after the opening of the Chicago drainage canal.

Advance notes upon the same subject, issued in 1900, gave the results of chemical and bacteriological examinations of samples of water at various points on these streams between Chicago and the Mississippi made during the summer and autumn of 1899, before the opening of the drainage canal. The present report gives, in addition to the figures then obtained, the results of further examinations made in 1900 with the drainage canal in use. The work was conducted by the State Board of Health, under the direction of Dr. John H. Long, professor of chemistry, Northwestern University Medical School, and Mr. Jacob A. Harman, civil engineer, of Peoria. Dr. Long was assisted in the qualitative bacteriological work by Professors F. Robert Zeit and Gustav Fütterer, of the Northwestern University Medical School. The reports of these gentlemen are prefaced by an introductory chapter of thirty-four pages by Dr. James A. Egan, secretary of the Illinois State Board of Health, upon the 'Pollution of the Illinois River as affected by the Drainage of Chicago and other Cities.' This contains a historical sketch of early investigations of the river, a compilation of various opinions upon the self-purification of streams and a summary of the results obtained by the recent investigations.

Dr. Long's report of the chemical and

bacteriological examinations occupies seventy-seven pages and that of Mr. Harman, entitled 'A Preliminary Sanitary Survey of the Illinois River Drainage Basin,' one hundred and five pages. They include tables showing population, rainfall, stream gaugings, water-supply and sewerage statistics, analyses, etc. The brief report by Professors Zeit and Fütterer describes the various species of bacteria found at each station, with special reference to their pathogenic qualities.

The most interesting feature of the report is naturally the comparison of the condition of the Illinois River before and after the opening of the Chicago drainage canal. In order to appreciate this a knowledge of the local conditions is necessary. For many years the bulk of the sewage of Chicago has discharged into the Chicago River, a small stream with north and south branches uniting in the heart of the city to flow into Lake Michigan. This has been a menace to the public water supply, which is taken from the lake, and in order to lessen the danger a pumping station was established at Bridgeport in 1865, by which the water from the polluted south branch was pumped into the Illinois and Michigan canal, whence it found its way westward into the Illinois and Mississippi Rivers. This not being sufficient to relieve the situation in Chicago a drainage canal was designed to connect the Chicago River with the Des Plaines River, which is one of the streams which unite to form the Illinois River. A western outlet to Lake Michigan was thus provided, which naturally changed the current in the Chicago River. After ten years of construction the canal was opened on January 17, 1900. Prior to this from 30,000 to 50,000 cubic feet per minute was pumped at Bridgeport, and it has been estimated that in 1899 this contained from 85 to 90 per cent. of the total sewage of Chicago. Since the opening of the canal the actual amount of sewage sent westward has increased, but the amount of water has increased in a far greater ratio, the law requiring a minimum flow in the canal of 300,000 cubic feet per minute. According to Dr. Long's report the increased dilution thus brought about has resulted in an improved condition of the sanitary quality of the water in the Illinois

River. The analyses upon which this opinion is based are too extensive to reproduce here, but those who dwell in the lower Illinois valley and those who have feared the possible effect of the sewage of Chicago upon the water supply of St. Louis should observe the following emphatic statement of Dr. Long: He says: "I believe that it may be safely said that if the whole of the sewage of Chicago were to be excluded from the Illinois River, the condition at Grafton (where it enters the Mississippi) would remain unchanged so far as its organic contents and bacterial organisms are concerned."

The character of the Chicago sewage, the condition of the various tributary streams, the self-purification of the Illinois River and its subsequent pollution by Peoria and other cities are all fully discussed in the report.

The analytical work appears to have been carefully done, but it is to be regretted that certain portions of what is now considered to be a complete water analysis are omitted. For example, the amount of coloring matter was not measured and consequently the determination of oxygen consumed cannot be fully interpreted. The measurement of turbidity was likewise omitted; nor is any mention made of microscopical examinations. Determinations of dissolved oxygen and free carbonic acid, taken in connection with the other observations, would have thrown much light upon the self-purification of the stream. Nevertheless, the results as they stand are of great value and reflect credit upon those who conducted the work.

It is the intention of the Illinois State Board of Health to extend observations of this character to other streams until the sanitary survey of the state shall be complete.

G. C. WHIPPLE.

Leitfaden der Wetterkunde. Gemeinverständlich bearbeitet von DR. R. BORESTEIN. Mit 52 in den Text eingedruckten Abbildungen und 17 Tafeln. Braunschweig, Friedrich Vieweg und Sohn, publishers. 1901. Price, 6 Mk.

This book is intended as a popular treatise on the weather, for the use of farmers, sailors and others whose pursuits are affected by the weather, and also for the benefit of all who

may be interested in natural phenomena. Its object is to give the elementary facts of meteorology and explain the scientific principles on which weather forecasts are made. The author hopes thus to enable his readers to better understand and apply the forecasts as made by the national bureaus and to make forecasts for themselves. The publishers explain that among other new things embodied in the book are the results of the scientific balloon ascents and an account of the various weather services of the world.

The book is interestingly written and well illustrated. The distribution of rainfall and temperature over Europe is graphically illustrated by four colored charts. Perhaps the most attractive feature in the book is the reproduction of the best of the pictures from the International Cloud Atlas, showing in approximately natural colors the different types of clouds, all of which are derived from photographs. This is a feature that other text-books would do well to copy.

The chief criticism of the book is that it is written almost entirely from a German standpoint. The quotations are chiefly from German authors and the illustrations are derived chiefly from German sources. The only map of the world contained in the book is one illustrating the distribution of pressure. Several pages are given to describing the weather service of Germany; only a paragraph is given to the weather service of the United States. The balloon ascents quoted were those made by the German Aeronautical Society, and no mention is made of modern kite work. Perhaps this was intended by the author, as he was writing chiefly for German readers, but a foreigner misses the broad cosmopolitanism such as is found, for example, in the work of Dr. Hann.

H. H. CLAYTON.

Who's Who in America. A Biographical Dictionary of Notable Living Men and Women of the United States. Edited by JOHN W. LEONARD. Chicago, A. N. Marquis and Company. 1901-1902. Pp. xvi + 1304.

The initial edition of this work, published two years ago, made a niche for itself in current literature and a place for itself on the most

convenient shelf of the student; and the second edition, now in distribution, seems still more useful. Primarily the book is a biographic dictionary of a perfection approaching the ideal, in which the lives of prominent Americans are written in sufficient fulness for practical purposes; it is also a directory to prominent Americans by full names and present addresses. Naturally the first question as to the value of such a book connects itself with the classification, *i. e.*, with the definition of prominence and with the editor's success in equitably cleaving the mass of 80,000,000 into portions of 12,000 and 79,988,000, respectively, along the precise lines of the definition. Of course the performance of this task would out-Hercules the classic hero; it can never be done with mathematical precision, and even if it were made right for one day it would be wrong for the next; yet the chief excellence of 'Who's Who in America' lies in the truly remarkable measure of success with which the editor has established and maintained his primary definition. It is this measure of success in classifying prominence which gives the work its greatest utility; for the user may be reasonably certain of finding within it desired facts relating to any celebrity, and this without undue labor of search through irrelevant biographic material.

The 1899 edition contained 8,602 names, of which 752 are omitted in the 1901 edition, 498 by reason of known death, and the remaining 254 for various reasons; the later edition includes 11,551 names. Classified by residence (as they are in the introductory pages), these celebrities are distributed throughout the 45 States, 6 Territories and 1 District of the United States, and 47 foreign countries; 11,137 reside in the United States, 370 live permanently abroad, and 44 do not report. Of those resident in the United States 2,849 are credited to New York, 1,010 to Massachusetts, 889 to District of Columbia, 880 to Pennsylvania and 704 to Illinois; then follow Ohio, 422; New Jersey, 314; California, 291; Connecticut, 266; Missouri, 222; Maryland, 205; and the remaining States and Territories yielding less than 200 each of the aggregate. It would not be easy to class the celebrities by vocation, and the editor has not attempted to do so; but scientists may

feel gratification in the fact that their important class has received especial care and effort, and that scientific eminence seems to have adequate recognition—indeed, scarcely a page is without one or more names distinguished in some line of scientific activity. Withal the book is a model of condensation and—considering the extreme difficulty of attaining accuracy in details of biography, bibliography, nomenclature, residence, etc.—a marvel of accuracy.

The new edition, like the old, is enriched by a readable prefatory narration of editorial experience, and still more by suggestive statistical tables, of which that entitled 'Educational Statistics' is a real contribution to knowledge. Of the 11,551 persons biographed, 9,760 furnished educational data, and in 8,141 cases the data permit useful classification. Of these 8,141 persons, 5,775 are collegians and 4,810 out of these graduates; 808 were educated only in common schools, 282 were privately educated, while 31 were self-taught. These figures, with the carefully selected data on which they rest, afford America's strongest argument in favor of higher education; at the same time they reveal the country's unparalleled element of strength in the possibility of eminence to those helped only by the public schools, and even to those not helped at all, along educational ways.

The book is notably fit in size, weight, quality of paper, typography, abbreviations, binding, and other matters which go to make up satisfactory book-making.

W J M.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *Botanical Gazette* for July contains the following papers: Charles E. Allen writes 'On the Origin and Nature of the Middle Lamella.' The general conclusion is reached that this structure is not merely the partition wall as laid down, either as a single or a double layer; nor is it merely an intercellular substance or cement, a means for binding the cells together. It is a wall layer with a complicated history, undergoing after its appearance changes in form, in mass, and in chemical composition. Carleton E. Preston has written upon 'Structural Studies of Southwestern Cactaceæ.' From a study of eight representative forms various

conclusions are reached, among which are the following: There is a slight variation in the roots as regards branching and vascular limits; in the stem there is a great range of structural deviations, which take place along definite lines and by definite steps, the variation extending to bundle branching and reticulation, extent of succulence, character of parenchyma, of pith and cortex, development of mucilage, and even to the kinds of elements entering into the xylem. Suggestive results from the systematic point of view were also obtained. Alfred Rehder has written upon *Vasilima* and *Schizonotus* of Rafinesque, both of which he regards as properly synonyms of *Sorbaria*. Arthur Bennett makes the first record of the appearance of *Potamogeton polygonifolius* in Newfoundland, the only other known North American situation being on the island of Nova Scotia.

In the numbers for August and September three continued papers appear. Dr. F. L. Stevens has written upon 'Gametogenesis and Fertilization in *Albugo*'; and Dr. W. L. Bray upon 'The Ecological Relations of the Vegetation of Western Texas.' Both of these papers will be noticed upon their conclusion in the October number. The third paper is by Dr. Florence May Lyon, entitled 'A Study of the Sporangia and Gametophytes of *Selaginella apus* and *S. rupestris*.' The description of *S. apus* is the first account yet published of the details of development of both gametophytes of any species of *Selaginella*. A preliminary study of the megaspore and female gametophyte of *S. rupestris* is added. The most striking fact observed is the persistent retention of the megaspores within the unshed sporangia throughout the formation of the prothallium and of the embryo. In the case of *S. rupestris*, at the time the strobilus is separated from the plant by the decay of the vegetative part beneath, it appears covered with sprouting plantlets. The megaspores of *S. apus* are shed before the embryo has emerged. The significance of this sequence of events lies in the resemblance to the formation of seeds in the higher plants. But one or two megaspores of *S. rupestris* form, whereas the normal number four appears in *S. apus*. The description of the male gametophyte

differs from that given by Belajeff. It consists of a single cell, presumably the vestige of the prothallium, and the two masses of spermatozoid-producing cells. Fertilization is accomplished in a manner suggestive at least of the seed plants. The microsporangia open with force when the male gametophytes are mature, and the latter are shed like pollen grains. The outer wall of the microspore has cracked open at this stage and the endospore protrudes in a papilla-like protuberance like a very short pollen tube. This ruptures and the spermatozoids are freed in a mass of slime that is attracted toward the archegonia. Microspores were found within the megasporangia, having been hurled in when the latter were gaping open. The bryophyte-like character of the spermatozoids claimed for the Lycopodiaceæ was not demonstrated in these two species. As regards their form they were typically fern-like, spirally coiled, and the presence of cilia not determined. The methods by which the strobili were sectioned with their nut-like spores *in situ* is given in detail.

In all the numbers there are the usual 'Briefer Articles,' 'Reviews of Current Literature' and 'News Items.'

THE August number of the *American Geologist* contains a history and biographical sketch of the late George M. Dawson, of Canada. The paper is accompanied by a portrait of Mr. Dawson and a bibliography of his writings. 'The Pleistocene Problem of the North Atlantic Plain,' by Geo. Shattuck, contains a discussion of the views of W J McGee and N. H. Darton followed by those of Professor R. D. Salisbury. The writer concludes by stating his own views based on considerable field work in the area. He claims that five terraces have formed in this period and he approaches their study through a study of the present work of the Chesapeake and the Atlantic Ocean. For these four formations below the present terrace he proposes the following names: (1) Talbot, (2) Wicomico, (3) Sunderland, (4) Lafayette. In the editorial comment is an extended description of 'The Department of Geology in the National Museum.' This discussion is accompanied with five plates illustrating types of the various

collections. Following this is the 'Review of Recent Geological Literature' and the 'Author's Catalogue of Recent Geological Literature.' The September number contains a valuable discussion of 'The Basic Rocks of Northeastern Maryland and their Relation to the Granite,' by Alfred Gray Leonard. The author describes several rocks, all from a limited area, ranging from acid to ultra-basic. He attempts 'to show that these types are intimately associated in their geological occurrence and closely related in composition; that many of the types graduate into others by intermediate varieties, and that they probably represent facies of one original magma.' The article is accompanied by four plates of microphotographs illustrating rock structures, and a map showing the distribution of the varieties in the area studied. 'A Preliminary Geologic Section in Alpena and Presque Isle Counties, Michigan,' by Amadeus W. Grabau, has a plate showing a geological section at Thunder Bay accompanied by a description of the various outcrops. This is followed by 'Editorial Comment on the Archæan of the Alps.'

THE October number of the *American Journal of Mathematics* (Vol. XXIII., No. 4) has the following articles:

Memoir on the Algebra of Symbolic Logic, by A. N. Whitehead; Secular Perturbations of the Planets, by G. W. Hill; Representation of Linear Groups as Transitive Substitution Groups, by L. E. Dickson; A Class of Number Systems in Five Units, by G. P. Starkweather.

The Osprey for August contains articles on 'Birds about Lake Tahoe,' by Milton S. Ray; 'Life History of the Prairie Warbler,' by Jno. W. Daniels, Jr.; 'Camping on the Old Camp Grounds,' II., by Paul Bartsch; 'Cage Birds of Calcutta,' by Frank Finn, and the seventh instalment of 'The Osprey or Fishhawk: Its Characteristics and Habits,' by Theodore Jill.

DISCUSSION AND CORRESPONDENCE.

DIFFERENTIATION OF SUBJECTS AND TITLES IN COLLEGES.

In your last issue Professor F. W. Rane makes objection to the all-comprising title of professor of agriculture, and very properly

points out that the subject is now so differentiated that the nomenclature in professorship should follow suit. While the claim is perfectly proper, I cannot suppress a smile in reading the signature of the 'Professor of Horticulture and Forestry.' Why should not Mr. Rane begin differentiation at home? Horticulture and forestry are two so widely different subjects that the man who proposes to teach them both must, indeed, be able to turn his coat most readily. Both, to be sure, have to deal with trees, being both branches of the wider field of arboriculture; but each deals with entirely different classes of trees, for entirely different purposes by, entirely different—I might almost say opposite—methods. The forester is after the substance of the tree; the final object of his efforts is attained by the cutting, the removal of the tree. The horticulturist's object is not the substance but the fruit, or, if he be a landscape gardener, the form and beauty of the tree, both aims being only fulfilled by the presence of the tree. These different objects are attained by entirely different methods, as could be readily pointed out, did space permit.

I would not wish to discourage any laudable attempt to make students of horticulture and of other agricultural branches know something of forestry, but it is a question whether they can get much professional knowledge of either the one or the other subject from an undifferentiated professor of horticulture and forestry. As we have now two fully organized colleges of forestry, the one at Yale with two, the other at Cornell with three, professors of forestry, without any other branches to teach, it would appear quite time for other colleges, who find it necessary or desirable to educate foresters, to realize the wide difference between the various branches of arboriculture, and not mix up botany, horticulture, landscape gardening and forestry in their courses and professors' titles.

B. E. FERNOW.

NEW YORK STATE COLLEGE OF FORESTRY.

A FINAL WORD ON DISCORD.

TO THE EDITOR OF SCIENCE: Mr. Max Meyer, in his criticism a few weeks ago, implied that I had made a mistake in a book review. This,

it appears, was not because I had objected to a certain numerical statement about discord, but because I had referred to a curve by the late Professor Mayer which Mr. Meyer considers worthless. The work of Helmholtz in the same domain he also considers worthless. He quotes Melde and Stumpf, who differ with Mayer and Helmholtz. He concludes by saying "Upon the *cause* of discord the psychologists have *not* agreed; it is yet unknown—at least to the psychologists."

For many years I have been convinced that beats do not constitute the sole cause of discord, but that probably they constitute one efficient and important element. So far as this may be admitted, Mayer's curve is the nearest approach to an expression of facts within the range he selected. The present controversy seems to be chiefly regarding authorities. Criticism intended to be destructive is not a substitute for constructive evidence. The opinions of Melde and Stumpf are of course worthy of respect, but they do not prove Helmholtz and Mayer to be wholly wrong. It does not seem to me that the subject is of sufficient importance to call for further discussion.

W. LE CONTE STEVENS.

WASHINGTON AND LEE UNIVERSITY,
October 12, 1901.

THE BICENTENNIAL OF YALE UNIVERSITY.

THE program of the bicentennial exercises of Yale University being celebrated this week is as follows:

MONDAY, OCTOBER 20.

- 10:30 A. M.—Divine service in the Battell Chapel. Sermon by the Rev. Joseph Hopkins Twichell, A. M.
- Special divine services in Center Church, sermon by the Rev. Newman Smyth, D. D.; in the United Church sermon by the Rev. Joseph Anderson, D. D.; in Trinity Church, sermon by the Rev. Walton Wesley Battershall, D. D.; and in the First Methodist Church.
- 3:00 P. M.—Address by the Rev. Professor George Park Fisher, D. D., LL. D., on 'Yale in its Relation to Christian Theology and Missions'; Battell Chapel.
- 8:00 P. M.—Organ recital by Professors Samuel Simons Sanford, A. M., and Harry Benjamin Jepson.

SUNDAY, OCTOBER 21.

- 9:30 A. M.—Dedication of the Ives-Cheney Memorial Gateway.
- 10:30 A. M.—Address by Thomas Thacher on 'Yale in its Relation to Law'; Battell Chapel.
- Address by Professor William Henry Welch, LL. D., on 'Yale in its Relation to Medicine'; Battell Chapel.
- 3:00 P. M.—Address of welcome to guests by President Arthur Twining Hadley, LL. D., with spouses; Battell Chapel.
- 5:00 P. M.—Reception of the guests of the university and representatives of the alumni by President Hadley, in the Yale Art School.
- 8:00 P. M.—Assembly of students and graduates on the campus.
- 9:00 P. M.—Torchlight procession of students and graduates.

TUESDAY, OCTOBER 22.

- 10:30 A. M.—Address by President Cyrus Northrop, LL. D., on 'Yale in its Relation to the Development of the Country'; Battell Chapel.
- Address by President Daniel Coit Gilman, LL. D., on 'Yale in its Relation to Science and Letters'; Battell Chapel.
- 2 P. M.—Football games at Yale Field; Yale University vs. Bates College; Yale University vs. team of graduates.
- 4:30 P. M.—Choral performance of Professor Horatio Parker's 'Hora Novissima,' by the Gounod Society and the New Haven Symphony Orchestra; Hyperion Theater.
- 8 P. M.—Illumination of the campus; student dramatic performance and singing in the campus amphitheater.

WEDNESDAY, OCTOBER 23.

(Commemoration Day.)

- 10 A. M.—Assembly of guests and graduates on the campus.
- 10:30 A. M.—Procession of guests and graduates to the Hyperion, as escort to President Roosevelt. Commemorative poem by Edmund Clarence Stedman, L. H. D., LL. D.
- Commemorative address by David Josiah Brewer, LL. D.
- Orchestral and choral music.
- Greek festival hymn by Professor Thomas Dwight Goodell, Ph. D., the music by Professor Horatio Parker, A. M.
- Conferring of honorary degrees on President Roosevelt and others.
- 2:30 P. M.—Concert by the Boston Symphony Orchestra, Mr. Wilhelm Gericke, conductor; Hyperion Theater.

4 P. M.—Dedication of Woodbridge Hall.

Address by Donald Grant Mitchell, LL.D.

5 P. M.—Farewell reception of the guests and graduates of the University by President Hadley and Mrs. Hadley, in the University Hall.

RESOLUTIONS ON THE RESIGNATION OF THE PRESIDENT OF COLUMBIA UNIVERSITY.

THE Council of Columbia University, representing the faculties, has adopted the following minute, on the occasion of the resignation of President Low :

When Mr. Low became the President of Columbia College, in the academic year 1889 90, the institution consisted of four faculties, in charge respectively of the schools of arts, mines, law and political science. These faculties numbered 122 officers of instruction ; and these schools were attended by 1,134 students. The faculties were connected with each other only through the president and trustees of the college ; and the schools existed alongside of each other without any principle or custom of reciprocity. The library of the college contained 91,000 volumes, and the wealth of the corporation was estimated at \$10,-500,000. The faculties, schools, library and entire equipment were crowded into the narrow and noisy quarters bordering upon the tracks of the New York Central railway.

To-day Columbia University consists of nine faculties, in charge respectively of Columbia College, Barnard College, Teachers College and the university schools of law, medicine, applied science, pure science, philosophy and political science. These faculties now number 385 officers of instruction ; and these colleges and schools are now attended by 4,500 students. The faculties are now coordinated with each other in the University Council in which all of the educational activities and interests of the university are officially represented ; and a complete system of reciprocity between all parts of the institution and also with the Union Theological Seminary now prevails. The library of the university now contains 311,000 volumes ; and the wealth of the corporation is now estimated at eighteen millions of dollars, of which one and one half millions of dollars, in round numbers, represent the splendid generosity and munificence of Mr. Low himself. And, finally, the university is now located upon a site and possesses a physical equipment unsurpassed in beauty, comfort and completeness by those of any institution of learning in the world.

This magnificent achievement, wrought within the short period of twelve years, has no parallel in the educational history of any country or of any age ; and

no further or higher proofs of Mr. Low's abilities as an educator and an administrator than the mere recital of these facts are necessary.

But Mr. Low brought to the solution of the problems of the university qualities even more important and needful than these intellectual powers. First and highest among these qualities, and most indispensable, was the power to win and to hold the full and unwavering confidence and the cordial and zealous cooperation of all his colleagues, a power which can come only from an innate love of truth, joined with an open mind, a high sense of justice, unbending integrity, kindness of heart and genuine deference in manner. Every officer of the university felt that his interests and the interests of his department were safe in the hands of Mr. Low, and that no occult influences would ever be allowed to prevail in the administration of the affairs of the institution.

"It is the recollection of these rare and invaluable traits even more than of his administrative abilities which makes the parting with him so hard and regretful and which moves this Council to express the hope and wish for itself and for the bodies represented in it that from his seat in the Board of Trustees of the University Mr. Low may still continue to manifest his old interest in the development of the university and may still exert his great powers in the promotion of its welfare.

"Though conscious that these words do not express with any adequacy the feelings of the members of this body concerning the obligations of the university and all of its officers to Mr. Low and their deep regret at his retirement from the Presidency yet your committee would beg to recommend that the minute be spread in full upon the records of the University Council and that the Secretary be directed to transmit a copy of it with a suitable letter to Mr. Low."

THE CARNEGIE TECHNICAL SCHOOLS.

THE report of the committee of the Board of Trustees of the Carnegie institutions at Pittsburgh has been made public. It formally approves the scheme of the sub-committee and of the advisory committee of experts on the 'Plan and Scope' of the proposed Carnegie technical system of industrial education, as outlined by the latter in the report published in *SCIENCE* in July last and commented upon in the address of Mr. Brashear before his section of the American Association for the Advancement of Science, which appeared in our issue of September 13.

The committee recommends the organization

of the central feature of a scheme to comprehend, ultimately, if properly sustained, a series of schools of graded character from the evening classes and the trade schools for artisans and youth, of both sexes, to the technical high school, the schools of engineering and architecture aggregated in a technical college, and to the aggregations of these schools and colleges in a technical university which shall include a department of research. It is proposed to employ the gift of Mr. Carnegie, presented at the time of his announcement of his ambition in this direction, in the establishment of a technical institution to occupy substantially the same position and to do practically the same kind of work as the Pratt Institute in Brooklyn, the Drexel in Philadelphia and similar schools in other large cities. It is recommended that a plot of land of about 60 acres area be at once secured and this institution immediately organized.

"The plan and scope as laid down by the committee and the experts invited to give counsel will make the school of national importance and place it in the front rank of similar schools in the world."

The endowment at present advised is said to be \$5,000,000, and the final and completed form of the 'university' will presumably require about double that sum.

When studying a plan and determining the scope of the institution, the expert advisers were called upon, each for a statement, and were later called together as a committee, and the present report states that 'appreciating the dignity and the magnitude of the subject, we were agreeably surprised to find that all reports agreed in their essential features.'

"Accordingly when the members of the Advisory Committee held their final meeting in June they had no difficulty in uniting in a general scheme for technical education."

The scheme was in outline the largest possible; the idea being to provide a model, so far as it might be carried, and to hold up an ideal toward which to approximate as time and means should permit. The introduction of manual training, in cooperation with the public schools, and a general system and policy of constant cooperation in all practicable ways,

the provision of day and evening classes for artisans, the organization of a scientific and technical high school for youth of both sexes unable to find means and time for a liberal education and yet requiring instruction in the fundamental principles of the industries into which they are to be inducted, together with provision for general education, in conjunction with the public schools, the neighboring university, the great libraries of Pittsburgh and vicinity and with the operations of the existing Carnegie Institute, art school and museum, constitute the first and a great task. Later, if practicable, the educational structure will be built up and down and broadened into a great system offering the industrial classes Huxley's ladder 'from the gutter to the university.'

"The Carnegie Technical College with its crowning features of scientific research and publication, must be left for future endowment. Its realization would complete a technical university unequalled in its scope and influence, an institution worthy to foster the highest aspirations of Pittsburgh—or of any metropolis, the committee might have added."

Finally, the committee remarks: "We would respectfully suggest to Mr. Carnegie the many advantages to be derived from handling as a whole, rather than in parts, whatever scheme of technical education he may contemplate."

"The Advisory Committee wisely recommends that an endowment should be provided of such magnitude and character as will safely maintain the required income on the face of falling rates of interest and the demands of a steady growth."

THE NEW YORK PATHOLOGICAL INSTITUTE.

ANNOUNCEMENT is made that the plan of reorganization of the Pathological Institute of the New York State Hospitals for the Insane undertaken by the State Commission in Lunacy is gradually taking shape. An advisory board has been appointed, whose duty it is to aid in the development of the Institute and the carrying on of its work on broad lines and to assist the new Director soon to be appointed. It is the aim of the reorganized Institute to carry on work in the sciences correlated with psychiatry

according to the original plan, but with some modifications intended to meet more immediately the needs of the hospitals. Original research in the various sciences having a bearing upon the subject of insanity will go on as before, but in addition the Institute will be utilized to give special instruction in clinical psychiatry, as well as methods of scientific research to the physicians on the staffs of the hospitals for the insane and to young men about to take up an asylum career. In order to obtain this clinical experience the Institution needs to be combined with a hospital for the insane, and to bring this about it is for the present to be connected with one of the asylums on Ward's Island, and until such time as a reception hospital for the insane can be established in Manhattan. In selecting the members of the Advisory Board, the Lunacy Commission deemed it expedient to have the three University Medical Schools of New York City represented, *viz.*: Columbia, Cornell and Bellevue-University. Furthermore it was decided to accord to the chief sciences correlated with psychiatry representations upon the Advisory Board. These sciences are pathology, chemistry, psychology and general biology. Inasmuch as the Pathological Institute was created for the utilization of the material of all the State hospitals, and for the purpose of raising the standard of scientific study, treatment and care of the insane under State care, it was thought best that these institutions should also have a voice upon the Advisory Board. A member to represent general clinical medicine and neurology was likewise selected. Accordingly the Commission in Lunacy has established an advisory board consisting of the following men: James Ewing, Professor of Pathology, Medical Department of Cornell University; Dr. Christian A. Herter, Professor of Pathological Chemistry, Bellevue and University Medical College; Dr. J. McKeen Cattell, Professor of Psychology, Columbia University; Dr. Hermon C. Bumpus, Assistant to the President of the American Museum of Natural History, to represent the department of General Biology; Dr. Henry Hun, Professor of the Diseases of the Nervous System, Albany Medical College, to represent Neurology and General Clinical Medicine; Dr. Charles W. Pilgrim, superin-

tendent of the Hudson River State Hospital, at Poughkeepsie, and Dr. A. E. Macdonald, superintendent of the Manhattan State Hospital, East, to represent the State Hospitals; Dr. Frederick Peterson, President of the Lunacy Commission, a member *ex officio*. All appointments to the advisory board are permanent except two. The two superintendents of asylums on the board were elected by the fourteen asylum superintendents of the State at a meeting held in Buffalo, September 28, for a term of two years only, thus permitting all the asylums to be represented in rotation on the board.

THE AMERICAN PHILOSOPHICAL SOCIETY.

A COMMITTEE of the American Philosophical Society has sent to members the following letter in regard to an annual general meeting of the Society in Easter week:

The American Philosophical Society, animated by the desire which led its founder, the illustrious Franklin, to issue his 'Proposals for promoting Useful Knowledge among the British Plantations in North America,' and which in 1743 resulted in the formation of this Society on a national basis, and in the selection of Philadelphia as its seat, because of its 'being the city nearest the centre of the continent colonies,' has for some time recognized the fact that the changes which the lapse of 158 years have wrought, demand modified conditions to meet existing requirements.

Ever since its foundation the national character of the Society has been maintained. In consequence there has latterly arisen among its members a conviction that the time has come when the interests of useful knowledge in the United States can be greatly promoted by the holding, in addition to its usual semi-monthly meetings, of at least one general meeting in each year, which from the information to be derived from the papers presented and their discussion by those most competent to add to our knowledge, shall attract the members of the Society from all parts of the country to their mutual advantage as well as to that of this, the first and oldest scientific society in America, and one of the oldest in the world.

With this view the Society has authorized the holding of a general meeting which for the ensuing year, has been fixed in Easter week and the undersigned have been appointed a committee to make the necessary arrangements.

Members desiring to present papers, either for themselves or others, are requested to send to the secre-

aries at as early a date as practicable and not later than February 15, 1902, the titles of the papers, accompanied by a brief abstract, so that they may be duly announced on the programme which will be issued immediately thereafter and which will give in detail the arrangements for the meeting.

The Publication Committee, under the rules of the Society, will arrange for the immediate publication of the papers presented.

It should be borne in mind that the Society, by means of its publications, which present a series covering 140 years and include *Transactions* in quarto and *Proceedings* in octavo, with its large exchange list embracing, practically, the scientific societies of the world, and with its exceptional facilities for immediate issue, offers unrivalled avenues for prompt publication and wide circulation of the papers read before it.

Mindful of the brilliant history of the Society, extending back into the first half of the eighteenth century, its members should obviously be solicitous that its career at the outset of the twentieth century shall fully maintain the high prestige which the preceding centuries have given to it both at home and abroad. Hence it is felt that with their cordial and active cooperation secured the proposed general meetings may be made a powerful factor in advancing the interests for the promotion of which the Society was founded.

SCIENTIFIC NOTES AND NEWS.

A MEETING of the executive committee of the American Society of Naturalists was held at Boston on October 19, to complete the arrangements for the Chicago meeting of the Naturalists and affiliated societies. The meeting of the Naturalists will be on Tuesday and Wednesday of Convocation week, that is December 31 and January 1. The discussion before the Naturalists will be on Wednesday afternoon, and the annual dinner, at which the president, Professor Wm. T. Sedgwick, will give the address, will take place in the evening. The subject selected for the discussion is 'The Relations of the American Society of Naturalists to other Scientific Societies.'

DR. WILHELM WALDEYER, professor of anatomy in the University of Berlin, has been sent by the University of Berlin and the Berlin Academy of Sciences as their representative at the bicentennial exercises of Yale University.

A GOLD plaque will be presented to M. Bertelot next month to celebrate the fiftieth anni-

versary of his entering as an assistant the chemical laboratory of the Collège de France.

MR. BARBOUR LATHROP, of Chicago, and Mr. D. G. Fairchild, of the U. S. Department of Agriculture, will leave San Francisco next month on another expedition, with a view to investigating exotic plants that might be introduced into the United States. They go first to the South Sea Islands and Australia and later to India.

PROFESSOR W. B. SCOTT, of Princeton University, is still in South America, working on the Patagonian Expedition Reports. When last heard from he was at Buenos Ayres, examining specimens in the museums of that place.

THE Hanbury gold medal for 1901 was presented on October 1 to Dr. George Watt by the president of the Pharmaceutical Society. This medal, which was established as a memorial to Daniel Hanbury, is awarded biennially for original research in the chemistry and natural history of drugs.

THE council of the Institution of Civil Engineers has, in addition to the medal and prizes given for communications discussed at the meetings of the institution in the last session, made the following awards in respect of other papers dealt with in 1900-1901: A Telford medal and a Telford premium to Reginald Pelham Bolton (New York); a Watt medal and a Telford premium to J. Emerson Dowson (London); a George Stephenson medal and a Telford premium to W. T. C. Beckett (Calcutta); a Manby premium to E. K. Scott (London); a Trevithick premium to T. A. Hearson, R.N. (London); a Telford premium to J. A. W. Peacock (Tantah, Lower Egypt).

DR. NORMAN MOORE gave the Harveian Oration before the Royal College of Physicians, London, on October 18.

PROFESSOR ROBERT KOCH has been sent by the German Government to Gelsenkirchen, where there is a serious outbreak of typhus, as many as fifty cases being reported in a single day.

DR. CHARLES HENRY BROWN, a New York physician, who has given special attention to nervous diseases and had for many years been

editor of the *Journal of Nervous and Mental Diseases*, died on October 15, at the age of fifty-four years.

GEORGE B. SIMPSON, for thirty-five years the accomplished delineator of fossils for the paleontological department at Albany and a well-known student of the fossil Bryozoa, died on October 15.

M. R. KÖNIG, of Paris, well known for his scientific instruments and his investigations on acoustics, has died at the age of sixty-nine years.

MR. WILLIAM WEST, known for his study of fresh-water algæ, has died in India from cholera, at the age of twenty-six years.

THE deaths are also announced of Dr. Peter M. Pokrowskij, professor of mathematics at the University of Kiew, and of Dr. Alex. F. Berger, docent in mathematics in the University of Upsala.

THE next International Congress of Physiologists will be held at Brussels in 1904, under the presidency of Professor Heger.

THE Nineteenth Congress of the American Ornithologists' Union will convene at the American Museum of Natural History, New York City, on Monday, November 11, at 8 o'clock p. m. The evening session will be devoted to the election of officers and members and the transaction of other routine business. The meetings, open to the public and devoted to the reading and discussion of scientific papers, begin on Tuesday morning and continue for three days. In connection with the Congress there will be a conference of representatives of the Audubon Societies, for the purpose of forming plans for more effective cooperation.

THE Coast and Geodetic Survey steamers *Pathfinder* and *MacArthur* have nearly completed the survey of the Fox Island channels which form the entrance or exit for all Bering Sea commerce. The steamers *Patterson* and *Gedney* are now charting Cross Island and Icy Straits, of the Southeast archipelago. The *Pathfinder* will proceed to the Philippines before long via Nagasaki to take up the work of surveying called for by the Philippine Commission.

THE Antarctic expedition from Sweden, under the direction of Professor Otto Norden skjöld, left Göteborg on the steamship *Antarctic* on October 16. Professor Nordenskjöld is accompanied by Professor Ohlin, the well-known explorer, and M. K. A. Anderson, as zoologists; Dr. Bodman, hydrographer and magnetician; M. Skottoberg, botanist, and Dr. E. Ekolof, medical officer. Captain Larsin, a Norwegian, who has already made several voyages to the South Polar regions, is in charge of the *Antarctic*. The vessel will proceed to Terra del Fuego and thence to the South Polar regions, where the field of exploration will not conflict with those chosen by Great Britain and Germany. Professor Nordenskjöld expects to land with a party while the vessel makes explorations about Terra del Fuego.

As we have already announced the coast and Geodetic Survey has established a magnetic observatory at Sitka, Alaska, and is constructing another at Honolulu. These observatories will cooperate with the German and British Antarctic expeditions in making simultaneous observations.

As the daily papers have very fully reported M. Santos-Dumont in his air ship on October 19, succeeded in circumnavigating the Eifel Tower and returning to Saint Cloud. The trip was made within the half hour allowed by M. Deutsch for the award of his prize, but owing to a delay in landing the prize was not awarded.

REUTER'S AGENCY gives the following information concerning Dr. Sven Hedin, the Swedish traveler, based upon a letter from him, dated July 10. It appears that Dr. Sven Hedin, at the time of the dispatch of the letter, was at the foot of the Akka Tagh, in Northern Thibet, and intended to proceed in the direction of Ladak in order to survey accurately the region about the source of the Indus. Next spring he proposed to return to Osh via Kashgar. Meanwhile, a caravan of 15 horses has arrived at Kashgar bringing the results of two years of the traveler's work in the shape of scientific collections, maps, photographs and diaries.

R. W. AMIDON, M.D., of New York City, is spending October and November near Chau-

mont, Jefferson County, N. Y., investigating ancient village sites. In this region there are mounds of various sizes, in the top of each of which is a saucer-shaped depression that is in every case about eight feet in diameter. It seems possible that these mounds may be the remains of earth-covered houses of various sizes, which had smoke holes approximately of the same diameter.

DR. MARCUS S. FARR, assistant in geology at Princeton, and Mr. Earl Douglass, fellow in biology, with a party of students spent the summer in geological explorations in the southern part of Montana. Valuable fossils were collected and are now being mounted at Princeton.

It appears that there will be no further contest in regard to the will of the late Jacob S. Rogers and that the Metropolitan Museum of Art will receive over \$5,000,000 for its endowment. It is perhaps scarcely necessary to state that the Museum includes archeology, as well as the fine arts, in its scope, and this large bequest will thus directly contribute to scientific work.

THE principal buildings for the St. Louis Exposition, as officially decided upon, will in many cases be larger than buildings constructed for similar purposes at previous expositions. There is to be an agricultural building, 700 by 2,000 feet; a manufacturers' building, 600 by 600 feet; a liberal arts building, 600 by 1,200 feet; a social economy building, 550 by 700 feet; a transportation building, 600 by 1,200 feet; an education building, 550 by 700 feet; an art building, 300 by 600 feet, with two wings, each 200 by 300 feet; a mines and metallurgy building, 600 by 1,200 feet; an electricity building, 600 by 550 feet, and a Government building, to cover 100,000 square feet. The estimated cost of these buildings is \$7,000,000. To these will probably be added buildings for fish and fisheries, for machinery, for forestry and for horticulture.

WE learn from *Nature* that a small residential laboratory has been opened at the Hakgala Botanic Gardens, near Nuwara Eliya, at an elevation of 5,600 feet above sea-level. The

laboratory is a branch of the Peradeniya Institution, and consists of a small building containing a working room 21 feet x 12½ feet, a living room, two bedrooms, kitchen, etc. The climate is temperate, fires being required in the evenings at least. The botanic garden itself is said to be very beautiful, and occupies an unrivaled position for the study of equatorial hill vegetation, for on one side there are jungles stretching for 25 miles or more into the wet region of the hills, on the other grassy plateau reaching for an equal distance into the dry region, and extending from 3,000 to 7,000 feet above sea-level. The garden itself contains both jungle and patana reserves of several hundred acres.

A COMMITTEE appointed by the recent German Geographical Congress has offered a prize of at least \$150 for a paper on 'The changes in the course of the Rhine between Bonn and Cleves in historic times, and how have they affected the settlements on its banks?'

THE foreign journals report that the Berlin Academy of Sciences and the Danish Academy at Copenhagen have decided to prepare a collection of all the medical works of antiquity under the title of 'Corpus Veterum Medicorum,' and will cause a thorough examination to be made of all libraries, Oriental and European, which are likely to contain MSS. dealing with medical subjects.

THE letter press of Britton and Brown's 'Illustrated Flora,' with some abridgment and numerous emendations, but without the illustrations, has been compressed into a single portable volume, which is to be published at once by Henry Holt & Co., under the title, Britton's 'Manual of the Flora of the Northern States and Canada.'

A REPRESENTATIVE of Reuter's Agency reports an interview with Herr Oscar Neumann, the eminent German explorer, who has recently completed an eighteen months' journey in Central Africa from Zeila to Khartum. Traveling for the most part through absolutely unknown country, he made some valuable discoveries, and has brought home the largest zoological collection ever made in Central Africa. He was also enabled to make a complete geological

survey. He met with no hostility on the part of the natives and had no fighting during the whole journey. The physical difficulties were, however, often very great. Describing his journey, Herr Neumann said: "Baron Erlanger and myself, accompanied by three Europeans—Dr. Ellenbech and Messrs. Heutemuller and Hillgart—left Zeila in January of last year, and journeyed into Somaliland, where we had considerable difficulty, and were unable to proceed east owing to the movements of the Mad Mullah. After crossing the Shibel River we traversed with difficulty a district full of caves and came to the land of the Arosi Galle. We visited the holy towns of Sheikh Hussein and the holy mountains of Abulnass and Abulcassim, which have never previously been explored. Subsequently we traveled northwest by a new route to Adis Abeba, crossing a plateau 9,000 feet high. We left the capital in November last, and proceeded southwest along the lakes to Lakes Stephanie and Rudolf. We adopted the new eastern route of the Great Rift Valley instead of following the tracks of Captain Wellby or Mr. Harrison. Between the Hawash River and Lake Stephanie we discovered that, instead of five lakes, there are no less than seven lakes, probably all relics of the great diluvial lake basin. After a slow and tedious journey we crossed the Omo River and traveled through the quite unknown Abyssinian provinces of Ksha and Konta, which have only been occupied since the Italian war. Subsequently I came to Kaffa, one of the richest provinces of Abyssinia, covered with dense forest, in which there is much coffee cultivation. My object now was to explore the sources of the Gelo River, an important affluent of the Sobat. I first passed through the land of Gimirra and the independent countries of Binescho and Scheko. Shortly afterwards I found the Gelo River and followed its course, but the further I proceeded the more difficult became the traveling. My caravan was now in a terrible plight. Glanders had again broken out, and out of 65 animals I had only 13 mules, two horses, and two donkeys left. I was therefore compelled to throw away tents, clothes, stores, etc., in fact everything but my books and collections. Our condition was made harder by

reason of the fact that we were going through a country which had almost been depopulated owing to Abyssinian raids. Suddenly a steamer appeared, having on board Slatin Pasha and Bluett Bey, Mudir of Fashoda, who took us in safety to Khartum." During the whole of this long and arduous journey Herr Neumann never had any trouble with the natives.

BEFORE the Section of Mathematics and Physical Science of the British Association, Dr. R. T. Glazebrook, the superintendent of the National Physical Laboratory, exhibited plans of the new institution now being erected at Bushey, gave a short history of the building, and described the objects with which it has been founded. According to the account in the *London Times* he said that the main building consisted of a substantial central block about 70 feet square standing on a vaulted basement. At each corner there was a large wing practically single-storied; the rooms in these were being fitted up for various special purposes. In the central building itself would be two general laboratories. There would be a large entrance-hall, arranged as an apparatus room, and a library. The basement contained six rooms of fair size; the floor had been covered with a thick layer of concrete. The walls were very thick, so that they were extremely steady, and the temperature and conditions all favorable for steady work. In addition there were other smaller rooms in the basement; two of these were entirely surrounded by thick interior walls and arrangements would be fitted to maintain a steady temperature throughout the year. At the back was another wing containing a number of rooms suited for special researches, and there a lift had been fitted and also a mercury column having a height of about 50 feet. For the more delicate physical work the ground-floor and basement of the old house afforded ample accommodation. For the engineering work a room 80 feet by 50 feet had been built, lighted from the north by a weaving shed roof. It was divided longitudinally into two bays by a series of rolled steel pillars. The one bay would contain a light traveling crane; along the other ran a line of shafting for driving the machinery and for experimental purposes. Adjoining this

laboratory was a drawing office, while the engine-house and boiler rooms were close at hand. Power, obtained from a 60-kilowatt Parsons turbine, would be distributed electrically to various parts of the laboratories; this form of engine was chosen for the express purpose of avoiding vibration as far as possible. The necessary tools were in order and in course of installation. The work which the committee hoped to attack in the first instance was that which had already been under the consideration of the Alloys Research Committee of the Mechanical Engineers. Apparatus for the photomicrographic examination of steel rails was being set up, and machines for testing the elastic properties of alloys were in course of construction. Pressure gauges and steam indicators would also be tested. The height of the building would not allow the mercury column, now being erected, to measure more than 200 pounds to the square inch, but apparatus was being constructed for pressures in excess of that amount. Considerable attention was to be given to high temperature thermometry, the testing of platinum thermometers, and the measurement of electrical quantities. Before the end of the year the committee hoped the laboratory would be fully and usefully occupied. Acknowledgment was made of the generosity of Sir Andrew Noble, who had given an excellent comparator, a dividing engine, and some measuring apparatus of the highest class to the laboratory.

At the recent Glasgow meeting of the British Association, Dr. A. G. Green read before the chemical section a paper on the coal-tar industry. According to the report in the *London Times*, he remarked that, owing to the numerous ramifications of the coal-tar industry and the manifold applications to which its products were applied, it might be regarded as the pulse of chemical industry as a whole. He had, therefore, traced the relative progress in the industry in England and Germany during the last fifteen years. At the commencement of that period England, although the originator of the manufacture of aniline dyes, was not holding its own against Germany, but was, at any rate, supplying Germany with the raw material. Now, even that was not the case,

for owing to the ample introduction of coke ovens, in which the by-products were recovered, Germany was producing coal-tar in plenty for its own use, and in the other departments of the industry the relative positions of the two countries was still worse for us. The export of coal-tar colors from Germany, exclusive of alizarines, was 4,646 tons in 1885 and 17,639 tons in 1899. In 1894 the value of the total exports of these colors amounted to £2,600,000, and in 1898 to £3,500,000. The value of the total chemical industry of Germany in 1897 was 46½ millions of pounds; at least a tenth of this might be put down to coloring matters and another tenth to other coal-tar products, making the coal-tar industry in Germany of an annual value of nine to ten million pounds. This remarkable activity has caused vast sums of money to be usefully invested and was giving employment to increasing numbers of work-people. The Badische-Anilin Fabrik in 1889 had a capital of £900,000, which had now been increased by £750,000, while the number of work-people employed, 4,800 in 1896, had risen to 6,485 in 1900. The total capital of the six largest coal-tar color firms in Germany amounted to at least 2½ millions; they employed about 500 chemists, 350 engineers and technical men, 1,360 business managers, clerks, and travelers, and over 1,800 work people. The total capital invested in the coal-tar color trade in England did not exceed £500,000, the total number of chemists employed could not be more than 30 or 40, and the number of workmen engaged in this manufacture probably did not amount to over 1,000. The exports of coal-tar colors from England had fallen from £530,000 in 1890 to £366,000 in 1900. The imports, on the other hand, had steadily increased from \$509,000 in 1886 to £720,000 in 1900. The colors used by the Bradford Dyers' Association were 10 per cent. of English make, 80 per cent. German, 6 per cent. Swiss, and 4 per cent. French. It was an apathy toward higher education and research that was the cause of this decadence. Moreover, the encouragement given to chemical research work by these great industries was enormous. Other industries of Great Britain were also threatened. The Germans were busy producing artificially

natural dye-stuffs, largely consumed in England and extensively grown in British possessions; indigo was the latest object of this particular kind of enterprise, and a sum of 1 $\frac{3}{4}$ millions sterling was being devoted to the achievement of the extermination of this natural dye-stuff.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. JOHN D. ROCKEFELLER has promised to contribute \$200,000 toward the endowment fund for Barnard College, Columbia University, provided that an equal sum is given by others before January 1, 1902.

THE corner stone of the new Medical Building of the University of Michigan was laid on the 15th inst., under the auspices of the State Medical Society, by Dr. Leartus Connor, the president of that body. Addresses were delivered in connection with the ceremonies by the Hon. Regent Kiefer, President Angell, Dr. J. A. McCorkle, professor of medicine in the Long Island College Hospital and a member of the class of '73 of the University of Michigan, and by Professor J. G. Adami of McGill University. The building, which has been made necessary by the rapid growth in recent years of the Medical Department, will contain the laboratories and class-rooms of the departments of hygiene, bacteriology, anatomy, histology and pathology, and the contracts for its erection call for an expenditure of \$88,000, exclusive of what may be required for the heating, plumbing and general equipment. The old Medical Building, which has been the home of the Medical School for fifty years, will be remodeled throughout and adapted for the use of the departments of pharmacology, physiology and chemistry.

AT the Massachusetts Institute of Technology Capt. William Hovgaard, of the Danish Navy, has been appointed professor of naval design in the department of naval architecture. Dr. H. P. Talbot has been made head of the department of chemistry. Dr. Talbot has for some years past been professor of analytical chemistry, and, since the departure of Dr. Drown, has in a measure acted as head of the department.

MR. HENRY M. HUXLEY has been made Hemenway fellow and assistant in anthropology at Harvard University.

THE New York *Evening Post* states that D. K. Zangogiannis, who was appointed professor of pedagogy at the University of Athens two years ago, and who had made a special study of German educational systems, has been deposed by the Government because of an article he wrote for a German periodical in which he criticised the Greek high schools.

DR. JOHN YOUNG, professor of natural history at Glasgow, has been obliged by the condition of his health to resign his chair after thirty-five years' service in the University. He will continue to act as curator of the Hunterian Museum.

DR. PURSER, professor of the institutes of medicine in the School of Physic, Trinity College, Dublin, has resigned the chair he has held for twenty-seven years.

AT Trinity College, Cambridge, the annual election to fellowships has been held, when four vacancies were filled. The new fellows in the sciences are Harold Albert Wilson, B.A., advanced student; certificate of research 1899 for papers on 'The electrical conductivity of flames containing salt vapors,' 'Velocity of solidification,' 'The influence of dissolved substances and of electrification on the re-formation of clouds,' and 'On the variation of the electric intensity along the electric discharge in rarefied gases'; Allen scholar, 1900; Clerk Maxwell scholar, 1901; and James Hopwood Jeans, B.A., bracketed second Wrangler, Mathematical Tripos, Part I, 1898; First Class, Division 1, Mathematical Tripos, Part II., 1900; Isaac Newton student, 1900; Smith's Prize, 1901.

DR. H. ERDMANN, of the University of Halle, has been appointed to a full professorship of inorganic chemistry, in the Technical Institute at Berlin. Dr. G. A. Gmeiner has been appointed professor of mathematics in the German university at Prague.

ON page 620 of the last issue of SCIENCE the word 'geological' was omitted before the word research in the sixth line.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE : S. NEWCOMB, Mathematics ; R. S. WOODWARD, Mechanics ; E. C. PICKERING, Astronomy ; T. C. MENDENHALL, Physics ; R. H. THURSTON, Engineering ; IRA REMSEN, Chemistry ; CHARLES D. <i>The Bicentennial of Yale University</i>	700
<i>Scientific Notes and News</i>	701
<i>University and Educational News</i>	704

In the mediæval convents, from which our academic usages are derived, there were annalists who noted the passing events. Dry and meager are such records—dry and meager will our annals seem unless we see in them the working of principles and methods during a period of two centuries. It will be my endeavor to set forth the relations of Yale to science and letters in such a way that with historic insight you may discover the tendency and the influence of the school in which we have been trained, and may thus appreciate its benefits more fully than ever before. I shall not follow closely the order of chronology, and under the circumstances of this address, I must omit the praise of living men, however richly deserved, nor can I mention many of the departed, however honored and beloved. Law, medicine and theology must be avoided; 'it is so nominated in the bond.' It will be good for each one of us to bear in mind the seven searching questions of an ancient critic—

Quis, Quid, Ubi, Quibus auxiliis, Cur, Quomodo, Quando,

and to remember also that there is no process by which we can draw forth in forty

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

* An address prepared for the Bicentennial Celebration, New Haven, October 22, 1901.

minutes the rich vintages stored up in a period of forty lustrums.

The Collegiate School of Connecticut began well; Yale College improved upon the Collegiate School; Yale University is better than Yale College. The process has been that of evolution, not of revolution; unfolding, not cataclysmic; growth, and not manufacture; heredity and environment, the controlling factors. What we are, we owe to our ancestry and our opportunities. Hence the 'Relation of Yale to Letters and Science' cannot be adequately treated without looking outside the walls, as well as inside—by considering the wilderness of Quinnipiac; the dependence of the colony upon the mother country; the bicephalous State of Connecticut; the prosperous city of New Haven and its proximity to the great metropolis; and especially by considering what has been going on in the macrocosm of literature and knowledge where we represent a microcosm. Such a survey I shall not attempt, for I must keep close bounds. Yet even brevity must not suppress the fact that among the original colonists of New Haven, the real progenitors of Yale College, were three broad-minded men of education—John Davenport, a student of Oxford and a minister in London; Theophilus Eaton, the King's ambassador at the Court of Denmark; and Edward Hopkins, a merchant of enterprise and fortune, and earliest benefactor of American learning. Their successors also, the men of 1701, James Pierpont at the front, were worthy exponents of the ideas they had inherited; they were the wisest, broadest and most learned men of this region in that day. Liberal ideas were then in the advance and, thank God, are not yet in the background.

New England brought from Old England the customs, the studies, the graduates of Oxford and Cambridge, not those of Scotland or France or Germany. The exotic

germs were nurtured by Harvard for more than sixty years before the times were ripe for a second college in this region. Harvard instructors, laws, courses, phrases, were then adopted by the Collegiate School of Connecticut, and our alma mater began her life as a child of the new Cambridge and a grandchild of the old. 'Harvard has nourished Yale eighty years kindly ordered in Providence,' are the words of President Stiles. Yale has never ceased to be grateful for this noble ancestry, nor broken the chain of historic continuity. Yale does not forget that an honorable pedigree is its priceless possession, and delights to-day to honor its ancestry.

The seventeenth century was not the most brilliant period of university education in the mother country. The functions of universities had been usurped by colleges. Their scope was restricted; their regulations rigid and petty. Science and letters were subordinate to logic and grammar, and the maintenance of orthodoxy. Nevertheless, the new school made the best of it—and while still without a fixed habitation or a name, acquired both influence and reputation. It began with books, not bricks; with teachers, the best that could be had; and with ideas in respect to intellectual discipline which soon bore fruit in the service of Church and State.

The division between our first and second centuries, corresponding with the eighteenth and nineteenth centuries of our era, is not simply determined by the calendar. There are two periods to be considered as well as two centuries, each deriving its characteristics from the spirit of the age. The first of these, our forefathers went through the good old colony times of dependence upon England; the Revolution; the establishment of constitutional government; and the enlargement of national life and hope. It was the period too when a free church was to be established in a free state, when Chris-

tianity was to be promoted without the rule of hierarchy. The business of a college was to train two sets of leaders, those who would develop and administer republican government under new conditions, and those who would be ministers of the word of God among a Christian people separated from the Establishment. For scholastic discipline the books and methods approved in the mother country and adopted in Harvard were the only instruments. Such words as letters and science were not in their vocabulary. Religion and law, or as they said, the church and state, were the dominant concerns of patriot and sage.

Days of privation, anxiety, dispute, apprehension and experiment, introduced a time of stability, prosperity and union—years of plenty after years of want—and the second century opened with courage equal to opportunities. It is true that the ideas of original research, of experiment and observation, now so familiar, were hardly perceptible, but science had begun its triumphal march, and the humanities, in a broad sense, were destined to engage more and more the attention of educated men.

In the first decade, our record of 'the noble living and the noble dead' includes the name of one who was trained by alma mater for more than provincial usefulness and fame, Dr. Jared Eliot, who like the sages of antiquity, had the cure of souls and the care of bodies. A physician as well as a presbyter, living in a country town, preaching constantly, traversing a wide district on errands of mercy, he showed the qualities of an original investigator. He could ask hard questions and proceed to search for their answers; he would make no assertions that were not based upon observation or experiment, and he submitted his conclusions, by the printing press, to the scrutiny of the world. These are his sayings: "Entering on the borders of terra

incognita I can advance not one step forward, but as experience, my only pole-star, shall direct. I am obliged to work as poor men live, from hand to mouth, and as light springs up before me, as I advance." Again: "As all theory not founded upon matter of fact and that is not the result of experience, is vague or uncertain, therefore it is with great diffidence that I have offered anything in way of theory which is only conjectural and shall always take it as a favor to be corrected and set right."

It is not too much to claim that he made the first contribution from this land of iron and gold to the science of metallurgy in a memoir entitled, 'The art of making very good if not the best iron from black sea sand'; and he was a century or more in advance of his times in the promotion of scientific agriculture, as any one may see by looking up the six tracts, which he published in quick succession, and afterwards collected in a volume, on 'Field Husbandry in New England.' His science did not drown his humor, and he has left this short biography of his laboratory assistant, who was skeptical about results and needed stimulus: "He being a sober man (says Eliot) who could use strong drink with moderation and temperance, I promised him if he could produce a bar of iron from the sand, I would send him a bottle of rum." Such in colonial days was the spirit that promoted research.

No wonder that Benjamin Franklin found Eliot out and wrote him affectionately, "I remember with pleasure the cheerful hours I enjoyed last winter in your company, and I would with all my heart give any ten of the thick old folios that stand on the shelves before me, for a little book of the stories you then told with so much propriety and humor." Poor Richard, when he ranked ten folios below the wit and wisdom of his friend in Guilford, paid a compliment to the collegiate school of Connec-

ticut, but he had not in mind the folios with which the college was founded.

If it be true that Eliot was chosen a member of the Royal Society of London, the distinction is very great, for only David Humphreys, among Yalensians, had the like honor before the recent triumvirate, Dana, Newton and Gibbs.

Of Jonathan Edwards, the philosopher and theologian, I have no right to speak, but he must not be exiled from men of letters, especially since it is customary in recent years to call him by the name of one of the most illustrious of epic poets. His contemporaries placed no limits on their praise, and even wrote on his tombstone *Secundus nemini mortalium*, thus transcending the well-known Florentian epitaph, *nulli aetatis suae comparandus*.

His grandson, with pardonable atavism, declares that he

in one little life the Gospel more
Disclosed, than all earth's myriads kened before,
and then, alarmed by his own eulogy, he
adds, "The reader will consider this propo-
sition as poetically strong, but not as
literally accurate."

Edwards may be called a poet suppressed. His writings are often noteworthy for the graceful language in which refined thoughts have expression, and although no rhymes or verses of his are extant, some passages have a Miltonic ring. The most orthodox among us may hazard the opinion that his visions of the future state are fitly classified as works of the imagination.

Many years ago this extraordinary man was likened by Dr. Samuel Osgood, of New York, to Dante, and this comparison has been recently amplified in two brilliant addresses by Dr. Allen and Dr. Gordon in the commemoration of Edwards at Northampton, a century and a half after his banishment. A cooler critic has called him a great glacial boulder, one of the two huge literary boulders deposited in New England

thought by the receding ice of the eighteenth century. These striking terms may excite a smile, but they are not uttered carelessly, nor are they misfit. The logic of Edwards is like a rock, fixed as those masses of stone upon yonder hill where the regicides took refuge, hard to move and not easily broken up. Cotton Mather was his fellow traveler upon the ice fields which once covered New England, leaving scratches and furrows on many an eminence.

It is pleasanter to think of the flaming preacher as the Dante of New England. His language often glows with fire; his words burn; his fancy carries him to the borders of the Inferno and to the gates of Paradise. Nor is this all we can say. Our Dante had his Beatrice, and the words in which he speaks of her may well be placed in a parallel with that which narrates the love of the Italian for the daughter of Folco. Hear the earliest record that has come down to us of Dante's precocious and enduring love. "She was perhaps eight years old, very comely for her age and very gentle and pleasing in her actions, with ways and words more serious and modest than her youth required; and besides this, with features very delicate and well formed, and further so full of beauty and of sweet winsomeness that she was declared by many to be like an angel." "Although a mere boy, Dante received her sweet image in his heart with such appreciation that from that day forward it never departed thence while he lived."

Four centuries after Dante, Jonathan Edwards made this note in respect to the New England maiden of fourteen years, who became his wife. "They say there is a young lady in New Haven who is beloved by that Great Being who made and rules the world, and that there are certain seasons in which the Great Being comes to her and fills her mind with exceeding great delight. * * * She is of a wonderful sweetness,

calmness and universal benevolence, especially after this Great God has manifested Himself to her mind. She will sometimes go about from place to place, singing sweetly, and seems to be always full of joy and pleasure, and no one knows for what. She loves to be alone, walking in the fields and groves, and seems to have some One invisible always conversing with her."

Dante and Edwards alike in love, alike in their spiritual fervor, and in their impressive imagery, were alike in exile—both were driven from their homes, both died among strangers, both have been honored with increasing reverence by the descendants of those who rejected them.

In his youth Edwards showed a noteworthy proclivity toward the study of nature. An article is extant which he wrote at the age of twelve, recording his observations upon spiders and displaying the same qualities as those of Lubbock and Maeterlinck. Moreover, his undergraduate notebook gives evidence that his mind was alert for knowledge in other fields, and that he could ask searching questions in physics, including electricity, meteorology, physical geography and vegetation. One who was familiar with these precocious memoranda remarks that if they were written, as supposed, between the ages of fourteen and sixteen, 'they indicate an intellectual prodigy which has no parallel.' If he had been taught to use the lens and the meter as he used the lamp, he might have stood among the great interpreters of nature—the precursor of Franklin, Rumford and Rowland.

He was nurtured by theological dialectics, and he excelled not in physics, but in metaphysics, so to-day instead of honoring him as a leader in literature or science, we can only acknowledge with filial reverence, his wonderful influence upon the opinions and characters of six generations. The laws of intellectual inheritance are obscure, and the

influences he has handed down cannot be measured. It is, however, noteworthy that three of his descendants occupied the presidential chair of Yale for nearly sixty years, many others have been among our teachers; indeed there are few years in our second century in which the faculty has not included one or more of his posterity. I have read the printed verses of seven of his descendants—no small part colored (may I be pardoned for saying so) with the cerulean hue of religious fervor.

It is interesting to dwell upon the names of Edwards and Eliot as men of more than provincial fame, because the number of Yalensians who can be regarded as contributors to literature and science prior to the Revolution is small. The historian, Tyler, has taken the year 1765 as the close of the sterile period, when colonial isolation was ended and American literature began to be worthy of the name. Before that time neither Harvard nor any of the other colleges has much to speak of; yet afterwards, until the close of the eighteenth century, the product is almost as scanty. A recent paper enumerates the texts by which the youthful minds were disciplined.* Although the manuals and the methods were not inspiring, they encouraged discrimination and that power which used to be called ratiocination, 'generation of judgments from others actually in our understanding.' You may say that this is not 'experimental science nor literary culture,' and you say well. The ore, indeed, may have been extracted by the Eliot process, from black sand, but the Bessemer process had not been invented for turning iron into steel; nevertheless, we have the assurance of a recent Massachusetts critic,† that the highest literary activity of the later eighteenth century had its origin at Yale College.

* By Professor Schwab.

† Barrett Wendell.

Our elder brethren of the eighteenth century, with whom most of us have no more acquaintance that we get from the hortus siccus of a biographical dictionary, were men quite as intellectual as men of our day. When their acquaintance is cultivated and when the minute incidents of their lives and their quaint characteristics are sought out, they are as interesting as our contemporaries. Let us cease to regard them as mummies. The story of Manasseh Cutler is a succession of romantic incidents. Bishop Berkeley's transitory interest in the college and his permanent influence upon it is a captivating record. Jeremiah Dummer, little more than a name to most of us, was called by Charles Chauncey one of the three greatest New Englanders. The story of Liberty Hall, where William Livingston lived with his charming family of daughters, might be commended as the basis of a novel to the author of Hugh Wynne. Rector Clap, the fighting rector, led a life full of racy incidents, and certainly we have no more picturesque character on the roll than Dr. Stiles, now reintroduced by Professor Dexter to the society of which he was once a distinguished ornament—that extraordinary polyhistor to whom all knowledge was attractive, all tongues appetizing and all events pregnant.

As we recall the writers of influence and distinction among our brethren, we cannot fail to observe the dominant religious spirit which most of them show, and it may be well at the outset to remind you that the identity of theology and poetry is not peculiar to New England. The earliest biographer of Dante declared that 'theology was nothing else than the poetry of God.' 'Not only is poetry theology, but theology is poetry,' says Boccaccio, and then he adds that if these words of his merit but little faith, 'the reader may rely on Aristotle, who affirms that he had found that poets were the first theologians.' Judged by this

standard, we might find a good deal of poetry in our Yalensian products, during the eighteenth century, but by the criteria of modern scholarship, not much that would be commended by Matthew Arnold, not much that our own anthologist would cull for preservation.

Before the middle of our first century there appeared in New York a volume containing seven hundred lines of verse, entitled 'Philosophical Solitude; or the choice of a rural life: by a gentleman educated at Yale College.' This anonymity did not long conceal the authorship of William Livingston, one of the brightest students of his time, distinguished in many ways—once as 'the Presbyterian lawyer,' and later as Governor of New Jersey and member of the Constitutional Convention. His brother, also a Yalensian, was a signer of the Declaration. The verses show the influence of Pope, and among other points of interest in them, are allusions to the writers whom this young graduate desired for his intimate friends in the rural life he intended to lead.

In the Revolutionary War, two of our brethren, while acting as chaplains, were composers of patriotic songs. Many years later, the inspiration of the muses descended upon a number of recent graduates, who became known as 'the Hartford wits,'—'four bards with Scripture names,' John, Joel, David and Lemuel, any one of whom could produce an epic as surely, if not as quickly, as the writer of to-day would compose an article for the *Yale Review*. The group included John Trumbull, a precocious youth fitted for college at the age of seven, whose burlesque treatment of the Revolutionary war called 'McFingal,' ran through thirty unauthorized editions; the versatile Joel Barlow, author of 'Hasty Pudding,' who worked for half his life, we are told, upon the 'Columbiad,' having in the interval of his engagements adapted Watts's Psalms to the use of Connecticut churches

and added several original hymns; David Humphreys, who translated a French tragedy, entitled the 'Widow of Malabar,' and composed several ambitious poems; and finally, Lemuel Hopkins, an honorary graduate. The Harvard historian whom I have already quoted has said that at the time the Hartford wit wrote, no Harvard man had produced literature half as good as theirs.

Perhaps one may, without offence, at this late day, refer to the ponderosity of this early poetry. 'McFingal' and 'Hasty Pudding' and the 'Progress of Dulness' would hardly be found amusing in these days, although they were mirthful. 'Greenfield Hill' is hard reading. The seriousness of such subjects as the 'Conquest of Canaan,' the 'Vision of Columbus,' the 'Anarchiad,' and 'The Last Judgment, a Vision,' was characteristic of the times and was adequately sustained by the serious treatment to which these themes were subjected. Indeed, in this period, lofty ideals were entertained, and long and elaborate poems were so naturally attempted that a commencement orator (as late as 1826) delivered a discourse on 'some of the considerations which should influence an epic or a tragic writer in the choice of an era.' The spirit of Hebrew poetry hovered over our elms, more constant than Calliope or Euterpe. It suggested dramas, which have died, it found expression in hymns, which have lived. I could name five of these. Brethren, answer the question of Emerson—

Have you eyes to find the five
Which five hundred did survive?

At the beginning of our second century we come upon the name of John Pierpont, preacher, patriot, advocate of every cause which would improve his fellow men, whose verses are at the front of two recent anthologies. Bryant just missed enrolment among us. He took a dismissal from Williams in

order to enter Yale, but he did not fulfil his purpose. Fitzgreen Halleck, a native of this county, did not go to any college. Not long after Pierpont, the two Hillhouses were graduated. The elder, James, was author of 'Percy's Masque' and three other dramas, the last of which, entitled 'The Judgment, a Vision,' was intended (says the author) to present 'such a view of the last grand spectacle as seemed most susceptible of poetical embellishment.' He was a gifted writer of fine taste and lofty ideals; and his writings were most highly esteemed by the generation to which he belonged. His name is dear to us as the poet of Sachem's wood, the beautiful park at the head of Hillhouse Avenue—the park and the avenue alike commemorating his distinguished father, to whom the city of Elms is beyond estimate indebted. For East Rock and West Rock he suggested the names of 'Sassacus' and 'Regicide.'

Later came Brainard, cut down in his youth, and brought to life at the call of Whittier; and William Crosswell, son of the rector of Trinity Church, one of the most cultivated of churchmen, whose poems, ten years after he died, were edited by Bishop Coxe. In the class of 1820 were two men whom we honor for so many other reasons that we forget their poetry—Woolsey and Bacon. As the first quarter of the century closed, the college diploma was given to James G. Percival, that unique, eccentric, impracticable combination of science and literature, learned to superfluity, versatile to inconstancy, loving nature, books, words, yet disliking men as he met them; geographer, geologist, linguist, lexicographer, poet, with much of the distinction and a fair amount of the infelicity which characterizes genius. His metrical studies are remarkable illustrations of the Laws of Verse. Next came N. P. Willis, graceful in prose and verse, remembered by some for his Biblical lyrics, and by others

for lines in praise of New Haven elms; and soon, Ray Palmer, whose sacred song has been translated into twenty languages, and sung in Arabic, Tamil, Tahitian, Mabratta and Chinese, as well as in the tongues of Christendom. George H. Colton, one of a family that has cultivated the muses, published a poem on Tecumseh soon after he graduated in 1840. Twenty years later came Weeks and Sill—Weeks who died before he had stretched his wings for the flights of which he was capable; and Sill, bright and beloved Sill, whose verses, collected since his death, exhibit as do his essays and letters, an intellect strong, unconventional and suggestive. These are not all the departed whom we may hold in honorable remembrance.

It is no part of my plan to say much about the living, but there are two writers entitled to special mention—Finch, the author of stanzas which have brightened the fame of Nathan Hale; and Stedman, anthologist and historian of Victorian poetry, the poet of yesterday and to-morrow, the youth who won his laurels as an undergraduate writer in the *Yale Literary Magazine*; the singer who wears them still upon his frosty brow.

The comparison has been made between the graduates of Harvard and of Yale, and the long and brilliant list of historians and poets of Cambridge has been contrasted with the shorter and less famous list of New Haven. Our friends at heart will doubtless attribute something, as is their wont, to the proximity of Boston, a beacon set upon the hill, a port of entry for the culture of other lands, where the Athenæum, still foremost among the society libraries of the United States, was an inspiring resort, close akin to the London Library, giving to men of letters both sustenance and stimulant. It is however, probable that the difference between the two colleges is due to the fact that in Eastern Massachusetts during the last century

dogmatic theology has been neglected and the ablest intellects have been free to engage in literary production. Perhaps this is true. I do not know. We may claim this, however, without making any comparison, that Yalensians from the beginning were brought up in obedience to 'Duty, stern daughter of the voice of God'; that the College was founded for the fitting of men to serve the church and state, and that the graduates of Yale, whether famous or unknown, are devoted to the service of their country and show that they have been trained to think, to reason, to write and to speak with freedom and with force. We can every one of us recall classmates and friends, men we have heard and men we have heard of, who have been like village Hampdens, or mute inglorious Miltons; and we can also recall those who have shown, at the bar and on the bench, in the cabinet and in diplomacy those qualities which under other conditions would have made them orators and authors. The point I make is this, that the Yale training has tended to the development of strength rather than of grace. "I thank God" said a famous preacher who studied in both places, "that I struck no literary roots at Yale and no theological roots at Harvard." "I thank God too," said one of his teachers at New Haven.

It is certainly true that hundreds of the graduates of Yale have been accurate and forcible writers, who have known what to say and how to say it; and that they have in this way rendered an incalculable service to the country, far and wide, even though we admit that, under the pressure of strenuous life, but few of them have shown those literary qualities which are usually evoked where writers and critics come in close relation to one another, as they do in cities and in large universities. Long ago, Bishop Fraser said of the United States, that the people were the most generally edu-

cated, if not the most highly educated, people in the world. Something like this we may say of the Yale alumni—if they number few men of genius, they number many men of talents, usefulness and power; if there are none who are equal to Tennyson and Schiller and Victor Hugo, there are many who have been the advocates of truth and the promoters of social reform, in terse and vigorous English. They have excelled in the pulpit and at the bar, and in the halls of legislation, so that without mentioning the names of men whom we have personally known, I will remind you of that long line of jurists and statesmen who were living near the beginning of our second century, William Samuel Johnson, Pelatiah Webster, John C. Calhoun, James Kent, Jeremiah Mason, and that constellation of New England theologians, an innumerable host, from Edwards to Taylor.

Professor Kingsley was called the Addison of America, and he had such wit, knowledge and grace as might have given him distinction in literary composition if he had so directed his energy; but he was one of those 'generally useful men' that this college produces, who held at one time what we should call four chairs. We should all be proud to claim as the product of our alma mater James Fenimore Cooper, but we cannot, for like Shelley from Oxford, he was driven out because of a boyish misdemeanor. Professor Kingsley once told me this story: The novelist Cooper, Judge Kane, of Philadelphia, and Hon. John C. Spencer, of New York met at a dinner. 'Where were you educated?' said one. 'I had the honor of being turned out of Yale College,' was the reply. 'And so did I,' said the second; and 'I had the same honor,' said the third. *Hæc fabula docet* that boyish liveliness is not always fatal to mature success. If we cannot claim Cooper, Theodore Winthrop is ours—the essayist and novelist, whose posthumous

fame shows what was lost to letters when he died a patriot's death upon the field of battle.

Lounsbury says that Cooper left Yale with little learning in his head and then he wittily adds, "No one will doubt this who has learned to view with profoundest respect the infinite capability of the human mind to resist the introduction of knowledge."

In the second quarter of the nineteenth century the influence of Coleridge is apparent. William Adams, Horace Bushnell, Lyman Atwater, William Watson Andrews and Noah Porter are conspicuous examples of this infusion of idealism. Their writings are in evidence. The powerful imagination which produced 'The Ancient Mariner' and 'Christabel' had been directed to the transcendent study of the Infinite, and many who turned away from the most rigid tenets of Calvin, and from the literal interpretation of the Old Testament, were strengthened and guided by the philosopher of Highgate. Bushnell confessed greater indebtedness to the 'Aids to Reflection' than to any other book—save the Bible. Of the theological emancipator, I am not called upon to speak—of the gifted writer more than passing mention must be made. His sermons, addresses and essays always arrested the attention and excited the imagination of those who heard and those who read them. For example, his estimate of Connecticut, his 'Age of Homespun,' indeed all the contents of his 'Work and Play,' and many parts of 'Nature and the Supernatural,' glow with life and fancy, and will be as good reading for our grandchildren as they were for our fathers. The incisive notes of his voice as I first heard it when an undergraduate, still ring in my ears—and his racy sentences, his inspiring and suggestive phrases, and the eloquence of his thoughts were even more impressive than his voice. The name of Horace Bushnell

is a precious heirloom handed down from the Yale of the last century to the Yale of the present. He was an orator, a poet, a lover of nature, and of man—fearless, original, persuasive, too liberal for the conservatives, too conservative for the liberals of that day, now honored in both their schools. Horace Bushnell is the greatest of this group. Indeed I should place him, in genius, next to Jonathan Edwards.

Not a few of our brethren have excelled in historical writing. Stiles wrote a history of the exiled Judges, and Benjamin Trumbull the history of Connecticut; Samuel Farmer Jarvis was designated historiographer of the Episcopal Church; Moses Coit Tyler is the historian of American literature; Andrew D. White is the defender of science versus bigotry, whose history should make us grateful that Yale has been one of the most important American agencies for the emancipation of the human intellect from ignorance and dogmatism; Charles L. Brice is the exponent of Gesta Christi; George P. Fisher, an honored member of the faculty for almost fifty years, stands in the foremost rank among the ecclesiastical historians of this country, and Leonard Bacon, the Puritan, always remarkable for clearness and vigor, whether religion or politics was his theme, is the author of discourses on the early days of New Haven, which remain unsurpassed in the field of local history. He was like a modern Isaiah, the trenchant defender of political righteousness. Stillé's pamphlet, 'How a Free People conduct a Long War,' was one of the most inspiring products of the uprising for the Union; and Schuyler's studies in Turkistan and his essays in diplomacy are enduring memorials of another 'all round man,' observer, critic, traveler, essayist, historian, diplomatist—good in whatever he undertook.

Comparative philology was introduced among us by Josiah W. Gibbs, but the

chief impulse in this direction came from Salisbury, the first to teach Sanskrit in America. He recognized the ability and secured the services of one who was not a graduate, it is true, but an adopted son, whose honors are our honors, whose fame carries the name of Yale to every university of the Indo-European world, that illustrious scholar, William D. Whitney. We must remember that James Murdock in 1851 published a translation of the Peshito Syriac version of the New Testament; that Moses Stuart at an earlier day carried from New Haven to Andover, an enthusiastic, if not always accurate, devotion to Biblical literature; and that a learned and devoted scholar, Eli Smith, within sight of Mt. Lebanon, translated nearly all the Bible into Arabic, as in later days Hiram Bingham translated it into one of the languages of the Pacific Ocean.

Another interesting phase of philological study is shown in the attention given to the study of the languages of the North American Indians. This began very early, when Sargent, Brainard, Spencer and Edwards were engaged as missionaries to the aborigines in Western Massachusetts and in Central New York. The philological importance of the American speech was recognized in recent days by James Hammond Trumbull, who with rare aptitudes for the elucidation of knotty problems, directed his attention to the Indian languages of the Eastern States, and was soon acknowledged as foremost in that uninviting and perplexing field of inquiry. Before long we shall have his lexicon of the Natick Speech, so that he who will may cultivate the love of comparative literature by reading Eliot's Indian Bible. Daniel G. Brinton in other branches of aboriginal research has also won renown.

An unusual manifestation of the love of letters is shown by the attention given during the last century to lexicography. For

a time Yale was a veritable storm-center. Webster versus Worcester, and Worcester versus Webster were chieftains in this 'Battle of the Books,' and both authorities were graduates of Yale. Lately, Whitney, W. the Third, has taken rank with the best antecedents, and a score of cooperative Yalensians, many of them specialists, have been engaged in the improvement of the three great dictionaries. It is customary to laugh at the changes in spelling proposed by Noah Webster, and certainly some of the Johnsonese definitions which he propounded were mirth-provoking—('sauce,' for example)—but revised and improved by Goodrich, Porter, Kingsley and others, his dictionary holds its own. Its popularity was due in part, no doubt, to Webster's spelling book, of which the annual sale at one time was twelve hundred thousand copies. By this primer a very great service was rendered to letters—for it helped to counteract any tendency toward provincial or dialectic peculiarities among the heterogeneous people of the United States.

Apart from theology, philosophy has engaged the attention of many of our ablest brethren. This is especially true of the time since Porter was called to the professorship which he held with conspicuous distinction for almost half a century, including the years of his presidency. A recent investigator has traced the influence of this able teacher, well versed in the modern writers of Germany, who made metaphysics interesting to those who were indifferent, and at his best in the analysis of conflicting theories and in the detection of subtle errors. As a lawyer for the defense, he would have been the peer of Rufus Choate. Not a few of his pupils have been led through philosophy to pedagogics and are winning distinction in this field.

This review would be incomplete if I did not mention the *Yale Literary Magazine*,

which for more than three score years has kept up the love of literature among the undergraduates, and has furnished them with appreciative readers, critical enough and friendly enough for discipline. Many editorial writers have been trained by their service on this magazine, since Evarts set the press in motion. Older Yalensians have had their opportunities in magazines of wider circulation, the *Christian Spectator*, the *New Englander* and the *Yale Review*, not officially connected with the college, but supported by the faculty.

The literary societies also, which for more than a century were maintained with vigor, seem to me to have been one of the very best agencies for youthful discipline. The spontaneous efforts of young men, excited by the emulation of their comrades, and controlled by the friendly criticism of their peers, were admirable exercises for the development of the love of poetry, oratory, essay writing and debate.

One of the greatest services which this college has rendered to literature and science has been the preparation of an innumerable host of teachers and professors. The list is too long for recapitulation here—but a few names must be recalled. The earliest was Jonathan Dickinson, first president of Princeton, deemed in his time the peer of Edwards, whose immediate successors were likewise Yalensians. Next came Samuel Johnson, the friend of Berkeley, first president of Columbia University, elected president of the University of Pennsylvania, and his more famous son, William Samuel Johnson, who succeeded to the presidency of Columbia, and stood in the first rank among the statesmen of the period just subsequent to the Revolution. From the Wheelocks, of Dartmouth to Sturtevant, of Illinois, Chauvenet, of St. Louis, and Chapin, of Beloit, the file leaders in our colleges have constantly been elected from Yale. At a recent date lived Thomas H. Gallaudet,

pioneer in the instruction of deaf mutes, and Henry Barnard, ever to be associated with Horace Mann, as advocate, expounder and promoter of the American system of common schools. Nor can I forget Henry Durant, and the other graduates of this college, who went to the Pacific coast, 'with college on the brain,' and planted in California the seeds of learning which now bear harvests of golden grain. A happy thought gave the name of Berkeley to the site near the Golden Gate, where an institution begun by our brothers fulfils the remarkable prophecies of Timothy Dwight, written in 1794 :

All hail ! Thou Western World ! by heaven designed

The example bright to renovate mankind !
Soon shall thy sons across the mainland roam
And claim on fair Pacific's shore a home.

Where marshes teemed with death, shall meads unfold,

Untrodden cliffs resign their stores of gold.

Where slept perennial night, shall science rise,
And new-born Oxfords cheer the evening skies !

Let us turn from letters to science. As I scan the administrative records, from the beginning onward, with the aid of our right well beloved and trustworthy archivists, the two Kingsleys and Dexter, when the scepter passes from one president to another, the balance is kept true. Pierson was an exponent of geometry and a defender of the faith, who wrote out lectures upon physics, and dictated them to successive classes ; Cutler's short service gives little indication of his attitude ; Williams loved public life more than academic perplexities ; Clap was a writer on ethical and astronomical subjects, a student of the Bible, scarcely equalled, says his successor, in mathematics and physics by any man in America ; Daggett, extremely orthodox, was scientific enough to warn his townsmen, scared by 'the Dark Day,' not to be alarmed nor 'inspired to prophesy any future events—till they should come to pass' ; Stiles was familiar with

every department of learning, 'theology, literature, science, whatever could interest an inquisitive mind * * * he included among the subjects of his investigations' ; * the elder Dwight is well known for the impulse that he gave to the expansion of the college in all directions ; the judicious Day was the author of a metaphysical study and of mathematical text-books ; Woolsey is distinguished as the promoter of classical literature, and at the same time as the president under whom the School of Science was developed ; Porter and the younger Dwight brought the University forward to its present comprehensiveness and influence in all branches of knowledge. Indeed, science and letters have always been the care of the corporation, and such will be the care while the helm is held by the discerning and vigorous pilot under whom the bark begins another voyage and so long as the alumni crew support the master and the mates.

Considering the hesitation with which the English universities recognized the study of nature as their concern, and how easy it is to awaken hostilities between the students of science and letters, or between ecclesiastics and naturalists, it is well to remember how early science came into the Yale curriculum, and how steadily it has held its place. A chair of mathematics, physics and astronomy was instituted thirty years before the professorship of ancient languages. As it is pleasant to associate the name of Sir Isaac Newton with the beginning of our library, it is likewise pleasant to remember Benjamin Franklin as a donor of scientific apparatus. 'Immortalis Franklinus' he was called by Stiles.

Before the college was fifty years old he became its valued friend, and was enrolled among the laureati in 1753. Four years previous, he had sent here an electrical

* J. L. Kingsley.

machine which enabled the young tutor, Ezra Stiles, to perform the first electrical experiments tried in New England. A Fahrenheit thermometer was a subsequent gift, and his influence led the University of Edinburgh to confer upon Stiles a Doctor's degree.

At the dawn of scientific activity in New England we see the commanding and attractive figure of our elder brother, Manasseh Cutler, storekeeper, lawyer, soldier, statesman, pastor, preacher, physician and naturalist, member of the Legislature and of Congress, appointed to the federal bench, advocate of the 'homestead' policy, and a pioneer among the settlers of the wilderness of Ohio. His greatest distinction is the part that he took in drafting and passing the ordinance of 1787, by which slavery was excluded from the Northwest Territory and a grant of the public domain was secured for the promotion of education. That is a record to be proud of, brethren of the Alumni, but it does not include the whole story. Cutler, a man of the true scientific spirit, an observer of the heavens above and of the earth beneath, is the father of New England botany. He made a noteworthy contribution to the memoirs of the American Academy, collected and described between three and four hundred plants of New England, and left seven volumes of manuscript notes, which are now in the Harvard herbarium, awaiting the editorial care of a botanical antiquary. Franklin and Jefferson valued him as a friend, and his correspondents in Europe were among the chief naturalists of the day.

About the beginning of the nineteenth century, Dwight and his three professors, who only uttered *sotto voce* the word university (though Stiles had written it in 1784), lest they should be regarded as pretenders, introduced a new era in which the progress has been constant and of increasing rapidity. In this new era, classical studies have been

promoted by Kingsley, the lover of antiquity, whose keen sword defended the study of classics; Woolsey, the lover of letters, who introduced to us Plato and the dramatists of Greece; Thacher, the lover of students; Hadley, the lover of lore; Packard, the lover of learning—and by the accomplished standard bearers still living; and science likewise had its skilled promoters: Silliman, leader in chemistry, mineralogy and geology, the alluring teacher, the captivating lecturer, unsurpassed by any, equalled only by Agassiz; Olmsted, the patient, inventive instructor, whose impulses toward original investigation were not supported by his opportunities; Loomis, interpreter of the law of storms and master of the whirlwind; Dana, the oceanographer, [who wore the tiara of three sciences; Newton, devoted to abstract thought, who revealed the mysteries of meteoric showers and their relation to comets, not before suggested; and Marsh, the inland explorer, whose discoveries had an important bearing on the doctrine of evolution—these all with the brilliant corps of the Sheffield Scientific School were men of rare ability who expounded and illustrated the laws of nature with such clearness and force that the graduates of Yale are everywhere to be counted as for certain the promoters of science.

Two agencies are conspicuous in the retrospective of this second era, the *American Journal of Science*, and the Sheffield Scientific School. Benjamin Silliman showed great sagacity when he perceived, in 1818, the importance of publication, and established of his own motion, on a plan that is still maintained, a repository of scientific papers, which through its long history has been recognized both in Europe and in the United States, as comprehensive and accurate; a just and sympathetic recorder of original work; a fair critic of domestic and foreign researches; and a constant promo-

ter of experiment and observation. It is a unique history. For more than eighty years this journal has been edited and published by members of a single family—three generations of them—with unrequited sacrifices, unquestioned authority, unparalleled success. In the profit and loss account, it appears that the college has never contributed to the financial support, but it has itself gained reputation from the fact that throughout the world of science Silliman and Dana, successive editors from the first volume have been known as members of the faculty of Yale. I am sure that no periodical, I am not sure that any academy or university in the land has had as strong an influence upon science as the *American Journal*.

A century has nearly passed since Benjamin Silliman was chosen a professor and went to Scotland, there to fit himself for the duties of the chair. What a century it has been! The widespread interest among our countrymen, in geology, mineralogy and chemistry is due in no small degree to his instructions here, and to the lectures that he delivered in every city between Boston and New Orleans.

The Sheffield school celebrated three years ago its semicentennial, and its useful services were rehearsed by one who will not venture to offer you a twice told tale. You must, however, permit him to remind you that fifty years ago the choice of studies was but timidly permitted in the traditional college, and that there was a strong demand for courses less classical, more scientific than were then offered. These wants the school supplied without antagonism or rivalry, though not without the awakening of alarm. It proved to be a rich addition to the resources and the renown of Yale, as every one admits. Its faculty was made up chiefly of men whose ideas were broad, whose distinction was acknowledged, whose methods were approved, and this, with the

munificent support of the benefactor whose name the school has been proud to bear, enabled Yale to stand forth as the ready, wise and resolute promoter of education in science. The alumni of the school are the proofs of its success.

Agricultural science in the United States owes much to the influences which have gone out from the Sheffield School. John P. Norton, John A. Porter, Samuel W. Johnson, William H. Brewer, each in his own peculiar way, has rendered much service. Johnson is preëminent, and in addition to his standing as a chemist, is honored as one of the first and most persuasive advocates of the experimental stations now maintained, with the aid of the Government, in every part of the country. We cannot forget the value of 'the crops'—we may forget how much their value has been enhanced by the quiet, inconspicuous, patient and acute observations of such men as those whom I have named, the men behind the men who stand behind the plow. They are the followers in our generation of Jared Eliot, the colonial advocate of agricultural science.

In the thirties there was an informal association which may be called a voluntary syndicate for the study of astronomy. Its members were young men of talents, enthusiasm and genuine desire to advance the bounds of human knowledge, but their time was absorbed by various vocations, and their apparatus seems lamentably inadequate in these days of Lick and Yerkes, of spectroscopes, heliometers and photography. Yet we may truly claim that the example and success of these Yale brethren initiated that zeal for astronomical research which distinguishes our countrymen.

The Clark telescope, acquired in 1830, was an excellent glass, though badly mounted, and was then unsurpassed in the United States. One of its earliest and noteworthy

revelations was the appearance of Halley's comet, which was observed, from the tower in the Athenæum, weeks before the news arrived of its having been seen in Europe. This gave an impulse to observatory projects in Cambridge and Philadelphia, and college after college soon emulated the example of Yale by establishing observatories in embryo, for the study of the heavens. The most brilliant luminary in the constellation was Ebenezer Porter Mason, a genius, who died at twenty-two, having made a profound impression on his contemporaries by discoveries, observations, computations and delineations. After his death, which was lamented like that of Horrox, it was not thought an exaggeration to compare his powers with those of Sir William Herschel—or even of Galileo. Under the leadership of Olmsted, Herrick, Bradley, Loomis and Hamilton L. Smith were associate observers, and they were afterwards reinforced by Twining, Lyman and Newton. Chauvenet became a writer and teacher of renown, and Stoddard carried to the Nestorians the telescope that he had made at Yale under the syndicate's influence.

The investigations of these astronomers were directed to the aurora borealis, the zodiacal light, the recurrence of comets, the meteoric showers, and the possible existence of an intra-mercurial planet. Newton became the most distinguished of the group. Partly by antiquarian researches in the records of the past, continuing the notes of Herrick, partly by mathematical analysis and a careful comparison of the paths of meteors he determined the periodicity of these mysterious and fascinating phenomena, and their relation to comets.

The astronomical syndicate of Olmsted and his pupils was long ago dissolved, but its spirit hovers near us, and beyond Sachem's wood, in the Winchester Observatory, skilled astronomers with their great heliometer are engaged upon problems

which were not even thought of by the discerning intellect of Mason and his brilliant confreres.

In the science of mineralogy Yale has long maintained the American leadership. Every one of us has heard the story of the candle-box of specimens, which Silliman carried to Philadelphia to be named, and every one of us has seen the subsequent accretions to the nucleus, beginning with the Gibbs cabinet, now shown in the Peabody Museum. No one is likely to overestimate the influence of this collection upon the mind of James D. Dana, nor to overestimate the value of his treatise on mineralogy which, revised and enlarged by able cooperators, continues to be a standard text-book in every country where mineralogy is studied.

In view of its recent acquisition, I am tempted to speak of the Museum as the 'House of the Dinosaur.' Its choice collections give an epitome of the sciences of mineralogy, crystallography, meteoroids, geology, paleontology and natural history, from the days of Silliman to those of the Danas, Brush, Marsh and Verrill.

The heart of a university is its library. If that is vigorous, every part of the body is benefited. Our college began with books; the incunabula were given by the founders, good books no doubt, if not a single volume relating to classical literature or the sciences was among them. Noteworthy accessions came at an early day, some of them from Elihu Yale. Think of eight hundred volumes sent from England, including the gifts of many famous writers. Remember such donors as Sir Richard Steele, of the *Spectator*, and the great Sir Isaac Newton, and then be grateful to forgotten Jeremiah Dummer, who collected and forwarded this precious invoice. Fifteen years later than Dummer's donation came nine hundred volumes from Bishop Berkeley, which with his bequest for scholarships and prizes, entitle him to receive the highest praise as

an early and liberal promoter of the humanities. Renewed homage should now be given to the benefactor whose timely and catholic bounty enriched this adolescent college. Therefore, let us repeat once more the verse of Alexander Pope and ascribe 'to Berkeley, every virtue under heaven.' Gratitude to this great philosopher shall not diminish our acknowledgments to that long line of donors who have made the library worthy of the university which has grown up around it.

Bibliographers and librarians are the servants of the temple—*servi servorum academicæ*—and such as Edward C. Herrick, Henry Stevens, William F. Poole, and James Hammond Trumbull, are rare men, conspicuous among the promoters of historical research.

In controversial periods the attitude of Yale has been very serviceable to the advancement of truth. The Copernican cosmography was probably accepted from the beginning, although elsewhere the Ptolemaic conceptions of the universe maintained their supremacy, and the notes which Rector Pierson made on physics when he was a student in Harvard come 'between the Ptolemaic theory and the Newtonian' (Dexter). When geology became a science, its discoveries were thought to be in conflict with the teachings of the scripture. Ridicule answered the arguments of science, and opprobrium was thrown upon the students of nature. Brave Silliman stood firm in the defense of geology, and although some of the bastions on which he relied became untenable, the keep never surrendered, the flag was never lowered. When the modern conceptions of evolution were brought forward by Darwin, Wallace and their allies, when conservatists dreaded and denounced the new interpretation of the natural world, the wise and cautious utterances of Dana at first dissipated all apprehensions of danger, and then accepted

in the main the conclusions of the new biological school. The graduates who came under his influence were never frightened by chimæras. Marsh's expeditions to the Rocky Mountains, and his marvelous discoveries of ancient life, made the Peabody Museum an important repository of geological testimony to the truth of evolution.

I remember the surprise of Huxley in 1875 when, at a dinner of the X Club in London, I told him of Marsh's discovery of the fossil horse. In the following year, the great English naturalist came to New Haven to see in the Peabody Museum that of which he had heard and read. In his lectures at New York he soon described the work of Marsh, and subsequently referred to its important bearings.

Scant justice has been done in this discourse to the sciences promoted at Yale—and the deficiency is the more apparent when I think of the men now living whose work has been precluded from our scope. The next centennial discourse will do justice to them. Among the departed whose careers were made outside the walls of Yale, Percival, the geologist of Connecticut and Wisconsin; J. D. Whitney, the geologist of California; Chauvenet, the mathematician; Hubbard, the astronomer; Sullivant, the chief authority in mosses as Eaton is in ferns; F. A. P. Barnard, the accomplished president of Columbia; Eli Whitney, the inventor of the cotton-gin, and S. F. B. Morse, whose name is familiar from its relation to the electric telegraph—are especially entitled to honorable mention in this jubilee. So is a much older graduate, David Bushnell, the inventor of submarine explosives—the precursor of the modern torpedists.

There is a good deal to think about in the annals of Yale. It is not a perfect record. Deficiencies, errors, failures are met with from time to time—such as are

found in every human institution, even in those most sacred. It is not my business to seek them or point them out. It is rather my privilege to honor the good men that have built up for us and for our successors this great edifice, upon the firm foundations of devotion and faith; to admire the skill, the prudence and the honesty with which inadequate resources have been husbanded; and especially to appreciate that admirable union of conservative and progressive forces which keeps hold of that which is good until the better is reached, that believes in the study of nature and all its manifestations, and of man and all that he has achieved in language, philosophy, government, religion and the liberal arts.

This honored and reverend seminary has taught thousands of men of talent to be wise and good citizens, avoiding avarice and pretense, ready for service wherever Providence might call them, in education, philanthropy, diplomacy, statesmanship, church-work, literature and science; not a few men of genius have submitted themselves to her discipline and acknowledged the inspiration derived from her counsels; some of her sons have laid down their lives for God and their country; many have carried to the ends of the earth her precepts and principles; all, or nearly all, have been the friends and supporters of republican institutions, the lovers of sound learning and good books, the promoters of science whenever their aid was wanted, its alert defenders against bigotry and alarm, confessors of the christian doctrine.

The new order which gives to adolescence an extreme freedom in the choice of studies may be more favorable than the old to the production of men of letters, poets, orators, historians, essayists—and of investigators who will extend the bounds of mathematical, physical and natural science. Nobody can tell. Every one is hopeful. But with

all their gettings, may the new generation emulate their forebears in wisdom, self-control, sound judgment, and in hearty appreciation of all that books have recorded and all that nature has revealed.

Much reproach has been thrown upon the studies of colonial days because they were mainly directed toward theology and philosophy, and because there was so little study of the natural world. It is well to reply that nature studies are the growth of the last century, since Berzelius, Cuvier and Liebig initiated the modern methods of inquiry, carried on by Faraday, Darwin and Dana. Remember also that rigid discipline in logic and dialectics makes clear and accurate thinkers, fitted to treat the current questions of society with discrimination, perspicuity and persuasion. If our grandfathers did not excel in what we are pleased to call literature, they were taught to follow the rule of an illustrious writer, 'to use words coinciding as closely as possible with what we feel, see, think, experience, imagine and reason.' Such men were fitted to take part in the great Revolution of 1776, and in the war of 1861; to be influential in the formation of the Constitution of the United States, and in the administration of justice and order in every State of the Union, qualified likewise to lead in the organization and development of academies of science and schools of learning, defenders of the faith, upholders of right conduct, advocates of civil service reform, promoters of literature and science, and in general, trained by such discipline as they here received in mathematics, logic, history, language, philosophy and science, to be the leading men in every community where their homes were placed.

On fame's eternal camping ground
 Their silent tents are spread,
 And glory guards, with solemn round,
 The bivouac of the dead.

DANIEL C. GILMAN.

THE GLASGOW MEETING OF THE BRITISH
ASSOCIATION FOR THE ADVANCE-
MENT OF SCIENCE.

THE GEOGRAPHICAL SECTION.

THE president of the Geographical Section, Dr. H. R. Mill, took as the subject of his address the definition of the task of scientific geography and the subdivisions of the subject. In giving a brief review of the ideas of the older geographers, attention was called to an important, but well-nigh forgotten, work by Nathaniel Carpenter, fellow of Exeter College, Oxford, published 1625, under the title 'Geographie Delineated forth in two Books, containing the Spherick and Topickall parts thereof,' a work characterized by a clear appreciation of the relations of the various subdivisions of the subject and by a clear perception of the good and the bad in the work of his predecessors and contemporaries.

Dr. Mill defined geography as 'the science which deals with the forms of relief of the earth's crust, and with the influence which these forms exercise on the distribution of all other phenomena,' and he divides the subject into: (1) Mathematical geography, which regards the earth as a spinning ball lighted and warmed according to a rigid succession of diurnal changes. (2) This merges into physical geography which is concerned with the contemporary changes in the crust and in the surrounding fluid envelopes. (3) Biogeography or the geographical distribution of life, and finally (4) Anthro-geography or the relation of man to the earth's crust, a subject which must be separated for the more general third division on account of the number of exceptions it presents to the laws governing the distribution of the lower forms of animal life and on account of the exceptional powers possessed by man for modifying the conditions of the earth's surface. Viewed from this broad standpoint it is evident that enough attention has not

been paid to geography by the universities. It is true that Oxford possesses a school of geography and Cambridge has a reader in that subject, while in this country physical geography receives most able attention in a few of our great universities; but more should be done towards coordinating the various subdivisions of the subject. Nowhere can this be better done than in the universities. Viewed in the broad sense, as outlined by Dr. Mill, geography would form a discipline worthy of a place upon our college curriculums; the practical advantages to be derived from a comprehension of the materials already in hand would be great both in direct results and in suggestions for future work.

Of this last Dr. Mill's address is a proof in itself and while many of his suggestions are more especially applicable to the needs of the British Isles, still some might be profitably carried out in connection with the surveys of this country. Thus maps showing the character of the superficial soil, such as the *cartes agronomiques* of France, would be a most valuable asset in the hands of any government and the same is true of carefully collated material with reference to the rainfall and configuration of stream-beds in different sections of the country, the horse-power of the rivers and streams being eventually determined from such data as has already been done in Finland. Mention may also be made of the population maps constructed by Mr. Bosse on the plan of indicating by dots the exact distribution of the population, the usual method of estimating population by counties or states giving but imperfect ideas of the true distribution. The population map of England shows in a most remarkable manner the relation of population to the geological character and configuration of the country and a knowledge of the conditions governing distribution in any country cannot fail to be of the

greatest importance from both political and sociological standpoints.

A number of papers describing itineraries in various portions of the world were presented to the section, but reference need be made to but few of these and of the more general topics discussed a few may be briefly mentioned. Professor Ireland, in a paper on 'The Geographical Limits of Popular Government,' maintained that climatic conditions unfitted the inhabitants of tropical regions for representative government, and in these regions the administration must be placed in the hands of trained Europeans. Dr. W. G. Smith presented an account of the botanical survey of Scotland, which is at present being carried out on the basis of a modification of the plan adopted by Professor Flahault of Montpellier. The entire flora is regarded as being composed of a number of 'plant associations,' in each of which there is one or more dominant species, and the object of the survey is to map out these associations. Maps of the associations of Northern Perthshire and of an area in the vicinity of Edinburgh have already been published and the work on Fife and Forfar is ready for publication. Professor Moreno, of the Museum of La Plata, gave an interesting account of the anthropogeography of the Argentine Republic, in the course of which he took the position that the races of South America were of great antiquity and that instead of the civilizations of Peru and Bolivia coming from the north, they were in reality much older than such civilizations as that of the Pueblos.

An account of the National Antarctic Expedition organized by the Royal and the Royal Geographical Societies was given by Dr. Scott Keltie, and Mr. W. S. Bruce described the plans of an expedition which he hoped to lead next year to the Weddell Sea and which he spoke of as the Scottish National Antarctic Expedition, since the

expenses have been entirely defrayed by Scotsmen. Captain Lemaire gave an interesting account of the Belgian Scientific Expedition to Ka-Tanga, Central Africa, in 1897, and spoke in hopeful terms of the possibilities of the high plateaus of that region for European colonization, stating that all the usual European vegetables and many fruits had already been cultivated with great success. Finally, a paper by Dr. A. Lawrence Rotch, director of the Blue Hill Observatory near Boston, was presented under the title 'Exploration of the Atmosphere at Sea by Kites.' It was pointed out that on land the use of kites was possible only when the wind blew at a velocity of over twelve miles an hour, but on ships this difficulty was done away with, the motion of the vessel giving the desired velocity. The importance of some knowledge as to the height to which the trade winds extended and also as to the direction and strength of the higher currents was pointed out and the possibility of acquiring such knowledge by the use of kites was suggested.

A conference was held with the Geological and Zoological Sections for the purpose of discussing the scheme of a survey of the lakes of the British Isles which is to be carried out by Sir John Murray and Mr. Lawrence Pullar. It is intended to make a complete survey of each lake from all standpoints, bathymetrical, thermometrical, geological, botanical and zoological. Many interesting suggestions were made in the discussion which followed the reading of a letter by Sir John Murray stating the plans that he had formed for the work and a resolution was passed expressing the gratification of the Sections that such a survey was to be carried out.

THE ANTHROPOLOGICAL SECTION.

The address of the president of the Anthropological Section, Professor D. J. Cun-

ningham, of Dublin, was devoted to a consideration of the characteristics of the human brain and their significance. After pointing out the necessity for greater attention on the part of craniologists to the relations which exist between the brain and the cranium, reference was made to the discussions as to the relative development of the occipital lobe in man and apes, which enlivened the meetings of the Association forty years ago. With the knowledge we now possess it seems strange that such a discussion was ever precipitated, for not only is the occipital lobe largely developed in the ape, but it possesses even a greater development than in man. Measured along its medial border the percentage length of the lobe to the entire length of the cerebrum in the baboon, orang and man is, respectively, 29.7, 23.2 and 21.2, and even these figures do not show the full preponderance of the occipital lobe in the ape, for its anterior border extends so far forward as to overlap a portion of the parietal lobe and form an occipital operculum, a condition entirely lacking in man. Instead, then, of the preponderance of the occipital lobe being the distinguishing feature of the human brain, it is the greater relative development of the parietal, which encroaches to a certain extent upon the territory occupied in the lower forms by the occipital.

The conclusions of Rüdinger, derived from a study of the brains of a number of distinguished men, that the intellectual endowment of an individual stands in relation to the development of the upper part of the parietal lobe, Professor Cunningham believes to be entirely without foundation. Indeed, in the evolutionary development of the cerebral cortex it is the lower part of the lobe which shows the greater relative increase and has extended itself both backwards and downwards, the latter process leading to a marked depression of the Syl-

vian fissure to an extent quite foreign to the brain of any ape. And in this connection it is interesting to note that the recent studies of the brains of the astronomer Hugo Gylden and of the mathematician Sophie Kowalewsky by Retzius, of Helmholtz, by Hansemann and of the musician Rudolph Lenz by Guszman, have all revealed an apparently marked development of the cortex of the lower parietal region. Furthermore, it is an interesting fact that in the left cerebral hemisphere the Sylvian fissure is more depressed than in the right. It is well known that physiologically the left hemisphere shows a decided preeminence, to account for which various theories have been suggested. That it is due to the greater bulk or weight of the hemisphere seems to have been disproved, nor can it be held to be due to the greater complexity of the convolutions, nor to a better blood supply.

What, then, may have been the cause both of this asymmetry and of the general development of the parietal lobe. Professor Cunningham points out that in the parietal region are the centers for the arm, hand, face, throat and mouth and, to a certain extent, the motor center for speech, and the center for the facial muscles. These latter, it is true, present a greater bulk in the ape than in man, but both they and the muscles governed by the other centers named are certainly more highly differentiated and capable of performing movements of greater refinement than in the ape, and it is this very degree of refinement which determines the amount of the area covered by a cortical center, rather than the mass of the organ supplied. On this basis, then, the greater development of the parietal lobe in man is readily explained, and since it is well known that the motor center for speech is asymmetrical and on the left side, an explanation is afforded of the asymmetrical development of the lower parietal region in

the human brain. Indeed Professor Cunningham holds that the "stimulus which must have been given to general cerebral growth in the association areas by the gradual acquisition of speech can hardly be exaggerated." "Some cerebral variation—probably trifling and insignificant at the start, and yet pregnant with the most far-reaching possibilities—has in the stem-form of man contributed that condition which has rendered speech possible. This variation, strengthened and fostered by natural selection, has in the end led to the great double result of a large brain with wide and extensive association areas and articulate speech, the two results being brought about by the mutual reaction of the one process upon the other."

Of the papers presented to the Section several were on matters of local archeology, Dr. R. Munro giving an account of a 'Kitchen-midden at Elie'; Messrs. J. G. Cunningham and Thomas Ross describing respectively Roman camps at Ardoch and Delvine and Dr. Duncan and T. H. Bryce reporting on 'The Results of their Excavations in the Island of Arran' where they found a number of skulls and implements evidently belonging to a prehistoric dolichocephalic race. Of somewhat more general interest were papers by Dr. J. F. Gemmill, who described the development of the human stapes, coming to the conclusion that it arose quite independently of the periotic bone and was developed from the hyoid, though not from its most proximal portion, this giving rise to the incus; by Mr. R. A. S. Macallister, on 'The Age of the Ogham writing in Ireland,' the conclusion reached being that for the most part the inscriptions were certainly christian in origin; and by Dr. Rivers, 'On the Functions of the Maternal Uncle in Torres Straits,' showing that the wife's brother was really the head of the house, even in tribes where the descent was now paternal.

Especial interest attached to a paper by Mr. Brant Sero, a Canadian Mohawk, on 'Dekanawideh, the law-giver of the Canienghakas,' in which was given an account of the law still in use, with some modifications, among the Canienghakas or Mohawks of Canada and of which the salient principle was the establishment of a totemic council of women, who in turn elected an hereditary council composed of seven lords or masters, who made the laws and whose titles descended through the maternal line.

A report was presented by Mr. R. A. S. Macallister on the recent excavations made under the Palestine Exploration Fund, the main purpose of which had been the recovery of the city of Gath. Though the work in this direction had proved unsuccessful much material had been collected which throws light on the culture of the inhabitants of Palestine at different periods. At Tel-es-Safi, a height overlooking the valley of Elab, a building was found at the depth of 14 to 18 feet which there are reasons for regarding as one of the 'high places' mentioned in the Book of Kings.

A report was also submitted upon the results of the Cretan explorations. Excavations which were begun in 1900 have been continued at Knossus and have revealed an ancient palace which there are reasons for identifying with the traditional House of Minos. Upon the walls and floors of this were remains of a large series of frescoes among which are full-length figures of the cup-bearer, interesting as being the first known portrayal of a man of the Mycenæan age. The art remains evidence a high degree of skill and artistic perception, and several finds illustrate a close connection with ancient Egypt and Babylonia. The most striking discovery, however, is that of a series of clay tablets engraved with a linear script and demonstrating the existence in prehistoric Hellas of a system of writing antedating by about eight centuries the

earliest known Greek inscriptions, and by six or seven the first dated record of Phœnician script. In addition to the linear tablets others of a contemporary age were discovered inscribed with characters of a hieroglyphic nature, probably of an entirely different language. Excavations have also been carried on at Praseos, the capital of the ancient Eteocretans, and have yielded an inscription in Greek characters of the fifth century B. C., but composed in the Eteocretan language, and excavations at Zakro, in the extreme east of the island, revealed about 150 clay impressions of Mycænæan gems and signets, some of which throw new light on the early religion of Crete.

In connection with the meeting of the Section a pleasing incident was the formal opening of the new Anatomical Laboratory of the University of Glasgow, erected with the aid of a bequest from the trustees of the late Mr. J. B. Thompson. The chair was occupied by Lord Lister, and speeches were made by Mr. Barr in behalf of the Thompson trustees, Principal Story on behalf of the University, Sir William Turner and Professor Cleland, who has presented to the University his large collection of anatomical preparations. At the close of the speech-making the guests were entertained in the new laboratories by Professor and Mrs. Cleland and were given an opportunity of examining the arrangement of the rooms and the collections.

THE PHYSIOLOGICAL SECTION.

The opening address of the Physiological Section, delivered by the President, Professor J. G. McKendrick, was a consideration of the dilemma suggested by Clerk Maxwell in his article on the Atom in the *Encyclopædia Britannica*. The dilemma was to the effect that a germ cell cannot be structureless, yet it is too small to contain a sufficient number of molecules to account

for all the characteristics which are transmitted by it. Professor McKendrick, on making calculations based on more modern data concludes that Maxwell's estimate of the possible number of molecules in an ovum is too small and instead of containing only something like a million the fecundated ovum may start with as many as twelve million million organic molecules, a number probably sufficiently great to account for the transmission of all hereditary characters. He also suggested that since the physicists conceive of molecules as being more or less in motion, it is possible that the activities of living matter may be due to a certain *kind* of motion as yet unknown to physicists.

Sir John Burdon Sanderson described the application of the telephone to the investigation of the rhythmic phenomena of muscles and detailed the results obtained by this method by Miss Buchanan, working in the physiological laboratory at Oxford, and which have already appeared in the *Journal of Physiology*. Professor Sherrington gave an account of experiments upon the cerebral cortical centers in two chimpanzees, the first experiments of the kind which had been performed on animals higher in the scale of life than monkeys. In one of the animals the cortical center for the hand was delimited and excised, the result being an immediate paralysis of the hand, which, however, in a few weeks completely passed away. In the second animal the center for the foot was similarly treated, with similar results. A study of the degenerated tracts in the first animal revealed the existence of a direct pyramidal tract in the spinal cord, a group of fibers which has hitherto been supposed to occur only in man. The degeneration resulting from the extirpation of the foot center did not affect this tract.

Dr. Kennedy, of Glasgow, described, with lantern views, a case in which a long-standing spasm of the facial muscles had been

greatly relieved by dividing the facial nerve and grafting its distal end upon the spinal accessory, the operation being an application of results obtained by experiments in nerve grafting performed on lower animals.

Professor Reed, of Dundee, pointed out that the assertion that proteids in solution exerted osmotic pressure was in all probability due to the use of impure preparations, since by using carefully washed recrystallized proteid no trace of such pressure could be obtained on a membrane formed of formalized gelatine. It would appear from this result that the so-called solutions of proteids were not true solutions but merely suspensions. Professor Reed also called attention to an observation he had made that the absorption of glucose by the intestine was favored by the presence of potassium salts as compared with those of sodium, and attributed the result to an ionic effect.

Dr. W. Brodie Brodie, of Glasgow, gave the results of experiments he had made on the action of oxalates on muscle tissue. He pointed out that it had been shown that the presence of calcium salts was necessary for the rhythmic contraction of the heart, and from his experiments it seemed probable that at the moment of muscular contraction there was a liberation of calcium from a salt of that metal present in the muscle substance. Oxalates did not destroy the irritability of resting muscles, although they did have that effect on muscles in a state of activity, and the results of previous observers require to be modified to this extent. It was probable that the action of the oxalate was due to the precipitation by them of the calcium liberated during contraction.

Professor Noel Paton reported on the results of observations made in conjunction with Drs. Gulland and J. S. Fowler on the hæmopoietic function of the spleen, and stated that they had not been able to obtain any evidence that the organ took part in the production of blood corpuscles.

Dr. W. H. R. Rivers gave an account of the measurement of a visual illusion in the cases of thirty-eight natives of Murray Island, Torres straits, compared with forty-two Englishmen. The apparatus used was the Müller-Lyer line with reversed arrowheads, the standard line having a length of 75 mm. The illusion proved to be much less, on the average, among the islanders, to whom the two lines appeared equal when the movable line measured 60 mm. while the same appearance occurred to the Englishmen at 55 mm. Dr. C. S. Myers reported some observations which he had made with Galton's whistle on the same islanders, which showed that at all ages they were unable to hear as high a note as inhabitants of Buchan, Aberdeenshire.

THE BOTANICAL SECTION.

The presidential chair of the Botanical Section was occupied by Professor I. Bayley Balfour, who selected for his address a discussion of the causes which have led the Angiosperms to become the dominant type of the existing flora. Before the appearance of the Angiosperms upon the earth's surface there was a dense vegetation, composed of Pteridophytes and Gymnosperms, but this is now represented by a relatively small number of forms, having been replaced by Angiosperms. What, then, were the causes which have led to the dominance of this latter type, what are the structural peculiarities which have given it the advantage over its predecessors? The climatic differences of our epoch, contrasted with earlier periods, naturally suggest themselves as factors in the change, and of these differences perhaps the most important is the great difference in the relative proportions of the land and water areas upon the globe. "The statement is warranted that the Angiosperms have become dominant in great measure because in their construction the problem of the plant's relationship to

water on a land area has been solved more satisfactorily than in the case of the groups that preceded them."

By the formation of the flower and seed the Angiosperms freed themselves from the risks which attend sexual reproduction in heterosporous Pteridophytes by providing a special nidus for the development of the germ and thereby rendering it directly independent of the presence of water. The tegumentary system of the Angiosperm ovule has for its primary function the conveyance and storage of water for the embryo and in addition serves as a food reservoir. The function of the ovular tegmina cannot now be regarded as of so much importance in the reproductive act as was formerly the case, and the existence of haustoria which penetrate them, either from the embryo itself or the embryo-sac, point clearly to their function as reservoirs of food and water. In passing it was pointed out that the classification of the Dicotyledons into Unitegmineæ and Bitegmineæ proposed recently by van Tieghem seems to rest upon an insecure foundation, since all the genera in certain families, such as the Rosaceæ and Ranunculaceæ are not alike in respect to the number of teguments.

And it is not only to this development of special water reservoirs for the ovule that the Angiosperms owe their advantage as a land-type, but in two features of their water-carrying system they are greatly superior to the older types. No one will deny that their general monostely is a more perfect arrangement for water carriage in a massive plant than is polystely, nor is there doubt that the vasa which are conspicuous characteristics of the Angiosperms are more favorable for a rapid transport of water than are tracheids.

Passing on to a consideration of the differentiation of the Angiosperms into classes, Professor Balfour discussed the new class proposed by van Tieghem, that of the

Liorhizal dicotyledons, and came to the conclusion that the two recognized families included in the class, the Nymphaeaceæ and Gramineæ, do not present sufficiently distinctive characters to warrant their separation from the already established classes. The most recent observations on the embryogeny of the Nymphaeaceæ seem to indicate that the apparent dicotyledonous nature of the embryo is due to the splitting of a simple cotyledon, and if this be correct the order is most properly assignable to the monocotyledons and the structure of the root-tip upon which von Tieghem lays so much stress is what might be expected. The idea that the epiblast of the embryos of the Gramineæ represents a second cotyledon, Professor Balfour is inclined to dispute, and points out that in any event its occurrence is not universal in the order, since it is present in *Triticum* and absent in *Secale*, present in *Elymus* and absent in *Hordeum*. The evidence as to the morphological significance of the structure is at present too obscure to warrant its being taken as a basis for the separation of the Gramineæ from monocotyledons.

Recognizing then but the two classes, Monocotyledons and Dicotyledons, the lecturer stated that if he were to express an opinion as to their phyletic relationship it would be that they had arisen on separate lines of descent. The Dicotyledons are by far the more adaptive and progressive, though this does not necessarily imply their more recent origin, and the advantages which they present over the Monocotyledons in their free internodal growth and copious root system as compared with the contracted stem growth and arrested root system of the latter, are but a carrying out of the structure of the embryo with its terminal plumular and root buds and its lateral cotyledons, so markedly different from what obtains in the Monocotyledons, in which the cotyledon is terminal, the plumu-

lar bud lateral and the primary root bud often internal.

As regards the genetic relations of the various groups into which the two classes are divided, Professor Balfour believes that there is "no evidence to sanction the belief, or even the expectation, that there is extant any family of Dicotyledons or Monocotyledons which represents, even approximately, a primitive type in either class. The stem in each has gone. We have the twigs upon a few broken branches."

The list of papers presented to the Section was somewhat extensive and mention can be made of only a few. Professor Letts and Mr. John Hawthorne submitted a report on some observations they had made upon the absorption of ammonia by *Ulva latissima*. They found that this sea-weed could absorb within twenty-four hours all the ammonia from a sample of rather highly polluted sea-water (containing 0.046 parts of ammonia per 100,000) and suggested the possibility of this characteristic of the *Ulva* being turned to practical account. Professor Marshall Ward presented the results of his observations on the brown rust of the brome grasses. The seeds of the grasses could be treated antiseptically and sown in nutritive solutions and when inoculated with uredospores would give rise to pure cultures of the rust. The results gave no support to the idea that there might be an internal or seminal infection and it was found that although the uredo was in all morphological respects the same in all species on which they were grown, the spores grown on *B. sterilis* would never infect a plant of *B. mollis*, although they could be readily transferred to other plants of *B. sterilis*. Spores from *B. mollis* would infect its allies such as *B. secalinus* and other species of the *Serrafalcus* group, but failed on members of the *Stenobromus* group and so with other cases.

Mr. A. C. Seward described some sections

of jet from Yorkshire which he had studied in the British Museum. Sections cut from specimens which consisted partly of petrified wood and partly of jet showed a gradual transition from Araucarian wood to pure jet lacking all indications of ligneous origin. It would seem from these sections that the Whitby jet was formed by an alteration of coniferous wood.

Other papers presented were on 'The Structure and Morphology of the Flowers of *Cephalotaxus*,' by Mr. W. C. Woodsell; 'The Histology of the Sieve-tubes of *Pinus*,' by Mr. A. W. Hill; 'A Contribution to our Knowledge of the Gametophyte in the Ophioglossales and Lycopodiales,' by Dr. W. H. Lang; 'The Vascular Anatomy of the Cyatheaceæ,' by Mr. D. T. Gwynne-Vaughan; 'The Anatomy of *Danaea* and other Marattiaceæ,' by Professor Brebner; 'Spore Formation in Yeast' by Mr. T. Barker; and on 'A Diplodia Parasitic on Cacao and on the Sugar Cane,' by Mr. A. Howard.

J. PLAYFAIR McMURRICH.

UNIVERSITY OF MICHIGAN.

SCIENTIFIC BOOKS.

Monographien aus der Geschichte der Chemie herausgegeben von George W. A. Kahlbaum, IV. and VI. Hefte. CHRISTIAN FRIEDRICH SCHÖNBEIN, 1799-1868. Ein Blatt zur Geschichte des 19. Jahrhunderts von Georg W. A. Kahlbaum, Ed. Schaer und Ed. Thon. Leipzig. 1899 and 1901. 2 vols. 8vo. Portraits.

The previous volumes of this series of 'Monographs' have dealt with 'Lavoisier's Theory and its Acceptance in Germany,' 'Dalton's Theory of Atoms in Modern Light,' 'Berzelius' Growth,' and the 'Correspondence of Liebig and Schönbein,' by divers writers; the volumes before us deal with the scientific labors and personal character of the eminent chemist and physicist Schönbein by one who enjoyed superior opportunities for his undertaking, occupying a chair in the University of Basel analogous to that held by the famous man, and favored with the friendship of his living heirs.

Through the liberality of the daughters and numerous correspondents of Schönbein, Dr. Kahlbaum had the privilege of handling and studying between 1,500 and 1,600 letters, as well as 350 printed papers from the brain and hand of the man he sought to portray. These letters were carefully catalogued and partially indexed to make them readily available. While occupied with his manuscript, he learned that Professor Ed. Schaer, a pupil of Schönbein was also at work on a biography of him, and correspondence led them to produce a joint work.

Such is the origin of these volumes, which contain more than 550 pages.

The scientific labors of Schönbein comprise his discovery of the passivity of iron, that of ozone, of guncotton and of collodion, besides the many lesser points which in his indefatigable studies of these bodies he encountered. He discovered the remarkable behavior of iron with nitric acid shortly after he had begun his duties as professor of chemistry and physics at the University of Basle, in 1835. Dr. Kahlbaum notes that Schönbein's discovery had been anticipated by James Keir in 1790, but entirely forgotten and neglected. Schönbein's researches on electrical topics were continued many years until 1849, but meanwhile the study of that illusive substance, ozone, discovered in embryo in 1839, absorbed much of his energy. The early history of the enormously difficult problems connected with ozone and the fallacy of 'antozone' are detailed in a satisfactory manner.

No one of the discoveries made by Schönbein made him more popularly known than that of guncotton, destined to play so important a rôle in international, as well as industrial, enterprises; this dates from 1846. Its value as a substitute for gunpowder was at once perceived, and experiments with firearms were instituted as early as May of the same year. It is a sad commentary on the unprofitableness of pure science from the money point of view that this prime discovery brought to Schönbein only eighteen to twenty thousand dollars, while Alfred Nobel gained through it more than ten million dollars!

The discovery of collodion has been claimed for several Americans and Dr. Kahlbaum has

made a careful study of these claims; it appears that Dr. Charles T. Jackson discovered the solubility of gun-cotton in January, 1847, and two of his students (Bigelow and Maynard) in February of the same year found the solution useful in surgical cases. The name collodion was given to it by Dr. A. A. Gould in 1848, by which time it was well known to American practitioners. The exact date of Schönbein's discovery is uncertain, but in February, 1847, De la Rive wrote from Geneva inquiring as to the nature of Schönbein's discovery 'here much discussed.' So it is clear that the invention was made on both sides of the Atlantic almost simultaneously and quite independently.

After pursuing studies at the Universities of Erlangen and Tübingen, Schönbein secured in 1825 the position of teacher in an institute at Epsom, England, and the two years he spent there had a marked influence on him through life. He attended at that time a lecture by Faraday, but did not seek his acquaintance; ten years later, having discovered the passive nature of iron in nitric acid, he addressed a letter describing this to Faraday, and this was the beginning of a correspondence and friendship lasting twenty-six years and only broken by the death of the Englishman. The 'Letters of Faraday and Schönbein' have been edited by Drs. Kahlbaum and Darbishire, and published in a handsome volume (London and Basle, 1899). Schönbein's correspondence with Liebig forms Heft V. of these *Monographien*.

Notwithstanding the arduous labors of Schönbein in his university duties and in the chemical laboratory, he found time for conducting a large correspondence with his brother scientists, and also for writing to the secular daily press; from 1831 to 1832 he was associate editor of the *Basler Zeitung* on a salary of sixty dollars per annum; he was a frequent contributor to the columns of Stuttgart newspapers, and to the *Schwäbische Mercur* from 1833 to 1848.

The portrait in the first volume shows a heavily built, thick set man, smooth shaven and with full head of hair; his physiognomy is singularly earnest, without being so charming as that of Bunsen. The volumes contain indexes of names of persons and brief tables of contents. HENRY CARRINGTON BOLTON.

Die Krystallisation von Eiweissstoffen und ihre Bedeutung für die Eiweisschemie. Von DR. FR. N. SCHULZ. Jena, Gustav Fischer. Pp. 43. 1901.

Not many years have passed since it was customary for physiological chemists, following the suggestion of Thomas Graham, to class proteid substances as *colloids*, in distinction from the *crystalloids* which readily pass through diffusion membranes. The fact that native proteids are indiffusible no longer necessarily implies that they are not capable of crystallization. The achievements of recent years in the preparation of various proteids, both animal and vegetable, in crystalline form have marked a great advance in the study of this important group of organic compounds. The prominent rôle which the proteids assume in the life-processes of all organisms has long made them conspicuous objects of investigation; and now that the possibility of separating them in crystalline form has given promise of improvements in the methods of purification and identification, a new impetus has been given to the investigation of the chemistry of the proteids.

Professor Schulz's monograph is a comprehensive compilation of the literature on the crystallization of the proteids. It includes a review of the occurrence of proteid crystals ready-formed in animal and plant tissues, and a more extensive description of the separation and properties of crystalline preparations from non-crystalline native proteid mixtures. This includes in particular the crystallization of egg- and serum-albumin and the readily obtained vegetable proteids. Other less certain instances (fibrin, casein, heteroalbumose, etc.) are considered in the light of the evidence at present available. Hæmoglobin and related compounds are treated in somewhat greater detail, which their earlier discovery justifies. It is a matter of historical interest to note that Schulz names B. Reichert as the discoverer of the blood crystals (1847), whereas this honor is usually assigned to Otto Funke (1851).

In the concluding pages of Schulz's monograph brief reference is made to the crystallography of the proteid crystals and the significance of crystallization for the chemistry of

the proteids. It is a satisfaction to American readers to find the American contributions to the literature of the subject adequately reported by a German writer. Dr. Schulz is a professor at Jena.

CHEMICAL SOCIETY OF WASHINGTON.

THE 128th regular meeting of the Washington Section of the American Chemical Society was held at Cosmos Club Hall, Thursday evening, October 10. The following program, was presented:

Dr. H. N. Stokes, 'Pyrite and Marcasite.' Dr. Stokes stated that the physical characteristics by which these geologically important dimorphous forms of iron disulphide are distinguished are not always applicable, especially when they occur in the form of concretions. The paper describes a method by which they can always be determined, which consists in boiling an excess of the carefully prepared mineral with a standard solution of ferric ammonium alum, under absolute exclusion of air, until the alum is completely reduced. The reaction takes place in two stages:

The second reaction is always incomplete, only a portion of the sulphur being oxidized to sulphuric acid. Under the standard conditions the percentage of sulphur oxidized is 60.4 in the case of pyrite and 18 in that of marcasite. The percentage of sulphur oxidized, or the *oxidation coefficient* (p), is obtained from the equation

$$p = \frac{8.333 b}{c - a} - 25,$$

which is deduced from the above equations, and in which a , b and c represent the permanganate equivalents of the standard solution and of the ferrous iron and total iron of the resulting solution, respectively. The proportion of the minerals in a mixture of both can be

determined to within 1 to 3 per cent. by finding its oxidation coefficients and referring to an empirical curve of oxidation coefficients obtained by experiments with artificial mixtures. It was shown that the concretions described by geologists and mineralogists as marcasite are frequently pyrite, that the density affords no criterion of the composition, and that the hypothesis that most specimens of pyrite and marcasite, even when well crystallized, are mixtures of the two, or paramorphs, is without foundation. It was also shown that their behavior towards cupric sulphate solutions is essentially similar and affords no evidence in support of the hypothesis of Brown that the chemical constitution of the two minerals, or the state of valency of the iron is different. The full details are to be found in the recently published Bulletin No. 186 of the United States Geological Survey.

W. H. Seaman, 'Insolubility of Inorganic Salts in Hydrocarbons'; contribution from the laboratory of Howard University Medical College. The author stated that several years ago he had the pleasure of announcing to the society a generalization on the insolubility of glycerol ethers in glycerol. Now he is able to make a still more important generalization, that all inorganic salts are insoluble in hydrocarbons of the paraffin series. Fifty-three different salts have been kept in contact with benzine, kerosene and soft paraffin for periods varying from two to six months, without taking up a sufficient quantity of any salt to produce any residue on evaporation in a watch glass that is visible by a pocket microscope.

The writer does not know of a single analysis of petroleum in which the presence of inorganic salts has been reported, and in view of the fact that the petroleum has been in contact with some kinds of salts since it was formed, the natural conditions go far to support the generalization stated. Only in the case of $(\text{NH}_4)_2\text{CO}_3$ was there any marked change; a brownish color was generally developed when in contact with this salt, the cause of which is not ascertained. At the suggestion of Professor F. W. Clarke, anhydrous Fe_2Cl_6 was prepared and tested, but the result was the same. The following is a list of the salts used:

Ammonium sulfocyanid, bromid, phosphate, oxalate, carbonate, chlorid, nitrate; antimony sulfid; barium chlorid, nitrate, carbonate, di-oxid; bismuth nitrate; arsenious acid; calcium chlorid and nitrate; ferric chlorid and ferrous sulfate; ferric ferrocyanid; magnesium carbonate; potassium bromid, cyanid, carbonate, iodid, bichromate, sulfate, chlorate; magnesium dioxid; potassium acetate; sodium bicarbonate, acetate, nitrate and sulfate; tartar emetic; zinc oxid; potassium ferrocyanid, chromate, hydrate, picrate, chlorid, nitrate; sodium borate, carbonate, chlorid, hydrate, nitrite, thiosulfate; ammonium molybdate, bichromate, sulfate; ammonia alum; magnesium sulfate and lithium carbonate.

L. S. MUNSON,
Secretary.

NEW YORK SECTION OF THE AMERICAN CHEMICAL SOCIETY.

THE first meeting of the N. Y. Section of the American Chemical Society, held on Friday evening, October 11, at the Chemist's Club was very largely attended. Professor Marston Taylor Bogert, of Columbia University, is the newly elected chairman of this Section, which, on September 30 last, entered upon the second decade of its usefulness with a membership of over four hundred. Upon the recommendation of the Executive Committee, the Section decided to award annually a medal to that member of the Section who shall have presented, during the preceding year, the best paper embodying original chemical research. The minor conditions affecting the award and a suitable name for the medal will be decided upon later.

The program of papers included a report by General Secretary Professor Hale upon 'The Recent Meeting of the American Chemical Society, at Denver.' Dr. McMurtrie gave an interesting account of a 'Short Trip among the Mines and Chlorination Works of the West.' Mr. Jacob G. Lipman, of the New Jersey Experiment Station, gave an account of his 'Studies in Nitrification.'

Professor Edward Hart, of Lafayette College, and Editor of the *Journal of the American Chemical Society*, read an interesting paper upon 'Technical Chemical Education,'

which brought forth a long discussion, participated in by prominent teachers of chemistry and industrial chemists. There seemed to be some weight of opinion in favor of the view that time may be spent in attempts to teach the details of such industries as dyeing, brewing, acid manufacture, etc., that might better be devoted to acquiring the broad general principles of chemistry, mechanics and engineering, leaving the technical training to be acquired in the factory or works.

Dr. H. W. Wiley, of the U. S. Department of Agriculture, gave a paper upon 'The Government Laboratories of Great Britain.' This was profusely illustrated by lantern photographs taken by Dr. Wiley. The director of this laboratory is Professor T. E. Thorpe, C.B., LL.D., F.R.S., past president of the Chemical Society. In regard to the equipment of this laboratory Dr. Wiley thinks we might do well to imitate its ideal system of ventilation and excellent apparatus. Solid silver flasks are used for saponification tests under pressure. On the other hand, British chemists in general will do well to imitate the American Society of Official Agricultural Chemists in regard to the adoption of standard analytical methods. In Professor Thorpe's laboratories some of the American 'official methods' have been adopted.

JOHN ALEXANDER MATHEWS,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science, of St. Louis, on the evening of October 21, 1901, forty-five persons present, Professor F. E. Nipher, of Washington University, delivered an address on 'Progress made in Physics during the Nineteenth Century.'

WILLIAM TRELEASE,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

PATAGONIAN PERSONALITIES.

A RECENT article in SCIENCE was none too soon in drawing attention to the puerilities and solecisms perpetrated by some botanists in their endeavor to grapple with the mysteries of the Latin language. We scarcely like to arouse the

anger of zoologists by suggesting that they are just as bad, but at any rate some of them are not far behind. It is therefore satisfactory to hear that the International Congress of Zoologists has decided that errors of etymology, orthography and grammar are not to remain perpetual disfigurements of scientific writings simply because some would-be systematist never went to school. But there is a class of names against which there is no rule, appalling though they often are to the mind of the scholar. We allude to the monstrosities pieced up out of modern proper names, or even barbarous dialect words, often in unnatural union with a Greek or Latin suffix, e. g., *Leedsichthys*, *Koninckocidaris*, *Lapuworthura* (a polite way of showing respect truly!), *Etheridgaster* (which does not mean airy stomach), *Urobenus* (not, as some ingenious German supposes, derived from *öpa* and *βαίω*, but an anagram of *Bournerus* by which a Mr. Bourne has been immortalized).

But all previous efforts—if one can dignify with such a term the results of pure laziness or incompetence—are left far behind by the latest fantasies of Florentino Ameghino in 'Notices préliminaires sur des Ongulés nouveaux des terrains crétacés de Patagonie,' published in the *Boletín de la Academia Nacional de Ciencias de Córdoba* (July, 1901). Zoologists may retort that this gentleman is only a paleontologist; well, then he should have more sympathy with the dead languages than to burden them with such abortions as the following: *Henricosbornia*, *Guilielmoscottia*, *Oldfieldthomasia*, *Ernestokokenia*, *Josepholeidya*, *Ricardolydekkeria*, *Guilielmoftoveria*, *Henricofilholia*, *Thomashuxleya*, *Edwardocopeia*, and others too many to quote. Space, however, must be found for two gems, further enriched by footnotes: *Maxschlosseria* 'J'ai employé le prénom sous la forme germanique plus en usage, car c'est la racine du nom latin, qui est trop long,' and *Asmithwoodwardia* 'Je n'ai utilisé que l'initiale du prénom, car autrement il aurait résulté un nom excessivement long. D'ailleurs, cet auteur signe d'habitude A. Smith Woodward.' That 'd'ailleurs' is delicious; the man would actually find excuses for not giving us *Arturo-smithivoodvardia*. Will the Zoological Congress

not insist on the completed form? Why should pure latinity dread an excessive length?

Seriously, is not this a little too much—too long, but too childish? It is only 45 years since a satirical rogue in the *Annals and Magazine of Natural History* suggested that incipient paleontologists might ease their brains by adopting such combinations as *Grayoconcha* and *Gouldornis*, for they would certainly never have been anticipated by any zoologist. Such sarcasm would not carry far to-day; we have by this time rivaled the imaginary *Unclesambo-crinus* of the same critic.

Ridicule will never check people with no sense of the ridiculous. Are rules any better? Needless to say the original Strickland code never contemplated the possibility of such aberrations; it was opposed to all personal generic names in zoology. The British Association Committee of 1864 wished to reject *Cookilaria* and *Morrhua tomcodus*, and considered that 'specific names from persons have already been sufficiently prostituted, and personal generic names have increased to a large and undeserving extent'; both are classed as 'objectionable.' The rules adopted by the International Zoological Congress of 1899 say that generic names must consist of a single word (art. 5); that they may be derived from either forenames used in antiquity, or from modern surnames (art. 6 *g*, *h*); that such names should not enter into the formation of compound words (art. 9); that when a surname is compound, only one of its components is to be used, *e. g.*, *Edwardsia* not *Milne-Edwardsia* (art. 7) and certainly never *Milnedwardsia* (art. 11). But *Amilnedwardsia*—!

It is perfectly obvious that the whole spirit of these rules is totally opposed to the action of Ameghino, and if their letter is not so too it is only because there are some things so ridiculous that nobody has ever dreamed of legislating against them. It remains to be seen whether the dignity, the common sense, and the fellow-feeling of zoologists are strong enough to ignore these Florentinameghinisms, which we should expect to see in some penny-a-liner's pseudo-scientific paragraph for a Sunday paper, rather than in the publications of a National Academy.

F. A. B.

SOME REMARKS ON PRESIDENT D. S. JORDAN'S
ARTICLE ON THE GEOGRAPHICAL DIS-
TRIBUTION OF FISHES.

PROFESSOR D. S. JORDAN has called attention to a number of highly interesting points in the geographical distribution of fishes,* and I should like to add a few remarks relating to some of the questions discussed.

1. *Similarity of Japanese and European (Mediterranean) forms.*

Although, according to Professor Jordan, this similarity does not seem to be so very much pronounced among fishes, we have other groups of marine animals in which the same striking fact has been noticed. The present writer has lately called attention to this with reference to the Decapod Crustaceans,† and has expressed the opinion that the connection of Japan and Europe by a continuous shore line was along the northern shores of Siberia, in a geological past when the climate of the circumpolar regions was a warmer one, so that at least subtropical animals could exist there. The continuous circumpolar distribution of the ancestors of the respective forms was broken up by the cooling of the pole, the species retreated southward, and found only in the Mediterranean and Japanese seas a congenial climate, where they continue to exist as *relics* of a former circumpolar distribution. Professor Jordan has apparently not taken into consideration this explanation, which might possibly also be advanced for some of the fishes of Japan and Europe.

2. *The submersion of the Isthmus of Suez.*

That there was no important connection between the Red Sea and the Mediterranean after the middle of the Tertiary is a well-known view. Hull‡ has demonstrated that the faunas of both seas were disconnected since Miocene time, but that in the Pliocene there was again an incomplete connection across the Isthmus of Suez by very shallow water. This agrees well with Professor Jordan's conclusions. Before Miocene, however, there must have been a wide

* 'The Fish Fauna of Japan, with Observations on the Geographical Distribution of Fishes,' SCIENCE, No. 354, October 11, 1901.

† Bronn's 'Klassen und Ordnungen des Tierreichs.' Arthropoda. Bd. 5, Abt. 2, p. 1,267. 1900.

‡ *Nature*, Vol. 31, 1885, p. 599.

and important communication between the Indian Ocean and the Mediterranean, as is shown by several interesting cases in the distribution of Crustaceans,* although it is impossible to say whether what is now the Isthmus of Suez played an important part in this question; the connection may have been somewhere else.

3. *The Cape of Good Hope as a zoogeographical barrier.*

Professor Jordan does not believe that the Cape of Good Hope offers an absolute obstacle to a migration of tropical Indo-Pacific species into the Atlantic. I do not hold the same opinion. Indeed, we know that the tropical fauna of the Indian Ocean extends southwestward along the coast of Natal and the Cape Colony, and some elements of it go even as far as Cape Town. But if we follow the shore line from here northward, along the western coast of Africa, we meet a considerable change of the climatic conditions, for from this point almost to the equator cold water is found. While it is thus true that the fauna of the Cape of Good Hope, as President Jordan says, shows a general relation to that of India and Australia, this applies only to the southern and the southeastern shores of the Cape Colony, while the western (Atlantic) side, together with the adjoining coast of southwest Africa, about as far as the mouth of the Congo, forms an impassable barrier to this tropical fauna of the Indo-Pacific.

4. *The Isthmus of Panama.*

It is beyond doubt that the Atlantic and Pacific Oceans were once connected with each other within the tropics: this connection existed up to the middle of the Tertiary, and it was closed during Miocene times. For this general assumption we possess an overwhelming mass of evidence. The question remains: Where was this connection of the two oceans situated? Formerly it was the general trend of opinion to assume a former depression of the Isthmus of Panama, but since Dr. R. T. Hill has shown that there are serious objections to this on geological grounds, we have to modify this theory. The present writer has tried † to do so with respect to v. Ihering's Archiplata-Archhelenis theory; the connection of the At-

lantic and the Pacific in the Tertiary times was identical with the 'sea separating Archamazonas and Archiplata, that is to say, across the South American continent about where there is now the Amazonas valley'—the Cordilleras not existing then.

5. *Explanation of the distribution of Galaxias.*

The genus of freshwater fishes, *Galaxias*, is represented only in South Australia, New Zealand, South America and South Africa,* and it has been taken as one of the instances which demonstrate the former connection of these parts by land, the Antarctic continent. Professor Jordan hesitates to accept the latter, and his chief arguments are: (1) That this supposed continental extension should show permanent traces in greater similarity in the present fauna both of rivers and of sea, and (2) that geological investigation must show reasons for believing in such radical changes in the forms of continents.

As to the first point—although this connection is quite remote in time—the cases of similarity in the present marine, fresh-water and land faunas are very numerous, and there is hardly any larger group of animals where such are lacking. This fact has been discussed by a large number of writers, † and the wealth of evidence brought to light compels us to recognize this Antarctica theory as well established. As to the second point, the geological proof for existence of 'Antarctica,' I refer only to Professor J. W. Gregory, ‡ who has shown that the tectonic configuration of Australia, New Zealand, South America and Antarctica—as far as we have any knowledge of the last—only tends to support the assumption of a former connection of these parts. That there is, generally speaking, ample reason for believing in 'radical' changes in the form of continents during the earth's history, has been demonstrated by geologists long ago, although it has become almost a fashion among biologists to disregard this line of evidence.

SHORTER ARTICLES.

CENTROID OF A QUADRANGLE.

So far as I can ascertain, the following construction is new. If it be old, it would seem worth while to recall attention to it.

To find the centroid of any quadrangle A, B, C, D , divide each side into three equal parts, and draw lines through adjacent points of division, as indicated in the figure. It is easy to prove that the new figure is a parallelogram, the center of inertia of which coincides with the center of inertia of the original quadrangle, both occurring at the intersection of the diagonals of the parallelogram. The areas of the two figures differ.

In that admirable digest, 'Des Ingenieurs Taschenbuch herausgegeben vom Verein Hütte,' 17th edition, no less than thirteen constructions are given for finding the centroid of quadrangular figures. It would seem to me that one convenient and easily memorized construction should suffice, and that the space thus saved should be otherwise utilized.

G. F. B.

EFFECT OF DIMINISHED AIR-PRESSURE ON THE PULSE.

TO THE EDITOR OF SCIENCE: In a recent trip to the summit of Pikes Peak I made some observations on the rate of my pulse which show a rapid increase of beat corresponding with a rapid decrease of pressure. The ascent was made from Manitou on the cog railway, and as I was comfortably seated all the way and spent most of the time looking from the car window, the influence of exercise on the results was eliminated, because there was no change in this respect. The train stopped after each climb of about 2,000 feet to take on water and at these

stops I took the rate of my pulse. The heights of the different points are taken from a guide furnished by the railway company, and these with the number of observed pulse beats per minute are given in the accompanying table.

RATE OF PULSE PER MINUTE.

Name of Station.	Height in Feet.	Rate of Pulse.	
		Ascent.	Descent.
Manitou.	6,662	78	78
Half Way House.	8,907	...	83
Gulch Tank.	10,067	85	85
Windy Point.	12,233	...	90
Summit Pikes Peak.	14,147	92	92

It is seen that the pulse increased regularly to the summit and decreased to the same amount on the way down. When near the summit I asked a lady sitting near me to give me her pulse rate and she found it the same as my own, namely, 92 per minute.

The average rate of my pulse at the same time of the day (near mid-day) at sea level is about 75.

The ascent was made on September 1, and the time occupied in the ascent and return was about four hours, between noon and 4 P. M. About an hour and a half was taken for the ascent and about an hour and a half for the descent, leaving about an hour for remaining on the summit.

I did not notice any difficulty of breathing while on the summit of the Peak, or any sensations markedly different from those experienced at sea level.

On the day of my visit the Peak was between two strata of cumulus clouds. One was evidently formed over the plateau to the west of the Peak and floated over some distance above the summit. The other stratum was formed over the plains to the east and was far below the summit of the Peak.

HENRY HELM CLAYTON.

BLUE HILL OBSERVATORY,
October 7, 1901.

NOTES ON INORGANIC CHEMISTRY.

THE nature of an antimony salt described in 1882 by Setterberg has lately been cleared up by Wells and Metzger, writing in the *American Chemical Journal*. This salt was formed by the

addition of cesium chlorid to a solution containing both the trichlorid and the pentachlorid of antimony, and was considered to be a mixed salt. In recovering cesium from some residues containing antimony, the authors precipitated it as the chloroplumbate. Instead of being yellow, like the pure salt, the lead salt was bright green, and examination showed that it was colored by an antimony salt, which was isomorphous with it. This proved to be Setterberg's salt, and showed from its isomorphism that its constitution is Cs_2SbCl_6 , containing therefore quadrivalent antimony. It crystallizes in black octahedra and belongs to the series of salts of which the most familiar member is the potassium chloroplatinate. This is the first known salt in which antimony is quadrivalent, although in the dioxid this valence is accepted by many chemists.

AN interesting application of the bioscope in crystallography is described in a paper recently presented to the American Academy of Arts and Sciences, by Professor Richards, of Harvard University, in conjunction with E. H. Archibald. The authors have studied the growth of crystals by photomicrography, taking successive instantaneous photographs of the growing crystal. This was accomplished with a very considerable degree of success, after overcoming very great mechanical difficulties. The object was especially to study the birth of crystals in order to determine whether crystallization is always preceded by the separation of an initially liquid phase, consisting of a supersaturated solution of the former solvent in its former solute. A number of observers have believed that with high microscopic powers they have detected the formation of minute globules at the moment of precipitation, and that these globules have soon joined and assumed crystalline form. The problem seemed possible of solution by taking a series of photographs of a solution just at the point of crystallization, and a large number of such photographs were obtained. The enlargement was over 4,000 diameters and both common and polarized light were used. In every case the earliest appearance of the crystal was distinctly crystalline, and no signs of globules were found. Hence if these occur preceding the crystal

phase, they are too small to be detected in a microscope of the power used. Incidentally it was found that the growth in diameter in the first second of the crystal's existence was vastly more rapid than during the subsequent period. "This exceedingly rapid initial diametric growth accounts for a lack of definition noticed in the first images—a lack of definition sufficient to have misled the eye, but not enough wholly to obscure the photographic evidence of crystalline structure." The same apparatus is now being used for the study of the change in the structure of steel at high temperatures.

THAT the question of the influence of boric acid and borax upon the health has not yet been definitely settled is evidenced by two papers on the subject, which have recently appeared in the *Journal of Hygiene* and the *British Medical Journal*. The first of these, by Tunnicliffe and Rosenheim recounts a series of experiments upon children, continued for twelve days, and the authors draw the conclusion that these substances are practically harmless. The other paper by Gruenbaum combats the deductions of the former, chiefly upon the grounds that the experiments were too few, continued for too short a period and were upon children over the age when milk is the principal article of food. In the author's opinion the fact that the boric acid and borax were rapidly excreted by the kidneys is evidence of their poisonous character.

IN a recent number of the *Comptes Rendus* Chaveau and Tissot answer the question as to whether an atmosphere which has been rendered deleterious by the presence of hydrogen sulfid can act as a poison through the skin or the outer mucous membrane, in the negative. A dog, with a canula connected with the outside air in its trachea, was placed in a closed box containing more than eight per cent. of hydrogen sulfid. After an hour the dog was still in good condition, while another dog not thus protected, succumbed in the poisonous atmosphere almost instantly. The authors conclude from this experiment that hydrogen sulfid acts as a poison only when taken into the lungs.

CURRENT NOTES ON PHYSIOGRAPHY.

DIKES AS TOPOGRAPHIC FEATURES.

DIKES are so generally the exclusive property of geological study that a good illustration of their topographic value is a welcome novelty. Rocky walls, shown by the removal of the weaker country rock from a vertical dike, have been occasionally mentioned in the reports of western surveys, but the finest example of the kind yet published is to be found in the Spanish Peaks (Colorado) folio of the U. S. Geological Survey, by Hills. Here a great number of dikes, arranged in a roughly radial pattern with respect to the denuded stocks of the Spanish peaks as a center, form numerous walls from 50 to 100 feet in height, stretching more or less continuously for five or ten miles or more. The weak horizontal Tertiaries have been worn away; but the dike wall retains some mark of their bedding, just as a casting shows the form of its mould. Several excellent photographic illustrations are appended; they are destined to frequent reproduction as type examples of this relatively rare class of topographic forms.

THE PLAIN OF ST. LAWRENCE VALLEY.

THE lower St. Lawrence valley is a broad and nearly level plain of post-glacial marine clays and sands, concerning which R. Chalmers gives some interesting information ('Notes on the Pleistocene Marine Shore-lines and Landslips of the North Side of the St. Lawrence Valley,' *Geol. Surv. Canada, Ann. Rep.*, XI. (1898), 1901, 63J-70J). The height of the plain seldom exceeds 15 or 20 feet along the river bank, but it increases towards the valley sides, and reaches 400 or 500 at the base of the Laurentide hills. The junction of the plain with these hills forms a very irregular line, often running up the river valleys in loops for considerable distances. Generally speaking, this line can be traced approximately on a good map by the absence of lakes on the marine area, whereas on the Laurentide area lakes are quite numerous. Occasionally the surface of the plain is seen to ascend by steps, each of which has apparently been a shore-line during the emergence of the plain from beneath the sea. Terraces and beaches occur on the hill slopes

above the plain; the highest reach altitudes of more than 800 feet.

Certain parts of the plain are subject to extensive landslips, apparently due to the sliding of water-logged silts into valleys that have been cut into the plain since its elevation. One in 1840 left a depression with a maximum depth of 30 feet below the adjoining plain over an area of 84 acres in the valley of Maskinongé river; this was described by Logan (*Proc. Geol. Soc.*, London, III., 1842, 767-769). The St. Albans landslip occurred in 1894; here the clays and sands slid bodily into the valley of the St. Anne de la Pérade for the space of $3\frac{1}{2}$ miles, leaving a depression a mile wide and averaging 100 feet deep. (See Laflamme, *Trans. Roy. Soc. Canada*, XII., 1894, 63; and Archibald and Mackenzie, *Railroad Gazette*, N. Y., June 29, 1894.) The most recent large slip occurred in the valley of Rivière Blanche in 1898, leaving a depression over 86 acres in area with a maximum depth of 28 feet. The softer material flowed out from underneath, while the upper and more coherent clay split into blocks and columns which were borne away by the sliding, surging mass. The movement continued for three hours; clay masses being then left stranded on the floor of the depression, while the mud flow spread over the valley to a depth of twenty-five feet or more for nearly two miles. Accounts of this slip have been given by Dawson (*Bull. Geol. Soc. Amer.*, X., 1899, 484-490) and Laflamme (*Rep. Comm'r Col. and Mines*, 1898, 131).

THE QUESTION OF PENEPLAINS.

DE LAPPARENT considers the origin of several peneplains in France as determined by geological evidence ('La question de pénéplaines envisagée à la lumière des faits géologiques,' *Verh. 7ten Internat. Geogr. Kongr.* (1899), Berlin, 1901, II., 213-220). It is here not a question as to the occurrence of peneplains, now more or less uplifted and dissected; the French examples of this class of forms are so striking that the author does not regard their verity as a matter open to discussion. It is only their origin that he studies. The peneplains more fully described are found in the Ardennes, Brittany, and the Central Plateau. Strati-

graphic evidence leads to the conclusion that these regions have repeatedly been land areas, and that the successive invasions of the sea found the lands so low and flat as to offer no scarps for the sea to work upon. Regarding Brittany, it is remarked that littoral deposits somewhat to the north (bordering the Cotentin) have been produced in the same neighborhood and at altitudes differing only by a few meters during eleven different periods beginning with the Trias, thus indicating an astonishing stability of this region during the time of its denudation to the peneplain form. Marine erosion is therefore excluded, and the peneplains are ascribed to subaerial denudation.

W. M. DAVIS.

RECENT ZOO-PALEONTOLOGY.

Fossil Reptiles of Europe.

THE latest paper upon the *Pterosaurs* is by Dr. Felix Plieninger.* Dr. Eberhard Fraas† proposes the name *Thalattosuchia* as a new group of marine crocodiles of the Jurassic formation, differing widely from all others in the extreme adaptation for aquatic life, especially in the total disappearance of the dermal armature and in the complete conversion of the limbs into paddles. The three chief genera *Metriorhynchus*, *Geosaurus* and *Dacosaurus* were placed by von Zittel in the family *Metriorhynchidae*, of the suborder *Eusuchia*. But according to Fraas they deserve a wider separation, since while most nearly related to the long-snouted crocodiles (*Longirostres*), they by no means present a transition to the short-snouted (*Brevirostres*), but represent an entirely independent group, exclusively adapted to marine life. The superficial resemblance of the skull to that of Ichthyosaurs is intensified by the reduction of the characteristic crocodylian sculpture and by the ossification of the sclerotic coat of the eye. The details, however, are quite distinctive. This constitutes the fifth independent group of marine reptiles, the others being the Plesiosaurs, Ichthyosaurs, Mosasaurs and Chelonians.

* 'Palæontographica,' Vol. XLVIII., 1901.

† 'Jahresb. d. Ver. f. vaterl. Naturk. in Württ,' 1901, p. 408.

MARSH'S COLLECTION OF BRIDGER MAMMALIA.

THIS unique collection of Eocene mammalia has been placed by Professors Beecher and Dana, of the Peabody Museum, in the hands of Dr. J. L. Wortman for systematic description.* As Dr. Wortman remarks, "The importance of the subject to the student of mammalogy can scarcely be overestimated, since these epochs witnessed the beginnings and branching off of many groups destined to play such a prominent part in succeeding mammalian development. This fact was fully appreciated by Professor Marsh, and he spared neither pains nor expense in making the collections as complete as possible." In the first part, on the Carnivora, Dr. Wortman proposes an important and what may prove permanent change, in grouping with the modern Carnivores all the Creodonta that are closely related to them under the new suborder Carnassidentia, and retaining the suborder Creodonta (Cope) only for the ancient types that are entirely aberrant. Valuable notes are given upon the ancestral foxes of Wyoming, and the evolution is traced as far as the Uinta. The author believes that all the placentals had a direct marsupial ancestry, not far removed from the mesozoic carnivorous marsupials. Attention may be called to the fact, opposed to this view, that all the mesozoic marsupials known have a highly specialized character, with inflected jaw and aborted milk dentition, so that they cannot be considered ancestral to the placentals. The value of these papers for future reference would be increased by the insertion of the museum numbers in connection with all descriptions and figures.

PLEISTOCENE HORSES OF NORTH AMERICA.†

IN the preglacial sands of the west and the cave and gravel deposits of the east, remains of horses are extremely numerous; no less than twenty-five species have been proposed and the nomenclature has been in a state of dire con-

* 'Studies on Eocene Mammalia in the Marsh Collection, Peabody Museum,' Part I. Carnivora, *Amer. Jour. Sci.*, May and June, 1901.

† Tooth Characters and Revision of the North American Species of the Genus *Equus*. By J. W. Gidley. *Bull. Amer. Mus. Natural History*, Vol. XIV., Art. IX., pp. 91-141, May, 1901.

fusion. At the suggestion of Professor Osborn, Mr. J. W. Gidley, of the American Museum, has undertaken a complete revision of all the types. It is found that the chief characters used in definition by Owen, Leidy and Cope are largely invalid. The teeth patterns only subject to a wide range of individual variability, and it is an absolute law that the upper portion of the crown is not only more complex, but differs absolutely in proportion from the lower portion; the molar teeth of a young horse thus present essentially different characters from those of an old horse, and ignorance of this fact has vitiated most of the previous definitions. This very careful revision results in the apparent determination of the valid species as follows: *Equus fraternus*, a small horse from the southeastern States; *E. complicatus*, about the size of an ordinary draught horse, from the southern and middle western States; *E. occidentalis* from California, of the same size as the above; *E. pacificus*, a very large animal characteristic of middle California and Oregon; *E. conversidens* from the Valley of Mexico and *E. tau* the smallest true horse, also from the Valley of Mexico; *E. semiplicatus* from western Texas, closely resembling *E. asinus*; *E. pectinatus* from the Port Kennedy bone cave of eastern Pennsylvania. *E. scotti* from the Staked Plains of Texas. The latter is a long-faced type of horse about the size of the largest western pony, but with a longer body, a much larger head, a shorter neck and back and steeply sloping sides, shaped very much as in the ass or quagga. The type of this species is now mounted in the American Museum of Natural History (see Fig. 1). It is the first complete skeleton of a Pleistocene horse discovered in America. It was found in association with four other skeletons, remarkably well preserved. The largest species of horse herein recorded is *E. giganteus* Gidley; sp. nov., the teeth exceeding by more than one third the diameter of those of the largest draught horses.

H. F. O.

THE BICENTENNIAL COMMEMORATION OF
YALE UNIVERSITY.

THE imposing exercises celebrating the two hundredth anniversary of the foundation of Yale College took place last week in accordance

with the program already published in this Journal. As President Northrop pointed out in his address, one hundred and five graduates of Yale have been president of a college; and eighty-five different colleges have at some time had a Yale graduate for president. Yale furnished the first president of at least eighteen colleges—Princeton, Columbia, Dartmouth, Georgia, Williams, Hamilton, Kenyon, Illinois, Wabash, Missouri, Wisconsin, Beloit, Chicago, California, Cornell, Western Reserve and Johns Hopkins. One of the most interesting addresses, given by Dr. Daniel C. Gilman, of the class of '52 and for twenty-five years president of the Johns Hopkins University, is published above.

The doctorate of laws was conferred on President Roosevelt and forty-six others, including the following men of science and college presidents:

John Harvard Biles, Professor of Naval Architecture in Glasgow University.

John Shaw Billings, Director of the New York Public Library.

Charles William Dabney, President of the University of Tennessee.

David White Finlay, Professor of the Practice of Medicine in Aberdeen University.

Jacques Hadamard, Adjunct Professor in the Faculty of Science at the University of Paris.

Samuel Pierpont Langley, Secretary of the Smithsonian Institution.

Albert Abraham Michelson, Professor of Physics in the University of Chicago.

William Osler, Professor of Medicine in Johns Hopkins Medical School.

Henry Smith Pritchett, President of the Massachusetts Institute of Technology.

Ira Remsen, President of Johns Hopkins University.

Ogden Nicholas Rood, Professor of Physics in Columbia University.

Wilhelm Waldeyer, Professor of Anatomy in the University of Berlin.

James Burrill Angell, President of the University of Michigan.

William Peterson, Principal of McGill University.

Seth Low, ex-President of Columbia University.

Jacob Gould Schurman, President of Cornell University.

Franklin Carter, ex-President of Williams College.

William Rainey Harper, President of the University of Chicago.

William Curtis Harrison, Provost of the University of Pennsylvania.

Francis Landey Patton President of Princeton University.

Benjamin Ide Wheeler, President of the University of California.

SCIENTIFIC NOTES AND NEWS.

THE National Academy of Sciences will hold a scientific session at the University of Pennsylvania, Philadelphia, beginning on Tuesday, November 12, at 11 a. m. A special stated session for the transaction of business will be held on November 13.

PROFESSOR GEORGE J. BRUSH, emeritus professor of mineralogy and formerly director of the Sheffield Scientific School of Yale University, received a loving cup from some of the former graduates, on the occasion of the recent bicentennial exercises.

THE first autumn meeting of the American Academy of Arts and Sciences was held at the house of Mr. Alexander Agassiz, president of the Academy, in Cambridge, Mass. After an introduction by the president and a statement for the Rumford Committee by Professor Cross, the Rumford medals were presented to Professors Barus and Thomson who responded with brief remarks. Mr. Agassiz then gave an account of the *Albatross* expedition to the tropical Pacific. George Wharton Pepper, of Philadelphia, was elected an associate fellow of the Academy.

THE Franklin Institute, of Philadelphia, has awarded to Dr. Porter Shimer, of the department of chemistry, Lafayette College, the John Scott legacy medal and premium for his improved jacketed crucible.

THE second annual Huxley lecture of the Anthropological Institute was delivered by Dr. Francis Galton, F.R.S., on October 29, his subject being 'The Possible Improvement of the Human Breed under the Existing Conditions of Law and Sentiment.'

THE Council of the London Mathematical Society for the ensuing year is as follows: *President*, Dr. Hobson; *vice-presidents*, Professor W. Burnside and Major MacMahon, R. A.; *treasurer*, Dr. J. Larmor; *honorary secretaries*, R. Tucker and Professor Love; *other members*, J.

E. Campbell, Lieut.-Colonel Cunningham, R. E., Professor Elliott, Dr. Glaisher, Professor M. J. M. Hill, H. M. Macdonald, Professor L. J. Rogers, A. E. Western, E. T. Whittaker and A. Young.

DR. C. H. GILBERT, of the department of zoology at Stanford University, has been appointed to take charge of the deep-sea investigations of the United States Fish Commission about the Hawaiian Islands. He will leave on the Government ship *Albatross* about December 1.

THE Navy Department has selected Lieut.-Commander W. H. H. Southerland to succeed Capt. C. C. Todd as chief hydrographer of the navy, and orders have been issued detaching him from the command of the *Dolphin*.

WE regret to learn that Mr. Thomas Meehan, the well-known horticulturist, is seriously ill.

DR. THEODORE HOUGH, of the Biological Department of the Institute of Technology, is at his Virginian home convalescing from a long attack of typhoid fever.

AN intercollegiate geological excursion was made to the Westfield valley in Central Massachusetts on Saturday, October 19, for the purpose of studying the formation of river terraces and the influence of rock ledges on their development. The excursion was under the leadership of Professor W. M. Davis, and was attended by forty-six teachers and students from twelve institutions—Yale, Amherst, Wesleyan, Williams, Mass. Institute of Technology and Harvard; Milton and Worcester Academies; Springfield High School and Westfield, North Adams and New Britain Normal Schools. Professors B. K. Emerson, H. E. Gregory, W. N. Rice, and R. T. Jackson were members of the party.

MRS. STANFORD has returned to San Francisco after a journey to Egypt, where she purchased for the Stanford Museum a valuable collection of Egyptian antiquities.

MR. H. KATO, of the Japanese Department of Agriculture, is at present in the United States, with the purpose of studying our fisheries.

DR. D. MORRIS, the British commissioner of agriculture for the West Indies, has returned to Barbadoes after a visit to London.

WE learn from *Nature* that Mr. J. R. Jackson, who for a period of forty-three years has been associated with the Royal Gardens, Kew, has resigned the keepership of the Museum of Economic Botany, and is succeeded by Mr. J. M. Hillier, whose place, in turn, has been taken by Mr. J. H. Holland, late of the botanic station at Old Calabar.

MR. KEITH LUCAS, B.A., of Trinity College, Cambridge, has been nominated to occupy the university table at the laboratory of the Marine Biological Association at Plymouth.

DR. OLIVER LODGE, formerly professor of physics at University College and now the principal of Birmingham University, delivered the opening address to the medical students of University College, Liverpool, on October 12. At the close of the proceedings a bust of Dr. Lodge was unveiled by Professor W. A. Herdman.

THE death is announced of Dr. Vonkrafft, of the Geological Survey of India.

MR. ANDREW CARNEGIE has offered to provide libraries at San Juan, Porto Rico and Nashville, Tenn., each at a cost of \$100,000. He has also given £37,000 for libraries at Dundee.

MRS. BLACKSTONE, widow of T. B. Blackstone, has offered to give the city of Chicago a \$100,000 library building, to be conducted as a branch of the public library.

DR. FREDERICK PETERSON offers a prize of \$200 for the best original unpublished contribution to the pathology and treatment of epilepsy. Papers received will be submitted to a committee, consisting of three members of the New York Neurological Society, and the award will be made upon its recommendation at the annual meeting of the board of managers of the Craig Colony, October 14, 1902. Manuscripts should be sent to Dr. Frederick Peterson, 4 West Fiftieth street, New York City, on or before September 30, 1902. The successful essay becomes the property of the Craig Colony and will be published in its medical reports.

FOR a number of years archeological expeditions to Iceland and Greenland have been conducted at the expense of the Danish 'Carlsberger Funds.' The directors have now decided to defray the expenses of Dr. Kinde in making excavations on the Island of Rhodes,

especially in the neighborhood of the ancient Acropolis.

ARRANGEMENTS have been made at the Millport Marine Biological Station, Scotland, for the erection of a research laboratory and also of a private boarding house. The site for the new buildings has been promised by the Marquis of Bute, and a gentleman who prefers to remain anonymous has given £3,000 towards their erection.

THE German Society of Men of Science and Physicians will hold its meeting next year at Carlsbad under the presidency of Dr. Hans Chiari, professor of pathological anatomy at the German university at Prague.

THE annual trip of the German Agricultural Society in 1903 will be made to the United States.

FOREIGN papers report the formation at Cape Town of a 'South African Association for the Advancement of Science,' to work as far as possible on the lines of the British Association. In July last a meeting was held to establish a congress of engineers, when an influential committee was appointed. The proposal gradually widened until at length it was found feasible to establish a local 'British Association,' and a meeting for that purpose was largely attended. Sir David Gill, the Astronomer Royal at the Cape Observatory, who presided, mentioned that in November last he had attended a meeting of the council of the British Association, at which a very strong desire was expressed to have a meeting of the British Association held in South Africa. He was sure, he said, that in the event of such a visit the hospitality of Cape Town and Kimberly and other centers would be quite equal to the strain which would be put upon it by the visit of distinguished men of science. Of course in the existing state of political affairs it was impossible to contemplate such a matter seriously, and they must leave the fuller consideration of the matter until the country was settled and they were in a position to exercise that hospitality. But if they founded some association of the kind now indicated, the year that the British Association came to South Africa they should naturally merge their meeting into that of the British Association, and their organization would natu-

rally facilitate matters and aid them in making a successful meeting when the British Association came there. Their primary object would be to found an association as far as it was practically possible on the lines of the British Association. The formation of the association having been decided upon by formal vote, the title was discussed, 'South African' being carried by 31 votes against 19 for 'African.'

THE Spanish minister of education has ordered that hereafter all museums shall be open the year round free, and any one allowed to make copies of photographs. He also requested teachers to take their pupils frequently to the museums.

A REPORT of the committee of the metric system has been presented to the British Association of Chambers of Commerce. The committee has unanimously adopted the following resolutions: "(1) That, after considering various suggestions, this committee is unanimously of opinion that the chambers should unite in urging upon the government the compulsory adoption of the metrical system of weights and measures, leaving matters of detail to be considered later. (2) That the committee is unanimously of opinion that a British decimal system of coinage must be on the basis of retaining the sovereign, with the florin as a unit, divided into a hundred cents or farthings. (3) The committee recommends that there should be nickel coins of five and ten cents, and bronze coins of one, two and four cents or farthings."

THE greatest steamship of the time, the *Celtic* of the White Star Line, has made her 'maiden' passage across the Atlantic and back, and her first record—8 days, 9 hours, 46 minutes running time, excluding the time lost by fog, which happened to be in this case 15 hours. This is, for the present at least, the largest steamship in the world. The *Oceanic* of the same line is five and a half feet longer but of less beam and tonnage. The *Celtic* is 700 feet 'over all,' of 75 feet beam and 49 feet depth, measuring 20,880 tons. The *Great Eastern*, for a half century the largest ship on the lists of the fleets of the world, was 680 by 84 by 48 feet, registering, gross, 18,000 tons. The *Celtic* is the first ship to exceed that, at the time,

wonder of the world, largely the basis of the fame of Brunel and Russell. The total weight—the 'displacement'—of the new ship, at maximum computed draft, 36 feet 6 inches, would be nearly 38,000 tons, as compared with about 32,000 tons for the *Great Eastern*. The largest naval vessels are of about one-half this last weight. The *Campania* registers about 13,000 tons, the *Kaiser Wilhelm der Grosse* 17,000, the *Deutschland* 16,500 and the *Oceanic* 17,250. The engines are of the quadruple-expansion type, 33, 47.5, 68.5 and 98 inches diameter of cylinders and 5 feet piston-stroke. Steam-pressure is carried at 210 pounds per square inch by gauge, and is produced by 8 double-ended 'Scotch' boilers, each 15.5 by 19.5 feet. The two smokestacks are each 14 feet in diameter. The ship has capacity for 2,700 passengers or more and for 12,000 tons weight of merchandise. The cost of this ship was \$2,500,000. The builders were Messrs. Harland and Wolff.

A REUTER telegram reports that the Liverpool School of Tropical Medicine has now completed the necessary arrangements for the dispatch of an expedition at once to the Gold Coast, and to the mining districts there. The school has secured the services as leader of this expedition of Dr. Charles Balfour Stewart, who will sail for West Africa this month. He will proceed first to Sierra Leone in order to study the methods now being employed there by Dr. Logan Taylor. After leaving Freetown, Dr. Stewart will proceed at once to Cape Coast Castle to attack the insanitary conditions there, as the mortality amongst the Europeans in that town is at present most serious. He will employ workmen for draining the ground and clearing the houses of broken water vessels and otherwise attacking the breeding-grounds of the mosquitoes. The expedition has been rendered possible owing to the generosity of a private individual who desires to remain anonymous. Anti-malarial operations will shortly be in full swing in Gambia, Sierra Leone, the Gold Coast and Lagos, the operations in the three first-named colonies being organized by and under the complete control of the Liverpool School of Tropical Medicine. Dr. Stewart received his professional

education at Cambridge, the Liverpool Royal Infirmary and Guy's Hospital, London. After qualification, he studied specially at Vienna and Freiburg. He was then invited by the Secretary of State for India to proceed to India for plague work; and labored both up country and also as an assistant to M. Haffkine in the Imperial Research Laboratory at Bombay. He then returned to England and has been constantly engaged in the Thompson Yates Laboratory, Liverpool, on research and the preparation of plague prophylactic, by the request of the Secretary of State for War and the Agent-General of Cape Colony.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. T. JEFFERSON COOLIDGE, late Minister to France, has given a fund of \$50,000 to the Jefferson Physical Laboratory of Harvard University for physical research. The income is to be expended at the discretion of the director, Professor John Trowbridge. Among the terms of the gift is the following: The income of this fund shall be used primarily for laboratory expenses of original investigations by members of the laboratory staff; but the director, at his discretion, may award therefrom an honorarium, of not more than \$500 per annum, for the private use of any person who—although receiving no salary from the university—may wish to carry on original investigations under his direction at the Jefferson Physical Laboratory.

THE General Electric Company has agreed to give \$12,500 for the establishment of a school of electricity at Schenectady, provided that an equal amount is secured from other sources. The school would be affiliated with Union College. It will be remembered that the New York legislature was asked last year to establish this school.

AT the final meeting of the committee engaged in founding a fellowship at the New York University, in memory of the late Oswald Ottendorfer, held recently, plans were made for turning over the amount of subscriptions to the University. The treasurer, James Speyer, reported that the fund aggregated \$20,199.85.

MR. GEORGE A. ARMOUR has given \$2,500 a year for five years for the maintenance and de-

velopment of the classical seminary at Princeton University. The university is the residuary legatee of the estate of Dr. John Sayre of Missouri, \$15,000 of which is now available. It has also lately acquired, through the gift of an unnamed donor, the property of the late Professor Guyot.

MR. EDWARD B. PAGE, of New York, has given to the Sheffield Scientific School of Yale University, \$6,000 to found scholarships.

ON the occasion of the laying of the corner stone of the new medical building of the University of Michigan, Dean Vaughan announced that a few prominent medical alumni of the university had established a fellowship in connection with the medical department, to be known as the Corydon L. Ford Fellowship, in memory of the first professor of anatomy in the university.

PRESIDENT ANGELL, of Michigan University, announces that an instructor in forestry is soon to be appointed.

PROFESSOR W. D. GIBBS, of the Ohio State University, has been elected professor of agriculture and director of the experiment station at the New Hampshire College of Agriculture and the Mechanic Arts at Durham, N. H.

PROFESSOR ARTHUR W. SMITH, who was at Tulane University last year, has been appointed professor of electricity and electrical engineering at the University of Mississippi.

MR. ANDREW CARNEGIE has accepted the Lord Rectorship of St. Andrew's University for the ensuing three years.

DR. JOHN PURSER, for forty years professor of mathematics in the Belfast Queen's College, has retired.

PROFESSOR W. SOMERVILLE, having accepted post at the Board of Agriculture, will resign the chair of agriculture at Cambridge University at the end of the present term.

PROFESSOR RÜDORFF, director of the Laboratory of Inorganic Chemistry in the Technical Institute of Berlin, has retired on account of his health.

PROFESSOR MAX WOLF, of Heidelberg, has declined the call to the professorship of astronomy at the university at Göttingen.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

EDITORIAL COMMITTEE : S. NEWCOMB, Mathematics ; R. S. WOODWARD, Mechanics ; E. C. PICKERING, Astronomy ; T. C. MENDENHALL, Physics ; R. H. THURSTON, Engineering ; IRA REMSEN, Chemistry ; CHARLES D. WALCOTT, Geology ; W. M. DAVIS, Physiography ; HENRY F. OSBORN, Paleontology ; W. K. BROOKS, C. HART MERRIAM, Zoology ; S. H. SCUDDER, Entomology ; C. E. BESSEY, N. L. BRITTON, Botany ; C. S. MINOT, Embryology, Histology ; H. P. BOWDITCH, Physiology ; J. S. BILLINGS, Hygiene ; WILLIAM H. WELCH, Pathology ; J. MCKEEN CATTELL, Psychology ; J. W. POWELL, Anthropology.

<i>University and Educational News.....</i>	744

WHEN at the Columbus meeting of the American Association I had the honor of making a 'Report on Non-Euclidean Geometry,' it was mentioned that my own 'Bibliography of Hyper-space and Non-Euclidean Geometry,' in the *American Journal of Mathematics* (1878), giving 81 authors and 174 titles, when reprinted in the collected works of Lobachevski (Kazan, 1886) gives 124 authors and 272 titles; while Roberto Bonola had just given (1899) a 'Bibliography of the Foundations of Geometry in Relation to Non-Euclidean Geometry,' containing over 350 titles with some repetitions.

Bonola in 1900 finished a second part of this bibliography, in which the single section headed 'Historical, Critical and Philosophical Writings' gives 96 authors and 150 titles. It thus becomes very evident that a most important function of your reporter is the selection of what writings to bring forward for especial mention as of paramount importance and typical of the main stream of advance.

In the Columbus report I particularly stressed the work of two authors whom I brought forward together and to whom I devoted about a quarter of that report.

The report first appeared in *SCIENCE* for October 20, 1899, and you may imagine

that it was reassuring when on October 22 (old style), 1900, the Commission of the Physico-Mathematical Society of Kazan found the scientific merits of the works of these authors, A. N. Whitehead and Wm. Killing equal for the great Lobachevski prize and had to decide between them by the drawing of lots.

In his report on the work of Whitehead, Sir Robert Ball says of the 'Universal Algebra':

"Several other writers, to whom of course Mr. Whitehead makes due acknowledgment, have approached the study of non-Euclidean geometry by the aid of Grassmann's methods, but the systematic and most instructive development of the subject in book VI. is, I believe, new, as are also many of the results obtained.

"The superiority of Whitehead's methods appears to lie in the two following features:

"1°. That he can treat n dimensions by practically the same formulæ as those used for two or three dimensions.

"In this I think he has made a considerable advance upon the methods, ingenious and beautiful as some of them no doubt are, which have been used by previous investigators.

"2°. The various kinds of space, parabolic, hyperbolic and elliptic (of two kinds), present themselves in Whitehead's methods quite naturally in the course of the work, where they appear as the only alternatives when certain assumptions have been made.

"Moreover the results have been obtained in such a way that it is easy for the reader to develop for one of the other spaces properties treated out in full for one space only.

"The book deserves in the highest degree the attention of the student of modern mathematical methods, and it marks so great an advance that it is, in my judgment, well worthy of the important prize in view of which this report is prepared.

"Mr. Whitehead's memoir on geodesics in elliptic space appears to me to indicate great power in dealing with a very difficult problem. I believe it to be of much importance, as the geodesics in the generalized space conceptions had been but little studied."

In the corresponding report on the work of Killing, Professor Engel, of Leipsic, says of the 'Grundlagen der Geometrie':

"This work is, from the first to the last page, a justification and detailed development of the circle of ideas which we are accustomed to understand under the expression 'non-Euclidean geometry.'"

"Already so many preliminary questions have been settled," said Killing in the preface to his first volume, "that the final solution can be hoped for at a not too distant time."

"These words written in 1893," says Engel, "have meanwhile most recently (1899) found a highly striking confirmation in many directions through Hilbert's investigations.

"The geometries possible with the Euclidean, namely the Lobachevski-Bolyaian, the Riemannian and the elliptic, Killing develops, each for itself, in Euclidean way up to a certain grade.

"Also it should not be forgotten that Killing was the first, who (1879, *Crelles Journal*, Bd. 83) made clear the difference between the Riemannian and the elliptic space (or as he calls it, the Polar form of the Riemannian).

"The fourth section treats the Clifford-Klein space-forms, in whose investigation Killing himself has taken a conspicuous part (by a work in Bd. 39 of the *Mathematische Annalen*, 1891). The great importance of these space-forms rests upon this, that they show with especial clearness, what a mighty difference it makes whether we, from the beginning, assume the geometric axioms as valid for space as a whole

or merely for an every way bounded piece of space. In the first case we obtain, besides the Euclidean, only the three previously mentioned non-Euclidean space-forms.

"In the second case appears also a manifoldness, at present not yet dominated, of different space forms.

"The treatment of continuity and the ratio-idea in Euclid gives occasion for a nearer investigation of the so-called Archimedes' Axiom.

"Finally, as the first attempt to illuminate in conjunction all the different questions which have grouped themselves about the problem mentioned, and to collect all the means, which numerous mathematicians, and not least the author himself, have made for solving the problem, this work will for long retain its value.

"That precisely the founding of geometry since the appearance of this book has been advanced in a wholly unexpected way by Hilbert, cannot lessen Killing's merit. His work remains still by far the best means for mastering the researches which have appeared in this realm up to 1898." These interesting extracts I take from the Russian pamphlet just issued at Kazan and furnished me by my friend Professor Vasiliev.

In his paper 'Ueber Nicht-Euklidische und Linien-Geometrie' (Greifswald, 1900), Professor E. Study voices a profound truth when he says: "The conception of geometry as an experimental science is only one among many possible, and the standpoint of the empiric is as regards geometry by no means the richest in outlook. For he will not, in his one-sidedness, justly appreciate the fact that in manifold and often surprising ways the mathematical sciences are intertwined with one another, that in truth they form an indivisible whole.

"Although it is possible and indeed highly desirable, that each separate part or theory be developed independently from the others and with the instrumentalities

peculiar to it, yet whoever should disregard the manifold interdependence of the different parts, would deprive himself of one of the most powerful instruments of research.

"This truth, really self-evident yet often not taken to heart, applied to Euclidean and non-Euclidean geometry, leads to the somewhat paradoxical result that, among conditions to a more profound understanding of even very elementary parts of the Euclidean geometry, the knowledge of the non-Euclidean geometry cannot be dispensed with."

That the world has caught one deduction from this deep idea, is shown by the fact of the almost simultaneous appearance of two text-books, manuals for class use, to make universally attainable this necessary condition for any thorough understanding of any geometry, even the most elementary; two intended, available popular treatises on this ever more essential non Euclidean geometry.

One of these, just being issued by G. Carré et C. Naud, 3 rue Racine, Paris, is 'La géométrie non Euclidienne,' by P. Barbarin, professor at Bordeaux, a place made sacred for non-Euclidean by the memory of Hoüel. How great and practical is the interest of this book can be gathered from the headings of its chapters.

I. 'General and historical considerations.' How the non-Euclidean doctrine was born and gradually developed.

II. 'Euclid's definitions and postulates.' Study of the rôle that they play in the principles of geometry.

Simple and elementary exposé of the three geometries after the method of Saccheri.

III. 'Distance as fundamental notion.' The definitions of the straight and the plane according to Cauchy. The works of M. De Tilly.

IV. 'General geometry in the plane and in space.' Résumé of the principal general propositions.

V. 'Trigonometry.' Elementary demonstration, after Gérard and Mansion, of the formulas for triangles and quadrilaterals.

VI. 'Measurement of areas and volumes.'

VII. 'The contradictors of the non-Euclidean geometry.' The principal objections made against the non-Euclidean geometry. Answers to be made thereto.

VIII. 'Physical geometry.' How we might attempt to find out if the physical world is not Euclidean; how angles and distances could be measured with a much greater approximation, for example, angles with an error much less than $\frac{1}{100}$ of a second.

A brief article by Professor Barbarin, 'On the utility of studying non-Euclidean geometry,' which appears in the May (1901) number of Professor Cristoforo Alasia's new Italian journal *Le Matematiche*, shows that Hoüel had reached the weighty insight which we have quoted from Study, namely, that knowledge of non-Euclidean geometry is essential for any mastery of Euclidean geometry.

Says Barbarin :

"I. The question of the source of the theory of parallels has been one of the most interesting scientific preoccupations of the century; it has made to flow torrents of books, and given theme to remarkable works. Thanks to the theorems of Legendre, to the discoveries of the two Bolyai, of Lobachevski and of Riemann; thanks to the original researches of Beltrami and of Sophus Lie, of Poincaré, Flye Ste. Marie, Klein, De Tilly, etc., we cannot any more be mistaken as to the true scope of the celebrated proposition which bears the name of Postulate of Euclid.

"1°. This is not in any way contained in the classic definitions of the straight and the plane.

"2°. This is, among three hypotheses equally admissible, and which cannot all be rejected, only the most simple.

"Is it perhaps chance alone which gave to the great Greek geometer the choice of his system of geometry? or did he perceive, at least in part, the difficulties and the greater theoretic complication of the other two? We shall never know with certainty.

"But in the presence of his work, so perfect and so rigorous, one thing, however, appears not to be doubtful: the place which he assigned to his proposition, the enunciation which he gave of it, attest that this proposition had to his eyes only the value of an hypothesis; otherwise he would have formulated it in other terms and would have attempted to demonstrate it.

"The ideas of Lobachevski and of Riemann were diffused only very slowly. They were so, above all, thanks to the translations of Hoüel.

"This scientist, whose activity and power of work were prodigious, could not resist the desire to master all the European languages, with the aim of being able to read in their original text, and then make known to his contemporaries the most celebrated mathematical works.

"He admired Lobachevski, whom he sur-named the *modern Euclid*, and in his course professed at the scientific faculty of Bordeaux, he did not let pass any occasion to put him in evidence.

"II. Hoüel was persuaded that the knowledge of the non-Euclidean geometry is indispensable for thoroughly mastering the mechanism of the Euclidean geometry.

"Despite its paradoxical form, this idea is most just.

"General geometry or *metageometry* contains in fact a great number of propositions common to all the systems, and which ought to be enunciated in the same terms in each

of these. If the general proposition can be demonstrated in terms general for these, such should be preferred, even if, to attain this, it be necessary to subject the ordinary form to some modification. To cite only one example, we take the convex quadrilateral inscribed in a circle.

"In Euclidean geometry, *the sum of two opposite angles is constant and equal to two right angles; in non-Euclidean geometry this sum is variable.* Notwithstanding this, the two forms may be reconciled, since in both cases *the sum of two opposite angles equals that of the other two*, and this is sufficient for a convex quadrilateral to be inscriptible.

"Confronting the proposition with that which concerns the circumscribed quadrilateral, we put in full light a correlation which, *à priori*, ought evidently to exist.

"This correlation, which is the very heart of general geometry, and which does not always appear in the ordinary geometry with the same clearness, can be utilized for finding new properties of the figures.

"*Example: Every conic is the locus of the points such that the sum of the tangents from these drawn to two circles is constant; every conic then will also be the curve envelope of the straights which cut two given circles under angles of which the sum is constant.* (Excellent problem for investigating directly.)

"III. Is it expedient to associate the non-Euclidean geometry with instruction, and in what measure?

"If we treat of higher instruction, with ardor we respond affirmatively.

"In the courses of higher geometry of the universities the names of Bolyai, Lobachevski, Riemann have their assigned place, and there are still divers unexplored domains on the road which these scientists have opened.

"In so far as it refers to secondary instruction, the question is more delicate. The programs of preparatory courses at the high schools contain all, or almost all,

special mathematics and spherical geometry.

"It would not be then a great inconvenience to there make opportunely a discrete allusion to general geometry: on the contrary, the attention of the students and their critical spirit would be held awake by the necessity of investigating if such proposition which is expounded to them is of order particular or general.

"At least two indispensable conditions should be satisfied; it is requisite:

"1°. *That in all the books put in the hands of the students, the hypothetical and wholly factitious character of the Euclidean postulate be put well into relief.*

"In my classes I have recourse with success to the simple procedure which follows, and which I recommend. Take the straight AB and the two equal perpendiculars AB, BD : the angles ACD, BDC are equal, and may be right, acute or obtuse. But whichever be the one among these three hypotheses which we assume for this particular quadrilateral, we must conserve it for all the other like quadrilaterals. We choose the system of geometry in which these are right angles, and which corresponds to the Euclidean hypothesis.

"2°. That the invertibility of the postulate of Euclid be completely given up in all the demonstrations in which it can be done without and where nevertheless it is wrongly used.

"See, for example, the theorem on the face angles of a trihedral or polyhedral angle.

"We should recognize that great advances have been made in these latter years in the sense indicated.

"If the ideas of general geometry tend to become popularized, the honor of it is due above all to the periodicals which have given their hospitality, and in special manner to *Mathesis*, so ably edited by our excellent confrère, P. Mansion of Ghent.

"In the course of the last eight or ten years this journal has published numerous articles on Metageometry, written with as much competence as good sense. We counsel their perusal."

It will be seen from our quotation, that Professor Barbarin bases his exposition on the method of Saccheri as the simplest.

The same is true in the other new textbook, 'Manning's Non-Euclidean Geometry.' (Boston, Ginn & Co., 1901, 8vo, pp. v+95.)

Saccheri's first proposition is (*American Mathematical Monthly*, June, 1894, Vol. I., p. 188):

"If two equal straight, AC, BD , make with the straight AB angles equal toward the same parts: I say the angles at the join CD will be mutually equal."

On the next page is "Proposition II. The quadrilateral $ABCD$ remaining the same, the sides AB, CD are bisected in points M and H . I say the angles at the join MH will be on both sides right."

Professor Manning paraphrases these two together on page 5.

"If two equal lines in a plane are erected perpendicular to a given line, the line joining their extremities makes equal angles with them and is bisected at right angles by a third perpendicular erected midway between them."

Under the heading 'Definitions,' Saccheri says: "Since (from our first) the straight joining the extremities of equal perpendiculars standing upon the same straight (which we will call base), makes equal angles with these perpendiculars, three hypotheses are to be distinguished according to the species of these angles.

"And the first, indeed, I will call hypothesis of right angle; the second, however, and the third I will call hypothesis of obtuse angle, and hypothesis of acute angle." This Manning paraphrases as follows, under the heading 'The Three Hypotheses':

"The angles at the extremities of two equal perpendiculars are either right angles, acute angles, or obtuse angles, at least for restricted figures. We shall distinguish the three cases by speaking of them as the hypothesis of the right angle, the hypothesis of the acute angle, and the hypothesis of the obtuse angle respectively."

Saccheri's Proposition III. is: "If two equal straight, AC, BD , stand perpendicular to any straight, AB : I say the join CD will be equal, or less, or greater than AB , according as the angles at CD are right, or obtuse, or acute."

This Manning paraphrases as follows: "The line joining the extremities of two equal perpendiculars is, at least for any restricted portion of the plane, equal to, greater than or less than the line joining their feet in the three hypotheses respectively."

In the same way is paraphrased Saccheri's Prop. IV., the converse of III.

Saccheri's corollary about quadrilaterals with three right angles is given by Manning on page 12.

Saccheri's Prop. V. is: "The hypothesis of right angle, if even in a single case it is true, always in every case it alone is true."

In giving this, Manning has: 'If the hypothesis of a right angle,' etc., evidently a slip for his usual *the* right angle. Of course the Latin original, of which I have, so far as I know, the only copy on this continent, has no article.

Prop. VI. and Prop. VII. are combined by Manning on p. 13.

Prop. IX. is reproduced on p. 14.

Prop. X. is given on p. 9.

In Prop. XI. Saccheri with the hypothesis of right angle demonstrates the celebrated Postulatum of Euclid, thus showing that his hypothesis of right angle is the ordinary Euclidean geometry.

Manning says, p. 27: "The three hypotheses give rise to three systems of geom-

etry, which are called the parabolic, the hyperbolic and the elliptic geometries. They are also called the Geometries of Euclid, of Lobachevski, and of Riemann." Now Saccheri in his demonstration of Prop. XI. makes, almost in the words of Archimedes, an assumption, introduced by the words 'it is manifest,' which we now call, for convenience, Archimedes' Axiom. In his futile attempts at demonstrating the parallel-postulate, Legendre set forth two theorems, called Legendre's theorems on the angle-sum in a triangle. They are:

1. In a triangle the sum of the three angles can never be greater than two right angles.
2. If in any triangle the sum of the three angles is equal to two right angles, so is it in every triangle.

In addition to assuming the infinity or two-sidedness of the straight, in his proofs of these theorems Legendre uses essentially the Archimedes Axiom. Thence he gets that the angle-sum in a triangle equaling two right angles is equivalent to the parallel-postulate, all of which is really what Saccheri gave a century before him, now just reproduced by Barbarin and Manning, as before by De Tilly. Even Hilbert in his 'Vorlesung ueber Euklidische Geometrie' (winter semester, 1898-99), for a chance to see Dr. von Schafer's Authographie of which I am deeply grateful to Professor Bosworth, gives the following five theorems and then says: "Finally we remark, that it seems as if each of these five theorems could serve precisely as *equivalent of the Parallel Axiom.*" They are

1. The sum of the angles of a triangle is always equal to two right angles.
2. If two parallels are cut by a third straight, then the opposite (corresponding) angles are equal.
3. Two straights, which are parallel to a third, are parallel to one another.
4. Through every point within an angle less than a straight angle, I can always

draw straights which cut both sides [not perhaps their prolongations].

5. All points of a straight have from a parallel the same distance.

But since then a wonderful discovery has been made by M. Dehn.

It was known that Euclid's geometry could be built up without the Archimedes axiom. So arises the weighty question: *In such a geometry do the Legendre theorems necessarily hold good?*

In other words: Can we prove the Legendre theorems without making use of the Archimedes axiom?

This is the question which, at the instigation of Hilbert, was taken up by Dehn.

His article was published July 10, 1900 (*Mathematische Annalen*, 53 Band, pp. 404-439).

Dehn was able to demonstrate Legendre's second theorem without using any postulate of continuity, a remarkable advance over Saccheri, Legendre, De Tilly.

But his second result is far more remarkable, namely, that Legendre's first theorem is indemonstrable without the Archimedes axiom.

To prove this startling position, Dehn constructs a new non-Euclidean geometry, which he calls a 'non-Legendrean' geometry, in which through every point an infinity of parallels to any straight can be drawn, yet in which nevertheless the angle sum in every triangle is greater than two right angles.

Thereby is the undemonstrability of the first Legendre theorem without the help of the Archimedes axiom proven.

Dehn then discusses the connection between the three different hypotheses relative to the sum of the angles [the three hypotheses of Saccheri, Barbarin, Manning] and the three different hypotheses relative to the number and existence of parallels.

He reaches the following remarkable propositions:

From the hypothesis that through a given point we can draw an infinity of parallels to a given straight it follows, if we exclude the Archimedes axiom, *not* that the sum of the angles of a triangle is less than two right angles, but on the contrary that this sum may be (a) greater than two right angles, (b) equal to two right angles.

The first case (a) is proven by the existence of the non-Legendrean geometry.

To demonstrate the second case (b), Dehn constructs a geometry wherein the parallel-axiom does not hold good, and wherein nevertheless are verified all the theorems of Euclidean geometry; the sum of the angles of a triangle is equal to two right angles, similar triangles exist, the extremities of equal perpendiculars to a straight are all situated on the same straight, etc.

As Dehn states this result: There are non-Archimedean geometries, in which the parallel-axiom is not valid and yet the angle-sum in every triangle is equal to two right angles.

Such a geometry he calls '*semi Euclidean.*'

Therefore, it follows that none of the theorems, the angle-sum in the triangle is two right angles, the equidistantial is a straight, etc., can be considered as equivalent to the parallel-postulate, and that Euclid in setting up the parallel-postulate hit just the right assumption.

This is a marvelous triumph for Euclid.

Finally Dehn arrives at this surprising theorem:

From the hypothesis that there are no parallels, it follows that the sum of the angles of a triangle is greater than two right angles.

Thus the two non-Euclidean hypotheses about parallels act in a manner absolutely different with regard to the Archimedes Axiom.

The different results obtained may now be tabulated thus:

The angle-sum in the triangle is:	Through a given point we can draw to a straight:		
	No parallel.	One parallel.	An infinity of parallels.
$> 2R$	Elliptic geometry	(Impossible)	Non-Legendrean geometry
$= 2R$	(Impossible)	Euclidean geometry	Semi-Euclidean geometry
$< 2R$	(Impossible)	(Impossible)	Hyperbolic geometry

Riemann, Helmholtz and Sophus Lie founded geometry on an analytical basis in contradistinction to Euclid's pure synthetic method.

They elected to conceive of space as a manifold of numbers. In the Columbus report is an account of the Helmholtz-Lie investigation of the essential characteristics of space by a consideration of the movements possible therein.

This is notably simplified if we suppose given *à priori* the graphic concepts of straight and plane, and admit that movement transforms a straight or a plane into a straight or respectively a plane. Killing determines analytically the three types of projective groups, but the same results are reached in a way geometric and purely elementary by Roberto Bonola in a beautiful little article entitled, '*Determinazione, per via geometrica, dei tre tipi di spazio: Iperbolico, Ellittico, Parabolico* (*Rendiconti del Circolo Matematico di Palermo*, Tomo XV., pp. 56-65, April, 1901).

In 1833 was published in London the fourth edition of an extraordinary book (3d Ed., 1830) by T. Perronet Thompson of Queen's College, Cambridge, with the following title:

'Geometry without Axioms.'

"Being an attempt to get rid of Axioms and Postulates; and particularly to establish the theory of parallel lines without recourse to any principle not grounded on previous demonstration.

"To which is added an appendix containing notices of methods at different times proposed for getting over the difficulty in the 'Twelfth Axiom of Euclid.'" Svo, pp. x + 148. This dissects most brilliantly twenty-one methods of getting rid of Euclid's postulate; so brilliantly that it deserves to be reprinted and could scarcely be improved upon. Then, nothing daunted by the failure of every one else of whom he has ever heard, the brave Thompson adds one of his own, which perhaps he also afterward impaled upon the point of his keen dissecting scalpel, for he lived long and prospered. In 1865 De Morgan, whose unknown letters to Sylvester I had the pleasure of publishing in the *Monist*, writes:

"With your note came an acknowledgment from General Perronet Thompson, B.A. of 1802, and Fellow of Queen's before he was an ensign. And he works at acoustics as hard as ever he did at the Corn Laws."

But even in 1833, had he but known it, the question of two thousand years, as to whether Euclid's Parallel-Axiom could be deduced, had been settled at last by the creation and indeed publication, by Bolyai, and also by Lobachevski, of a geometry in which it is flatly contradicted.

The newly created methods, which thus settled this old, old question, give entirely new views concerning the investigation of axioms in general; and this diamond mine has been masterfully preempted by Hilbert, of Göttingen. His wonderful 'Grundlagen der Geometrie' is ablaze with gems from this non-Euclidean mine.

After Bolyai and Lobachevski, Hilbert's closest forerunner is Friedrich Schur, of Karlsruhe. One of the most fundamental advances of this decade is the strict rigorous reduction of the comparison of areas to the comparison of sects.

This was first given on January 23, 1892, by Schur before the Dorpater Naturforscher-Gesellschaft.

The account printed in Russia in the society's *Proceedings*, a *Referat* given by Schur, is of course almost inaccessible, nor is this inaccessibility much lessened for us by the fact that it has been translated into Italian (*Per. di Mat.*, VIII., p. 153).

The essence of the matter is the proof that, a certain sect being taken as the measure of the area of a triangle, the *sum* of these sects is *the same* for any set of triangles into which a given polygon can be cut, and so gives a sect which may be taken as the measure of the area of the polygon. The *Referat* begins as follows:

"On the surface content of plane figures with straight boundaries, by Friedrich Schur.

"So simple a problem as the measuring of plane figures with straight boundaries as it seems from the literature to me accessible, has not yet been set forth with the rigor and purity of method herein possible.

"Not to mention the introduction of endless processes, still general magnitude-axioms are used unjustifiably, which are only then immediately clear when these magnitudes are straight sects, their comparison therefore capable of being made by superposition.

"Such a general magnitude-theorem, which is used in all text-books of elementary mathematics known to me in proving the theorem of the equal area of two parallelograms with common base and equal altitude, is, *e. g.*, this, that the subtraction of equal magnitudes from equal magnitudes gives again equal magnitudes.

"If the sides of the two parallelograms lying opposite the common base have a piece or at least a point in common, then the two parallelograms can at once be cut into parts such that each part of the one parallelogram corresponds to a part congruent to it of the other parallelogram.

"On the contrary, if those two sides have no point in common, then it has been be-

lieved that this method of proof for the equality of area, simple and standing upon a sharp definition, must be renounced, and it has been replaced, as is known, by this, that each of the two parallelograms is represented as the difference between the same trapez and one of two congruent triangles.

"But before the measurement of plane surfaces by sects has been attained, which just first becomes possible through the theorem to be proven, the application of the above magnitude-theorem is justified by nothing.

"We must therefore throw away this method of proof, and that so much the more, as in every case each of two parallelograms with common base and equal altitude in very simple way comprehensible to every scholar can be so cut into a number of parts that to each part of the one parallelogram corresponds a part congruent to it of the other.

"One may find that, *e. g.*, set forth in 'Stoltz's Vorlesungen' ueber allgemeine Arithmetik, I. Theil (Leipzig, 1885), S. 75 ff.

"We can still somewhat simplify this method, and lessen the number of parts. Draw, namely, through each of the two end-points next one another of the sides lying opposite the common base, parallels to the sides of the other parallelogram, and prolong these to the two outer of the sides not parallel to the base. The join of the two end-points so obtained is then parallel to the base, and cuts from the two parallelograms two new parallelograms which without anything further are divided into triangles every two congruent to one another.

"If then the sides opposite the common base of the remaining parallelograms again have no common point, then we proceed just so with them, and come thus, after a finite number of repetitions, to a pair of

parallelograms, to which the customary procedure can be applied.

"If the distance of those two neighboring end-points of the sides opposite the base is greater than the n fold of the base, on the other hand at the highest equal to the $(n + 1)$ fold of the base, then is each parallelogram cut into a trapez (respectively triangle), three triangles and n parallelograms, and each of such parts of the one parallelogram corresponds to a part congruent to it of the other." Now it so happens that I myself had reached this method and published it seven years before Schur in my 'Elements of Geometry' (John Wiley & Sons, New York). It may be described more concisely as taking away pairs of congruent triangles each with base equal to the common base of the two parallelograms and sides respectively parallel to their other pairs of sides, until we have left two parallelograms to which the customary dissection into a triangle and trapezoid will apply, to finish with congruent parts.

But this demonstration, though the very simplest possible, yet postulates the Archimedes axiom, though neither I myself, in 1885, nor Schur, seven years later, in 1892, said a word about this assumption. However, before 1898 Schur became conscious that elementary geometry can be built up without the Archimedes axiom. He states this in the preface to his remarkable 'Lehrbuch der analytischen Geometrie' (Leipzig, Veit & Comp., 1898), referring to his article 'Ueber den Fundamentalsatz der projectiven Geometrie' *Math. Annalen*, Bd. 51), where he proves the theorems of Desargues and of Pascal without using either the parallel postulate or the axiom of Archimedes, proving that the ordinary sect-calculus can be built up independently of number-measure and the Archimedean postulate.

Professor Anne Bosworth, of Rhode

Island, has followed this up by actually constructing in her doctor's dissertation at Göttingen (1900), under Hilbert, a sect-calculus independent of the parallel-axiom.

This is a beautiful piece of non-Euclidean geometry, and is, so far as I know, the first feminine contribution to our fascinating subject.

In 1899 appeared Hilbert's 'Grundlagen der Geometrie,' in which the remarkable contributions of Schur are all retouched by a master hand.

In Schur's proof of the Pascal theorem the space axioms are used. Hilbert replaces them by the parallel-axiom, thus proving Pascal as a theorem of plane Euclidean geometry.

Schur makes a sect-calculus, and shows that the theory of proportion can be founded without the introduction of the difficult idea of the irrational number. He indicates that this could be done without the Archimedes axiom.

Hilbert actually does it.

Schur proves for the first time the fundamental theorem for a rigorous treatment of area.

Hilbert simplifies this proof, and proceeds to treat this whole subject without the Archimedes axiom, making here the new distinction between *flächengleich* and *inhaltsgleich*.

Two polygons are said to have *equal surface* when they can be resolved into a finite number of triangles congruent in pairs.

Two polygons are said to have *equal content* if it is possible to add to them polygons of equal surface, so that the two new compound polygons have equal surface.

Thus Euclid only tried to treat *equal content*, and Hilbert is here a return to the great Greek.

The intense interest in all these unexpected developments is voiced in a handsome volume: 'Questioni riguardanti la geometria elementare' (Bologna, 1900, 8vo,

pp. vii + 532), edited by Federigo Enriques, who has been chosen to contribute the part on the foundations of geometry to the great German Encyclopædia of the Mathematical Sciences, and who contributes the first article (28 pages) to this Italian work. It is entitled 'On the Scientific and Didactic Importance of the Questions which Relate to the Principles of Geometry.'

The whole book may be properly described as an outcome of the non-Euclidean geometry, but more specifically, the longest of the fourteen articles which make it up is by Bonola: 'On the Theory of Parallels and on the non-Euclidean Geometries' (80 pages, 26 figures).

The first fifty of his eighty pages are devoted to an historico-critical exposition; the last thirty to general theory, hyperbolic geometry, elliptic geometry. Though the article was published only last year, it is in certain respects antiquated. The proofs freely use the Archimedes postulate, without saying anything more about it than I did in 1885, that is, nothing at all. His § 7 is headed 'Postulates Equivalent to the Postulate of Euclid,' and gives those adopted by Proclus, Wallis, Bolyai Farkas, Carnot, Legendre, Laplace, Gauss. But now we know that all these men failed in attempting to rival the choice of Euclid. Their axioms are not the equivalent of his immortal postulate.

In this section the name Legendre is misspelled, and in § 5 Bonola says, "The attempts of Legendre for the demonstration of the Euclidean hypothesis, published in the various editions of the 'Elements' of Euclid, which appear under his name," etc.

Of course Legendre never published any edition of Euclid. It was on the contrary Legendre's geometry which cursed the subject with that definition, "A straight line is the shortest distance between two points,"

which still disgraces the beautifully illustrated book of Phillips and Fisher of Yale.

Again, in § 12 Bonola misquotes in a very important particular the title of the only thing Bolyai János ever published, his renowned appendix, in which title, instead of 'Johanne Bolyai de eadem,' Bonola has 'Johanne Bólyai de Bólya.' Again in § 8 Bonola is still expressing the hope that the examination of the unedited manuscripts of Gauss may show some ground for the pretence that Gauss had some part, however minute, in the creations of Bolyai, Lobachevski and Riemann. But these manuscripts have already been most sympathetically edited by Professor Paul Staeckel, their publication making a goodly quarto, in a review of which for SCIENCE under the heading 'Gauss and the non-Euclidean Geometry,' I find they only strengthen the already existing demonstration that neither of the creators of the non-Euclidean geometry owed even the minutest fraction of an idea or suggestion to Gauss.

This is reproven by the correspondence of Gauss and Bolyai Farkas, so sumptuously published in royal quarto by the Hungarian Academy of Science, edited by Staeckel and Franz Schmidt, chiefly valuable for its references to the immortal boy, Bolyai János, of whom unfortunately no portrait exists.

And now a word in conclusion.

Thinking is important for life. So much so that evolution in thinking has dominated all other evolution. In all thinking enters a creative element. There is not any pure receptivity. Nothing can be described except in terms of a precreated theory. The business of science is the making of these theories, and the continual remaking and bettering of these theories. The higher races of mankind, and chiefly the Greeks, created and elaborated a scheme for dominating what a popular terminology

calls the facts and laws presented by the spatial relations of things.

This scheme was only one of an indefinite number of possible schemes, but as coordinated and systematized by a great constructive genius, Euclid, the first professor of mathematics at the University of Alexandria, it proved so efficient, so effective for life, that all educated men accepted it as part of their common equipment.

Though it promises no heaven, though it threatens no hell, though it mentions no angels, no devils, yet Euclid's elements of geometry, simply as conveying a necessary instrument for the conduct of civilized life, has appeared in more than one thousand four hundred different editions [Professor Riccardi: *Saggio di una bibliografia Euclidea* (Bologna, 'Memorie' (5), I., 1890)].

Euclid gave to educated mankind a common language for description of the spatial, a common mental basis for thought about extension. Euclid's geometry is a certain theory for a specific natural science, a mental construction to explain, to master, to communicate or transmit, and to prophesy certain physical phenomena, the spatial or extensive phenomena. Therefore, the body of its doctrine is a system of theorems deduced in a logical way from certain unproven and in part absolutely and finally indemonstrable assumptions. Such a one is the world-renowned parallel-postulate, which is absolutely incapable of being proved in any way whatsoever, mental or physical, speculative or experimental, deductive or inductive. Therefore, to substitute for it a contradiction of it, in Euclid's scheme of fundamental assumptions, is to get with certainty another equally logical theory to do all that Euclid's geometry has ever done.

Of such systems each may throw light on the other, each may possess special advantages for particular applications.

But more than that: three such systems

used simultaneously may be able to accomplish what no one of them could do. This is beautifully illustrated in a theory communicated to me by F. W. Frankland, using a cosmic medium in which small regions of elliptic and hyperbolic space alternate, given a strain toward parabolic space which produces an elasticity or resilience simulating the properties with which physicists have endowed their hypothetical ether.

GEORGE BRUCE HALSTED.

UNIVERSITY OF TEXAS.

THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE.

SECTION H, ANTHROPOLOGY.

THE effect of environment on the success of a meeting was well demonstrated at Denver. Local interest in the Section of Anthropology, fostered by the Colorado Cliff Dwellings' Association, had reached such a pitch even in advance of the opening session that the small room originally intended for the Section was abandoned for one with a seating capacity of 200. This large room was converted into a bazaar of rare aboriginal ceramics, Navajo blankets, basketry and pictures of Indian scenes by a committee from the Cliff Dwellings Association consisting of Mrs. J. D. Whitmore, Mrs. G. T. Sumner and Mrs. W. S. Peabody, all of Denver.

The meeting was memorable for sustained interest. The attendance was unprecedented, averaging at least 150 for the morning sessions; the afternoon audiences were also large.

Section H was organized on Monday morning, August 26, after the adjournment of the General Session, in accordance with the provisions of the constitution. The officers for the Denver meeting were as follows:

Vice-President, J. Walter Fewkes.
Secretary, George Grant MacCurdy.

Sectional Committee: A. W. Butler, vice-president, Section H, 1900; Frank Russell, secretary, Section H, 1900; J. Walter Fewkes, vice-president, Section H, 1901; George Grant MacCurdy, secretary, Section H, 1901; Mrs. M. L. D. Putnam, Frank W. Blackmar, G. A. Dorsey.

Member of Council, W. J. McGee. *Member of General Committee*, Mrs. W. S. Peabody.

Retiring Vice-president Butler's address, entitled, 'A Notable Factor in Social Degeneracy,' was delivered Monday afternoon. It was printed in SCIENCE of September 20.

The titles of papers presented before the Section are accompanied by brief abstracts in so far as it has been possible to secure these from the authors.

1. 'Exhibit of Curves of Speech': E. W. SCRIPTURE.

An exhibit of a series of plates containing the curves of vibration traced from a gramophone plate containing Rip Van Winkle's Toast spoken by Joseph Jefferson. In the absence of the author, the paper was presented by Mr. MacCurdy. It will be printed in Scripture's 'Elements of Experimental Phonetics.'

2. 'Influences of Racial Characteristics on Socialization': FRANK W. BLACKMAR.

Racial characteristics are the great barriers that prevent a complete socialization of the human race; the race idea, or consciousness on the part of two groups of people that they are different in origin and structure is a detriment to perfect social union; a transition from the old family, or ethnographic, status to the modern, or demographic, society has been exceedingly difficult; the race idea has been the hindering cause in the progress of democracy; the historical examples of the social difficulties of Greece, Rome the Iroquois tribes and the Aztec federation; the difficulties of socialization appear in the development of homogeneous society in large cities; difficulties arising from an attempt to socialize widely divergent races; when common marriage relations are pro-

hibited by law, custom or prejudice the basis for social amalgamation is wanting; the inter-marriage of superior and inferior races results in an offspring inferior to the lowest of the united races. It is possible, however, through artificial selection, to unite the best elements of each race and hence raise the standard of the lower race. The variation in results from the inter-marriage of widely differentiated races as observed in the characteristics of the offspring.

It must be observed then, first, that a perfect social union is not possible between races that cannot intermarry; second, that intermarriage is not probable among widely divergent races if once included in the same social system; third, that intermarriage is not desirable between widely divergent races because controlled by lower sentiments and usually practiced by the lower elements, thus leading to degeneration; fourth, that race prejudice, so far as it prevents the union of widely divergent races, is good rather than evil. When different races, widely separated as to origin or widely divergent in culture, live under the same government, each must have its place; a government founded on justice must protect the weaker race and preserve its rights; examples from studies of the social and political status of the African race in America; examples from studies of the social and political status of the American Indians; a plea for a more careful study of races as a basis for socialization and a means for procuring rational legislation.

Discussion: Butler pointed out the necessity of understanding the psychic standpoint of a people in order to understand the influences of race or culture. McGee emphasized the invigorating influences of blood-blending when the stocks are not too greatly diverse, as shown, for example, by the British and American peoples, and then

mentioned culture as a factor of paramount importance in ethnic and demotic development. This paper was also discussed by Russell and Dorsey.

3. 'The Anthropological Collections of Yale University Museum': GEORGE GRANT MACCURDY.

An abridged statement relative to the size and character of the collections which, it is hoped, may be of service to students making a comparative study of museums of anthropology. They comprise from 15,000 to 18,000 specimens representing geographically thirty-six states and territories, Hawaii and the Philippines, besides forty foreign countries. The greater part of the material is archeological. The antiquities from Central America alone number over 3,000, including fifty-three gold ornaments from the Province of Chiriqui. The collection of Missouri pottery, more than 1,000 pieces in all, is one of the largest and best in the country. A representative series from the Quaternary and cavern deposits of western Europe, the Swiss Lake Dwellings, and the shell heaps and dolmens of Scandinavia has recently been installed. In respect to physical anthropology, the museum possesses several hundred crania, chiefly Amerindian, Hawaiian and New Guineaian.

4. 'Report on Work recently done by the Department of Anthropology, Field Columbian Museum': by the curator, GEORGE A. DORSEY.

Discussion: J. Walter Fewkes.

5. 'Political and Social Conditions in the Hawaiian Islands': DAVID STARR JORDAN.

6. 'Notes on Criminal Anthropology': AMOS W. BUTLER. A study of the individual family characteristics of inmates of the Indiana Reformatory. The results of four years of operation of the indeterminate sentence and parole law in that State.

7. 'The Nature of Sun Worship': J. WALTER FEWKES.

The two chief gods of the Pueblos are the sky god and the earth goddess. The sky god has a variety of names, some of which are the same as his attributes, as: wind, lightning, rain, etc.; others are simply clan names for the same god. The sun god is a being symbolized by the sun. The sun is a shield carried by the sky god. This sky god or sun god (the names are interchangeable) is the male principle—*i. e.*, the god of germs. His house is in the underworld. The female principle is the earth goddess, the goddess of germs. The god of fire was a god of life which practically originated as sky god. Differentiation came later. Inasmuch as the underworld was the home of the sky god and also regarded as the home of the dead, the sun as ruler of the underworld was regarded as the god of death. The sky god and earth goddess are personated by animal forms and the names of these animals are sometimes applied to them, *e. g.*, the sky god is often called the thunder bird. So the earth goddess is called the spider woman. Thus, in popular stories, they say the spider woman created man. Creation, as we understand it, is a foreign conception to primitive man; it is always akin to birth. The sky god and earth goddess are father and mother to all men, and animals as well. The earth is preexisting in their belief. Religious beliefs and practices are simply magical. Primitive man believes that everything has a magic power. The earth has magic power. The sky is regarded as a solid body and has its magic power. Every man, animal and object has its magical power, and the object of worship is to make use of this magical power to bring about desired results. For example, suppose a man wishes to bring rain. He owns certain fetiches whose magic power is great enough to compel the magic power of the sky to make it rain. He knows certain songs or prayers which will do the same.

He exerts this power in the form of a rite or ceremony.

8. 'Some Remarks upon the Attitude of the Citizens of the Southwest toward Archeology': FRANK RUSSELL.

A paper based upon observations made during an extended archeological reconnaissance in Arizona and adjoining territories. This research developed the fact that the average ranchman or miner takes an active interest in the antiquities of his locality, and usually formulates theories that are sometimes startling to the archeologist. The author also discussed the attitude of the Mormons, the extent of unscientific exploration and vandalism; besides relating personal experiences.

Discussion: Dorsey, Fewkes and Hewitt.

9. 'The Proposed Cliff Dwellers' National Park': EDGAR L. HEWITT.

The following is a summary of Mr. Hewitt's paper:

(a) The geological conditions of Pajarito Park, illustrated by photographs and an archeological map. (b) Nature and extent of the ruins thereon; illustrated by photographs of cavate lodges; ground plans of ruins known as Tchrega, Navakwa, Tsankawi and Otowi; maps of mesas on which these ruins are situated, and restorations in water-color of Tchrega and one section of cliff showing cavate lodges. (c) The pictography of the ancient inhabitants, illustrated by series of photographs from Puye and Pajarito. (d) Historical sketch of the movement providing for the setting aside of the Pajarito region as a national park. (e) Discussion of House Bill No. 13,071, known as the Lacey Bill.

Discussion: Blackmar, Fewkes, Dorsey and McGee. The last named emphasized the necessity of preservation of antiquities. He had drafted a general law for the preservation of antiquities on lands belonging to the United States. Had it passed, it would be easy to have states act on lands belong-

ing to them. The Public Lands Committee has recommended the setting apart of Pajarito Park as a national park to be called 'The Cliff Dwellers' National Park.'

One of the direct results of Mr. Hewitt's paper was the appointing of the following committee to draft resolutions on the preservation of the ancient monuments of the Southwest:

Edgar L. Hewitt, Chairman,
Amos W. Butler,
George A. Dorsey,
George Grant MacCurdy.

The report of this committee, after being accepted by the Section, was adopted by the Council and read in general session Friday morning.

10. 'Some Pawnee and Wichita Games':
GEORGE A. DORSEY.

Discussion: Russell, Culin, McGee and Fewkes.

11. 'The Teaching of Anthropology in the United States': GEORGE GRANT MAC-CURDY.

Information relative to the teaching of anthropology in our institutions of learning, collected at the request of the 'Committee on the Teaching of Anthropology in America.' It was found upon investigation that thirty-one universities and colleges now offer instruction in anthropology. They are: Beloit College, Beloit, Wis.; Bellevue College, Bellevue, Nebr.; Boston University; Brown University; Clark University; College of Physicians and Surgeons, Boston; Columbia University; Columbian University, Washington, D. C.; Creighton University, Omaha, Neb.; Dartmouth; Georgetown University, Washington, D. C.; Harvard; National University, Washington, D. C.; New York University; Niagara University, Niagara County, N. Y.; Phillips Academy, Andover, Mass.; Ohio State University, Columbus; University of California; University of Chicago; the Universities of Illinois, Indiana, Kan-

sas, Minnesota, Missouri, Nebraska, Pennsylvania, Vermont, and Wisconsin; Western Reserve University; Willamette University, Salem, Oregon; Yale University. Of the thirty-one institutions offering anthropology, it is found to be an adjunct of sociology in nine, of philosophy in five, of psychology in three, of geology and zoology in five, and of medicine in one; while in five instances it stands practically alone and in three it is unclassified.

Discussion: Blackmar, McGee, Dorsey and Farrell.

This paper will be printed in SCIENCE.

12. 'Current Questions in Anthropology':
W J MCGEE.

Discussion: Russell, Dorsey and others.

13. 'Analogy between Writing and Speech': ROBERT ARMSTRONG.

(a) All alphabetic characters are analogous, in (1) *material* and in (2) *function*, to the voice elements. (b) Written or printed letters have usually no analogy of character to the sound elements they represent. (c) Perfect analogy between graphic signs and spoken sounds is not attainable. But in proportion as alphabetic signs can be modeled from the sound elements they respectively represent, written or printed words will approach spoken words in character, and hence, in facility, economy and all that is desirable in written or printed words.

Charts were used in illustration of the subject.

14. 'Notes on the Archeology of Cuba':
STEWART CULIN.

15. 'The Problem of the Cliff Dwellers':
J. WALTER FEWKES.

A discussion of the relation of ancient Cliff Dwellers to modern Pueblos, showing a kinship in culture which does not, however, imply a kinship of blood. There was at least some kinship of blood. Some of the cliff houses in the Cañon de Chelly have been inhabited in historic times. There is a clan living now at Moki whose ancestors

once lived in the Chelly cañon. A very old woman of Moki still lives whose mother was born in a Chelly cañon cliff house. The cliff house may have been very old at that time, however. There are some very old cliff houses, while others are comparatively modern.

Discussion: Dorsey, Holsinger and ex-Governor Prince, of New Mexico. Governor Prince said the territory of New Mexico had offered the Old Palace in Santa Fé as a branch of the Smithsonian Institution.

A paper by J. Crawford on 'Sculptured Stone Images of Man by the Aborigines in Nicaragua,' and one by Charles E. Slocum, entitled, 'A Plea for Greater Simplicity and Greater Accuracy, in the Writings of the Future, regarding the American Aborigines,' were read by title.

On Tuesday, at 4 p. m., Section H adjourned to hear Mrs. John Hayes Hammond's lecture on 'The Cliff Dwellings of Colorado,' illustrated by lantern slides.

Dr. Fewkes's lecture Friday evening, on 'The Moki Snake Dance,' illustrated by lantern slides, was also of special interest to anthropologists, though not a part of the regular program.

A letter was read from Miss Alice C. Fletcher, who, in her enforced absence on account of illness, sent greetings to the Section; also a letter from Mrs. Daniel G. Brinton, to the effect that a new edition of 'The American Race' would appear in September of this year.

The report of the 'Committee on the Teaching of Anthropology in America,' which was read before Section H by Dr. McGee, was printed in SCIENCE of September 6, p. 353.

The report of the 'Committee on Anthropometric Measurements,' including the request for a grant of \$50, was recommended and later adopted by the Council.

Section H was authorized to hold a winter meeting, the time and place to be decided

upon by the Sectional Committee. The winter meeting will be held in Chicago during Convention Week of 1901-02.

The newly elected officers for the Pittsburg meeting are:

Vice-President, Stewart Culin, of the University of Pennsylvania.

Secretary, Harlan I. Smith, of the American Museum of Natural History, New York.

The invitation extended to Section H by Mr. and Mrs. Gilbert McClurg, of Colorado Springs, to inspect their cliff dwelling collection on Monday, September 2, was very generally accepted. The same week, a party of anthropologists visited the cliff dwellings of the Mesa Verde in southwestern Colorado as guests of the ladies of the Directorate of the Colorado Cliff Dwellings Association, of which Mrs. McClurg is Regent.

GEORGE GRANT MACCURDY,
Secretary of Section H.

EARLY WINTER COLORS OF PLANT FORMATIONS ON THE GREAT PLAINS.*

ONE who has not been upon the Great Plains in the early winter, after the autumn frosts have changed the prevailing green of the landscape, can have little conception of the variety of the colors which meet the eye. These include several shades of red, two or more of orange, one or more of yellow, two of green, a dark blue, a purple, several browns and blacks, and many grays. With a little practice the eye can distinguish from twenty to twenty-five shades of color, sometimes blending into one another almost insensibly, or standing out in marked contrast upon the landscape picture.

It does not require long study to show that so far as the natural vegetation is concerned these colors conform to the distribution of the various plant formations, and

* Read before the meeting of the Botanical Society of America, in Denver, August, 1901.

that we have here a natural color-scheme in which the plant formations are mapped on the landscape. Let me attempt to reproduce some of the color pictures I have seen.

First, give the picture a general gray tone, which may include the sky as well as the earth surface. In the background where the hills slope away to the horizon are great patches of dull red or purple, bordered by the silvery gray of the buffalo grass. Here in the foreground may be a stretch of light yellow marking the area of a field of maize stalks still standing where they grew, and there may be a gray, velvet-like meadow of buffalo grass, with dashes of brick-red now and then on its surface where the bunch grasses stand, or where the red stems of the knotweeds mark the winding course of a 'draw.' Here and there the landscape shows a black spot where the farmer has plowed up the rich soil in readiness for the spring's plantings. Crossing a ravine we find the sloping sides red with the bunch grasses, below which is a belt of yellow 'prairie grass' bordering the dry bed of the brook, the latter marked here and there with red-twigged willows. In the distance, where a stream winds its way along, is a black line of cottonwood trees, whose trunks and larger branches show black against the gray background, and on nearer approach we note the silvery sheen of their twigs contrasting with their dark stems and branches. A plum thicket in a ravine forms a dark-blue patch, with a background of dull red knotweeds, or bunch grass, further back shading into the silvery gray of the buffalo grass.

Now we see a silvery gray meadow of buffalo grass with faint patches of reddish color scattered over it; back of it a fringe of cottonwood and box elder trees with dark trunks, the latter loaded with their light brown fruits, and still back of these the slopes with alternating silvery gray patches of buffalo grass and the dull red of the

bunch grasses, running up to the sky line of light ochre where a field of maize is still standing. To complete the picture add a few stacks of alfalfa, now dark brown or black, and a spectral windmill here and there outlined in somber colors.

Allow me to show you one more picture seen near Minden, under the ninety-ninth meridian. Here is a little valley framed in with a brick-red border of bunch grass which grew on its sloping sides: next to it are patches of yellow switch grass and silvery gray buffalo grass, and a rich, velvety maroon spot where the ripe fruits of the smooth sumach give their color to the scene. The floor of the valley is covered with the red knotweed whose red is deepened in a central strip to a rich purple-red where a water course has encouraged the red-stemmed *Polygonums* to grow.

I need not attempt to place before you more of these general views. In all cases the picture has a basis of gray, and on this are laid reds, yellows, blues, purples, browns and blacks, etc. Let us inquire into the meaning of these strips and patches of color.

When the autumn drought and the early winter frosts stop the growth of vegetation the green shades of summer, themselves by no means uniform, are replaced by the hues indicated in the preceding paragraphs. The practiced eye can distinguish the plant formations on the open plains by their shades of green when the vegetation is in its vigor, and it appears that the early winter coloration is in a measure related to this fact. The boundaries of the formations are more sharply defined in the early winter, since the color differences are emphasized. I have not, however, been able to determine any law of color change in the plants of different formations. In fact it appears that each plant is a law unto itself. Thus the light green of the low bunch grass (*Andropogon scoparius*) gives place to a red,

as does the still lighter green of the tall knotweed (*Polygonum ramosissimum*), while the nearly similar pale green of the buffalo grass (*Bulbils dactyloides*) turns to a silvery gray. On the other hand, the richer green of the switch grass (*Panicum virgatum*) turns to a red orange below and a light yellow above, and the dark green of stinkweed (*Dysodia papposa*) as seen in the summer is replaced in early winter by a pronounced brick-red. Yet in the midst of these changes the clumps of dagger weed (*Yucca glauca*) and the bunches of cactus (*Opuntia humifusa* and *O. polyacantha*) retain their green color, and in fact, are the only green things in the landscape.

I may summarize the facts so far as I have observed them by grouping the plants under the colors they assume, as follows :

RED.

Bunch grasses (*Andropogon furcatus*, and *A. scoparius*).

The first (tall bunch grass) is sometimes of a rich orange-red running to dull red, and the second (low bunch grass) is from brownish red to brick-red and purple, fading out sometimes to a dull gray.

Knotweeds (*Polygonum ramosissimum* and *P. emersum*), with the stems of various shades of red, in the second species running to purple red.

Willows (*Salix fluviatilis*) with red twigs.

Stinkweed (*Dysodia papposa*), whole plant becoming brick-red.

ORANGE.

Bunch grass (*Andropogon furcatus*); as noted above, this species sometimes assumes a rich orange-red color.

Switch grass (*Panicum virgatum*) the lower portions of the seeding plants are often of a red-orange color.

YELLOW.

Maize fields during the autumn and early winter assume many shades, from the deepest yellow to a pale straw color.

Switch grass (*Panicum virgatum*); the upper portions of the seeding plants are often of a light yellow color.

GREEN.

Dagger weed (*Yucca glauca*) and prickly pear cactus (*Opuntia hemifusa* and *O. polyacantha*) constitute the only green vegetation on the plains in the winter.

BLUE.

Plum thickets (*Prunus americana*), seen at a little distance are distinctly of a dark blue color.

PURPLE.

Sumach fruits (*Rhus glabra*), ranging from a dull purple to a rich maroon-purple.

Low bunch grass (*Andropogon scoparius*), as noted above this species ranges from dull red to purple.

Knotweed (*Polygonum emersum*) although usually red, sometimes it becomes a purple-red.

BROWN.

Russian thistle (*Salsola tragus*), brown to blackish-brown, and the same may be said for weed fields in general.

Plum twigs (*Prunus americana*); although plum thickets when seen at a little distance are dark blue, the twigs when seen near at hand are reddish brown.

Box elder fruits (*Acer negundo*), light brown, and as they are very abundant they give the trees their color when seen near by.

BLACK.

Cottonwood tree trunks and branches (*Populus deltoidea*) seen at some distance are brownish-black to black.

Plowed land, burned areas and wagon trails all show black or nearly so on the landscape.

GRAY.

Buffalo grass (*Bulbils dactyloides*), from a light or silvery green in the summer, this species changes to a light gray or silvery gray in the winter.

Grama (*Bouteloua oligostachya*), gray.

Beard grass (*Aristida* sp.) light gray.

Tickle grass (*Panicum capillare*), silvery gray.

Low bunch grass (*Andropogon scoparius*); as indicated above, this may fade out to a dull gray.

Cottonwood twigs (*Populus deltoidea*), grayish-white.

I may close this paper with a couple of sections observed between Oxford and Minden, Nebraska.

In the one case (Figs. 1 and 2) a ravine, with moderately abrupt but regularly sloping sides, was observed to have a central band

FIG. 1. Ground plan of ravine. *a*, yellow; *b*, red; *c*, gray; *d*, red.

(*a*) of yellow (switch grass) which occupied the entire floor. On each side was a belt (*b*) of red (bunch grass) which occupied the lower and more sloping part of the side of the ravine. On the shoulder of the ravine, running down to the more precip-

FIG. 2. Section of ravine; *a*, yellow; *b*, red; *c*, gray; *d*, red.

itous part and back to the edge of the level ground was a broader belt (*c*) of gray (buffalo grass and grama), and back of this again came the red of the bunch grass (*d*) which colored the general surface of the plain.

In another case (Fig. 3) a gentle slope with somewhat terraced surface was ob-

served with a peculiar distribution of color. There were three steps on the slope, each not more than twenty to thirty centimeters

FIG. 3. Section of terraced slope; *a*, *a*, *a*, red; *b*, *b*, *b* gray.

in height, and a couple of meters apart, the surface sloping gently from step to step. On each terrace the upper edge near the step (*a*) was red with bunch grass, while the lower portion (*b*) was gray with Buffalo grass and grama. This was repeated exactly upon each terrace, giving the whole view a very singular appearance.

CHARLES E. BESSEY.

THE UNIVERSITY OF NEBRASKA.

RUDOLPH KOENIG.

ON the second day of October, 1901, Rudolph Koenig passed away at his home in Paris in his sixty-ninth year. He had been in failing health for several years.

Rudolph Koenig was born in Koenigsberg, Prussia, on the 26th of November, 1832. At his home he received nothing beyond the usual high school training given in the local gymnasium, in which his father was the teacher of mathematics and physics. He went to Paris at the age of nineteen years, and in the French metropolis he spent most of his manhood. Here he began life as an assistant in the manufactory of a celebrated violin maker, Vuillaume, where he manifested unusual aptitude both as a mechanic and as the possessor of an extraordinarily delicate and correct ear for music. Such leisure as he could command was devoted to the study of mechanics and physics.

Within a half-dozen years the young acoustician was enabled to undertake business on his own account, having already attracted the notice of men of science by his ingenuity, patience and accuracy. In 1859 he issued his first catalogue of acoustic

apparatus. From that day to the present Koenig's instruments, and especially his tuning forks, have been generally recognized as standard.

Koenig was not satisfied to fill orders and maintain his reputation as a constructor of instruments. He early perceived the value of the graphic method for the study of harmonic motion, and to this he devoted much time and labor during the first few years after establishing himself independently. Wertheim and Duhamel had already used the tuning fork with style attachment for the registration of simple vibrations, as suggested a half century previously by Dr. Thomas Young in England. Koenig extended it to the study and registration of compound harmonic motion for both parallel and rectangular vibrations. The mathematical analysis of wave motion had been abundantly brought out in technical treatises, and Lissajous had but recently excited admiration by his optical method of presenting rectangular vibrations. Koenig devised the method of recording these directly from the sounding tuning fork. At an international exhibition held in London in 1862 he exhibited an album containing a large variety of such phonograms, recorded with apparatus of his own device, and accompanied with the tracings of the corresponding theoretical curves. This was the starting point for the use of the graphic method of self-registration which has since been so extensively employed in laboratories of physics, physiology and psychology.

It was at the same exhibition that Koenig made known a wholly new method of causing the effects of sonorous vibration to become visible by utilizing the delicate sensitiveness of flame to variations of atmospheric pressure. The suggestion had come from America, where Le Conte had published, in 1858, his observations on the effect of sound waves upon naked gas flames.

Koenig devised the manometric capsule, and resorted to Wheatstone's application of the revolving mirror for spreading the flame images. The last improvements on this method have been made by the application of instantaneous photography to perpetuate the images, some of the best of this work having been done within the last few years by Hallock in New York and Merritt in Ithaca. The manometric flame is not equal to the tuning fork curve as a means of studying the composition of vibration, but the novelty and attractiveness of the method quickly made its author famous. He received a number of medals, and in 1868 the honorary degree of doctor of philosophy was conferred upon him by the university of his native city, Koenigsberg, in acknowledgment of his meritorious original work in science.

Prior to 1882 Koenig had published about sixteen scientific papers, some in the *Comptes Rendus*, but most of them in the *Annalen* of Poggendorff and Wiedemann. These were gathered into a volume entitled, 'Quelques expériences d'acoustique.' Since that time he has published a number of contributions to *Wiedemann's Annalen*, the last of which appeared in the summer of 1899. Failing health had already put a check upon his activity, but his passion for experimental research continued long after the time when most men lose their enthusiasm for abstract investigation. All his research work was the outcome of the love of science without the promise of pecuniary reward. It was done, moreover, with full knowledge that as a branch of pure science acoustics had been forced to the background by such subjects as heat, and more especially electricity, in which the field has become widened almost without limit during the last two or three decades.

In the absence of systematic university training in early manhood Koenig as an investigator in physics was compelled al-

ways to work at some disadvantage. He had an abiding faith in experiment, and was not afraid to proclaim the results of his careful, painstaking work, even if it seemed to contravene the conclusions of those whose theoretic preparation was better than his. The subject of musical quality was one which he attacked with characteristic patience. With the mathematical theory of combination tones, as brought out by Helmholtz, and the two subdivisions of difference tones and summation tones, Koenig was not prepared to grapple. With his naturally acute and highly trained ear he sought in vain to perceive the summation tones for which theory provided, and he reached the conclusion that they had no objective existence. Difference tones, or beat tones, as he called them, are easily perceived, and he spent much time in the investigation of such tones due to the interference of upper partials. It was in furtherance of this investigation that he invented the wave siren; and as a result of experiment with it he concluded, in opposition to the view of Helmholtz, that musical quality is determined not only by the number, the orders and the relative intensities of the upper partials which accompany a given fundamental tone, but also by their mode of phase combination. To test this the wave siren was certainly better than the apparatus employed by Helmholtz; but the perception of the result requires an experienced ear. The experiment is more psychological than physical. Upon the present writer, while cooperating with Koenig in his laboratory, and upon others also, the decided impression was that Koenig's conclusion was correct. But the subject is still one for investigation.

A monumental piece of mechanical work accomplished by Koenig was his great tonometer, consisting of hundreds of accurately adjusted and properly labeled

tuning forks arranged in a series, each making a definite and small number of beats with the preceding and following ones, so that the frequency of any source of sound approximately simple can be at once ascertained by direct comparison. The range extends through all the tones ordinarily employed in music. To have access to this tonometer the late Professor A. M. Mayer spent the summer of 1892 in Paris, where he secured the cooperation of Koenig in his research on the variation of the modulus of elasticity of different metals with change of temperature, as indicated by the pitch obtained by transverse vibration of bars. Koenig's keen ear was applied also in Mayer's investigation regarding the duration of the residual auditory sensation when beats are produced by neighboring tones in different parts of the musical scale. The author's conclusion was that, between the limits of 100 and 4,000 vibrations per second, there was closer accordance between the results of calculation and observation than in the case of any other physiological law for which the attempt had been made to express sensation mathematically. So well trained was Koenig's ear that in the tuning of the standard forks issued from his laboratory there was little need for any better guide than his own auditory sensation. After the pitch had been provisionally attained in this way it was corrected by other and more exact methods, but the correction was always very small.

It seems scarcely probable that Koenig will have any successor. For a man now to devote his whole life to the science of acoustics would be a piece of specialization for which but little reward can be expected. The progress of science has its phases of relative importance and that of acoustics seems now to be past. Koenig is dead, and his friends will remember him with affection and respect. His devotion to acous-

tic science was unique. His life was that of the recluse bachelor, and his later years brought anxiety and privation because his science had lost its value as a means of support. He will not soon be forgotten; but likewise no one will aspire to take his place.

W. LE CONTE STEVENS.

WASHINGTON AND LEE UNIVERSITY,
LEXINGTON, VIRGINIA.

SCIENTIFIC BOOKS.

1. *Hygiene and Public Health*. By LOUIS PARKES, M.D., D.P.H., London University, and HENRY KENWOOD, M.B., D.P.H., F.O.S. Sixth edition, 1901. Philadelphia, Pa., P. Blakiston's Son & Co., publishers. With numerous illustrations. Pp. 732. Price, \$2.50.
 2. *The Theory and Practice of Military Hygiene*. By EDWARD L. MUNSON, A.M., M.D., Captain, Medical Department, U. S. Army. First edition, 1901. New York, Wm. Wood & Company, publishers. Illustrated by eight plates and nearly four hundred engravings. Pp. 971. Price, extra muslin, \$8.00; leather, \$8.75.
 3. *A Manual of Practical Hygiene*, for students, physicians and medical officers. By CHARLES HARRINGTON, M.D., Assistant Professor of Hygiene, Medical School of Harvard University. First edition, 1901. Philadelphia and New York, Lea Brothers & Co., publishers. Illustrated with twelve plates and one hundred and five engravings. Pp. 729. Cloth, \$4.25 net.
 4. *The Principles of Hygiene*; a practical manual for students, physicians and health officers. By D. H. BERGEY, A.M., M.D., First Assistant, Laboratory of Hygiene, University of Pennsylvania. Philadelphia, W. B. Saunders & Co., publishers. Pp. 495. Price, cloth, \$3.00 net.
 5. *School Hygiene*. By EDWARD R. SHAW, Professor of the Institute of Pedagogy, New York University. First edition, 1901. New York and London, The Macmillan Company, publishers. Pp. 260. Price, cloth, \$1.00.
- In view of the act that hygiene is not an independent science, but a correlation of the teachings of physiology, chemistry, physics, meteorology, pathology, epidemiology, bacteriology and sociology, it is not surprising that the progress of this branch has been phenomenal. Over twenty text-books have been issued during the last ten years, and all but Parkes's in the above list are products of the present year. Indeed, this science was scarcely taught in any of our medical schools twenty years ago, and has received such an impetus during the past two decades that many regard it of modern origin. Such, however, is not the case, for on turning to early history, we almost invariably find that the health of the population has been made the subject of legislation. Hygiene was practiced by the Egyptians, the old Indians and Hebrews, and a study of the habits of the primitive peoples shows that a desire to prevent disease is innate to all men. The Greeks and Romans paid special attention to the physical culture of their youth, public water supplies and baths, and Athens and Rome were provided with sewers at an early period of their history. During the Middle Ages sanitation received a decided check; ignorance and brutal prejudices appear to have been the ruling spirits, and for many reasons it was the most unsanitary era in history. About this time most of the towns in Europe were built in a compact form, surrounded with walls; the streets were narrow and often winding for defensive purposes, shutting out light and air from the houses. The accumulation of filth was simply frightful. Stables and houses were close neighbors, human filth was thrown on the streets or manure heap. The dead were buried within the church-yards. Sewers and aqueducts having been permitted to fall into disuse, the inhabitants were compelled to resort to wells with polluted subsoil water. All the conditions were favorable for the spread of infectious diseases, and in the fourteenth century alone the oriental or bubonic plague, according to Hecker, carried off one-fourth of the population of Europe. The mortality in towns was greater than their birth rate, and the city population until the close of the eighteenth century had to be recruited continually from the country. The repeated invasion of pestilential diseases, however, compelled everywhere some sanitary efforts in the way of

widening streets for the purpose of supplying more air and light to habitations, better methods for the collection and removal of the wastes of human life, improvement in connection with infant and orphan asylums and in the management of schools and prisons.

The nineteenth century can boast of many advances in hygiene, particularly since the European invasion of cholera in 1830. English towns which had been visited by this disease, and those fearing similar scourges, freely instituted sanitary reform in the establishment of sewers, public water supply, sanitary homes for wage-earners, etc., but even during the Crimean War, the medical officers of the army evinced a shameful ignorance of the principles of sanitation and induced Edmund A. Parkes to write his manual of Practical Hygiene, and his teachings have borne ample fruit, especially in the improvement of the air we breathe and the water we drink. The question, has human suffering been mitigated and human life greatly prolonged by efforts in sanitation, can be emphatically answered in the affirmative. The average length of human life in the sixteenth century was only between 18 and 20 years; at the close of the eighteenth, it was a little over 30 years, while to-day it is over 40 years. Indeed, the span of life since 1880 has been lengthened about six years, as shown by statistics in Mulhall's Dictionary of Statistics (4th Edition, London, 1899). Mr. William A. King, Chief Statistician in the U. S. Census Office, informs the writer that from the results of the mortality returns for the twelfth census, for the States in which the returns were secured from registration records in both 1890 and 1900, there appears to be an absolute decrease in the general death rate of about 1.8 per 1,000 of population. This decrease seems to be most marked in the rate due to scarlet fever, whooping cough, diphtheria and croup (combined), typhoid fever, malarial fever, consumption, diarrheal diseases and diseases of the nervous system, the decrease in the mortality in diphtheria and croup amounting to more than 50 per cent. On the other hand, the rate due to cancer and tumor (combined), Bright's disease, heart disease and dropsy (combined) and pneumonia is apparently greater than in 1890, the increase be-

ing most marked in the case of Bright's disease, cancer and tumor and pneumonia. The results in the decreased rate of diphtheria, croup, scarlet fever, typhoid fever, whooping cough, consumption, malarial fever and diarrheal diseases are the direct outcome of preventive medicine and are as gratifying as they are striking. We note with regret the increased rate in Bright's disease, heart disease, dropsy and pneumonia, and may well pause to inquire whether our ever-increasing annual 'national drink bill,' averaging 17.68 gallons per capita, may not be a factor in the development of these diseases, especially since there is reason to believe that the habitual and immoderate use of alcohol, apart from increasing the connective tissue and causing cirrhosis, also produces fatty degeneration, especially of the heart, liver and arterial coats, probably because it promotes the conversion of albuminoids into fats. Since our knowledge of the nature of infectious diseases has been more and more defined, scientific methods for their prevention have been applied. We have learned, too, that in addition to the germ there must be a suitable soil for its proliferation, and that sanitation will not only destroy the environments for its development without the body, but also place the system in the best possible condition to resist its toxic action. The application of this knowledge has saved millions of lives, besides an incalculable amount of human suffering and distress, not to mention the economic aspect of the question. When we remember all this and the fact that Jenner's discovery, at the close of last century, of a fundamental and practical method of producing artificial immunity has been far eclipsed in the last 20 years, and that we possess to-day not only curative but also protective sera for diphtheria, erysipelas, tetanus, plague and possibly cholera, tuberculosis, typhoid fever, pneumonia and a number of other immunizing agents for diseases of man and the lower animals, we have reason to believe that the solution of the problem of immunity is only a question of time and we may indeed expect great possibilities in our battle against infectious diseases. Great as our progress has been, much remains to be done. While every scientific physician familiar with biological research knows full well that if the

methods of prevention recommended by sanitarians, including the prompt disinfection of the dejecta of every typhoid fever patient, the expectoration and excretion of diphtheria and tuberculosis patients, for example, were adopted, these diseases would be reduced to a minimum and probably eradicated in the course of a few years. The facts are, these recommendations have not been generally adopted, because the knowledge gained by experimental medicine is not sufficiently diffused even among physicians. We hail, therefore, with special delight the appearance, in 1901, of five American text-books on this important subject. Dr. Louis Parkes's book is the sixth edition of a very popular text-book, in both England and America. It contains 12 chapters on water; the collection, removal and disposal of excretal and other refuse; air and ventilation; warming and lighting; soil and building sites; climate and meteorology; exercise and clothing; food, beverages and condiments; communicable diseases and their prevention; hospitals; disinfection; statistics; sanitary law and administration. The work is authoritative, and until the appearance of the American Text-books, by Rohé, Egbert and Coplin, enjoyed great popularity in our medical schools.

Dr. Munson's royal octavo volume of 948 pages is the best work in the English language on military hygiene. He has handled the subject in a masterly style. His literary skill, thoroughness and painstaking research, practical experience and expert knowledge of sanitary chemistry have combined to produce a treatise of rare merit. The work is divided into 27 chapters, and, in addition to the subjects treated of by Parkes and other authors in the general principles of hygiene, deals, of course, also with the selection and development of the recruit, the march in campaign, camp sites, the sanitary administration of the camp, post barracks and hospitals, diseases of the soldier, military mortality and morbidity, the habits of a soldier as affecting his efficiency, the hygiene of hot and cold climates, the hygiene of the troop-ship, etc.

Every chapter in the book is encyclopedic in character and contains a mine of the latest information of great value not only to the student of military hygiene, but to the general student

as well. So, for instance, the chapters on the selection and development of the recruit are of equal importance to those interested in personal hygiene and physical training. The chapter on water contains 150 pages, and is in many respects superior to the standard works exclusively devoted to the consideration of this important requisite. The chapter on the ration with his article on food in the hygiene of hot and cold climates covers over 160 pages and is practically a comprehensive treatise on food, dietaries, the preparation and preservation of food and its relation to health and disease. It contains facts not to be found in any other work.

The chapter on camp sites and the sanitary administration of camps is most admirably disposed of. Had the knowledge contained therein been more generally diffused among medical men and especially among the officers of the line, the disgraceful unsanitary scenes of our military camps during the recent Spanish-American war would not have been observed.

Chapter XV., on diseases of the soldier, is of extreme interest, especially the consideration of infective diseases, such as typhoid fever, which the author very properly considers as being the most important disease affecting soldiers. It is to be regretted that the lessons of the civil war and the note of warning sounded by Surgeon-General Sternberg at the outbreak of the Spanish-American war had made so little impression upon those entrusted with the care of our troops.

The chapter on excreta, sewage and refuse is very complete. The author's conclusion that typhoid cases are much more numerous in communities where fecal matters are collected in pits, pails, earth closets, etc., than among those provided with water-closets and sewers, was emphasized by the writer in his report on the prevalence of typhoid fever in the District of Columbia in 1895, and a probable explanation was offered by him in stating "these makeshifts, even if there were no wells, are still a source of danger in so far as they favor the transmission of germs by means of infected flies, nor can the possibility be ignored that the germs in leaky or overflowing boxes may reach the upper layer of the soil and with pulverized dust gain access to the system." It is a matter

of regret, therefore, that while 41 per cent. of our population live in towns having public water-supplies, only 28.7 per cent. are supplied with sewers, the neglect of which compels recourse to these makeshifts and leads to soil pollution and the evils referred to.

Space will not permit the presentation in detail of all the salient features of this excellent treatise. Our experience in the past shows the absolute necessity of sanitary training on the part of officers of the line. This work should be in the hands of every officer in the army and accessible to every enlisted man. We also venture to express the hope that a chair of hygiene will be created in connection with the military and naval academies. Such a step with men like Dr. Munson as professors would prove of incalculable value to the nation; indeed, the principles and practice of hygiene should be taught in every high school and college of the land, for nothing will contribute more to the sum total of human happiness than the preservation of health and eradication of preventible diseases.

Professor Harrington's manual is also complete, authoritative, practical and modern. It is divided into seventeen chapters, and we are pleased to note that a chapter on the 'Hygiene of Occupation' has been introduced and disposed of in a very satisfactory manner. The relations of occupation to health and life were studied as early as 1700 by Ramazzini, an Italian physician, and since then numerous monographs have appeared. We know to-day that persons habitually engaged in hard indoor work present a higher mortality than persons more favorably situated, and that the character of occupations influences to a great extent not only the average expectation of life, but also the prevalence of certain diseases. We know, for example, that tuberculosis is much more frequent among persons engaged in dust-inhaling occupations, and that the sharp angular particles of iron and stone dust are more liable to produce lesions of the respiratory mucosa than coal, flour, grain and tobacco dust. We know, too, that certain establishments are more or less productive of noxious and offensive gases, and that workers in lead, mercury, arsenic, phosphorus, poisonous dyes, etc., suffer especially from the injurious effects, and that other occu-

pations, such as mining, railroading and contact with moving machinery involve special danger to life and limb. For all these reasons the laboring classes need special protection, and in order to render this efficient, it must be provided by the enactment and enforcement of suitable laws. In 1864, 1867 and 1878, England enacted the so-called factory laws, while the first law as regards factory safety and sanitation in this country was enacted in Massachusetts in 1877, since which time 32 states have enacted similar laws. As a result of these laws, the majority of which were enacted during the past decade, commendable progress has been made in the way of ventilation, heating, lighting, removal of dust and injurious gases, means of escape in case of fire and prevention of injuries by moving machinery.

Dr. Harrington is quite right in saying: "It is often difficult or impossible, in the study of the effects of occupation, to eliminate outside influences which may affect the health of the worker as much or more than the circumstances of his trade. A hundred men, for example, from different strata of society, some married, others single; some living in comfortable houses, others in cheerless unsanitary tenements; some spending their evenings in wholesome recreation amid wholesome surroundings, others doing evening work in places of public entertainment and elsewhere, or spending their time and wages in the paths of vice; some naturally robust, and others inclined to disease, engage in the same occupation at the same time."

The writer has always felt that these and other factors, such as faulty nutrition, the result of badly prepared food and cold lunches, cannot fail to lower the power of resistance to disease, especially when the individual, in consequence of these very causes, has also become a victim of the alcohol habit, and has advocated the erection of sanitary homes for wage earners at reasonable rentals, the encouragement of cookery schools, the establishment of sanitary lodgings, model eating-houses and other betterments of industrial conditions. Dr. Harrington's book is well illustrated and will meet the needs of the student.

Dr. Bergey's book has just appeared and has been prepared, in the author's language, 'to

meet the needs of students of medicine in the acquirement of knowledge of those principles on which modern hygienic practices are based ; to aid students in architecture in comprehending the sanitary requirements in ventilation, heating, water supply and sewage disposal, and to aid physicians and health officers in familiarizing themselves with the advances made in hygienic practices in recent years.' The volume, while not exhaustive, is accurate and will meet the demand in a very satisfactory manner. We regret, however, that neither this book nor Harrington's volume refers to the important subject of sexual hygiene and the prevention of venereal diseases, which affect not only the offender, but innocent wives, the offspring and not infrequently other innocent persons. According to Fournier, one-seventh of the population of Paris is syphilitic, and Morrow, from statistics gathered in New York, believes it is quite possible that Fournier's figures may apply to New York. Neisser holds that gonorrhoea is, with the exception of perhaps measles, the most widespread of all diseases. Other authorities have computed that 80 per cent. of all deaths from disease of the uterus and its annexes are of gonorrhoeal origin, while according to Professor S. M. Burnett, of Georgetown University, 15,000 of the 50,000 blind persons in the United States lost their sight from blennorrhoea in the newborn, which, according to his calculation, involves a financial loss to the commonwealth of seven and one-half millions annually.

The measures which have been proposed for the control of the social evil and the prevention of its consequences are numerous enough, but not so easy of practical application. On the whole, it is believed that the remedy lies in public education. Public lecturers on the purity of man commit a serious mistake, however, when they picture the consequences of the social evil, without offering a suitable remedy. We should make a strong plea in favor of continence, and tell our young men that while the sexual passion is very strong, it can be accelerated or delayed, excited or lowered, by the influence of the will. We should assure them that by the cultivation of pure thought, removal of temptation, normal

mental and vigorous physical exercise, continence may not only become possible, but easy.

None of the books in the above list will fulfill a more important mission than the modest volume on School Hygiene, by Professor Edward R. Shaw, of the New York University. It is a timely book belonging to the Teachers' Professional Library series, and it is hoped it will enjoy a wide circulation, because, as the author very properly says, "The home may be educated to a great extent through the school. As the school, therefore, reacts closely upon the home, a knowledge of that which is hygienically best can in no other way be so quickly and thoroughly diffused."

The chapters treat of the school room, the school building, school grounds, warming and ventilation, sanitation, school baths, school furniture, posture and physical exercise, eyesight and hearing, handwriting, conditions conducive to healthful mental work, and diseases which concern the school. Every chapter is replete with information of great value and should be thoroughly absorbed by architects, school boards, teachers and parents. The book is accurate and reliable and the style clear and convincing.

During the year ending June 30, 1900, there were 15,341,220 children enrolled in the common schools of our country. When we consider that the mental and physical vigor of a nation depends largely on the environments of childhood and youth, it seems strange that up to within forty years little or no attention should have been paid to the hygiene of schools.

The author treats this important subject in a systematic and comprehensive manner, and no one can overestimate the practical results of his valuable teachings. Chapters IV. and V. are especially important, treating as they do of warming, ventilation, latrines, out-houses for country schools, plumbing, water supply, drinking-cups, daily cleaning of the school building, the cleaning of desks and seats, the disinfection of pencils and books, etc. Chapter VI., on school baths, should attract widespread attention, and shows what has been done in Europe, where the idea originated, and also in Boston, New York, and Chicago. According to the author, two distinct aims are held in view in the

provision which is made by school systems for bathing. The first aim is for physical exercise and health; when this is the aim a swimming tank is provided.* * * The second aim is to produce cleanliness and to teach cleanliness. The most satisfactory means to attain the second aim seems to be that of the shower-bath. In some schools a bath-tub is employed, but this cannot be used as economically in regard to time as the shower-bath; it must also be cleaned after each using. It will be understood, of course, that dressing rooms are necessary in connection with the baths. * * * The testimony of those who, under the conditions above mentioned, have instituted school baths is strong with reference to the physical and moral results arising therefrom. * * *

The writer is strongly in favor of swimming tanks in all high schools; such baths, after an ordinary cleansing shower bath, apart from bringing into play every muscle of the body, exert a general tonic effect and could be thrown open in the afternoons and evenings to adults, and thus subserve the purpose of public baths, of which there is a lamentable lack.

The chapter on eyesight and hearing is especially strong and suggestive of good results. The author, after referring to proper and sufficient lighting of the school room, points to the interesting investigations of Iaval, Cattell and Sanford, how vision may be impaired by texts printed in too small letters, the alterations needed in the forms of letters, the proper size of type for school books, color and surface of the paper for school books, the size of writing on the blackboard, the objection to the use of slates, color of writing ink, postures, use of fine maps, duty of parents in preventing children at home from reading excessively at night, or in the waning light, or sewing with black thread on black cloth with defective illumination.

The author's views on defective hearing are also extremely sound when he says, "if we are to educate children, it is supremely wise to know as many of their physical defects as possible, and especially is this true as regards defects of the two most important avenues of sense, the eye and the ear; for only by means of this knowledge can the teacher work intelligently and avoid unnecessary strain on the part

of the pupil and waste of effort on his own part. Careful investigations point to the broad fact that about 20 per cent. of school children possess some defect of hearing. It will be seen that the child of average ability who has some undetected defect of hearing will frequently be done an injustice and rated as dull or inattentive, not through any fault of his own, but because of a lack of knowledge on the part of the teacher of the true cause."

These abstracts sufficiently indicate the thoroughness which characterizes this most useful book.

GEO. M. KOBER.

GEORGETOWN UNIVERSITY,
WASHINGTON, D. C.

Manual of the Flora of the Northern States and Canada. By NATHANIEL LORD BRITTON, Ph.D., Director-in-Chief of the New York Botanical Garden; Emeritus Professor of Botany in Columbia University; Vice-President of the New York Academy of Sciences. New York, Henry Holt and Company. 1901. Duodecimo. Pp. x + 1080.

The appearance of a new manual of botany is an event of no small moment when it comes from the hand of one recognized as an authority in systematic botany. The 'Illustrated Flora of the Northern United States, Canada, and the British Possessions,' by Dr. Britton and Judge Brown, in 1896-7-8, marked an epoch in North American botany, and at once created an imperative demand for a handy field manual in the form of an abridgment of the large work. It is to meet this demand that the work before us is intended. In its preparation Dr. Britton has availed himself of the descriptions in the 'Illustrated Flora,' which are transcribed with little or no modification excepting the necessary one of changing English to metric measurements. Many species not described in the 'Illustrated Flora' are added, and not a few genera, bringing the total number of species to about 4,500 as against 4,162 in the original work. When we remember that the latest edition of Gray's 'Manual' contained descriptions of 3,298 species, and Coulter's 'Manual,' 1,881 species, it is evident that the utmost brevity has been imperative. Abbreviations are freely

used, although not to the extent so familiar in similar German manuals. Practically all synonyms are omitted, and this, while inconvenient for some users of the book, is no doubt the better policy in a compact manual. In this the author follows the wise example of Gray's 'Manual.' Synonymy, with all its confusing difficulties, need not be brought to the beginner's notice, and for the older botanist, anything short of full citations (impossible in such a manual) is of little or no use.

Students will be interested in noticing that 'Order' and 'Family' are not identical groups, but that they stand in their proper relation in this book, as in zoological manuals. The full citation of authorities for species, including double citation where necessary, and the citation of the author of each family name, are welcome novelties in an American botanical manual. As to the nomenclature used, the statement is made in the preface that "the principles adopted by the botanists of the American Association for the Advancement of Science at a meeting held in Rochester, N. Y., in 1892, and in Madison, Wis., in 1893, supplementary to the Code of Nomenclature adopted by the International Congress of Botanists held in Paris, France, in 1867, have been followed." Accordingly, we have here a manual in which the much-discussed 'Rochester Rules' are in force, and from this time forward young botanists will be taught this nomenclature from the first. There will henceforth grow up a generation of botanists for whom the names here given are orthodox.

This book must at once find its way into the schools and colleges, to which it may be commended for the students in systematic botany.

It remains to be said that the publisher has met and successfully solved the difficult task of bringing so large an amount of matter within the compass of a book not too large for easy carrying into the field. It might easily have been made still smaller and lighter by the use of still thinner paper, and a little closer trimming of the margins. As compared with the pocket edition of Gray's 'Manual' this is a much larger and heavier book; if printed on the same paper and trimmed as closely, this book would weigh but twenty ounces, instead of thirty as

it does now. We suggest that in future editions the printer and binder try to make some improvement in this respect.

CHARLES E. BESSEY.

SCIENTIFIC JOURNALS AND ARTICLES.

The American Naturalist for October contains the third and concluding part of W. M. Wheeler's 'Compound and Mixed Nests of American Ants,' the three forming an excellent compendium of our knowledge on the subject. Bashford Dean presents some interesting 'Notes on Living Nautilus' and Charles C. Adams has an article on 'Base-leveling and its Faunal Significance,' with illustrations taken from the topography and distribution of mollusks in the southeastern United States. The balance of the number is taken up with numerous reviews of scientific literature.

The Journal of Comparative Neurology for October. 'The Cranial Nerves and Cutaneous Sense Organs of the North American Siluroid Fishes,' by C. Judson Herrick. This is a detailed exposition of the components of the cranial nerves of the catfish and of the structure and innervation of the cutaneous sense organs. Of the latter there are four types, three classed as neuromasts (Merkel's *Nervenhügel*) and one as terminal buds (*Endknospen*), the former innervated by lateralis nerves, the latter by communis. 'The Psychological Theory of Organic Evolution,' by H. Heath Bawden, is an attempt to put some meaning into the term mental evolution without falling into the error of talking about unconscious mental states. Natural selection may in some instances be a survival of the fittest among accidental variations, but in many cases natural selection takes place in and through the conscious adaptation of means to ends. The condition of consciousness is organic tension. The evolution of consciousness has followed the path of critical stress in adaptation of organic forms. Hence the criterion for the presence of consciousness is not simply adaptation of means to ends, but adaptation under conditions of organic tension, *i. e.*, the ability to vary the use of means in the attainment of an end.

The Popular Science Monthly for November has for frontispiece a portrait of Charles Darwin

and the first article is taken from the *Journal of the Linnean Society* for 1858, being the now historic paper 'On the Tendency of Species to form Varieties; and on the Perpetuation of Varieties and Species by Natural Means of Selection' by Charles Darwin and Alfred Wallace. A. E. Verrill tells 'The Story of the Cahow' an unknown and probably extinct bird found abundantly on the Bermudas at the time of their discovery. The use of the bird and its eggs for food was the cause of its speedy extermination. Under the caption 'Psychiatry—Ancient, Medieval, Modern,' Frederick Lyman Hills gives a brief history of the methods employed for the treatment of the insane from early times to the present. John E. Gorst makes a plea for 'The National Control of Education' and Edward L. Thorndike discusses 'The Evolution of the Human Intellect.' Bradley Moore Davis considers 'The Origin of Sex in Plants' and David Starr Jordan has a brief article on 'The Fishes of Japan' with observations on the distribution of fishes. Paleontologists will hardly accept Dr. Jordan's three laws governing animal distribution as all-sufficient. The final paper is by A. C. Haddon on 'The Omen Animals of Sarawak' and contains much interesting information.

The Auk for October opens with a welcome article by William Brewster entitled 'An Ornithological Mystery' describing the notes and nest of a bird found in the vicinity of Cambridge, Mass., which so far has not been seen, but is presumably the little black rail. A. C. Bent describes, with photographs, the 'Nesting Habits of the Anatidæ in North Dakota' and Arthur H. Howell gives 'A Preliminary List of the Summer Birds of Mount Mansfield, Vermont,' including 86 species. J. A. Farley tells of the 'Alder Flycatcher (*Empidonax trailii alnorum*) as a Summer Resident of Eastern Massachusetts,' and Outram Bangs has a paper 'On a Collection of Birds made by W. W. Brown, Jr., at David and Divala Chiriqui' including descriptions of several new species and subspecies. Hubert Lyman Clark treats of 'The Classification of Birds,' as based on their pterylosis, an excellent paper, but one which will impress many as an additional piece of evi-

dence that birds may not be classified by one character only. William Alanson Bryan gives a 'List of the Hawaiian Birds in the St. Louis College Collection, Honolulu, H. I,' and finally, Francis J. Birtwell describes the 'Nesting habits of the Evening Grosbeak (*Coccothraustes vespertinus*).' The notes and reviews are numerous.

Bird Lore for September–October has a frontispiece showing the fine 'Bird Rock Group' of sea birds recently placed on exhibition in the American Museum of Natural History. H. W. Henshaw concludes his 'First Impressions of Hawaiian Birds,' Ralph Hoffman tells of 'A Chebic's Second Brood' and we have the regular instalment of 'Birds of the Season,' discussing the bird life of October and November in various parts of the United States. For young observers we have an account by A. V. Kidder of 'A Bittern at Close Range,' and we have Notes from Field and Study, Reviews, and the section devoted to 'The Audubon Societies.'

The Plant World for September has articles on 'Notes on Trees of Cuba,' by Valery Havard, a biographical sketch of the late 'Dr. Charles Mohr,' by S. M. Tracy; 'The Pasque Flower,' by John M. Holzinger, and many interesting briefer items. The instalment of the 'Families of Flowering Plants,' by Charles L. Pollard, continues the description of various families of the order *Sapindales*.

Popular Astronomy for November continues the study of the light curve of the new star in Perseus, by Dr. H. C. Wilson, and includes a chart of this curve which has been compiled with great care from many sets of observations. Dr. Lewis Swift, who has but recently given up the directorship of Mount Lowe Observatory on account of failing sight, permits the publication of a photograph of his various medals. This is accompanied by a brief résumé of his life as an astronomer, and of the discoveries for which the medals were awarded. Dr. T. J. J. See, of the Naval Observatory, contributes 'Preliminary Investigations of the Probable Diameters, Masses and Densities of those Satellites which have Measurable Discs,' and W. F. Denning, of England, writes of 'The Motion of the Great Red Spot and other

Markings on Jupiter.' Other articles are: 'The Astronomy of the Nebulæ,' by W. W. Payne; 'The Coming Opposition of Eros,' by Mary Clark Traylor; 'The Limits of Vision,' by Edwin Holmes, and 'The Brightness of Star Light,' by J. E. Gore.

DISCUSSION AND CORRESPONDENCE.

THE UNIVERSITY OF WEST VIRGINIA.

WITH the final resignation of Jerome Hall Raymond, last March, from the presidency of West Virginia University, and the election of Dr. Purinton, of Denison, to succeed him, another turbulent period in the history of that institution has come to an end.

It is worth noting that no one of the six men who have served as presidents of the West Virginia University since its foundation in 1867 has proved generally acceptable to the people of the State, and that no one has been less acceptable than President Raymond. And yet, according to a statement made to the writer by one member of the University faculty who has always lived in Morgantown, no other president began his work under more auspicious circumstances. The board of regents had a good working majority of intelligent men who were deeply interested in the welfare of the University and who were anxious to give a hearty support to their enthusiastic young president. The people in the surrounding community and the members of the faculty were also more friendly and more inclined to be pleased with Mr. Raymond than they had been with any of his predecessors.

Notwithstanding all this, trouble was inevitable. The president was young, aggressive and thoroughly saturated with the spirit of unlimited, rushing expansion which had prevailed in the University of Chicago during the preceding five years. The faculty of the West Virginia University, on the other hand, did not at that time (1897) contain a single Ph.D. from any reputable university. Some of the professors were therefore naturally unfit to be in charge of any department in a modern college or university, and their unfitness became especially glaring through the new president's vigorous attempts to convert the old Morgantown institution into a miniature copy of the

University of Chicago. Several of the professors, moreover, not only lacked the training necessary to make them competent instructors in a university, but were in addition so addicted to financial schemes and to politics as to be a hindrance to the peaceful development of any state institution of learning.

Unhampered and alone, Mr. Raymond succeeded for a time in carrying out his plans in the management of the University. The University catalogue was entirely remodeled on the plan of the University of Chicago catalogue, and the studies were correspondingly rearranged; the summer quarter was added, and the four-quarter system with the 'quarterly convocations' was introduced; an unlimited elective system of studies leading to one degree only (B.A.) was adopted; faculty meetings were abolished, and the president's plans and changes were all carried out by means of committees of his own appointment.

All these changes and many others less fundamental, though scarcely less irritating to one or another among the professors, followed in rapid succession. One by one the older members of the faculty came to feel that they were entirely unsatisfactory and that the president would like nothing better than to replace them as soon as possible by men of his own selection. This led to a tacit or open combination of the greater number of the professors against the president—a result which might have been expected, especially considering the records of forced resignations, reappointments and quarrels of various kinds which formed a part of the previous history of the University. The opposition spread rapidly not only among the students and the people of Morgantown but also throughout the State, where it unfortunately developed into a narrow-minded support of 'West Virginians' as against 'foreigners.' The temper of some of the crudest of Mr. Raymond's enemies is well illustrated by the extravagant vulgarity of the attacks which were made upon him during the winter and spring of 1900 by the *Clarksburg News* and the *New Dominion* of Morgantown. The unpopularity of the president alike among the faculty, students and the people, especially the local people, was in addition much increased by his

pronounced antagonism toward smoking, drinking and dancing. His unflinching and uncompromising defence of the doctrine of evolution in season and out of season further brought him into sharp antagonism with the strong church-going element of the State.

Nor did the new members of the faculty whom the president brought to the university serve to strengthen his position, partly because the local animosity against the president was turned into suspicious reserve toward these who were supposed to be his friends, and partly because there was probably not a single one among them who did not disapprove of the president's policy in one or another essential point. It must be noted that the president did his utmost to secure the most able and well-trained young men that the salaries offered could procure; but the policy of the university was not in the least affected thereby, because President Raymond continued to settle all questions himself, and the new professors as well as the old were distributed among the various committees so as to insure a majority in favor of the president's views.

No fair-minded person can doubt that President Raymond worked as only a man in his best years can work for the advancement of the university. To be sure considerable energy and some money were wasted on untimely features, such as the premedical course, the domestic science, the department of pharmacy, the work for Ph.D., and the correspondence courses. But after all this has been admitted there can be no doubt that the standard of scholarship was raised through Dr. Raymond's efforts far above what it had ever been before in West Virginia.

The most striking illustration of this general advancement is perhaps to be found in the equipment and management of the university library at the beginning and at the end of Mr. Raymond's administration. Before his arrival the books were all inside an iron railing, and in charge of a lady who did not pretend to know anything about the classification of books. Her chief function was to see that the books did not disappear. The place was open less than six hours a day, and during those hours the space outside the iron railing is said to have been the noisiest and most disorderly place on the

campus. This fall a thoroughly modern library building is being finished, and, what is more to the point, the library has been as pleasant, orderly, and well arranged as any one could wish during at least the last two years, that is, ever since the present librarian was able to bring order out of the previous chaos. The library is now open from 8 a. m. to 10 p. m., every week-day, and from 4 to 6 p. m. on Sundays and holidays. The amount of money which was spent for current literature and books under President Raymond's regime was also about all that could reasonably have been asked for, and this money was largely spent under the direction of the young instructors whom he had brought there, because there seemed to be very little demand for more literature from the older professors. Several departments of the university are now fairly well equipped with standard and recent literature.

Another striking illustration of how Mr. Raymond endeavored to raise the standard of the work done in the university is found in the changes which he introduced in the scientific departments. At the beginning of his administration botany, zoology, physiology, anatomy, and materia medica were taught by one man (an M.D.). During the last two years anatomy was not taught, and the other four subjects were represented by two Ph.D.'s and one M.D. Another Ph.D. was appointed assistant professor in chemistry. The department of physics was not changed, but it was well known that this was due only to the fact that the president could not change everything at once.

The climax came in the spring of 1900 when the president asked the board of regents for the resignation of five of the old professors, and in addition formally expressed his disapproval of two others as well as of the director of the experiment station. This step, bold and ill-advised as it seemed, was partly a measure of self-protection, for some of the men whose resignations were demanded were then openly doing everything in their power to bring about the downfall of Mr. Raymond. The board of regents did not grant the president's request, because four of the nine members composing the board were at this time opposed to the president, and further, because to grant such a request then

would almost certainly have brought the University into the politics of the State during the elections of last fall. The failure of the board to support the president on such an important matter left him, on the other hand, no other dignified course than to resign. The following letter of resignation was indeed promptly sent to the board :

TO THE HONORABLE BOARD OF REGENTS.

Gentlemen : I hereby place in your hands my resignation of the Presidency of West Virginia University.

I am moved to do this, and thus to give up some of the most deeply cherished hopes of my life, because I see no prospect of final success in my work.

It is impossible to build up a university save on the basis of sound morals and sound scholarship with the generous cooperation of those engaged in the work. I have asked the removal of certain men known to you and to me and to the community to be grossly deficient in one or all of these regards. This demand your honorable Board has refused to grant for reasons which I cannot deem sufficient. I therefore ask you to relieve me of my responsibility for the conduct of the University, this act to take effect June 2, 1900.

Respectfully,

JEROME H. RAYMOND.

The board refused to accept this letter of resignation by a vote of five to four. President Raymond's friends on the board thereupon persuaded him to withdraw the letter.

As soon as the fall elections were over two of the resignations which Mr. Raymond had asked for were demanded by the board of regents (by a vote of five to four). The men refused to resign, and the subject was brought into the courts. The right of the board to dismiss the professors was sustained by the court by a vote of two to one, the judge who voted against the board being a relative of one of the dismissed professors. A private libel suit was at the same time instituted by one of the dismissed men against the president. This suit is still pending and is not expected to be dropped, because the prosecuting attorney is as bitter an enemy of the president as is his client.

The last chapter of President Raymond's career in West Virginia followed in the spring. The legislature was in session, and appropriations had to be asked for by the board

of regents. The report which they submitted to the legislature is a strong, well-written statement of how the University affairs were managed. Nothing could, however, stem the tide of feeling which had been worked up against the president. The legislature ordered an investigation into the affairs of the University. The essential points of the report which was submitted to the legislature by the committee appointed to carry out this investigation are contained in the following paragraph closing the report :

Your committee was at great pains to investigate the criticisms that have been generally made through the state in regard to the executive head of the University. A great deal of testimony was before the committee upon this subject. The president of the University is to be commended for his zeal and energy and devotion to the work of his office. We, however, regard some of his views and policies as not suited to the conditions as they exist among us. This together with his youth and inexperience and want of tact in dealing with men lead us to the conclusion that the best interests of the University would be subserved by a change in the presidency thereof. We are led to this conclusion by the overwhelming force of the evidence before us in our investigation, and we, therefore, recommend that such change shall be made.

Along with this change, it is the further opinion of your committee that there should be a complete reorganization of the board of regents, and that in such reorganization there should be no local regent appointed upon the new board.

There can be no doubt that the report of the committee reflected the prevailing sentiment in the legislature. The investigation could, however, not have been very thorough since it lasted but two days; nor could the report submitted have been exclusively intended to improve the management of the affairs of the University. This is clearly shown for instance in the following paragraph.

In view of the great prominence given in colleges to physical exercise, the committee is of the opinion that the instructor in the gymnasium, who now receives a salary of only eight hundred dollars, should receive the salary of a full professor.

The instructor in question was an undergraduate student whose record of scholarship

during at least one quarter of the year '99-'00 fell below the average necessary for permission to continue his studies.

Mr. Raymond's administration ended precipitately after this report had been presented to the legislature. To the bill providing funds for the maintenance of the University was added a clause which stipulated that none of the funds could be used until Mr. Raymond's resignation had been accepted by the board of regents. Both the president and the board that had supported him were thus legislated out of office.

The new board met in June and elected Dr. Purinton, of Denison, to the presidency of West Virginia University. The following additional changes have since been made in the management of the instruction at the University: The professor of botany was dispensed with on economic grounds, and the department of botany was left in charge of the professor of zoology. The professor of philosophy was given the department of economics, the new president taking charge of the department of philosophy. The premedical and the domestic science departments were abolished, and the head of the domestic science, a Ph.D. in sociology, was made assistant professor of sociology. One of the two professors who had been compelled to resign in the fall by the old board of regents was reelected for one year, and for that year was given a leave of absence without pay. The departments of English literature and rhetoric were divided, and the English literature was given to a Morgantown lady without university training, who had attained some local literary distinction as secretary of the Morgantown Fortnightly Club. The assistant in rhetoric was offered an assistantship in mathematics, and on refusing to teach mathematics was dropped. The professor of German the following day went before the board in regard to their action on the assistant in rhetoric, and as a result the latter was reinstated with an increase of salary of three hundred dollars.

In view of all that has happened at West Virginia University during the past year, it is not easy to foresee what will be its history in the immediate future.

CANNONADE AGAINST HAIL STORMS.

TO THE EDITOR OF SCIENCE: My attention has been called to an article by Professor W. S. Franklin, in your esteemed journal of September 27, page 496, on the control of the weather.

Professor Franklin's argument for the rational plausibility and possible effectiveness of cannonading with vortex rings 'for *inaugurating* at will the storm movements of atmosphere' is very surprising in view of two facts: 1st, Stiger and his followers do not maintain that the rising vortex rings *initiate* storms, but that they *destroy* storms, at least hail storms, turning them aside from their intended paths or converting the hail to rain; 2d, the cannonade against hail has been prosecuted for centuries, and the special vortex ring cannonade has been practised by tens of thousands during the past three years, and yet thus far there has not been reported a single case where cannonading has been logically demonstrated to have been effectual. Hail storms move, divide and pass by on either side, develop and decay, just the same whether the cannons are fired or no! The popular faith in cannonading that seems to prevail among the peasantry of southern Europe is a craze that has no scientific basis whatever. If Professor Franklin has any faith in this process he has but to submit it to a thorough experimental trial: Get a dozen of his neighbors to load their rifles with five ounces of gunpowder, which is the charge recommended by Stiger, leave off the wad so as not to burst the guns, and all fire away as fast as possible when a hail storm is approaching. After actually witnessing the failure of this process let him sit down and calculate approximately the relative amounts of energy in the explosions and in the hail storm.

The importance of unstable equilibrium in the atmosphere is a matter that has been so thoroughly investigated since the days of Espy, that Professor Franklin has only to study the modern literature of meteorology and the mechanics of whirlwinds in order to realize the folly of his argumentation.

The Weather Bureau needs, and hopes to obtain, the hearty cooperation of the best men in American science in order to overcome the dif-

faculties inherent in the study of meteorology, but I believe that such suggestions as those of Professor Frauklin are not the best that science has to offer.

CLEVELAND ABBE.

THE SACRAMENTO FOREST.

TO THE EDITOR OF SCIENCE: In south central New Mexico, capping the scarp of the great monoclinal mountain known as the Sacramento, and overlooking to the west the Tularosa desert, is a unique and beautiful forest tract. It forms a detaining mat of vegetation which supplies a large group of running streams and their dependent agriculture. It is, also, a moist and forested resort for the vast desert which encircles it for hundreds of miles. Already 150 miles of railway carry many tourists north from El Paso to picturesque Cloudcroft from all parts of Texas, Arizona and New Mexico; when the scenic beauties of the place are more widely known, the place will become a Mecca for lovers of nature.

The forests consist of pines, firs and balsams, of many species and of great size, trees twenty-five feet in diameter being quite common.

In all there are about twenty-five townships of forested land, some of which is included in the Mescalero Indian reservation.

Saw mills are already at work devastating this little-known but beautiful forest area. The importance of preserving this watershed cannot be too strongly insisted upon and it is hoped that all friends of forestry will use their influence to this end.

ROBERT T. HILL.

October 19, 1901.

THE WORK OF THE BEAUFORT LABORATORY OF THE U. S. FISH COMMISSION.

UNDER the administration of the present commissioner, Hon. Geo. M. Bowers, the facilities for biological investigation at the Beaufort (N. C.) Laboratory of the U. S. Fish Commission are constantly increasing. During the past season the laboratory was open from the middle of May until the end of September, and every reasonable request for equipment was granted. Tables were occupied by the following gentlemen, grouped under the institutions

with which they are connected: *Bryn Mawr College*, Professor T. H. Morgan. *Columbia University*, Professor E. B. Wilson, Mr. H. B. Torrey, Mr. J. C. Torrey. *Dartmouth College*, Dr. J. H. Gerould. *Johns Hopkins University*, Professor W. K. Brooks, Dr. Caswell Grave, Mr. R. P. Cowles, Mr. D. H. Tennent, Mr. O. C. Glaser, Mr. R. E. Coker, Mr. J. A. E. Eyster. *University of Alabama*, Professor J. Y. Graham. *University of Missouri*, Professor Geo. Lefevre, Dr. W. C. Curtis. *University of North Carolina*, Professor H. V. Wilson, Mr. C. A. Shore. *Washington and Jefferson College*, Professor Edwin Linton, Mr. C. W. Stone. The investigations carried on were of a varied character, embracing such diverse problems as the systematic zoology and natural history of parasites in edible fish; the effect on the tissues of the oyster of a prevalent trematode parasite; the nature of the food and the rate of growth of planted oysters; the cell-lineage and embryology of *Thalassema*; the embryology of *Chaetopterus*, of the oyster, of *Ascidia*, of *Phoronis*; regeneration in *Phoronis*; the metamorphosis of echinids and ophiurans, of barnacles; the systematic zoology of tunicates, of sponges, of echinoderms; cell phenomena in the formation of organs in half and quarter larvæ of sea-urchins.

Many zoologists will be glad to hear that *Phoronis* (*P. architecta* Andrews) turns out to be very abundant at Beaufort. Mr. Cowles has found the form to be a tractable one, living easily in the laboratory and depositing eggs freely. Biologists who are occupied in the study of the fundamental morphogenetic activities of protoplasm will be interested to learn that the delicate striæ which have been described (Conn) as radiating from the surface of the *Thalassema* egg were found (by several observers) to be fine threads, which in places branch and anastomose. With a Zeiss 2 mm., such filaments may easily be seen over the surface of the egg after the formation of the egg membrane, and later over the free surfaces of the first blastomeres. The filaments give every evidence of being protoplasmic, and clearly belong in the category of the 'filose processes' discovered by Mrs. E. A. Andrews ('Spinning Activities of Protoplasm,' *Journ. Morphology*, VII., 2, 1897).

The work of the past season was carried on in the rented building which has served as temporary quarters for the laboratory since its inauguration three years ago. Ground was broken for the new building in September, and another year should see the station in its permanent home.

H. V. WILSON.

UNIVERSITY OF NORTH CAROLINA,
October 21, 1900.

EXHIBITION OF A STUDENTS' SOCIETY OF SCIENCE.

THE Students' Society of Science, formed by and of students in the New York City high schools, held its second annual exhibition on October 11, 1901, at the home of the president. Exhibits were shown in the departments of botany, zoology, conchology, mineralogy, paleontology, geology and anthropology.

The exhibits were in every case explained and described by printed cards. Colored plates prepared by the boys accompanied each collection and showed how the various classifications were made. The collections themselves were prepared so as to show variations of certain properties which defined each group. Thus there were separate divisions in the department of mineralogy, which described and explained each of the several properties of hardness, cleavage, color, refraction and crystallization.

The department of biology presented collections and plates explanatory of the morphological differentiation and evolution of animals, the progressive specialization of the cell, and interesting cases of plant and animal reproduction. Special studies were shown of marine invertebrate zoology, the Arthropoda, and of the structure and anatomy of birds.

The Jones conchological collection, comprising several thousand specimens from all parts of the world, and a large number of selections from the Hawley herbarium, were of particular interest and beauty.

Several large colored plates descriptive of the American fossil beds accompanied the paleontological collection, the gaps in the collection being filled by sketches and plates, which showed a remarkable degree of ingenuity and correctness of knowledge on the part of the young collectors.

The entire exhibition showed what can be done by a few earnest young students of nature who take the trouble to go below the surface of mere collecting for sport. When we consider that the oldest member of this young society is but fifteen years of age, and that they received no outside aid whatever in the preparation of their collections, the result of their work is truly remarkable.

SCIENTIFIC NOTES AND NEWS.

A MEMORIAL meeting in honor of the late Henry Augustus Rowland was held at the Johns Hopkins University, on October 16. The principal address was made by Dr. T. C. Mendenhall.

THE Sociedad española de Historia Naturel of Madrid has established a new class of *socios honorarios*, limited to ten in number and at a special meeting in March last elected the following eight persons: Sir Archibald Geikie of London, Ph. van Tieghem of Paris, Adolph Engler of Berlin, Santiago Ramón y Cajal of Madrid, Carl Brunner von Wattenwyl of Vienna, Lord Avebury (Sir John Lubbock), of England, Albert Gaudry of Paris and Samuel H. Scudder of Cambridge, Mass.

ON the occasion of the celebration of Virchow's eightieth birthday last month, his bust in marble was presented to the Pathological Institute at Berlin.

DR. CHARLES E. MUNROE, professor of chemistry and dean of graduate studies in Columbian University, has been appointed by the Swedish Academy of Sciences one of the representatives to recommend candidates for the Nobel prize in chemistry.

DR. and Mrs. T. C. Mendenhall sailed from New York for the Azore Islands on October 29.

DR. L. O. HOWARD, chief entomologist of the Department of Agriculture, returned to Washington on October 27 from a protracted tour of California, Oregon, Washington, Idaho, Mexico and Texas, where he has been conducting field investigations and examining the work of field agents.

DR. ANDREW D. WHITE, ambassador to Germany and ex-president of Cornell University, returned to his post in Berlin on October 31.

PROFESSOR WILLIAM LIBBEY, of Princeton University, and his family have sailed for Europe and will be absent for a year.

It is reported that the Duke of the Abruzzi will visit the United States next February, with a view to arranging for another expedition to the North Pole.

DR. WILHELM WALDEYER, professor of anatomy at Berlin, was entertained at dinner in New York City on October 26. Addresses were made by Drs. George W. Jacobi, A. Jacobi, William H. Welch and Carl Beck.

DR. OTTO NORDENSKJÖLD, leader of the Swedish Antarctic expedition, was entertained by Sir Clements Markham, president of the Royal Geographical Society at the Royal Society's Club, London, on October 25. The *Antarctic* left Falmouth the following day for Buenos Ayres and the Falkland Islands.

DRS. BEYER, Formento and Salomon, of New Orleans, have been appointed civilian members of the government Yellow Fever Institute.

DR. R. G. PERKINS has been given an appointment to carry on research at Western Reserve University under the Rockefeller Institute for Medical Research. Similar appointments at McGill University have been given to Dr. G. A. Charlton and Dr. P. G. Wooley.

PROFESSOR HUGO MÜNSTERBERG, of Harvard University, will give a series of eight Lowell lectures at the Massachusetts Institute of Technology, beginning on November 11, on 'The Results of Experimental Psychology.'

MR. GEROW D. BRILLE, a graduate of Cornell University, has been appointed director of the Agricultural School and Experiment Station, to be established by the United States Government on the island of Negros in the Philippines.

W. D. STRAIGHT, instructor in drawing in Cornell University, has resigned to accept a position in the customs service in China.

PROFESSOR LAWRENCE BRUNER and a party from the department of entomology and ornithology of the University of Nebraska, as we learn from *The Auk*, spent during the early summer some time in the Pine Ridge region of northwestern Nebraska, investigating the birds of the region and making collections.

DR. REID HUNT, associate professor of pharmacology in the Johns Hopkins Medical School has spent the summer at the Montana Agricultural Experiment Station, Bozeman, investigating certain poisonous plants for the U. S. Department of Agriculture. Part of the work was done in conjunction with Mr. V. K. Chesnut, of Washington. Considerable attention was given to one of the so-called 'loco' or crazy weeds, and some progress was made in discovering the mode of action of this plant, which has baffled investigators for so many years.

THE *Revue générale des sciences*, as we have already noted, organized this year a scientific excursion to Asia Minor and Palestine. The party sailed from Marseilles on September 14 on the steamship *Senegal*, chartered for the excursion. Shortly afterwards two members of the crew were found to be affected with the plague, and the steamship returned. There were a number of scientific and medical men in the party.

SIX deaths from the bubonic plague have occurred at Liverpool, and the disease has reappeared in Glasgow.

DR. CALMETTE, director of the Pasteur Institute at Lille, was, as we recently reported, bitten in the hand by one of his rattlesnakes while he was making experiments. Dr. Calmette immediately inoculated himself with his antivenomous serum, but it was found necessary to amputate one of his fingers.

THE Royal University of Ireland has conferred its D.Sc. on Mr. Walter Noel Hartley, F.R.S., professor of chemistry in the Royal College of Science for Ireland.

SURGEON-GENERAL W. TAYLOR, M.D., C.B., has been appointed Director-General of the British army medical service.

THE fund which is being raised to found a memorial to the late Dr. D. J. Leech, for twenty years professor of materia medica and therapeutics at the Owens College, Manchester, has now reached the sum of £1,230.

PRIVY COUNCILOR MAERCKER, professor of agricultural chemistry at the University of Halle, died on October 20.

CANNON ISAAC TAYLOR, the author of an excellent work on 'The Alphabet' and other archeological books, died on October 18 at the age of seventy-two years.

THE eleventh congress of Russian Naturalists and Physicians will meet at St. Petersburg on January 2, and will remain in session for ten to eleven days. The sections into which the association is divided are mathematics and mechanics, astronomy and geodesy, physics, physical geography, geography and statistics, agriculture, chemistry, geology and mineralogy, botany, zoology, anatomy and physiology, scientific medicine, and hygiene. Three days are to be devoted to general sessions and seven days to the meetings of the sections.

AT the recent International Congress of Criminal Anthropology at Amsterdam it was decided that the next congress will be held at Turin in 1906.

AN Australasian Ornithologists' Union is about to hold its first meeting at Adelaide. The society will publish a magazine called *The Emu*.

A COMMISSION, under the presidency of M. Léon Bourgeois, has recommended the addition of new laboratories to the Conservatoire des arts et métiers at a cost of about \$100,000.

THE Berlin correspondent of the *British Medical Journal* writes that the 'Virchow Day' lengthened out to a 'Virchow Week,' for the series of ovations that began on Saturday, October 12, did not find their close until Friday, October 18. On Monday evening, October 14, the Imperial Chancellor and Countess von Bülow gave a dinner in honor of Virchow, at which many of the foreign delegates and Berlin notabilities were present. On Tuesday evening an imposing public meeting gave evidence of the enthusiasm felt by the Berlin Liberals for Virchow as a politician. Eugen Richter, the great radical orator, made a flaming speech, in which sharp hits at the present political situation alternated with expressions of deepest gratitude for Virchow's untiring, courageous and lifelong labors in the cause of political freedom. That Virchow's political career has been one of real work can be best illustrated by the fact that for twenty-five years he was presi-

dent of the parliamentary audit committee. On Friday evening the town council and magistrates gave their great Virchow banquet in the city hall. What Virchow has done for public hygiene and town sanitation is known all over the world. No one could have put into better words the debt our generation owes him than did Virchow himself, when, in returning thanks for the speech in his honor, he said—without mock humility and without vanity either—that if he was proud of any achievements it must be the achievements in the domain of public health, since it was by his efforts, through the establishment of the system of drainage which he had recommended and the sewage farms constructed under his directions, that Berlin had become the healthiest city in the world. All the medals, addresses, pieces of statuary and paintings presented to Professor Virchow by learned societies and public personages are on view in the Central Hall of the Industrial Art Museum.

THE London *Times* states that the Crystal Palace authorities have decided to hold an American exhibition next year. It will be strictly confined to a display of the wealth, industry, science and art of the United States. The space of the palace will be divided so as to allow the exhibits to be ranged into ten classes, which will be found to cover exhaustively the vast resources, instructive and interesting, of that country. During the exhibition some of the leading American entertainments and shows will be introduced, in addition to the regular palace program, and in the grounds characteristic American sports will be conducted by representative teams. An important feature in connection with the exhibition will be the institution of a commercial bureau, under the direction of a committee of representative American and British firms. An American advisory committee has been formed, consisting of the officers, general committee and many prominent members of the American Society in London, who are working in co-operation with Mr. Henry Gillman to make the exhibition the most complete and representative one ever held. The English advisory committee includes the Lord Mayor, Earl Grey, the Earl of Crewe, Sir Douglas Fox, Viscount Dun-

cannon, Sir Henry Irving and Mr. Winston Churchill, M.P. Mr. Ernest Schenk, chairman of the Crystal Palace Company, has been for some time in America in connection with the arrangements, and has everywhere met with most cordial approval of the project. The American exhibition will extend from May to September.

THE Department of Agriculture is in receipt of a communication from Mr. R. J. Alfonso, agronomical engineer in Cuba, and secretary of the provincial 'Junta' of agriculture, commerce and industries of the Province of Puerto-Principe, in which he expresses his desire to be brought in contact with some of the leading manufacturers of agricultural implements in the United States in the hope that some of them may be induced to contribute to the agricultural museum his association is in process of organizing some of their implements, or models of the same. He expresses the hope that their enterprise and liberality in this respect would not go unrewarded, as such exhibits would serve a very useful purpose in the way of advertising their manufactures.

WE learn from the London *Times* that the committee appointed by the Board of Trade to inquire and report as to the best means by which the state or local authorities can assist scientific research as applied to problems affecting the fisheries of Great Britain and Ireland has met for the purpose of taking evidence. Sir Herbert Maxwell, M.P., presided. Dr. T. Wemyss Fulton, scientific superintendent to the Scottish Fishery Board, and Mr. E. W. L. Holt, scientific adviser to the fisheries branch of the Department of Agriculture, etc., Ireland, were examined, and Mr. G. C. Bompas and Professor G. B. Howes gave evidence with regard to the Buckland fish collection at South Kensington. Professor E. Ray Lankester, the president, and Mr. E. L. Allen, the director of the Marine Biological Association, and Mr. R. A. Dawson, superintendent under the Lancashire and Western Sea Fisheries Committee, also attended. Professor Herdman, F.R.S., a member of the committee, submitted a scheme for fishery investigations in the Irish Sea.

A BRITISH foreign office report gives some information regarding the bill on the subject of

the draining of the Zuyder Zee recently introduced in the Second Chamber of the States-General by Mr. Lely, the Minister for the Waterstaat, who likewise furnished the Chamber with a memorandum in explanation of the measure, giving a historical retrospect of all former proposals of this nature, as also the most complete details concerning his own proposal. It appears from the London *Times* that the plan consists of first enclosing and afterwards gradually partially reclaiming the Zuyder Zee, the pumping out of the water to be effected by steam pumps. The first work will be the construction of a dam from Wieringen, in North Holland, to Piaam, in Friesland. This dam will have sluices into the North Sea. The next works will be the creation of two polders, or areas of dry land reclaimed from the Zuyder Zee; the first, between Wieringen and Medemblik, to be called the 'North-West,' or 'Wieringen Polder,' and the second, between Hoorn and Marken, to be called the 'South-West,' or 'Hoorn-Polder.' The rest will remain a fresh-water lake, at all events in so far as Mr. Lely's plan is concerned, but should the latter prove successful, his ministerial successors may in days to come create two more polders on the northeast and southeast of the lake. The two polders will be of the following area, viz., the Wieringen Polder, 21,700 hectares, containing 18,700 hectares of fertile land; and the Hoorn Polder, 31,520 hectares, containing 27,820 hectares of fertile land. The entire work is to be completed in 18 years. The enclosing dyke from Wieringen to Piaam will be finished in the ninth year. In the eighth year will be commenced the works for dyking the Wieringen Polder, which in the 14th year will be dry and ready for sale. In the 11th year the similar works on the Hoorn Polder will be begun, and will be completed in the 18th year, when an area of upwards of 46,500 hectares of fertile soil will have been reclaimed. The cost of this gigantic work is estimated in round numbers at 95,000,000*fl.* (£7,916,667), which amount is to be raised by loans, and it is proposed to pay off the principal and interest by an annual increase of the Budget of 2,000,000*fl.* (£166,667) during a *maximum* period of 60 years.

UNIVERSITY AND EDUCATIONAL NEWS.

THE Council of Birmingham University have authorized the preparation of plans for buildings to cost about \$1,000,000.

THE engineering departments of Leland Stanford University have been granted \$50,000 for equipments.

A BACTERIOLOGICAL laboratory is to be erected at the State Agricultural College, Lansing, Mich., at a cost of \$50,000. This sum does not include the cost of the equipment, which will be the best attainable.

NORTHWESTERN University has received an anonymous gift of \$15,000.

GEORGE C. FRENCH, of Mexico, Oswego County, N. Y., has given \$4,000 to Syracuse University toward founding a chair of mathematics as a memorial to his brother, the late Dean, John R. French, of that institution.

THE professors at the Paris School of Anthropology offer the following courses for the year 1901-1902: M. Papillault: Anatomical anthropology, external form and proportions of the human body; special study of variations due to social environment. M. Capitan: Prehistoric anthropology, bases of prehistoric studies: petrography, paleontology, industry. M. André Lefevre: Ethnography and linguistics, France during the fourteenth century. Charles V. and Charles VI., the hundred years' war, letters, art, language. M. Georges Hervé: Ethnology, ethnology of Europe, Alsace. M. Adrien de Mortillet: Ethnographic technology, the industry of modern primitive races compared to tertiary and quaternary industry. M. J. V. Laborde: Biological anthropology, biological introduction to criminal anthropology. The predisposition to crime in the organic and functional evolution of man. M. Franz Schrader: Anthropological geography, terrestrial laws and human customs. M. L. Manouvrier: Physiological anthropology, comparative study of the sexes; view point of sociology. M. Charles Letourneau: Sociology [history of civilizations]; the conclusions of ethnographic and comparative sociology. M. P. G. Mahoudeau: Zoological anthropology, ori-

gin of man; genealogy of the hominidæ. The courses began on November 4 and are public; there are no tuition fees.

PROFESSOR WILLIAM S. ALDRICH, late of the University of Illinois, has entered upon his duties as director of the Thomas S. Clarkson Memorial School of Technology, Potsdam, N. Y. Among other recent appointments to the staff of the Clarkson School are Professor Edwin Haviland, Jr., B.S. (Swarthmore), M.A. (Cornell), who will occupy the chair of civil engineering, and Mr. W. S. Graffan, B.S. (Worcester Polytechnic Institute), who has been appointed superintendent of shops.

THE Ontario Government has appointed Dr. T. L. Walker, at present assistant superintendent of the Indian Geological Survey and curator of the Calcutta Museum of Geology, to the chair of mineralogy and petrography in Toronto University. Dr. Walker is a graduate of Queen's University, Kingston.

DR. D. S. KIMBALL has resigned the chair of machine design in Cornell University to accept a position with an electric company, and is succeeded by Dr. C. E. Coolidge. At the same university Mr. William Riley has been appointed instructor in entomology.

DR. A. E. SHUTTLEWORTH has resigned the chair of chemistry in the Ontario Agricultural College to accept a technical position. He is succeeded by Dr. Harcourt.

THE following changes in the science faculty of Syracuse University were announced at the opening of the year: C. B. Thwing, Ph.D. (Bonn), has been elected professor of physics, filling the vacancy caused by the resignation of Professor Eugene Haanel. At the time of his election Dr. Thwing was professor of physics in Knox College, Galesburg, Ill. F. A. Saunders, Ph.D. (Johns Hopkins), has been elected instructor in physics; H. C. Cooper, Ph.D. (Heidelberg), instructor in chemistry and E. H. Kraus, Ph.D. (Munich), instructor in mineralogy.

J. O. QUANTZ, Ph.D. (Wisconsin, 1897), has been called to the chair of psychology at the State Normal School at Oshkosh, Wisconsin.

I.

I SHOULD hardly have ventured to talk on the subject of ore deposits to an audience which contains many men much more familiar with mines than I, if I had not approached the subject from a different point of view. The point of view from which the subject of ore deposits has been most frequently considered has been that of a study of ore deposits themselves. A geologist or mining engineer has studied this or that ore deposit, or a number of ore deposits in different districts, and has then generalized concerning the ore deposits of other districts, and perhaps of the world. I also have considered the subject of ore deposits to some extent from that point of view, but if I had done this only, I should not have ventured to give a general address upon the subject.

A number of years ago I began the study of the alterations of all rocks, by all processes and by all agents, in order, if possible, to ascertain how it is that the rocks change from one form to another. That rocks are metamorphosed has been known for many years. It has been realized that one mineral changes into another mineral;

*The Popular Scientific Lecture of the American Association for the Advancement of Science, complimentary to the citizens of Denver, delivered at Denver, Col., in the High School Auditorium, Monday evening, August 26, 1901.

that one rock changes into another rock; that rocks may have different textures, structures and compositions from those they originally had. The chief immediate agent producing these changes is underground water. Everywhere underground water permeates the rocks. Everywhere it is the medium of exchange by means of which the mineral particles are changed from one form to another.

In order, therefore, to understand this matter of the alterations of rocks, it became necessary to consider the flowage of the underground water; to attempt to ascertain, if possible, how it moves through the rocks, in what directions, to what depth it penetrates, whence it comes, whither it goes. After a certain number of principles and conclusions had been reached upon the alterations of all rocks, by all processes—and especially by the work of underground water with the help of heat derived from the igneous rocks, from dynamic action, and the increment due to depth—it seemed to me that many of the principles of ore deposition followed as corollaries from these general principles. Therefore, it is from this general point of view that the question is discussed tonight; not from that of a particular ore deposit or particular district.

For many years ore deposits have been classified into those which are produced (1) by the direct action of igneous agencies, (2) by the process of sedimentation and (3) by the action of underground water. There is no difference of opinion as to the existence of all these three classes; but there is a difference of opinion as to their relative importance. Some hold that deposits of igneous origin are of very great importance. By this I mean ore deposits which have been directly formed by some of the strange processes of vulcanism. Also it is certain that large quantities of ore, and especially the placer gold deposits, are largely

the result of the process of sedimentation. But I hold that the greater number of ore deposits, those which contribute most to the wealth of Colorado, to the entire Cordilleran region, to the Lake Superior region, to the Mississippi Valley, to the Appalachian region, are those deposited by underground water; that is, they are the direct result of the work of the permeating solutions, which go for at least a considerable depth below the surface of the earth; and are taking material into solution all the time, depositing material from solution all the time. During the journey these underground waters take up from igneous, aqueous and metamorphic rocks the sparsely disseminated metallic material which is of consequence to man. This material is deposited in the openings of the rocks and within the more easily replaced rocks in sufficient abundance to form ore deposits. With the exception of iron, the quantity of metal which is contained in an ore is ordinarily small; in the case of gold, usually an exceedingly small fraction of one per cent.; in the case of silver, usually less than one per cent.; in the cases of copper, lead and zinc, from one per cent. to a rather high percentage, but in the great majority of instances less than 20 per cent. It therefore appears that the majority of so-called ores consist mainly of deposited materials other than the metals which are extracted from them. This predominant material is known as gangue, and plainly was deposited simultaneously with the ores, in the openings of the rocks, or else replacing rock material.

In a given instance to attempt to answer the question as to the source of the gold or the silver or any other metal, without at the same time considering the minerals with which it is associated, is futile. If we can answer the question as to where the gangue minerals came from, and how they got into the positions they now occupy, the question is in large measure answered as to

how the metal got there, and how it was deposited.

I shall not attempt to give all the evidence that the metallic ores and gangue are deposited by underground waters; but I wish to call attention to certain structures of veins which seem to favor this view. [At this point a number of lantern slides were used, illustrating the following statements.]

A massive rock may be produced by direct igneous agencies; sediments are arranged in strata and beds. But material showing a comb structure—or, as Posepny calls it, crustification—and the filling about particles of rock, is usually produced by underground water. No agent other than water can penetrate between the grains throughout a sandstone formation, or a conglomerate formation such as that of the Calumet and Heckla, or between the fragments of a great tuff formation such as that of the San Juan district of Colorado, and deposit material so as to transform them to hard rocks by cementing the particles. Many cracks and crevices, great and small, form in the rocks by the deformation to which they are subjected. Igneous material can intrude the rocks in a most intricate fashion and occupy these openings; yet in the great majority of instances the extremely intimate introduction of material is accounted for by transportation and deposition of material by underground waters. Those in this audience familiar with Colorado ore deposits know that many of the valuable minerals are in veins, many of them narrow, or between very small fragments within the rocks. Not only do the ores occur in the larger openings, but they frequently occur for some distance from the veins in the extremely minute, often subcapillary, openings of the wall rocks, or even replacing the individual particles of the wall rocks. But farther from the veins, if the metals are

present at all, they are only in exceedingly minute quantities. In the larger openings and adjacent to these openings the values are chiefly found. These facts are beautifully illustrated at Cripple Creek. No known agent except underground water is capable of penetrating the very small, and especially the subcapillary, openings, and depositing material.

My primary assumption is, therefore, that the great majority of ores are deposited by underground waters at the places where they are now found. Nearly all that follows is confined to this class of ores. Ores directly produced by igneous processes, and those formed by processes of sedimentation, are only indirectly considered this evening.

The second fundamental principle which I shall try to develop is that the waters derived the ores from the outer part of the crust of the earth—the part which I have called the zone of fracture. Even as late as 1893, at the World's Fair Congress, at Chicago, it was argued by Posepny that the ores came from the barysphere, or heavy-sphere, from well down within the earth; although even Posepny conceded that the agent which transported and deposited the metals at the places where they are now found was underground water. Posepny's theory of the derivation of the ores from deep within the earth is a very attractive one; because, if it be true, the deeper a mine, the richer an ore deposit is likely to become. Indeed, it is the belief of 90 per cent. or more of prospectors that if they only could get deep enough, deposits of surpassing richness and magnitude would be developed. But it seems to me that the hypothesis that the ores are derived by the underground waters from deep within the earth has no foundation in fact. It is alike opposed to the principles of physics and to observations in the field.

It must be remembered that gravity is a gigantic force ever at work pulling toward

the center of the earth. And it must be remembered that all rocks are limited in strength. The strongest rock tested has a crushing strength of something more than 40,000 pounds per square inch. A column of such a rock 10 or 12 miles high would be crushed by its own weight. It is easily calculable that if we suppose the outer part of the crust of the earth to be composed only of the strongest rocks, and we imagine openings to exist in these rocks, then at a certain depth these cracks must be closed by the pressure. And this deduction has been experimentally proved. Professor Adams, of Montreal, has shown that rocks subjected to pressures in all directions greater than their crushing strength may be mashed, and no perceptible openings produced. Therefore, openings of great size cannot be assumed to exist below a very limited depth in the crust of the earth. This conclusion is fully verified by observation. By examining the rocks in the cores of mountain ranges where there has been deep denudation, we may see what has happened to them when well below the surface. In the Front Range of Colorado, and at various places in the world, where the rocks have been deformed at considerable depth below the surface of the earth (ignoring recent fractures which have been produced since the rocks came near or to the surface), the process has taken place without the formation of openings larger than those discernible only with the microscope. Therefore, from the point of view of pure physics, from the point of view of experiment, and from the point of view of observation alike, we reach the conclusion that no large or continuous cracks or crevices exist except for a very limited depth below the surface of the earth.

In order to deposit the metals and gangue of an ore deposit, a vigorous circulation is required. The vigorous circulation of underground water is necessarily confined

to that part of the crust of the earth where there are continuous cracks and crevices of considerable size. As the openings decrease in size, the resistance due to friction increases rapidly; and where the openings are subcapillary, it is enormous, being in fact sufficient to practically check circulation. In Colorado a common gangue material is quartz. Springs have been analyzed, and it has been found that the water issuing from such springs bears perhaps one part in one hundred thousand, or one part in a million, of silica. It is probably rather uncommon for a solution to deposit as much as one part by weight in one hundred thousand of the gangue and ore material. If this be so and the gangue be quartz, in order to fill an opening with ore and gangue, at least 260,000 times as much water must have passed through it.

It therefore follows that if the majority of ore deposits are placed where they are by underground waters—and from this there seems no escape—the processes of their gathering and deposition must be mainly confined to the outer few miles of the crust of the earth. This is called the zone of fracture. *Therefore my second fundamental conclusion is that the ore deposits are derived from the zone of fracture.*

But is there an adequate source of supply of metallic material in the outer part of the crust of the earth? In answer to this question, it may be said that calculation clearly shows the relatively small quantities of ore which exist could have been derived from the zone of fracture, even if the rocks contain an exceedingly small fraction of one per cent. of metal. To illustrate, Mr. Buell has calculated for Professor Chamberlin, for the Wisconsin lead and zinc district, that if the richest portion of the district be taken, and it be assumed that the supply extended only one-half as far beyond the deposits as the radius of the productive area, and the depth of vertical distribution be confined

to 100 feet, one fourteen-hundredth of one per cent. of the metals in the rocks could supply all the lead and zinc which has been or is likely to be taken from the district. It is therefore not necessary to suppose that there is more than a minute quantity of metallic material in the zone of fracture, to furnish a supply adequate many times over to account for all the deposits which have been mined or are likely to be mined.

So far as the specific work of underground water is concerned, we have already seen that the metals for the ores are derived from the zone of fracture. But it does not follow that important supplies of metals to be later yielded to the water may not come from deeper within the earth. As a result of various causes, which cannot be discussed this evening, the igneous rocks rise from an unknown depth below the surface of the earth into the zone of fracture or even quite to the surface. Such igneous rocks bear materials out of which many important ore deposits are largely or wholly derived. Indeed, if we go far enough back in the history of the earth, all rocks were probably derived from the igneous rocks. So, directly or indirectly, the ultimate source from which ores are derived by underground water is igneous rocks, either ancient or modern. On this point there are no differences of opinion.

But there are differences of opinion as to the manner in which the ores are derived from the igneous rocks. Some geologists hold that the direct processes of igneous action produce many ores. They say that during the process of crystallization of the igneous rocks the ores are segregated by magmatic or pneumatolitic processes. There are cases in which this is probably true, as, for instance, the unimportant titaniferous iron ores of the Adirondacks and the Lake Superior region. Certain ores, as the tin

ores, possibly have this origin. But it is yet unproved that the great mass of ores, which are known as the oxidized ores, the carbonate ores, the sulphide ores, and the tellurid ores, have been thus derived. We know of these classes of ores that a large part have been taken from the rocks and brought to their present positions by underground water. Why, then, assume some other process of segregation for which there is no adequate evidence, when we have a wholly adequate agent in underground water? In the great majority of cases the ores are taken from the igneous, sedimentary and metamorphic rocks by the underground waters; are carried to their present positions by the underground waters, and deposited by the underground waters at the places where they are now exploited.

The next question which naturally arises is the source of the underground water. It is believed that the water is predominantly of meteoric origin; in other words, is the water which falls from the atmosphere upon the valleys and hills and mountains of Colorado and other parts of the world. It is true that each igneous rock usually carries a small amount of water; and in the aggregate this amount may be very great. Indeed, it may be that all the water upon the surface of the earth and that in the openings of the zone of fracture was originally derived from the igneous rocks. But even if this be true, it does not follow that in a given district, at the particular epoch in which the ore deposits were formed, the water directly derived from the igneous rocks is adequate or even important in accounting for this deposition. As already explained, it is necessary to consider not only the ore but the gangue material with which it is related; and it has been seen that in order to deposit an ore and its accompanying gangue probably required tens of thousands or even hun-

dreds of thousands of times as much water. The vast quantity of water necessary cannot be derived from the igneous rocks present at a given time and place, although they may have contributed a portion of it. But it is held that the major portion of this vast quantity of water could only have been derived from the rainfall. *My third fundamental premise is, therefore, that the circulating underground water is mainly of meteoric origin.*

The question which now arises is the cause of the flowage of underground water. Why does it move? Until we know the force which drives it, we cannot know the manner in which it circulates. Geologists have frequently appealed to the great energy of the subterranean heat, due to depth or to igneous rocks, to drive this water. But this is not enough. How does this subterranean heat act in producing this circulation? A few miles west of Denver are the crystalline or core rocks of the Front Range. To the east of these there is a series of sedimentary beds, some of which are water-carriers, and which dip below impervious strata. The water rises to the surface at Denver. Why is this so? Simply because the water is at a higher level where it enters the formations than where it issues at the surface. The force which drives the water is gravitative stress. Gravitative stress is everywhere and all the time at work. The longer column is pulled downward with greater force than the shorter column. The difference in the height of the two columns is called head. Therefore, the water in the longer column moves downward, and that in the shorter upward. *We now reach my fourth fundamental premise: That gravitative stress is the chief cause of the circulation of underground water.*

The flowage of water in the Denver artesian basin does not require the force of the subterranean heat below. But there is a way in which the subterranean heat can

promote the circulation of underground water; and, indeed, does. This is by heating it. When the water is heated as a result of the contact with igneous rocks, or heated because it penetrates deep into the earth, it expands. If it expands unequally, as it is likely to do, one column may become lighter than the other, even if they are of the same height. If so, circulation would be set up. This is the principle of hot-water systems of heating buildings. The heat of the fire expands the water and forms two columns of unequal density. Under this condition of affairs gravity pulls the denser column harder, and a circulation takes place. Therefore, the heat of the igneous rocks acting upon the underground solutions, or the heat of the rocks due simply to depth, provided the circulation be of sufficient speed, may result in flowage. Thus there are two causes which result in the underground circulation, which may work separately or together—(1) head, and (2) variable temperature. But in either case continuous movement of the water in a definite direction, or its circulation, is due to gravitative stress.

Therefore, we have these four fundamental premises: (1) *The chief class of ore deposits is segregated by underground water;* (2) *the source from which the water derives the metals is the zone of fracture;* (3) *the circulating underground water is mainly of meteoric origin;* (4) *the force which drives the water in its circulation is gravitative stress.*

It is now necessary to consider in some detail the manner in which underground water moves. For a long time I have realized that if underground water had a difference in head it might penetrate to a great depth and rise again to the surface; but I did not realize that it was not necessary to assume exceptional openings for such a circulation. I assumed that where such a circulation took place exceptionally favorable channels were available;

but a recent paper by Professor Slichter* upon the motion of ground waters showed me that this was an entirely unnecessary assumption, and gave me the additional data needed upon this point. This chart (Fig. 1) is a horizontal diagram. A repre-

FIG. 1.

sents one well and *B* another well, separated by a homogeneous porous medium. Into the well *B*, I pour water. In the well *A* there is no water at the outset; and the water flows from the well *B* to the well *A* through the medium. What is the path of the water? Its flowage is represented by the curved lines. Some of the water goes in a nearly direct course. Another part takes a somewhat curved course. Still other parts of the water follow a very indirect course, represented by the longer curved lines. All the available cross section is utilized. If, for instance, this room were filled with water, and water were running in at one place in the front end of the room and were escaping at one place in

the rear end of the room in equal quantity, would the water simply follow the direct line between the two openings? You know perfectly well it would not. The entire available cross section of the room would be utilized, although the more direct course would be utilized to a greater extent than the more indirect course. This is intended to be illustrated on the chart (Fig. 1) by the lines representing the nearly direct courses being close together, and the lines representing the indirect courses being farther apart.

This chart (Fig. 1) then represents the horizontal circulation. If we pass to the vertical circulation the flowage is represented by this chart (Fig. 2). The water is being poured into the well *B* and passes to the well *A*. The water follows the course of the curved lines, so that with a difference in head equal to the difference in the level of the water in the two wells, a considerable part of the water being poured into *B* and passing through the homogeneous porous medium to *A* penetrates a considerable depth, from which it rises and enters the well *A*. Now what will be the limit in nature of the downward search of underground water? We have already given it. Manifestly the lowest limit of effective circulation at any place is the bottom of the zone of fracture at that place. The zone of flowage below is practically impervious. However, an impervious limiting stratum may exist at depths far less than the bottom of the zone of fracture. An impervious limiting stratum, perhaps a shale, may be found at a depth of 300 feet or less, or at any depth intermediate between this and the bottom of the zone of fracture for the strongest rocks. Where there are one or more pervious strata which are inclined, and above, below and between which are impervious formations, there may be two or more nearly independent circulations. To illustrate, at Denver, the

* 'Theoretical Investigation of the Motion of Ground Waters,' by C. S. Slichter, Nineteenth Ann. Rept. U. S. Geol. Surv., 1899, Pt. II., pp. 295-384.

porous strata of the Fox Hills, Laramie and Arapahoe formations have more or less independent circulations. If a limiting stratum be supposed to be half way down on the chart (Fig. 2) the lines of flow above

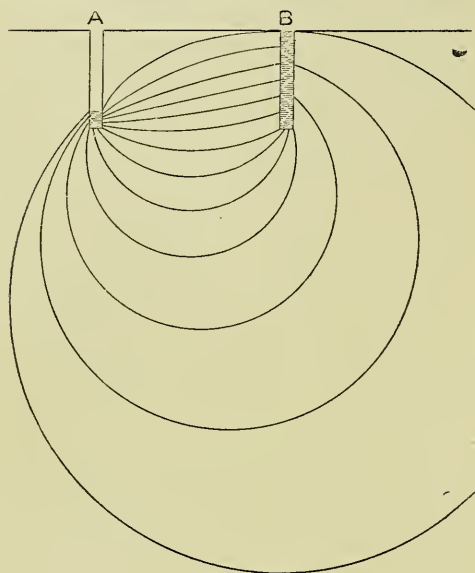

FIG. 2.

this stratum would not be as they are now, but would be flatter and would be limited by the impervious rock.

Under natural conditions, wherever there is an impervious rock there is a limit of some particular circulation in that direction. A limiting stratum may, therefore, be very near the surface, at the bottom of the zone of fracture or at any intermediate depth; and theoretically a moderate head is sufficient to do the work of driving the water to any of these depths. Indeed, there is no escape from the conclusion that at least some circulation does occur in the deeper parts of the zone of fracture with a very moderate head. Of course, in proportion as the head is great the circulation at depth is likely to be vigorous. But it may be objected that a deep circulation, while theoretically possible, must be exceedingly small in quantity, and consequently of

comparatively little account in the deposition of ores. But the consideration of the underground circulation in reference to the Denver artesian wells shows that this objection has little weight. Moreover, the deeply circulating water, if less in quantity than that near the surface, takes a longer journey and is longer in contact with the rocks through which it is searching for the metals. Not only so, but it is at a higher temperature than the water at higher levels; and this also is favorable to taking mineral material in solution. And, finally, because it has a higher temperature, it has less viscosity. While the variable viscosity of water is not so very important in reference to circulation in supercapillary tubes, in capillary tubes, which constitute a very large fraction of underground openings, and especially those at considerable depth, the viscosity is important—the flowage increasing directly as the viscosity decreases. The viscosity of water at 90° C. is only one-fifth as much as it is at 0° C.; and, therefore, with a given head of water in capillary tubes, if the temperature be considerably increased—and but a moderate depth is required to give considerable increase—the water moves several times as fast as it would at the surface under conditions similar in all respects save temperature. Therefore, because of these three factors, long journey, high temperature and low viscosity, we cannot exclude the deep circulation from consideration. This circulation is, indeed, believed to be very important in the deposition of ores.

We are now prepared to consider the actual journey of underground water. Where water falls upon porous ground it finds innumerable openings through which it enters and begins its underground journey. This circulating water, as far as practicable, under the law of the minimum expenditure of energy, follows the paths of easiest resistance. But these are the larger

openings, because resistance due to friction along the walls and within the current is very much less per unit circulation in large than in small openings. While, therefore, water enters the ground at innumerable small openings, as it goes down it more and more seeks the larger openings. Once found, it holds to them. The farther it continues its journey, the greater the proportion of the water which follows the larger openings. But if this be true, the water in its descending course is more likely to be widely dispersed and in the smaller openings; and in its upward course more likely to be concentrated and in the larger openings.

We can now follow the course of underground water in detail, but in doing this it is necessary to consider the elements of the problem separately. It is only by passing from a simple case to the very complex one of nature that we can understand the latter. Here is a chart (Fig. 3) which shows the

FIG. 3.

imaginable case. In this illustration we have represented the surface of the earth and the level of ground water. By the level of ground water is meant the depth at which the water saturates the rocks—that is, where the water remains at practically a permanent level. Above this level the paths of circulation are practically vertical; below this level the paths are curved. Of the water which enters the slope of a hill and issues in the adjacent valley, a portion flows along the slope of the hill, a portion in a less direct route, and a portion in a very circuitous route. Below the level of ground water all the openings in the rocks, great and small, are filled with water. In the case represented I have supposed that all the water enters at a single point, *A*; and that all of it issues at a single point, *B*. The curved lines represent the flowage of the water through a homogeneous porous medium.

In the next chart (Fig. 4) I have supposed water to enter at three points

FIG. 4.

surface of a slope, the level of ground water and the flowage of water in the simplest

and issue at one; and I have supposed the flowage from each point of entrance

to occur just as if no water were entering anywhere else, and, therefore, the systems of flowage to be superimposed. Of course this is not a real case. Underground water does not diverge from a single point and converge at another point in independence of the water entering at other points. The water entering at innumerable points in vertical section and in horizontal section mutually interferes, and makes the course for any given particle of water rather simple. This I have tried to represent by another chart (Fig. 5). In this chart I

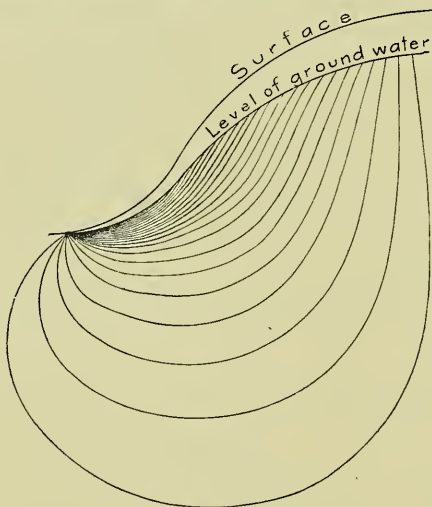

FIG. 5.

have supposed particles of water to enter at equal horizontal intervals, and issue at a single point. You note that the water near the crest begins its journey by almost vertical descent. In proportion as the entering water is near the valley the horizontal component becomes more important. The water near the valley follows a comparatively shallow course; but this water uses all the available space near the surface, and consequently the water entering at the higher ground necessarily follows a long, circuitous and deep course. The chart (Fig. 5), therefore, represents the flowage with many points of entrance and

a single point of exit, where there is interference of the circulating waters.

A portion of the water follows an approximately direct path; a portion of it less direct paths; and a portion of it a very roundabout path. That is, the underground water, following the lines of least resistance, takes not only the direct passages, but also the indirect passages. The lines in the more direct path are closer together, and the indirect path farther apart. These facts have been ascertained by experiment and by mathematical analysis. But everywhere gravitative stress is the driving force. The case represented by the diagram (Fig. 5) is an ideal one. Under the complex conditions of nature there is usually great departure from the simplicity represented; but in some districts this ideal simplicity must have been approached. For instance, except for the disturbance due to cutting dikes, the circulation in the past in the San Juan district of Colorado must have been very nearly like that represented in the diagram. Early in Tertiary time there was in that district a great volcanic plateau. Early in the erosion history of this plateau, the conditions must have been the same as at present in the Yellowstone Park and other volcanic plateaus of the West. At the stage when the San Juan plateau was still the dominating topographic feature, but cut by canyons, the conditions were practically identical with the conditions represented by the diagram. The water sank into the ground upon the hills and the plateau; it issued at the valleys, much of it having first penetrated far below the level at which it issued. The water carried on its search for metals through the volcanics, almost as shown in the diagram, except in so far as it was influenced by larger cracks or crevices, or by cutting dikes, or by impervious layers.

The principles illustrated by these diagrams show it is not necessary that

there shall be a difference of elevation of thousands of feet between where the water enters and where it issues, in order that the rocks shall be searched for depths of thousands of feet. A few hundred feet is sufficient. Therefore, the underground waters, falling on the slopes, passing through the areas where they may gather material, and issuing at various places in the valleys, have an opportunity to pick up the ores, provided the metals exist in the rocks traversed. By the water the metals are carried to the places where they now are.

Thus far it has been supposed that the ground is uniformly porous, like an evenly grained sandstone without joint or fracture of any kind, in which the water can go in all directions with equal ease. But absolute uniformity does not exist in nature. The openings in rocks are never of uniform size; they are never equally distributed.

It is now necessary to take up the final important point in the circulation of underground water. So far as it can, it passes from small openings to large openings. Where the openings are small the resistance per unit area is very large. Where the openings are exceedingly small, the resistance is very great. Where the openings are large, the resistance is slight; and the water, following the lines of least resistance, travels to the extent that space permits in the trunk channels. To illustrate, every engineer knows that if water be carried in pipes from the hills to the mines, one pipe will carry vastly more water in a given time with a given head than many smaller pipes of the same aggregate cross section. This is because of friction, which increases rapidly as the cross section decreases. And water does the same thing in natural as in artificial pipes. Therefore, the underground water more and more follows the larger courses. It falls everywhere on the slopes of the hills; it enters the ground everywhere. Therefore, in its earlier course it is

widely disseminated, and thus dispersed can most effectively pick up the valuable metals with which it comes into contact. But as the journey is continued, it collects more and more into the larger channels. But in the early part of the journey of ground water its vertical component is apt to be downward. But as it must sooner or later reach the surface, in the later part of its journey its vertical component is apt to be upward. However, it has just been seen that the early part of its course is apt to be in small openings, and the later part in larger openings. As it collects in the larger channels, it is more likely to be ascending. Therefore, upon the average—I say upon the average—descending water is mainly in the small openings, and ascending water mainly in the large channels.

It is now advisable to consider the circulation in definite vertical large, or trunk channels. Suppose half way down the slope there is a vertical opening of unusual size

FIG. 6.

transverse to the plane of the chart (Fig. 6), and another similar opening below the valley. If you please, we will call them fissures. These fissures, because large openings, will be fully utilized by the underground water. We readily see that ground water will enter the higher fissure at many points and from various directions.

Ordinarily it will enter the upper part while it is still descending; it will enter the central part laterally; it will have begun its ascent before it enters the lower part. Therefore, a fissure upon the middle of a slope will be very likely to receive water from above, from the side and from below. But at a certain area of a fissure well up on the slope the water continuously received at the upper side of the fissure will escape laterally at the lower side. This water and that entering the ground below the upper fissure will make its way to the fissure below the valley. But here the level of ground water is at the surface. Consequently all the water entering this fissure will ascend quite to the surface, and issue as a spring. If there be a fissure at the crest we can see that the descending water will go a long way down; but the waters will nowhere be ascending. If there be a fissure on the slope, both descending and ascending waters will ordinarily be active; although it is of course recognized that in fissures thus located the conditions may be such that the waters will ascend or descend only. If there be a fissure below a valley where the level of ground water is at the surface the water will all be ascending; and there will be no descending water. At such places we have springs. Springs do not issue from the tops of mountains, but from slopes and valleys, most frequently the latter. Illustrating this are the Yellowstone Park springs of the Firehole River. The waters which feed the springs fall upon the crests and slopes of the mountains adjacent; on their way to the valley go deep below the surface, and at the Firehole ascend as hot springs and geysers. The water is driven by gravity due to a considerable head and the lower temperature of the descending column.

You are all doubtless aware that three theories are maintained as to the course of the waters which deposit ores. Some hold

that the waters doing the work are descending; others that they are laterally moving; others that they are ascending. The first is known as the descension, the second as the lateral-secretion, and the third as the ascension theory. If my argument be correct as to a limit to the zone of fracture, fissures, as well as all other openings, must gradually become smaller and smaller, and finally die out altogether. Water in a fissure may descend or may ascend for a considerable distance; but it is perfectly clear that, so far as fissures are concerned, except for the small amount entering the surface openings, the water must enter laterally. Consequently, if we apply the lateral-secretion theory broadly enough, we may say that all the waters which feed the fissures are lateral-secreting waters. But if we are descensionists, and consider only the upper part of a fissure on the slope—and that is what many very naturally have done, because this is the part of the fissure most easily observed—we may say that the waters which are doing the work are descending waters. Or, if we are in such a district as that of the Comstock lode, in which are found great volumes of ascending water, we may say that the waters which are depositing the ores are ascending. All may be correct. But in the past Sandberger held that lateral-secreting waters in the narrowest sense did all the work, and he refused to believe that ascending and descending waters were of importance; and Posepny held that ascending waters did nearly all the work, and gave small consideration to the lateral-secreting and descending waters; whereas you see with perfect clearness that each theory is incomplete. All are needed; they supplement one another.

The next point to consider is why the metals are precipitated in veins. The salts of the valuable metals may come from any of the places visited by the oc-

cupping waters. If one take a number of chemical solutions in the laboratory, and dump them together in a beaker, probably precipitation will occur. These conditions are precisely those of underground solutions in trunk channels. The water from one source meets the water from another source in the trunk channels. Analyses show that waters from different sources have different compositions. They bear different metals and precipitating agents. When they come together in the trunk channels, and mingle, precipitation is likely to take place. You, who are practical mining men, like your veins to intersect, or two veins to unite. The explanation of the frequent increased values at or adjacent to an intersection is simply that the different trunk channels bear solutions of different kinds, and when they mingle at or near the intersections, ore precipitation is likely to occur. One solution may bear its mite of silver or gold, and the other the precipitating agent, or both solutions may carry the metals, and when the two come together the ore be thrown down. However, this is not the only way in which precipitation may take place. In many instances the precipitation is due to the wall rock. The wall rock, or the solutions furnished by it, react upon the solutions coming from somewhere else, and precipitation occurs. These two causes for precipitation are not the ones which are ordinarily mentioned in treatises on ore deposits. The causes commonly assigned in text-books for precipitation are the diminishing temperature and pressure of the rising solutions. While these are real causes for precipitation, I believe them to be subordinate to the influence of the mingling of solutions from various sources in the trunk channels, to the influence of the wall rocks, and especially to the first.

C. R. VAN HISE.

(*To be concluded.*)

THE PHYSICAL SCIENCES AT THE BRITISH ASSOCIATION.

THE meeting last September at Glasgow, which was attended by nineteen hundred persons, was smaller than the last two meetings held in that city, and fell slightly below the average of the British Association gatherings. This was chiefly the result of the unexpectedly small number of local associate members enrolled, accounted for by the fact that an International Exhibition with several collateral congresses had satisfied whatever desire the inhabitants of the Scotch metropolis may have had to increase their knowledge of scientific matters. The foreigners numbered only twenty-one, but some who might have attended this meeting had already been in Glasgow early in the summer as delegates to the jubilee celebration of the University. Since the president of the Association this year is one of the most distinguished physicists in Great Britain, it was natural to expect a large gathering of workers in his branch of science, but here also certain well-known names were missed from the list of members, which may likewise be attributed to the above cause. The meetings of all the sections were very conveniently held in the splendid University buildings on Gilmore Hill, the Physical Section holding its sessions in the Natural Philosophy Class Room, rendered famous by Sir William Thomson, now Lord Kelvin. The only criticism that could be made of the local arrangements was the absence of notices at the doors of each section indicating what paper was being read, but the same complaint has frequently been heard at our American Association meetings.

Professor Rucker's presidential address, which has already appeared in SCIENCE, was a scholarly defense of the atomic theory of matter, but some disappointment was manifested that the objections of its opponents were not definitely stated. Lord Kelvin, who seconded the vote of thanks to the

speaker by a short address of his own (as is customary in England), was rather bitter in his denunciation of those who did not accept the theories advanced. Hence it seems doubtful if the popular audience carried away a fair appreciation of the question. The two evening lectures were noteworthy because given by men whose names are household words in the scientific world. Professor Ramsay's topic was 'The Inert Constituents of the Atmosphere,' and though the unfortunate failure of the light prevented some of his diagrams from being visible at the proper time, the lucid explanations made the discourse entirely intelligible. Especially interesting was the description of the long and painstaking experiments and researches which resulted in the famous discovery of argon in 1894, followed in 1895 by that of helium, and in 1898 by that of three other elements to which the names of neon, krypton and xenon were applied. The second lecture, on 'The Movements of Plants,' by Mr. Francis Darwin, was a beautifully simple exposition of a most abstruse subject, namely, how gravity acted to force plants to grow along vertical lines. While the lecturer thought that plants might be classed as vegetable automata, yet he was inclined to believe that mind was always implicated in life, and that, with a fuller knowledge of consciousness, we should admit that the rudiments of the psychic element existed even in plants. There follows an abstract of the presidential addresses and of the work of the Sections of Mathematics and Physical Science, Chemistry and Engineering.

MATHEMATICS AND PHYSICAL SCIENCE.

The president of this Section was Major P. A. MacMahon, F.R.S., and his address dealt first with the position that mathematical science occupied at the beginning of the nineteenth century in the British Isles and on the continent of Europe. As

regards organization and cooperation in mathematics, Germany, he thought, stood first now. The illustration offered by international cooperation in astronomy afforded a useful object lesson to all men of science, and might encourage those who had the ability and the opportunity to make strenuous efforts to further progress by bringing the work of many to a single focus. In pure science a free interchange of ideas was possible, but in applied physics the commercial spirit exercised an influence, and it was the duty of the Association to take an active attitude toward this blot on the page of applied science. The importance of science teaching in secondary schools had been overlooked. Those concerned in our industries had not seen the advantage of treating their workshops and manufactories as laboratories of research, and the Government had given too meager an endowment to scientific institutions and had failed adequately to encourage scientific men. At the present time, the number of workers is so large, the treatises and scientific journals so numerous, the ramifications of investigations so complicated that it was scarcely possible to acquire a competent knowledge of the progress being made in the many divisions of science. Hence the so-called specialist has come into being, and the word was often used as a term of opprobrium or as a symbol of narrow-mindedness. What is required is not the disparagement of the specialist, but the stamping out of narrow-mindedness, and of ignorance of the nature of the scientific spirit and of the life-work of those who devote their lives to scientific research. The specialist who wishes to accomplish work of the highest excellence must be learned in the resources of science and have constantly in mind its grandeur and its unity. Lord Kelvin and Professor Rucker offered the motion for a vote of thanks, and then the regular work of the

Section was begun. Papers were read by Professors A. Gray, F.R.S., J. S. Dunlop and A. Wood, on 'Elastic Fatigue as shown by Metals and Woods'; by Professor G. Quincke, of Heidelberg, on 'The Clearing of Turbid Solutions and the Influence of Light on the Motion of the Suspended Particles'; by Professor A. Gray, F.R.S., on 'The Relation between Temperature and Internal Viscosities of Solids'; by Professor W. Ramsay, F.R.S., and G. Senter, on 'Hydrostatic Pressure'; by E. H. Griffith, F.R.S., on 'The Freezing Points of Certain Dilute Solutions'; and by Dr. R. T. Glazebrook, F.R.S., on 'The Buildings of the National Physical Laboratory.' Dr. Glazebrook, who is the director of this new institution, gave a history and description of the building now being fitted up in Bushy Park, ten miles southwest of London, and described the objects for which it had been founded, as reported on pages 662-663 of SCIENCE.

On September 13 the Section was divided into two parts, Physics and the newly organized subsection of Astronomy. In the former Dr. Glazebrook read the report of the Committee on Electrical Standards, which stated that no evidence of any marked change in the relative values had shown itself. Mr. S. Skinner read a note on 'A Comparison of the Deposits in Silver Voltameters with different Solvents,' and Professor A. Schuster, F.R.S., presented one on 'The Conduction of Electricity through Mercury Vapor.' Dr. V. Crémieu, of Paris, spoke on 'The Magnetic Effects of Electric Convection' in which he showed that an electrically-charged body in motion has not the same electromagnetic properties as an electric current, but, as Lord Kelvin remarked, if these experiments are regarded as conclusive the present electromagnetic theory must be rejected. Other papers were by G. M. Minchin, F.R.S., on 'Photoelectric Cells'; by B. Hopkinson, on 'The Ne-

cessity for Postulating an Ether'; and by Professor F. C. Bose, on 'The Change of Conductivity of Metallic Particles under Cyclic Variations of Electromotive Force.' The Astronomical subsection met under the presidency of Professor H.H. Turner, F.R.S., of Oxford (who took the place of Dr. Copeland, Astronomer Royal for Scotland, detained by illness), and he delivered an address on cooperation in astronomical work, with special reference to the astrographic chart. While agreeing with Major MacMahon as to the value of cooperation, Professor Turner called attention to the harm that might result from undertaking too much and through the checking of original research. The most important astronomical papers were by Professor G. Forbes, F.R.S., on 'The Position of a Planet beyond Neptune,' and by Father A. L. Cortie, of Stonyhurst, who proved that the faculæ on the sun's surface followed the same law of drift as the spots. Professor Turner exhibited a copy of the first photograph of the spectrum of a lightning flash obtained by Professor E. C. Pickering, of Harvard Observatory.

At the next meeting of the Physical Section two papers, by Professor E. W. Morley and Mr. C. F. Brush, of Cleveland, were presented by the former gentleman, the first being on a new gauge for small pressures, designed especially to measure the pressure of aqueous vapor (which will be described in the *American Journal of Science*), and the second on the transmission of heat through water vapor. Other papers were by Messrs. C. Bedford and C. F. Green on 'A Method of Determining Specific Heats of Metals at Low Temperatures'; by Professor H. L. Callandar, F.R.S., on 'The Variation of the Specific Heat of Water'; two papers on the Lippmann electrometer by Messrs. F. G. Cottrell and J. A. Craw and one by Dr. M. W. Travers and G. Senter on 'A Comparison of Constant Volume and Con-

stant Pressure Scales for Hydrogen between 0° and 190° C.' The Committee on Radiation in a Magnetic Field also reported. The mathematicians of the Section met with the Educational Science Section in a joint discussion on the teaching of mathematics, opened by Professor J. Perry, F.R.S., of the Royal College of Science, South Kensington, and participated in by Professor A. R. Forsyth, F.R.S., of Cambridge, Professor A. W. Rücker, now principal of the University of London, Professor S. P. Thompson, F.R.S., of the same university, and others.

On Monday, the 16th, the Section again met in two departments—Mathematics and Physics. In the former, with Major MacMahon as chairman, there were papers by Professor G. Mittag-Leffler, of Stockholm, by Professor G. H. Darwin, F.R.S., by Professor A. G. Greenhill, F.R.S., and others, besides the report of the Committee on Tables of Certain Mathematical Functions. In the department of Physics, under Dr. Larmor, F.R.S., two interesting reports were presented, by Professor J. D. Everett, F.R.S., for the Committee on Underground Temperature, in which the temperatures recorded in the Calumet and Hecla mines were compared with the temperatures in the deepest shaft in the world, situated in Upper Silesia, and the sixth report of the Committee on Seismological Investigations, drawn up by Professor J. Milne, F.R.S., which stated that there were 36 seismological stations abroad and in Great Britain provided with seismographs recommended by the Committee. Among the physical papers, Dr. Crémieu offered one on 'Gravitation' and Dr. C. E. Guillaume, also of Paris, sent as a basis for discussion a proposition for a new unit of pressure, called the megadyne per square centimeter, which differs little from the present atmospheric unit. Considering the status of meteorology in Scotland, surprisingly few communications in

this science were offered, and these suffered from being scattered through two sections. In the Physical meeting just mentioned, there were two suggestive papers by Mr. W. N. Shaw, F.R.S., secretary of the London Meteorological Office, and Mr. R. W. Cohen on 'The Seasonal Variation of Air Temperature in the British Isles and its Relation to Wind Direction,' and on 'The Effect of Sea Temperature on the Seasonal Variation of Air Temperature of the British Isles.' The next day the department of Meteorology met under Professor Turner, but, excepting the report of the Committee on the Ben Nevis Observatory, which was drawn up, as usual, by that Nestor among meteorologists, Dr. Alexander Buchan, F.R.S., the sole paper was by Mr. F. N. Denison, of Victoria, B.C., on 'The Seismograph as a Sensitive Barometer.' The author concluded that since the earth is depressed under areas of high barometric pressure and elevated under areas of low pressure, horizontal pendulums might warn the advent of great Atlantic storms before they reached the west coast of Ireland, but in the discussion that followed, doubt was expressed as to whether the observed effect had been assigned to the right cause. On account of the interest of the president of the Geographical Section, Dr. H. R. Mill, and of its recorder, Mr. H. N. Dickson, in meteorology, their Section also received three papers relating to this science, including one by Mr. Dickson on 'The Mean Temperature of the Atmosphere and the Causes of Glacial Periods.' 'The Systematic Exploration of the Atmosphere at Sea by Means of Kites,' illustrated by the first meteorological records high above the Atlantic, was discussed by the writer who, being a member of two sectional committees, was able to urge the grant of money appropriated for conducting meteorological researches with kites in Great Britain. Mr. W. N. Shaw exhibited to the Geographical Section a series of

twenty-three daily weather maps that were published in various parts of the world at the commencement of the twentieth century. With the exception of Africa, only a small portion of the north of which continent was mapped, South America and a part of eastern Asia, every part of the world has charted each day the weather conditions prevailing over it.

The communication that attracted the greatest popular interest in the Physical Section was by Lord Kelvin on 'The Absolute Amount of Gravitational Matter in any Large Volume of Interstellar Space.' This was a summary of his article in the *Philosophical Magazine* for August (see also *Nature* of October 24), the conclusion being that the matter contained in the universe could not be much more than a thousand million times the mass of the sun, the number of these bodies, estimated at one thousand million, occupying only twenty-seven thousandths of the proportion of space in the universe. Dr. Glazebrook then opened a discussion on optical glass and explained the assistance which the National Physical Laboratory might render in determining the properties it should possess and the best forms of lenses for various purposes. After the reading of several optical papers, Dr. W. J. S. Lockyer, assistant director of the Solar Physics Laboratory at South Kensington, spoke on the evidence of a thirty-five-year period in the occurrence of sunspots, which coincided with the climatic variations indicated by Professor Brückner, of Berne, and with the frequency of auroras and magnetic storms observed since 1833. The closing session of the Section on September 18 was mostly devoted to the magnetic papers. A report presented by the Committee on the Determination of Magnetic Force on board Ship related to the instruments supplied to the English antarctic ship *Discovery* and to the German antarctic ship *Gauss*. Captain E. W. Creak, F.R.S., described a

new form of instrument for observing the magnetic dip and intensity at sea which was designed to replace Fox's apparatus. Lloyd's needles are applied to an instrument that can be used on a gimbal-table on board ship and the *Discovery* and the *Gauss* have been so fitted. The numerous communications to the Physical Section were of a high order and, considering the technical and special nature of many of them, the attendance was well maintained.

CHEMISTRY.

Professor Percy F. Frankland, F.R.S., Professor of Chemistry in the University of Birmingham, delivered the inaugural address, as president of the Section, on the subject of 'The Position of British Chemistry at the Dawn of the Twentieth Century.' He first pointed out that the history of British chemistry, as indeed of British science in general, was remarkable in that it was made up almost entirely of achievements which were the result of private enterprise. The foundation of University College, and other institutions for higher education, by private initiation, and without a particle of assistance from the public exchequer, was quite in keeping with the history of a country in which it was recognized that the Government did not lead, but only followed where it was drawn or propelled. There could be no doubt that the extended cultivation of scientific chemistry in Great Britain, which was such a noticeable feature of the concluding years of the nineteenth century, has been greatly assisted by the research scholarships open to all branches of science and paid with the income produced by the surplus from the Exhibition of 1851. Until recently it had been the feeling of a powerful majority that public money should only be spent in such a way as directly to benefit very large numbers, and in the case of educational funds, therefore, it was only their utilization for

the benefit of the masses that would be entertained. Now, in the matter of higher scientific education, at any rate, it was becoming more and more widely recognized that its starvation, through attention being exclusively directed to the low-level education of the masses, was defeating the very ends which this policy had in view. It was rapidly dawning upon many that 'the greatest Empire which the world has ever seen' could not be maintained unless Englishmen cast off insular prejudices and traditions and made a careful study of those points in which other nations were their superiors, with a view to intelligent adaptation and development, as distinguished from mere initiation, of their methods to particular needs of the British Isles. If the higher teaching of science was to be really encouraged, the first necessity was that this higher teaching should offer a sufficiently attractive career to the man of ambition as well as to the enthusiast. It was not reasonable to fix a definite stipend to a particular chair, and should the best man be required the best price must be paid for him, while, if the British universities were to keep abreast of those of other countries, the chair must be thrown open to all the world. The period of academic study should be extended from three years to five, and the migration of students from one university to another ought to be encouraged. Higher education and true universities were among the most potent factors in breaking down the hereditary stratification of society and in minimizing the advantages depending upon the accident of birth, so that, with the greatly enhanced facilities which must be provided for students without means, they should afford in the future, even more than they had done in the past, an avenue for the humblest boy of talent to that position which he was, by natural endowment and by his own exertion, best fitted to fill in the interests of

the state. British chemical work at the dawn of the twentieth century is satisfactory in many ways, for while almost all the great problems are being worked at, some of the recent progress of chemical science is more or less specifically British, *e. g.*, the isolated labors of Dr. Perkin in the field of magnetic rotatory power; Sir William Crookes's exploration of the phenomena occurring in high vacua; the researches of Abney, Russell and Hartley on the absorption spectra of organic compounds; the investigations of Harold Dixon and Brereton Baker of the behavior of substances in the complete absence of moisture; the extension by Pope and Smiles of asymmetric atoms; the near approach to the absolute zero of temperature by Dewar; and those marvelous discoveries of Rayleigh and Ramsay which have not only introduced us to five new aerial elements, but have revealed the existence of a hitherto unknown type of matter, which is apparently incapable of entering into chemical combination at all.

After the usual vote of thanks, moved by Sir Henry Roscoe, F.R.S., and seconded by Dr. T. E. Thorpe, F.R.S., the Section proceeded to the reading and discussion of papers. Dr. W. T. Lawrence brought forward the question of duty-free alcohol for chemical laboratories. He pointed out that workers in England were placed at a great disadvantage in comparison with workers in Continental laboratories, owing to the charge made on alcohol which was required in very large quantities in research. Abroad, when duties were exacted, they were remitted in the case of chemical laboratories so as not to impede the progress of the work of investigation. It was stated by others that some researches had been stopped half-way on account of this extra expense. Professor A. Michael, of Tufts College, Mass., explained that in the United States the duties were remitted when application was duly

made by the president of an educational institute. As a result of the discussion a committee was appointed to take what steps it could to procure duty-free alcohol and ether for chemical research. Dr. A. G. Green read a paper on 'The Decadence of the Coal Tar Industry in Great Britain and its Growth in Germany' of which an abstract was given on page 663 of SCIENCE. The report of the Committee on preparing a new Series of Wave-length Tables of the Spectra of the Elements was presented. The next day, after papers by Professor A. Brown on 'Enzyme Action,' and by Professor W. Marckwald, of Berlin, on 'Radium,' with demonstrations, the Section resolved itself into parts, one, under the president, considering sanitary and allied matters; the other, under Sir William Roberts-Austen, F.R.S., hearing metallurgical papers. In the former subsection, Professor E. A. Letts read a paper by himself and Mr. R. F. Blake on 'The Chemical and Biological Changes occurring during the Treatment of Sewage by the so-called Bacteria Beds,' in which it was pointed out that in the bacterial treatment of sewage in contact beds the organic nitrogen in the crude sewage was not all converted into the oxidized form of nitrate, this loss being partially due to the formation of free nitrogen, which was either evolved as gas or carried away dissolved in the effluent, and partly due to nitrogen absorbed into the tissues of animals and plants that feed on the sewage. Dr. S. Rideal in the next paper pointed out that the loss of nitrogen was caused in part by a black humus substance, allied to peat, which he had found was formed in all the present methods of bacterial process. This substance contained seven per cent. of nitrogen and was so stable that it did not decompose or give rise to smell, even if it was broken. Dr. Rideal also contributed a paper on 'Sulphuric Acid as a Typhoid

Disinfectant,' in which he said that the outbreak of enteric fever among the troops in South Africa had led Dr. Porter and himself to try to find a chemical salt that could be added to infected water by soldiers on the march and would insure the death of the typhoid germ, if present. Such a salt is sodium bisulphate, and a gram to the pint, after fifteen minutes, purified the water, while four grams of sulphuric acid to the gallon freed sewage or drainage water from typhoid organisms. Mr. Wm. Ackroyd read a paper on 'The Inverse Relation of Chlorine to Rainfall,' in which he showed that when daily estimations of the amount of chlorine were made it clearly appeared that minimum amounts of rainfall were marked by maximum amounts of chlorine contents and *vice versa*. Mr. Ackroyd also detailed the results of his investigation of the distribution of chlorine in Yorkshire. A report was made by the Committee on the Relation between the Absorption Spectra and Chemical Constitution of Organic Substances.

Among the papers before the Metallurgical subsection, one of the most interesting was on 'The Minute Structure of Metals,' by Mr. G. T. Beilby, from which it appeared that the microscopical examination of metallic surfaces, produced in various ways, showed that the metal substance appeared in them as minute granules or scales, or as a transparent glass-like substance. The persistence of these minute scales under all kinds of mechanical and thermal treatment, the remarkable uniformity of their size and appearance in metals of all the leading groups, their disappearance into the transparent form and their reappearance again, apparently unchanged in size or otherwise, all these seemed to afford fair ground for the conjecture that they were in some way definite units in the structure of metals. Mr. Beilby also submitted a joint paper by

himself and Professor G. G. Henderson on 'The Action of Ammonia on Metals at High Temperatures,' which stated that the physical effect of the treatment in every case was to disintegrate the metals completely, while a large proportion of the ammonia was resolved into its elements. Three papers on aluminum and its alloys, together with the report of the Committee on the Nature of Alloys, were presented.

The papers on organic chemistry, to which September 16 was devoted, drew but a small audience, owing to their highly technical nature. The reports of the Committees on Isometric Naphthalene Derivatives and on Isomorphous Derivatives of Benzene were taken as read. Professor A. Michael, of Tufts College, contributed three papers, one being on 'The Genesis of Matter,' in which he assumed that at the birth of matter there were two forms of 'protyle' corpuscles endowed with opposite polarity and only two forces—gravitation and chemical affinity—the temperature being near the absolute zero. Gravitation acted on these corpuscles, and when they came within the sphere of chemical affinity they united, converting part of their chemical energy into heat. It was probable that the non-metals in the genesis of matter would be first formed, and that as the temperature decreased the metallic elements began to form. At the next meeting of the Section the papers on general and physical chemistry were so numerous that it was necessary strictly to limit the time of each speaker. Professor J. Sakurai, of Tokio, speaking on 'Some Points in Chemical Education,' said that chemical education, as at present carried on, was inefficient and unsatisfactory. Chemical education was a sound course for those who would become chemists or for those who applied that science in special directions, but it was no less important for its educational value in secondary schools. Nevertheless, modern

chemistry was still taught largely in the same dry and descriptive way as in the old days. He deprecated the term 'physical chemistry' as misleading and suggested that 'general chemistry' be used in its stead. Chemical laboratories in universities and colleges, he thought, should be institutions which contributed to the sum total of the knowledge in which men were trained and not mere workshops for apprentices. In the discussion that followed it was the general opinion that a thorough training in analysis should precede research work. Mr. W. Thomson read a practical paper on the 'Detection and Estimation of Arsenic in Beer and Articles of Food,' and Dr. E. F. Armstrong discussed 'The Equilibrium Law as Applied to Salt Separation and to the Formation of Oceanic Salt Deposits.' Its application to the formation of deposits, of potash and other salts, formed by the gradual drying up of ancient seas, is of interest and from a model, representing the successive changes observed on concentration of solutions containing several inorganic salts, it was possible to forecast the order in which salts would separate on concentration, and also the relative amounts deposited at any stage. The Committee on the Bibliography of Spectroscopy reported. At the closing session of the Section Dr. J. Gibson read a paper on 'The Electrolytic Conductivity of Halogen Acid Solutions,' in which he showed that there was a marked difference in the chemical behavior of the solutions of acids, according as the concentrations were above or below the concentrations corresponding to their respective maximal specific conductivities. Mr. P. J. Hartog, in describing 'The Flame Coloration and Spectrum of the Nickel Compounds,' said that nickel acetate produced an evanescent purple tinge and a persistent red coloration in the Bunsen flame. Professor Smithells remarked that, although experiments with nickel had been made for

years this property had not been observed, and the coloration perhaps might not be due to nickel. After papers by Dr. Farmer, on 'The Methods of Determining the Hydrolytic Dissociation of Salts, and by Dr. J. S. Patterson, on 'The Influence of Solvents on the Rotation of Optically Active Compounds,' the meeting terminated, having been less well attended, in spite of the interesting papers, than was the case at Bradford last year.

ENGINEERING.

This Section suffered severely in coming immediately after the assembling at Glasgow of the important International Engineering Congress, the Congress of Naval Architects and the Electricians' Association, all of which detracted from both papers and members. As a consequence, not a single paper on marine engineering, and only two papers pertaining to electricity were offered to the Section this year.

The president, Col. R. E. Crompton, M.Inst.C.E., in his address discussed first some of the interesting problems presented by recent development in means of locomotion on land, which demand the best thought, not only of our engineers, but of every one interested in the improvement in the means of traveling and in the more rapid transportation of goods. During the past few years a great improvement in the speed of trains and in the comfort of passengers on the American and Continental railways has been made, and while it appears that England has now been beaten in the matter of extreme speed on railways, it is probable that the English railways still provide a larger number of rapid trains than do either the American, German or French. The speed limit of railways of the present system of construction is reached at about sixty-five or seventy miles an hour, and it is improbable that anything greatly in excess of seventy miles an hour will be attained

until an entirely new system of construction is instituted. The high speed service contemplated intends to obtain speed exceeding one hundred miles an hour by providing electrical means of haulage sufficient to propel light trains consisting of a single or, at most, a few cars run at short intervals of time. In the United Kingdom there are only a few journeys of sufficient length to make saving of time of great importance, but the case is far different in America and on the Continent where the business centers are much farther apart, and this topographical question would cause our English engineers to be at a disadvantage. A most important problem in locomotion is that caused by the congestion of street traffic in towns, and although the provision of electric tramways is undoubtedly an economical means of carrying passengers, yet these tramways could not be laid in existing thoroughfares without considerably reducing the total road-carrying capacity at times of heavy pressure of traffic, and so both for ordinary and pleasure transportation it appears probable that a motor-car service carried out on well-made roads would compete favorably with, and in many ways might be preferable to, tramway service. One of the topics that has been most strongly discussed during the past year is the position which Great Britain holds, relatively to other countries, as regards supremacy in engineering matters. The chief difference between the manufacturer here and the manufacturer in America is that the latter invariably makes goods in large quantities to standard patterns, which is much less the case in England. Many years ago, Sir Joseph Whitworth impressed on the world the importance in mechanical engineering of extreme accuracy and of securing the accurate fit and interchangeability of parts by standard gauges, but these ideas have not been acted upon to the extent that they should. Up to the present time the

Board of Trade has dealt with the simple standards of weight, capacity and length, but in other countries national standardizing laboratories have been provided. At last, through the exertion of the council of the Royal Society, the British Government has been moved to give a grant in aid and to cooperate with the Royal Society to establish a National Physical Laboratory. The vote of thanks to Col. Crompton for his address was moved by Sir Alexander Binnie and seconded by Sir Frederick Bramwell.

Mr. D. H. Morton, M.Inst.C.E., spoke on 'The Mechanical Exhibits of the Glasgow Exhibition,' which he said were, in general, disappointing, because in many departments the international character to which the Exhibition, as a whole, laid claim, was entirely wanting; because some of the most important developments in recent years were illustrated inadequately or not at all, and because the Exhibition failed to give any full idea of the magnitude and the variety of those enterprises which have made the city of Glasgow, with its surroundings within a radius of thirty miles, one of the world's great centers in metallurgy, mechanical engineering and shipbuilding. The collection of ship models historical and contemporary, was probably the finest demonstration of Clyde naval architecture ever seen, although marine engineering was so inadequately represented elsewhere. Nevertheless, the dominant Exhibits were the trophies in steel, and the exhibition might, indeed, be said to mark the triumph of steel, and particularly of cast steel. Mr. John R. Wigham explained a method of employing petroleum as an illuminant for beacons and buoys, to give a continuous light for a month or longer without any attention whatever. He exhibited also a 'New Scintillating Lighthouse Light,' by which the sailor was not deprived of the benefit of the powerful flash of the revolving

lense, and yet did not have to pick it up at intervals, for this light is continually visible, the lenses being so placed with regard to each other and so revolved that the impression of the flash of one beam remains on the retina of the observer's eye till that of the succeeding beam takes its place, the practical effect produced being a continuously visible scintillating light. Mr. J. E. Petavel described a recording manometer for high-pressure gas explosions, in which elastic compression of metal replaces the spring of the ordinary indicator, a movement of a thousandth of an inch, corresponding to a pressure of 1,200 pounds per square inch, being shown by a ray of light deflected on to a recording cylinder. On the following day Mr. Norman D. MacDonald, of Edinburgh, read a comprehensive and interesting paper on 'Railway Rolling Stock, Present and Future.' Outside Great Britain it appeared settled that the compound locomotive would be the engine of the future. The boiler pressures, both in America and on the Continent, are much higher than in England, and for English roads the American type of engine, with equalizing levers and water-tube grate, offered advantages. In the discussion of the paper the progressive character of railway engineering in the United States was attributed to the attention paid by American universities to the testing of locomotives, and also to the good work done by the various railway clubs in spreading the knowledge of locomotive practice among young engineers. Mr. P. Bunau-Varilla, formerly engineer-in-chief of the Panama Canal, spoke on the relative advantages of the Nicaraguan and Panama routes for a canal from the Atlantic to the Pacific, favoring the latter on account of the masonry dam, which, with the locks, must be built and maintained in a country subject to frequent earthquakes, if the former be chosen. Moreover, ships would there encounter violent gales, strong

river currents, constant changes of depth, and many curves of short radius.

Monday is usually devoted to electrical engineering but, as already remarked, there were but two papers approaching that character this year. Mr. Killingworth Hedges contributed a paper on 'The Protection of Public Buildings from Lightning,' remarking that in 1888 the subject had been discussed jointly by the Physicists and Engineers of the Association, but that there had been no official report as to the effect of lightning strokes upon buildings protected by conductors since the Lightning Rod Conference of 1882. In the discussion it was said that architects could not be expected to pay more attention to protection of buildings from lightning until engineers had definitely decided what practice should be followed, there being at present many conflicting views. - 'The Commercial Importance of Aluminium' and 'Aluminum as a Fuel,' were discussed respectively by Professor E. Wilson and Sir Roberts-Austen, F.R.S., the former considering chiefly its advantages as an electrical conductor. Mr. J. Dillon described a method of recording soundings by photography, for the use of engineers; Dr. Vaughan Cornish discussed the height and length of waves observed at sea, and Mr. R. L. Jack showed pictures of native bridges in Western China.

Two reports of committees were presented to this Section. Professor H. S. Heleshaw made a preliminary report for the Committee on Resistance of Road Vehicles to Traction, from which it appeared that some work had been done with a motor-car and experiments had been made on an artificial track so as to test the resistance of various materials. Mr. W. H. Price reported for the Committee on the Small Screw Gauge that, while it had been recommended last year that the thread of the British Association screw-gauge should be altered in certain particulars, and the proposals had

attracted much attention, yet so far the recommendations had had no practical results. Professor G. Forbes explained a portable folding range-finder, for use with infantry, based on the instrument of Adie and utilizing stereoscopic vision. After papers by Mr. Mark Barr, describing his ingenious machines for engraving the matrices used in type-founding, by Mr. C. R. Garrard, on 'Recent Development of Chain Driving,' by Mr. T. A. Hearson, on 'Measurement of the Hardness of Materials by Indentation by a Steel Sphere,' by Mr. E. T. Edwards, on 'The Critical Point in Rolled Steel Joists' and by Mr. J. W. Thomas, on 'Air Currents in Churches' the Section adjourned a day before the other sections. Notwithstanding the paucity of papers, they were of fair quality and covered a wide range of subjects.

BLUE HILL METEOROLOGICAL
OBSERVATORY.

SCIENTIFIC BOOKS.

Smokeless Powder, Nitro-cellulose and Theory of the Cellulose Molecule. By JOHN B. BERNADOU, Lieutenant U. S. Navy. N. Y., John Wiley & Sons. 1901.

This work consists of eighty pages of new matter and of one hundred and thirteen pages of translation and reprints. The newly presented portion treats of: (1) Origin of the cellulose nitrates; the names by which they have been sometimes designated; and the meanings that the author gives to the terms he employs; (2) to 'the earlier views as to nitro-cellulose composition and constitution'; (3) to 'the conception of progression in relation to composition and constitution'; (4) to 'solutions of nitro-cellulose' and 'theory of the cellulose molecule.' It will be observed that in this brief space the author has set for himself a most ambitious program, especially as he applies himself to the solution of one of the unsolved problems of chemistry and one which chemists have regarded as presenting the most profound difficulties. Naturally those chemists into whose hands this book may come would turn at once

to the author's 'theory of the cellulose molecule,' curious to ascertain the data upon which the author's theory is based, the methods of reasoning by which he arrives at his conclusions, and the form that his theory takes. He will find that it is based on the statements of Cross and Bevan that in mercerizing cellulose with sodium hydroxide a definite reaction takes place 'in the molecular ratio $C_{12}H_{20}O_{10} : 2 NaOH$ accompanied by combination with water (hydration)'; that the compound thus formed is decomposed on washing with water, 'the cellulose appearing in a modified form, viz., as the hydrate $C_{12}H_{20}O_{10} \cdot H_2O$ '; that by treatment with alcohol 'one half of the alkali is removed * * * the reacting groups remaining associated in the ratio $C_{12}H_{20}O_{10} \cdot NaOH$ '; that the process of mercerization is accelerated 'on exposure to a lye of 1.225 - 1.275 sp. gr.' * * * 'by reduction of temperature,' which, Bernadou states, presents 'an analogy to the increased solubility of nitro-cellulose in ether and ether-alcohol upon application of cold'; that the quantitative regeneration of cellulose from thio-carbonate solutions and the saline character of aqueous solvents of cellulose led Cross and Bevan to express the belief that cellulose yields only under the simultaneous strain of acid and basic groups, and to assume, 'that the OH groups in cellulose are of similarly opposite function,' but 'that apart from any hypotheses, we may lay stress on the fact that these processes (of dissolving cellulose) have the common feature of attacking cellulose in the two directions corresponding with those of electrolytic strain.'

With these data and some few experiments of his own on solubility at low temperatures, Bernadou sets out to demonstrate the constitution of the cellulose molecule. He finds it necessary, however, at the outset to assume that ethyl hydroxide has the constitution which chemists have assigned to dimethyl oxide, and then taking as his empirical formula $C_{12}H_{20}O_{10}$, without giving any experimental data for doing so, he writes the constitutional formula for cellulose as a closed chain with double bonds for the central carbon atoms, notwithstanding that Cross and Bevan (the authority he quotes) in speaking of the celluloses say, on page 2 of 'Cellulose,' 1895: "Their reactions are those of 'sat-

urated' compounds. Their empirical formulæ and relationships to the carbohydrates of lower molecular weight further indicate 'single-bond' linking of their C atoms as exclusively prevailing." On page 81 of 'Researches on Cellulose,' 1901, Cross and Bevan give a ring formula for cellulose as proposed by Vignon, but it is quite different from any given by Bernadou and the recent experimental data which suggest such an arrangement are cited. Having thus obtained a 'satisfied' molecule, Bernadou notes that the existence of the 'double central carbon bonds' permits the formula for the molecule, 'on its entering into combination,' to be written with its four 'ethylene' bonds as linking, and then that, 'without radical modification,' these median bonds may be terminal. By now splitting this last molecule transversely he obtains the formula for his $C_6H_{10}O_6$, which he states 'is the simplest expression for cellulose' and 'represents not the molecule, but the type unit of cellulose as it enters into combination through its four free single carbon bonds,' and with this 'type unit' he proceeds to build 'polymers' exhibiting his 2-phase and 5-phase molecules, the latter being a cycle.

Of these he says, "It is evident that under such an assumption the molecule may possess an infinity of phases. On this assumption, and, it seems to me, on this assumption only, may we account for definite chemical composition of the cellular form in the plant structure. For we may regard the cell as built up from an aggregate of molecules of identical composition but of progressively varying numerical phase. The cell may begin with molecules of low phase and end with molecules of high phase, or conversely."

Again, "The conventional ring-formed combination of elemental particles shown in the polyphase molecule strongly suggests the vortex-ring theory of the composition of matter (as applicable to the *molecule*)."

And again, "Such a molecule would increase in amplitude according to the number of elemental particles entering into its composition; and the thought suggests itself that *progressive variation in the amplitude of the molecular ring is a characteristic of organic life*. Or, conversely, we may state that we may seek for the beginnings

of organic life—or at least of plant life—in the polymerization of the carbohydrates.”

Lieutenant Bernadou seems to misconceive the meaning and value of graphic formulæ, for while chemists hold that they are simply convenient conventional methods for expressing the ascertained facts of chemistry, and true only to the extent that they express those facts, Lieutenant Bernadou appears to regard them as original sources of information.

The useful portions of this book are the translations of the papers of Vieille and of Bruley on the Nitration of Cotton, and that of Mendeléef on Pyrocollodion Smokeless Powder, though the value of the last is lessened by the omission of all reference to the source from which it is drawn, especially as the author states in the preface that these are only ‘translations of certain portions of their works on explosives.’ It should be understood that while translations are a convenience, one who differs from an author should not rely upon a translation, but should first consult the original publication before expressing this difference, and the translator should be willing to have this comparison of his translation readily made by giving his sources.

The record of the results of a few experiments on the solubility of cellulose nitrates at low temperatures in continuation of the work of McNab is interesting. If Lieutenant Bernadou had but multiplied these experiments and reported them in a simple manner he would have produced something more useful to mankind than the speculative essay he has chosen to present.

CHARLES E. MUNROE.

Select Methods of Food Analysis. By HENRY LEFFMANN and WM. BEAM. Philadelphia, Pa., Blakiston's Son & Co.

It is stated by the authors that “this book is intended to be a concise summary of analytic methods adapted to the needs of both practicing analysts and advanced students in applied chemistry.”

The first part of the work, pages up to 68, is occupied with a brief description of the principal analytic methods employed, including spectroscopy, microscopy, polarimetry, methods of determining melting and boiling points and other general operations.

In the part given to applied analyses, comprising the rest of the book, are articles devoted to general methods for the examination of poisonous metals, colors and preservatives, while under special methods are treated the processes for determining carbohydrates, fats and oils, milk and milk products, tea, coffee and cocoa, condiments and spices, alcoholic beverages and flesh foods.

An appendix contains tables of specific gravities of water, conversion tables for thermometric degrees, tables of elements, symbols, and atomic weights, and plates showing the structure of tea leaves and starches.

In regard to the analytical methods the authors say: “The bulletins of the United States Department of Agriculture (Bureau of Chemistry) and of the Association of Official Agricultural Chemists are now nearly all out of print and scarce. The present work contains a large amount of the data and processes given in those publications, together with data from reports of some of the State agricultural experiment stations.”

In addition to this general acknowledgment, the articles copied directly from the above publications are credited in the text in most cases. The authors have reproduced the plates of tea leaves and starch granules of the Bureau of Chemistry, of the Department of Agriculture, stating that the originals in many cases have been retouched by Dr. Beam.

The work is illustrated with 53 figures in addition to the plates of leaves.

This work will prove of great help to analysts who do not have access to the literature of the subject or who have not the time to make their own investigations thereof. The matter is well arranged and classified and in convenient form for reference.

H. W. WILEY.

The History of Medicine in the United States, etc., to the Year 1800. By FRANCIS RANDOLPH PACKARD, M.D. J. B. Lippincott Co., Philadelphia. 1901. 8vo. Pp. 542. Illustrated.

The difficulties to be encountered in writing a history of early medicine in America have hitherto deterred authors from attempting this really herculean task, and it is not surprising, therefore, that we find Dr. Packard, in this hitherto untrodden field, claiming for his work

rather the rôle of a series of essays and compilations than of a continuous historical work. The thirteen original colonies were so scattered, so remote from and so independent of each other, that each formed a community to itself, and any attempt at a general history must deal largely and directly with these separate centers. A vast amount of research must therefore be made into records, many still in manuscript, from New Hampshire to Georgia, and this would take more time and means than medical historians—whose work must always be largely, as Dr. Packard says, a labor of love—can give. It is an encouraging circumstance that these records are gradually being made known through individual research, as evidenced by papers appearing from time to time in the journals and even by more pretentious works; and the time is probably not far distant when sufficient material will be at hand for a comprehensive historical work. But even now we can hardly feel that Dr. Packard has exhausted all readily available sources of information. In the writer's own community for example he has entirely overlooked such sources that are at his very elbow in the library of the College of Physicians and Surgeons of Philadelphia. And it is in no invidious spirit that we are led to remark that whilst Philadelphia was the chief medical metropolis of the colonies, there were other medical centers even then, and even in rural sections there were physicians of wide repute and influence whose names and records cannot be omitted from such a work. The South particularly furnished many such men educated abroad and endowed with all the learning of their day. An item of page 156 of Dr. Pepper's work would seem indeed to indicate that the physicians of the Middle and Southern States had better training than those of New England. It is there stated that of the 63 Americans who graduated in medicine at the University of Edinburgh between the years 1758 and 1788, *but one* came from the New England colonies. When we recall that Edinburgh was the chief place of resort for medical students going abroad, and that a large proportion of the 63 came from Southern States, it seems strange that this section should be comparatively so ignored by Dr. Packard. Take

the state of Maryland, for example, one of the oldest and most important of the thirteen colonies. I find in the list of authorities 'chiefly consulted' by Dr. P., 67 in number, but *one* from Maryland, viz., 'McSherry's History of Maryland.' And in the 16 pages of index there are *but 13* references bearing in any way upon this state and its doctors. It would be easy to show that Maryland does not deserve this slight.

There are several errors and omissions to be noted, but we have only space for the following: At pages 11 and 12 Mr. Pratt is appointed surgeon to the plantation in 1632 and perishes in a shipwreck in 1645 (!). At page 90 vaccination is said to have been announced by Jenner in 1779. At page 432 inoculation is said to have been 'introduced' in 1712. In the copy of Dr. John Archer's diploma, the first conferred in America, page 161, there are several inexcusable errors, in one place nearly a whole line being omitted. At page 62 it is stated that the first recorded autopsy in America occurred in 1674, whereas several recorded in Maryland preceded this by about thirty years. We also know of at least two medical societies not included in the 17 stated to have existed prior to 1800. These facts could have easily been ascertained by Dr. Packard. At page 36, it is said the degree of M.D. was conferred at the University of Aberdeen in 1650, which we feel sure is a mistake. The omissions, as we have noted, are many, but surely the author should have referred to Drs. Henry Stevenson, James Smith and Gustavus Brown, of Maryland, the first maintaining for many years the only inoculating hospital in America, the second doing more perhaps for the introduction of vaccination over the United States than any other person whomsoever, the third, besides eminence in other respects, having the distinction of being called in consultation in the last illness of George Washington.

Dr. Packard has given full and graphic descriptions of the yellow fever epidemics in Philadelphia and has thrown much light on the medical development of the continental army during the Revolution. In an interesting account of the introduction of anæsthesia, he gives due credit for the discovery to Dr. Craw-

ford Long, of Georgia, who first used sulphuric ether to produce unconsciousness in surgical operations in 1842, four years before its use at the Massachusetts General Hospital.

In conclusion, if in our rôle as critic and reviewer we have said anything to make the reader think ill of Dr. Packard's book, we desire now to take it all back and to assure him that it is a most interesting and valuable contribution to American history and literature.

E. F. C.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *Botanical Gazette* for October contains the following papers: F. L. Stevens publishes the third and last part of his paper entitled, 'Gametogenesis and Fertilization in *Albugo*.' A multiple fertilization was unknown before its discovery by the author in *Albugo Bliti*, the only species of *Albugo* previously investigated exhibiting simple fertilization. The present paper includes *A. Portulacæ*, *A. Tragopogonis* and a reinvestigation of *A. candida*, and shows that these species, together with *A. Bliti*, form a series differing in the prominence of the 'receptive papilla,' the development of the cœnocentrum, and in the functional egg nuclei. The conclusion is reached that the primitive forms were multinucleate, and that the uninucleate condition is a derived one. In its ontogeny *A. Tragopogonis* indicates this, its oosphere in early stages being multinucleate, and later becoming uninucleate by degeneration of supernumerary nuclei. The cœnocentrum, an organ of hitherto unknown function, is shown to serve in the nutrition of the surviving female nucleus. Many conditions are noted which tend to confirm Strasburger's theory regarding kinoplasm and its relation to sexual differentiation.

W. L. Bray completes his paper on 'The Ecological Relations of the Vegetation of Western Texas.' It is a general discussion and analysis of this interesting field, and is designed primarily to form the basis of a detailed botanical survey of the State. The author considers at some length the relation of the vegetation to the climatic factors of temperature, moisture, winds and sunlight; and to the so-called edaphic factors of physiography, soil structure and other geological phenomena.

The greater part of the paper, however, is given to a discussion of the plant formations of the region under the following general heads: (1) Grass formations; (2) woody formations, including numerous types of arborescent and chaparral formations; (3) water storage formations; (4) formations of cryptogamous xerophytes; and (5) halophytic plants. The following propositions summarize the main features of the discussion: (1) The climatic conditions conspire to make the west Texas region a typical 'grass plains country'; (2) in its temperature relations the vegetation ranges from the tropical to the transition zones; (3) the region is marked by several climatic types which are enumerated; (4) the original formations are undergoing profound changes due to human agencies, the tendency being to break up the grass formations and to permit the encroachment of woody vegetation; but areas of arborescent vegetation are being denuded of valuable timber, thus forcing the question of water supply and control of floods.

Mr. James B. Dandeno points out the confused usage of physiologists in designating the solutions with which they have worked. The term 'normal solution' has been used by some for solutions containing a gram equivalent per liter of solution, by others for those containing a gram equivalent per liter of water, and by still others for gram molecule per liter solution. After defining these three carefully and calling attention to the usage of chemists, he cites examples of confused usage by physiologists, and urges that care be taken to distinguish between different sorts of solutions and to avoid misuse of the term 'normal.'

Mr. Burton E. Livingston adds to his previous contribution on the same subject an account of several lines of experimentation, which extend his previous results and confirm his conclusions already expressed. In the new experiments upon *Stigeoclonium tenue* he has used solutions of non-electrolytes (in this case sugars), and also solutions containing both sugar and mineral salts; further, he has cultivated these plants on porous plates, in gelatin, in darkness, and under conditions where evaporation would concentrate solutions. He finds in all cases that osmotic pressure is the deter-

mining factor for the form of the plant, whether the cells are immersed in solution or supported upon gelatin or upon porous plates; and as darkness has no effect upon the form of this plant, its polymorphism does not depend upon photosynthesis. His physiological experiments have been supplemented by a considerable series of physico-chemical tests in order to determine whether error had been introduced into his experiments by assumption that complete ionization occurred in his solutions of electrolytes. He finds that the osmotic pressure calculated by the freezing point method, and in some cases also by the boiling point method, conforms so closely to the osmotic pressure calculated on the assumption of complete ionization, that no error had been introduced, the differences between the calculated and determined pressures lying entirely within the range of the pressure limits found for the several responses of the plant.

T. C. Johnston publishes some results in connection with intramolecular respiration, and Dr. J. Schneck records some interesting observations on *Aquilegia Canadensis* and *A. vulgaris*.

SOCIETIES AND ACADEMIES.

AMERICAN MATHEMATICAL SOCIETY.

A REGULAR meeting of American Mathematical Society was held at Columbia University on Saturday, October 26, extending through the usual morning and afternoon sessions. The first part of the afternoon session was devoted to a joint meeting with the American Physical Society at which a paper 'On the Theory of Elastic Plates' was read by Professor J. Hadamard, the representative of the University of Paris at the recent Yale Bicentennial. About forty persons were present at the joint session, which was presided over by President Michelson, of the Physical Society. At the separate session of the Mathematical Society, at which Vice-President Thomas S. Fiske occupied the chair, thirty-three members of the Society were in attendance. Twelve persons were elected to membership: Mr. C. H. Ashton, Harvard University; Professor H. Y. Benedict, University of Texas; Dr. William Findlay, Columbia University; Dr. W. B. Fite, Cornell University;

Professor G. W. Greenwood, McKendree College; Professor F. W. Hanawalt, Iowa Wesleyan University; Dr. E. V. Huntington, Harvard University; Professor H. W. Kuhn, Ohio State University; Dr. I. E. Rabinovitch, New York City; Professor W. D. Tallman, Montana State Agricultural College; Mr. H. M. Tory, McGill University; Mr. A. H. Wilson, Princeton University. Seven applications for membership were received. The By-laws of the Society were amended to provide that the presidential address shall hereafter be delivered at the last meeting of the presidential term. As the amendment takes effect at once, President Moore's address will be postponed to the annual meeting of December, 1902.

The following papers were presented at this meeting:

PROFESSOR G. A. MILLER: 'On the abelian groups which are conformal with non-abelian groups.'

DR. H. F. STECKER: 'Concerning the elliptic \wp ($g_2; g_3; z$)-functions as coordinates in a line complex, and certain related theorems.'

MISS I. M. SCHOTTENFELS: 'Generational definition of certain groups of order 960.'

PROFESSOR OTTO STOLZ: 'Zur Erklärung der Bogenlänge und des Inhaltes einer krümmen Fläche.'

DR. L. P. EISENHART: 'Conjugate rectilinear congruences.'

PROFESSOR S. E. SLOCUM: 'The symbols of the infinitesimal transformations which generate the parameter groups corresponding to all possible types of structure of two-, three- and four-parameter complex groups.'

DR. E. V. HUNTINGTON and DR. J. K. WHITTEMORE: 'Some curious properties of conics touching the line infinity at one of the circular points.'

PROFESSOR J. HADAMARD: 'On the theory of elastic plates.'

PROFESSOR E. B. VAN VLECK: 'On the zeros of fundamental integrals of regular linear differential equations of the second order, with a determination of the number of imaginary roots of the hypergeometric series.'

DR. E. J. WILCZYNSKI: 'Reciprocal systems of linear differential equations.'

DR. I. E. RABINOVITCH: 'On some contradictions involved in the elliptic geometry in a point space.'

DR. EDWARD KASNER: 'Determination of the integrals in the calculus of variations leading to an assigned system of extremals.'

The members of the two societies lunched together at the University restaurant, and in

the evening several of the members dined at Mock's restaurant in Forty-Second street. These opportunities for informal intercourse are always an enjoyable feature of the meetings. The Christmas meetings of both societies extend through the two days, Friday and Saturday, December 27-28, and it is hoped that a considerable number of the members will arrange to attend the informal dinner which will be arranged for Friday evening.

F. N. COLE,
Secretary.

SECTION OF GEOLOGY AND MINERALOGY OF THE
NEW YORK ACADEMY OF SCIENCES.

THE first meeting of the Section was held on October 21. In calling the meeting to order the chairman spoke of the loss to the Academy and to science occasioned by the deaths of Dr. T. G. White, secretary of the Section, and Professor Joseph Le Conte, corresponding member of the Academy. A committee consisting of Professors J. J. Stevenson and J. F. Kemp was appointed to draw up suitable minutes in reference to Dr. White and Professor Le Conte. Dr. E. O. Hovey, of the American Museum of Natural History, was then elected secretary of the Section.

The following program was offered: Dr. A. W. Grabau spoke on 'Recent Contributions to the Problem of Niagara.' He said that Davis has shown that the topography of the Niagara region conforms to the type generally found in ancient coastal plains, the original features of which have been more or less modified by subsequent warpings, and by glacial erosion and deposition.

The Niagara escarpment is the inface of the Niagara cuesta, traceable through the Indian Peninsula and Grand Manitoulin Island. The Ontario lowland is continued in the Georgian Bay lowland. A second cuesta—the Onondaga—has its inface slightly developed north of Buffalo, but becomes prominent in the Lake Huron valley, where its inner lowland forms the deeper part of the lake. The third cuesta and lowland (the Erie) occurs north of the second.

The Tertiary drainage is supposed to have been to the southwest, instead of the north-

east, as Spencer holds. The principal streams of that time are supposed to have been (1) the Saginaw, whose path is indicated in part by Saginaw Bay and the deep channel between the Indian Peninsula and Grand Manitoulin Island; (2) the Dundas, breaching the Niagara cuesta at Hamilton, Ont., and crossing the Erie lowland near Fort Stanley; and (3) for a time, at least, the Genesee, though this may later have had a northward course. The subsequent streams tributary to these consequents carved the various lowlands. St. Davids channel is regarded as an obsequent stream, which was accidentally discovered by the Niagara. The whirlpool gorge was probably, in part, the southward continuation of this stream, and not wholly postglacial.

Professor J. F. Kemp's first paper was on the 'New Asbestos Region in Northern Vermont.*' He said that asbestos has recently opened up on a commercial scale in the towns of Eden, Lamoille Co., and Lowell, Orleans Co., Vt. The towns are adjacent, although in different counties. The asbestos lies from 15 to 25 miles north of Hyde Park, a station on the St. Johnsbury and Lake Champlain R. R. As is quite invariably the case, it occurs in serpentine, either in veins or in matted aggregates along slicken-sided blocks. The serpentine where the best fiber is found lies on the south shoulder of Belvedere Mountain, and forms an east and west belt. It is bounded on the north and west by hornblende-schist, which forms the summit of the mountain. The contact on the west is a visibly faulted one, and that on the north is probably also of the same sort, because the hornblende-schist rises in a steep escarpment.

The serpentine seems to have been derived from enstatite, diallage and probably olivine, since unaltered nuclei of these minerals are found in it. The vein asbestos ranges from a fiber of microscopic length up to $\frac{1}{4}$ of an inch as thus far exposed. It is fine and silky and of excellent grade. It would, however, be classed as second grade according to the Canadian practice, which makes a first grade, of fiber above $\frac{3}{4}$ of an inch (about $2\frac{1}{2}$ in. being the maximum), and a second grade of $\frac{3}{8}$ in. to $\frac{3}{4}$

* Communicated by permission of the Director of the U. S. Geological Survey.

in. All below this and all fiber not vein fiber goes to the mill and is mechanically separated, as the third grade. In the Vermont localities the slip fiber is exposed on the property of the New England Co., and of its neighbor, the American Co. The vein fiber is limited, so far as yet opened up, to the property of Mr. M. E. Tucker and associates.

It is difficult, with the data in hand, which were gathered under the direction of Dr. C. W. Hayes, of the U. S. Geological Survey, to trace the geological history of the serpentine, but it must have been originally either an igneous pyroxenite or peridotite or else a richly magnesian siliceous limestone. There are such slight traces of calcium-bearing minerals, however, that the former supposition has the greater weight. The hornblende-schist consists in largest part of common green hornblende but one may also observe epidote, zoisite and some minor accessories.

Professor Kemp also gave a paper on the 'Physiography of Lake George.' The observations, extending over several years, have suggested the following conclusions: Lake George occupies a submerged valley very similar to many others in the Adirondacks which are not submerged. The valley has been largely produced by faulting, and the fault-scarps still remain in precipitous cliffs, whose sharpness has not been much affected by weathering and erosion. Before the Pleistocene the valley was probably a low pass with both a north and a south discharge. The portion rich in islands near Pearl Point and the Hundred Island House was probably the divide, and the islands represent the old hillocks near the top of the divide. At the south the water is backed up by sands and morainal matter in the valleys on each side of French Mountain, viz., at the head of Kattskill Bay and at Caldwell. On the north they are held in by Champlain clays and syenitic gneiss at the Ticonderoga outlet, and probably by morainal material at the low pass just south of Rogers Rock and leading out to the very depressed Trout brook valley, just west of Rogers Rock and Cook mountains. Trout brook is now as much as a hundred feet lower than Lake George at points south of the Ticonderoga barrier. The northern barrier is rock,

because the Ticonderoga river passes through a narrow and shallow channel in the exposed ledges a mile south of its actual first waterfall. There is here a broad flat valley buried in clays, however, beneath which an old channel may lie submerged. At the same time the marked depth of the Trout brook valley to the west makes this the natural outlet, and there is reason to believe from the general topography that the discharge passed north into the Champlain valley near the south boundary of Crown Point. It is also not to be overlooked that a valley with much drift leads eastward to Lake Champlain, from the head of Mason's Bay.

A curious feature that is common to both shores of the lake north of Sabbath Day Point (and perhaps also south of it) is the presence of pot holes of great perfection and as high at times as 80 feet above the present level of the lake. These are best developed on Indian Kettles Point, about two miles north of Hague. They were doubtless excavated by lateral or subglacial streams when the ice filled the lake valley, because in no other conceivable way could flowing water be forced into such unnatural situations.

There is great need of a good hydrographic survey of the lake, and of detailed pilot charts, with soundings. They would be of great service, not alone to navigators, but to science as well. So far as could be learned from local fishermen, whose deep trolling for lake trout gives them familiarity with the bottom, there appear to be channels whose general trend is parallel with the long dimension of the lake, and which have precipitous sides, precisely like the valleys and gulches now visible. The lake is relatively shallow as compared with Lake Champlain. In Lake George, the greatest depth is believed to be near Anthony's Nose, and to reach 190 feet. Elsewhere the deep parts are placed at about 100 feet, more or less. All this, however, requires confirmation by soundings. With regard to the physiography of the bottom one cannot say to what extent the valley has been filled by drift, but the islands to which physiographic importance has here been given are rock.

RICHARD E. DODGE,
Secretary pro tem.

BOTANICAL SEMINAR OF THE UNIVERSITY
OF NEBRASKA.

AT the regular meeting on November 1, Dr. Roscoe Pound read a paper on 'The Purpose and Force of Botanical Laws,' directing attention to the fact that rules of procedure in science are as necessary as they are in civil life, and indicating that the method by which laws are obtained in the one case must be similar to those in the other. The paper was discussed by Professor Bessey (who spoke of the supposed danger of a repression of originality through the action of laws of science); Dr. Wolcott (who called attention to the code of laws and their successful execution in ornithology); and Dr. Clements (who discussed a proposed series of regulations in regard to the nomenclature of plant geography).

DISCUSSION AND CORRESPONDENCE.

PREGLACIAL DRAINAGE IN SOUTHWESTERN
OHIO.

TO THE EDITOR OF SCIENCE: In the issue of SCIENCE of October 4, Professor Arthur M. Miller offers an objection to the conclusions of Mr. Fowke, made from his studies on the drainage features of southwestern Ohio, in which Mr. Fowke has shown (*Bulletin of the Scientific Laboratories of Denison University and Special Paper No. 3 of the Ohio State Academy of Science*) that the preglacial drainage of the section of the Ohio river from Manchester, Ohio, to Madison, Ind., was to the northward along the line of the lower Big Miami and the Mill creek valleys to Hamilton. It has been my pleasure to have studied somewhat carefully the region under discussion in my field work, and the objections which seem so apparent to Professor Miller have not appeared so to me. While I would agree in the main with Professor Miller in his argument concerning the formation of reentrants made by up-stream cutting against an escarpment and the stratigraphic relations of stream gradient and dip, under which similar reentrants would be formed by streams flowing in the direction of the dip, I cannot see that there is much force in the application of these principles to the problem under discussion. There is no question but

that many of the reentrants found in the Clinton limestone outcrop of the region shown by Professor Miller's map were made in the manner he suggests. I have observed many of them in the field. But at the same time there are many possibilities of there being, in this same region, large valleys deeply buried under the mantle of drift running in the opposite direction from that of these reentrants which were formed by the backward-cutting streams. In all cases which I have observed of these reentrants made by backward-cutting streams, they might have as well formed part of a system of lateral tributaries to a main northward-flowing stream as to that of a southward-flowing one. Unfortunately the region which Professor Miller has chosen in his map and studies is not the same as that which furnished the data for the determination of the northward direction of the preglacial waters from the vicinity of Cincinnati and it would be hardly necessary to review these data at this time, as the full reports are easily accessible in the articles referred to and are not discussed by Professor Miller. It may be well to state, however, that the criteria used in the location of the preglacial lines of drainage are not confined to a study of comparative 'width-of-channel' of streams, but the conclusions are based upon a broader study of topographic forms, comparative erosion, distribution and direction of shingling of old gravels on the old graded valley floors, normal and abnormal stream relations and many other similar lines of evidence.

In Professor Miller's closing paragraph he speaks of the symmetry shown by the streams north and south of the Ohio river as adding force to the argument in favor of the present arrangement of the streams being also the preglacial arrangement, and he considers the Ohio as the main and parent stream. There seems to be an abundance of evidence, already published, to show that in preglacial times a strong watershed crossed the Ohio river near Manchester, Ohio, and that the section of the Ohio immediately above Manchester found its way up the reversed Scioto in preglacial times. With the Ohio river above Cincinnati reduced to a small stream (which Mr. Fowke calls Old Limestone) heading only at Manchester, it

is evident that the Miami, Licking and Kentucky rivers were all very much larger streams than Old Limestone, and if we should assume that the section of the Ohio below Cincinnati flowed, in preglacial times, in its present direction, the symmetry which Professor Miller sees in the present arrangement would appear most asymmetric.

I feel sure that a careful field study of the topographic features within a radius of twenty miles from the city of Cincinnati will convince any one of the truthfulness of Mr. Fowke's deductions.

W. G. TIGHT.

UNIVERSITY OF NEW MEXICO.

PERMANENT SKIN DECORATION.

THE July-December, 1900, issue of the *Journal of the Anthropological Institute* publishes an abstract (No. 117) of Mr. H. Ling Roth's article 'On Permanent Artificial Skin Marks, a Definition of Terms.' The author distinguishes four varieties, all collectively and rather loosely designated by travelers 'tattooing.'

I. The Tahitian punctured method—practiced also by sailors, soldiers, etc.—by which a design is pricked into the cuticle, leaving a smooth even surface of skin.

II. The Maori chiseled type, produced by an adz-like implement, in addition to the Tahitian pricker, and exhibiting when completed a fine pigmented groove.

III. The West African incised variety—usually, but not always, non-pigmented—wherein deeper and wider grooves are cut—not *tapped*—with a knife, bone or hardwood chisel.

IV. The raised scar ('*cicatrice saillante*') of Tasmanians, Australians, Central Africans, etc., resulting from the continued irritation of the original incision, the insertion of foreign matter and the over-production of reparative tissue lifting the design in welts.

Mr. Ling Roth considers it desirable that the Tahitian word 'tatu' be confined to the first-named process, the native designation 'moko' be recognized for the second; for the third and fourth respectively, the terms *cicatrix* and *keloid* are offered.

This classification, looking toward greater precision in the use of descriptive epithets, is

avowedly based chiefly on the character of the implements used and the method of their employment. The author has, however, overlooked two types as well marked as any of those included, the Dayak and the Eskimo. The former make use of a wooden block upon which the desired pattern is figured in relief. It is transferred to the skin by percussion, the block being pounded with an iron bar. Regarded from the side of its probable descent, this method must be deemed a subvariety of II. Classed by the tool producing it, it forms a distinct variety.

The other and more important omission, the inductive or line tattooing of the Eskimo seems most nearly related to type I, the latter form indeed occurring side by side with it. In the central regions, according to Dr. Boas, a needle and thread covered with soot is passed under the skin, the point of the instrument also being rubbed with a mixture of the juice of *Fucus* and soot or gunpowder. ('Central Eskimo,' p. 561.) The two processes recur more or less intimately associated over the greater part of the Eskimo habitat. The writer of this note would suggest for this inductive variety (type V.) the use of the Central Eskimo word 'kakina' (pronounced *kakeena*)='tattoo marks,' a term derived from the verb 'kakiva'='pierces it,' as in sewing, so as to make the point appear again on the same side. (See Rink, 'Eskimo Tribes,' p. 117.)

The main objection to the differentiation of these two types (II. b and V.) is the difficulty of distinguishing between II. a and II. b, and between I. and V., when neither the operation nor the implement has been observed.

MAGAZINE ENTOMOLOGY.

TO THE EDITOR OF SCIENCE: Columns open for attack have surely room for defense—wherefore permit me to say to the critical Mr. Smith, of New Brunswick, that I fear he does not quite understand the article he criticises. The paper in *McClure's* for September is part of a book not meant in the least to be scientific, entomologic, or any other 'ologic, but simply to set down things seen, and heard, and done, by two

fairly intelligent young people, living next to the ground upon a plantation in middle Tennessee.

Now as to hellgramites—the name may not properly apply to the white grubs, or rather, grayish-white ones, which were the choicest of all bait. But local fishermen called them so, and accepted it as a matter of fact that they were larvæ of the dragon-fly. Since I was setting down things actually true of a certain limited scope, not discoursing, *ex cathedra*, upon entomology, I felt justified in putting down the local name—with no thought of *lèse majesté* against the hellgramite and his adherents. I thought if my work was to have the value of verity I must make it square with what I knew, rather than the word, the latest word, of science. I fancy if explorers—say Stanley or Baldwin—came out of strange places, recording that the popular beliefs there were consonant with the newest discoveries, their work would have less worth and gain less currency. However, that has nothing to do with this particular case. Explorers are fallible persons—almost as fallible as myself. The only infallibles are those aggrieved persons who are always trying their cases in the newspapers.

Wherefore it is with something of amazement that I read Mr. Smith's positive assertion: "Pithy stems are rarely used by locusts, if at all, and dying twigs are never attacked." Will he kindly tell me, if pithy stems are never used, what sort are? No twig or stalk within my knowledge is, in its early stages of growth, without pith. In woody plants, after the wood ripens the pith becomes a fine line, and as the twig develops into a bough, wellnigh invisible. But assuredly if there is a deciduous tree whose new growth is not, while new, pithy, I have never seen nor heard of it. And at the risk of seeming more than ever contumacious, I repeat that some locusts—Tennessee locusts—did choosedying twigs to lay their eggs in—I watched them do it through many a summer hour, in the big oak whose bough almost touched my upstairs window. The twigs were of new wood—the last spring's growth—but yellowing, and beginning to wither. I do not recall ever seeing a sound twig stung by the ovipositor. The locust, or rather the female locust, has two fine

saws, lying either side the ovipositor. With these saws she scratches the bark before depositing the egg. As to Betty-bugs three inches long—they are facts, not fiction. A Mississippi reader has just written, promising to send me one of them next season. He adds the interesting information that when one of the big Bettys falls upside down, one can see upon its under side a number of parasites. Regarding the June bug's identity, that was a matter of countryside belief, backed with pretty good olfactory proof of the transformation. And certainly plenty of true June bugs, green above, all yellow underneath, mingled amicably enough in the flights and hummings of the tumble bugs, black and green.

Let me say further—of the magazine articles, and the whole book—that my aim was not to instruct, but to record a phase of life known to me at first hand. Mr. Smith and the gentlemen of his kidney who assume that whatever is outside their own experience is necessarily false, have, without intending it, done me a real service, by showing me that before the book appears I must so elaborate its *motif*, and make it so glaring, and obvious, that even a way-faring man, almost an infallible one, if he reads at all, will be forced to read aright.

MARTHA McCULLOCH-WILLIAMS.

Very little comment on the above is really necessary. If Mrs. Williams is giving records of superstitions and country beliefs she owes it to her readers, as well as herself, to make it perfectly clear that this is the case, and that they are not intended to be received as instruction or as statements of fact. I am unable to see the bearing of some of Mrs. Williams's references to Stanley, etc., but that I presume is due to my own obtuseness. So I did not dream that an oak twig could ever be called 'pithy.' If the explanation were not made by a lady I should call it quibbling. It is a real pleasure to me to realize that I have done Mrs. Williams a favor, and I hope it will inure to the benefit of the readers of her forthcoming book. It is of course adding another to my sins; but I cannot refrain from saying that no insect to which the name 'locust' was ever justly applied in any publication known to me, has 'two

ne saws, lying either side of the ovipositor.' Nor, if a cicada is referred to, does the description of the method of oviposition accord with the fact. Finally, it might be desirable for Mrs. Williams to get the real facts concerning honey bees, that the rate of her 'fair intelligence' in middle Tennessee be not fixed unjustly low.

CURRENT NOTES ON PHYSIOGRAPHY.

THE HIGH PLAINS OF COLORADO, KANSAS AND TEXAS.

THE attractions of the diversified Cordilleran region have caused the relative neglect by the geologist and the geographer of the more monotonous area of the Great plains during the last thirty years of exploration. Following the recent increase of attention to this extensive area, we now have an admirably lucid report on 'The High Plains and their Utilization,' by W. D. Johnson (21st Ann. Rep. U. S. Geol. Surv., pt. IV., 1901, 601-768, many excellent plates and figures), giving description and explanation to a stretch of the highest and smoothest part of the Plains, from 150 to 200 miles east of the mountains, in Colorado, Kansas, Texas and New Mexico. The largest continuous area here included is that of the Staked plains, between the Canadian and Pecos rivers, but more attention is given to certain smaller areas, separated by successive west-east valleys and extending through Kansas and Colorado northward towards Platte River. The strata of the High plains are chiefly silts, irregularly interstratified with gravel and sand in linear arrangement, but in lines slightly divergent and crossing. Silt is the most abundant material, yet coarser deposits are so plentiful that the whole loose accumulation is sometimes referred to as the 'Tertiary gravel.' This extensive deposit, in some places 500 feet thick, is the product of aggradation by braided or laced streams, whose load of material from the mountains could not all be carried across the gentle slope of the Plains. Evidence of this origin is found not only in variable composition and irregular stratification, but also in the trains of well-rounded gravel, derived from the resistant rocks of the mountains, stretching forward with the slope of the Plains, and be-

coming finer textured eastward. The lacustrine origin of these strata, usually advocated heretofore, but discountenanced by Gilbert and Haworth, is considered by Johnson and again rejected on good grounds. The fluvialite deposits mantle an uneven surface of older rock, eroded by an ancestral drainage system. They originally formed a vast 'débris-apron' of numerous laterally confluent river fans of long radius, with continuous slope eastward from the mountain base. The region was then a fluvialite plain of great dimensions, similar to that which to-day stretches southward from the base of the Himalayas, in northern India, and similar to the extensive piedmont fluvialite plains of mountain waste that are so commonly and appropriately associated with great mountain ranges in one or another phase of their maturity. But the High plains are now trenched by the west-east valleys worn by the successors of the streams that built the plains; this being the result of some change (preferably the increase of rainfall that accompanied the glacial period) whereby the capacity of the streams to erode was restored. Moreover, the fluvialite mantle has been worn away along two north and south belts. One is the arid belt near the mountain base, where vegetation is so scanty that the small rainfall has sufficed to wear away much of the river-made strata in the excavation of lateral valleys. The other belt begins 100 or 200 miles further east, where the rainfall is heavier and where the headward (westward) growth of many streams is pushing back a badland escarpment. Between these two degraded belts the tattered remnants of High-plains mantle are still smooth and uncut, because under their subhumid climate they have a close-knit cover of sod which has held fast under their light rainfall.

The dead-flat upland of the High plains is lightly pitted here and there by shallow circular depressions, up to 1,000 yards across. These hollows are not due to wind action, for however dusty the gales may be on the arid belt further west, the winds blow clear on the sodded plains. Some of the hollows are crater-like; many are encircled by cracks and rims of slightly settled grounds, and all except the small 'buffalo wallows' are regarded as sinks

due to some action of underground water. Being out of the reach of irrigation from the rivers, and not having enough rainfall for agriculture, the utilization of the High plains must be chiefly as cattle ranges for which water may be gained by wells and windmills.

SOUTH SHORE OF HUDSON STRAIT.

THE forbidding character of a rocky upland that has been recently and severely glaciated and that still possesses a severe climate is well portrayed in Low's 'Report on an Exploration of Part of the South Shore of Hudson Strait * * *' (Geol. Surv. Canada, Ann. Rep., XI., 1901, L.): "The rocks met with are all of great antiquity, and all are more or less altered by pressure, induced by intrusions of igneous masses which have folded the bedded series and have produced foliation in much of the otherwise massive granites, gabbros," etc. (p. 31 L.). The crystalline rocks usually form a highland which reaches altitudes between 1,000 and 2,000 feet near the sea, and is often plateau-like in the extent of its rolling uplands between deep and sharp-cut valleys or canyons. Here rock and boulders are abundant and soil is very scanty; here are abundant lichens and some flowering plants, but no trees. Elsewhere the rocks are stratified and gently inclined, forming low ridges with steep outcrop faces and gentle back slopes. Below 300 feet the surface is generally mantled with marine clays, marked with terraces. But as the land rose from its postglacial submergence, the headlands "have been smoothed and polished by the pounding of floating ice, which has removed nearly all the drift from the points, leaving the solid fresh rock always exposed."

THE ORIGIN OF WATERFALLS.

THE 'Festschrift des Geographischen Seminars der Universität Breslau zur Begrüssung des XIII. Deutschen Geographentages' contains, among various essays, most of which turn toward historical geography, an article on the Origin of Waterfalls, by F. Sturm (pp. 122-132, Breslau, 1901). Besides the numerous rapids and falls which originate at points where a young stream passes from a more to a less resistant rock, or where a new course has been taken in consequence of drift barriers, a num-

ber of special cases are instanced, such as rapids in a main stream where side streams form boulder dams, illustrated by the Colorado in its canyon; rapids occurring where travertine is deposited in a stream channel, as illustrated at several points in Bosnia, and falls over fault escarpments, such as those of the Oxara in Iceland. The order in which different kinds of falls are presented is empirical rather than genetic.

Falls at the mouths of hanging valleys are explained as resulting from the faster erosion of the main than of the side stream; strong glacial erosion of the main valleys in excess of that in the side valley is discredited. It is not noted in this connection that hanging side valleys with falls leaping from their mouths into broad-floored main valleys are known only in glaciated districts; and that in non-glaciated areas, side streams 'hang' above their masters only in the earliest stage of a new cycle; accordant junction of side and main stream being developed about as soon as the main stream has graded its channel, and long before it has broadly opened its valley floor.

W. M. DAVIS.

CURRENT NOTES ON METEOROLOGY.

METEOROLOGICAL EQUIPMENT OF THE 'DISCOVERY.'

THE meteorological equipment of the British Antarctic exploring vessel *Discovery* is described by Dr. H. R. Mill in *Symons's Meteorological Magazine* for September. The Stevenson screen contains a wet and dry bulb thermometer, a mercurial maximum, and a Six's maximum and minimum thermometer. A barometer, on the Kew pattern, is in the magnetic house, and a barograph is kept in one of the companions. A thermograph and a hair hygograph are placed on the outer wall of the magnetic house. The three recording instruments are kept running to Greenwich time. The temperature readings are checked by means of an Assmann Aspiration Psychrometer, and sling thermometers are also provided for comparison. Rainfall observations are to be made with a marine rain-gauge and evaporator of Dr. Black's pattern. For carrying out observations in the free air, a captive balloon is carried, and kites

are to be used for greater elevations. Meteorographs after the Blue Hill pattern are to be sent up with the kites. Spirit thermometers, for dry and minimum readings, graduated to -90° F.; special screens; low-reading thermographs; sunshine recorders adapted to the peculiar conditions which are to be met with in the high latitudes; earth thermometers, etc.—are also provided. A Dines pressure anemometer and an anemograph of similar pattern are to be used at land station on the Antarctic continent.

CHARLES MELDRUM.

THE death, on August 28 last, of Dr. Charles Meldrum, for many years director of the Royal Alfred Observatory, Mauritius, should not be passed by without at least a brief mention in these Notes. Dr. Meldrum did a work of the greatest importance for meteorology in connection with the cyclones of the Indian Ocean, to the study of which he devoted a large part of his life. His name will also always be associated with the question of the relation of sun-spots and rainfall, a subject in which he was much interested. Dr. Meldrum was one of the founders of the Meteorological Society of Mauritius, Government Meteorological Observer, Director of the Royal Alfred Observatory, and, during the last ten years of his life, a member of the Government Council of Mauritius.

BIBLIOGRAPHY.

THE annual bibliographical number of the *Annales de Géographie* (No. 10, for the year 1900) contains the usual notices of climatological publications bearing the date 1900. The reviews are arranged by subjects as well as by countries, and there is an author and a subject index. This bibliography is chiefly geographical, but climatology is given its proper share of attention.

R. DEC. WARD.

HARVARD UNIVERSITY.

SCIENTIFIC NOTES AND NEWS.

THE Elisha Kent Kane Medal of the Geographical Society of Philadelphia has been presented to Dr. A. Donaldson Smith, the African explorer.

PROFESSOR E. RAY LANKESTER has been elected a corresponding member of the Göttingen Society of Sciences.

DR. RICHARD P. STRONG has been appointed director of the Government Biological Laboratory recently established in Manila.

SIR WILLIAM WHITE, since 1885 director of naval construction in the British Navy and the author of important publications on naval architecture, is about to resign.

IT is said that Dr. Wolf Becher, of Berlin, is preparing a biography of Professor Rudolf Virchow.

A LECTURESHIP in moral science will be established at Cambridge University as a memorial to the late Professor Sidgwick. The sum of £2,450 has been subscribed for this purpose.

A DIFFICULTY has arisen, says *Nature*, concerning the site on which the new Pasteur statue in Paris shall be erected. The use of a space in the Square Médicis in the Quartier Latin has been granted, but this spot is being tunneled for a railway, and it is feared, in consequence, that the statue may be too weighty for it. Other places, such as the Place du Panthéon, the Place de la Sorbonne and the entrance of the Avenue de l'Observatoire, are under consideration.

CHARLES A. BACON, professor of astronomy at Beloit College and director of the Smith Observatory, died on November 6, aged forty-one years.

PROFESSOR M. MAERCKER, director of the agricultural experiment station at Halle, Germany, and professor of agricultural chemistry in the Agricultural Institute, died on October 19, 1901.

THE preliminary plans have been accepted for a new building for the Department of Agriculture at Washington. These plans contemplate a magnificent marble structure of classic design, something over 300 feet long, with wings at either end extending to the rear to accommodate the various laboratories of the department. It is expected that the details of interior arrangement will need to be changed to some extent to suit the needs of the various bureaus and divisions of the department, but these plans will serve as a working basis. About 158,400 square feet of space are provided. Lord & Hewlett, of New York, are the architects.

THE American Morphological Society will meet in Chicago in affiliation with the American

Society of Naturalists, beginning on Wednesday, January 1.

THE American Psychological Association has fixed the first day of its Chicago meeting for December 31. The Western Philosophical Association will this year meet in conjunction with the American Psychological Association. Professor Josiah Royce, of Harvard University, is president of the Psychological Association, and Professor Frank Thilly, of the University of Missouri, is president of the Philosophical Association.

THE Society for Plant Morphology and Physiology will hold its fifth annual meeting at Columbia University, New York City, on December 31 and January 1 and 2.

THE Association of American Agricultural Colleges and Experiment Stations meets in Washington on November 12, 13 and 14. It will be followed by the meeting of the Association of Official Agricultural Chemists on November 15, 16, and 18.

THE sixth celebration of Founder's Day at the Carnegie Institute, Pittsburgh, took place on November 7. The principal speaker was Ex-President Grover Cleveland. The occasion was made memorable by the opening of the Sixth International Exhibition of Contemporary Paintings and by the display of a larger number of new exhibits in the Carnegie Museum. Among the latter are the skeleton of *Titanotherium*, and portions of the skeleton of *Diplodocus Carnegii*, recently restored under the care of Professor J. B. Hatcher, a fine specimen of *Rhinoceros simus* Burchell, a collection of petroglyphs from western Pennsylvania, and large additions to the collections of mammals and birds, as well a long array of exhibits in other departments of the Museum.

MR. C. W. GILMORE, who has been employed during the past summer in continuing the excavation at Camp Carnegie, on Sheep Creek, Wyoming, begun two years ago by the Carnegie Museum, completed his work last week. A carload of fossils, consisting principally of the remains of a very large and perfect specimen of *Brontosaurus* has been shipped to Pittsburgh and will shortly be delivered at the Museum.

THE collection of land, marine and fresh-

water shells, belonging to the estate of the late W. D. Hartman, M.D., of West Chester, Pa., has been purchased by the Carnegie Museum in Pittsburgh. Over nine thousand species are represented in the collection, which contains many types and cotypes. It is particularly rich in North American species and in the species found on the islands of the Southern Pacific. The addition of the Hartman collection to the other conchological collections which have in recent years been secured by the Carnegie Museum gives this institution one of the largest assemblages of conchylia in the United States.

IN September the Wisconsin Natural History Society sent two expeditions to the neighborhood of the Fox River in Waukesha County for the purpose of making surface surveys of a number of still unrecorded mound groups which are liable to be destroyed when the land is put under cultivation as is to be done next year. The first expedition surveyed and plotted four groups and several isolated works in the vicinity of Big Bend. One of them is indicated on Dr. Laphan's map, but no description is given by him. The second expedition was sent to the neighborhood of Mukwanago, about four miles from the first party. It surveyed a number of burial and oblong mounds. Nearly all the burial mounds were found to have been disturbed by farmers and others living in the region.

THE Russian Imperial Geographical Society has received news from the Kozloff expedition, sent out to explore the headwaters of the Hoang River. It is said that valuable collections have been obtained.

A COPENHAGEN despatch says that Dr. Nansen, the Arctic explorer, is arranging for biological research in northern waters; Norway, Sweden, Denmark, England, Holland, Russia and Germany to take part in it. The Danish Government has resolved to invite the interested states to hold a conference at Copenhagen to discuss the subject.

THE Twentieth Century Club of Boston has arranged for six lectures on 'The Needs of Popular Education in the United States.' The opening lecture was delivered by President Eliot, of

Harvard University, on November 9, with a general introduction and survey. The succeeding lectures will be as follows: 'The Public School System,' Dr. William DeWitt Hyde, president of Bowdoin College, November 16; 'Supplementary Educational Agencies,' Dr. George Harris, president of Amherst College, November 23; 'The Place of Industrial and Technical Training in Popular Education,' Dr. Henry S. Pritchett, president of the Massachusetts Institute of Technology, December 7; 'The Place and Function of Science in Popular Education,' Dr. Ira Remsen, president of Johns Hopkins University, December 14; 'Comparison of American and Foreign Systems of Popular Education,' Dr. G. Stanley Hall, president of Clark University, December 21.

THE National Geographic Society has issued its program of lecture courses for the coming season. The popular course consisting of thirteen lectures will be delivered in the National Rifles Armory, on Friday evenings at 8 o'clock, commencing November 8, and alternating with the Technical Meetings which will be held in the Assembly Hall of Cosmos Club. The following dates have been definitely assigned:

November 8, 'The Twelfth Census,' HONORABLE FREDERICK H. WINES, Assistant Director of the Census.

November 22, 'The Interior of Borneo,' PROFESSOR A. C. HADDON, Cambridge University.

December 6, 'Peary's Progress toward the Pole,' HERBERT L. BRIDGMAN, Vice-President Arctic Club of America.

December 20, 'The Trans-Siberian Railway,' HONORABLE E. J. HILL.

January 3, 'The New Mexico,' HONORABLE JOHN W. FOSTER, Ex-Secretary of State.

January 17, 'American Progress and Prospects in the Philippines,' GENERAL A. W. GREELY, Chief Signal Officer, U. S. A.

Arrangements have also been made for the following popular lectures, at dates to be announced later.

'The Appalachian Forest Reserve,' HONORABLE JAMES WILSON, Secretary of Agriculture.

'The Warship and its Work,' REAR-ADMIRAL W. S. SCHLEY.

'Fifty Years of Immigration,' HONORABLE E. F. MCSWEENEY, Asst. Com. Immigration.

'Cliff Dwellings of Mesa Verde,' MRS. JOHN HAYS HAMMOND.

'Explorations in New York City,' MR. JACOB A. RIIS.

'Finland,' MR. GEORGE KENNAN.

Provisional arrangements have been made for lectures on Pacific Cables, Actual and Proposed; Our Coming Oceanic Canal; America before the Advent of Man; Chinese Problems; Lands and Life in Ocean Depths; Columbia; Danish West Indies, and Afghanistan—the Buffer State. Regular meetings of the Society for the reading of technical papers and discussions will be held in the Assembly Hall of Cosmos Club on Friday evenings, at 8 o'clock, and alternating with the popular lectures. The following are announced:

November 1, 'Symposium on the Growth and Prospects of the Society,' President A. GRAHAM BELL followed by Professor Heilprin and others.

November 15, 'The Lost Boundary of Texas,' MARCUS BAKER, Cartographer, U. S. Geological Survey.

November 29, 'The Best Isthmian Canal Route,' ARTHUR P. DAVIS, Chief Hydrographer, Isthmian Canal Commission.

THE Christmas course of six lectures to young people, at the Royal Institution, will this winter be delivered by Professor J. A. Fleming, F.R.S., professor of electrical engineering in University College, London. His subject is 'Waves and Ripples in Water, Air and Ether.' Sir H. Trueman Wood will deliver the next Christmas Juvenile Lectures at the Society of Arts, the subject being 'Photography and its Applications.'

A STATEMENT concerning the vital statistics of the city of Havana for the month of September, 1901, compiled from official reports on file in the division of insular affairs of the War Department and abstracted in the daily papers, shows that the health conditions were decidedly the best attained in any month. The least number of deaths occurring in any previous September since 1889 was 496 in 1899; the greatest number, 2,397, in 1898; average, 877. For September, 1901, there were 339 deaths. The least number of deaths occurring in any one preceding month during the last eleven years was in February, 1901, when there were 408 deaths. The lowest death rate for Sep-

tember in the years referred to was in 1899, when the death rate was 34.48 per thousand. For September, 1901, the death rate was 15.64 per thousand. Taking the yellow fever year as commencing April 1, the record of the past eleven years shows that for the six months up to the first of October the smallest number of deaths from this disease occurred in 1899, when there were 36 deaths; the greatest number in 1897, when there were 659 deaths—average, 296 deaths. This year, during the same period, there were only five deaths.

SIR CLEMENTS A. MARKHAM, president of the Royal Geographical Society, has given out for publication a communication stating that despatches received from the Cape give details of the voyage of the *Discovery* and announce the departure of the Antarctic expedition from Simon's Bay on October 14 on the voyage to Lyttelton, the last port of call before entering the ice. Experience of the performances of the ship has been acquired during a voyage of 58 days—33 under steam and 25 under sail. She might make a reasonably good passage under sail with a fair wind, but she makes excessive leeway when close hauled; her canvas area is too small, and she must be accounted a poor sailer. She is, however, an excellent sea boat, which is the main point, and in a fresh breeze with a heavy sea she is very stiff and dry. She has, on the whole, done as well as can be expected for a vessel of her type. Her coal consumption is, however, disappointing. The economy of the engines is less than expected, and the necessity for nursing coal in future operations is proportionately increased. Officers and men have had a very trying time in the tropics. The ship leaked, from causes which can no doubt be obviated. But as the provision cases were stowed in the holds down to the keelson and the water rose amongst them it was necessary to clear the holds, to construct floors with an amply sufficient bilge space beneath and to restore the holds again—all this under a tropical sun. The engineering department had still more severe work, owing to the long spell of steaming with the thermometer at 140° F. in the engine-room, and the engines, being new, required more than ordinary care and adjustment.

UNIVERSITY AND EDUCATIONAL NEWS.

THE council of New York University has decided to celebrate the seventy-fifth anniversary of the founding of the University in October, 1905. An effort will be made to collect \$2,000,000 for an endowment fund.

DR. OSLER, of the John Hopkins University, has given to the medical library of McGill University a number of rare books on medicine. The medical library has been much improved in the alterations of the building.

THE Library of the Chemical Department of the University of Vermont has just been augmented by the addition of some 400 volumes, chiefly German chemical journals. These are mainly the gift of F. W. Ayer, of New York, who subscribed \$1,000 to the special fund.

IT is announced that Andrew Carnegie will give \$500,000 to build and equip a technical college in southern Scotland. The institution will probably be located at Galashiels, counties of Roxburgh and Selkirk.

THE widow of the late professor of the history of medicine at Vienna, Dr. Puschmann, has bequeathed her entire property, about a quarter of a million dollars, to the University of Leipsic.

THE Liverpool City Council has unanimously resolved to make application to Parliament for powers to enable the council to contribute money from the rates toward the formation and maintenance of a university in the city.

BEGINNING with the academic year 1905-06 all students desiring to enter the first year of the medical course of the University of California, and all new students seeking advanced standing must present evidence of having completed at least two full years of preliminary training in the undergraduate department of a college or university of recognized standing. Satisfactory evidence must also be presented that during these two years the applicant has completed courses in chemistry (12 hours for a year), physics (13 hours), biology (6 hours), and has a reading knowledge of French and German.

THE new chemical laboratory of the University of Oregon, for which appropriations

were made during the last two sessions of the Legislature, has been completed and equipped, and is now occupied by the department of chemistry. The building is a three-story brick structure, finished with Roman cement, and is 100 feet long by 46 feet deep. It contains sixteen rooms, of which thirteen are now in use. Four large laboratories are for student use, and will accommodate over 200 students working in sections. The lecture room has a seating capacity of one hundred and fifteen persons; it is completely equipped with separate preparation room, rear hood, 28 foot table provided with down draught, projecting spectroscope and polariscope, etc. The building also contains four private laboratories, two store rooms, a dark room, a balance room and a private office for the director. The three rooms not yet fitted up are all of large size. The laboratories are ventilated by a large Sturtevant centrifugal exhauster, driven by an electric motor; all the rooms are wired for light and for power, and are heated by steam. Gas is furnished by a 100-light Detroit combination machine. The total cost of building, furniture, apparatus and chemicals was \$22,500.

THE trustees of Williams College met in New York City on November 8, with a view to selecting a president for the College, but were unable to come to a decision. Of the fifteen trustees in attendance it is said that five voted for Dr. E. H. Griffin, professor of the history of philosophy at the Johns Hopkins University and dean of the college faculty, and three for Dr. Henry Lefavour, professor of physics at Williams College and dean of the faculty.

IN the Medical Department of the University of Pennsylvania Dr. Charles Mills has been appointed clinical professor of nervous diseases, in the place of Dr. Horatio Wood, resigned; Dr. W. G. Spiller, assistant professor of nervous diseases, and Dr. Charles Burr, professor of mental diseases.

ASSISTANT PROFESSOR S. LAWRENCE BIGELOW has been made acting director in charge of general chemistry at the University of Michigan during Professor Freer's absence in the Philippines. Mr. A. M. Clover has been appointed acting instructor in chemistry. R. T.

Sanford and N. F. Harriman have been appointed assistants in the chemical laboratory.

A. B. MACALLUM, Ph.D., has been promoted to a full professorship of physiology in the University of Toronto.

THE following appointments have been recently made at the University of Oregon: E. D. Ressler, A.M. (Ohio State University), assistant professor of education; Henry D. Sheldon, Ph.D. (Clark), assistant professor of philosophy and education; Richard H. Dearborn, B.S. (Cornell), instructor in electrical engineering; Charles W. M. Black, Ph.D. (Harvard), instructor in mathematics; Orin F. Stafford, A.B. (Kansas), instructor in chemistry; Percy P. Adams, A.B. (University of Oregon), assistant instructor in civil engineering; Archibald A. Atkinson, A.B. (Pacific University), assistant instructor in biology; P. Irving Wold, B.S. (University of Oregon), assistant instructor in physics; R. R. Renshaw, scholar and assistant in chemistry.

PROFESSOR J. B. GARNER, of the Bradley Institute at Peoria, has been appointed professor of chemistry in Wabash College.

MR. LYMAN F. MOREHOUSE, an assistant in the physical department of the University of Michigan, has accepted a position as an instructor at Washington University, St. Louis. Mr. Lindley Pyle will fill the vacancy at the University of Michigan.

PHILIP B. HAWK, M.S., has been elected to succeed W. D. Cutler, A.B., as assistant in the department of physiological chemistry of Columbia University, at the College of Physicians and Surgeons.

CLARK WISSLER, A.B. (Indiana), Ph.D. (Columbia), has been appointed instructor in psychology in the School of Pedagogy of New York University, and Dr. J. E. Lough has been promoted from an instructorship to an acting professorship.

PROFESSOR HUGH L. CALLENDAR, F.R.S., has been appointed to the professorship of physics in the Royal College of Science, vacant by the resignation of Professor Rücker, who has become principal of the University of London.

WE have now traced the metals of many ores to their first positions in the veins. In order to understand other cases, we must recall the facts as to the relations of 'richness with depth.' At this point I take my illustrations from regions outside of Colorado. James Douglass says that in the Appalachian region every copper mine has diminished in richness with depth. Near the surface rich oxidized products were found. Near the level of ground-water rich belts of sulphides occurred—in some instances extraordinarily rich. Below the level of rich sulphides every old mine has passed into cupriferous pyrrhotite, a sulphide of iron bearing a very small percentage of copper. In the Sierra Nevadas, of California, Mr. Lindgren states that near the surface the values range from \$80 to \$300 per ton; but a little way below the level of ground-water these values fall to \$20 or \$30 per ton, and no exceedingly rich deposits are found. You all know the history of the Comstock lode; and of the great bonanzas found above or about the 2,000-foot level, and which did not extend deeper. In the Lake Superior region the greatest iron-ore mines in the world occur; fourths or more of the entire product of iron of the United States comes from that region; but at the present time vastly more

iron has been taken out above the 1,000-foot level than below it. If time sufficed, similar instances from all the old mining regions of the world could be cited.

I by no means assert that the above illustrations represent an invariable rule. Indeed, this is not the case. But the illustrations undoubtedly do represent the average relation of richness and depth.

Now this story is an entirely different one from the illusion of increased richness with depth based upon the supposition that the metals for the ores are derived from the unknown depths of the earth. If that theory be true, it is natural to believe that ore deposits upon the average will become richer with depth. But if it be a pure unverified hypothesis, not supported by any facts, it is of vital importance for practical mining men to know this, since the knowledge will save them vast sums of money expended in exploration under a false theory. So far as I am aware of the facts, I do not know of a mining region in the world which supports the theory of increased richness with depth, if the unit of measure be taken as one thousand feet, if the first thousand feet be compared with the second thousand, and the second thousand with the third, and so on. In fact, nine mines out of ten, taking the world as a whole, are poorer the second thousand feet than they are the first thousand feet, and are poorer the third thousand feet than they are the second thousand feet. Many ore deposits have been exhausted or have become so lean as not to warrant working before the 1,000-foot level is reached; a large proportion before the 2,000-foot level is reached; while comparatively few ore deposits have been found to be so rich as to warrant working at depths greater than 3,000 feet.

There are, however, some ore deposits which are not known to gradually decrease in richness with depth so far as yet ex-

ploited. There are a considerable number of deposits which perhaps after a first rapid decrease in richness maintain their tenor pretty well to the depth of 1,000, 2,000 or even 3,000 feet, and some few deposits maintain their richness at even greater depths. But we cannot reasonably hope that a deposit will get richer with depth, provided we use a 1,000-foot unit for measurement. The most sanguine view which is ever justified for any deposit is that, using a 1,000-foot unit, the second shall be as good as the first, and the third as good as the second. While the above is true, there are very great irregularities in the richness of ore deposits, both favorable and unfavorable, due to multifarious causes, which I cannot possibly discuss to-night, but which I considered somewhat fully in my Institute paper.* These irregularities are especially marked in the upper 1,000 feet of a deposit; so that in many cases, if the unit of measurement were 25 feet or 100 feet, or in a few cases 500 feet even, it might be said that deposits are becoming richer with depth; although the reverse also occurs in many cases. The truth is that in the upper parts of ore deposits the variations in richness with depth are extreme, and no definite rules can be laid down in reference to them.

This rule of the diminution of richness with depth is one of averages only when considerable depths are taken into account. The factors entering into the production of an individual ore deposit are so numerous, and the irregularities are so great, that the rule cannot be asserted in advance of development of an individual mine without a study of the conditions there obtaining.

Now what is the explanation of these irregularities and of the very general diminution of richness with depth? What is the

* 'Some Principles controlling the Deposition of Ores,' by C. R. Van Hise: *Trans. Am. Inst. Min. Eng.*, Vol. XXX., 1900, pp. 102-112.

explanation in some cases of the relatively even values at different depths? The last question will be first considered.

In those instances in which the tenor is maintained or practically maintained from the surface to a great depth, the ore is believed to be the result of a single concentration by ascending waters. Such ore deposits may continue without any appreciable diminution in richness to the lowest limits to which man may expect to penetrate the earth; but these are exceptional cases. Even ore deposits which are the result of a single concentration by ascending water may diminish in richness at considerable depth. It has been seen that in the fissure at the bottom of the valley on this chart (Fig. 6) the water ascends to the surface. It is evident that the upper part of the fissure receives the greatest supply of water, and this water to a large extent does not penetrate any great depth; while the lower part of the fissure receives less water, but this water penetrates to a considerable depth. It may happen that the water relatively near the surface traverses the rocks containing the main supply of metals and, therefore, brings the chief contributions of valuable material, or such waters may carry the precipitating agent. In such instances the ore deposits produced by ascending water alone would diminish in richness with depth; but such decrease would not be likely to be very rapid. Upon the other hand, if the above conditions be reversed, a deposit may increase in richness for a considerable depth; but as a matter of fact this appears to be a very infrequent case.

As illustrations of the ore deposits of the class produced by ascending waters alone are the copper deposits of Lake Superior. These deposits, while very bunchy and extremely irregular in the distribution of copper, are wonderfully persistent in depth. The copper of the ore was deposited in the

metallic form. As compared with sulphides, this material is not readily oxidized. In this district the rocks above the level of ground-water are not appreciably weathered. Doubtless there was a belt of weathered material before the glacial epochs, but if so, it has been swept away by ice erosion; and since the glacial period sufficient time has not elapsed to weather appreciably the rocks which now lie within the theoretical belt of weathering. If there once were in this district an upper belt of weathering in which there were deposits of exceptional richness, this material has been removed. However, in this district, a first concentration by ascending waters was adequate, but it is not often that a first concentration produces deposits of such richness as those adjacent to Calumet and Houghton on Keweenaw Point; and, indeed, this is exceptional even in the Keweenaw of the Lake Superior region; for while concentrations of copper have occurred at many points in the rocks of this period, as yet at no other locality have those concentrations been found to be so abundant and rich as to warrant exploitation on a large scale.

I now turn to the question as to the cause of frequent diminution of richness of ore deposits with depth. The explanation of the very frequent diminution of value with depth seems to me to lie in the secondary effect of descending currents upon deposits first deposited by ascending waters. Many or most of such ore deposits are believed to be the products of two concentrations, the first by ascending, the second by descending waters. In this connection it is necessary to call attention to the fact that a large proportion of the deposits which are being exploited are below part of a slope. It may be said that the reason for this is that the low grounds are more difficult to explore and work; but giving due allowance for this,

it still seems to me that the majority, perhaps the great majority, of very rich deposits are below slopes and crests, and not below the valleys. I believe the richer deposits are below the slopes, because at these places a second concentration is possible and probable.

Returning now to this chart (Fig. 6), we shall direct our attention to the fissure on the slope. This fissure once extended up through the overlying rocks which have been removed by denudation. What has become of the ore in the part of the fissure which has been worn away? If, for instance, it carried five per cent. of copper, what has become of it? A part of it would have been scattered far and wide through erosive action; but a part of it would have been taken into solution and redeposited in the same vein deeper down. In the belt of weathering oxidized salts, such as sulphates, would form; the descending waters would carry these products downward; and it is my belief that they would react upon the solid, lean sulphides below with the result of precipitating the metals from the descending solutions. Now this has been held to be a mere unverified assumption by some geologists, but it seems to me that they have not fully considered the certain effects of the chemical laws concerned. We know if in a laboratory a solution of copper sulphate or other copper salt be placed in contact with iron sulphide, that copper will be thrown down as copper sulphide. If the copper solution be placed in contact with a lean copper-iron sulphide, a sulphide richer in copper will be produced. And if these reactions occur in the chemical laboratory, will they not as certainly occur in the laboratory of nature, although perhaps more slowly?

At this point it is to be recalled that in many ore deposits above the level of ground-water oxides and carbonates occur, while below the level of ground-water are sul-

phides. Moreover, at high levels these sulphides are rich in valuable metals, and usually become poorer in these metals and richer in iron sulphide at the lower levels. You will remember at Butte, Mont., at and for a distance below the level of the ground-water, are rich copper sulphurets which grade at depth into leaner copper sulphides containing correspondingly large amounts of iron sulphide. You will remember the same is true of the entire Appalachian region. You will remember that frequently above the level of the ground-water gold lodes are exceedingly rich. What is the explanation of these similar facts? What is the explanation of the exceptional or even extraordinary richness of the deposits at and near the level of ground-water, and of the low grade of galena, blende or pyrites deep below the level of ground-water? In my opinion the only plausible explanation is that the rich parts of the deposits have received two concentrations, the first by ascending waters and the second by descending waters. The metals of the rich portions of the deposits were largely contributed by the parts of the deposit above, or once above, the rich parts. In some cases portions of the depleted veins remain, as at Butte; but frequently the depleted parts of the veins have been removed by erosion. The remote source of the material was, therefore, the metals deposited by the first concentration. But let us follow the matter still further. In the majority of cases, as denudation continued, the parts of the ore deposits produced by the second concentration rise into the belt of weathering. They may there be partly or wholly transformed into rich oxidized products, or they may be depleted to extend the rich deposits below. In the concentration by descending waters the chief chemical reactions are believed to be between the oxides or salts of the valuable metals and the sulphide of iron; although, of course, similar reactions

occur between the salts of silver and gold and other metals, and the sulphides of lead and zinc.

Time does not permit the consideration of the various reactions which result in the re-concentration by descending waters. These I shall be obliged to take for granted this evening, but those who care to follow the subject further may find a treatment of this part of it in my full paper upon the deposition of ores, published in Volume XXX. of the *Transactions of the American Institute of Mining Engineers*.

During the process of re-concentration erosion steadily goes on, perhaps to a depth of 1,000 or 5,000 or even 10,000 feet, or more. As denudation steadily lowers the surface of the country, the material deposited by the first concentration is picked up and gradually carried down along the vein by the descending waters. This material reacts upon the other materials, and is largely reprecipitated.

In the foregoing statements the second concentration of metals by solution, downward transportation and precipitation by reactions upon the sulphides of an earlier concentration has been emphasized. However, it is not supposed that this is the only process which may result in enrichment of the upper parts of ore deposits by descending waters. The enrichment of this belt may be partly caused (1) by reactions between the downward-moving waters carrying metallic compounds and the rocks with which they come in contact, and (2) by reactions due to the meeting and mingling of the waters from above and the waters from below.

1. The metallic compounds dissolved in the upper parts of the veins, carried by descending water, may be precipitated by material contained in the rocks below. This material may be organic matter, ferrous substances, etc. So far as precipitating materials are reducing agents, they

are likely to change the sulphates to sulphides, and precipitate the metals in that form. While sulphides may thus be precipitated either above or below the level of ground-water, they are more likely to be thrown down below the level of ground-water. Other compounds than reducing agents or sulphides may precipitate the downward-moving salts in other forms than sulphides.

2. In a trunk-channel, where waters ascending from below meet waters descending from above, there will probably be a considerable belt in which the circulation is slow and irregular, the main current now moving slowly upward and now moving slowly downward, and at all times being disturbed by convectional movements. Doubtless this belt of slow general movement and convectional circulation would reach a lower level at times and places of abundant rainfall than at other times and places, for under such circumstances the descending currents would be strong. The ascending currents, being controlled by the meteoric waters falling over wider areas, and subject to longer journeys than the descending currents, would not so quickly feel the effect of abundant rainfall. Later, the ascending currents might feel the effect of the abundant rainfall and carry the belt of upward movement to a higher level than normal. However, where the circulation is a very deep one, little variation in ascending currents results from irregularities of rainfall.

In the belt of meeting ascending and descending waters (see Fig. 6) convectional mixing of the solutions due to difference in temperature would be an important phenomenon. The waters from above are cool and dense, while those from below are warm and less dense. In the neutral zone of circulation the waters from above would thus tend to sink downward, while waters from below would tend to rise, and thus

the waters would be mingled. Still further, even if the water were supposed to be stagnant at the neutral belt, it is probable that by diffusion the materials contributed by the descending waters would be mingled with the materials contributed by the ascending waters.

Ascending and descending solutions are sure to have widely different compositions, and precipitation of metalliferous ores is a certain result. As a specific case in which precipitation is likely to occur, we may recall that waters ascending from below contain practically no free oxygen and are often somewhat alkaline, while waters descending from above are usually rich in oxygen and frequently contain acids, as at Sulphur Bank, described by Le Conte.* The mingling of such waters as these is almost sure to result in precipitation of some kind. Le Conte further suggests † by the mingling of the waters from below with those from above that the temperature of the ascending column will be rapidly lessened, and this also may result in precipitation.

The metals precipitated by the mingling of the waters may be contributed by the descending waters, by the ascending waters, or partly by each. In so far as more than an average amount of metallic material is precipitated from the ascending waters, this would result in the relatively greater richness of the upper part of veins independently of the material carried down from above.

In all the cases considered the precipitation and enrichment of the upper parts of deposits follow from the reactions of downward-moving waters. Their effect may be to precipitate the metals of the ascending water to some extent, and thus assist in the

first concentration. But the results of these processes cannot be discriminated from the concentration resulting from an actual downward transportation of the material of an earlier concentration. In concluding this part of the subject, *it is held that the downward transportation of metals already in lodes is the most important of the causes explaining the character of the upper portions of ore deposits; and that their peculiar characters are certainly due to the effect of descending waters.*

The concentrations by ascending and descending waters have been considered as if they were mainly successive. In some instances this may be the case; but it is much more probable that ascending and descending waters are ordinarily at work upon the same fissure at the same time, and that their products are, to a certain extent, simultaneously deposited. For instance, under the conditions represented by this chart (Fig. 6) a first concentration by ascending waters is taking place in the lower part of the fissure, and a reconcentration by descending waters is taking place in the upper part of the fissure. Between the two there is a belt in which both ascending and descending waters are at work. The rich upper part of an ore deposit which is worked in an individual case may now be in the place where ascending waters alone were first acting, where later, as a consequence of denudation, both ascending and descending waters were at work, and still later, where descending waters alone are at work. The more accurate statement concerning ore deposits produced by ascending and descending waters is, therefore, that ascending waters are likely to be the potent factor in an early stage of the process, that both may work together at an intermediate stage, and that descending waters are likely to be the potent factor in the closing stage of the process.

Also, for the sake of simplicity in the consideration of the concentrations I have

* 'On the Genesis of Metalliferous Veins,' by Joseph Le Conte, *Am. Jour. Sci.*, 3d ser., Vol. XXVI., 1883, p. 9.

† Le Conte, *op. cit.*, p. 12.

disregarded the lateral elements of the moving water. In many cases superimposed upon the vertical movements in the fissures or other openings are lateral movements, as a result of which the deposits, instead of being in vertical positions, are inclined, often much inclined, and indeed may be horizontal. Moreover, the horizontal extents of the deposits may be much greater than the vertical extents. Reduced to a simple and broad statement, *the first concentration of many ore deposits is the work of a relatively deep-water circulation, while the reconcentration is the result of reactions upon an earlier concentration through the agency of a relatively shallow water circulation. Commonly the deep-water circulation is lacking in free oxygen and contains reducing agents, and the shallow water contains free oxygen. The deep water is, therefore, a reducing, and the shallow water an oxidizing agent.*

In addition to the general factors already considered there are many special factors which have a most important, indeed, very often a controlling influence in the production of ore-chutes and in the localization of ore in certain areas and districts. Some of these factors are the complexity of openings, the presence of impervious strata at various depths, the presence of pitching folds, the character of the topography. I see, however, that my time is nearly gone, and I shall not take up their discussion this evening, but must refer those especially interested in this phase of the subject to my full paper already mentioned.* I must, however, note that impervious strata are frequently of controlling importance in the underground circulation. Often deep and shallow water circulations are separated by such strata. Often also, as the result of the removal of impervious strata by denudation, the previous deep circulation

ceases and the action of the shallow circulation is inaugurated.

At this point it may be well to briefly recall the most fundamental features of the water circulation which produces the ore deposits. First comes the downward-moving, lateral-moving waters of meteoric origin which take into solution metalliferous material. These waters at depth are converged into trunk channels, and there, while ascending, the first concentration of ore deposits may result. After this first concentration many of the ore deposits which are worked by man have undergone a later concentration, not less important than the earlier, as a result of shallow descending or lateral-moving waters. In other cases, a concentration by descending, lateral-moving waters alone is sufficient to explain some ore deposits. It thus appears more clearly than heretofore that an adequate view of ore deposits must not be a descending-water theory, a lateral-secreting water theory or an ascending-water theory alone. While an individual ore deposit may be produced by one of these processes, *for many ore deposits a satisfactory theory must be a descending, lateral-secreting, ascending, descending, lateral-secreting theory.*

But there is no question in my mind that this theory is still insufficient to fully explain many of the ore deposits. No knowledge is ever complete. We move step by step, carrying a theory nearer and nearer completion. If, however, a theory be based on good work, it usually will not prove to be false; it will be found to be incomplete. Sandberger was not wrong when he said lateral secretion explained many things in reference to ore deposits. He was wrong only when he excluded other factors. He became unscientific when he carried his theory further than his observations justified. While the theory here proposed is believed to make an important advance, it will sooner or later be found to be incom-

*'Some Principles controlling the Deposition of Ores,' by C. R. Van Hise, *Trans. Am. Inst. Min. Eng.*, Vol. XXX., 1901, pp. 112-146.

plete. I trust it will not be found to be false. But the most that I can hope for it is that it is approximately correct as far as it goes.

It is believed that the principles which have been presented lead to a new and natural classification of the ore deposits produced by underground water. As already noted, ore deposits may be divided into three groups: (1) Ores of igneous origin, (2) ores which are the direct result of the processes of sedimentation, and (3) ores which are deposited by underground water.

Since the ores produced by igneous agencies and those produced by processes of sedimentation have not been considered in this paper, a subdivision of these groups will not be attempted.

Ores resulting from the work of ground-water, group (3) above, may be divided into three main classes:

(a) Ores which at the point of precipitation are deposited by ascending waters alone. These ores are usually metallic or some forms of sulphurets; but they may be tellurides, silicates or carbonates.

(b) Ores which at the place of precipitation are deposited by descending waters alone. These ores are ordinarily oxides, carbonates, chlorides, etc., but silicates and metals are exceptionally included.

(c) Ores which receive a first concentration by ascending waters and a reconcentration by descending waters. The concentration by ascending waters may wholly precede the concentration by descending waters, but often the two processes are at least partly contemporaneous. The materials of class *c* comprise oxides, carbonates, chlorides, and rarely metals and silicates, above the level of groundwater, and rich and poor sulphurets, tellurides, metallic ores, etc., below the level of ground-water. At or near the level of ground-water, these two kinds of products are more or less intermingled, and there is

frequently a transition belt of considerable breadth.

How extensive are the deposits of class *a* I shall not attempt to state. Indeed, I have not such familiarity with ore deposits as to entitle me to an opinion upon this point. However, a considerable number of important ore deposits belong to this class. This class is illustrated by the Lake Superior copper deposits.

The ore deposits of class *b* are important. Of the various ores here belonging probably the iron ores are of the most consequence. All of the iron ores of the Lake Superior region now being exploited are of this class.

It is believed that the ore deposits of class *c* are by far the most numerous. I suspect that a close study of ore deposits in reference to their origin will result in the conclusion that the great majority of ores formed by underground water are not the deposits of ascending waters alone, but have by this process undergone an early concentration, and that descending waters have produced a later concentration, as a result of which there is placed in the upper 100 to 1,500 or possibly even 3,000 feet of an ore deposit a large portion of the metaliferous material which originally had, as a result of the early concentration, a much wider vertical distribution.

The depth to which rich deposits of the classes produced or concentrated by descending water extend is a very important question; but time does not permit adequate discussion of it. The factors entering into the problem are very numerous and complicated. Only a single one of these will be briefly considered, and this is the topography. Where the relief is small, the vertical effect of descending solutions extends upon the average to less depths than where the relief is great. But even where the relief is moderate the descending solutions may be effectual to a considerable

depth, as shown by the Lake Superior iron mines. And where the topographic forms are those of great and sharp relief, there the descending waters go to very great depths. In the San Juan region, for instance, are wonderfully steep slopes and very great canyons. Here the water descends a long way on its downward course before it turns laterally and upward on its way to the valleys. I have visited the San Juan region during the past week with other geologists, and in some cases we saw the effect of descending water to a depth of 3,000 feet below the surface. It has already been explained that in the early history of this region the conditions were ideal for a first precipitation of ores by ascending waters. They are now no less ideal for a re-concentration by descending waters.

If the classification advocated be based upon facts, it gives valuable criteria to mining men for the exploration and exploitation of their mines. Many millions of dollars have been lost needlessly in exploitation by not understanding or paying attention to this matter. In many cases it can be ascertained to which of these three classes an ore deposit belongs.

The character of a deposit in most cases will determine this. Where the ores are deposited by ascending waters alone it has been pointed out that this is favorable to their continuity to great depth. Therefore, where a given ore deposit has been shown to belong to this class, the expenditure of money for deep exploration may be warranted, although, as already pointed out, such deposits may decrease in richness with depth. Where a deposit is produced by descending waters alone, the probable extent in depth is much more limited. In such cases, when the bottom of the rich product is reached, it would be the height of folly to expend money in deep exploration. Where the ore deposit belongs to the third class, that produced by

ascending and descending waters combined, there will, again, be a richer upper belt composed of rich oxidized and sulphureted deposits which we cannot hope will be duplicated at depth. To illustrate: It would be very foolish, at Ducktown, Tenn., to sink a drill hole or shaft into the lean cupriferous pyrrhotite with the hope of finding rich sulphurets such as those which were mined near the level of groundwater. Those who have spent money in deep prospecting of the lean pyrrhotite in the Appalachian range will doubtless agree to this statement. Deposits produced by two concentrations may grade into the class produced by ascending water alone, and after the transition the deposit may be rich enough to warrant exploitation at depth; but if such work be undertaken it must be done with the understanding that the rich upper products will not be reduplicated at depth. It therefore appears to me that the determination to which of the classes of ore deposits produced by underground waters a given ore deposit belongs has a direct and very important practical bearing upon its exploration and exploitation.

In conclusion, I hold if mining engineers and superintendents understand the work of underground water, understand why and how ore deposits are made, less money will be expended in fruitless exploration; money will not be wasted in searching for deposits at places where nature never placed a deposit. Therefore, it seems to me to be the part of wisdom for a mine owner or manager to make a complete scientific investigation of a deposit of which he has charge in order to ascertain to which of these three classes the deposit belongs; and then to carry out the exploration and exploitation according to the principles which apply to the particular case.

C. R. VAN HISE.

UNIVERSITY OF WISCONSIN.

SECTION E, GEOLOGY AND GEOGRAPHY.

ABSTRACTS of papers read before the Section on August 26-29, 1901, are as follows:

'Some Problems of the Dakota Artesian System': JAMES E. TODD.

This paper presents some of the unsolved problems found in several years' study of the artesian wells of South Dakota. The artesian system shows four or five aquifers, or water-bearing strata, more or less completely separated from one another. Our first problem is, how is this separation accomplished? By sheets of clay wholly, or in part by mutual precipitates between two kinds of water? Again, artesian waters may be divided into soft and hard, and both kinds are found in the same aquifer in different localities. This presents the question, what decides the mineral content of the water at any place? Is it what is brought from its original source, or the composition of the rock in which it is found? The latter seems most accordant with the facts. Again, though from the hydraulic gradient the flow seems to be uniformly towards the southeast, the soft waters in each aquifer are found toward the northwest, and the hard to the southeast. Therefore, another problem is, how can we explain the lime and less soluble salts replacing the soda and more soluble salts in the same stream? Again, a prominent content of the water about Pierre, and extending westward indefinitely, is natural gas, and this gas has been identified with the water itself and not with any carbonaceous stratum above. What then is the origin of the gas? The high temperature with which it is associated, 92° to 102° F., and its intimate mixture with the water, suggest a chemical origin, but nothing in that line, which has been hinted by any chemist, can be conceived to occur in this region. There is no trace of volcanic or crustal disturbance, but from geological relations there is strong ground for believing that extensive carbon-

aceous deposits may have been formed in the Carboniferous period a little west of Pierre, the eastern edge of which the Dakota formation, which bears the water, directly overlaps. Subterranean heat may distill the gas into the overlying water stratum, carrying the higher temperature from below, and perhaps adding to it by condensation. But, perhaps more strange, a few miles east of Pierre the gas disappears and the temperature of the water declines 20 degrees or more. We have, therefore, another very obscure and difficult problem. What becomes of the gas? This problem in some respects resembles the disappearance of soda ingredients in the water, mentioned above. Perhaps the readiest suggestion is that the gas escapes from the water to the surface, by its greater penetrating power, but no gas springs have been found, and only a little at higher levels, which has been discovered in shallow wells. We have already alluded to the phenomenally high temperature of some wells. This has been well discussed by Darton in the 18th Annual Report U. S. G. S. The oxidation of pyrites he considers inadequate, yet as the higher temperatures are connected with the presence of sodium chloride and gas, so far as we know, it is strongly impressed upon us that some chemical reactions yet undiscovered have something to do with the high temperature, origin of gas, and disappearance of sodium salts in the great eastward-flowing streams of artesian waters.

'Interpretation of Some Drainage Changes in Southeastern Ohio': W. G. TIGHT.

This paper traces some old river valleys and indicates the sequence of events during the changes and the time of the inauguration of the changes.

'Moraines and Maximum Diurnal Temperature': JAMES E. TODD.

It has been noted that the moraines in the James River valley are frequently

wider and rougher on the west side of the valley than on the eastern. This is particularly true of those later than the first, for they are formed on a quite smooth plain. The first is much influenced by pre-glacial topography. Moreover the western sides of the loops are apt to be at lower altitudes. In seeking for an explanation for this, we find nothing more satisfactory than the fact that the maximum diurnal temperature is uniformly considerably higher after noon, hence the western half of an ice lobe will receive more heat and consequently be more active, *i. e.*, move faster, bring more débris, melt more rapidly, be more apt to detach and bury more ice blocks. The lower altitude may result from the melting back of the ice farther on a concave surface, such as is apt to be left by the former ice sheet. A corollary of this general proposition is that in the northern hemisphere the southern side of an east- or west-flowing glacier will tend to exhibit similar phenomena for a similar reason, *viz.*, because of the southern position of the sun. Instead of curving such glaciers toward the north, as argued several years ago in one of our prominent scientific journals, it will rather tend to quicken the motion in the ice toward the south, though at the same time, because of greater melting, it may not widen the ice, but the contrary. If the débris transported is abundant it may turn the course of the glacier northward, somewhat as the deposition of sediment in a delta or an alluvial fan may divert the stream which forms it. Of course the influence here recognized is not all-powerful, but may be counteracted in certain cases by other conditions.

'On *Campodus*, *Edestus*, *Helicoprion*, *Acanthodes*, and other Permo-Carboniferous Sharks': C. R. EASTMAN.

The genus *Campodus*, known only by fragmentary remains from the Coal Measures, was shown by St. John and Worthen, and later by Max Lohest, to have possessed

a typical Cestraciant dentition. The researches of these authors were based upon a unique example of the left ramus of the lower jaw, from which the anterior and posterior extremities were missing. Two specimens are now known, belonging respectively to the Museum of Comparative Zoology at Cambridge and the State University of Nebraska, which exhibit the symphyseal series of teeth and incidentally throw new light on the relations of *Edestus*, *Helicoprion* and the like. In one jaw of *Campodus*, presumably the lower, there was one arcuate, median azygous series of symphyseal teeth, opposed to which in (presumably) the upper jaw were two corresponding series separated by a slight interval. As successional teeth were developed the functional ones became coiled in a regular arc like *Edestus*, with the coronal buttresses directed inward (posteriorly). The complete whorls of *Helicoprion* are believed to represent a more advanced stage of an entirely homologous dental structure. A new and very large species of *Acanthodes*, represented by a pectoral fin, numerous spines and shagreen, was reported from the Coal Measures of Mazon Creek, Illinois, and reference made to the occurrence of *Phoebodus* in the Keokuk Limestone of Iowa and Permian of Nebraska. The large variety of *Ctenacanthus* spines occurring in the Kinderhook Limestone of Iowa fall into two principal categories, one long and slender and gradually tapering, the other short and blunt. These are probably to be correlated with the first and second dorsal fins of the same individual, instead of being regarded as distinct species.

'Note on Certain Copper Minerals': ALEXANDER N. WINCHELL.

Chalcopyrite has been found more than once as an accidental product in metallurgical operations, but bornite has never been described as formed in the same way, nor as produced artificially by sublimation.

Both these minerals form at the smelter of the Butte and Boston Consolidated Mining Co., at Butte, Montana. They form slowly, attaining their maximum thickness of about four inches in the course of six months to a year. They form in the Allen-O'Harra calciner along the rails in the bed of the furnace. In fact, they not only form beneath the flanges of the rails, but also slowly replace the rails themselves. When the rails are taken out they have only a thin upper surface layer of iron remaining; all the rest has been transformed into chalcopyrite and bornite, with the exception of that portion of the rails completely embedded in the brick bed of the furnace. An examination of these sulphides shows that, while they are somewhat impure from mechanically admixed quartz and perhaps some other foreign matter, they exhibit the true characters and chemical composition of chalcopyrite, coated in places with films of bornite. Both minerals have been formed by sublimation, and not by fusion, since the temperature of the furnace never rises high enough to fuse the ores present. Since these minerals replace and destroy the iron rails of the calciner, their formation leads to the necessity of removing and replacing the rails with new ones once every ten or twelve months.

'Note on the Minerals Associated with Copper in Parts of Arizona and New Mexico': GEO. H. STONE.

In the mountain ranges of southeastern Arizona and southwestern New Mexico are numerous copper-bearing veins in limestones and shaley limestones of Carboniferous age. In respect to the kinds of copper compounds and the occurrence of quartz and hydrous gangue minerals, these veins are not very different from the copper-bearing veins of Colorado and the States northward. Fluorspar is rare, and the sulphates scanty. It is in respect to the kind and quantity of their anhydrous silicates that

they are notable. One of the common gangue minerals is pyroxene. Occasionally it occurs as distinct and easily recognizable four-sided needles. Generally it forms small columnar or stellate crystallizations that are scattered through the decomposed and partially replaced lime rock, or it may be enclosed in quartz. Sometimes it forms slabs of asbestos up to two inches in thickness having their fibers parallel and at right angles to the surface of the slab. In a few cases I noticed these slabs having their fibers interlaced in all directions, and then they are very tough and elastic. The pyroxene occurs both in limestones and in porphyry dikes that penetrate the limestones. Asbestos occurs as a gangue mineral at Ward, Boulder County, Colorado, and in some others of the mountain districts, but I have never seen it so abundant as in the Chiricahua range in Cochise County, Arizona. Another common mineral in the veins in question is epidote. It occurs filling small cavities both in limestones and porphyries, and is very common as a product of contact metamorphism. But now and then it occurs in large quantities as gangue material proper. Thus in the California Mining District in the Chiricahua mountains there is a copper-bearing vein which for nearly a mile is composed of a solid mass of epidote wherever it has been opened by cuts and shafts. It is of various widths up to 5 feet. By far the most abundant of the anhydrous silicates in these veins is garnet. It is generally green, but occasionally brownish or yellowish green, and sometimes carmine or rose red. The copper is sometimes found impregnating the garnet mass, but more often occurs in porous quartz alongside of the larger garnet bodies. The garnets occur in irregular masses in the limestone, and often line drusy cavities. They are plainly a replacement of the limestone due to vein metamorphism of the country rock. In parts of the Chiricahua

mountains the copper veins are marked by belts of limestone more or less charged with garnet up to fifty or more feet in breadth.

In the region in question during the upheaval of the mountains, we find that where the strains were relieved by faulting and the uptilting of monoclinical blocks, the limestones retain their fossils and original amorphous condition. But where anticlines were formed there was much lateral (horizontal) pressure, the limestones are re-crystallized to a semi-marble, and the fossils are obliterated. This may be termed regional metamorphism. The same sort of recrystallization has taken place in the lime rock along the copper-bearing veins, and we may term it vein metamorphism.

'The Minerals and Mineral Localities of Texas': FREDERIC W. SIMONDS.

There has been, so far as the author is aware, no attempt to list in a complete form the mineral species occurring in Texas. In the 'Mineral Resources of the United States,' for 1882 (Washington, 1883), Professor John C. Smock, of the Geological Survey of New Jersey, who was charged with the preparation of the material illustrative of the 'Eastern Division,' published two tables for the purpose of showing the mineral resources of Texas. The first included 'Ores, Minerals and Mineral Substances of industrial importance and known occurrence, which are at present mined'; and the second, 'Ores, Minerals and Mineral Substances of industrial importance and known occurrence, but which at present are not mined.' Of the former, eight are mentioned; of the latter, 32. In the 'Mineral Resources' for 1887 (Washington, 1888), the same tables, with slight modification, mainly in the matter of additional localities, are repeated. In the First Annual Report of the Geological Survey of Texas (Austin, 1890), Mr. W. von Streeruwitz published a list of minerals, 63 in number, observed in the Trans Pecos

region, but the details of occurrence and localities were, unfortunately, not given (pp. 225-226). In the same volume, Dr. Theo. B. Comstock records 111 minerals collected in the 'Central Mineral Region'—the Llano country. This 'includes only those which occur as crystals or in special or rare situations,' and is regarded by him not as complete, but as affording a 'preliminary list of localities' (pp. 379-391). A list of those minerals and rocks of Trans Pecos Texas which, up to this time, could be classified by their appearance, blow-pipe tests and laboratory work, constitutes Chapter IV. of a 'Report on the Geology and Mineral Resources of Trans Pecos Texas,' by W. H. von Streeruwitz (Second Annual Report of the Geological Survey of Texas, pp. 710-713, 1890). It is, as the writer states, "far from being complete, but it comprises a number of the more important and valuable minerals, building stones and ores of west Texas, giving the localities where they were found." Unfortunately, the State does not possess a collection containing all minerals which I have thus far been able to list; and, as a consequence, the information concerning this occurrence has been derived from many sources, viz.: from a careful examination of the various reports relating to the geology of the State and its resources, keeping in mind at all times the value, as far as it could be estimated, of the observer as an authority. On the same basis, the various scientific journals have been gone over, and the 'transactions' of the different learned societies. Thus far, I have recorded as occurring in Texas one hundred and fifty minerals, varieties, and mineral substances, exclusive of rocks, of which eight are at present of economic importance, viz.: petroleum, coal, lignite, limonite, salt, gold and silver. Of localities the number has, even within the last few months, been enormously increased.

'Note on the Extinct Glaciers of New Mexico and Arizona': GEO. H. STONE.

In southwestern Colorado there were once extensive glaciers on the La Plata and San Juan mountains. The largest of these was 70 miles long and filled the valley of the Las Animas river. It deposited a terminal moraine just north of Durango, Colo., but appears not to have reached so far south as the 37th parallel of latitude. In New Mexico east of the Rio Grande the only extinct glaciers that I have been able to trace were along the high range that forms the southern extension of the Sangre de Christo range of Colorado. Each lateral valley of this range contained its glacier both in Colorado and as far south in New Mexico as a point not far north of Santa Fe. In the region south of the Galisteo are the Ortiz, San Pedro, San Dias, Pederal, Gallina and Jicarilla mountains. I have visited all these mountains and found no proof of the former existence of glaciers. South of White Oaks is a lofty north and south range—the Sierra Blanca. It is the highest range in that part of New Mexico, probably rising to near 11,000. It is a place of great snowfall, as its name signifies. In valleys of northern exposure I found large masses of snow late in June. I was not able to find moraines. West of the Rio Grande the main southeast spur of the San Juan mountains passes into New Mexico as the Conejos range. This range falls rapidly toward the south and was glaciated for not more than 30 to 50 miles south of the Colorado-New Mexico line. South of this there are no mountains in western New Mexico so high that we could expect to find traces of glaciers on them until we reach the lofty Mogollons. They have a heavy snowfall. They are rather inaccessible and I have not visited them. I have explored the higher mountain ranges that lie south of the Gila river in New Mexico and Arizona, but no moraine

or other sign of a glacier was I able to find. The farthest south and west I have found traces of extinct glaciers is at Prescott, Arizona. Around Prescott are numerous moraines. The highest part of the névé of this glacier could not have been much above 9,000 feet. The central part of the glacier is approximately in N. Lat. 34° 30'. The occurrence of an ancient glacier so far south as this was probably due to a very great snowfall owing to the proximity of the ocean. It is doubtful if there was any mountain range high enough to have had its glaciers in glacial time between Prescott and the Sierra Nevada. Probably there were then small glaciers in some of the cirques of northern exposure among the mountains directly southeast of Prescott. We may yet find that the glaciers reached their southern limit in the Mogollon mountains of New Mexico and Arizona.

'The Pre-glacial Surface Deposits of Lower Michigan': A. C. LANE.

Some years ago in working out the general system of drainage of the basin of the Great Lakes, before it was disarranged by the ice from the north, Professor J. W. Spencer drew a sketch map indicating the great streams flowing down to Lake Michigan and Saginaw Bay and joining the Laurentian River, which flows off across Canada. In this scheme of drainage he has been followed by most of the writers since, and his work has been somewhat elaborated by Mr. E. H. Mudge in an article in the *American Journal of Science*, Volume 4, 1897, page 383. There were, however, certain arguments against the idea that the center of lower Michigan drained through the Saginaw Bay. Directly in the mouth of the bay is a group of islands, the Charity Islands, which are composed of cherty, sub-Carboniferous limestone, of about the age of the Upper St. Louis. On both sides of the bay occur outcrops of the same limestone. The mouth of the bay is shallow,

and the ledges of limestone can almost be traced continuously across it not far below the lake surface, and as the elevation of the bed rock surface around in Bay County is, as Spencer and others have remarked, considerably below the present lake surface, it seems hard to assume that any river used to flow northeast out of the Bay. The results of my studies of the rock surface topography of Huron County, published in Volume 7 of our reports, based on the extensive lists of borings catalogued there, showed clearly a river system flowing southeast, gathering strength. Again when I came to discuss the general subject in Water Supply Paper No. 30, it became evident that the Saginaw lobe of ice did not advance as far, proportionately, as Michigan or the Huron-Erie, being retarded, apparently, by this limestone ridge. And, moreover, the result of borings for coal, oil, gas and salt throughout the Saginaw valley made it pretty clear that, before the ice age this valley did not drain as at present, but to the west and northwest. The evidence which I presented on this point, in Water Supply Paper No. 30, was very candidly accepted by Mr. Mudge, who at the same time pointed out some emendations in detail. Since, however, authors are still following Spencer, it may not be inappropriate to call attention to the subject once more and to present some of the elevations above tide which make it reasonably certain that the drainage of lower Michigan was to the northwest. The coal basin of Michigan is surrounded by a series of ramparts of which the sub-Carboniferous limestone, Marshall sandstone, Devonian limestone and Niagara limestone are the most important. It is probable that in the neighborhood of Saginaw Bay all these ramparts were broken down by pre-glacial rivers, except the innermost, curved to the right and left, so that finally when the ice overrode this the lobe

extended in the general direction of the ice motion, that of Saginaw Bay. The shore of Saginaw Bay has now been so completely lined with borings that it is not conceivable that any valley of the first order 300 feet below lake level can go out that way, while it is only a few miles south, in Saginaw County and west of it, that we find bed rock elevations of only 300 and 400 feet below tide. The west part of the State is so heavily covered with drift that our information regarding the bed rock surface is much more scanty, but we know that in the northwest part, bed rock surface is below sea level. The great group of lakes resembling somewhat the Finger Lakes of New York, and the bays which are associated, Great and Little Traverse Bays, require special explanation, and seem to find it in some large pre-glacial valley that had irregular pre-glacial topography, such as would be found where the escarpments of the middle and lower Devonian limestone come close to master valleys. It seems to me possible that before the last ice age the main streams connecting the valley of Lake Michigan with that of Lake Huron may have passed from just north of Petoskey to somewhere near Cheboygan; at any rate, there was a considerable stream there. So far as the present indications of levels are concerned, it would seem as though the *streams were flowing to the south rather than to the north*, but before we can settle this question, we must hear from the geologists of other States.

The following papers were also read before the American Geological Society and the Section.

1. 'Account of the Colorado Excursion': C. R. VAN HISE.
2. 'Junction of the Lake Superior Sandstone and the Keweenaw Traps in Wisconsin': U. S. GRANT.
3. 'Hydrographic History of South Dakota': J. E. TODD.

4. 'The Still Rivers of Western Connecticut': W. H. HOBBS.

5. 'Geology of the Northeast Coast of Brazil': JOHN C. BRANNER.

6. 'Classification of the Geological Formations of Tennessee': JAMES M. SAFFORD.

7. 'Horizons of Phosphate Rock in Tennessee': JAMES M. SAFFORD.

8. 'The Oscillations of the Coast Ranges of California': A. C. LAWSON.

9. 'Some Features of the Geology of Golden, Colorado' (a paper preparatory to the excursions in Morrison and Golden on Tuesday and Wednesday): H. B. PATTON.

MEMBERSHIP OF THE AMERICAN ASSOCIATION.

THE following have completed their membership in the American Association for the Advancement of Science during the month of October:

Hendery Allison, M.D., 149 Richmond Terrace, Port Richmond, N. Y.

Jacob H. Arnold, Teacher of Natural Science, Redfield College, Redfield, South Dakota.

Samuel M. Bain, Professor of Botany, Univ. of Tenn., Knoxville, Tenn.

Dr. Philip P. Calvert, Professor of Zoology, Biological Hall, Univ. of Pa., Philadelphia, Pa.

John J. Davis, Attorney-at-law, Clarksburg, W. Va.
Miss Anna M. Deens, Botany and Zoology, 216 North Ave., W., Allegheny, Pa.

Miss Abigail C. Dimou, Zoology, Radnor Hall, Bryn Mawr, Pa.

Manuel V. Domenech, Civil Engineer and Architect, Lock Box 151, Ponce, Porto Rico.

Fred. N. Duncan, Chemist, Georgetown, Texas.

Gano S. Dunn, Electrical Engineer, Crocker-Wheeler Co., Ampere, N. J.

Edward M. Ehrhorn, County Entomologist, Santa Clara Co., Mountain View, Cal.

Sumner B. Ely, Mechanical Engineer, Vandergrift Building, Pittsburg, Pa.

Robert Gauss, Editor *Denver Republican*, Denver, Colo.

Professor Chas. B. Gilbert, Educator, 106 Brunswick St., Rochester, N. Y.

Charles P. Greenuough, Attorney-at-law, 39 Court St., Boston, Mass.

Mrs. Margaret L. Griffin, Botany and Geology, Keene, N. H.

Wm. C. A. Hammel, Department of Physics, State Normal School, Baltimore, Md.

Judge Lynde Harrison, Lawyer, 52 Hillhouse Ave., New Haven, Conn.

Edwin Hebden, Principal, Group A, Public Schools, 730 Colorado Ave., Baltimore, Md.

Ray V. Hennen, Civil Engineer, care of Carter Oil Co., Sistersville, Tyler Co., W. Va.

Sidney Hosmer, Electrical Engineer, 3 Head Place, Boston, Mass.

Edward H. Kraus, Instructor Mineralogy, Syracuse Univ., 615 Butternut St., Syracuse, N. Y.

Lucinus S. McCoy, Whitten, Hardin Co., Iowa.

George D. Markham, 4961 Berlin Ave., St. Louis Mo.

Hu Maxwell, Treasurer Transallegheny Historical Society, Morgantown, W. Va.

Miss Florence Parker, Geology, 10,340 Longwood Ave., Chicago, Ill.

John Patton, Counsellor-at-law, 925 Mich. Trust Co. Bldg., Grand Rapids, Mich.

Samuel K. Reifsnnyder, Instructor Science, High School, 73 Embury Ave., Ocean Grove, N. J.

Dudley S. Reynolds, M.D., Louisville, Ky.

James F. Rhodes, Author and Historian, 392 Beacon St., Boston, Mass.

Maurice Ricker, Zoology, High School, Burlington, Iowa.

Milnor Roberts, Professor Mining and Metallurgy, Univ. of Washington, Seattle, Wash.

Sanford Robinson, Civil and Mining Engineer, Steeple Rock, Grant Co., New Mexico.

David J. Satterfield, D.D., President, Scotia Seminary, Concord, North Carolina.

Miss Clara B. Sayre, South Bethlehem, Pa.

Wm. J. Sutton, Geologist, Esquimalt & Nanaimo Ry. Co., Victoria, B. C.

E. S. G. Titus, Entomologist, Nat. Hist. Bldg., Urbana, Ill.

David M. Totman, M.D., Physician and Surgeon, 303 Montgomery St., Syracuse, N. Y.

Andrew J. Townson, President, Board of Education, Granite Building, Rochester, N. Y.

Dr. Frederick C. Waite, Assistant Professor of Histology and Entomology, Medical Dept., Western Reserve Univ., Cleveland, Ohio.

Charles R. Walker, M.D., Concord, New Hampshire.

Joseph R. Watson, Professor of Natural Science, Berea College, Berea, Ky.

Wm. G. Wilkins, Professor of Mining Engineering, Western Univ. of Pa., Westinghouse Bldg., Pittsburg, Pa.

THE AMERICAN MICROSCOPICAL SOCIETY.

THE twenty-fourth annual meeting of the Society was held in Denver, August 29 to 31. As anticipated, the attendance was not large, yet the strong series of papers presented and the completion of the Spencer-Tolles Fund make the occasion a noteworthy one. At the business session on Thursday there were read reports of the secretary, treasurer and custodian on the condition of the Society, and the usual committees were appointed. Some minor changes in the by-laws of the Society were recommended and subsequently adopted. The report of the Committee on the Spencer-Tolles Fund showed that it had finally been brought to the limit of \$1,200, set at the New York meeting, and recommended that a specific sum be set aside yearly from the income for the encouragement of such definite research of a microscopical character as shall be approved. The committee reported \$50 available for use in the current year, and the final apportionment of the amount was left to the Executive Committee.

The meeting on Thursday evening was

in charge of the Colorado Microscopical Society. After an address of welcome by the president of that organization, Dr. A. M. Holmes, and a response by the retiring president of the American Microscopical Society, Dr. A. M. Bleile, the annual address was read by the incoming president, Dr. C. H. Eigenmann, on 'The Solution of the Eel Question.' The paper was illustrated by both charts and lantern slides and proved of great interest. At the close a most pleasant informal reception was tendered the visiting society and guests by the Colorado organization, to whom most cordial thanks are due for many hospitalities.

The following papers were among those presented at the general sessions of the Society:

'The Early Morphogenesis and Histogenesis of the Liver in the Pig': D. C. HILTON, Chicago, Ill.

'The Histology of the Stigmata and Stomata in the Peritoneum': A. E. HERTZLER, Halstead, Kas.

'A Rearrangement of the Families and Genera of the Conjugatæ': C. E. BESSEY, Lincoln, Neb.

'A New Species of *Crinothrix* (*C. manganifera*): D. D. JACKSON, New York City.

'The Amount of Dissolved Oxygen and Carbonic Acid in Natural Waters and the Effect of these Gases on the Occurrence of the Microorganism': G. C. WHIPPLE and H. N. PARKER, New York City.

'Notes on Colorado Protozoa, with Description of New Species': A. E. BEARDSLEY, Greeley, Col.

'Notes on Colorado Entomostraca': A. E. BEARDSLEY, Greeley, Col.

'A Review of the American Species of *Cochleophorus* and *Curvipes*': R. H. WOLCOTT, Lincoln, Nebr.

'An Apparently New *Hydra* from Montana': M. J. ELROD, Missoula, Mont.

'Some Histological Features of *Echinorhynchi*' (Illustrated): H. W. GRAYBILL, Lincoln, Neb.

'The Debt of American Microscopy to Spencer and Tolles': W. C. KRAUSS, Buffalo, N. Y.

'Mounting Soft Tissues for Microscopical Examination': M. A. D. JONES, New York City.

'Modification of Some Standard Laboratory Apparatus': S. H. GAGE, Ithaca, N. Y.

'Laboratory Photographic Apparatus': S. H. GAGE, Ithaca, N. Y.

'The Plankton of Lake Maxinkuckee, Ind.': CHAUNCEY JUDAY.

The following officers were elected for the year 1901-02 :

President, Dr. Charles E. Bessey, University of Nebraska, Lincoln, Nebr.

First Vice-President, Dr. E. A. Birge, University of Wisconsin, Madison, Wis.

Second Vice-President, Mr. John Aspinwall, New York City.

Elective Members of the Executive Committee, Dr. A. M. Holmes, Denver, Col.; Dr. V. A. Latham, Chicago, Ill.; Mr. G. C. Whipple, New York.

Secretary, Dr. Henry B. Ward, University of Nebraska, Lincoln, Nebr.

Treasurer, Mr. J. C. Smith, New Orleans, Louisiana.
Custodian, Mr. Magnus Pflaum, Pittsburg, Pa.

Resolutions of regret at the death of ex-President E. W. Claypole, the sad news of which came to the Society as it was in session, were read and ordered spread upon the minutes of the Society.

HENRY B. WARD,
Secretary.

TOTAL ECLIPSE OF THE SUN.*

AMONG the unsolved problems for the twentieth century are many relating to the central luminary of our system. Many points of scientific interest to students of solar phenomena are still to be discovered, and it is true that when we come to consider what we do not know about the sun, we are rather startled to find our knowledge about the heavenly body which has most interest to us human beings so incomplete. The distance is not known to the accuracy which we wish it, and very little is known of the laws of motion at the surface of the sun or the manner in which light and heat are sent out. The spectroscope tells us what metals are present at the surface of the sun, but, as yet, it has not decided the question of the extent of the different gases, nor the position of the 'reversing layer.' In fact, the very existence of the 'reversing layer' has been disputed. The most beautiful of all natural

phenomena, the corona, is to us an unsolved mystery. Much time has been spent delineating its form, and in late years some connection has been established between the form of the corona and the sun-spot period; but what is the meaning of this connection? and in turn, what is the relation between sun spots and terrestrial magnetism? The spectroscope tells us that 'coronium' forms a constituent of the corona, but what is 'coronium'?

These and many other points are still to be solved by astronomers and physicists. Their solution depends almost entirely on the observations, on the average, of only a few minutes each year, for it is only when the sun is eclipsed that most of these problems can be investigated.

The United States government recognized the importance of these inquiries, and through Congress appropriated money to equip and send out an expedition to observe the eclipse of the sun visible in the island of Sumatra in the East Indies, on May 18, 1901.

This expedition consisted of thirteen, a number which would have caused terror to enter the hearts of people less sensible than astronomers. This is the largest party, we believe, ever sent out by any government for such a purpose.

The thirteen were made up of two separate parties, two members, Professor C. G. Abbot and his assistant, Mr. Draper, representing the Smithsonian Institution, and eleven the Naval Observatory. Six belonged to the staff of the observatory, and consisted of Professor A. N. Skinner, U. S. N.; Professor W. S. Eichelberger, U. S. N.; Professor F. B. Littell, U. S. N.; Mr. L. E. Jewell, Mr. W. W. Dinwiddie and Mr. G. H. Peters. The remainder of the party was made up of Professor E. E. Barnard, Yerkes Observatory; Dr. W. J. Humphreys and Mr. H. D. Curtis, of the University of Virginia; Dr. N. E. Gilbert, of Hobart College, and the writer.

* Read before the New York Academy of Sciences, November 4, 1901.

The members crossed the continent by various routes, meeting together for the first time in San Francisco. Transportation was furnished by government steamers, and on February 16, on board the army transport *Sheridan*, the expedition started to demonstrate that the earth is round by sailing west in order to reach the East Indies. The Army was to care for the party as far as Manila, and from there to Sumatra the Navy Department was to attend to us. Life on board the transport was very pleasant, many entertainments being provided by the officers, soldiers—and astronomers, too—to while away the hours.

Honolulu was reached the morning of February 25. A three days' stay there enabled the party to see most of the sights of the island of Oahu, making a most pleasant break in our voyage of thirty days to Manila. The Social Science Club of the Hawaiian Islands was exceedingly kind to the astronomers. Among the courtesies shown was a drive up the historic Pali, a huge precipice with a sheer drop of 500 feet, over which one of the old kings is said to have driven his enemies to their death. In the evening a meeting of the club was held at which Professor Barnard gave one of his interesting illustrated talks. The three days' stay was exceedingly interesting, giving an excellent opportunity of seeing how the United States was progressing in the government of his new outside dependencies.

The 180th meridian was crossed at 11:40 on the night of March 4, and as a result our day of March 5 was of only twenty minutes' duration. On crossing the line, Father Neptune and his court paid the ship a visit, the celebration of which was greatly enjoyed by soldiers, sailors and passengers.

Manila was reached on March 18, and a stop of eight days was made while arrangements were made with the Navy Department to carry us the remaining 2,200 miles

to Sumatra. The Manila observatory, which was visited several times, is doing an exceedingly important work, the value of which is recognized by the United States authorities. The predictions for typhoons come from the observatory, and in view of the enormous shipping of the port, this service is invaluable. A time service and weather bureau with 76 stations are about to be instituted by the observatory authorities. Of course, the most interesting sights to Americans were the Spanish wrecks at Cavite, monuments to the valor of Admiral Dewey.

The U. S. S. *General Alava*, a former Spanish ship, was put at the disposal of the expedition, and on March 26 we set sail for Sumatra. Pleasant weather was experienced through the China and Java Seas. The equator was crossed on March 31, and 'Neptunus Rex' was celebrated in true man-of-war style.

On April 2, the ship passed within half a mile of Krakatau, excellent opportunity thus being given to see this historic volcano. Where, before the eruption of 1883, had been a hill of perhaps 1,000 feet, bottom is now not reached at the depth of 164 fathoms.

On April 4, the *General Alava* steamed into the beautiful harbor of Emma Haven, the port of Padang, the capital of the island of Sumatra, and a first glimpse was obtained of the Malay, with whom the next two months were to make us so well acquainted. We were the first astronomical expedition to arrive, ours being, in fact, the first American ship which ever entered port there. But in a few days Professor Perrine and the astronomers from the Massachusetts Institute of Technology arrived, to be soon followed by parties from England, Holland, France, Russia, Japan and India.

It took some time to get accustomed to the East Indian ways, particularly the cus-

toms of eating and bathing, and many amusing incidents were the result. In the East Indian hotels the bath rooms are away out in the yard, a hundred yards or more from your bedroom. There is no bath-tub like ours—in fact, plumbing of any sort is unknown there—and the bath is taken by dipping water from a cistern by means of a bucket and throwing it over yourself—and a very good bath it gives, too. One of our English friends mistook the cistern for his tub, and got in, greatly to the consternation of the Malays.

The Dutch did everything in their power to make our stay in the island pleasant, with the result that everything was accomplished with remarkably little trouble and difficulty. Free passes were furnished to all astronomers, all freight was transported without charge, and laborers, consisting mainly of convict coolies, were furnished in as large numbers as were wished. In fact, too much cannot be said in praise of the courtesy and kindness of the Hollanders to all the foreign astronomers. The scientists became known so quickly to the Dutch and Malays, that 'Zoneclips' soon became the talisman that made all things work together for our good.

Before reaching Sumatra it had been decided to divide the expedition into two parts, the main portion going to Solok, near the central line of totality, and a smaller number to Fort de Koch, near the northern limit of the path; both stations being on the line of the 'Staatspoorweg op Sumatra,' the government railroad running about 100 miles inland. After two weeks' stay in the island, and in view of the fact that so much cloudy weather was experienced each day at the time of totality, it was decided best to still further divide the expedition. Consequently, another station was established at Sawah Loento, the terminus of the government railroad, twenty miles beyond Solok.

The American governmental party was thus divided into three. Everybody was hard at work by the middle of April, but as we had to depend on Malay bricklayers and carpenters, work did not progress as rapidly as was desired. These *orang tukang* are frightfully slow, always squatting down to work, and using tools of the most primitive sort. It was a sore trial, indeed, seeing everything proceed at such a snail's pace, but by dint of hard labor, and much talking of Malay on our part, with several English expletives thrown in, everything was all up and adjusted in good time.

At Solok, where the main part of the expedition was located, an almost ideal spot was found for an eclipse camp. This was an old fort recently evacuated by the Dutch, the buildings serving as most excellent sheds for storing the instruments. Professor Barnard had with him the 61½-foot lens with which he obtained such good results at the 1900 eclipse at Wadesboro. This was used in connection with a cœlostat, the telescope tube being horizontal, and ending in a dark room where the plates, in holders, were to be placed on a sliding carrier at eclipse time. One plate used by him, measuring 40 x 40 inches, was to be exposed at the middle of totality for two minutes and a half. The other plates were 30 x 30 and 11 x 14, but notwithstanding their great weight, so carefully was the construction looked after that the plates were changed remarkably quickly. True, totality lasted 5 min. 51 sec. at Solok, but the seconds are valuable, even with such a great duration.

Professor Abbot was prosecuting his researches along two lines. With a highly sensitive bolometer, which has been brought to such a high degree of excellency at the Smithsonian Institution, he was investigating the heat of the moon and the corona; and with four photographic lenses of 11 feet focus, searching for intra-Mercurial plan-

ets. A region about $20^{\circ} \times 24^{\circ}$ was covered in the vicinity of the sun, and the exposures were duplicated in order to check all suspected objects.

The spectroscopic work was under the general direction of Mr. Jewell. He himself used a 21-foot concave grating, used without slit as an objective grating. Mr. Dinwiddie employed a 6-inch prismatic camera, and Professor Littell a flat grating with slit, in order, if possible, to detect the rotation of the corona. Professor R. W. Wood's apparatus was used by Dr. Gilbert, and several small cameras by Mr. Curtis.

At Fort de Koch were two instruments, the 40-foot photoheliograph and the spectroscope in charge of Mr. Peters and Dr. Humphreys, respectively. The latter was a direct concave grating used without slit, and had a ruled surface of 8×5 inches. It was one of the last gratings ruled by Schneider under the direction of Professor Rowland, and was the largest grating ever made. Unfortunately, the diamond broke down in the middle of the ruling, and it was found necessary in Sumatra to cover up half of the grating; but notwithstanding this fact, spectra of remarkable brilliancy and definition were obtained.

At Sawah Loento were placed two instruments under the direction of the writer. The spectroscope was a 6-inch flat grating of 15,000 lines, used without a slit in connection with a quartz lens of 72-inch focus. The camera had a focal length of 104 inches and an aperture of 6 inches, which, however, was stopped down to $4\frac{1}{2}$ inches.

This was the instrumental outfit of the governmental parties.

At Sawah Loento were also situated the Massachusetts Institute party, and Mr. and Mrs. Newall, of Cambridge, England, the work of the former embracing a general photographic program, together with investigations of the magnetic disturbance during the eclipse. Our English cousins had some

very important spectroscopic problems to carry out.

The three stations situated within fifty miles of the equator had difficulties to contend with that could not be shouldered on to the backs of the Malays. The hot tropical country requires a great amount of rain, and from our experience it seems to get all it needs. At Padang, according to the meteorological reports, there is an annual rainfall of 187 inches, an average of half an inch each day. In fact there is seldom a day without rainfall. Up to the first of May, the sun had hardly been seen by us in Sumatra. The result was that great difficulty was experienced in getting enough clear weather to adjust the instruments, the nights being as cloudy as the days. Professor Barnard carried with him some portrait lenses in order to continue his photographic work on the Milky Way, and carry his investigations into the southern heavens. Those who know Professor Barnard will acknowledge that he tried hard enough to make the exposures, but he failed, owing to continued cloudy weather, to get a single fully exposed plate.

As the time approached closer and closer to the day of the eclipse, great concern was felt as to the probability of a clear sky for the all-important six minutes shortly after noon, on the day of May 18, 1901.

At Sawah Loento it dawned clearer than it had been for a week, but about eight o'clock it clouded up and dashed the hopes of everybody to the ground. About ten it cleared beautifully, and our hopes soared again. First contact was observed with a perfectly clear sky, but soon clouds began to gather, and half an hour before totality the sky was completely overcast.

A direct-vision spectroscope was employed to watch the 'flash,' but so cloudy was it that the first 'flash' passed unnoticed and the total phase had begun before we were hardly aware of it. It remained

cloudy throughout the eclipse, but was a trifle clearer than at the beginning of totality, so that the 'coronium' line was very well seen. The second 'flash' appeared stronger than we would have thought possible through the clouds. The reappearance of the sun was welcomed by a shout from the Malays assembled in the valley.

On the spectrographs taken during totality nothing of the coronal spectrum was visible. The hydrogen lines H and K appeared, but these were due to the upper chromosphere. Although an exposure was made about the time of the first flash, nothing was found of this on the photographic plate. The second flash, however, showed more than was expected, and gave results fairly well developed. The photographs of the corona showed an extent of about a diameter, but with very few details of streamers.

At Solok the weather was even worse than at Sawah Loento; so dense were the clouds, in fact, that the position of the sun could hardly be seen. Mercury and Venus, which were visible at Sawah Loento throughout totality, were seen only for a few seconds at Solok. So cloudy was it that Professor Abbot did not even attempt anything with his bolometer. With the exception of this, all other programs were carried out as if it had been clear. The results, however, were almost *nil*. Where Professor Barnard had hoped for marvelous results of detail on his large 40 x 40 plate, hardly a trace of even a prominence was seen.

One hour after the eclipse was all over, the clouds cleared away, and a beautiful blue sky remained for the rest of the day. Alas! that the eclipse did not occur at one o'clock instead of at twelve.

A few hours after the work was over at Solok, word came to the despondent people there, that at Fort de Koch the weather had been perfect and that the program had

been carried out without a hitch. This was good news indeed. Several excellent spectrographs were obtained with the concave grating; the photographs taken with the 40-ft. showed splendid detail in the polar and equatorial streamers. Thus it happened that one party of the American expedition met with perfect success, one with partial success, but the third with no results at all to show for the hard work and time spent.

The other observers in Sumatra fared about as well as did the Naval Observatory party, the clouds being general over the region covered by the scientists. Nowhere else were they as dense as at Solok, but at no place where an astronomical expedition was located were perfect weather conditions experienced except at Fort de Koch.

To meet such a perplexing state of affairs is rather disappointing after traveling half way around the world in search of scientific knowledge, but it is to be expected when the object of investigation is the sun. The conditions were not so bad as at the eclipse of 1896, when no sun at all was seen, but, coming so soon after the 1900 eclipse which was so generally observed in this country, and with such perfectly blue and tranquil skies, the contrast was anything but pleasant.

At Sawah Loento, totality lasted 5 min. 41 sec. The chromosphere and prominences at mid-totality would, it would have been thought, have been so thoroughly covered up that the atmosphere would not have been lit up to any great extent, and consequently it would be very dark during totality. This was expected, and to prepare for it lanterns were got ready to aid the time-keepers and observers to see. But the expected did not happen, and at no time during totality was it too dark to see the hands of an ordinary watch. In fact, it was hardly any darker than at the eclipse of last year, which the writer saw from

Griffin, Ga., situated near the northern edge of the path of totality and experiencing a duration of only 38 sec. The reason for the brightness of the air was evidently the sun shining on the clouds, which in turn illuminated the atmosphere. The clouds were cirro-cumulus, and, no doubt, very high.

It is almost too early to tell just how much our knowledge of the sun has been increased, but it is certain that much of scientific value will be added to science as a result of the observations of the eclipse of May 18, 1901.

To astronomers the voyage itself was interesting in showing the stars of the southern hemisphere, and in losing sight for a couple of months, of Polaris, the star that appeals to all of us as a personal friend.

Perhaps, outside the eclipse, the most striking feature of the expedition astronomically was the independent discovery on May 3 of the great comet, the honor belonging to Mr. Dinwiddie of the Naval Observatory. It was indeed a magnificent sight, appearing shortly after sunset, with a sweeping tail visible to the naked eye for more than eight degrees in length. We watched eagerly during every clear night—but unfortunately there were not very many beautiful nights—and it was photographed by Professor Barnard. But, if the great comet was seen, the sudden outburst of the star in Perseus escaped our attention. After leaving San Francisco, heavy weather and cloudy nights were experienced till after leaving Honolulu, February 28. As there is as yet no cable to the Hawaiian Islands—but this, we hope, is to come in the near future—no tidings were received of the new star until after the arrival of the party in Sumatra, when Perseus was no longer visible.

The expedition arrived in San Francisco July 16.

The next eclipse that will be generally

observed is that of August 30, 1905, which will be visible in Labrador, Spain, and northern Africa. The points of investigation will be along the same lines as carried out by the American parties, but it is to be hoped that better weather conditions will be experienced than in the Sumatra eclipse of May 18, 1901.

COLUMBIA UNIVERSITY.

SCIENTIFIC BOOKS.

Alaska: Volume I., Narrative, Glaciers, Natives, by JOHN BURROUGHS, JOHN MUIR and GEORGE BIRD GRINNELL; Volume II., History, Geography, Resources, by WILLIAM H. DALL, CHARLES KEELER, HENRY GANNETT, WILLIAM H. BREWER, C. HART MERRIAM, GEORGE BIRD GRINNELL and M. L. WASHBURN. New York, Doubleday, Page and Company. 1901. [Superimprinted] Harriman Alaska Expedition, with the cooperation of the Washington Academy of Sciences. [Edited by DR. C. HART MERRIAM.] With 39 colored plates, 85 photogravure plates, 5 maps and 240 text figures. Pp. xxxvii + 383. Price, \$15.

The Harriman Expedition of 1899 was one of the scientific events of that year; and the issue of this sumptuous summary of results is one of the literary events of the current year. Conceived as a pleasure trip, matured in mind as a summer school for a family and a few friends, the Harriman outing took final form as an expedition for research in a region of paramount present interest to science, industry, commerce and public policy. The sea trip—the essential part of the expedition—was made in the steamer *George W. Elder*, with an aggregate personnel (including officers and crew) of 126. The 'scientific party' numbered 25, and there were three artists, two photographers, two stenographers, a surgeon, an assistant surgeon and a trained nurse, besides eleven hunters, packers and camp hands. Nor was the 'scientific' corps such in name only; none were smatterers, and all ranged from distinction through eminence to preeminence in their respective lines, which included anatomy, botany,

engineering, ethnology, forestry, geography, geology, mineralogy, ornithology, paleontology and zoology. Along all these lines the researches were energetic and successful; and the more general results are incorporated in the two volumes just issued, and in a series of special memoirs now in the course of publication by the Washington Academy of Sciences, but designed for ultimate reissue in volumes supplementary to those under notice. These volumes themselves, produced as they were by leading authorities, must form a standard source of knowledge concerning Alaska; and when the series is completed it will undoubtedly command a high place among the classics of place and country.

The body of the first volume opens with a narrative of the expedition by John Burroughs; then follow chapters on the 'Pacific Coast Glaciers,' by John Muir, and on the 'Natives of the Alaska Coast Region,' by George Bird Grinnell. The second volume comprises 'The Discovery and Exploration of Alaska,' by William Healey Dall; 'Days Among Alaska Birds,' by Charles Keeler; 'Forests of Alaska,' by Bernard E. Fernow; 'General Geography,' by Henry Gannett; 'The Alaska Atmosphere,' by William H. Brewer; 'Bogoslof, Our Newest Volcano,' by C. Hart Merriam; 'The Salmon Industry,' by George Bird Grinnell; and 'Fox Farming in Alaska,' by M. L. Washburn. There is also a preface by Mr. Harriman and an introduction by Dr. Merriam, together with an opening poem by Charles Keeler; while the work ends (save for the excellent Index) with an effective poem by Dall, captioned 'The Song of the Innu' and (somewhat tautologically) listed as 'The Innu' People.' It would be impracticable to abstract the papers prepared by the several contributors; it must suffice to note that they are, without exception, excellent, authoritative, well written, and carefully edited by a participant in the expedition, himself a recognized authority in scientific matters. Merely as examples, it may be noted that the chapter on glaciers came from the pen of the world's most sympathetic student of ice fields and ice streams; that the historical chapter was written by the leading authority on Alaskan exploration; and that the account of

Alaskan geography and the accompanying maps were prepared by our foremost practical geographer. The maps, although small, show the general features of the territory satisfactorily; they are, of course, quite up to date, embracing the results of all surveys up to 1900, including those of the expedition itself, as well as those of the U. S. Geological Survey and the U. S. Coast and Geodetic Survey.

The volumes are especially notable for the beauty and fidelity of the illustrations, most of which were based on photographs. The lithograph plates have never been excelled in delicacy and refinement of both color and form; many of them are pictorial gems, displaying landscape and waterscape, mountain and valley, flower and foliage, fur and feather, with a faithfulness seldom sought and never passed. The photogravures are of corresponding excellence; while the text figures combine artistic quality and graphic fidelity in remarkable degree. The typography, paper and binding are correspondingly sumptuous; so that the book is a thing of beauty as well as an object of utility.

Perhaps the most serious defect of the work (despite evident editorial care, which might well have been more prominently acknowledged) is the discontinuity naturally growing out of the multiple authorship; another defect, which must somewhat discommode librarians and dealers as well as students, is the absence of a definite title. 'Alaska,' indeed, stands out boldly on the title-page in carmine ink, while the publisher's imprint and the expeditionary superimprint and vignette are uniform, but otherwise the title-pages are diverse—and worst of all, the title on the back is not that of the book but that of the expedition. W J M.

Ind.
The Protozoa. By GARY N. CALKINS, Ph.D.
 Columbia University Biological Series, Vol. VI. New York, Macmillan Co. Price, \$3.

It is no easy task to compress into a volume of scarcely more than 300 pages a résumé of even the more important facts and theories relating to a large group of organisms like the Protozoa. The difficulty of the task is apparent when one stops to consider that the very position of the Protozoa in the animal kingdom has of necessity enveloped them in a nimbus of

biological speculation. They have been and will long continue to be the one group about which cluster the numerous theories of biogenesis, the origin of the Metazoa, the origin and significance of sex, heredity and death, the dawn of consciousness and instinct and innumerable problems of lesser magnitude. Dr. Calkins is to be congratulated on having worthily overcome, or at any rate adroitly avoided, many of the difficulties of this task. At the same time he has upheld the high standard of scholarship set by the previous volumes in the well-known 'Biological Series.'

As Dr. Calkins informs us in his preface, "The subject-matter of the volume is treated from three points of view: (1) The historical, to which the first chapter is devoted. (2) The comparative to which five chapters are given, one to the group of Protozoa as a whole, the other four to the main classes. (3) The general, to which three chapters are devoted. One of these is given to the phenomena of old age or senile degeneration in Protozoa and renewal of youth through the union of two individuals, and to the bearing of these phenomena upon sexual reproduction in general. Another is given to the special structures of nuclei and centrosomes of the Protozoa; this, the most technical chapter in the book, is introduced because of the growing importance which the Protozoa have in the problems of cellular biology, especially with those dealing with the origin of the division-center and its accompanying structures in the cells of the Metazoa. The last chapter is devoted to a consideration of the physiology of the Protozoa, with especial reference to the Protozoa as *organisms* endowed with the powers of coordination and of adaptation, which up to the present time have eluded physical and chemical analysis."

In pursuing this general plan the author has consistently resisted the temptation of involving himself in undue detail, and it is evident that he has everywhere striven to give proper shape and proportions to his work. In some parts of the volume, however, this brevity almost borders on meagerness and obscurity. The student who has long been irritated by the unsatisfactory text book accounts of the life-

histories of the Sporozoa will certainly wish that Dr. Calkins had expanded his excellent chapter on these organisms and introduced a fuller account of recent works on the Gregariniada and Hæmosporidia. We miss, *e. g.*, an account of *Apiosoma bigeminum*, the source of Texas fever, and its transfer by the cattle-tick (*Boophilus bovis*) in a manner analogous to the transfer of *Plasmodium malarix* by the mosquito (*Anopheles*). We should also have welcomed a fuller treatment of the geographical distribution of the Protozoa in general, their modes of dissemination and the phenomena of anabiosis.

Many morphologists and physiologists will wish that the author had dealt more critically with the conception of 'rejuvenescence,' a conception which smacks of 'Naturphilosophie' and is at most only an anthropomorphic 'Photographie des Problems.' The facts of parthenogenesis, both natural and artificial, appear flatly to contradict the assumption of Maupas and others that the temporary or permanent union of two exhausted cells results in one or two rejuvenated ones. This view was repudiated by Weismann on very good grounds several years ago.

The work of Calkins contains a classification of the Protozoa carried out to the families and genera. Unfortunately it is appended to three separate chapters and printed in such a form as to violate the very first rules of taxonomy. Classes, sub-classes, orders and suborders are all introduced in the same style of type and the various groups are coordinated in such a manner as to render a rapid and easy survey of the classification difficult, if not impossible. Taxonomy is the quintessence of our present morphological knowledge, and it is time that the prejudices of the narrow-gauge morphologist be not still further fostered by negligence in tabulating the essentials of the very science to which he is devoting himself with the characteristic myopia of one who sees not the forest because he is studying the venation of its leaves.

The volume is written throughout in a good, orderly style. Words like 'mononucleate' and 'unshelled,' in the sense of 'shell less' are conspicuously rare. The illustrations are clear, though occasionally too coarse for representations of such minute organisms. This is very

noticeable when they are compared with the delicate figures of Bütschli. Scarcely more than one tenth of the figures are original, and although the author has endeavored to avoid the commonplace in his selections from other writers, there is still a goodly array of the old and tiresome figures which seem to be as immortal as the Protozoa they represent, if one may judge from their perpetual metempsychoses in our zoological charts and text-books. The volume closes with an extensive, but by no means complete, bibliography and a good double index.

There can be no doubt that the volume should and will find a place in all our laboratories as a handy compendium of a marvelous group of organisms of basic importance in all our work in zoology, physiology and comparative psychology.

W. M. WHEELER.

Annual Report of the Chief of the Bureau of Steam Engineering. 1901. Washington, Government Print. 1901. 8vo. Pp. 70.

Admiral Melville reports in this document upon the condition and progress of the engineering branch of the United States navy, its personnel and material. The report is concise, clear, frank and illuminating. This Bureau has charge of all the machinery, of the navy, designs the engines, the boilers and machinery of the naval fleet, writes the specifications and contracts for such as may be built by private constructors, supervises the construction, makes the tests of completed machinery and has charge of the maintenance and repair of all such machinery. It expends \$3,000,000 to \$4,000,000 each year, mainly in repairs and preservation of the engines and boilers of the fleet. Of this work the report gives a detailed account, which is, however, not of special interest to the layman.

The new Naval Academy buildings, now under construction, are expected to cost about \$7,000,000. Admiral Melville asks that, of this total, about \$250,000 be applied to the construction of a laboratory for research in the physical sciences having direct application in engineering and marine construction. The building is to be two stories in height and 150 by 110 feet in plan, conforming in style of architecture

to the buildings, planned for the Academy, now in progress. It is proposed to appropriate \$150,000 for its equipment. This enterprise, if perfected, is another step in the direction of conforming the plan and workings of the Naval Academy to those of the great technical colleges of the world, and especially in the incorporation into its curriculum of experimental work in research as well as professional instruction.

With the resources of the general government available, the comparatively small expenditures needed to make the military and naval academies professional schools of the highest class, not only, as previously, in their organization and administration, but also in their equipment and in a complete and thoroughly modern curriculum, should be readily obtained, and these schools should take their rightful places as ideal, representative and model professional schools, in the extra-professional departments as well as in those which are purely vocational. In the applied sciences, particularly, they should be made perfect exemplars of the type which every civil as well as naval and military institution of learning should approximate as closely as means and the character of its faculty may permit.

Admiral Melville is pioneering here as effectively as when within the arctic circle and more usefully than ever did any explorer. He demands that the scientific departments of the Naval Academy, and especially the professional engineering division, be 'placed upon an equality with several universities whose colleges of mechanic arts and science in equipment far surpass the engineering outfit of the academy plant.'

The staff for this laboratory is to be organized from cadets and their teachers with, perhaps, one of the officers of the old engineer corps as its director. It is not only to be used in the investigation of the technical problems of the engineer department and of the naval service, but in the furtherance of the schemes of inventors where promising to be useful to the government or the public, also in testing all the appliances related to naval work; the materials and apparatus purchased by the Navy Department; and in the investigation of

especially important questions, such as relate to the economy of liquid fuel, the value of the steam-turbine, the form and proportions of propellers, the use of electricity and the value of electric apparatus and transmissions, the causes and preventions of corrosion of boilers, condensers and machinery, the best forms of boiler, the balancing of engines, the development of a storage battery suitable for naval use and the use of compressed air and of gas and oil engines.

The splendid work of the laboratories of the colleges and technical and professional engineering schools of our own country and, particularly, of Germany is referred to as illustrating the promise of this enterprise.

The Chief of Bureau devotes some space to the subject of the personnel and the organization of the naval establishment, stating that the 'Personnel bill' has thus far failed of complete and satisfactory result and asserting that it can only be expected that its purpose will be effected when the officers of the navy of every class cordially unite to carry its provisions into effect completely and efficiently. He quotes Mr. Roosevelt, who, in the original report upon this plan, asserted 'every officer on a modern war vessel has to be a fighting engineer.'

The union of the engineer corps with the line of the navy, however, has not been a complete success, so far as intended to provide the service with a body of officers equally at home above and below decks and capable of efficiently handling the great 'war-engine' in its every department and detail. The young officers should be given large and responsible charge of work in the engineering departments and trained as experts; otherwise that failure which was anticipated by many friends of the navy during the discussion of the bill, as a possibility if not a probability, must be looked for as certain.

It is stated that for every three officers taken from the engine-room for duty on deck, only one has been transferred from deck to engine-room, and the vitally essential care of motive power is coming thus to be impossible; unless, indeed, a radical change of method be adopted. The 'engineer's war-engine,' according to Roosevelt, must be in the care, each in his

province, of a crew of officers and men competent, individually as well as collectively, to handle its complicated and costly machinery with efficiency and economy. Thus far the new provision of law has not insured even the maintenance of the former efficiency of the great machine. The condition is critical and the Chief of Bureau shows courage as well as discretion in his discussion of the subject.

R. H. THURSTON.

Roscoe-Schorlemmer's Lehrbuch der organischen Chemie. Von JUL. WILH. BRÜHL, Professor an der Universität Heidelberg. Sechster Theil, bearbeitet in Gemeinschaft mit Eduard Hjelt und Ossian Aschan. Braunschweig, Friedrich Vieweg und Sohn. 1901. Pp. xxxix + 1045. Price (bound), M. 24.

This is the eighth volume of the German edition of Roscoe and Schorlemmer's 'Treatise on Chemistry,' and is the sixth part of the portion dealing with organic chemistry. It includes a consideration of the vegetable alkaloids, glucosides and bitter principles, natural coloring matters, chlorophyll, lichen substances and such indifferent bodies of vegetable origin as have not been considered in previous volumes.

Somewhat more than one half of the volume is given to the alkaloids. The primary classification of these is based on the group characteristic of their structure. This gives the pyrrolidine, pyridine, quinoline and isoquinoline groups and a group containing alkaloids of unknown structure. Within each group they are further classified in accordance with the plant or family of plants from which they are derived, this latter classification depending on the well-known fact that alkaloids found in the same plant, and often those found in different plants of the same family, usually have closely related structures.

About one fourth of the book is given to the glucosides and about eighty pages are given to chlorophyll and the same number to lichen substances. The discussion of chlorophyll is especially full and satisfactory and includes a good bibliography of the subject. In this portion, especially, the needs of the biologist as well as of the chemist have been considered.

The general plan of the work includes a historical account of the discovery and study of the more important substances considered. While it lays no claim to that exhaustive completeness in detail which is characteristic of Beilstein's Handbook, it is much easier to secure from it a knowledge of the present views of the structure of particular compounds, and of the basis on which such views rest. Considerably more space is given to the alkaloids than is devoted to the same topic in Beilstein. The book covers the literature of its subject up to a very recent date and the information to be found in it is very reliable and satisfactory.

W. A. NOYES.

SCIENTIFIC JOURNALS AND ARTICLES.

THE first number of the first volume of the *American Journal of Anatomy* was published on November 7, its contents being as follows:

'The Development of the Limbs, Body-wall and Back': CHARLES RUSSELL BARDEEN and WARREN HARMON LEWIS.

'The Intralobular Framework of the Human Spleen': PRESTON KYES.

'Studies on the Neuroglia': G. CARL HUBER.

'The Normal Histology of the Human Hemolymph Glands': ALDRED SCOTT WARTHIN.

'On the Morphology of the Pineal Region, based upon its Development in *Acanthias*': CHARLES SEDGWICK MINOT.

THE editorial board, consisting of Lewellys F. Barker, University of Chicago; Thomas Dwight, Harvard University; Simon H. Gage, Cornell University; G. Carl Huber, University of Michigan; George S. Huntington, Columbia University; Franklin P. Mall, Johns Hopkins University; Charles S. Minot, Harvard University; George A. Piersol, University of Pennsylvania, and Henry McE. Knower, Secretary, Johns Hopkins University, have sent with the first number the following prospectus: *The American Journal of Anatomy* has been founded to collect into one place, and present in a worthy manner, the many researches from our investigators, now scattered through many publications at home and abroad. Human anatomy in America needs as high a standard of reference as it has in other countries. Without such a standard it fails to make for itself any proper,

satisfactory or stimulating impression. The best interests of modern scientific medicine will be greatly advanced by the upholding of such a standard in this fundamental subject through a journal of high character. Many aspects of comparative anatomy, embryology, histology and cytology are so intimately bound up with the problems of human anatomy that these subjects will be included within the scope of the new journal. It will be the aim of *The American Journal of Anatomy* to recognize this close natural relationship between the various branches of the science, and to publish results of the best original work of American students of anatomy. The most cordial assurance of support has been given by the collaborators, and this we believe is sufficient indication of the results to be expected. A number of generous persons, whose names will appear later, have given some financial support to help us in gaining a foothold in a suitable manner. The journal must, however, look to those who are to be benefited by its publication for its real and permanent support; and a good list of regular subscribers is expected and required to maintain it. It is hoped that those interested in promoting a worthy development of research in America, in the subjects included within the scope of this journal, will energetically assist us.

THE October number of the *American Geologist* contains a number of interesting articles. John A. Dresser writes on 'The Petrography of Shefford Mountain.' The mountain discussed is one of a series of volcanic hills in the St. Lawrence Valley about fifty miles east of Montreal, Canada. The author concludes that the mountain is a laccolith, and that it contains three different flows represented by three different classes of rocks, viz: essexite, nordmarkyte and pulaskite. 'Paleontological Speculations,' by S. P. Gratacap is a continuation of a discussion begun in a number of a preceding volume. Mr. Warren Upham discusses 'Niagara Gorge and Post Glacial Time,' in which he gives some reasons based on recent investigations for estimating the duration of the Niagara River at 7,000 years. It is claimed that this estimate is more in harmony with estimates from other sources by Winchell,

Andrews, Emerson and others, than the longer period usually ascribed to this work. A 'Note on Certain Copper Minerals,' by A. W. Winchell, describes chalcopyrite and bornite found as an accidental furnace product replacing the iron rails in a calciner at a copper mine in Montana. The editorial comment includes an obituary notice with a short biography of Edw. W. Claypole, of Pasadena, California.

THE first number of a journal devoted to biological chemistry, entitled *Beiträge zur chemischen Physiologie und Pathologie—Zeitschrift für die gesammte Biochemie*, and edited by Dr. Franz Hoffmeister, professor of physiological chemistry at Strassburg, was issued recently. Its appearance may be interpreted as the outcome of the increasing application of chemical methods to the solution of biological and pathological problems.

SOCIETIES AND ACADEMIES.

NATIONAL ACADEMY OF SCIENCES.

THE National Academy held its autumn meeting at the University of Pennsylvania, Philadelphia, on November 12, 13 and 14. The papers entered to be read were as follows:

'Note on Linear Force exerted by Growing Crystals': GEORGE F. BECKER.

'Note on the Orogenic Theory of Tilted Blocks': GEORGE F. BECKER.

'On the Vaso-motor Supply of the Lungs': HORATIO C. WOOD, JR. (Introduced by George F. Barker.)

'Biographical Memoir of Frederick Augustus Genth': GEORGE F. BARKER.

'On the Pseudo-catalytic Action of Concentrated Acids': JAMES M. CRAFTS.

'On the Use of the Stereographic Projection in Making Accurate Maps; with Criticism of some Recent Methods of Map Projection': SAMUEL L. PENFIELD.

'On the Logic of Research into Ancient History': CHARLES S. PEIRCE.

'Observations on Tungsten': EDGAR F. SMITH.

'The Monatomic Gases': GEORGE F. BARKER.

'Snake Venom in Relation to Hæmolysis, Bacteriolysis and Toxicity': S. WEIR MITCHELL and SIMON FLEXNER.

'The Tendency of Complex Chemical Radicals to control Crystallization because of their Mass Effect; a Study in Isomorphism': SAMUEL L. PENFIELD.

'On the Nature of the Double Halides': IEA REMSEN.

'Biographical Memoir of General John Newton': CYRUS B. COMSTOCK.

'Dolichocephaly and Brachycephaly as the Dominant Factors in Cranial Evolution': HENRY F. OSBORN.

'Cranial Evolution of *Titanotherium II.*': HENRY F. OSBORN.

'Latent or Potential Homology': HENRY F. OSBORN.

'A New Gauge for the Direct Measurement of Small Pressures': EDWARD W. MORLEY and CHARLES F. BRUSH.

'Transmission of Heat through Vapor of Water at Small Pressures': EDWARD W. MORLEY and CHARLES F. BRUSH.

'On the Newer Forms of Incandescent Electric Lamps': GEORGE F. BARKER.

'On Quadrant Electrometry with a Free Light Needle highly charged through a Conductor of Ionized Air': CARL BARUS.

'On Nuclear Condensation in the Vapor of Non-Electrolytes like Benzene; and on Graded Condensation': CARL BARUS.

'The Work of the International Association of Academies': HENRY L. BOWDITCH.

'A Method of Rearing Marine Larvæ': CASWELL GRAVE. (Introduced by William K. Brooks.)

THE ACADEMY OF SCIENCE OF ST. LOUIS.

AT the meeting of the Academy of Science of St. Louis, on the evening of November 4, 1901, Professor Alexander S. Chessin spoke 'On the Motion of a Top, taking into Account the Rotation of the Earth,' giving an abstract of his researches on the earth's rotation as manifested in the motion of bodies on its surface, the details of which he hoped to present shortly in a series of papers.

Two persons were elected to membership in the Academy.

WILLIAM TRELEASE,
Recording Secretary.

THE ELISHA MITCHELL SCIENTIFIC SOCIETY.

THE 137th meeting of the Society was held on November 12, 7:15 P. M., in the chemical lecture room, Person Hall, University of North Carolina. The following papers were read:

'A Short Cut Percentage Calculation': E. V. HOWELL.

'Cold Light': J. W. GORE.

CHAS. BASKERVILLE,
Secretary.

DISCUSSION AND CORRESPONDENCE.

PHYSIOLOGICAL EFFECTS OF DIMINISHED AIR PRESSURE.

TO THE EDITOR OF SCIENCE: In a communication published in SCIENCE for November 1 (p. 696), Mr. H. H. Clayton, of Blue Hill Observatory, gives some observations on the number of his pulse-beats, noted during a recent ascent of Pikes Peak by railroad. The pulse increased from 78 beats per minute at Manitou (6,662 ft.) to 92 at the summit of the mountain (14,147 ft.). Mr. Clayton's note recalls some similar observations made by the writer in Peru in 1897, during two ascents of El Misti (19,200 ft.), then the site of the highest meteorological station in the world, established by Professor S. I. Bailey, and operated by the southern station of the Harvard College Observatory at Arequipa. Both ascents were made on mule-back, so that no physical exertion was necessary. The first ascent was on October 7, the start being from the Observatory (8,050 ft.) on October 6. Although provided with clinical thermometers and with a sphygmograph, the writer suffered so severely from mountain sickness that he made very little use of his instruments. His temperature at 5:30 p. m., October 5, twelve hours before leaving Arequipa, was $98^{\circ}.4$; his respiration 24, and his pulse 90. On the summit of El Misti the body temperature was $96^{\circ}.4$; the respiration 34, and the pulse 110. Twelve hours after arrival at Arequipa the figures were $98^{\circ}.0$, 24 and 85 respectively. A rather unsatisfactory sphygmograph curve was obtained on the summit.

The second expedition to El Misti was made on November 9, 1897, and on this trip the writer suffered much less from mountain sickness than on the previous one. At an altitude of 15,700 ft. a short walk of about 100 yards was taken to the instrument shelter. Two stops were necessary on the way, to get breath. An hour after this exercise, the pulse was 128, the body temperature $97^{\circ}.0$, and the respiration 30. The corresponding figures twelve hours before leaving Arequipa were 91, $98^{\circ}.6$ and 20. The night was spent at 15,700 ft. The body temperature immediately after waking in the morning was $96^{\circ}.2$; the pulse 112, and the respiration 30. Twenty minutes

after reaching the summit, the temperature was $97^{\circ}.2$, the pulse 120, and the respiration 32. In an hour and a half the respiration was 35, the pulse and temperature remaining the same. In two hours the temperature was $96^{\circ}.8$, the pulse 112, and the respiration 34. Three fairly good sphygmograph curves were obtained on the summit. These curves possess some interest as being, so far as I have been able to learn, the first, with possibly one exception, to be secured at so great an altitude as 19,200 ft. At any rate, no curve from so great an altitude was reproduced until a copy of one of these tracings from the Misti summit was printed in an article by the writer in the *Journal of the Boston Society of Medical Sciences* for June, 1898.

On the second expedition to El Misti the descent was begun two hours and a half after reaching the top. At the hut at the base of the mountain (15,700 ft.), after walking to and from the shelter, the pulse was 130, but the respiration had decreased to 30. One hour after arriving at Arequipa the temperature was $98^{\circ}.2$, the pulse 116, and the respiration 22, and twelve hours after arrival the pulse had fallen to 82—about the writer's normal at the Observatory—and the respiration to 22, the normal being 20.

In counting the pulse on the summit it was quite unnecessary to place the finger on the wrist. The heart-beats could plainly be heard.

PRACTICAL AMELIORATIONS OF ENGLISH GRAMMAR.

EVERY year or so a 'practical grammar' of our mother-tongue is announced as on the eve of publication, and, when the book appears, every teacher and student who had been hoping for some real progress in ridding the language of the impedimenta of barbarism and the useless paraphernalia inherited from classical schematism, experiences a keen sense of disappointment.

Perhaps the greatest intellectual feat so far accomplished by English-speaking peoples all over the globe has been to free their mind-tool so largely from the shackles of grammar. So much having been done already in this direc-

tion, we ought to make further advances toward ideal speech. All such advances will serve English well in the struggle for adoption as the world-language, for the more cosmopolitan, the less grammatical, in the classical sense, must it be.

It needed no prophet to foretell the fate of Latin as a would-be international tongue. In the nature of the case, it could never be more than the artificially propagated and sustained speech of more or less extensive and widely scattered societies, cliques, clubs and associations (political, religious, scientific, etc.), for the mind of the Aryan and Semitic races was capable of something higher than speaking through a death-mask, and other populous nations have also to be reckoned with—nations like the Chinese, Japanese, Malays, Hindus—who cannot be expected to welcome a dead language over against a live one. Evolution, too, has written a like epitaph over Greek, which some enthusiasts would fain have us accept as a universal language. No such backward step is probable or even possible. Against all competitors in the field, English is favored by its increasing degrammatization and the open hospitality it extends to new words from every language under heaven.

Phonetic spelling must triumph in the end, and as complete a victory waits also for free speaking and free writing—*i. e.*, language untrammelled by grammatical artificialities. Not a backward-looking Volapük, but English with its face to the future foreshadows the true world-language. Phonetic spelling has already made a good beginning, which suggests the possibility of similar intentional reforms in English grammar. The present writer will content himself with specifying certain ameliorations of grammar, which, perhaps, may serve, like the ten 'rules' for amended spelling proposed in 1883 by the English and American Philological Associations, or the list reported by the American Committee in 1886, as starters for more ambitious movements of reform.

The list is as follows :

1. Drop the so-called *subjunctive mood* altogether. It is moribund in much of our best prose, and can be allowed to die out of our

poetry with no injury to rhyme or reason, strength or beauty.

2. Drop *inflected forms for the past tense and past participle*, making all new verbs, whether introduced from foreign tongues or made within the language itself, conform to the type of *hit, let, etc.* In America, in particular, drop *gotten*.

3. Avoid the use of *differing forms for verb and noun*. Follow the model of *boycott*, under 'rule' 2.

4. Avoid the use of *plural forms of nouns*, making all new substantives, whether borrowed from other languages or born of the mother-tongue, conform to the model of *sheep, deer, etc.*

5. Avoid the use of *Greek or Latin names for 'new things.'* Follow the good example of certain scientists, and name them after their discoverer, the place of origin, etc. Make new words here conform to the model of *galling, ampere*, and the like.

6. Avoid the use of *feminine forms of nouns* previously employed with reference to males, letting the thought control the grammar. Drop particularly *authoress, poetess, etc.*

7. Avoid forming *adverbs by inflection*, using for all new words of this class the same form for adjective (or other word) and adverb.

8. Omit the conjunction *that* wherever possible. For example, in such cases as 'I know *that* he is dead.'

9. Use *but* and *as* as full-fledged prepositions.

10. Drop *whom*, using *who* for both cases.

11. Ceasing the attempt to distinguish between *who* and *that*, and *that* and *which*, let the fittest survive in each instance.

12. Use the pronouns compounded of *self* and their plurals, both as subjects and objects.

13. Drop the *apostrophe* in the *possessive case*.

Other suggestions might be made, but these cover sufficient ground for the present.

SHORTER ARTICLES.

CATALASE, A NEW ENZYM OF GENERAL OCCURRENCE.

THE study of the enzymes has been pursued with growing interest by a number of scientists during later years. These unorganized ferments being substances of a highly ephemeral

nature, the method of investigating them has departed somewhat from the paths usually followed in determining the composition, effects and rôle, of organic combinations in vegetable and animal organisms. The nature of the enzym is still a matter of much doubt. Of their action we are more sure, and it is along this line that we have become familiar with the nature of some members of this very interesting group of compounds. The rôle of the enzym in the life processes may also in some cases be defined with certitude.

Beginning with a few, the study of unorganized ferments has brought to light many others. Out of the growing number some are already put to important uses, while others bid fair to become of great value to many industries. Dr. Oscar Loew in his studies on tobacco (Rpt. No. 68, Div. of Veg. Phy. and Path. U. S. Dept. of Agr.) goes further in the study of unorganized ferments than ascribing to one a special rôle and shows the general distribution and seeks a reason for its existence of an enzym, to which he gives the name catalase.

In the work with this enzym, in which the writer took some part, the most striking characteristics were its very general dissemination, its persistence, and its ability to break down hydrogen peroxid. In the examination of a large number of animal and vegetable organs this enzym was found present, in greater or less amount, in every instance. Its differentiation from other unorganized ferments is established by a large number of tests with various reagents. Among other characteristics it was found to be more persistent than any other known enzym. This was especially noted in dried vegetable substance as seeds and leaves, being found present in a herbarium specimen of the latter examined after a lapse of over 50 years.

The ability of catalase to break down hydrogen peroxid appeared to be its most striking peculiarity, and this led the author to believe that it might perform such a service in the phenomena displayed by living matter. Tests go to show that it belongs to the class of oxidizing enzymes and its very general occurrence and uniform actions indicate that it plays some important rôle in physiological processes.

From his studies the author gives the following as the most plausible explanations of the action of catalase in vegetable organism: (1) It destroys instantly the hydrogen peroxid, probably formed in cells during the oxidation caused by the respiration process; (2) it loosens chemical affinities in certain compounds so that the protoplasm can more easily split or oxidize them. "In other words, catalase might represent an aid for fermentative as well as for respirative phenomena." D. W. MAY.

U. S. DEPARTMENT OF AGRICULTURE.

TOADS KILLED BY SQUASH-BUGS.

DURING the past summer the Entomological Department of the New Hampshire College Agricultural Experiment Station carried on investigations on the common squash-bug (*Anasa tristis*), which has been so abundant in some portions of the State the past season. Mr. Kirkland, in Bulletin 46, Mass. Agr. Exp. Sta., recorded the bug to have been found in the stomach contents of toads; Mr. Chittenden, in Bulletin 19, 1899 (New Series), U. S. Dept. Agr., states that Dr. Judd likewise found a bug in a toad's stomach. This suggested that the toad is probably an enemy of the squash-bug, and experiments, made to determine this, showed the following interesting results: When a squash-bug nymph of the fifth stage was suddenly introduced into a half pint, open, wide-mouthed specimen jar containing a half grown live toad, so that the Batrachian would get the full effects of the pungent fumes given off by the bug, the toad was thrown into a temporary stupor, the effect being similar to that of chloroform. As the number of bugs was increased the effect on the toad was increased. When as many as seven bugs were introduced the toad fell into a profound stupor and died in the course of twenty-four hours.

On September 8, an adult, that had been kept in the laboratory vivarium with a scant food supply for several days, was placed in a quart jar of the same construction as the one mentioned above, and eight bugs were introduced; these bugs, however, had been so much disturbed previously that the source of the pungent secretion had been temporarily exhausted. The toad hesitatingly devoured three, after

which she would remove with her front feet every specimen that made an attempt to ascend the wall of her enclosure; but these bugs were not eaten. The toad was then transferred to another jar of the same size and construction and eight bugs were suddenly introduced from the squash leaf so that the toad would get the first and fullest effects of the odor; the result was that the animal went through a series of contortions followed by a short period of stupor similar to that mentioned before. Upon recovery the toad was again removed to the vivarium where it now lives in partial hibernation.

A young red spotted salamander was affected and killed as easily as the half-grown toad, while for the common field frog a greater number of bugs were required to bring about similar effects, the frogs also being killed. Many experiments with snakes were tried, but no ill effects from the secretion of the bugs were apparent.

The odor that the bug gives off emanates from a clear, slightly greenish liquid expelled from the extremity of the alimentary canal; when it comes in contact with the air the odor is given off almost instantaneously while the liquid remains to evaporate.

These experiments are still in progress and when completed will be published in detail. They seem to open up an interesting field for investigation as to the protective value of the odoriferous secretions of many of the Heteroptera.

EXPERIMENT STATION, DURHAM,
October 29, 1901.

CURRENT NOTES ON METEOROLOGY.

THE WEATHER BUREAU.

THE address presented at the Convention of Weather Bureau officials, held at Milwaukee last August, by Professor Willis L. Moore, Chief of the Weather Bureau, is printed in the October number of the *National Geographic Magazine*. The salient facts in the history of the weather service are given, and special emphasis is laid on the tangible results of the Weather Bureau's work. It is a pleasure to see the name of Professor Cleveland Abbe, the fore-

most living American meteorologist, linked with the names of Redfield, Espy, Maury and Loomis in this article. Some of the statistics given by Professor Moore are worthy of note here. Thus, in the case of cold-wave warnings, the statement is made that 100,000 telegrams and messages are frequently distributed within a few hours. During one cold wave \$3,400,000 worth of property is estimated to have been saved as a result of the information issued by the Weather Bureau. The system of distributing warnings of gales dangerous to navigation is so perfect that "the Chief of the Weather Bureau, or the forecaster on duty at the Central Office, can dictate a storm warning and feel certain that inside of one hour a copy of the warning will be in the hands of every vessel master in every port of material size in the United States, provided that it is his desire that a complete distribution of the warning be made."

Reference is made to the important work of the Bureau in connection with measurements of snowfall in the high mountains of Montana, Wyoming, Idaho, Utah, Arizona and New Mexico, which make it possible to estimate the probable supply of water to be expected for irrigating purposes, and also to the recently inaugurated forecasts of wind direction and velocity for a period of three days after steamers sail from European or North American ports. At the conclusion of his article, the Chief of the Weather Bureau rightly criticizes the press for the attention it gives to the long-range forecast frauds, which deceive so many persons. Last year's appropriation of \$1,058,320 for the Weather Bureau was certainly small, considering the value of the work done.

MONTHLY WEATHER REVIEW.

THE *Monthly Weather Review* for July (issued in October) contains the usual number of interesting articles. In 'The Thunder-storm: A New Explanation of one of its Phenomena,' Byron McFarland gives his reasons for not accepting the common explanation of the origin of the squall wind in thunder-storms, viz., that this squall is due to the 'kick' of the rapidly ascending air, and advocates the theory that the cool air within the thunder-storm accounts for

the phenomena of the outflowing squall. A. L. Rotch contributes a short account of a meteorological balloon ascension in which he took part at Strassburg last July. Professor R. E. Dodge describes some diurnal winds in northwestern New Mexico, which are developed on very faint gradients. A translation, by Professor Cleveland Abbe, of the introduction to Marcel Brillouin's recent volume 'Mémoires Originaux sur la Circulation Générale de l'Atmosphère,' brings before American readers an excellent brief historical summary of the various important contributions made by Ferrel, Thomson, Siemens, and others, to the subject of the general circulation. 'Yukon Weather' is the title of a paper by U. G. Myers, Section Director of the Weather Bureau in Alaska. Professor Abbe, in his 'Notes by the Editor,' discusses the relation between the scientific work of the Weather Bureau and the long-range forecasts made by those who believe in lunar or stellar influences, and in this connection gives a translation of the paragraphs of Angot's 'Traité de Météorologie' which deal with this subject. An account of the Milwaukee convention of Weather Bureau officials concludes this number of the *Review*.

GEOLOGICAL CHANGES OF CLIMATE IN THE EASTERN CORDILLERAS.

A RECENT paper by Professor N. S. Shaler, on 'Broad Valleys of the Cordilleras' (*Bull. Geol. Soc. Amer.*, Vol. 12, 271-300), explains certain features of these valleys by an increased erosive action due to an ancient temporary increase of rainfall in preglacial time. The source of the larger part of the rainfall in the Mississippi valley drainage area is evidently in the basin of the Gulf of Mexico and the Caribbean Sea. When these waters were of greater extent, the evaporation from them might well have produced a much heavier rainfall over the Cordilleras than is now found there. There is evidence in the broad valleys of several oscillations of climate. At the present time the conditions of the eastern section of the Cordilleras indicate a recent return to an arid climate. The taluses are evidently increasing. "Unless the Gulf of Mexico," Professor Shaler concludes, "should again be brought over a considerable part of the southern lowlands, there seems to be no

reason to expect that there will be any increase of rainfall in this area."

TREE PLANTING ON THE PRAIRIES.

WILLIAM L. HALL, assistant superintendent of tree planting in the Division of Forestry, believes that the time has come for an extensive development of forest plantations throughout the Middle West, in consequence of the rapid diminution of the supply of natural timber in the Mississippi valley (Yearbook Dept. of Agriculture for 1900). Over extensive areas the prices of posts, telegraph poles and cross-ties much exceed the cost of growing them. This difference promises profit in timber growing. Ten years ago the area for profitable tree planting was, chiefly for climatic reasons, thought to be much smaller than it is now known to be. The past year has seen the establishment of nearly 100 plantations by individuals in co-operation with the Division of Forestry, and during the present year more trees will be planted than ever before. Mr. Hall believes that if 500,000 acres of timber, well distributed throughout the Middle West, were planted annually, the production would still be inadequate to meet the demand, and liberal profits could still be hoped for. R. DEC. WARD.

PROPOSED AMERICAN ELECTRO-CHEMICAL SOCIETY.

A MEETING was held on November 1 at the rooms of the Engineers' Club in Philadelphia, to discuss the question of the advisability of organizing a national electro-chemical society on the same general plans as the American Chemical Society and the American Institute of Electrical Engineers. Some twenty or thirty persons from different parts of this country, who were thought to be interested in the subject of electro-chemistry, had been asked to be present or to express their views by letter. Among the communications received, the majority, especially from the electrochemical industries, were in favor of the formation of such a society; the minority thought the time had not come yet for such a society, that the American Chemical Society and the American Institute of Electrical Engineers filled the needs, that there were already a number of other societies at which papers on this subject could be read, etc.

Those present included representatives from New York City, from the Cornell, Lehigh and Johns Hopkins Universities, from the American Chemical Society, the American Institute of Electrical Engineers, the Franklin Institute, etc. Professor J. W. Richards, vice-president of the American Chemical Society, acted as chairman, and Carl Hering, past president of the American Institute of Electrical Engineers, as secretary. All those present were heartily in favor; the only doubt expressed was whether a sufficient number of members could be obtained to make such a society a success. A committee was appointed, with Dr. Chas. A. Doremus, of the College of the City of New York, as chairman, to canvass for members; and if seventy-five or over pledge themselves to join, the society will be formed. In that case, certain committees which were appointed will arrange for holding a formal meeting at which the society will be founded and papers read and discussed. Anyone desiring to become a member is asked to communicate with Dr. Doremus at the above address.

It was furthermore decided to be the expression of those present that the name of the organization should be the American Electro-chemical Society; that the dues should not exceed \$5.00 per year, and that at first only a few meetings of a few days each should be held per year, and that they be held in different cities, as the society is to be a national one.

The fact that papers on the subject of electro-chemistry are now scattered over a half dozen or more existing national societies was thought to be in itself a very good reason for bringing them all together into one, where they could then be properly discussed, which is not now the case. Attention was also called to the fact that the annual electro-chemical products of this country already amount to nearly \$100,000,000, which is far greater than in all the other countries combined. Germany, which comes next with \$14,000,000, has a flourishing electro-chemical society with about 40 members in the United States.

THE UNITED STATES NAVAL OBSERVATORY.

THE board of visitors of the U. S. Naval Observatory, consisting of Professors C. A. Young,

C. F. Chandler, Asaph Hall, Jr., E. C. Pickering and Ormond Stone and President W. R. Harper, have recently held a meeting and submitted a report to Secretary Long. Extracts from the report published in the Washington *Evening Star*, are as follows:

"It is recommended that no astronomical director be appointed at present, as a dual headship has been found to work unsatisfactorily, and under the existing law the appointment of an astronomer as sole director of the observatory—which the board considers the proper solution of the question—is impracticable. Vacancies should not be filled among assistant astronomers nor among professors of mathematics in the navy without examination for each vacancy occurring. No distinction should be made between employees of the observatory and other applicants. The responsibilities of the positions of assistant astronomer and professor of mathematics are distinctly different from those of computer, although much of the required experience may properly be gained in connection with the latter position and be credited in the examinations for the higher positions. As far as is consistent with the routine needs of the institution, the duties of the computers should be so arranged as to encourage them to prepare for advancement within the observatory itself. In no case should appointments be made to the observatory merely by transfer from other bureaus or offices in the service, nor should appointments ever be made even temporarily without competitive examination."

Applying these principles to practice the board declines to name a person to fill the vacant office of assistant astronomer at the observatory and instead recommends that the appointment be made after a civil service examination under the auspices of the commission.

Coming to the more important subject of the actual head of the observatory, which involves the issue between the scientists and the line officers, the board says:

"As every other prominent observatory is under the direction of an astronomer, we wish to record our deliberate and unanimous judgment that the laws limiting the superintend-

ency to a line officer of the navy should be changed so as to provide that the official head of the observatory—perhaps styled simply the director—should be an eminent astronomer appointed by the President, by and with the advice and consent of the Senate, holding this place by a tenure at least as permanent as that of the superintendent of the coast survey, or the head of the geological survey, and not merely by a detail of two or three years' duration. Only in this way can there be a continuous and effective policy of administration which will insure astronomical work of a high order. In rank, salary, privileges and prestige he should be superior to any other official on the ground.

“The limitation in the selection of assistants should also be removed, and the assistant once appointed should be secure against detachment or removal except by the action, for cause, of the director. The institution should be related to the Navy Department, if continued under its control, in some such way as the Royal Observatory at Greenwich is related to the British admiralty. It should be put under the control of the secretary directly, and not through a bureau as at present.”

In conclusion the Board finds objection to the manner in which appropriations have been made in support of the observatory, saying that it is not easy to determine what portion of the expenditures pertains properly to astronomical work, what portion to the naval work, and what portion to the improvement and care of the grounds as a part. The cost of maintenance for the last fiscal year was \$108,428, of which amount \$21,258 was expended in salaries.

SCIENTIFIC NOTES AND NEWS.

DR. J. WILLARD GIBBS, of Yale University, has been awarded the Copley Medal of the Royal Society for his contributions to mathematical physics.

HENRY M. HOWE, professor of metallurgy at Columbia University, has been elected an honorary member of the Russian Technical Society at St. Petersburg.

DR. E. A. DE SCHWEINITZ, dean of the Columbian University Medical School and direct-

or of the Biochemic Laboratory, U. S. Department of Agriculture, has recently been elected a corresponding member of the Epidemiological Society of London, and also of the ‘Society for Combating Tuberculosis,’ of Berlin.

PROFESSOR WILLIAM F. WILLOUGHBY, recently expert in the U. S. Department of Labor and now of Harvard University, has been appointed treasurer of Porto Rico.

PROFESSOR LUIGI PALAZZO has been appointed director of the Central Meteorological and Geodetic Institute at Rome.

DR. VON WETTSTEIN, of the University of Vienna, who was sent by the government to study the flora of Brazil, has returned.

It is stated by the Berlin correspondent of the *Times* that Professor Paul Ehrlich, of Frankfurt-on-the-Main, has been enabled to devote himself to a special study of the disease of cancer in consequence of a bequest of the interest for three years of a sum of 500,000 Marks dedicated to this purpose by a Frankfurt banker, the late Herr Theodor Stern. Other sums contributed by private individuals will bring up the amount to be devoted to this special investigation of cancer by Dr. Ehrlich to 40,000 Marks, or \$10,000 a year. In Berlin there exists a special committee for the investigation of cancer, which studies pathological accounts of cases and collects statistics and medical literature on this subject. Professor von Leyden is at the head of the committee, and Professor von Kirchner, of the medical department of the Ministry of Public Instruction, is one of its members.

THE Craig Colony Prize of \$200 has been awarded to Professor Carlo Ceni, of Pavia, Italy, for an essay, entitled ‘Serotherapy in Epilepsy.’

AT the scientific meeting of the Zoological Society of London, on November 19, papers were read by Professor Ray Lankester, on ‘*Okapia*, a New Genus of Giraffidæ from Central Africa,’ and by Mr. Oldfield Thomas ‘On the Giraffe discovered by Sir Harry Johnston near Mount Elgon, Central Africa.’

THE work of putting in place at Wood’s Holl a boulder to serve as a memorial to the late Professor Spencer F. Baird is now completed.

The erection of this monument is the outcome of the action of the American Fisheries Society at a meeting held at Wood's Holl in the summer of 1900, when resolutions presented by Dr. H. M. Smith, providing for an appropriate memorial to Professor Baird, were unanimously adopted. The boulder is of granite, weighs about six tons, and was taken from the shores of Nonamesset Island by permission of Mr. J. Malcolm Forbes, whose father, the late John Murray Forbes, manifested great interest in the establishment and work of the station. The memorial will be completed when a suitably inscribed artistic bronze tablet is attached to the stone. This will probably be deferred until next spring.

A MEDALLION in memory of Dr. W. Kühne, formerly director of the Physiological Institute, was unveiled at the University of Heidelberg on October 20.

PROFESSOR RICHMOND MAYO-SMITH, since 1883 professor of political economy and social science at Columbia University, died, as the result of a fall, on November 11. He was born in Ohio in 1854 and graduated from Amherst College in 1875. Professor Mayo-Smith was the author of numerous important contributions to statistics and other departments of political economy, including books on 'Emigration and Immigration' (1890), 'Sociology and Statistics' (1895) and 'Statistics and Economics' (1899). He was the only representative of political science in the National Academy of Sciences.

THE death is announced of Professor Ralph Tate, since 1876 professor of natural science in the University of Adelaide. He was the author of numerous papers on geology and zoology and was in 1893 president of the Australasian Association for the Advancement of Science.

DR. ALEXANDER HUGHES BENNETT, the eminent physician, known for his work on diseases of the nervous system, died in London on November 1, at the age of fifty three years. On his special subjects of epilepsy and paralysis he had written largely, and was the author of the well-known 'Practical Treatise on Electro-diagnosis in Diseases of the Nervous System,' and of the smaller text-book founded upon that work.

MR. HENRY SPENCER SMITH, one of the original fellows of the Royal College of Surgeons, London, died on October 29, at the age of eighty-eight years. Mr. Smith was secretary to the first government inquiry into the pathology and treatment of contagious diseases, and was a fellow and formerly vice-president of the Royal Medico-Chirurgical Society. He contributed frequently to the medical journals and translated several works, including Professor Schwann's work on 'Microscopical Researches into the Accordance in the Structure and Growth of Animals and Plants,' which obtained for its author, in 1845, the award of the Copley Medal of the Royal Society of London.

WE also regret to record the deaths of Dr. Marcel Nencki, professor of biological chemistry in the University of St. Petersburg, at the age of 56 years; of Professor Max Märcker, director of the Agricultural Experiment Station at Halle, at the age of 59 years, and of Professor Miguel Colmeiro, director of the Botanical Gardens at Madrid, at the age of 86 years.

MR. ANDREW CARNEGIE has given \$1,000,000 as an additional endowment of the Carnegie Institute and has added \$1,000,000 to the million dollars he has already given toward an endowment of the Carnegie Polytechnic Institute, to be erected at Pittsburg. Mr. Carnegie has also offered \$50,000 to Springfield, Mo., for a free public library building.

A NEW YORK State civil service examination will be held in various cities throughout the State on or about December 7, 1901, for the position of director of the New York State Pathological Institute, with a salary of \$5,000. The subjects and weights for the examination are: Pathological anatomy of the nervous system, technique and methods of neural investigation, architecture of the nervous system and lines of research to be applied to the study of the pathology of insanity, 8; experience, 2. The position is open to non-residents of the State, subject to the provision that if the eligible list contains the names of three or more persons who are citizens and residents of New York State, such persons shall be preferred in certification over non-residents. Examinations will also be held for the positions of assistant

in the Antitoxin Laboratory, and assistant bacteriologist, both in the Department of Health, at salaries of \$750 and \$500, respectively. The former position is open only to women, and subjects of examination and their relative weights are as follows: Bacteria, their nature, position among other living objects, functions, classification, principles of bacteriological manipulations, methods of making and testing culture media, sterilization of instruments and media, preparation of diphtheria toxin, etc., 8; experience and education, 2. The position of assistant bacteriologist is open only to licensed medical practitioners of New York State. The incumbent must give half his time to the work, which must be the first charge on his time. The examination will cover general knowledge of bacteriology and special knowledge of the methods and problems of the preparation of diphtheria and other antitoxins.

THE U. S. Civil Service Commission announces that at the request of the Board of Visitors to the United States Naval Observatory, an examination will be held on December 11, 12, 13, 1901, at various places throughout the United States, for the position of assistant astronomer in the U. S. Naval Observatory, at a salary of \$1,800 per annum.

The subjects and weights are:

Pure mathematics, practical and spherical astronomy, celestial mechanics, general mechanics, optics, and French and German.....	20
Experience (a) in making astronomical observations, (b) in making astronomical computations, (c) in making and repairing, mounting and dismounting, and in caring for astronomical instruments, including auxiliary apparatus.....	40
Ability to carry on original astronomical investigations, as evidenced by printed or written memoirs, certificates, etc.....	40
Total.....	100

The examination on the technical subjects first named will be entirely of a scholastic character and will occupy three days. Under the second and third subjects applicants will be expected to submit evidence of their experience and ability. This evidence should be full and complete. Age limits, 20 to 45 years.

A TELEGRAM has been received at the Harvard College Observatory from Professor W. W. Campbell at Lick Observatory stating that from a Crossley photograph, Professor Perrine finds that four principal condensations in faint nebula surrounding Nova Persei moved southeast one minute arc in six weeks. Professor G. E. Hale, from the Yerkes Observatory, reports that from photographs of Nova Persei on November 9 Ritchey finds the nebula probably expanding in all directions, this certainly being true of the southern half.

AN international sanitary congress will be held in Paris during the week of February 15-21, 1902. Among the subjects to be discussed will be the rôle of mosquitoes in the spread of yellow fever, malaria and filariasis, quarantine, and the value of municipal sanitation in the prevention of epidemics.

THE Institution of Junior Engineers opened its winter session on November 1, at the Westminster Palace Hotel. The new President, Sir John Jackson, was installed, and delivered his inaugural address, in which he dealt chiefly with the relations between employers and employed.

THE biennial dinner of the Physical Society of London will be held at the Hotel Cecil on Friday, November 15.

WE learn from the *Journal of the American Medical Society* that it is proposed to unite the scientific institutes at Hamburg under one direction, somewhat in the form of a university, and the directors and lecturers will compose the faculty, issue reports, etc. The official title of the faculty will be the 'Professorenconvent' of the Scientific Institutes. Besides promoting individual research, the institutes will carry on research desired by men of science and advise in scientific matters generally.

PREPARATIONS are being made for the despatch of a new Norwegian expedition to determine more exactly the position of the north magnetic pole. The expedition will be under the direction of M. Amundsen, a Norwegian, who was one of the officers in M. Gerlache's Antarctic expedition.

A CABLEGRAM to the New York *Sun* states that a striking discovery has been made during

excavations which were necessary to raise one of the monoliths in the famous prehistoric group at Stonehenge in Wiltshire into an upright position. The men engaged in the work have found numerous neolithic implements, which had evidently been used in cutting and squaring the stones, and, when blunted, had been turned into the bedding on which the stones are supported. The discovery is held to prove that the unique spectacle of Stonehenge is anterior to the Bronze Age and that the structure still visible was certainly built before 1500 B. C.

FOREIGN journals give particulars respecting a new meteorological station which has been established at Achariach, in Glen Nevis, Scotland. The situation is such that a spur of Ben Nevis shuts in the valley to the west, and the height above sea-level is only 165 feet. The intention of the founder of the station—Mr. R. C. Mossman of Edinburgh—is ‘to study the thermal conditions in the valley and on the adjacent hillsides during anticyclones in winter.’ It seems that in calm, cold weather and with a high barometer it not seldom happens that the mountain summits are much warmer than the valleys which are filled with cold air chilled by radiation from the surrounding hills. The height to which this lake of cold air extends is to be the principal subject of investigation. The station is well equipped with a complete set of the best instruments.

THE London *Times* calls attention to the fact that the late M. I. C. Jacobsen presented to the State or spent for scientific or philanthropic purposes nearly 20,000,000 kroner. He created the ‘Carlsberg Fund,’ which now amounts to 12,500,000 kroner and recently celebrated the 25th anniversary of its foundation. On this occasion his son, M. Carl Jacobsen, has added as a donation his own brewery, only reserving for himself and his family one third of the income for fifty years. The value of this gift is calculated at 10,000,000 kroner. M. Carl Jacobsen two years ago presented Copenhagen with what was certainly the largest private collection of sculptures in the world—its value being 12,000,000 kroner—and with many other large donations.

WE learn from the *Auk* that the large collection of birds’ eggs, nests and skins brought together by Miss Jean Bell, of Ridley Park, Pa., has been purchased by Mr. John Lewis Childs, of Floral Park, New York. It is said to contain about 30,000 eggs and 1,000 nests, and is reported to be one of the finest and most complete private collections of North American birds’ eggs extant. It includes many rarities, and is rich in large sets of comparatively rare species, the collection having been formed through the combination of several noteworthy private collections.

THE program for the forthcoming session of the Royal Geographical Society of London is announced as follows: At the opening meeting, on November 11, Sir Harry Johnston proposed to give a paper on Uganda and the bordering countries, through which he made several journeys in his capacity as special commissioner. Not only will the paper be illustrated by a large number of slides, including a colored one of the Okapi, but Sir Harry will give phonographic reproductions of the songs of the natives. At the second meeting, on November 25, the president, Sir Clements Markham, will give a short opening address, and he will follow that with a paper on King Alfred and the geography of his time. During the evening Dr. Vaughan Cornish will give an extremely interesting cinematographic representation of the Bore of the Severn. The paper at the meeting on December 9 will be by Mr. Douglas Freshfield, on the ‘Glaciers of Kauchinjunga,’ the results of his recent expedition to that vastly interesting region; it will be illustrated by many lantern slides, mainly from photographs taken by Signor Sella, who accompanied the expedition. Among the papers to be expected after Christmas are the following: ‘An Expedition across Abyssinia, through Kaffa and the Region to the West and North,’ by Dr. Oscar Neumann; the ‘Maldives,’ by Mr. J. Stanley Gardiner; ‘Journeys in Western China,’ by Dr. R. L. Jack; ‘The Influence of Geographical Conditions on History and Religion, with Special Reference to Asia Minor,’ by Professor W. M. Ramsay; ‘Four Years’ Travel and Survey in Persia,’ by Major Molesworth Sykes; ‘An Expedition from Omdur-

man to Mombasa by Lake Rudolf,' by Major H. H. Austin; 'Southwards on the Antarctic Ship *Discovery*,' by Mr. George Murray, F.R.S., and Dr. Hugh Robert Mill; 'A Journey from Quetta to Meshed by the New Nushki Trade Route,' by the Earl of Ronaldshay; 'The Bedford Level and Experimental Demonstration of the Rotundity of the Earth,' by Mr. H. Yule Oldham; 'The Snows of Canada,' by Mr. Vaughan Cornish; 'Antarctic Glaciation,' by M. Henryk Arctowski, and 'Methods and Appliances in the Teaching of Geography,' a special lecture for teachers, by Mr. A. W. Andrews. The paper by M. Arctowski will be given at an afternoon meeting, while Mr. Andrews's lecture will be given at a special meeting on a date and at an hour likely to be convenient to teachers in and around London.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. WILLIAM WYMAN announces that \$750,000 has been raised of the \$1,000,000 necessary to make available his offer to the Johns Hopkins University of 60 acres of land in the Northern Annex. Mr. William Keyser gave \$200,000 of the amount. The names of all the contributors to the fund will not, however, be announced until it is complete.

KENYON COLLEGE has received from various sources \$100,000 towards its endowment and \$50,000 for a new dormitory.

AN industrial college for women, to be called The Simmons Female College, will be shortly established in Boston, in accordance with a bequest made by John Simmons in 1875. The estate, which was subject to a life interest, now amounts to over \$2,000,000.

MR. B. F. BARGE, B.A. (Yale '57), has added \$2,500, to the same sum given by him recently to Yale University. The money is to endow a mathematical fund.

BY the will of the late E. P. Barker, Amherst College and Alfred University each receive \$1,000.

MR. and MRS. E. C. THOMPSON, of Indianapolis have added \$20,000 to the \$10,000 previously given by them to Butler College in that

city, for the construction of the Bona Thompson Library, as a memorial to their daughter.

MR. B. A. PALMER, of New York, has made a gift of \$30,000 to Union Christian College, Merom, Ind.

DRURY COLLEGE, at Springfield, has received \$8,000 from E. A. Goodnow, Esq., of Worcester, Mass., for scholarships for young women.

THE Duke of Sutherland has decided to erect a large technical school near Golspie, Sutherland. Building and equipment will cost £10,000, and in order to place the institution in an independent position it is said that Mr. Carnegie has offered another £10,000 as an endowment.

MRS. FITZPATRICK has given £2,000 to found a lectureship on the history of medicine, in the Royal College of Physicians, London, in memory of her late husband, Dr. Thomas FitzPatrick.

THE Horace Mann school building of Teachers College, Columbia University, will be dedicated on December 5. The principal address will be by ex-President Daniel C. Gilman, of the Johns Hopkins University.

EDWARD P. HYDE, A.M. (Johns Hopkins, 1900), has been given a fellowship in physics in the Johns Hopkins University.

MR. R. P. PARANJPYE, who was bracketed senior wrangler in 1899, has been elected to a fellowship at St. John's College.

DR. HANS SOLEREDER, of Munich, has been appointed professor of botany and director of the Botanical Institute at the University at Erlangen. Dr. V. Schiffner, associate professor of systematic botany in the German University at Prague, has been called to a similar position in the University of Munich. A full professorship of astronomy in the University of Göttingen has been offered to Dr. Karl Schwarzschild, docent at Munich. Dr. G. Kowalewski, docent in mathematics at Leipzig, has been called to an associate professorship in the University at Greifswald, and Dr. Julius Sommer, docent at Göttingen has been appointed professor of mathematics in the Agricultural School at Bonn-Poppelsdorf.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE RELATION OF YALE TO MEDICINE.*

ON this fourth jubilee of Yale University, speaking, as I trust I may, in behalf of many hundreds of physicians who have received their liberal or professional education in this institution, I bring affectionate greetings to our alma mater, and offer our hearty congratulations on this happy anniversary. With all the sons of Yale we join in the prayer of President Stiles: 'Peace be within thy walls, O Yale, and prosperity within thy palaces.'

Yale is related to medicine most directly through her medical department, but also through all who have studied here and subsequently practiced the art or cultivated the science of medicine. The Medical School, although the first department added to the College, was not established until over a hundred years after the foundation of the Collegiate School at Saybrook. From the beginning, however, graduates of the College are to be found in the ranks of medical practitioners, and any account of the relation of Yale to medicine would be most incomplete without some consideration of the alumni of the eighteenth century who were physicians. Their history makes a large part of the medical history of Connecticut during that century, but it is not limited to this State.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKee Cattell, Garrison-on-Hudson, N. Y.

* An address delivered October 21, 1901, at the two hundredth anniversary of the founding of Yale College.

EIGHTEENTH CENTURY.

Doubtless the student of universal medical history, who, after tracing the wonderful development of medicine in the century of Harvey, Malpighi and Sydenham, is engaged in following medical progress through the eighteenth century, marked by such names as those of Boerhaave, Haller, Morgagni and Hunter, would not turn aside long to note what the physicians of Connecticut or, indeed, of any part of America were doing at that time. Still the records of these early Yale physicians have the interest which attaches to the beginnings of things which have become important, and for us the special and sympathetic interest which belongs to the annals of family and country.

When the first physicians who had received their collegiate training at Yale appeared upon the scene early in the eighteenth century, the state of medicine in this country had not advanced materially beyond the primitive condition of the early colonial days. We encounter, as in the early history of medicine everywhere, three classes of medical practitioners: the priest-physician, the regular physician educated and practicing according to the recognized standards of the day, and the empiric or charlatan. What Cotton Mather called 'the angelical conjunction' of the cure of the soul and of the body was to be found most frequently and in its best type in New England. Here the regular training of physicians was almost wholly by apprenticeship for three or four years to some practitioner of repute. As vividly portrayed by a Connecticut physician, "The candidate 'served his time,' as it was then called, which was divided between the books on the shelf, the skeleton in the closet, the pestle and pill-slab in the back room, roaming the forests and fields for roots and herbs, and following, astride of the colt he was breaking, the horse which was honored with the saddlebags."

Nor was this condition very materially changed during the eighteenth century by the founding of the Medical Departments of the College of Philadelphia (now the University of Pennsylvania) and of King's College (now Columbia) in the decade before the Revolution and of those of Harvard in 1783 and of Dartmouth in 1797. During this century only two graduates of Yale College (John A. Graham, Y., 1768, and Winthrop Saltonstall, Y., 1793) had received a medical degree in course. The number of students from the New England colonies who resorted to the medical schools of Edinburgh, London or Leyden was extremely small, much smaller than that from the Middle and Southern colonies.

With the exception of a law passed in New York in 1760 and a similar one in New Jersey in 1772, there was no effective legislative control of medical practice in any of the colonies. Any one who chose could practice, and the root-doctors and Indian doctors of Connecticut had their counterparts elsewhere. More from the sparseness and poverty of the population than from the absence of disease, the remuneration from medical practice was so small that the physician often added some other occupation, most frequently agriculture, to the practice of his profession.

There were no hospitals, except pock-houses, and practically no medical organization. There was little opportunity for intercourse and interchange of views between physicians in different parts of the country, so that local peculiarities of practice were more common then than now. The only text-books were European, the most authoritative on medical practice being the works of Sydenham and of Boerhaave, later also of van Swieten, Mead, Huxham and Cullen. There was no American medical journal until near the end of the eighteenth century.

With two or three exceptions the few

original medical publications, mostly short pamphlets, by American physicians before the Revolution contained scarcely any personal observations of importance, so that the names of these physicians are remembered to-day by their reputation among their contemporaries and their influence upon their successors, rather than by any actual contributions to medical knowledge.

After this necessarily brief statement concerning some of the conditions of medical practice in the New England colonies, we are better prepared to appreciate the position and work of those graduates of Yale College in the eighteenth century who became physicians.

The course of studies at the College was planned rather for the preliminary training of ministers than of doctors, but it furnished a classical education, which was then more necessary for the study of medical books than it is to-day. There seems to have been at least some interest in the College in medical knowledge, if one may judge from the titles of some of the early theses and from the possession by the College of a human skeleton and 'paintings of the human body skin'd,' as they are inventoried. President Stiles occasionally delivered a lecture on medicine, and in his recently published 'Literary Diary' he gives an interesting outline of one of these lectures, the main headings being, I. Anatomy; II. Pathology; and III. The Methodus medendi (one of the sub-headings here being 'Efficacious medicines but few')—sufficiently comprehensive, it may be said, for a single lecture even in those days.

The success attained by the Yale physicians of the eighteenth century indicates that the College then, as ever since, supplied its graduates with a training of mind and character adapted to the circumstances of time and place, and fitting them for the work of life in any field.

Mainly by the aid of Professor Dexter's

invaluable two volumes of 'Biographical Sketches of the Graduates of Yale College,' covering the period from 1701 to 1763, and a kind personal communication relating to the remaining classes, I have been able to determine that there were at least 224 Yale graduates in course of the eighteenth century who practiced medicine. This figure, which is certainly somewhat below the correct one, is 9.7 per cent. of the entire number of Bachelors of Arts for the same period—a percentage about the same as the corresponding one for the nineteenth century.

Of the seven graduates in arts from the College in the first two decades of the eighteenth century who became medical practitioners, all, with one exception, were also clergymen, and of the seventy-two physicians graduated in arts in the first half of the century nearly one-fourth were clerical, whereas after this there are only a very few names of clerical physicians.

All who are familiar with the early colonial history of New England know what an interesting class the clerical physicians were. Not a few of them were educated, skilful physicians, who ranked among the leading practitioners and teachers of medicine in their day, while others were, on the medical side, scarcely more than 'comforters of the sick,' as they were sometimes called, rather than active practitioners. One of the earliest and most celebrated of this class of physicians was the Rev. Thomas Thacher (1620-1678), of Boston, the direct ancestor of our own honored and beloved Latin professor of the same name. His name is preserved in medical annals as that of the author of the first solely medical publication in America, a broadside folio which appeared in Boston in 1677, and is entitled: 'A brief rule to guide the common people of New England how to order themselves and theirs in the small pocks or measles.'

But of all those who combined the offices

of clergyman and physician, not one, from the foundation of the American colonies, attained so high distinction as a physician as Jared Eliot of the class of 1706, who was the first graduate of Yale College to enter upon the practice of medicine. His name is preceded in the triennial catalog by that of Phineas Fiske of the class of 1704, who was eminent both as a divine and as a physician, but whose shorter professional career did not begin until five or six years after that of Eliot.

The name of Jared Eliot is a worthy one to lead the long line of over 2,300 physicians who have received their liberal or professional education at Yale College. The grandson of the Rev. John Eliot, the Apostle to the Indians, he spent his long, twofold professional life of fifty-four years in the town of Killingworth (now Clinton) in this State, where he succeeded in the ministerial office his teacher, Abraham Pierson, the first rector of this College. Of fine bodily presence and engaging personality, for many years an influential trustee of Yale College, the library fund of which was started through his bequest, the friend and correspondent of Benjamin Franklin, Bishop (then Dean) Berkeley and other learned men, a fellow, it is said, of the Royal Society and recipient of a gold medal from the London Society of Arts, accounted in his day an excellent botanist, chemist and practical and scientific agriculturist, Eliot, as is stated by Dr. James Thacher in his *American Medical Biography* (1828), 'was unquestionably the first physician of his day in Connecticut,' and in chronic complaints "he appears to have been more extensively consulted than any other physician in New England, frequently visiting every county of Connecticut, and being often called in Boston and Newport." It is also said of him that "for forty successive years he never omitted preaching either at home or abroad on the Lord's day."

With evidences of such manifold activity one is prepared to accept the statement in his funeral sermon: "Perhaps no man slept so little in his day, and did so much in so great variety."

It is customary to speak of Jared Eliot as 'the father of regular medical practice in Connecticut,' and when one considers the number of physicians who were trained under him, and that among these were such leaders of the profession and successful teachers of medicine as his son-in-law and successor in practice, Benjamin Gale (Yale, 1733), and Dr. Jared Potter (Yale, 1760), the title seems justly conferred.

Among other clergymen noted in their day as medical practitioners may be mentioned Eliot's classmate, Jonathan Dickinson, the first president of Princeton College, whose paper published in 1740, entitled, 'Observations on that terrible disease, vulgarly called the throat distemper,' is the first medical publication by a graduate of Yale College, and the third on diphtheria by an American; Benjamin Doolittle, Yale, 1716, Northfield, Mass., 'well skilled in two important arts,' according to his epitaph; Timothy Collins, of the class of 1718, traditions of whose practice are still current in Litchfield County; Isaac Browne, of the class of 1729, an early member of the New Jersey Medical Society, the first State Society organized in this country; Moses Bartlett, 1730, the pupil and son-in-law of Phineas Fiske, described on his monument as 'a sound and faithful divine, a Physician of Soul and Body,' and the father of a son of the same name, graduated in 1763, who was one of the last of the clerical physicians; Dr. John Darbe, of the class of 1748, who received the honorary degree of M.D. from Dartmouth in 1782, and is the first graduate of Yale College to become doctor of medicine; and Manasseh Cutler (Yale, 1765), skilled in medicine as well as in many other arts.

The first non-clerical physician in the list of graduates is Jeremiah Miller of the class of 1709, who settled in New London. He seems, however, to have been more engrossed with other occupations than with medicine, so that Professor Dexter names John Griswold of the class of 1721, of Norwich, Conn., as 'the earliest graduate of the College who devoted himself exclusively to the profession of medicine.'

Among the two hundred and more eighteenth-century graduates of Yale whose principal or sole professional occupation was medicine are to be found the names of many physicians whose memories are preserved, and of whose useful lives and faithful service in their calling this College may justly be proud. Some were among the most influential and widely known medical men of their time and country. Such were Alexander Wolcott (1731), whose scholarly attainments in medicine are attested by the interesting collection of his books still preserved; Benjamin Gale (1733), one of the few pre-Revolutionary American physicians who have left published records of valuable medical observations; Leverett Hubbard (1744), incorporator and first president both of the New Haven County Medical Society and of the Connecticut Medical Society, for many years the recognized head of the profession in this city and county; Eneas Munson (1753), successful, able and learned, one of the longest-lived and most remarkable physicians of his day, the first name in the medical faculty of the Yale Medical Institution; Jared Potter (1760), described by Dr. Bronson as 'the most celebrated and popular physician in this State' in the first decade of the nineteenth century; Mason Fitch Cogswell (1780), one of the 'Hartford wits,' before the arrival of Nathan Smith, the most distinguished surgeon in this State, whose name has a permanent place in the history of

surgery; Eli Todd (1787), the first superintendent of the Retreat for the Insane at Hartford, who is honored by humanitarians and physicians alike as 'the first in this country to introduce the more humane methods of care and treatment of the insane'; John Stearns (1789), professor of medical theory and practice in the College of Physicians and Surgeons, western district of New York, president of the New York State Medical Society, who has the credit of first calling the attention of the medical profession to the use of ergot in obstetrics, and Thomas Miner (1796), whose ingenious and erudite essays on fevers and other medical subjects, written partly in conjunction with Dr. Tully, attracted wide attention and much comment both in this country and in Europe. To those familiar with this period of American medical history, particularly in Connecticut, other names will occur which might with equal propriety be mentioned, did time permit.

Some who belonged to the medical profession are better known as holders of high public office, and for their services to their country, than as physicians. Of the five medical signers of the Declaration of Independence two were graduates of Yale, both in the class of 1747—Oliver Wolcott, Governor of Connecticut, who studied medicine with his brother Alexander, already mentioned, and practiced for a short time in Goshen, in this State, and Lyman Hall, the first Governor of the independent State of Georgia, where he followed his profession with marked success. Nathan Brownson, of the class of 1761, who was Governor of Georgia, a member of the Provincial Congress and of the Continental Congress, and the holder of other high public offices, was likewise a practicing physician and was appointed by Congress deputy purveyor of hospitals and later to the charge of the southern hospitals in the revolutionary war.

The importance of the services of Yale graduates as surgeons and surgeons' mates in the French and Indian war and the Revolutionary war is not to be measured only by the passing mention which I find it possible to give to them here. I have found the names of ten graduates who served in a surgical capacity in the former war, headed by the doughty clerical physician, Timothy Collins (1718), the first Yale army surgeon.

In 1776 the General Assembly of Connecticut appointed a committee of eighteen of the leading physicians of the State to examine candidates for the positions of surgeons and surgeons' mates in the Continental Army, and some idea of the standing of Yale graduates then in medical practice in Connecticut may be gained by the facts that this Committee was headed by Alexander Wolcott and contained ten graduates of the College.

The earliest Yale graduate who held a commission in the American Revolution was a physician, Joshua Babcock of the class of 1724, Major General of the Rhode Island militia. He had walked the hospitals in London in 1730, being the first graduate of the College to study medicine in Europe, and for nearly twenty-five years was an active practitioner in Rhode Island. Mr. Henry P. Johnston's book, 'Yale and Her Honor Roll in the American Revolution,' gives the records of twenty-three graduates who served as surgeons or surgeons' mates in this war, and of six other physicians who were officers in the army.

The first bestowal of the degree of Doctor of Medicine in America was by Yale College in 1723, when Dr. Daniel Turner, a well-known London physician and voluminous medical writer received the honorary degree. The first American medical degree in course was given by the College of Philadelphia, now the University of Pennsylvania, in 1768. The first graduate of Yale College to receive a medical degree in

course was John Augustus Graham of the class of 1768, who was graduated bachelor of medicine from Columbia in 1772, and the first to be admitted to the doctorate of medicine in course was Winthrop Saltonstall of the class of 1793, M.D. Columbia, 1796.

There are certain directions in which Yale graduates during the eighteenth century especially contributed to the improvement of medical conditions in this country, an improvement everywhere slow and well marked only after the Revolution.

The Yale physicians of the eighteenth century, with a few not very important exceptions, which I have mentioned in a note,* were trained at home and were thrown in unusual degree upon the results of their own experience. While in the main their practice is not known to have differed from that which prevailed at the time, there is evidence of some local peculiarities. There developed early in Connecticut that special interest in the indigenous *materia medica* which, transmitted in direct succession from Jared Eliot, through Benjamin Gale, Jared Potter and Eneas Munson, became a distinguishing characteristic of Eli Ives and William Tully, the professors of *materia medica* and therapeutics in the Yale Medical Institution in its early years. This contributed to a less violent system of treatment of diseases than was customary in those days. Even in early colonial days a mild treatment of fevers prevailed in New Haven, according to Hubbard, who in writing of this town in his History of New England recorded that "The gentle conductitious aiding of nature hath been found better than sudden and violent means of purgation or otherwise; and blood-letting, though much used in Europe for fevers, especially in the hotter countries, is found deadly in this fever, even almost without

* The notes accompanying this address are omitted from this publication.

exception." In all probability the unusual success achieved by Benjamin Gale and certain other Connecticut physicians in the inoculation and treatment of smallpox is to be attributed to the mild, cooling and open treatment which they adopted, rather than to the preliminary mercurial treatment to which they ascribed it. These tendencies, for they were only such, did not find, however, their full expression until the appearance of Nathan Smith's work on 'Typhous [typhoid] Fever' in the next century.

Connecticut physicians were pioneers in the work of organization of the medical profession, and in this work graduates of Yale were prominent. The oldest existing medical society in this country is the still active and flourishing Litchfield County Medical Society founded in 1765 and preceded only by two short-lived voluntary organizations, one in Boston and the other in New York.

The first organized effort on the part of the profession to secure effective legal regulation of medical practice in the colonies was in 1763 when physicians of Norwich, Conn., petitioned the General Court for an act of incorporation, which was, however, not granted. The name of Elisha Tracy of the class of 1738 appears among the signers of this interesting memorial. This first unsuccessful attempt was the beginning of a series of efforts which, largely through the initiative of the Medical Society of New Haven County, organized in 1784, resulted in the incorporation of the Connecticut Medical Society in 1792. In the meantime State medical societies had been formed in New Jersey (organized in 1766, incorporated in 1790), Massachusetts (1781), Delaware (1789) and New Hampshire (1791).

The charter of the Connecticut Medical Society is, in most respects, an admirable instrument, and, as regards the organiza-

tion of State medical societies, historically almost as interesting as the famous Connecticut constitution of 1639. It embodies in a simple and practical fashion democratic and federative principles of organization and government resembling those adopted by the Commonwealth, and remains to this day a model for similar societies in other States. Of those concerned in the establishment of this Society graduates of Yale were the most active and influential, and they compose over one-third of the charter members. The first president was Dr. Leverett Hubbard (Y., 1744), and upon his death Dr. Eneas Munson (Y., 1753), was chosen his successor and held the office for seven years.

The most noteworthy contribution to medical literature before the Revolution by a graduate of Yale was Benjamin Gale's (Y., 1733) 'Historical memoirs relating to the practice of inoculation for the smallpox, in the British-American provinces, particularly in New England,' published in 1765 in the *Philosophical Transactions* of London. This creditable and historically interesting paper attracted attention both here and abroad, chiefly on account of its advocacy of the mercurial treatment before inoculation. It may here be mentioned that one of the most valuable of the Yale bicentennial publications, the 'Literary Diary' of President Ezra Stiles, edited by Professor Dexter, contains some interesting historical matter upon this subject of mercurial inoculation, as indeed it does relating to a number of other subjects of medical interest.

After the war of independence we find in American medical writings greater productivity and originality than before, attributable largely to the increased medical and surgical experience gained during the war, and to the higher degree of self-reliance, engendered by the political conditions.

The first original separate medical work in this country after the close of the Revolutionary war was the volume published in New Haven in 1788, entitled, 'Cases and Observations by the Medical Society of New Haven County in the State of Connecticut.' This publication, which contains twenty-six papers reporting cases of disease and autopsies, is an event of importance in American medical bibliography, not so much on account of the intrinsic value of the communications, although several are interesting, but because, in evidence of the newly-awakened medical life of the young republic, there is collected here for the first time a series of independent, original observations and studies by different American physicians. Nothing of the kind had appeared before in this country. One-third of the contributors to this volume are graduates of Yale.

Nine years later, in 1797, was started the first American medical journal, *The Medical Repository*, published in New York, and its projector was the talented and scholarly Elihu Hubbard Smith of the class of 1786, with whom were associated Dr. Samuel L. Mitchell and Dr. Edward Miller. Dr. Smith, the father of American medical journalism, died much lamented the following year. Although so young, he was physician to the New York Hospital, the editor of several works, and a contributor to literary periodicals as well as to his own journal, in which his scholarly papers on the plague of Athens and the plague of Syracuse can still be read with pleasure and profit. The establishment of *The Medical Repository*, which was continued until 1824, was of great service in promulgating medical knowledge and stimulating medical thought and writing in this country at the close of the eighteenth and in the early years of the nineteenth centuries.

The graduate of Yale, however, whose published contributions in the eighteenth

century are of the greatest permanent value to medicine was not a physician, but was that useful and versatile man, Noah Webster, of the class of 1778. Noah Webster is the first epidemiologist which this country has produced. In 1796 he published 'A collection of papers on the subject of bilious fevers, prevalent in the United States for a few years past,' and in 1799 appeared in two volumes a work, well known to all students of epidemiology, entitled, 'A brief history of epidemic and pestilential diseases,' which is of unusual interest, and on account of its records and observations of epidemic diseases in this country has an enduring value. There are scattered papers by him on various medical subjects, and one of these buried in *The Medical Repository* (Second Hexade, Vol. II.) should be rescued from forgetfulness. In this critique of Erasmus Darwin's theory of fever Noah Webster gives a well-reasoned, clear and definite presentation of that modern theory, associated with Traube's name, which explains febrile elevation of temperature by the retention of heat within the body.

NINETEENTH CENTURY.

With the turning of the century Yale College, under the guidance of the first President Dwight, passed not only in name but also in spirit from the eighteenth to the nineteenth century. It was transformed from a local to a national institution, and it entered upon a new era of expansion in which seeds were planted destined in the natural course of development to grow into the spreading tree of a university. The first fruit of this new university idea was the establishment of the Medical Department, some account of which will now engage our attention.

The need at that time of a medical school in this place is apparent from the fact that only eight or nine graduates of the

College before the foundation of the medical department in 1810 had received a medical degree in course, although a much larger number had spent a year in study at a medical school.

A part of the plan proposed in 1777 by a committee of the General Assembly to enlarge Yale College, provided a board of civilians was added to the corporation, included the establishment of professorships of medicine and of law. In the same year Dr. Stiles, before his entrance upon the duties of the presidency to which he had been elected, 'drafted a plan of an university, particularly describing the law and medical lectures,' to be laid before the committee of the General Assembly. These negotiations were at the time unsuccessful, and when at last in 1792 the closer union between the State and College was effected, these early proposals had dropped out of sight.

In two respects the circumstances attending the establishment of the Yale medical department are of peculiar interest. The initiative came from within the College and not from without, and the form of union between the College and the Connecticut Medical Society is something unique in the history of medical schools.

The idea of founding a medical department connected with the College unquestionably originated with President Dwight and was a part of his plan for extending the scope and usefulness of the institution. This broad-minded man was, as is well known, much interested in natural science, and he considered in his writings several matters of medical interest. One of the letters in his 'Travels in New England and New York' contains an argument, really remarkable in the light of our present knowledge, in support of his conclusion that malaria is caused by minute living organisms.

It is clear from several passages in the autobiographical reminiscences published

in Professor Fisher's 'Life of Benjamin Silliman' that at the time of Professor Silliman's appointment to the chair of chemistry and natural history in 1802 a medical department was definitely contemplated, and that his appointment was regarded as an important step toward that end. The plan had from this time the hearty sympathy and active support of Professor Silliman. 'Expecting,' as he says, 'from the first to be ultimately connected with a medical school in Yale College,' he attended both in Philadelphia and in Edinburgh, where he had gone mainly for chemical study, courses of lectures upon anatomy, materia medica, botany and theory and practice of medicine, coming under the influence of such famous medical teachers as Wistar and Barton in the former city, and James Gregory and John Barclay in the latter.

For centuries the medical departments of universities were the home of all that there was of chemistry and of other branches of natural and physical science, and it is significant that the medical department of this University came into being at the time when Benjamin Silliman had made New Haven the most important center for scientific work and influence in this country. It can hardly be an accidental coincidence that among the graduates of Yale College in the early years of Professor Silliman's teaching are found the names of such men as William Tully, Alexander H. Stevens, who represented medicine at the one hundred and fiftieth anniversary of this University; Jonathan Knight, Edward Delafield, John Wagner, Samuel H. Dickson and George McClellan, who became physicians and surgeons of national and international fame.

In 1806 the corporation of the College passed a resolution for establishing a medical professorship, and the Rev. Dr. Nathan Strong, of Hartford, who introduced the

resolution, and Professor Silliman were appointed a committee to examine and report, and to devise means for effecting the object.

It is to be emphasized that the Medical Department is the direct offspring of Yale College, and was not started, as nearly every other medical school in this country has been, by a group of outside physicians who have subsequently sought connection with a college. Even if there were no other claims, this origin should entitle the Yale Medical School for all time to the fostering care and support of its parent.

In order to understand the occasion for the negotiations which now ensued between the corporation of the College and the Connecticut Medical Society, it is to be borne in mind that this Society was possessed, through its charter of 1792, of unusual prerogatives which gave it control of medical education in this State. It was not only an examining and licensing body, which was proper, but also a degree-conferring body, which was decidedly improper and a usurpation of a function which should belong only to a college or university. From the beginning the Society had actively exercised all of these functions, and had furthermore made several regulations, which it was empowered to do, regarding medical education.

It was evidently necessary for the College to come to some sort of understanding with the Medical Society, and to induce it, if possible, to relinquish some of its chartered privileges.

It is not necessary here to enter into the details of these negotiations between the College corporation and the Medical Society, which extended over three years, especially as these have been fully set forth in a readily accessible paper by Dr. E. K. Hunt, a generous benefactor of the Medical School. Suffice it to say that concessions were made on both sides, and that, largely through the

efforts of President Dwight and Professor Silliman, representing the College, and of Dr. Eli Ives, representing the Medical Society, a satisfactory and amicable arrangement was reached, apparently without a great deal of friction, and was embodied in 'Articles of Union,' which constitute the act creating 'The Medical Institution of Yale College,' passed by the General Assembly in 1810 at the October session.

This act fixed the number of professors at four ('to include a complete circle of medical science'), the price of the ticket, and the time of examinations; provided for the establishment of a botanical garden, and of collections in anatomy and in *materia medica*; for a joint committee of an equal number of persons from the Medical Society and the corporation to nominate professors to be chosen by the corporation, and also for a like joint examining board, in which the president of the Society had the casting vote in case of a tie; repealed the right of the Society to grant honorary degrees in medicine, which could thereafter be conferred by the president of the College upon recommendation of the Society; provided that each county could send, upon recommendation of the Society, a gratuitous student, and fixed the term of medical study for college graduates at two years, and for others at three years, attendance upon a single course of lectures being requisite for the license, and upon two courses for the doctorate.

It is evident from this summary that the Connecticut Medical Society shared to a considerable degree with the College the control of the Medical Institution. I do not suppose that the College would have entered into this agreement with the Medical Society, had not the circumstances been such as I have mentioned. Nevertheless this union between the College and the State Medical Society had at that time distinct advantages, the most important of

which was the securing of the active interest of the physicians of the State in the new institution. In general the circumstances connected with the foundation and conduct of most medical schools in this country have not been calculated to secure the interest and sympathy of the great body of the medical profession.

No more competent testimony to the benefits derived from the union which existed here could be desired than that of Dr. Jonathan Knight, who says, in his introductory lecture in 1853: "The result of this arrangement has been eminently happy; all unpleasant feeling was at once and forever allayed; the members of the Society became interested in the School; we have at all times had the benefit of their council and support, and it gives me pleasure to state that no instance of disagreement has ever arisen among the members of the board, or between the School and State Society; on the contrary, each has regarded the other as a fellow laborer in the endeavor to promote and advance the interest of medical science."

The relations continued harmonious throughout the remaining period of existence of the agreement between the Society and the Medical School, but with changed conditions the union ceased to be useful and in some ways had become embarrassing, so that in 1884, by mutual consent, it was annulled, and the entire control of the School, the official name of which had meantime been changed by the new charter of 1879 to that of 'The Medical Department of Yale College,' passed into the hands of the University.

The charter of 1810, by its limitation of the number of professors and of the period of undergraduate medical study and its regulation of other matters better left to the discretion of the College, was an extremely inelastic instrument, and it is not surprising that repeated legislative changes

were found necessary. There have been not less than four distinct charters of incorporation of the Medical School, and in addition five or six amendatory acts. The present charter, which seems to be free from the defects of its predecessors, was enacted in 1879.

At the time of its incorporation in 1810 the Medical Institution of Yale College was the sixth medical school in the United States, the others being the medical department of the University of Pennsylvania, founded in 1765, the College of Physicians and Surgeons in New York, founded in 1807, but a descendant of the medical department of Columbia University, established in 1768, and the medical departments of Harvard (1783), of Dartmouth (1797), and of the University of Maryland (1807).

A commodious stone building on Grove Street, erected by Mr. James Hillhouse, was obtained for the use of the Medical School, and in 1814 this with an adjacent plot of ground was purchased by the aid of a generous donation by the State of twenty thousand dollars, obtained largely through the efforts of Dr. Nathan Smith. This building, which is now South Sheffield Hall, was the location of the Medical School until its removal in 1859 to its present site on York Street.

The members of the first faculty of the Medical School, appointed in 1812, were, in the order of arrangement of their names in the College catalogue, Eneas Munson, professor of materia medica and botany; Nathan Smith, professor of the theory and practice of physic, surgery and obstetrics; Eli Ives, adjunct professor of materia medica and botany; Benjamin Silliman, professor of chemistry and pharmacy, and Jonathan Knight, professor of anatomy.

Dr. Munson, to whom I have already referred, was an octogenarian at the time of his appointment, which was, as was intended, only an ornamental one, Dr. Ives, the adjunct professor, his pupil and friend,

performing the active duties of his chair. The remaining members of this faculty made a group of medical teachers who could challenge comparison with any similar group in this country. Of Benjamin Silliman it is not necessary for me to speak further, as his most important work lay outside of the immediate field of medicine, and will be considered by another speaker.

Dr. Nathan Smith, when he came to New Haven from Dartmouth, was already a star of the first magnitude in the medical firmament. Starting a poor boy in a small village in Vermont, he managed by his own efforts to obtain a good general education and then at the Harvard Medical School and in Great Britain a medical education of a character then almost unknown in New England. He was the originator of the Dartmouth Medical School in 1797, the most distinguished member of the first medical faculty of Yale, and in 1820 the organizer of the Medical Department of Bowdoin College. He did much of his most important work in New Haven, where he remained until his death in 1829.

Nathan Smith shed undying glory upon the Yale Medical School. Famous in his day and generation, he is still more famous to-day, for he was far ahead of his times, and his reputation, unlike that of so many medical worthies of the past, has steadily increased as the medical profession has slowly caught up with him. We now see that he did more for the general advancement of medical and surgical practice than any of his predecessors or contemporaries in this country. He was a man of high intellectual and moral qualities, of great originality and untiring energy, an accurate and keen observer, unfettered by traditions and theories, fearless, and above all blessed with an uncommon fund of plain common sense.

Nathan Smith's essay on typhus fever, published in 1824, is like a fresh breeze from

the sea amid the dreary and stifling writings of most of his contemporaries. The disease which he here describes is typhoid fever, and never before had the symptoms been so clearly and accurately pictured. He recognized that this fever is due to a specific cause and is self-limited. It took courage in those days for a physician to write, "During the whole course of my practice I have never been satisfied that I have cut short a single case of typhus, which I knew to be such," and again, "It does not follow of course that this disease in all cases requires remedies, or that a patient should necessarily take medicine because he has the disease." To him the *lancet* was not the '*magnum donum Dei*' that it was to Benjamin Rush, and he did more to do away with its indiscriminate use than any single man. The treatment which he advocated—cold water, milk, and avoidance of all violent remedies—is practically the same as that now employed, but it was many a day before physicians came to accept Dr. Smith's revolutionary views.

To the surgeon Nathan Smith's paper on the pathology and treatment of necrosis has in course of time become as much of a classic as the essay on typhus fever is to the physician. Here we find the same admirable description of symptoms, and the introduction of methods of treatment which anticipated modern surgery. This is not the occasion, even did time permit, to describe Dr. Smith's achievements in surgery. It must suffice to say that he was the first to perform a number of important surgical operations, and that in this branch, not less than in medicine, he was an innovator and reformer.

Although none of Dr. Smith's colleagues can be placed in the same rank with him as contributors to medical knowledge, they were men of excellent attainments and became distinguished teachers.

Dr. Eli Ives was connected with the

Medical School until his death in 1861, having succeeded to the professorship of theory and practice of physic upon the death of Dr. Smith in 1829, and becoming emeritus in 1853. He was a highly respected physician of large practice in this city. He was widely known as a botanist, and was credited with the most extensive knowledge of the indigenous materia medica of any man of his day, a taste for which he had acquired from his preceptor, Dr. Munson. His mind was richly stored with facts, and all were impressed with the value of his teachings.

Dr. Jonathan Knight, who was only twenty-three when appointed professor, became one of the most influential men in the medical profession of this country, having been twice president of the American Medical Association. He was transferred to the chair of surgery upon the death of Dr. Hubbard in 1838. Of dignified personal appearance and manner, with well-balanced mental powers, and fine literary culture, Dr. Knight has probably never had his superior in any medical school in this country as a finished lecturer. He was an active teacher in the Medical School for fifty-one years, dying only a few months before Professor Silliman, the latest survivor of the first medical faculty.

With this able and devoted group of teachers and a class of thirty-three students the Medical School began its work in November, 1813. To follow in detail its history from that day to this would far exceed the limits of this address. I regret that I can do no more than make mention of some of the professors who have passed to the majority: Thomas Hubbard, of necessity an inadequate successor of Dr. Nathan Smith in the chair of surgery, a plain, self-taught man, of whom Dr. Knight says that he filled his position to the time of his death in 1838 'with great and increasing reputation to himself and benefit to the institu-

tion'; William Tully, a really remarkable man, of whom I had hoped to say much more, erudite, original, an experimentalist, unrivaled in his knowledge of the materia medica, an extensive contributor to medical literature; Charles Hooker, of good scientific training, who had the great merit of introducing the newer medicine with its methods of physical examination into New Haven, a writer of valuable papers on auscultation and percussion and on physiological subjects; Henry Bronson, scholarly, devoted to antiquarian research, contributor of important papers on medical history and biography; Worthington Hooker, interested in medical education and the improvement of professional organization, a facile writer, widely known as a useful popularizer of natural science; Moses Clark White, for thirty-three years professor of pathology, who taught as early as 1860 the use of the microscope in medicine in this School; Leonard Jacob Sanford, a faithful teacher of anatomy for nearly a quarter of a century, devoted to the interests of the Medical School; James Kingsley Thacher, endowed with unusual intellectual powers and capacity for original scientific investigation, eminent as a comparative anatomist, abreast of modern physiology and clinical medicine, whose early removal by death was an irreparable loss to this Medical School and to medical and biological science.

While I refrain in general from mention of the names of those who are still living and are the faithful and able successors of these distinguished men, I cannot in this connection pass over the name of Dr. Charles Augustus Lindsley, a member of the medical faculty for thirty-seven years and its executive officer for twenty-three years, a devoted teacher and eminent sanitarian.

The period of greatest prosperity of the Medical School, until quite recent years, was the first two decades of its existence, in which the average annual attendance of

students was between 70 and 80. The annual attendance then fell to an average of between 30 and 40 for the four decades from 1850 to 1890. Since 1895 it has for the first time exceeded 100. Up to 1894 the largest class was that of 1822, which numbered 92, the largest number of graduates in any year up to 1897 being 36 in 1829. Of the 1,221 graduates of the medical department up to and including 1900, 27.6 per cent. were also college graduates, and of these three-fourths were graduates of Yale College or the Sheffield Scientific School. The highest ratio of college graduates (40.6 per cent.) was in the decade 1881 to 1890, when the total number of graduates was smallest.

It is pleasant to recall that the medical department, established through the efforts of the first President Dwight, entered upon a second era of prosperity in the administration of the second President Dwight, who in his annual reports has forcibly presented the needs and the possibilities of this first offspring of the College.

The standards of the Yale Medical School have always been kept high in comparison with those prevailing at the time, and at certain periods the School has taken the lead in movements to improve medical education, which from about the end of the third to the middle of the eighth decades of the past century was in a woeful plight in America.

At the beginning the course of medical lectures here extended through six months, a longer period than obtained at the time in any other medical school in this country.

The first organized effort to raise the standard of requirements for medical education in the United States was made by a Convention of Delegates from Medical Societies and Medical Schools which met in Northampton, Massachusetts, in 1827. The Yale Medical School faithfully conformed to the recommendations of this convention, and went to the trouble of securing in 1829

from the Legislature an amendment of its charter whereby the period of medical study was increased to four years for all who were not college graduates, and to three for graduates, and knowledge of Latin and of natural philosophy was required for matriculation. The Medical College soon found itself standing almost alone, 'faithful among the faithless,' and, in order to preserve its own existence, it was compelled after three years to return to the old order as regards the length of the period of medical study, although it retained the preliminary requirements, which, however, afterwards became inoperative, as they were so far above the demands of other colleges.

The inadequacy of the system of didactic lectures for the training of medical students was nowhere in this country earlier recognized than here. In 1855 the course was supplemented by daily recitations, and, as their advantages were realized, they received in the following years greater and greater emphasis, until they in combination with laboratory practice became, at least as early as 1867, a distinctive, and certainly a valuable feature of the school.

In 1879 the Yale medical department placed itself in the front rank, as regards its standards, with only a few companions at that time, by introducing a stated matriculation examination and a three years' graded course, lengthened in 1896 to four years. Clinical instruction and the recitation and laboratory plan of teaching, which had been early adopted, continued to be the basis of the course. The thoroughness of the training is attested by the unusual success of the graduates of the Yale medical department in competitive examinations for positions in the army and in hospitals, and in State Board examinations for license to practice.

With the laboratory building erected in 1893, and the clinical building now in process of construction, the teaching re-

sources of the medical department have been greatly increased, and there is every indication that it has entered on a new era of success and usefulness, but it cannot reach the height of its endeavor or of the position properly belonging to an important department of this great University without a large increase of its present meager endowment.

Of the total number of physicians who have received their liberal education at Yale College and the Sheffield Scientific School, less than one-fifth are graduates of the Yale medical department, and it is pertinent to inquire how their alma mater has fitted them for their subsequent professional studies. For the great majority and until comparatively recent years this collegiate training was furnished by the old-fashioned classical course, and there can be no question but that this, combined with other influences of college life, gave an excellent discipline of mind and character, but with no peculiar adaptation to the study of medicine.

The advance of medical science and art during the last half century has given ever-increasing prominence to the value to the student of medicine of a good practical knowledge of chemistry, physics and general biology. It is to the great credit of this University that this need was first clearly recognized and supplied in this country by the Sheffield Scientific School, which in 1870 offered well-planned courses in these branches of science, announced as intended especially for the preliminary training of prospective medical students. With the establishment of the Laboratory of Physiological Chemistry four years later the distinctive pre-medical biological course was fully organized, and since 1889 this has been open also to students in the academical department.

No more convincing testimony to the importance of this new departure in collegiate

education is needed than the mere mention of the names of some of those who were graduated from the Scientific School in the ten years following the establishment of this course and who have acquired distinction in medicine or in sciences akin to medicine. Fortunately I can not illustrate my argument here by the selection of names from those who have passed away, and I trust that it will not be considered invidious if I cite names so familiar to physicians and biologists as those of Prudden, T. H. Russell, Hun, W. B. Platt, Chittenden, Yamagawa, Curtis, Sedgwick, Gilman Thompson, E. B. Wilson, Mitsukuri, H. E. Smith, E. A. Andrews, Ely. Not only has the laboratory of physiological chemistry under the direction of Professor Chittenden been of great service in the preparation of students for the study of medicine, but its contributions to a science of great medical and biological importance are unequaled in number and value in this country and have given it rank with the best laboratories of its kind in the world.

There have been all told not far from 2,300 graduates of Yale in all its departments (including the medical), who have become physicians, not counting twice the names of those graduated from more than one department. Of the graduates in arts (1702-1897) about 1,100 (9 to 10 per cent.) have entered the medical profession, the percentage being about the same for the eighteenth and the nineteenth centuries, but varying considerably in different years and decades, as appears from data which I have inserted in a note.* Especially significant is the fact that from the classes of 1822, 1824, 1825, 1826, and 1828, when the medical department was at the height of its early prosperity, the number of graduates in arts who became physicians was 80 per cent. above the general percentage

* The notes accompanying this address are omitted from this publication.

for the nineteenth century, and that over 41 per cent. of these received their medical degree from the Yale Medical School, as against 24 per cent. in general for the period since the opening of the medical department. Of the graduates of the Scientific School (1852-1897) at least 193 (9.1 per cent.) were later graduated in medicine, 22.3 per cent. of these receiving their degree from the Yale medical department.

It is of course out of the question to attempt to give here even the most summary account of the more than two thousand Yale physicians of the nineteenth century. Among those no longer living are the names of such famous men as Alexander H. Stevens, Samuel H. Dickson, George McClellan, Nathan R. Smith, William Power, Alfred Stillé, Samuel St. John, William H. Van Buren, Edmund R. Peaslee, J. Lewis Smith, Daniel G. Brinton, William T. Lusk and many others deserving of mention did time permit. The graduates of Yale in the medical profession have contributed their full share to the making of the medical history of this country. Over one hundred became professors in medical colleges, especially noteworthy being the number and distinction of those who have been and who are connected with the medical schools in New York City. At least thirty have been presidents of their State medical societies.

In all these two hundred years of her existence men have gone forth from Yale who have adorned the profession of medicine. Among them have been great teachers, leaders who have advanced medical knowledge, improved medical and surgical practice, and raised the standards of professional life and of medical education, men who have served their country in a professional capacity in peace and in war, and many more who have led the useful lives of general practitioners, honored in their homes and by their colleagues, and con-

tributing to the welfare of the communities where they have lived.

In centuries past the greatest renown of many universities lay in their medical faculties. There have been later times when the conditions of medicine and of medical education made it less fit to enter into the life and ideals of a university. It is not so to-day. Medicine has now become one of the great departments of biological science with problems and aims worthy of the highest endeavor of any university, surely none the less worthy because they are associated with human interests of the highest importance.

The union of medical school and university should be of mutual benefit. Medicine needs the influences of a university for its highest development, and the usefulness and fame of a university are greatly increased by a strong medical department. There is to-day no direction of scientific research more productive in results of benefit to mankind and in the increase of useful knowledge than that upon which medicine in these later years has entered, and there can be no nobler work for a university than the promotion of these studies.

But medical teaching and research can no longer be successfully carried on with the meager appliances of the past. They require large endowments, many well-equipped and properly-supported laboratories, and a body of well-paid teachers thoroughly trained in their special departments. With an ampler supply of such opportunities as these there is every reason to believe that the Yale medical department would take that important position in the great forward movement of modern medicine to which its origin, its honorable history and the fame of this ancient University entitle it. May the next Jubilee find medicine holding this high position in Yale University!

WILLIAM HENRY WELCH.

VARIETAL MUTATION IN THE TOMATO.

THE following remarks refer to the origination by mutation* of a strongly marked and distinct variety of tomato from seed of an old and well-known variety, under ordinary cultivation in an isolated garden plot; and to the subsequent duplication of that case of mutation upon the same ground and under the same conditions of cultivation, but in plants produced from other seed of that old variety, which was grown in a different and distant region. The mutation in these two cases is remarkable in that it was uniformly manifested in every plant of each of the two crops in which it occurred; that it produced plants which were widely different from the parent plants; that the second case was an exact repetition of the first, and that it occurred in both cases under circumstances that preclude the probability that it was the result of cross-fertilization.

My observations in these cases were made in connection with amateur gardening upon my house-lot in Washington, a statement of the results of which follows in narrative form. I chose the Acme variety of tomato for cultivation because of its long-known excellence, and the cases referred to occurred unexpectedly in the variety thus chosen. In the spring of 1898 I purchased a dozen young plants which had been produced from seed by a gardener in the vicinity of Washington, and transplanted them in my garden plot. As the plants matured and fruited they showed all the recognized varietal characteristics of Acme, a description of which is herewith given for the purpose of comparing it with other varieties presently to be mentioned. The plants were large and diffuse, the color of the foliage being a medium shade of green;

haulms slender, somewhat numerous, some of them reaching a length of more than six feet; the petiole-midrib long and slender; leaflets moderately narrow, distant, petiolulate and only slightly rugose; fruit depressed-globular in shape, with an occasional tendency to become transversely oval, uniformly ripened, fleshy and well flavored; and in ripening the change from the chlorophyl-green to crimson, passing through more or less of yellow.

I selected seeds from one each of the earliest and most characteristic fruits of several vigorous plants of this crop of 1898, and made a mixed packet of them. These seeds I planted in 1899, expecting to produce true Acme plants, because of my care in selecting and preserving the seeds, because of the comparative stability of that variety, and because no other tomato plants were grown with them, or in their neighborhood, from which cross-fertilization might have occurred. To my surprise, however, all the plants which grew from these seeds were distinctly different from the parent plants of the year before, both as to habitus and as to fruit, and all were uniform in their new characteristics. They were sturdy and compact plants with foliage of a deeper green than that of the parent plants; haulms few and strong, the more vigorous reaching a length of about four and a half feet, or an average of about two-thirds the length of the parent plants; petiole-midrib short and strong; leaflets moderately broad, not distant, sessile or nearly so, and strongly rugose; fruit similar to that of the parent plant in size, shape and consistence, but more delicate in color, which changes from the chlorophyl-green to cherry-red or light crimson through a neutral or flesh color, a yellow tint seldom appearing. It is also singularly free from the pronounced tomato flavor of the common kinds. The seeds which I saved from this new variety were accidentally destroyed

* In this article I use the term 'mutation' in the phylogenetic sense that has been given to it by Professor Hugo de Vries in his exhaustive work, 'Die Mutationstheorie,' Leipzig, 1901.

and I supposed the variety was therefore lost; but two years later I recovered it upon the same ground and under the same conditions of isolation and cultivation, but from a new source as to seed.

In the spring of 1900 I bought from a Philadelphia company of seed-growers a packet of their 'selected Acme Tomato' seed, grown and gathered on a Pennsylvania farm in 1899. From a part of these seeds I grew thirty plants to maturity, every one of which was true to the Acme variety as described in the second paragraph of this article. In this case also there was no probable source of cross-fertilization, and I carefully saved a mixed packet of seed selected from typical fruits of several of the best plants, as I did in the former case. These seeds I planted in my garden plot in 1901, not doubting that they would produce true Acme plants, notwithstanding my former experience. On the contrary, however, all the plants grown from those seeds were not only quite different from the parent Acme plants, but they were in all respects, both as to habitus and as to fruit, like those which grew upon the same ground in 1899, which are described in the third paragraph of this article, and which variety I believed was lost at the end of that year. That is, in 1900 and 1901 I exactly repeated my experience of 1898 and 1899, the second experience having been with seed from an entirely new source, as already stated. The new variety belongs to a group of varieties of which the two known to gardeners as the 'Potato-leaf Honor Bright' of Livingston and the 'Dwarf Champion' of Ferry, respectively, may be taken as types. It is quite a different group in several respects from that to which the Acme belongs. For convenience of reference I will designate this new variety as the 'Washington.'

When, in the spring of 1901, I planted the seed of the Acme plants, which I had

grown in 1900, I at the same time planted the remainder of the Pennsylvania packet of Acme seed, carefully keeping separate both the seed and the resulting plants. The second portion of the Pennsylvania seeds produced true Acme plants, as did those of the first portion in 1900, and, although they grew vigorously, their fruit was more than two weeks later in ripening than was that of the Washington variety, thus adding another element of difference between the two varieties. This second planting was fortunate because it gave excellent opportunity to compare the two varieties with each other in all stages of their growth. As the plants of both varieties matured their differences of habitus became very conspicuous; indeed, it was readily observable with the appearance of the first leaves of the plantlets.

While all varieties of cultivated plants which are reproduced from seed are notably unstable in their varietal characteristics, some varieties, of even the same species, are more unstable than others. This varietal instability of cultivated plants is manifested in both mutation proper and atavic reversion. The first is regenerative, and divergently progressive, especially in respect of results desired by the horticulturist, and the second, degenerative and convergently retrogressive. The tendency to mutation proper in cultivated plants is generally manifested in connection with selective cross-fertilization, but in view of my experience herein recorded, and of that of other persons in other cases, it cannot be doubted that it often occurs spontaneously in plants that have been fertilized only by pollen from those of their own variety. The tendency toward degenerative change in cultivated plants is apparently an inevitable result of promiscuous cross-fertilization, and is toward the primitive, uncultivated condition of the species. I, of course, assume that the Washington variety of tomato

herein described originated by spontaneous, saltatory mutation, without cross-fertilization, and that this form of mutation differs only in degree, not in kind, from the saltatory origin of new species which has been elaborately described and demonstrated by Professor de Vries in his work already referred to.

This manner of origination of the Washington variety of tomato is assumed for the following reasons: (1) No probable source of cross-fertilization was discovered by careful investigation; (2) all the new plants were identical with one another in their varietal character; and (3) the mutation in question was exactly repeated in a succeeding crop under like conditions of isolation and cultivation. If my Acme plants had received adventitious fertilization by pollen from any other than flowers of their conate crop-associates, the cross-fertilization would doubtless have been incomplete as to the whole crop and various as to the kinds of hybrids produced. Even if it were credible that the first case of complete mutation of my whole crop might have been the result of cross-fertilization from some unknown source, it would still be too much to believe that exactly the same result could have been produced a second time in succeeding years by such adventitious means.

Saltatory mutation may be said to have both a predisposing and an exciting cause, the former being always present, at least latently, and the latter acting only under the stimulation of changed conditions; but I do not propose to discuss the nature of either of them. While the exciting cause of saltatory mutation in plants very often acts in connection with the process of cross-fertilization, it sometimes, as has been shown, acts independently of it. In such cases as that which is here recorded one naturally seeks the exciting cause in some peculiarity of the physical conditions under which the plants grew. I by no means as-

sume that the exciting cause of the mutation which produced the Washington variety of tomato will be found in the physical conditions of my garden and its vicinity, but the following mention is made of those conditions, that they may be considered in any inquiry that may be made concerning it. My ground is in a northern suburb of Washington and, before the Civil War, it was part of a worn-out farm of stiff clayey soil. It is somewhat dry, but was watered freely with Potomac river water, especially during the hot summer months. It was fertilized with stable manure, lawn-mowings (used also as mulching) and crude sodium nitrate, the last about half an ounce to the plant, applied in weak solution near the roots. Besides the evident obscurity of the exciting cause of the case of mutation in question, when considered with, as well as aside from, reference to these conditions, it should also be mentioned that no similar case has been reported from other gardens around Washington in which tomatoes are grown, although practically the same conditions prevail in many of them that exist in mine.

That the mutation which produced my new Washington variety was not atavic, or retrograde, in character is shown by the horticulturally improved characteristics of the fruit, and by the fact that the entire habitus of the plant is unlike that of the parent Acme, and also unlike that of the plants from which the Acme was originally produced. In both fruit and habitus the new variety is also very unlike those common tomato plants and fruit to which all improved varieties sooner or later convergently revert under promiscuous cross-fertilization and careless cultivation. Although the Acme is one of the least unstable of the very many varieties of tomato which gardeners have recognized, its deterioration by atavic reversion is very common and is readily observable in the markets of Wash-

ington, where gardeners have brought the fruit during more than twenty years; but few of them have kept it pure. One may there trace the reversion through various grades from the typical to almost worthless kinds.

In view of all the facts that have here been stated, there seems to be no room for doubt as to the spontaneous, saltatory and phylogenetic character of the mutation which produced the Washington variety of tomato. Whether it will show the usual degree of varietal stability in future seed propagation, and whether any similar mutation will occur in other varieties of tomato under conditions similar to those of my garden, remain to be demonstrated.

SCIENTIFIC BOOKS.

A Treatise on Zoology. Edited by E. RAY LANKESTER. Part III. The Echinoderma, by F. A. BATHER, assisted by J. W. GREGORY and E. S. GOODRICH. London, A. and C. Black. 1900. Pp. vii + 344.

The student of zoology, if he wishes an elementary text-book, finds as great difficulty in making his selection as he does in buying a new bicycle or typewriter. Apparently the more advanced student will not be thus hampered by any embarrassment of riches, for it is doubtful whether any other work aims as high and attains as much as the volume under review.

The average worker who has added somewhat to his primary zoological training finds it a dreary and often fruitless performance to extract the new facts of science or the present state of knowledge on any particular topic from the almost endless collection of 'elementary' text-books, no matter how valuable they may be in fulfilling their true function. It is almost equally tiresome to sift out the same information from the great mass of technical papers on particular things. The present volume supplies in a large degree this deficiency for the Echinoderma, and is a most welcome addition

to general zoological literature. The entire series is planned to include ten parts, of which this is the third. Each of the larger groups of animals is to be described by a separate author after a definite model, in order to secure uniformity in both scope and method.

The general systematic survey of the phylum Echinoderma, with its seven classes, is quite full and comprehensive and includes the main facts of ontogeny, phylogeny, anatomy and classification. The orders and families are all clearly defined and most of the prominent genera are reviewed or mentioned. One of the striking features of this volume is the fulness with which the fossil forms are treated, thus according them their true value in any general treatise on echinoderm morphogeny. Instead of the starfishes and sea-urchins constituting the entire program, or 'whole show,' as they do in the minds of the average student and in half the text-books, here they form but the last two of the seven classes recognized, and the length of their discussion is in proper proportion. It is sincerely to be hoped that similar true values will be given among other classes, whether extinct or not.

The phylum Echinoderma comprises two divisions or grades, the Pelmatozoa and the Eleutherozoa. In the first are the classes Cystidea, Blastoidea, Crinoidea and Edrioasteroidea. In the second grade are the Holothuroidea, Stelleroidea and Echinoidea. This arrangement shows the unequal value of the classes and does not express their phylogenetic relations. The latter probably would be more truly represented, according to Bather, by placing a primitive class, Amphoroidea, at the base and deducing from it several lines of descent, namely, Edrioasteroidea, Anomalocystida, Aporita, Rhombifera and Diploporita. From the Edrioasteroid line, it is supposed, there sprang first Holothurians, then Stelleroidea, then Echinoidea. The Blastoids are included in the Diploporite line, and from them as a fresh development with a new lease of life arose the important class Crinoidea, whose discussion occupies, as is wholly proper, nearly one-third of the present volume.

The class Stelleroidea comprises the Asteroidea and Ophiuroidea, generally considered as quite distinct. Some recent genera, how-

ever, and many of the fossil forms, show that no clear line of separation can be drawn, though the names are still retained for simple convenience.

The usual primary subdivisions of the Echinoidea into two subclasses, the Palæechinoidea and Euechinoidea, have been abandoned and the older divisions, Regularia and Irregularia, adopted. The primitive ancestral Echinoid is unknown, though it is evident that the first forms were small sac-like bodies, with the mouth and anus at opposite poles and the muscular body supported by a series of angular plates, of which five pairs were perforated by pores. The thickening of the plates and the consequent loss of flexibility is believed to explain the reduction in the number of vertical rows taking place in the passage from paleozoic to neozoic genera.

C. E. BEECHER.

Studien über die Narcose, Zugleich ein Beitrag zur allgemeinen Pharmakologie. By E. OVERTON. Jena, Gustav Fisher. 1901. Pp. 195.

The chief object of these studies is the presentation of a new theory of narcosis which was put forward simultaneously but independently by Overton and H. Meyer. The essential point of the theory is that narcotics are such substances which are more or less soluble in the lipoids of the nerve cells, chiefly cholesterin and lecithin. However, as all substances reach the nerve cells only after being taken up by the blood and the lymph, they have in the first place to be soluble in the chief medium of these fluids—*i. e.*, water. The question, therefore, whether and in what degree a substance is a narcotic—*i. e.*, whether and in what degree it is able to enter into the nerve cell—depends upon whether and how much this substance is more soluble in fats than in water; in other words, the narcotic capacity of a substance depends upon the coefficient of its solubility in organic solvents divided by its solubility in water.

The book consists of two parts. The first part deals in an interesting and instructive way with the general aspect of the subject of narcosis. At the start the author shows that the distinction made by Claude Bernard, Dastre and other French writers, between anæsthetics

and narcotics cannot be maintained. Neither does the practical separation of the inhalation anæsthetics from the other narcotics have a scientific basis. There is, however, according to the author, a distinct difference between indifferent narcotics and narcotics of a basic character. The latter vary in their effects upon animals as well as plants from species to species; while the indifferent narcotics affect all vertebrates and some invertebrates in the same degree, provided the concentration of the narcotic within the blood of the animal is taken as a basis for the unit, and not the quantity of the narcotic used up in the production of the narcosis of the animal. The writer discusses the various steps which a narcotic has to pass through from its administration to the animal to its arrival in the body cells, and the different modes of penetration of the several layers of the cell, according to the compound employed as a narcotic. He then describes in detail the methods employed by Paul Bert, as well as those employed by himself, to obtain a constant concentration within the plasma of the blood of the volatile as well as of the non-volatile narcotics.

The author reviews the different theories of anæsthesia: hyperæmia, anæmia, Claude Bernard's semi-coagulation of the protoplasm, Dubois's theory of partial dehydration of the protoplasm. He quotes further Richet's rule that a compound is the stronger an anæsthetic the less soluble it is in water; and after reviewing our present knowledge of the presence of cholesterin and lecithin in the nerve tissues, he mentions that already as early as 1847 Bibra and Harless have suggested that there might be a connection between anæsthesia and the capacity of the anæsthetics to dissolve fats; and that L. Hermann has further suggested that cholesterin and lecithin of the ganglion cells might present the point of attack of the anæsthetics.

Turning to his own above-mentioned theory Overton states that he studied the solubility of the narcotics in olive oil, on account of the difficulty of obtaining sufficient quantities of lecithin, and describes in detail the physical and physiological methods employed by him for determining the division-coefficient (Thei-

lungs coefficient) $\frac{\text{oil}}{\text{water}}$ of the many indifferent and basic anæsthetics. His studies led him to the conclusion that the narcotic power of a compound depends in the first place upon its division-coefficient between the aqueous medium and the cholesterin-lecithin solvents of the organism, provided the absolute solubility of the compound in the cholesterin-lecithin solvent is not below a certain minimum.

In the second part detailed descriptions and tables are given of the numerous experiments made on a great many compounds, establishing in each one its division-coefficient and its narcotic power. The compounds comprise indifferent and basic narcotics, also antiseptics and antipyretics which possess more or less anæsthetic powers as secondary effects. The author draws from his numerous experiments the conclusion that the longer and the less branched the carbon chains of a compound are, the stronger is its narcotic power, and that the substitution of a hydrogen atom by a hydroxyl group diminishes, and the substitution by an alkyl group increases, the narcotic power of a compound. Overton thinks that the indifferent narcotics interfere probably in a physical way with the cholesterin and lecithin of the cells, while the basic narcotics interfere also with the protoplasm of the cell, hence the greater clinging of the latter group of narcotics to the cells and their deleterious effects.

Overton's book is a very valuable contribution to biology and pharmacology; it opens new fields and new methods of research and will prove to be a fruitful stimulus to student and investigator.

S. J. MELTZER.

NEW YORK.

Les matières colorantes naturelles. By V. THOMAS (Chef des travaux de chimie appliquée à la Faculté des Sciences de Paris). Une publication de l'Encyclopédie Scientifique des Aide-Mémoire. Publiée par Gauthier-Villars, Paris, sous la direction de M. Léauté (Membre de l'Institut). Pp. 180.

It is probable that no department of chemistry, during the past thirty years, has experienced a more marvelous development and

elaboration than that relating to the artificial dyestuffs. At the present time these synthetic dyes are numbered by the thousand, and millions of dollars are invested in their commercial production. Two of the largest chemical factories of the world are devoted to this industry, one employing over 200 trained chemists, the other over 160, practically all of them Ph.D. men from the universities. The relation between the structure of these dyestuffs and their tinctorial value has been definitely established for most classes of artificial colors, and the literature of the subject is vast in extent.

The result of this tremendous activity in the field of artificial colors has been that the natural colors have been correspondingly neglected, and it is only within quite recent years that attention has again been directed to these substances, many of which have been familiar since ancient times. These scattered researches upon the tinctorial constituents of plants used in dyeing have been collected, digested, and the results presented in a condensed form by the author. The work is ably and carefully done, the chapter upon the Flavone Colors being especially praiseworthy.

In this volume the author treats only those natural coloring matters which are commonly regarded as derivatives of benzophenone, xanthone or flavone, thus including the majority of the natural yellow dyes.

Each chapter opens with general statements concerning that particular group of colors, its history, development, etc. This is followed by a detailed description of the individual colors, giving history, preparation, properties, tinctorial value, etc., the reactions and syntheses by which the constitutional formula has been elucidated being clearly and concisely explained. References to original articles are numerous, and in some cases (*e. g.*, syntheses in the flavone group) quite extensive.

The separate chapters deal with the following colors:

I. Derivatives of benzophenone.—Maclurin and derivatives, catechin and derivatives, kinoin.

II. Derivatives of xanthone.—Indian yellow, euxanthone, gentisin and gentisein, datiscetin, paradatiscetin.

III. Derivatives of flavone (phenylpheno- γ -pyrone).—Chrysin, tectochrysin, apigenin, acacetin, luteolin, quercetin, rhamnetin, isorhamnetin, rhamnazin, fisetin and derivatives, morin, myricetin, k ampferid, galangin, loto-flavine.

The volume concludes with an alphabetical table of the coloring matters and their derivatives, giving the name of the compound, its melting point, and the reference to the page of the text where the same may be found described in detail, thus constituting an excellent index.

The book presents an able review of a field which is frequently unjustly slighted in the larger text-books. It can be heartily commended to those interested in this branch of organic chemistry.

MARSTON TAYLOR BOGERT.

Pflanzenphysiologie. Ein Handbuch der Lehre vom Stoffwechsel und Kraftwechsel in der Pflanze. Von DR. W. PFEFFER. II. Kraftwechsel. Zweite vollig umgearbeitete Auflage. Leipzig, Wm. Engelmann. 1901. Pp. 353.

The first volume of this comprehensive work appeared in 1897 and was reviewed by the writer of this note in *SCIENCE* (7: 318. 1898). The recent part deals with the general action of growth, and the influence of various factors upon it, the inherent causes of specific form, variation and heredity, rhythm and resistance.

The commendation given the first volume of this splendid work seems equally well deserved by the second. The citations of literature are quite inclusive up to 1900, and many of the more important papers appearing since that time are given, although not much time could have been given to a consideration of their contents.

It is to be said that the author has not had so much critical editorial work before him in the preparation of the present part as in the first volume, since the greater number of principles discussed are in the form in which they have been accepted for a decade. Much of the material rests exactly as it was left by Pfeffer's lengthy papers of a few years since upon transformations of energy, and in other sections the subject matter has remained almost undisturbed since the first edition of the book.

Some of the phases of the activity of the plant discussed do not appear to have been carried to the extent that might be reasonably expected from a work of this character. Thus in dealing with the influence of light upon plants, the author has not followed to a logical conclusion the discussions foreshadowed in the preface.

The influence of water content upon growth and form, correlation, reproduction and regeneration comes in for a well-conceived treatment, and the pages devoted to these topics are valuable additions to literature.

The first volume has already been translated by Dr. Ewart in a manner adding much to its scientific and practical value, and it is to be hoped that he will be as speedy and attentive in editing the present volume. An unusually large number of typographical errors will doubtless be reduced to a minimum in the process.

The fulness of discussions, exactness and pertinence of citations, together with the grasp of the subject and breadth of view of the author, make this book very easily the greatest work yet produced on plant physiology, and in the historical development of the subject it will prove to be as valuable as the notable volume of Sachs.

D. T. MACDOUGAL.

SCIENTIFIC JOURNALS AND ARTICLES.

THE October (closing) number of Volume 2 of the *Transactions of the American Mathematical Society* contains the following papers: 'Geometry of a Simultaneous System of Two Linear Homogeneous Differential Equations of the Second Order,' by E. J. Wilczynski; 'Theory of Linear Groups in an Arbitrary Field,' by L. E. Dickson; 'On Certain Aggregates of Determinant Minors,' by W. H. Metzler; 'Ueber die Anwendung der Cauchy'schen Multiplikationsregel auf bedingt convergente order divergente Reihen,' by A. Pringsheim; 'Ueber den Goursat'schen Beweis des Cauchy'schen Integralsatzes,' by A. Pringsheim; 'New Proof of a Theorem of Osgood's in the Calculus of Variations,' by O. Bolza; 'On Certain Pairs of Transcendental Functions whose Roots Separate each other,' by M. B ocher; 'On the System of a Binary Cubic and a Quadratic and the

Reduction of Hyperelliptic Integrals of Genus Two to Elliptic Integrals by a Transformation of the Fourth Order,' by J. H. McDonald; 'On the Theory of Improper Definite Integrals,' by E. H. Moore; 'On the Convergence and Character of a Certain Form of Continual Fraction,' by E. B. Van Vleck; Notes and Errata, Volumes 1 and 2.

The October number (Volume 8, No. 1) of the *Bulletin of the American Mathematical Society* contains the following articles: 'The Eighth Summer Meeting of the American Mathematical Society,' by F. N. Cole; 'The Ithaca Colloquium,' by Edward Kasner; 'Upon the Non-Isomorphism of two Simple Groups of Order $8\frac{1}{2}$,' by Ida M. Schottenfels; 'Concerning Surfaces whose First and Second Fundamental Forms are the Second and First Fundamental Forms respectively of another Surface,' by Alexander Pell; 'Notes,' and 'New Publications.' The November number of the *Bulletin* contains: 'On Wronskians of Functions of a Real Variable,' by Maxime Bôcher; 'The Configurations of the 27 Lines on a Cubic Surface and the 28 Bitangents to a Quartic Curve,' by L. E. Dickson; 'The Fiftieth Annual Meeting of the American Association for the Advancement of Science,' by G. A. Miller; 'Riemann-Weber: Partial Differential Equations of Mathematical Physics,' by J. S. Ames; 'Notes,' and 'New Publications.'

SOCIETIES AND ACADEMIES.

AMERICAN PHYSICAL SOCIETY.

THE fall meeting of the American Physical Society was held at Columbia University on Saturday, October 26, President Michelson presiding. The first paper, by F. L. Tufts, described experiments on the effects of stationary sound waves on unignited gas jets. The disturbances caused in such jets by sound waves were made visible by means of the 'Schlieren Methode,' the source of illumination being the spark of an induction coil. The jet was found to assume a vibrating sinuous form, with increased amplitude at greater distances from the orifice. The results could be explained upon the assumption that the initial velocity of the gas, upon issuing from the orifice, is the re-

sultant of its own proper velocity and that due to the vibration of the sound wave. Photographs of unignited jets when disturbed in this way were shown. A second paper by Mr. Tufts dealt with experiments with the ordinary organ pipe. The Schlieren method was applied in this case to show the vibrations of the blast of air blown against the tongue of the pipe, and photographs were shown which gave excellent confirmation of the usual theory of the action of such pipes.

A note on the use of the Arons' mercury lamp as a source of illumination in certain color experiments was presented by Ernest Merritt. The light from the mercury arc is chiefly due to three lines in its spectrum, lying respectively in the violet, the green and the yellow. These lines are sufficiently near to the three primary colors to make the light of the lamp seem not greatly different from white; but when the lamp is used to illuminate colored objects the absence of the red is rendered evident. Red objects, for example, usually appear black when seen by this light. When a selection is made from colored worsteds, such as are used in the ordinary test for color-blindness, the selections are much the same as those made by a red-blind individual.

After the noon recess the Physical Society joined with the Mathematical Society during the reading of a paper by M. Hadamard on the 'Theory of Elastic Plates.' In the afternoon session a note was presented by Wm. Hallock on 'Measurements of Subterranean Temperatures,' in which were given the results of the most recent work on this subject. An instrument for the measurement of entropy was described by A. G. Webster. This 'entropy meter' had not been actually constructed, nor did the speaker think that it would make a very practical apparatus. It showed a possible method, however, by which entropy changes might be automatically registered and measured. Mr. Webster also reported the results of experiments upon the audibility of sound over grass and water. It was found that under similar conditions of quietness, etc., a given sound could be heard almost exactly four times as far over water as over grass. The assumption that water is a perfect reflector, while grass

is a 'black body' toward sound waves, is not sufficient to explain this difference.

ERNEST MERRITT.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 342d meeting was held on Saturday evening, November 2.

Mr. H. J. Webber exhibited specimens of the pineapple suffering from the disease termed 'root bind.' This was caused by planting improperly trimmed cuttings, which caused the roots as they developed to wind tightly around the stalk, causing defective nutrition and finally death.

Charles Louis Pollard gave some 'Notes on a Trip to Mount Mitchell,' made during the present spring for the purpose of obtaining botanical specimens and of studying incidentally the distribution of certain species of violets.

H. J. Webber described 'A Cow Pea Resistant to Root Knot Worm,' stating that in examining an extensive series of cow peas and other plants this one variety had been found entirely free from the parasites, although growing immediately between two varieties that were badly affected. The root knot worm, a small nematode, not only affected cow peas, but very many plants, doing serious damage, and the finding of the cow pea led to the hope that other plants might be found equally resistant, while by planting the pea as an alternating crop it would be possible to lessen the numbers of the worms.

Frederick V. Coville gave an 'Exhibition of Specimens of Alaskan Willows,' including examples of all species from that region. For descriptive purposes the speaker grouped these willows in three divisions, the tree, bush and procumbent forms, exhibiting a series of slides showing the floral divisions of Alaska and illustrating the habitat of the various groups. The different species were described in some detail as to their range, abundance or rarity, date of discovery and economic value when the species was of sufficient size.

M. A. Carleton spoke of the 'Characteristics and Distribution of Xerophytic Wheats,' illustrating his remarks with lantern slides of the Russian wheat region. The speaker said that wheats were grouped in eight divisions: (1) Common; (2) Club or square head; (3) Poulard;

(4) Durum or macaroni; (5) Polish; (6) Spelt; (7) Emmer; (8) Eiuikorn.

What might be called xerophytic or drought-resistant wheats belong to several of these groups, but the most important ones belong in the durum or macaroni wheat group. This is the group, therefore, which was chiefly discussed. These wheats differ from the ordinary wheats as now known in this country by having rather large flattened heads with large chaff and very large yellowish white grains which are extremely hard and vitreous in fracture, and often rather transparent. They always have beards, which are usually very long. In some varieties the heads and beards are black. These wheats are very resistant to drought, being able to grow where the rainfall is as low as ten inches per annum. They also resist the leaf rust very greatly, but are more or less subject to stem rust when it occurs in very great abundance. They are also seldom injured by bunt, smut or other diseases. Naturally they are adapted to semi-arid or arid regions, and at present are growing mainly in east and south Russia, Algeria, Argentina, parts of India and in various portions of the Orient and Mediterranean region. In this country they are especially adapted to our semi-arid plains from North Dakota to Texas.

The investigations of this department on the basis of soil and climate have led us to believe that those wheats will yield about one-third more to the acre in our semi-arid regions than other wheats, and what is more important, produce a constant yearly crop in large portions of that region where other wheat cannot be grown at all. Numerous practical tests have since proved this prediction to be justified. At the same time these wheats are the very best adapted for making macaroni, and there is now a great demand for them from this country, the people in Europe having learned of what good quality they are. Wherever they have been tried for the purpose, they also are considered to make excellent bread. In the establishment of these durum wheats we have a striking example of the beneficial results that may follow purely scientific investigations.

T. W. STANTON,

Secretary.

THE TORREY BOTANICAL CLUB.

AT the meeting of the Club on October 8 the scientific program consisted of informal reports of summer's work, including reports from Dr. Rydberg, of his visit to Sweden and Norway; from Mr. Murrill, of his attendance on the Botanical Congress at Geneva; from Mrs. Harris, of work among the lichens in the Adirondacks; and from Mrs. Britton, of work among the mosses there and in the Catskills, with advance notes reporting Dr. Britton's collection in the West Indies. Dr. Underwood spoke of his collecting in Porto Rico, examining thoroughly the eastern part of the island during five weeks spent there. He collected over 1,000 numbers of dried plants and sent back a large number of cacti now growing in the Botanical Garden. He was afterward in the Berkshire Hills for two weeks, then attended the A. A. S. meeting at Denver, Colorado, and spent some time in botanical work throughout many parts of that State, collecting about 600 numbers of the fall flora, particularly about Ouray and Pikes Peak.

The secretary reported extension of range of *Aster curvescens* by his discovery of its growth in quantity in the southern Berkshire Hills.

Dr. MacDougal reported his work in Montana where he aided in maintaining a summer laboratory for four weeks at Big Fork, at the north end of Flathead L., and entertained Dr. H. C. Cowles and twenty students of the University of Chicago. Dr. MacDougal then joined a collecting party exploring a part of northern Montana not known to have been before visited by a botanist, except as Canby gave it a flying trip in 1884. Dr. MacDougal collected about 900 flowering plants. Some days of every week the work was among snow and ice, with alpine flora, lakes a mile long of snow-water, chiefly without outlet and without life, as they freeze solidly to the bottom. He exhibited a panoramic view of the mountains seen across Flathead L., with numerous photographs showing the technique of collecting and camp equipment.

Dr. M. A. Howe reported on his eleven weeks' collecting trip for marine algæ in Nova Scotia and Newfoundland. He made about ten principal stays of a week each, at Yarmouth, Digby, Grand Pré; at Pictou, a station for

Fucus serratus, and where he obtained it in quantity; at Cape Breton; on the south end of Newfoundland, the richest locality in the larger kelps. There and along the south and east coast of Newfoundland is almost treeless, as is generally reputed, but firewood and lumber are obtainable 20 miles inland, and the west shore is forested with spruce, fir and tamarack, with yellow and white birch. Journeying east through the practically uninhabited interior, a thin coniferous forest was met, especially all around the numerous lakes. Where fires had been through it, for 20 or 30 miles, all was a flaming purple of fire-weed (*Epilobium*).

Dr. Howe mentioned the current names for the three native berries eaten so commonly there, *squashberry* for *Viburnum pauciflorum*; *baked apple berry* for *Rubus chamæmorus*; and *partridge berry* for *Vaccinium vitis-idaea*, called Swedish cranberry in parts of the U. S. where imported from Scandinavia. Dr. Howe remained four weeks in Newfoundland, and was afterward at Halifax Harbor, N. S., where Harvey, author of the *Nereis*, had made important collections.

Dr. R. M. Harper reported collecting again in Georgia, with about 500 numbers, visiting many new localities, traveling about 1,400 miles by rail, and doing much work on plant-distribution. He spoke particularly of the remarkable flora of the sandhills in Bulloch Co., resembling the 'scrub' flora in Florida. Photographs of these and other parts visited were shown. Along shady banks of the Chattahoochee River, some 50 miles from Columbus, he found some southern species, reaching their northern limit. In the Pine Mountains, southernmost eastern extension of the Appalachians, he found on the northern slopes an interesting mixture of Southern and Northern species. The southern slopes are covered with the long-leaved pine, with the flora characteristic of the pine barrens of the southern coastal plain. Among the interesting plants collected by Mr. Harper were *Elliottia* and, at Thomasville, Ga., *Nymphæa orbiculata*.

Brief remarks followed regarding fall blossoming and foliation in New York City, and Dr. Underwood exhibited a fresh specimen of *Botrychium dissectum*. It was noted by Mrs. Britton

and others that the maples, lindens and button-woods in Union Square, Washington Square and Madison Square are now covered with fresh leaves as in May, owing to defoliation by caterpillars; that the catalpas, honey locusts and poplars were but little eaten, and are not, therefore, covered with fresh leaves, but were injured by an early drought, and have sent out new shoots to replace those lost; these new shoots are now covered with fresh young leaves. The English elms in Washington Square were little eaten and have no new leaves. Horse-chestnuts have new shoots and some have new blossoms. Cherry trees have also been in bloom again. The magnolias and tulip trees of Bronx Park have blossomed and fruited twice this year.

EDWARD S. BURGESS,
Secretary.

THE SCIENCE CLUB OF THE UNIVERSITY OF
WISCONSIN.

The first meeting of the Science Club of the University of Wisconsin for the present college year was held on Thursday evening, October 31. The newly elected officers of the Club are: President, Professor W. W. Daniells; Vice-President, Professor Wm. H. Hobbs, Secretary and Treasurer, Professor L. S. Smith.

Two papers of both scientific and economic interest were presented, the first by Dr. C. K. Leith, on the 'Mesabi Iron Range of Minnesota,' and the second by Professor C. R. Van Hise, on 'The World's Past, Present and Future Supply of Ores.'

Dr. Leith's paper was based on a monographic report on the Mesabi iron-bearing district of Minnesota which he is preparing for the U. S. Geological Survey. He sketched the marvelous development of the range from the time of its discovery ten years ago to its present position as the greatest iron range in the world. The range exhibits Archean, Lower Huronian and Upper Huronian rocks in typical development, and with relations so clear as to make the Mesabi almost a type district for these three pre-Cambrian series. The iron ores are confined to the 'iron formation,' which forms the middle horizon of the nearly flat-lying Upper Huronian series. The iron formation consists of ferruginous cherts, ferruginous

slates and iron ore, all of which give evidence of having resulted from the alteration of a rock made up of green ferrous silicate granules. The granules contain fifty per cent. silica and thirty per cent. ferrous iron, with little or no potash. They were called glauconite by Spurr, but their study by the U. S. Geological Survey shows them not to be glauconite of organic origin, but a ferrous silicate deposited on the sea-bottom through chemical reactions. The iron ores have resulted from the alteration of this type of rock through the agency of underground waters. The ores are now found where the action of these waters has been vigorous. These places are the southward-pitching troughs of the gently folded iron formation, and in the parts of the troughs lying along the middle slopes. The bottoms of the troughs are mainly slaty layers within the iron formation itself.

The iron-ore deposits of the Mesabi are similar to those of other ranges of Lake Superior in having resulted from the alteration of some earlier rock, in having been concentrated by underground water, and in occurring in troughs with impervious basements. However, in the Mesabi the rock from which the iron ores resulted is the green ferrous silicate, while in the other districts it is iron carbonate. In the Mesabi the pitching troughs containing the iron-ore deposits have very gentle dips and great horizontal dimensions, while the pitching troughs in the other ranges are narrow and sharp, and have great vertical dimensions. Finally, and possibly in some way connected with these features, in the Mesabi district the ores are exceedingly soft and friable, while the old range ores are fairly hard.

Dr. Leith illustrated the various methods of mining the Mesabi ores, the most striking of which is loading by steam shovels directly on to cars. He described also the great mines of the district, several of which are shipping over 1,000,000 tons of ore a year.

The amount of ore in sight on the Mesabi is roughly estimated at 500,000,000 tons, or about twice as much as there is in sight on all the rest of the Lake Superior ranges together. It is also far in excess of all the ore now known in other parts of the United States. The development of the Mesabi range has lowered the

price of ore for the American steel manufacturers; and this fact alone, regardless of any superiority in methods, would give them the advantage in foreign markets. In Europe at the present time the situation as to the iron ore supply, as to the demand for same, and as to prices, is not greatly dissimilar to what it might have been in the United States had no Mesabi range been discovered to ease the demand for old range ores and to lower prices. A great basal factor, then, in the superiority of the United States in the iron and steel trade is the Mesabi iron range. The United States Steel Corporation controls from 70 to 80 per cent. of this raw material, and hence its future influence on the iron and steel trade of the world may be conjectured.

Professor Van Hise followed with a brief general discussion of the world's past, present, and future supplies of ores. He called attention to the tremendous revolution in mining ores of all kinds which has occurred in the past century, and ventured the opinion that in the past fifty years more ore has been mined in the world than in all its previous history.

The above papers were discussed by Professor J. Morgan Clements. Professor Clements also summarized the relation of the work which the U. S. Geol. Survey has been doing in the Lake Superior region, as well as in other mining districts of the United States, to an intelligent exploration for ore deposits and the scientific development of the same when they are found.

A resolution of sympathy in memory of the late Professor Nelson O. Whitney, of the Engineering Faculty of the University of Wisconsin, presented by Professors J. B. Johnson, F. E. Turneure, and Louis Kahlenberg, was adopted by the Club. L. S. SMITH.

THE SCIENTIFIC ASSOCIATION OF THE UNIVERSITY OF MISSOURI.

THE Association has elected the following officers for the ensuing year: President, Professor W. G. Brown; Vice President, Professor C. F. Marbut; Secretary, Dr. Charles Thom; Treasurer, Professor C. A. Ellwood; Chairman of Executive Committee, Dr. C. M. Jackson. At a meeting October 14, Professor H. B. Shaw displayed a series of lantern slides illustrating the

important features of the largest and most successful electrical plants in the United States. At its regular meeting on the last Monday night of each month a paper is presented embodying some original work done by the author. At its supplementary meeting held usually on the second Monday night, a popular presentation of some scientific subject offers each department an opportunity to present matters of general interest from any source.

CHAS. THOM,
Secretary.

UNIVERSITY OF MISSOURI.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis on the evening of November 18, twenty-four persons present, the following subjects were presented:

Mr. F. C. Baker, some interesting molluscan monstrosities.

Dr. Stuart Weller, Kinderhook faunal studies. III. The faunas of beds No. 3 to No. 7 at Burlington, Ia.

Professor William Trelease read an untechnical address on the progress made in botany during the nineteenth century.

One person was elected to membership in the academy.

WILLIAM TRELEASE,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

THE PYTHON IN PENNSYLVANIA.

TO THE EDITOR OF SCIENCE: On August 9, a python, probably *Python natalensis*, was found in the grass on Presque Isle, Pa., by three young men from Erie who, as they supposed, killed it and took it to the city. However, it revived and was exhibited in the window of the Tribune bicycle store. On August 29 I measured and weighed it. The length was about seven feet four inches, greatest girth eleven and one-half inches; weight, seventeen pounds. That evening it pushed away the wire netting from one corner of its cage and escaped. It probably took up its residence under a building in the rear of the store, but had not been seen when last I heard, October 14. Reports of the liberation of large snakes in the vicinity of

Presque Isle I investigated, but they proved to be unfounded. Who can tell how this African snake found its way to the shore of Lake Erie and how long it had found subsistence there?

E. L. MOSELEY.

SANDUSKY, OHIO,

SHORTER ARTICLES.

THE UNEXPLAINED SOUTHERLY DEVIATION OF FALLING BODIES.

THE formula published by Mr. Roever, of Washington University (SCIENCE, July 12, 1901, p. 70), giving the southerly deviation of falling bodies due to the earth's rotation, is of special interest, because it marks a fresh attack upon a problem which in my 'History of Physics,' p. 75, I call an unsolved problem. The difficulty lies in a wide discrepancy between the theoretical and the observed results. The latter are over 1,000 times greater than the former.

1. *Experiments.*—When Robert Hooke undertook to verify experimentally Newton's prediction of an easterly deviation of falling bodies, due to the earth's rotation, he reported also a small southerly displacement.*

When in 1791 G. B. Guglielmini again undertook to verify Newton's prediction by a series of experiments from a tower at Bologna, a southerly deviation was again observed. He found H ('height' or distance fallen through) = 241 Paris feet (78.3 m.), E. D. ('easterly deviation') = 8.375 lines (18.894 mm.), S. D. ('southerly deviation') = 5.272 lines (11.894 mm.).†

In 1802 J. F. Benzenberg experimented from the St. Michael's tower in Hamburg. H = 235 feet (76.3 m.); E. D. = 3.99 lines (9.00 mm.); S. D. = 1.5 lines (3.4 mm.).‡

* See Ball, 'An Essay on Newton's Principia,' pp. 146, 149, 150.

† See Gilbert's *Annalen*, Vol. XI., p. 172; Vol. XII., 1803, p. 372; Vol. XIV., p. 222. Rosenberger, in his 'Geschichte der Physik,' Vol. III., p. 96, refers to Guglielmini's book, 'De diurno terrae motu, experimentis physico-mathematicis confirmato,' Bologna, 1792, but as early as 1803 the book is spoken of as being very rare.

‡ Gilbert's *Ann.*, Vol. XIV., p. 222. Rosenberger refers to Benzenberg's book, 'Versuche über die Gesetze des Falles,' Hamburg, 1804.

In 1804 Benzenberg experimented in a shaft of a coal mine at Schlebusch. H. = 260 ft. (84.4 m.). An E. D. was noticeable, but on selecting from the total number those experiments which, in his judgment, were made under the most favorable conditions, there seemed to be no indication of a S. D.*

In 1831 F. Reich experimented in a mine-shaft at Freiberg. H. = 158.5407 m., E. D. = 28.396 mm., S. D. = 4.374 mm. These results are deduced from six series of experiments. Altogether 106 balls were dropped. Reich's are the most carefully conducted experiments on the subject which have been made. Yet they differ much among themselves, though not as much as those of Benzenberg.†

In 1848 W. W. Rundell published experiments made in the shaft of a Cornish mine.‡ Balls were dropped through a distance of one-fourth of a mile and a S. D. of 10 to 20 inches (25 to 51 cm.) was noticed. From the account of the experiments it is difficult to convince oneself that sufficient precautions were taken against disturbances from air-currents.

All observers experimented with metallic balls. Are these observed southerly displacements due wholly to experimental error? Though we may incline to that opinion, we cannot deny the force of Benzenberg's remark: 'Sonderbar bleibt doch diese Tendenz der Fehler nach Süden.'

2. *Theory.*—Mr. Roever is not the first to derive a formula for S. D., due to the attraction of the rotating earth. This was done in 1803 by Gauss § and by Laplace.||

Neglecting the resistance of the air, Gauss obtained

$$\begin{aligned} \text{E. D.} &= y = \frac{1}{3} \cos \phi \, g \, \text{int}^2, \\ \text{S. D.} &= x = \frac{1}{3} \cos \phi \, \sin \phi \, g \, n^2 t^4, \end{aligned}$$

where u is the angular velocity of the earth, ϕ the latitude. Applying this to Benzenberg's

* Gilbert's *Ann.*, Vol. XVIII., p. 381.

† See Poggendorff's *Ann.*, Vol. XXIX., 1833, p. 494. Rosenberger refers to Reich's book, 'Fallversuche über die Umdrehung der Erde,' Freiberg, 1832.

‡ Robertson's *Mechanic's Magazine*, London, Vol. XLVIII., p. 485.

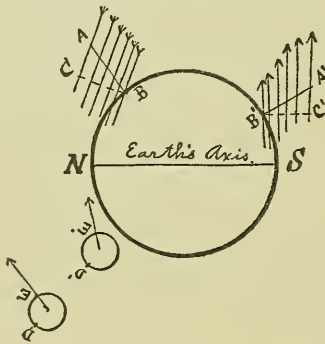

§ Gauss, 'Werke,' Vol. V., 1877, p. 495.

|| *Bull. d. sciences par la Soc. Philomath.*, Plairial an 11 (1803).

data, Gauss took $\frac{1}{2} g t^2 = 235$, $\phi = 53^\circ 33'$, $t = 4$ seconds, $nt = \frac{360}{3} \frac{6}{5}$ spatial minutes, and $1' = \frac{1}{3438}$ radians. Gauss found E. D. = 3.91 lines, the experimental value being 3.99. The formula gives S. D. = .00046 lines, the experimental value being 1.5 lines.

The resistance of the air was found by both Gauss and Laplace to make no appreciable difference in the S. D. Several writers deduced formulæ which seemed to give a much larger S. D. than those of Gauss and Laplace, but in every case some error in the reasoning has been detected.* The deductions of Gauss and Laplace have, thus far, stood the test of criticism.

Other than gravitational agents were considered by Oersted and Sir John Herschel.† They suggested that the 'electric currents * * * known to be circulating around the earth in the direction of the parallels of latitude' induce currents in a falling metallic body and cause deflection to the south. But they became doubtful of this explanation by the remarks of Grove, who said that "inasmuch as a falling body was

* See Gauss's criticism on Olbers, Gauss' 'Werke' Vol. V., p. 495; reference to Guglielmini's speculations in Gilbert's Ann., Vol. XII., p. 372; M. Petit's article in *Comptes Rendus*, Vol. XXXIII., p. 193, 1851, and M. Dupré's criticism of that article in Vol. XXXIV., p. 102, 1852, as well as Rosenberger's criticism of Dupré, in *Gesch. d. Physik*, Vol. III., p. 436; W. C. Redfield in *Am. Journal of Science*, Vol. III., p. 283, 1847, and the correction on p. 451 of same volume; the theoretical part, contributed by Professor Cowie, in W. W. Rundell's article, *Mechanic's Magazine*, Vol. XLVIII., p. 488.

† *Am. Journal of Science*, Vol. III., 1847, p. 139; *Report British Assoc.*, 1846, Misc. Communicat., p. 2.

moving between electrical currents, placed both north and south of its line of fall, in his opinion the effect of the one would counterbalance that of the other, so as together to produce no effect."

I myself have been considering the effect of a metallic ball falling through the varying magnetic field of the earth. Electric currents will be generated in the ball. Resolve the motion of the ball in the northern hemisphere into two components, one component, *AC*, parallel to the lines of force, the other, *CB*, perpendicular to them. The motion along *AC* produces no current in the ball. That along *CB* generates a current in a plane normal to the earth's magnetic lines of force. By Lenz's law, there is a resistance to and diminution of the motion producing the current. Hence, in all regions north of the magnetic equator there results a northerly deviation. Similar reasoning shows that south of the magnetic equator a falling metallic body experiences a southerly deviation.

Moreover, if the dip is greater in the lower levels of the atmosphere, then it will be seen from the two positions of the ball in our figure, that there is a relative motion of rotation between the ball and the earth's lines of magnetic force. The ball has in the northern hemisphere an *apparent* rotation about an axis pointing east and west, in a direction counter-clockwise when seen by an observer looking westward. Hence by Lenz's law the ball will experience a *real* rotation in a clockwise direction about the same axis. The interaction between the rotating ball and the air will cause the ball in the northern hemisphere to drift southward.

I have been unable to secure accurate data for the determination of the magnitude of the two effects, but, taking the largest rate of variation in the magnetic intensity and the dip, along a vertical line, given by Humboldt,* both effects are found much too small to cause a deviation measurable in an experiment.

It is evident that the problem of the southerly displacement of falling bodies needs reinvestigation, experimentally, and perhaps also theoretically. The Washington Monument, in

* *Cosmos*, Vol. V., pp. 97, 115, London, 1872.

our national capital, might be a good place for experimentation.

FLORIAN CAJORI.

COLORADO COLLEGE,
COLORADO SPRINGS.

ASTIGMATIC IMAGES OF THE BOTTOM OF A POOL
OF WATER.

IF light radiate from a point below the surface of water, it can pass out through the surface only within a circle forming the base of a right cone whose semi-angle is the critical angle.

Consider such rays lying in a vertical plane passing through the radiant point. The rays which have passed out into the air, if produced below the surface, are tangent to a virtual caustic. This caustic is a portion of the evolute of an ellipse, one cusp of which is in a vertical through the radiant point, and at a depth $\frac{d}{n}$, where d is the depth of the radiant

point, and n is the index of refraction. The branches of the caustic are tangent to the surface in the circle determining the critical angle. Successive sets of consecutive rays having an increasing angle of incidence do not intersect at a common point, but they intersect at consecutive points on the caustic. If the vertical plane be rotated slightly in azimuth, the rays from the same radiant point will intersect in the caustic in its new position. This caustic from the same radiant point will always lie on a surface of revolution, formed by revolving the caustic in any vertical plane about the vertical line through the radiant point.

If the radiant point be viewed by an eye placed at a fixed point, the pupil of the eye may be conceived divided into vertical zonal elements. Rays from the radiant point in these various elements will intersect in a definite area upon the surface of revolution. The point would, therefore, appear as a hazy patch upon the caustic surface. The text-books all represent the apparent position of a coin seen through a water surface, as being lifted up and towards the eye of the observer, upon the caustic surface.

It is, however, evident that if the rays diverging from the radiant point in all azimuths, and at a fixed angle of incidence, be produced backwards after passing out into the air, they

will all intersect in a common point upon the vertical line through the radiant point. If, therefore, the pupil of the eye be divided into horizontal zonal elements, all the rays entering the eye will have a virtual intersection on this vertical line. The focus of the upper zonal elements of the eye will be slightly below those of the lower. Nevertheless, the intersection of all rays entering the eye from the radiant point will be upon a line, instead of being spread out over an area as in the other case. The fact is that a plumb line deeply piercing still water appears straight throughout. The image upon the vertical line is much more distinct than that formed upon the caustic surface. The latter image imparts a haziness to the appearance of the body viewed, but the apparent position is determined by lines which intersect in a common point, rather than by those which do not.

With this view of the matter the writer in May, 1881, presented to the Academy of Science of St. Louis a discussion of the apparent form of the flat bottom of a pool as seen through the surface.* The appearance was found to be represented by a conchoid, which was related in a simple way to the conchoid of Nicomedes. The equations of both curves were deduced, and several other cases were discussed.

In a recent number of *Annalen der Physik*,† Mattheissen has deduced the equations of these two conchoids and has pointed out that the surface produced an astigmatic effect. He likewise deduces the equation for the nebulous image due to intersection upon the caustic. The minimum of this surface and that of the conchoid are coincident and tangent to each other, and they have the water surface as a common asymptote.

FRANCIS E. NIPHER.

NOTES ON INORGANIC CHEMISTRY.

THE earliest determinations of the density of sulfur vapor were by Dumas and Mitscherlich, and gave figures which pointed to the molecule S_6 , and this has passed current until quite recent times. In 1860 Deville and Troost found

* *Trans. Acad. of Sc. of St. Louis*, Vol. IV., No. 2, p. 325.

† No. 10, 1901, S. 347.

that above 860° the sulfur molecule consists of two atoms, S_2 . More recently by boiling point and freezing point methods the molecule of sulfur in solution has been found to contain eight atoms, S_8 , and it has been inferred that the same molecule exists in sulfur vapor just above its boiling point. In the *Berichte* of the German Chemical Society, Biltz goes over the whole ground, especially examining the density of the vapor under diminished pressure at the boiling point. The greatest density he could obtain corresponded to the molecule S_7 , but this was not found to be a constant point. The conclusion he draws is that two molecules only of sulfur exist, one S_8 and the other S_2 , and that at the boiling point the molecule with eight atoms begins to decompose into molecules of two atoms. This decomposition is progressive, until at 850° it is complete, the gas at this temperature consisting wholly of the molecules S_2 .

A PATENT has recently been taken out by the Clayton Aniline Company, limited, of Manchester, for the continuous concentration of sulfuric acid, which involves the use of cast-iron vessels in the place of platinum. The dilute acid is allowed to flow in a continuous stream on to the surface of a large mass of hot concentrated acid contained in a large cast-iron pan. The concentrated acid must be of a strength not less than ninety to ninety-three per cent. From the bottom of the pan the concentrated acid is drawn off at such a rate as to keep the level of the acid in the pan constant. The great advantages claimed for the process are the simplicity and the cheapness of the plant, and it has already been shown that for most uses the acid concentrated in iron pans is satisfactory.

ABOUT a year ago an article appeared in the *Comptes Rendus* by Gautier, in which the position was taken that arsenic in minute quantities is a normal constituent of the human body. By a new and very delicate method the author found and determined quantitatively arsenic in numerous organs of the body, notably in the pancreas, brain, thymus gland and skin. Since, after digestion of the pancreas with pepsin, the arsenic remained in the nuclein residue, the existence of an arsenic-nuclein was assumed.

In the last number of the *Zeitschrift für Physiologische Chemie* there is a paper by Hödlmoser, combating Gautier in every point. In eighteen cases the pancreas and liver were examined by Gautier's method, and in fifteen other cases the same organs were examined by a method, pronounced by the author even more delicate, and in no case was any trace of arsenic found. Numerous other experiments were carried out, carefully following the work of Gautier, but always with negative results. No explanation is offered of the great discrepancy between the author's results and those of Gautier, but one is promised.

THE subject of the toxic action of boric acid is brought up anew by a description in the *Therapeutic Gazette*, by Dr. J. F. Rinehart, of two cases, occurring in his practice, of poisoning by boric acid. Each was after the administration of the acid in five-grain doses every four hours. The symptoms of poisoning appeared after several days and consisted chiefly of an erythematous eruption over the body, accompanied by extreme weakness. The patients recovered slowly on ceasing to administer the drug. The conclusion drawn by Dr. Rinehart is that "any use of boric acid as a preservative of foods should be prohibited by law, as the poisonous effect of any quantity sufficient to preserve food would appear to be proven." This conclusion would, however, seem to be somewhat overdrawn, as it is hardly probable that any such quantities of the acid as were administered in the above cases would ever be ingested from foods in which it was used as a preservative. The chief danger to be apprehended from the indiscriminate use of boric acid in foods, as was recently noticed in this column, is in the case of young children, where they are fed on milk preserved by borax. Here danger may well be apprehended. In any case food preserved by boric acid should be distinctly so labeled.

J. L. H.

CURRENT NOTES ON PHYSIOGRAPHY.

THE RIVER SYSTEM OF CONNECTICUT.

THE discovery of numerous parallel faults arranged in several systems in the small Triassic area of the Pomperaug valley in western Connecticut, and the coincidence of many

streams with lines parallel to one or another of these fault systems has led Hobbs to infer a very general dependence of stream courses on fault lines or on faulted troughs ('The River System of Connecticut,' *Journ. Geol.*, IX., 1901, 469-485). He notes that the modern school of physiographers attach 'little importance to geological structure planes as a factor in determining the position and the orientation of water courses'; and if it is joint and fault planes that are meant by 'structure planes' this comment is probably deserved as far as explicit mention of such controls is concerned. Nevertheless, the value of faulting in initiating surface inequalities, and hence in determining the course of consequent streams at the time of faulting, as well as in producing planes of structural weakness, and hence in determining the later development of subsequent streams, has not been altogether overlooked. But it is under the interaction of many controls that modern physiography finds explanation for river courses, and it is the want of consideration of other controls than faults that leaves Hobbs' paper unconvincing.

The author extends the systems of fault lines from the small Pomperaug basin all over Connecticut, preserving them rigidly straight and parallel throughout. He then compares these lines with the stream courses as shown on the topographic map of the State, and where a fair coincidence is found he concludes that there is a relation of cause and effect, thus explaining 'the definite orientation of water courses.' There are serious difficulties in the way of accepting this conclusion.

It is inherently improbable that the Pomperaug fault lines possess an extension all over the State in systems so rigid as are here postulated. Some one of the infinite varieties of curvature is much more probable than the highly specialized case of straight paths. Strict parallelism is also improbable as compared to the many possible patterns of more or less distinct divergence. The possibility of accidental coincidence between eight systems of lines, seven of which run between S. 48° W. and S. 44° E., and the river courses of a region whose slope is southerly and whose structural features (independent of faults) frequently have a similar

trend, is not given sufficient consideration. Moreover, the branchwork pattern of the Connecticut valleys has little resemblance to the network pattern of valleys that have been worn along ancient fault lines in a well-faulted area: the Stockholm district of Sweden, for example. This typical district shows a most characteristic oblique reticulation in the arrangement of its valleys, such as would be expected in a maturely dissected upland, obliquely criss-crossed by many fault lines; and it has numerous isolated lozenge-shaped uplands occupying the meshes in the network of fault-line depressions. In Connecticut the valleys have not a reticulated pattern, and the uplands as a rule are not lozenge-shaped, but give forth spurs between ramifying valleys. Well defined as is the fault-line network in the Stockholm district, its lines are neither straight nor in groups of parallels; they exhibit just such irregularities of curvature and divergence as might be expected in a geological instead of in a geometrical design.

While faulted troughs (*Graben*) might have guided many Connecticut streams for a time after the Triassic deformation, it is highly improbable that such courses could persist during the deep denudation that the region as a whole has since suffered, in the course of which many streams would presumably desert their original courses in the process of adjustment to new-found structures. While the brecciated belts of fault planes might during the denudation of the region frequently gain the patronage of subsequent streams, all other belts of weak structures would be active competitors for such patronage; yet no account is taken of such competition, although it must have been common. The northward course of the Farmington, for example, follows the weak beds of the lower Trias, and is oblique to the known faults of its district. Many of the existing streams in the lowlands have courses consequent upon the form of the glacial drift; such is the case with the Quinnipiac below Meriden; and if some of these streams have now cut down here and there to bed rock, it is only by the chance of superposition that the rock is found, as in the Connecticut above Hartford. The possibility that the lower courses of the Connecticut and Housatonic have gained their southeast trends

by superposition from a now vanished cover of Cretaceous strata is rejected because fault planes 'would, in the opinion of the writer, afford the simpler explanation.' But while simplicity is a strong recommendation in artificial mechanism, it cannot be logically employed as a means of choice between two theories of river development; if that were so, no rival could be found for the Gordian method of locating the Susquehanna and other Appalachian rivers by antecedence. Fault breccias, where they occur, may certainly exert much influence on the development of river courses in Connecticut; but until their occurrence in the central and eastern part of the State is proved by something more trustworthy than the graphic extension of systematic lines from the western part, this explanation of stream orientation may be regarded as standing in an interrogative rather than in a demonstrative attitude.

LAKE WINNIPEG.

LAKE WINNIPEG, 260 miles long, with an area of nearly 10,000 square miles or a little less than that of Lake Erie, is a member of the series of lakes that occupies an inner lowland of the ancient coastal plain, marginal to the great Laurentian highland of eastern Canada. Reports by Dowling and Tyrrell give a number of physiographic details concerning the Winnipeg basin ('Report on the Geology of the West Shores and Islands of Lake Winnipeg,' Geol. Surv. Canada, XI., 1901, F. 'Report on the east shore of Lake Winnipeg. . . .' Ibid, G.). The lake is 710 feet above sea level, with a general depth of from 40 to 60 feet. Its eastern border is relatively straight, although minutely irregular in the smaller view. The rock floor here is of Archean gneisses and granites, with a few schists, all reduced to a surface of small relief, over which post-glacial lacustrine clays have been spread to an altitude of 150 feet over the lake. The clay plain is forested, but if cleared and drained it may become 'rich agricultural land.' Further eastward, the generally even but minutely rugged Archean rises above the clays, first in isolated knobs, then in larger patches, finally occupying all the surface; it is severely glaciated, bearing little drift, but with many small lakes

in its hollows. The east shore of the lake is frequently bordered by low clay cliffs; but rocks appear in low points and islands, beyond which there are many shoals. The west shore of the lake is very irregular, a frayed outline of Cambro-Silurian strata; cross-bedded sandstones below, and even-bedded limestones (Trenton) above. These rocks frequently form bluffs, back from which the country is generally level, but rising slightly further westward. Over this upland is a mantle of boulder clay, showing faint lines of stratification as if deposited in a body of water. The boulder clay frequently assumes the form of drumlins, and many of these are noted along the lake shore and on islands, where they are cut back into cliffs, while curved beaches are strung along between them, as on the southeastern coast of Lake Ontario.

The outline of the western shore strongly suggests an effective glacial erosion, by which the Trenton border has been shaped, somewhat as has been described by Chamberlin for similar outcrops in southern Wisconsin. The similarity of Winnipeg and its fellows to Onega and Ladoga of northern Russia has often been remarked, and seems to be increased as new details are gathered.

A PIEDMONT LAKE IN BAVARIA.

WÜRM or Starnberger Lake, 15 miles southwest of Munich, is one of several water-bodies piedmont to the Alps on the upland of southern Bavaria. It has recently been monographed by W. Ule ('Der Würmsee (Starnbergersee) in Oberbayern, eine limnologische Studie.' *Wiss. Veröffentl. Ver. f. Erdkunde, Leipzig*, V., 1901, 211 p., 15 figs., 5 pl., atlas of 8 sheets). The lake has an area of 57.1 sq. kil.; an altitude of 584 met., and a maximum depth of 123 met. It lies in the Deckenschotter, or oldest glacial gravels, occupying part of a valley that was primarily the result of stream erosion between the first and second glacial epochs; but the valley has been much modified by deposits of drift from branches of the Isar glacier during the second and third glacial advances. Glacial erosion is given small value in this distal portion of the glaciated area. A slight deformation, producing a depression along the mountain base,

is thought to have had some small share in aiding the formation of a lake basin here as elsewhere along the piedmont belt; but the evidence of this is in chief part borrowed from the district of Lake Zurich, and that evidence has been somewhat discredited, as far as lake-making is concerned, in recent years. A chapter is given to the systematic relations of the lake; the element of time, or stage of development, is given too small a share in the proposed classification. Neither the interglacial valley in the Deckenschotter nor the later glacial advances are described in terms of youth, maturity or old age. Temperature, color, transparency, waves, currents, changes of level, and composition are all duly considered. The monograph as a whole is very clearly written; its chapters are closed with concise summaries, and it has current page headings and an excellent index; advantages that do not always accompany scientific publications.

W. M. DAVIS.

THERMODYNAMICS OF THE GAS-ENGINE.

The second report of the Gas-Engine Committee of the Institution of Mechanical Engineers of Great Britain was presented on the 18th of October by Professor Burstall, of Birmingham University, and the results of experiments, preparations for which were described in the first report (*Proceedings*, 1898) were given. They involve some important details of a novel character and throw some light upon previously obscure points in the theory of that now important prime mover.

Illuminating gas was employed having a mean heating value of about 4.8 calories per liter. A new form of igniting apparatus permitted the ignition of even very weak charges with completeness and certainty, the current being obtained from four cells of the storage battery, with a low voltage and a comparatively heavy current, insuring a 'short and thick' spark.

Varying compression was adopted to determine the effect of such variation upon the efficiency of the motor, and, with each compression, varying mixtures of air and gas, changing about one per cent. at each new series of tests, supplied data for ascertaining the relative values of these mixtures.

For the first time, so far as the writer is aware, the theory of the gas-engine as here applied was constructed with the assumption of a variation of specific heats with temperature, following M.M. Mallard and Le Chatelier. The following are Professor Burstall's formulas:

$$K_v = a + sT; \quad K_p = b + sT;$$

$$K_p - K_v = \text{const.} = b - a = R.$$

$$H_v = (w_1 + w_2) \int_{T_1}^{T_2} (a + sT) \delta T;$$

$$= (w_1 + w_2) [a(T_2 - T_1) + s/2 \cdot (T_2^2 - T_1^2)].$$

$$H_p = (w_1 + w_2) \int_{T_2}^{T_3} (b + sT) \delta T;$$

$$= (w_1 + w_2) [b(T_3 - T_2) + s/2 \cdot (T_3^2 - T_2^2)];$$

where H_v and H_p are the quantities of heat added during the periods of constant volume and constant pressure, respectively; w_1 and w_2 are the weight of air and gas, and the weight of residual products from the previous stroke in the clearance spaces.

The equation of the adiabatic also differs from that for constant values of specific heats, thus:

$$\delta q = K_v \left(\frac{dT}{dv} \right) \delta v + K_p \left(\frac{dT}{dp} \right) \delta p;$$

$$dT/dp = v/R; \quad dT/dv = p/R;$$

$$\delta q = K_v v/R \cdot \delta p + K_p p/R \cdot \delta v = 0.$$

$$(a + sT)v \delta p + (b + sT)p \delta v = 0.$$

$$(b - a) \log_e v + a \log_e (pv) + spv/R = \text{const.}$$

$$p^a v^b e^{\frac{pv}{R}} = \text{constant.}$$

The correspondence of the actual expansion lines of the indicator diagram with the adiabatic for variable specific heats was found much closer than for the usual assumption of constant values with varying temperatures. In the computations of the heat-balance the usual method would give results about fifteen per cent. lower than with variable specific heats.

The entropy equation becomes, in the latter case,

$$\phi = a \log_e \frac{T}{T_0} + R \log_e \frac{V}{V_0} + S(T - T_0);$$

where V and V_0 are the volumes at temperatures T and T_0 , respectively.

In determining the temperatures, the Callendar platinum instrument was employed; but a peculiar and ingenious special construction was adopted to secure safety of the instrument against injury by the action of the charge. Among other interesting determinations made with this thermometer, were the temperatures of the charge at various distances from the cylinder-wall. It was found that the charge was distinctly hotter at the core than adjacent to the metallic surface of the cylinder, the difference ranging from one to two hundred degrees centigrade.

The gas used required 5.49 volumes of air for combustion and produced 0.5672 volumes of CO and 1.257 volumes of steam. After combustion the volume is, total dry, 4,996. The weights were, gas, per meter, 0.6; air, 1.29. Heating values were 553 B. T. U. per cubic foot, 4,850 cal. per cubic meter.

The engine was six inches by twelve and ran at about 200 revolutions per minute and at from 90 to 100 per cent. of its rated power; usually at about 95. The compression in Series I. ranged up to from 200° C. to 300° C., and the index of the compression-curve, $pv^n = C$, from 1.28 to 1.445; its maximum being found at 311° C.; but the irregularities of the figure are too great to reveal any law. Probably 1.33 may be taken as the figure for approximate computations. The expansion-curve value of $n = 1.4$, as an average, or very nearly that, ranging from 1.328 to 1.501. The mechanical efficiency was from 68 to 80 per cent., averaging about 75.

In the final series of trials, with compression ranging from 327° C. to 452° C. as maxima, the index of the expansion-curve was about 1.3, varying from 1.2 with an exhaust temperature of 637° C. to 1.344 with a temperature of exhaust of 862° C. The compression-curve was less variable; the index averaged very nearly 1.35. The mechanical efficiency varied from 0.64 to 0.83, and the thermal efficiency from 18.1 to 22.7 per cent.

The employment of compression produced, on the whole, an increasing total efficiency with increasing terminal pressure, though reducing mechanical while augmenting thermodynamic efficiency. From 13 to 16 per cent.

of the heat-supply appeared as useful work outside the machine. The gas used ranged from an average of 24.6 cu. ft. per I.H.P. per hour to 19.7, and from 34.9 per B.H.P. to 28.5. The jacket carried away about 30 per cent. of the heat developed, the exhaust about 45 per cent. and radiation about 3. The heat-balance for the most efficient case was

$$\begin{array}{rcccccc} \text{I.H.P.} & \text{Jack.} & \text{Exh.} & \text{Rad.} & \text{Loss.} & \text{Total.} \\ 23.1 & + 30 & + 42.6 & + 3 & + 1.3 & = 100. \end{array}$$

R. H. THURSTON.

THE NEW STAR IN PERSEUS.

PROFESSOR W. W. CAMPBELL, director of the Lick Observatory has issued the following bulletin:

A discovery of extraordinary interest to astronomers has just been made by Professor Perrine in reference to the new star in the constellation Perseus. This star appeared suddenly and unexpectedly last February, having been discovered by Anderson in Edinburgh. In some four days its brightness increased from invisibility in ordinary telescopes until it became the brightest star in the northern sky. All available astronomical resources throughout the world were immediately devoted to the investigation of this remarkable object.

Many interesting facts concerning it have been brought to light. To mention only a few, its brightness diminished irregularly from that of the most prominent star in the northern sky in February until in June it was on the limit of visibility for trained and sensitive eyesights, where it has since remained. The star's atmosphere was violently disturbed, as shown by a study of its spectrum in the spring months and since June, at least, the spectroscope has shown that it is now a nebula, though retaining to the eye and in the telescope the point-like form of an ordinary star. The disturbance that gave rise to the new star was sufficiently violent to convert it from a dark invisible body into a gaseous nebula.

In August Professor Max Wolf, of Heidelberg, Germany, secured a four-hour exposure photograph of the region of the sky containing the new star. His negative showed the existence of some extremely faint nebulous patches

about five minutes of arc south of the star, but with no evidence of any relationship between the nebulous clouds and the star.

On September 20 Ritchey at the Yerkes Observatory photographed the same region with a more efficient instrument and found that the nebulous cloud was very nearly circular, some ten minutes of arc in diameter, but of varying intensity in its different parts with the new star situated near the middle of the nebulosity.

A recent photograph, secured by Professor Perrine with the Crossley reflector, recorded the principal features of the nebulous cloud. He compared his photograph with the Yerkes photograph of the same object and made the interesting discovery that the brightest portion of the nebula, at least, and perhaps the whole nebula, had moved to the southeast more than one minute of arc in the past six weeks.

This observation is in every respect unique. Motion on this enormous scale or one fiftieth part of this scale has never been observed for any celestial body outside the solar system, and it is morally certain that the observed phenomenon is closely related to the violent disturbances which gave birth to the new star. It is perhaps as wonderful and important as any fact yet determined in connection with new stars.

THE U. S. NAVAL OBSERVATORY.

IN his annual report to the President, Hon. John D. Long, Secretary of the Navy, indorses the recommendation of the board of visitors to the Naval Observatory, that a civilian astronomer be placed at the head of that institution. Mr. Long says:

"Attention is called to the first and very important report of the board of visitors to the Naval Observatory. I earnestly commend its recommendations to careful consideration. This board was created by act of Congress in March last. I believe its visitations will be found valuable in making the observatory efficient and in rank with the best institutions of the land. It appears that no other observatory in the world has the expenditure of so much money, but also that its results are not commensurate with those of some other observatories the expenditures of which are less. Its

head should of course be the best astronomer, who has proper administrative qualifications, that can be found in the country. It is especially desirable that he should have continuity of tenure, and the observatory has undoubtedly suffered from frequent changes in its superintendents.

"While the average term of service of superintendents at Greenwich has been twenty-eight years and at Harvard fifteen, at the Naval Observatory it has been only a little over three. I urgently recommend that the legislation of the last Congress to the effect 'that the superintendent of the Naval Observatory shall be, until further legislation by Congress, a line officer of the navy of a rank not below that of captain,' be repealed, and that on the contrary it be enacted that there shall be no limitation upon the field from which the superintendent is to be selected. As well might the above-quoted statute have provided that the Commissioner of Fish and Fisheries should be selected from the line of the Marine Corps, or the Director of the Geological Survey from the line of the army.

"There is no vital relation between the navy and the observatory. It may happen that some naval officer is preeminently qualified for such a place, in which case he would be appointed to it, but the country is entitled to have unlimited range of selection. The present limitation, which shuts out the whole body of civilian astronomers and even any astronomer in the navy who does not happen to be in the line, or, if in the line, below the rank of captain, is peculiar. Only a very small proportion of naval officers are not below the rank of captain, and as most of them are required for naval services—a requirement which is now increasing—the list from which selection can be made is a noticeably small one. It is evident, too, from the wording of the above quotation from the statute, that Congress in passing it had in mind further legislation in this respect."

SCIENTIFIC NOTES AND NEWS.

THE Council of the American Association for the Advancement of Science will meet at the Quadrangle Club, adjoining the grounds of the University of Chicago, on the afternoon of Wednesday, January 1. Section H, Anthro-

pology, of the Association will also meet at Chicago during convocation week.

DR. L. O. HOWARD, chief of the Division of Entomology of the U. S. Department of Agriculture and permanent secretary of the American Association for the Advancement of Science, will give the annual lecture at the Chicago meeting of the American Society of Naturalists.

THE American Academy of Arts and Sciences has given Professor R. W. Wood, of the Johns Hopkins University, an appropriation of \$350 from the Rumford fund to aid in the continuation of his researches on the anomalous dispersion of sodium vapor. An account of the results obtained thus far will appear shortly in the *Proceedings of the Royal Society of London*.

PROFESSOR FERDINAND FREIHERR VON RICHTHOFEN, who holds the chair of geography at Berlin, has received from the German Emperor the gold medal for science for his services in supplying the German expedition to China with valuable maps.

DR. SETH LOW has resigned the presidency of the American Geographical Society, New York. He was elected to this office a year ago to succeed the late Judge Charles P. Daly.

THE regents of the State University of Iowa have granted Professor C. C. Nutting, the head of the department of zoology, leave of absence for three months, in order to enable him to join the United States Fish Commission steamer *Albatross* on its cruise to the waters of the Hawaiian Islands. Professor Nutting will have charge of the work on marine invertebrates.

MR. STEWART CULIN made a trip during the summer, on behalf of the Hon. John Wanamaker, in the interests of the Archeological Museum of the University of Pennsylvania, visiting Louisiana, New Mexico, Arizona and California. He secured some 6,000 archeological and ethnological specimens, chiefly from the southwest.

MR. YELJI NAKAJIMA, chief engineer of the city of Tokyo, and professor in the Imperial University, with Mr. Rintaro Naoki, and Mr. Shikajiro Hattori, engineers of Tokyo, are at present in the United States studying engineer-

ing works, especially those concerned with water supply.

CAPTAIN WILLIAM CROZIER has been appointed chief of ordnance in the army with the rank of brigadier-general. Captain Crozier was formerly instructor in mathematics at West Point, and was appointed recently professor of natural and experimental philosophy to succeed General Michie, but declined the position.

ASSISTANT-SURGEON JOHN F. ANDERSON, of the United States Marine-hospital Service, has been detailed by President Roosevelt to go to Liverpool to investigate the recent outbreak there of the bubonic plague.

CAPTAIN E. L. MUNSON, assistant-surgeon U. S. A., has recently been appointed assistant professor of military hygiene in the Army Medical School in Washington, D. C.

MR. IRA A. COLLINS, recently a teacher at Ridgewood, N. J., has gone to the Philippine Islands for three years to teach for the United States Government. He will endeavor to introduce visual instruction in the schools, using lantern slides in teaching the history and geography of the United States to the natives. Mr. Collins, being also able to make plaster life masks and photographs, hopes to send some such anthropometric data to the museums of this country.

DR. WALTER HOUGH has recently returned from a five months' exploring trip in northeastern Arizona, bringing a large collection of archeological and ethnological material for the National Museum. Fifty-four or more sites were examined, and in 18 of these excavations were made, comprising the ruins lying east of Holbrook, Arizona, in the Petrified Forest Reserve; ruins on the north border of the Apache Reserve, and ruins in the Jedido Valley, Hopi Reserve.

DURING the past summer, Mr. Frank M. Chapman, the associate curator of the departments of mammalogy and ornithology, of the American Museum of Natural History, New York City, made an extended trip in the western British possessions. In Manitoba he secured material for groups of cormorants, Wilson's phalarope and the yellow-headed blackbird.

In the Selkirk Mountains he secured the specimens needed for a group of the American dipper or water-ousel.

WE trust that the announcement of the death of Dr. Arthur König, professor of physics in Berlin, published in the *New York Evening Post* and other journals, is incorrect. It seems probable that there is confusion, owing to the recent death of Dr. R. König, of Paris.

MR. THOMAS MEEHAN, the well-known horticulturist and botanist, died in Germantown on November 19. He was born in England in 1826 and came to this country at an early age. Dr. Meehan was botanist of the Pennsylvania State Board of Agriculture, vice-president and one of the curators in charge of the herbarium of the Philadelphia Academy of Natural Sciences, editor of *Meehan's Monthly*, was a fellow of the American Association for the Advancement of Science and a member of numerous other scientific societies. He was the author of valuable papers in botany and horticulture.

DR. WILLIAM FISHER NORRIS, professor of ophthalmology in the University of Pennsylvania, died in Philadelphia on November 18. He was born in that city in 1839, and graduated from the academic and medical departments of the University of Pennsylvania. Dr. Norris was well known for his researches and publications on diseases of the eye. In conjunction with Dr. C. A. Oliver he edited the standard 'System of Diseases of the Eye,' and was the author of a 'Text-book of Ophthalmology.'

DR. ALBERT LEARY GIBON, medical director of the United States Navy, retired with the rank of commodore, died from apoplexy in New York on November 17. Born in Philadelphia sixty-nine years ago, he received his education there and at Princeton College. He was made professor of chemistry and toxicology in the Philadelphia College of Medicine and Surgery in 1853, but resigned to enter the navy in 1855. He had been president of the American Academy of Medicine, of the American Public Health Association and of the Association of Military Surgeons, and was the author of contributions to naval hygiene and public health.

THE American Physiological Society will hold its fourteenth annual meeting in Chicago, on Monday and Tuesday, December 30 and 31, 1901. The sessions will be held at the Physiological Laboratory of the University of Chicago. The headquarters of the Society will be at the Hotel del Prado, 59th Street and Washington Avenue, near the University. Information regarding other local arrangements and railway rates will be furnished later. Members of the Society will please inform the Secretary at their earliest convenience whether they intend to be present and what communications they desire to make. Those who will require apparatus or other necessities for the making of demonstrations may communicate with Professor Jacques Loeb, University of Chicago.

THE steamer *Gauss*, bearing the German Antarctic Expedition, which sailed from Kiel August 11, has arrived at Cape Town.

THE New York Zoological Park has received large accessions of animals from Maine and from Hamburg. They include buffaloes, elks, bears, baboons and other animals. The gelada baboons are said to be the only specimens in captivity.

THE American Museum of Natural History, New York City, has acquired an important collection of mammals and birds from the State of Vera Cruz, Mexico, which contains good series of specimens of several species not before represented in the museum collection. The Museum has also received from the Duke of Loubat a valuable collection of mammals chiefly from the State of Jalisco, which adds much valuable material. A third collection of mammals and birds has been received from Venezuela, collected by Mr. Klages; and a final instalment of birds and mammals of the H. H. Smith collection from the Santa Marta district of Colombia has also come to hand.

THE New York *Independent* publishes an article on the Nobel Foundation by the secretary of the Swedish Nobel Committee, Dr. C. L. Lange, according to which the first distribution of the five prizes will take place on December 10, of the present year, and the amount of each prize will be about \$40,000. The amount that has been deducted from the income for local

uses is said to be one quarter of the whole amount or about \$65,000 a year.

The Journal of the American Medical Association understands that one of the wealthy families of Chicago is arranging to endow, in a most liberal manner, an institution for the study and scientific investigation of infectious diseases. The details and particulars have not yet been made public, but it is reported that it will be second in importance only to that of the gift by Mr. Rockefeller.

The Publishers' Weekly gives some information in regard to the export and import of books and other printed matter for the first nine months of the present year. The value of the imports is \$2,868,489, and of the exports \$2,592,268. As compared with the same period of last year, the imports have increased about \$360,000, and the exports about \$270,000.

UNIVERSITY AND EDUCATIONAL NEWS.

As a gift of a graduate, whose name is withheld, a new building will be erected at Harvard University at a cost of nearly \$100,000. The building will contain an auditorium having a seating capacity of about 1,000.

DR. GEORGE WOODWARD has made a gift of \$20,000 for the establishment of a Woodward Fellowship in Physiological Chemistry at the University of Pennsylvania.

RECENT contributions to the Oberlin College endowment fund are: C. B. and E. A. Shield, of Chicago, \$10,000; Merritt Starr, of Chicago, \$2,500; Dr. L. C. Warner, of New York, \$3,000 from a fund now held in trust by him.

MRS. L. J. WOOD, of Jamaica Plain, Mass., has given \$1,000 to the Physical Laboratory of the Johns Hopkins University for new apparatus.

It is reported in the daily papers that a recent decision of the United States District Court of the State of Michigan greatly increases the value of the estate of William Lampson, bequeathed to Yale University. By this decision the University comes into possession of land supposed to contain large quantities of copper.

THE building at the University of Michigan devoted to physics and chemistry is being remodeled, and the alterations are now well advanced.

THE list of graduate students in Cornell University for the current year is published. It includes the names of 163 candidates for advanced degrees; of these 96 are for Ph.D., 40 for A.M., 13 for M.M.E., 11 for M.S. in Agriculture, 2 for D.Sc., and 1 for M.C.E. There are 185 graduate students in regular university courses and 15 who are not candidates for any degree. Mr. J. W. Prince (C.M.) holds the Sibley Fellowship in M.E. and Mr. L. D. Crain (Perdue) the university fellowship in the same subject. Of the 15 candidates for no degree, 2 are in M.E. Of the 185 graduates, mainly A.B.'s in the regular courses, 60 are in M.E., 68 in medicine and the remainder in various courses.

THE department of botany, of the Iowa State University, conducted its first summer school of botany at Lake Okoboji during the summer. The session continued from July 27 to August 20, and proved very successful. The summer-school laboratory was located by Professor Macbride near Okoboji post office, a central point with respect to the most diversified botanical region in the State. The work was in charge of Assistant Professor B. Shimek, and consisted chiefly of field excursions and the subsequent elaboration and laboratory investigation of the material so secured.

It is announced that Professor Robert Craik, M.D., LL.D., dean of the faculty of medicine and Strathcona professor of hygiene and public health at McGill University, will resign his position and receive a seat on the Board of Governors. Dr. Craik has been connected with McGill for over half a century.

At the University of Toronto, Dr. Howard Barnes has been appointed assistant professor of physics.

At the University of Michigan, Messrs. A. M. Clover, R. F. Sanford and N. F. Harriman have been appointed instructors in the chemical laboratory, and Instructor G. O. Higley has returned from a year's leave of absence in Zurich.

SCIENCE

IN reviewing the scientific work of Professor Rowland one is most impressed by its originality. In quantity, as measured by printed page or catalogue of titles, it has been exceeded by many of his contemporaries; in quality it is equaled by that of only a very, very small group. The entire collection of his important papers does not exceed thirty or forty in number and his unimportant papers were few. When, at the unprecedentedly early age of thirty-three years, he was elected to membership in the National Academy of Sciences, the list of his published contributions to science did not contain over a dozen titles, but any one of not less than a half dozen of these, including what may properly be called his very first original investigation, was of such quality as to fully entitle him to the distinction then conferred.

Fortunately for him, and for science as well, he lived during a period of almost unparalleled intellectual activity, and his work was done during the last quarter of that century to which we shall long turn with admiration and wonder. During these twenty-five years the number of industrious cultivators of his own favorite field increased enormously, due in large measure to the

* Address by Dr. T. C. Mendenhall at the Memorial Meeting at the Johns Hopkins University on October 16.

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

stimulating effect of his own enthusiasm, and while there was only here and there one possessed of the *divine afflatus* of true genius, there were many ready to labor most assiduously in fostering the growth, development and final fruition of germs which genius stopped only to plant. A proper estimate of the magnitude and extent of Rowland's work would require, therefore, a careful examination, analytical and historical, of the entire mass of contributions to physical science during the past twenty-five years, many of his own being fundamental in character and far-reaching in their influence upon the trend of thought, in theory and in practice. But it was quality, not quantity, that he himself most esteemed in any performance; it was quality that always commanded his admiration or excited him to keenest criticism; no one recognized more quickly than he a real gem, however minute or fragmentary it might be, and by quality rather than by quantity we prefer to judge his work to-day, as he would himself have chosen.

Rowland's first contribution to the literature of science took the form of a letter to *The Scientific American*, written in the early autumn of 1865, when he was not yet seventeen years old. Much to his surprise, this letter was printed, for he says of it, 'I wrote it as a kind of joke and did not expect them to publish it.' Neither its humor nor its sense, in which it was not lacking, seems to have been appreciated by the editor, for by the admission of certain typographical errors he practically destroyed both. The embryo physicist got nothing but a little quiet amusement out of this, but in a letter of that day he declares his intention of some time writing a sensible article for the journal that so unexpectedly printed what he meant to be otherwise. This resolution he seems not to have forgotten, for nearly six years later there appeared in its columns what was, as far as is known, his

second printed paper and his first serious public discussion of a scientific question.

It was a keen criticism of an invention which necessarily involved the idea of perpetual motion, in direct conflict with the great law of the conservation of energy which Rowland had already grasped. It was, as might be expected, thoroughly well done and received not a little complimentary notice in other journals. This was in 1871, the year following that in which he was graduated as a civil engineer from the Rensselaer Polytechnic Institute, and the article was written while in the field at work on a preliminary railroad survey. A year later, having returned to the Institute as instructor in physics, he published in the *Journal of the Franklin Institute* an article entitled, 'Illustrations of Resonances and Actions of a Similar Nature,' in which he described and discussed various examples of resonance or 'sympathetic' vibration. This paper, in a way, marks his admission to the ranks of professional students of science and may be properly considered as his first formal contribution to scientific literature; his last was an exhaustive article on spectroscopy, a subject of which he, above all others, was master, prepared for a new edition of the *Encyclopædia Britannica*, not yet published.

Early in 1873 the *American Journal of Science* printed a brief note by Rowland on the spectrum of the Aurora, sent in response to a kindly and always appreciated letter from Professor George F. Barker, one of the editors of that journal. It is interesting as marking the beginning of his optical work. For a year, or perhaps for several years, previous to this time, however, he had been busily engaged on what proved to be, in its influence upon his future career, the most important work of his life. To climb the ladder of reputation and success by simple, easy steps might have contented Rowland, but it would have been quite out of har-

mony with his bold spirit, his extraordinary power of analysis and his quick recognition of the relation of things. By the aid of apparatus entirely of his own construction and by methods of his own devising, he had made an investigation, both theoretical and experimental, of the magnetic permeability and the maximum magnetization of iron, steel and nickel, a subject in which he had been interested in his boyhood.

On June 9, 1873, in a letter to his sister, he says: "I have just sent off the results of my experiments to the publisher and expect considerable from it; not, however, filthy lucre, but good, substantial reputation." What he did get from it, at first, was only disappointment and discouragement. It was more than once rejected because it was not understood and finally he ventured to send it to Clerk Maxwell, in England, by whose keen insight and profound knowledge of the subject it was instantly recognized and appraised at its full value. Regretting that the temporary suspension of meetings made it impossible for him to present the paper at once to the Royal Society, Maxwell said he would do the next best thing, which was to send it to the *Philosophical Magazine* for immediate publication, and in that journal it appeared in August, 1873, Maxwell himself having corrected the proofs to avoid delay. The importance of the paper was promptly recognized by European physicists, and abroad, if not at home, Rowland at once took high rank as an investigator.

In this research he unquestionably anticipated all others in the discovery and announcement of the beautifully simple law of the magnetic circuit, the magnetic analogue of Ohm's law, and thus laid the foundation for the accurate measurement and study of magnetic permeability, the importance of which, both in theory and in practice during recent years, it is difficult to

overestimate. It has always seemed to me that when consideration is given to his age, his training, and the conditions under which his work was done, this early paper gives a better measure of Rowland's genius than almost any performance of his riper years. During the next year or two he continued to work along the same lines in Troy, publishing not many, but occasional, additions to and developments of his first magnetic research. There was also a paper in which he discussed Kohlrausch's determination of the absolute value of the Siemens unit of electrical resistance, foreshadowing the important part which he was to play in later years in the final establishment of standards for electrical measurement.

In 1875, having been appointed to the professorship of physics in Johns Hopkins University, the faculty of which was just then being organized, he visited Europe, spending the better part of a year in the various centers of scientific activity, including several months at Berlin in the laboratory of the greatest continental physicist of his time, von Helmholtz. While there he made a very important investigation of the magnetic effect of moving electrostatic charges, a question of first rank in theoretical interest and significance. His manner of planning and executing this research made a marked impression upon the distinguished director of the laboratory in which it was done and, indeed, upon all who had any relations with Rowland during its progress. He found what von Helmholtz himself had sought for in vain, and when the investigation was finished in a time which seemed incredibly short to his more deliberate and painstaking associates, the director not only paid it the compliment of an immediate presentation to the Berlin Academy, but voluntarily met all expenses connected with its execution.

The publication of this research added much to Rowland's rapidly growing reputation, and because of that fact, as well as on account of its intrinsic value, it is important to note that his conclusions have been held in question, with varying degrees of confidence, from the day of their announcement to the present. The experiment is one of great difficulty and the effect to be looked for is very small, and therefore likely to be lost among unrecognized instrumental and observational errors. It was characteristic of Rowland's genius that with comparatively crude apparatus he got at the truth of the thing in the very start. Others who have attempted to repeat his work have not been uniformly successful, some of them obtaining a wholly negative result, even when using apparatus apparently more complete and effective than that first employed by Rowland.

Such was the experience of Lecher in 1884, but in 1888 Roentgen confirmed Rowland's experiments, detecting the existence of the alleged effect. The result seeming to be in doubt, Rowland himself, assisted by Hutchinson, in 1889, took it up again, using essentially his original method, but employing more elaborate and sensitive apparatus. They not only confirmed the early experiments, but were able to show that the results were in tolerably close agreement with computed values. The repetition of the experiment by Himstedt in the same year resulted in the same way, but in 1897 the genuineness of the phenomenon was again called in question by a series of experiments made at the suggestion of Lippman, who had proposed a study of the reciprocal of the Rowland effect, according to which variations of a magnetic field should produce a movement of an electrostatically charged body. This investigation, carried out by Crémieu, gave an absolutely negative result, and because the method was entirely different from that employed by Row-

land and, therefore, unlikely to be subject to the same systematic errors, it naturally had much weight with those who doubted his original conclusions.

Realizing the necessity for additional evidence in corroboration of his views, in the fall of the year 1900 the problem was again attacked in his own laboratory, and he had the satisfaction, only a short time before his death, of seeing a complete confirmation of the results he had announced a quarter of a century earlier, concerning which, however, there had never been the slightest doubt in his own mind. It is a further satisfaction to his friends to know that a very recent investigation at the Jefferson Physical Laboratory of Harvard University, in which Rowland's methods were modified so as to meet effectively the objections made by his critics, has resulted in a complete verification of his conclusions.

On his return from Europe, in 1876, his time was much occupied with the beginning of the active duties of his professorship, and especially in putting in order the equipment of the laboratory over which he was to preside, much of which he had ordered while in Europe. In its arrangement great (many of his friends thought undue) prominence was given to the workshop, its machinery, tools, and especially the men who were to be employed in it. He planned wisely, however, for he meant to see to it that much, perhaps most, of the work under his direction should be in the nature of original investigation, for the successful execution of which a well manned and equipped workshop is worth more than a storehouse of apparatus already designed and used by others.

He shortly found leisure, however, to plan an elaborate research upon the mechanical equivalent of heat, and to design and supervise the construction of the necessary apparatus for a determination of the numerical value of this most important

physical constant, which he determined should be exhaustive in character and, for some time to come at least, definitive. While this work lacked the elements of originality and boldness of inception by which many of his principal researches are characterized, it was none the less important. While doing over again what others had done before him, he meant to do it, and did do it, on a scale and in a way not before attempted. It was one of the *great* constants of nature, and, besides, the experiment was one surrounded by difficulties so many and so great that few possessed the courage to undertake it with the deliberate expectation of greatly excelling anything before accomplished. These things made it attractive to Rowland.

The overthrow of the materialistic theory of heat, accompanied as it was by the experimental proof of its real nature, namely, that it is essentially molecular energy, laid the foundation for one of those two great generalizations in science which will ever constitute the glory of the nineteenth century. The mechanical equivalent of heat, the number of units of work necessary to raise one pound of water one degree in temperature, has, with much reason, been called the Golden Number of that century. Its determination was begun by an American, Count Rumford, and finished by Rowland, nearly a hundred years later. In principle the method of Rowland was essentially that of Rumford. The first determination was, as we now know, in error by nearly 40 per cent.; the last is probably accurate within a small fraction of 1 per cent. Rumford began the work in the ordnance foundry of the Elector of Bavaria at Munich, converting mechanical energy into heat by means of a blunt boring tool in a cannon surrounded by a definite quantity of water, the rise in temperature of which could be measured. Rowland finished it in an establishment founded for

and dedicated to the increase and diffusion of knowledge, aided by all the resources and refinements in measurement which a hundred years of exact science had made possible.

As the mechanical theory of heat was the germ out of which grew the principle of the conservation of energy, an exact determination of the relation of work and heat was necessary to a rigorous proof of that principle, and Joule, of Manchester, to whom belongs more of the credit for this proof than to any other one man or, perhaps, to all others put together, experimented on the mechanical equivalent of heat for more than forty years. He employed various methods, finally recurring to the early method of heating water by friction, improving on Rumford's device by creating friction in the water itself. Joule's last experiments were made in 1878, and most of Rowland's work was done in the year following. It excelled that of Joule, not only in the magnitude of the quantities to be observed, but especially in the greater attention given to the matter of thermometry. In common with Joule and other previous investigators, he made use of mercury thermometers, but this was only for convenience, and they were constantly compared with an air thermometer, the results being finally reduced to the absolute scale. By experimenting with water at different initial temperatures he obtained slightly different values for the mechanical equivalent of heat, thus establishing beyond question the variability of the specific heat of water. Indeed, so carefully and accurately was the experiment worked out that he was able to draw the variation curve and to show the existence of a minimum value at 30 degrees C.

This elaborate and painstaking research, which is now classical, was everywhere awarded high praise. It was published in full by the American Academy of Arts and

Sciences by the aid of a fund originally established by Count Rumford, and in 1881 it was crowned as a prize essay by the Venetian Institute. Its conclusions have stood the test of twenty years of comparison and criticism.

In the meantime, Rowland's interest had been drawn, largely, perhaps, through his association with his then colleague, Professor Hastings, towards the study of light. He was an early and able exponent of Maxwell's magnetic theory, and he published important theoretical discussions of electromagnetic action. Recognizing the paramount importance of the spectrum as a key to the solution of problems in ether physics, he set about improving the methods by which it was produced and studied, and was thus led into what will probably always be regarded as his highest scientific achievement.

At that time the almost universally prevailing method of studying the spectrum was by means of a prism or a train of prisms. But the prismatic spectrum is abnormal, depending for its character largely upon the material made use of. The normal spectrum as produced by a grating of fine wires or a close ruling of fine lines on a plane reflecting or transparent surface had been known for nearly a hundred years, and the colors produced by scratches on polished surfaces were noted by Robert Boyle, more than two hundred years ago. Thomas Young had correctly explained the phenomenon according to the undulatory theory of light, and gratings of fine wire and, later, of rulings on glass, were used by Fraunhofer, who made the first great study of the dark lines of the solar spectrum. Imperfect as these gratings were, Fraunhofer succeeded in making with them some remarkably good measures of the length of light-waves, and it was everywhere admitted that for the most precise spectrum measurements they were indispensable. In their

construction, however, there were certain mechanical difficulties which seemed for a time to be insuperable. There was no special trouble in ruling lines as close together as need be; indeed, Nobert, who was long the most successful maker of ruled gratings, had succeeded in putting as many as a hundred thousand in the space of a single inch. The real difficulty was in the lack of uniformity of spacing, and on uniformity depended the perfection and purity of the spectrum produced. Nobert jealously guarded his machine and method of ruling gratings as a trade secret, a precaution hardly worth taking, for before many years the best gratings in the world were made in the United States.

More than thirty years ago an amateur astronomer, in New York City, a lawyer by profession, Lewis M. Rutherford, became interested in the subject and built a ruling engine of his own design. In this machine the motion of the plate on which the lines were ruled was produced at first by a somewhat complicated set of levers, for which a carefully made screw was afterwards substituted. Aided by the skill and patience of his mechanic, Chapman, Rutherford continued to improve the construction of his machine until he was able to produce gratings on glass and on speculum metal far superior to any made in Europe. The best of them, however, were still faulty in respect to uniformity of spacing, and it was impossible to cover a space exceeding two or three square inches in a satisfactory manner. When Rowland took up the problem, he saw, as, indeed, others had seen before him, that the dominating element of a ruling machine was the screw by means of which the plate or cutting tool was moved along. The ruled grating would repeat all of the irregularities of this screw, and would be good or bad just as these were few or many. The problem was, then, to make a screw which would be practically

free from periodic and other errors, and upon this problem a vast amount of thought and experiment had already been expended.

Rowland's solution of it was characteristic of his genius; there were no easy advances through a series of experiments in which success and failure mingled in varying proportions; 'fire and fall back' was an order which he neither gave nor obeyed, capture by storm being more to his mind. He was by nature a mechanic of the highest type, and he was not long in devising a method for removing the irregularities of a screw, which astonished everybody by its simplicity and by the all but absolute perfection of its results. Indeed, the very first screw made by this process ranks today as the most perfect in the world. But such an engine as this might only be worked up to its highest efficiency under the most favorable physical conditions, and in its installation and use the most careful attention was given to the elimination of errors due to variation of temperature, earth tremors and other disturbances. Not content, however, with perfecting the machinery by which gratings were ruled, Rowland proceeded to improve the form of the grating itself, making the capital discovery of the concave grating, by means of which a large part of the complex and otherwise troublesome optical accessories to the diffraction spectroscopy might be dispensed with. Calling to his aid the wonderful skill of Brashear in making and polishing plane and concave surfaces, as well as the ingenuity and patience of Schneider, for so many years his intelligent and loyal assistant at the lathe and work-bench, he began the manufacture and distribution, all too slowly for the anxious demands of the scientific world, of those beautifully simple instruments of precision which have contributed so much to the advance of physical science during the past twenty years.

While willing and anxious to give the

widest possible distribution to these gratings, thus giving everywhere a new impetus to optical research, Rowland meant that the principal spoils of the victory should be his, and to this end he constructed a diffraction spectrometer of extraordinary dimensions and began his classical researches on the solar spectrum. Finding photography to be the best means of reproducing the delicate spectral lines shown by the concave grating, he became at once an ardent student and, shortly, a master of that art. The outcome of this was that wonderful 'Photographic Map of the Normal Solar Spectrum,' prepared by the use of concave gratings six inches in diameter and twenty-one and a half feet radius, which is recognized as a standard everywhere in the world. As a natural supplement to this he directed an elaborate investigation of absolute wave-lengths, undertaking to give, finally, the wave-length of not only every line of the solar spectrum, but also of the bright lines of the principal elements, and a large part of this monumental task is already completed, mostly by Rowland's pupils and in his laboratory.

Time will not allow further expositions of the important consequences of his invention of the ruling engine and the concave grating. Indeed, the limitations to which I must submit compel the omission of even brief mention of many interesting and valuable investigations relating to other subjects begun and finished during these years of activity in optical research, many of them by Rowland himself and many of them by his pupils, working out his suggestions and constantly stimulated by his enthusiasm. A list of titles of papers emanating from the Physical Laboratory of the Johns Hopkins University during this period would show somewhat of the great intellectual fertility which its director inspired, and would show, especially, his continued interest in magnetism and electricity, leading to his

important investigations relating to electric units and to his appointment as one of the United States delegates at important international conventions for the better determination and definition of these units. In 1883 a committee appointed by the Electrical Congress of 1881, of which Rowland was a member, adopted 106 centimeters as the length of the mercury column equivalent to the absolute ohm, but this was done against his protest, for his own measurements showed that this was too small by about three-tenths of one per cent. His judgment was confirmed by the Chamber of Delegates of the International Congress of 1893, of which Rowland was himself president, and by which definitive values were given to a system of international units.

Rowland's interest in applied science cannot be passed over, for it was constantly showing itself, often, perhaps, unbidden, an unconscious bursting forth of that strong engineering instinct which was born in him, to which he often referred in familiar discourse and which would unquestionably have brought him great success and distinction had he allowed it to direct the course of his life. Although everywhere looked upon as one of the foremost exponents of pure science, his ability as an engineer received frequent recognition in his appointment as expert and counsel in some of the most important engineering operations in the latter part of the century. He was an inventor, and might easily have taken first rank as such had he chosen to devote himself to that sort of work. During the last few years of his life he was much occupied with the study of alternating electric currents and their application to a system of rapid telegraphy of his own invention. A year ago his system received the award of a grand prix at the Paris Exposition, and only a few weeks after his death the daily papers published cablegrams

from Berlin announcing its complete success as tested between Berlin and Hamburg, and also the intention of the German Postal Department to make extensive use of it.

But behind Rowland, the profound scholar and original investigator, the engineer, mechanic and inventor, was Rowland the man, and any estimate of his influence in promoting the interests of physical science during the last quarter of the nineteenth century would be quite inadequate if not made from that point of view. Born at Honesdale, Pennsylvania, on November 27, 1848, he had the misfortune, at the age of eleven years, to lose his father by death. This loss was made good, as far as it is possible to do so, by the loving care of mother and sisters during the years of his boyhood and youthful manhood. From his father he inherited his love for scientific study, which from the very first seems to have dominated all his aspirations, directing and controlling most of his thoughts. His father, grandfather and great-grandfather were all clergymen and graduates of Yale College. His father, who is described as one 'interested in chemistry and natural philosophy, a lover of nature and a successful trout-fisherman,' had felt, in his early youth, some of the desires and ambitions that afterward determined the career of his distinguished son, but yielding, no doubt, to the influence of family tradition and desire, he followed the lead of his ancestors.

It is not unlikely, and it would not have been unreasonable, that similar hopes were entertained in regard to the future of young Henry, and his preparatory-school work was arranged with this in view. Before being sent away from home, however, he had quite given himself up to chemical experiments, glass-blowing and other similar occupations, and the members of his family were often summoned by the enthusiastic boy to listen to lectures which were fully

illustrated by experiments, not always free from prospective danger. His spare change was invested in copper wire and the like, and his first five-dollar bill brought him, to his infinite delight, a small galvanic battery. The sheets of the *New York Observer*, a treasured family newspaper, he converted into a huge hot-air balloon, which, to the astonishment of his family and friends, made a brilliant ascent and flight, coming to rest, at last, and in flames, on the roof of a neighboring house, and resulting in the calling out of the entire fire department of the town. When urged by his boy friends to hide himself from the rather threatening consequences of his first experiment in aeronautics, he courageously marched himself to the place where his balloon had fallen, saying, 'No! I will go and see what damage I have done.'

When a little more than sixteen years old, in the spring of 1865, he was sent to Phillips Academy at Andover, to be fitted for entering the academic course at Yale. His time there was given entirely to the study of Latin and Greek, and he was in every way out of harmony with his environment. He seems to have quickly and thoroughly appreciated this fact, and his very first letter from Andover is a cry for relief. '*Oh, take me home!*' is the boyish scrawl covering the last page of that letter, on another of which he says, 'It is simply horrible; I can never get on here.' It was not that he could not learn Latin and Greek if he was so minded, but that he had long ago become wholly absorbed in the love of nature and in the study of nature's laws, and the whole situation was to his ambitious spirit most artificial and irksome. Time did not soften his feelings or lessen his desire to escape from such uncongenial surroundings, and, at his own request, Dr. Farrand, principal of the academy at New Jersey, to which city the family had recently removed, was consulted as to what ought to

be done. Fortunately for everybody, his advice was that the boy ought to be allowed to follow his bent, and, at his own suggestion, he was sent, in the autumn of that year, to the Rensselaer Polytechnic Institute at Troy, where he remained five years, and from which he was graduated as a civil engineer in 1870.

It is unnecessary to say that this change was joyfully welcomed by young Rowland. At Andover the only opportunity that had offered for the exercise of his skill as a mechanic was in the construction of a somewhat complicated device by means of which he outwitted some of his schoolmates in an early attempt to haze him, and in this he took no little pride. At Troy he gave loose rein to his ardent desires, and his career in science may almost be said to begin with his entrance upon his work there and before he was seventeen years old.

He made immediate use of the opportunities afforded in Troy and its neighborhood for the examination of machinery and manufacturing processes, and one of his earliest letters to his friends contained a clear and detailed description of the operation of making railroad iron, the rolls, shears, saws and other special machines being represented in uncommonly well executed pen drawings. One can easily see in this letter a full confirmation of a statement that he occasionally made later in life, namely, that he had never seen a machine, however complicated it might be, whose working he could not at once comprehend. In another letter, written within a few weeks of his arrival in Troy, he shows in a remarkable way his power of going to the root of things which even at that early age was sufficiently in evidence to mark him for future distinction as a natural philosopher. On the river he saw two boats equipped with steam pumps, engaged in trying to raise a half-sunken canal boat by pumping the water out of it.

He described engines, pumps, etc., in much detail, and adds, "But there was one thing that I did not like about it; they had the end of their discharge pipe about ten feet above the water, so that they had to overcome a pressure of about five pounds to the square inch to raise the water so high, and yet they let it go after they got it there, whereas if they had attached a pipe to the end of the discharge pipe and let it hang down into the water, the pressure of water on that pipe would just have balanced the five pounds to the square inch in the other, so that they could have used larger pumps with the same engines and thus have got more water out in a given time."

The facilities for learning physics, in his day, at the Rensselaer Polytechnic Institute were none of the best, a fact which is made the subject of keen criticism in his home correspondence, but he made the most of whatever was available and created opportunity where it was lacking. The use of a turning-lathe and a few tools being allowed, he spent all of his leisure in designing and constructing physical apparatus of various kinds with which he experimented continually. All of his spare money goes into this and he is always wishing he had more. While he pays without grumbling his share of the expense of a class supper, he cannot help declaring that 'it is an *awful* price for one night's pleasure; why, it would buy another galvanic battery.' During these early years his pastime was the study of magnetism and electricity, and his lack of money for the purchase of insulated wire for electromagnetic apparatus led him to the invention of a method of winding naked copper wire, which was later patented by some one else and made much of. Within six months of his entering the Institute he had made a delicate balance, a galvanometer and an electrometer, besides a small induction coil and several minor pieces. A few weeks later he announces the finishing

of a Ruhmkorff coil of considerable power, a source of much delight to him and to his friends.

In December, 1866, he began the construction of a small but elaborately designed steam engine which ran perfectly when completed and furnished power for his experiments. A year later he is full of enthusiasm over an investigation which he wishes to undertake to explain the production of electricity when water comes in contact with red-hot iron, which he attributes to the decomposition of a part of the water. Along with all this and much more he maintains a good standing in his regular work in the Institute, in some of which he is naturally the leader. He occasionally writes: 'I am head of my class in mathematics,' or 'I lead the class in natural philosophy,' but official records show that he was now and then 'conditioned' in subjects in which he had no special interest. As early as 1868, before his twentieth birthday, he decided that he must devote his life to science. While not doubting his ability 'to make an excellent engineer,' as he declares, he decides against engineering, saying: "You know that from a child I have been extremely fond of experiment; this liking, instead of decreasing, has gradually grown upon me until it has become a part of my nature, and it would be folly for me to attempt to give it up; and I don't see any reason why I should wish it unless it be avarice, for I never expect to be a rich man. I intend to devote myself hereafter to *science*. If she gives me wealth I will receive it as coming from a friend, but if not, I will not murmur."

He realized that his opportunity for the pursuit of science was in becoming a teacher, but no opening in this direction presenting itself, he spent the first year after graduation in the field as a civil engineer. This was followed by a not very inspiring experience as instructor in natural science in

a western college, where he acquired, however, experience and useful discipline.

In the spring of 1872 he returned to Troy as instructor in physics, on a salary the amount of which he made conditional on the purchase by the Institute of a certain number of hundreds of dollars' worth of physical apparatus. If they failed in this, as afterward happened, his pay was to be greater, and he strictly held them to the contract. His three years at Troy as instructor and assistant professor were busy, fruitful years. In addition to his regular work he did an enormous amount of study, purchasing for that purpose the most recent and most advanced books on mathematics and physics. He built his electro-dynamometer and carried out his first great research. As already stated, this quickly brought him reputation in Europe and, what he prized quite as highly, the personal friendship of Maxwell, whose ardent admirer and champion he remained to the end of his life. In April, 1875, he wrote, "It will not be very long before my reputation reaches this country," and he hoped that this would bring him opportunity to devote more of his time and energy to original research.

This opportunity for which he so much longed was nearer at hand than he imagined. Among the members of the Visiting Board at the West Point Military Academy in June, 1875, was one to whom had come the splendid conception of what was to be at once a revelation and a revolution in methods of higher education. In selecting the first faculty for an institution of learning which, within a single decade, was to set the pace for real university work in America, and whose influence was to be felt in every school and college of the land before the end of the first quarter of a century, Dr. Gilman was guided by an instinct which more than all else insured the success of the new enter-

prise. A few words about Rowland from Professor Michie, of the Military Academy, led to his being called to West Point by telegraph, and on the banks of the Hudson these two walked and talked, 'he telling me,' Dr. Gilman has said, 'his dreams for science, and I telling him my dreams for higher education.' Rowland, with characteristic frankness, writes of this interview, 'Professor Gilman was very much pleased with me,' which, indeed, was the simple truth. The engagement was quickly made. Rowland was sent to Europe to study laboratories and purchase apparatus, and the rest is history, already told and everywhere known.

Rowland's personality was in many respects remarkable. Tall, erect and lithe in figure, fond of athletic sports, there was upon his face a certain look of severity which was, in a way, an index of the exacting standard he set for himself and others. It did not conceal, however, what was, after all, his most striking characteristic, namely, a perfectly frank, open and simple straightforwardness in thought, in speech and in action. His love of truth held him in supreme control, and, like Galileo, he had no patience with those who try to make things appear otherwise than as they actually are. His criticisms of the work of others were keen and merciless, and sometimes there remained a sting of which he himself had not the slightest suspicion. 'I would not have done it for the world,' he once said to me after being told that his pitiless criticism of a scientific paper had wounded the feelings of its author. As a matter of fact, he was warm-hearted and generous, and his occasionally seeming otherwise was due to the complete separation, in his own mind, of the product and the personality of the author. He possessed that rare power, habit in his case, of seeing himself, not as others see him, but as he saw others. He looked at himself and his own work exactly

as if he had been another person, and this gave rise to a frankness of expression regarding his own performance which sometimes impressed strangers unpleasantly, but which, to his friends, was one of his most charming qualities.

Much of his success as an investigator was due to a firm confidence in his own powers, and in the unerring course of the logic of science which inspired him to cling tenaciously to an idea when once he had given it a place in his mind. At a meeting of the National Academy of Sciences in the early days of our knowledge of electric generators he read a paper relating to the fundamental principles of the dynamo. A gentleman who had had large experience with the practical working of dynamos listened to the paper, and at the end said to the academy that unfortunately practice directly contradicted Professor Rowland's theory, to which instantly replied Rowland, 'So much the worse for the practice,' which, indeed, turned out to be the case.

Like all men of real genius, he had phenomenal capacity for concentration of thought and effort. Of this, one who was long and intimately associated with him remarks, "I can remember cases when he appeared as if drugged from mere inability to recall his mind from the pursuit of all-absorbing problems, and he had a triumphant joy in intellectual achievement such as we would look for in other men only from the gratification of an elemental passion." So completely consumed was he by fires of his own kindling that he often failed to give due attention to the work of others, and some of his public utterances give evidence of this curious neglect of the historic side of his subject.

As a teacher his position was quite unique. Unfit for the ordinary routine work of the class room, he taught, as more men ought to teach, by example rather than by precept. Says one of his most eminent

pupils, "Even of the more advanced students, only those who were able to brook severe and searching criticism reaped the full benefit of being under him, but he contributed that which in a university is above all teaching of routine, the spectacle of scientific work thoroughly done and the example of a lofty ideal."

Returning home about twenty years ago, after an expatriation of several years, and wishing to put myself in touch with the development of methods of instruction in physics, and especially in the equipment of physical laboratories, I visited Rowland very soon after, as it happened, the making of his first successful negative of the solar spectrum. That he was completely absorbed in his success was quite evident, but he also seemed anxious to give me such information as I sought. I questioned him as to the number of men who were to work in his laboratory, and although the college year had already begun he appeared to be unable to give even an approximate answer. 'And what will you do with them?' I said. 'Do with them?' he replied, raising the still dripping negative so as to get a better light through its delicate tracings, 'Do with them?—*I shall neglect them.*' The whole situation was intensely characteristic, revealing him as one to whom the work of a drill-master was impossible, but ready to lead those who would be led and could follow. To be neglected by Rowland was often, indeed, more stimulating and inspiring than the closest personal supervision of men lacking his genius and magnetic fervor.

In the fulness of his powers, recognized as America's greatest physicist, and one of a very small group of the world's most eminent, he died on April 16, 1901, from a disease, the relentless progress of which he had realized for several years and opposed with a splendid but quiet courage.

It was Rowland's good fortune to receive

recognition during his life in the bestowal of degrees by higher institutions of learning; in election to membership in nearly all scientific societies worthy of note in Europe and America; in being made the recipient of medals of honor awarded by these societies, and in the generously expressed words of his distinguished contemporaries. It will be many years, however, before full measure can be had of his influence in promoting the interests of physical science, for with his own brilliant career, sufficient of itself to excite our profound admiration, must be considered that of a host of other younger men who lighted their torches at his flame and who will reflect honor upon him whose loss they now mourn, by passing on something of his unquenchable enthusiasm, something of his high regard for pure intellectuality, something of his love of truth and his sweetness of character and disposition.

T. C. MENDENHALL.

*REPORT OF THE BOARD OF VISITORS TO
THE NAVAL OBSERVATORY FOR
THE YEAR 1901.*

IN pursuance to a call issued by the Secretary of the Navy, a meeting of the Board of Visitors to the Naval Observatory was held in Washington, beginning April 9, 1901. The Board was organized by the selection of Charles A. Young as chairman and Ormond Stone as secretary. Another meeting was held in Washington, beginning October 29, 1901. At both of these meetings, and afterwards by correspondence, as careful an examination as time permitted was made, directly and by committee, of the condition and needs of the Observatory, and of such other matters as are referred to in the law creating the Board. In this examination the Board was greatly aided by conferences with the Secretary of the Navy, the Superintendent and staff of the Naval Observatory, officers of the Civil Service

Commission, and others, all of whom have given the Board their most cheerful assistance. As a result of the deliberations of the Board the following recommendations are respectfully offered for consideration:

ASTRONOMICAL DIRECTOR.

It is recommended that no astronomical director be appointed at present, as a dual headship has been found to work unsatisfactorily, and under the existing law the appointment of an astronomer as sole director of the Observatory—which the Board considers the proper solution of the question—is impracticable.

METHOD OF FILLING VACANCIES.

Vacancies should not be filled among assistant astronomers nor among professors of mathematics in the Navy without examination for each vacancy occurring. For example, the results of a given examination should not be used for filling a subsequent vacancy, except in so far as such results may properly form a part of a new independent examination. No distinction should be made between employees of the Observatory and other applicants. Employees should, however, of course, be at liberty to present evidence of experience or capacity as shown by their work at the Observatory in the same manner as other candidates present similar evidence as shown by their work elsewhere. The responsibilities of the positions of assistant astronomer and professor of mathematics are distinctly different from those of a computer, although much of the required experience may properly be gained in connection with the latter position and be credited in the examinations for the higher positions. At the same time it is important that the positions of computer should be filled by persons whose prime interest is in practical and theoretical astronomy and whose ambition it will be to occupy higher positions in the Observatory. As far as is

consistent with the routine needs of the institution, the duties of the computers should be so arranged as to encourage them to prepare for advancement within the Observatory itself. The positions of piece-work and of regular computers are essentially of the same nature, and promotion from one of these grades to the other may very properly be made, but always on the basis of merit rather than length of service. In no case should appointments be made to the Observatory merely by transfer from other bureaus or offices in the service, nor should appointments ever be made even temporarily without competitive examination.

ASSISTANT ASTRONOMERS.

In accordance with the principles herein stated, instead of recommending the name of a person to fill the vacancy now existing among the assistant astronomers at the Naval Observatory, we recommend that an examination be held with the assistance of the Civil Service Commission, in accordance with an announcement, a copy of which accompanies this report as Exhibit A, the examiners to be the members of the Board of Visitors for the time being. In order to carry this out, it is requested that Departmental Order No. 14 be so modified that employees of the Naval Observatory may have the same right to apply as other persons.

ADMINISTRATION OF THE OBSERVATORY.

We desire to call attention to the fact that the enactment which created the Board of Visitors provides that "the Superintendent of the Naval Observatory shall be, until further legislation by Congress, a line officer of the Navy of a rank not below that of captain," thus implying that a change in the law is in contemplation. As every other prominent observatory is under the direction of an astronomer, we wish to record our deliberate and unanimous judgment that the law should be changed so as

to provide that the official head of the Observatory—perhaps styled simply 'the director'—should be an eminent astronomer appointed by the President, by and with the advice and consent of the Senate, holding this place by a tenure at least as permanent as that of the superintendent of the Coast Survey, or the head of the Geological Survey, and not merely by a detail of two or three years' duration. Only in this way can there be a continuous and effective policy of administration which will insure astronomical work of a high order. In rank, salary, privilege and prestige he should be superior to any other official on the ground.

The limitation in the selection of assistants should also be removed, and the assistant once appointed should be secure against detachment or removal except by the action, for cause, of the director.

The institution should be related to the Navy Department, if continued under its control, in some such way as the Royal Observatory at Greenwich is related to the British Admiralty. It should be put under the control of the Secretary directly, and not through a bureau as at present.

SCOPE AND PLAN OF WORK.

The relation of the United States Naval Observatory to astronomy is unlike that of any other observatory in the country. A private observatory is usually devoted to a special line of work selected by its director, or by the head of one of its departments. This work is then carried on in the manner and in the special directions chosen by the officer in charge. The Naval Observatory, on the other hand, is maintained at the expense of all the people of the United States, and its work should not be entirely determined by the wishes and interests of any one individual; a principal use should be to supply the wants of astronomy by undertaking researches which have been

neglected elsewhere, either because they are too expensive or for other reasons. It is believed that the policy of undertaking neglected work, and doing what is most needed and not what is most attractive, would commend itself to Congress, to astronomers and to the people.

The Naval Observatory should cooperate with the other observatories of the country, use its influence to prevent needless duplication of work, and supply important deficiencies in work done elsewhere.

Great care should be taken in preparing a permanent scheme of work in the preparation of which the opinions of experts in each department should be carefully considered.

Important changes in such a plan should be made only after careful consideration, and should in general relate to details of observation, reduction and form of publication, rather than to objects or classes of investigation. The officers required to carry out this work should be selected for special fitness or experience, as well as for general astronomical knowledge, and a change in duty should be seldom made and then only for important reasons. If any observer has by years of experience attained great skill with a meridian circle, to place him in charge of an equatorial would be much like making a sailing master of an engineer, however skilled he may be. Great care should be taken in the assignment of duties to different members of the observing staff in order to secure a satisfactory distribution of force among the instruments and to avoid undue concentration or the reverse. At the same time the special aptitudes of individuals should be kept in mind, and their interest enlisted by giving them as far as possible independence of responsibility.

The following provisional plan is suggested for criticism and amendment:

The meridian circle is necessarily one of

the most important instruments in a government observatory. Daily observations should be made, whenever possible, of the sun and moon, and of sufficient number of standard stars to determine accurately the error of the standard clock and the constants of the instrument. The major planets should be observed on a certain number of nights every year to correct their ephemerides, but not often enough to curtail seriously the other work of the instrument. A system of standard stars should be selected by cooperation with the various national almanacs and observatories, and a certain number of observations of each of these stars should, if possible, be secured each year. In planning the observations, the determination of their absolute and not merely their relative positions should be taken into consideration. In preparing a list of standard stars it is suggested that instead of attempting to observe all stars brighter than a given magnitude, it might be better to take only those of about the same magnitude and spectrum, in order to eliminate errors due to magnitude and color, and to choose those nearly equally spaced in the sky, adding such polar and equatorial stars as will culminate at nearly equal intervals and will not interfere with one another. It would also be necessary to include all the very bright stars as a basis for daylight observations. As examples of special researches that might have been taken up under such a system may be mentioned the comparison stars for Victoria and Sappho proposed by Dr. Gill in 1889, and the comparison stars selected by the Astrophotographic Conference of 1900 for observations of Eros.

The altazimuth instrument should perhaps also be used for observing the moon when off the meridian, and for determining the time when clouds render it impossible to observe on the meridian. The observation of zenith stars should be continued

with the prime vertical instrument and vertical circle. These observations, which appear to be of a high degree of excellence, have now lasted eight years, and should be maintained for at least eleven years longer, or through a complete metonic cycle, to furnish a good determination of the constant of nutation. An additional computer is much needed for the reduction of this work.

The determination and distribution of accurate time will always be an important function of a government observatory, and requires a careful administration. Not only is the exact time required for rating the chronometers of the Navy, but at present time signals are distributed by telegraph from the Naval Observatory throughout the country. The value of accurate time to the people generally is so great that no reasonable effort should be spared to reduce the inevitable errors from every source as much as possible. Formerly large sums were expended by railroads, cities, factories and makers of clocks and watches in the purchase of time signals, furnished by various observatories. To many observatories this was an important source of income.

In 1883 the astronomers of the country, recognizing the great value of a system of uniform standard time, used all their influence toward securing its adoption, notwithstanding the obvious danger to their private interests—since under such a system it would be possible for a single institution to furnish time to the whole country. In fact, in 1891 the Naval Observatory assumed the task. While the time as now distributed from the Observatory is sufficiently accurate for most business purposes, since a nonaccumulating error of a few seconds is of little importance in that view, it appears, however, that at considerable distances from Washington the errors are often considerably greater than

under the old system, when the time was communicated from a standard clock not very far away, the errors being often large enough to interfere with the utility of the signals for chronometer rating and scientific purposes. The difficulty lies largely in the methods by which the time is transmitted by the telegraph, but more in the slightly irregular rate of the standard clock through long intervals of cloudy weather during which star observations cannot be obtained.

It would seem that by cooperation with other observatories a considerable improvement might be made, by arranging matters so that every night, or at least on nights during which the weather is bad at Washington, these observatories should each send a time signal to the Naval Observatory, indicating also the interval since the last observation.

It is difficult to see any way in which the efficiency of the Navy is increased by means of the 26-inch equatorial telescope. If left idle, however, it would be a subject for severe criticism, owing to the large sums of money already expended upon it. Its work should, therefore, be planned wholly in the interests of astronomy. The same principle should be adopted as with the other instruments. Researches should be undertaken which have been neglected at other observatories, duplication of work should be carefully avoided, and no investigation should be undertaken that can be done equally well with smaller instruments. The following examples of the species of work to be undertaken may be mentioned: A list of double stars which are too difficult to be observed with small instruments, and of which no recent accurate measures have been made, should be prepared with the advice of specialists in this department, and measured with the greatest accuracy; binaries and suspected binaries should, of course, receive special attention; neglected

asteroids and variables should similarly be followed; the observations of the satellites should be continued with this instrument, especially those of Saturn and Uranus, which are likely to be neglected at European observatories for the next few years owing to their southern declinations.

Lost asteroids, and perhaps others, can best be found and followed by photography. The spectroscopic approach and recession of the stars is at the present time under investigation with so many very large telescopes that this work may be left to them. The number of known spectroscopic binaries, however, is so great that it may be necessary hereafter to follow them carefully to determine the laws governing their motions. The work of the 12-inch equatorial should supplement that of the 26-inch.

In general the plan of work should be altered but rarely, and then only when changes seem imperative. Special attention should be given to work neglected elsewhere, and every effort made to render our knowledge of astronomy as complete as possible.

AMERICAN EPHEMERIS AND NAUTICAL ALMANAC.

Among the most important scientific publications of the Government of the United States are those issued by the Office of the American Ephemeris and Nautical Almanac. The first and best known is the Almanac issued every year, which gives name to the office. Four European countries—Great Britain, Germany, France and Spain—make similar publications, and a great saving might be effected by carrying still further the plan of cooperation already in part adopted. To avoid errors certain elements are computed independently three times, but if this is done for all five of the almanacs evidently much work is wasted. So far as possible the same quantities should be published in all of the

almanacs, and computed independently as many times as may be deemed necessary. Ninety-six pages are devoted to that important and laborious problem, the exact path of the moon. Here an independent computation seems needless when we consider that the only American observatory at which the position is regularly determined is at Washington. The occasional observations made at other places have, in general, but little permanent value, and for observations of the moon at sea far less accurate positions are needed. In fact, 72 additional pages are devoted to lunar distances. In order that the saving suggested may be accomplished without delaying the publication of the Almanac, arrangements should be made with the foreign almanac offices to complete their computations at least a year longer in advance than is done at present.

A second most important consideration is that changes should be made only after a most careful examination and consultation with astronomers for whose benefit the Almanac is printed, and with the approval of the Board of Visitors. Changes not only cause great inconvenience, but often render it necessary to employ some other almanac when reducing the observations extending over a long period of years. The changes suggested below are so extensive that they should be made only if approved by American astronomers in general.

Washington mean time is not used even at Washington, and its use in the Almanac seems superfluous. Greenwich mean time, as modified in standard time, is in universal use in the United States, and is already used in a large part of the Almanac. Central time, which differs from Greenwich time by exactly six hours, might be conveniently used to simplify the interpolation for the transits of the moon and planets.

The phase angle, i , should be given for

the outer planets as well as for Mercury and Venus.

The ephemerides of the satellites are often insufficient for even the identification of these bodies. This is particularly the case with Hyperion and Iapetus. For the latter even the apparent ellipse is not given. It will probably not be necessary to return to the bulky tables of the satellites of Jupiter, published yearly in the Almanac before 1882. It would be convenient to have the correction to the ephemeris given when it is known—for instance, the ephemeris of Mimas for this year (1901) is in error by about four hours. Accordingly it is invisible on account of the ring at the predicted times of elongation.

The published positions of observatories should be changed only after careful consultation with the directors. If a system of longitude like that of the Coast Survey is adopted, it should be so stated in the description. The statement that 'the latest available data have been used' is too indefinite.

A great saving in expense might be effected by the adoption of some of the changes mentioned above. This would permit the insertion of valuable data now omitted. For instance, the list of star places might be greatly extended, ephemerides for physical observations of the moon and planets might be inserted, and approximate ephemerides of Eros and of some of the more interesting asteroids, such as Hungaria, Tercidina, Sirona and Polyhymnia.

It is recommended that these and similar changes be proposed to astronomers, and that they be invited to suggest others, as was done by Professor Newcomb when taking charge of the office.

A series of papers of very great scientific value, entitled 'Astronomical Papers prepared for the use of the American Ephemeris and Nautical Almanac,' has been

issued by this office during the last twenty years. The 'Contribution to Celestial Mechanics,' made while the office was under the direction of Professor Newcomb, was a notable one, and a continuation of the papers mentioned is greatly to be desired. A continued investigation of the motion of the moon is especially recommended.

INSTRUMENTS.

The Board at its meeting in April appointed a committee which made as careful an inspection of the instruments of the Observatory as was possible during the time at its disposal. On the whole, the 26-inch equatorial is in good condition. It is recommended that this instrument be supplied with a micrometer at least equal in quality to that constructed for the large equatorial of the Pulkowa Observatory. Also a good field illumination should be provided, as well as a symmetrical illumination for the wires.

Since the visit of the committee in April a number of improvements have been made on the 12-inch equatorial; a bright field illumination is still needed. An investigation of the object glass, which gives poor stellar images, is now in progress by Mr. King, the officer in charge. This examination will show whether the glass is merely out of adjustment or should be refigured.

Extensive repairs are needed for the 9-inch transit circle, and especial attention is invited to Exhibit B, which gives a list of the most important improvements referred to.

A number of changes have been made in the 6-inch transit circle; these and others still needed are referred to in Exhibit C. For both transit circles collimators should be provided having object glasses of larger apertures, and also better means should be provided for obtaining the necessary meteorological data.

The prime vertical transit should be pro-

vided with a long focus lens and an azimuth mark. The house containing the altazimuth is too small. The present building should be replaced by one of such size that collimators may be placed inside of the dome, and, as in the case of the prime vertical, a long focus lens and an azimuth mark should be provided.

For use with the meridian and prime vertical instruments three new chronographs are needed.

Special attention is called to the importance of a careful study of each instrument of the Observatory and a prompt publication of the results of such investigations.

LIBRARY.

The Library contains 18,025 bound volumes and 3,891 pamphlets. It is devoted to astronomy and mathematics, and the allied sciences, and is particularly rich in complete sets of the publications of observations, academies, and learned societies of Europe, many of which are rare as well as modern treatises and reports of investigations. It is admirably arranged and is in excellent order. The assistant librarian in charge has made considerable progress in the preparation of a comprehensive card catalogue, which will render the material on the shelves much more available.

The appropriation of \$750, which is now provided for the Library, is not sufficient for its needs. About \$350 of this is required to keep up the scientific journals and the works, such as yearbooks, which appear periodically. The remainder of the appropriation is not sufficient to provide the new books, engravings, photographs, and fixtures required, and to fill up gaps in the Library when special opportunity offers. It is recommended that the appropriation be increased to \$1,000.

ADDITIONAL REQUIREMENTS.

In the opinion of the Board, there is urgently needed—

1. A repair shop for the instrument maker.
2. Residences for those who are regularly engaged in late night observations.

EXPENDITURES.

The expenditures for the Naval Observatory are presented in Exhibit D.

From the manner in which the appropriations have been made, it is not easy for the Board of Visitors to determine what portion of the expenditures pertains properly to astronomical work, what portion to naval work, and what portion to the improvement and care of the grounds as a park.

Respectfully submitted.

THE ASSOCIATION OF AMERICAN AGRICULTURAL COLLEGES AND EXPERIMENT STATIONS.

THE fifteenth annual convention of the Association of American Agricultural Colleges and Experiment Stations was held at Washington, D. C., November 12 to '14. President A. W. Harris, of the University of Maine, presided at the general sessions and delivered the president's annual address. This address set forth clearly the more important things for which the land-grant colleges stand and summarized the results of their work. The land grant act of 1862 was considered important not only as providing for agricultural education, but as the first sufficient recognition of study and investigation as the basis of the best success in the arts and industries. It also proclaimed the duty of the national government to promote industrial education, and in its results demonstrated the effectiveness

of governmental cooperation. The most important of the direct results of this act to agriculture was the experiment station. "If the agricultural college did nothing more than to establish, maintain, and officer the experiment station, it would be justified many times over." The establishment of the agricultural colleges also caused the strengthening and broadening of industrial education along all lines and has culminated in a great system of technical education. "It is also a great result of the land-grant college to have asserted and established the doctrine that education in all its forms, from the lowest to the highest, is a State function in which the State has the fullest rights and for which it must bear the responsibility, sharing the privilege and responsibility with private corporations only as it thinks best." The speaker considered state aid and control in higher education as necessary to the best national development, and especially so because in this way the results of higher education become the property of all the people. The address concluded with an eloquent tribute to the memory and worth of Justin S. Morrill.

The report of the Executive Committee presented by its chairman, President H. H. Goodell, of the Massachusetts Agricultural College, called the attention of the Association to the fact that the bill for the establishment of schools or departments of mining and metallurgy in connection with the land-grant colleges passed the Senate, but failed to be called up in the House of Representatives during the last session of Congress. The introduction of a similar bill into Congress early in its next session was recommended.

The report of the Committee on Revision of the Constitution called forth a vigorous discussion. The Association refused to change its name. Among the important amendments adopted were those providing that the election of officers shall be by bal-

lot upon nominations made on the floor of the convention, and that the program of the annual conventions of the Association shall hereafter be made up and distributed sixty days before the meeting of the convention; and "the subjects provided for consideration by a section at any convention of the Association shall concentrate the deliberations of the section upon not more than two main lines of discussion, which lines shall so far as possible be related. Not more than one-third of the working time of any annual convention of the Association shall be assigned to miscellaneous business."

The Committee on Graduate Study at Washington reported that no progress had been made since the last convention in securing a Government bureau in Washington for the administration of graduate work. The Association directed the committee to continue its efforts in this direction and, in the meantime, to secure if practicable the same opportunities for study and research in other departments of the government as are at present afforded graduate students in the Department of Agriculture. A resolution was also adopted by the Association recording its appreciation of the action of the government in making available the facilities for research and advanced work in the Department of Agriculture, and expressing a desire that these facilities may be still further extended and that a national university devoted exclusively to advanced study and graduate and research work be established.

The sixth report of progress was submitted by the Committee on Methods of Teaching Agriculture. Attention was called to the publication by the Department of Agriculture of the syllabi of courses in agro-techny, rural engineering and rural economics prepared by the committee last year. In surveying the progress of agricultural education in this country during re-

cent years the committee "found abundant evidence that the attitude of this Association and the work of this committee as its representative have already borne good fruit in stimulating and aiding the movement for the specialization of agricultural instruction in our colleges, the strengthening of agricultural faculties, and the bettering of the material equipment for agricultural education." The committee announced its intention to prepare and publish during the coming year a report on the courses in agronomy in our agricultural colleges and the facilities for instruction in this subject.

The Committee on Cooperative Work between the Stations and the Department of Agriculture made the following recommendations as supplementary to those embodied in the report submitted at the last convention: "(1) 'When cooperation is desired by the station it is deemed advisable that the proposal for such cooperation be made to the department by the director of the experiment station; where on the other hand the department desires the cooperation of the station, it is deemed advisable that the proposal be made in the first instance to the director rather than to members of the staff. (2) While it is well understood that no financial obligations can be undertaken beyond the end of the fiscal year, yet it should be recognized that any arrangement for joint experimentation which requires some years to complete creates a moral obligation upon both parties to carry the work to a conclusion. (3) Where a line of investigation has been in progress in any State under the auspices of either institution it is, as a rule, unwise for the other party to undertake independently the same line of investigation at least until after full consultation upon the subject.'"

The committee was continued with the addition of Professor B. T. Galloway of the Department of Agriculture.

The report of the Committee on Indexing Agricultural Literature called attention to the fact that progress in this direction could not be made by the Department of Agriculture until its library was provided with funds for this purpose. A paper on 'Agricultural College Libraries,' prepared and presented by Miss Josephine A. Clark, librarian of the Department of Agriculture, and a member of this committee, completed the report. This paper emphasized the great importance of libraries as aids to the work of investigation and instruction and pointed out the necessity of systematic arrangement and complete cataloguing of agricultural libraries. Arrangements in progress by the library of the Department for assisting agricultural colleges in classifying and cataloguing their libraries were explained.

The report of the bibliographer, A. C. True, noted the work of a bibliographical character being done by the Department of Agriculture, and enumerated with explanatory notes forty-four general and partial bibliographies in lines relating to agriculture issued during the past year.

The general plan of the graduate summer school of agriculture, as proposed by the Ohio State University at the last convention and approved by the Executive Committee, was explained by President W. O. Thompson of the University. It was stated that sufficient encouragement had been received from the leaders of agricultural education and research to warrant a decision to hold the first session of the school at the Ohio State University at Columbus, Ohio, during the summer of 1902. It was announced that Secretary Wilson had cordially approved the plan for this school, and that, acting under his advice, Doctor A. C. True, director of the Office of Experiment Stations, had consented to act as dean of the school. The Ohio State University makes itself responsible for the general management of the first session of

the school, but if it proves a success it is proposed to make it a cooperative enterprise, to be managed by a committee of control appointed by the Association. Future sessions may be held at institutions in different parts of the country. This plan for the school was endorsed by the Association and a prospectus of the first session will soon be issued.

The Association voted in favor of exhibits illustrating the progress of instruction and research in agriculture and the mechanic arts, at the St. Louis Exposition in 1903, and committees on these exhibits were appointed.

The resolution introduced by Professor W. A. Henry, of Wisconsin, was adopted by the Association, urging upon Congress "the necessity and wisdom of providing a building for the accommodation of the Department of Agriculture which in magnitude shall be sufficient to provide for its future, as well as present, needs, and which will properly represent in its architecture the enormous importance of agriculture in this country, and which will constitute a worthy addition to the government buildings of the capital of the United States."

In the section on college work a paper on the relation of agricultural colleges to the proposed national university, by President W. O. Thompson, of the Ohio State University, was presented in which the writer affirmed that in his judgment "the relation of the agricultural colleges to a national university should be that of sympathetic cooperation and enthusiastic support, as against all other measures whether proposed as substitutes or stepping-stones." This paper called forth a lively discussion in which it appeared that there was a general sentiment in the section in favor of securing some agency under government control for making the laboratories, museums, libraries, and other educational facilities in Washington available to advanced students.

W. M. Liggett, Dean of the College of Agriculture of the University of Minnesota, read a paper on the value of short courses, in which he described the different courses in agriculture given in Minnesota, and stated that he considered the short courses valuable adjuncts to the longer courses.

Honorable J. H. Brigham, Assistant Secretary of Agriculture, spoke of the short courses as a means not only of giving valuable instruction to farmers, but also of bringing about more cordial relations between the agricultural colleges and farmers. In his judgment "the best way to secure the support of farmers is to let them come to the college even for a short time and see that you are trying to do good."

In the section on agriculture and chemistry considerable time was given to a consideration of the question to what extent the Department of Agriculture and the experiment stations may profitably cooperate in the study of grass and forage plant problems and the lines of work which are likely to yield the most important results. Professor B. T. Galloway, chief of the Bureau of Plant Industry, gave a brief history of the cooperative forage plant work of the Department and the stations. He expressed his opinion that the success of the movement depended on grouping the stations with reference to the problems to be solved in different sections of the country, and devising a working plan for each group. The following lines of work were suggested: (1) The introduction of crops from foreign countries, (2) growing and disseminating introduced crops after they have become in a measure established, (3) dissemination of native crops of local value, (4) breeding crops for certain conditions, (5) increasing production by improved cultural methods. Professor R. H. Forbes, director of the Arizona Experimental Station, described the grass and forage crop conditions of that Territory, and gave an account of the co-

operative investigations carried on there. These investigations have for their object the improvement of the ranges through the exclusion of live stock, the sowing and harrowing in of seeds of native plants, the introduction of new forage plants suited to the arid region, and the construction of small embankments for holding the storm water. As conducted for two years on a reserve of 350 acres they have given promising results. Professor F. Lamson-Scribner, agrostologist of the Department of Agriculture, gave an account of the cooperative work under his direction, which includes arrangements with seventeen experiment stations.

The problems of irrigation in humid regions and the investigations in progress in this line were described and discussed by Professor Elwood Mead, of the Office of Experiment Stations; Professor E. B. Voorhees, director of the New Jersey Experiment Stations; F. H. Newell, of the U. S. Geological Survey and Professor H. J. Waters, director of the Missouri Experiment Station.

Papers on plant breeding were presented by Professor W. J. Stillman, of the Washington Agricultural Experiment Station, and Professor W. M. Hays, of the Minnesota Experiment Station. There was also a paper on the artificial plant food requirements of different soils and the methods employed in fertilizer experiments, by Doctor B. W. Kilgore, director of the North Carolina Experiment Station.

In the report of the section on horticulture and botany the marked strengthening of advanced courses in these subjects in colleges was pointed out. The demand for especially qualified men in horticulture was stated to be greater than the supply. There has recently been rapid progress in bacterial and physiological investigations and special studies on the selection and breeding of plants. At the meeting of the

section there was an earnest discussion of the relations of instruction and research in horticulture in the agricultural colleges, called forth by a paper by Professor E. S. Goff, of the University of Wisconsin. The question of cooperation between the farmer and the experiment station, and the best methods of such cooperation, were also much discussed on the basis of the paper by J. Craig, of the New York Cornell Experiment Station. Other papers were also read in this section on observations concerning the first and second generations of plants, by Professor B. D. Halsted, of the New Jersey Agricultural Experiment Stations; on the effect of light and heat on the germination of Kentucky blue grass, and on the quality of some commercial samples of grass and clover seed, by E. Brown of the Bureau of Plant Industry.

Professor L. C. Corbett, of this Bureau, described the experimental farm of the Department of Agriculture which is being established on a part of the Arlington estate near Washington. It is intended to plant on this farm extensive collections of varieties of fruits in order to have authentically named specimens for comparative studies; cultural experiments with fruits and crops, and phenological investigations are also to be undertaken there. Mr. F. D. Gardner, of the Office of Experiment Stations, who is in charge of the newly established experiment station at Porto Rico, made an interesting exhibition of fruits which he had brought from that island; and H. J. Webber, of the Bureau of Plant Industry, exhibited specimens of cowpeas which are believed to be resistant to the attacks of nematodes.

In this connection it may be well to state that a newly organized society of official horticultural inspectors for the United States and Canada held its sessions in Washington, November 11 to 13. Representatives from fifteen States were present.

Professor S. A. Forbes, of the University of Illinois, presided. With regard to the limits of time within which nurseries may be inspected, it was found impossible to determine upon any definite period for all States, since the local conditions, requirements of State law, and other demands of State inspectors rendered uniformity in this matter impossible. In a discussion of the nursery pests which are to be regarded as dangerous enough to influence the granting of a certificate those mentioned by different inspectors as of chief importance included the crown gall, peach yellows, pear blight, San Jose scale, woolly aphid and sinuate pear borer. In a discussion of the question of the best insecticide for orchards infested with San Jose scale, the fact was brought out that the results of experiments with kerosene, crude petroleum and mechanical combinations of both these substances with water were not uniform in different States. Resolutions were passed to the effect that the time of inspection should be left to the discretion of the inspector of each State; that the certificate should not extend beyond the time of the beginning of the breeding period of the San Jose scale for the next year; that one form of certificate should be issued as a rule, which should be so worded that the stock could be sold after objectionable stock had been treated, as suggested by the inspector; and that in States which required inspection of nursery stock the expenses of inspection should be borne by the State.

The report of the section on entomology presented by Professor M. V. Slingerland, of the Cornell University Experiment Station, reviewed the progress of entomology during the past year, especially as regards instruction, investigation and inspection. At the meeting of the section the following papers were read: 'A Year's Experience with Crude Petroleum in New Jersey,' by Professor J. B. Smith, of the New Jersey

Experiment Stations; 'Some of the most Important Insects in Massachusetts,' by Professor H. T. Fernald, of the Massachusetts Hatch Experiment Station; 'The Time of Emergence and Oviposition of the Spring Brood of the Hessian Fly,' by H. Garman, of the Kentucky Experiment Station; 'Life History of the Sugar Cane Borer in Louisiana,' by Professor H. A. Morgan, of the Louisiana Experiment Stations; 'Florida Observations and Experimental Work,' by H. A. Gossard, of the Experiment Station of Florida; 'Apple Aphids,' by E. D. Sanderson; 'A Folding Fumigator,' by F. A. Sirrine, of the New York State Experiment Station.

The report of the section on mechanic arts was presented by Professor H. W. Tyler, of the Boston School of Technology. This gave at some length the progress of instruction in mechanic arts during the year.

A reception tendered to the Association by the Secretary of Agriculture and Miss Wilson was numerously attended by the delegates and their ladies, and was thoroughly enjoyed by all who participated in it.

The following officers of the Association for the ensuing year were elected:

President, W. M. Liggett, of the College of Agriculture of the University of Minnesota; Vice-Presidents, W. O. Thompson, of the Ohio State University; H. J. Waters, of the University of Missouri; J. H. Washburn, of the Rhode Island College of Agriculture and Mechanic Arts; J. H. Worst, of the North Dakota Agricultural College; and J. C. Hardy, of the Mississippi Agricultural and Mechanical College; Secretary-Treasurer, E. B. Voorhees, of the New Jersey Experiment Stations; Bibliographer, A. C. True, of the Department of Agriculture; Executive Committee, G. W. Atherton, of the Pennsylvania State College; H. H. Goodell, of the Massachusetts Agricultural College; Alexis Cope, of the Univer-

sity of Ohio, and H. C. White, of the Georgia State College of Agriculture and Mechanic Arts.

Officers of sections: College Work, J. L. Snyder, of the Michigan Agricultural College, chairman; W. E. Stone, of Purdue University, Indiana, secretary; Agriculture and Chemistry, H. J. Waters, of the University of Missouri, chairman; C. G. Hopkins, of the University of Illinois, secretary; Horticulture and Botany, J. Craig, of the New York Cornell University, chairman; A. Nelson, of the University of Wyoming, secretary; Entomology, F. M. Webster, of the Ohio Experiment Station, chairman; H. E. Summers, of Iowa State College, secretary; Mechanic Arts, H. W. Tyler, of Massachusetts Institute of Technology, chairman; F. A. Anderson, of the Kentucky Agricultural and Mechanical College, Secretary.

A. C. TRUE.

MARCEL NENCKI.

By the death, on October 14, of Professor Marcel Nencki, director of the Laboratory of Physiological Chemistry in the Institute of Experimental Medicine at St. Petersburg, physiological chemistry has lost one of its most active workers. Professor Nencki was born in Poland, January 15, 1847. After completing his medical studies at Berlin, he went to Berne in 1872, as assistant in the Pathological Institute of the Swiss University. At the same time he became Privatdocent in physiological chemistry; and his appointment to a chair in that subject, in 1877, was among the earliest recognitions which the science received as an independent field of study. In 1891 Professor Nencki went to St. Petersburg to take charge of one of the laboratories in the newly founded Institute, being succeeded at Berne by the late Professor Drechsel.

Of Professor Nencki's extensive contributions to organic chemistry, physiological chemistry and bacteriology, it will suffice

here to recall his investigations on the chemistry of putrefaction and on the chemical processes which take place in the intestine; his studies on the behavior of aromatic bodies in the animal organism; his thorough researches on the pigments of the blood and on animal pigments in general; the investigation of the formation of ammonia and urea in mammals; and his last published paper (with N. Sieber) on the chemical composition of enzymes. In 1897, on the twenty-fifth anniversary of the beginning of his scientific activity, there appeared a volume entitled 'Sommaire des travaux accomplis par M. le professeur M. Nencki et ses élèves dans ses laboratoires à Berne et à St. Petersburg.' 1869-1896. In recent years he has collaborated with Professor Andreasch in editing Maly's 'Jahresbericht über die Fortschritte der Thierchemie.' Although interrupted thus early, the work of a lifetime earnestly devoted to the pursuit of scientific truth has left many records of permanent value.

L. B. M.

SCIENTIFIC LITERATURE.

Studien über den Körperbau der Anneliden, V.

By EDUARD MEYER. Translated from the original Russian. In Mittheilungen aus der Zoologischen Station zu Neapel, XIV., 3, 4, 1901. Pp. 338, 6 double plates.

Of the many attempts that have been made to explain the historical origin of the mesoblast and cœlome in higher animals, none is of greater interest than that of Professor Eduard Meyer, of the University of Kasan, whose views find their latest and fullest development in the present masterly paper, the product of many years of painstaking research by an uncommonly clear-sighted observer. All students of embryology are familiar with Hatschek's pregnant suggestion, made in 1877, that the mesoblastic pole-cells, characteristic of annelidan and molluscan development, were originally germ-cells, and that the cœlome of the annelids shows essentially the same relations as the gonad-cavities of the platodes. Accepting this sugges-

tion, R. S. Bergh, in 1885, maintained that the segmented cœlome of annelids is homologous with the cavities of the gonad-follicles of platodes and nemertines, and that the primitive function of the peritoneal epithelium of annelids was that of a germinal epithelium. The same conclusion was independently reached by Meyer and developed by him in 1890, as a sequel to his embryological studies on *Psygmobranchus*, into a general theory, of which the essential points are that the mesoblast-bands (developed from the pole-cells) of annelids are homologous, as a whole, with the paired gonads of the platodes; that by a change of function many of the primitive germ-cells gave rise to somatic mesoblastic elements; that by this process a 'secondary mesoblast' arose; and that lastly, by a partial process of substitution, the secondary mesoblast, in a greater or less degree, took the place of the primary mesoblast of the platode, which, however, still appears in the ontogeny as the 'larval mesenchyme' and some other structures. These last assumptions were not mere guesses, but were based on careful observations which showed that in at least one larval annelid (*Psygmobranchus*) there are two entirely distinct sources of mesoblast, namely, a 'primary mesenchyme' derived from the ectoblast, and a 'secondary mesoblast' derived from the pole-cells, and forming the 'mesoblast bands' in the ordinary sense. The former gives rise to the larval muscles, some of which are only temporary or provisional structures (including the protrochal ring-muscle), and to some of the adult muscles, including those of the gut, of the dissepiments, and the circular muscles of the body-wall. The latter gives rise to the peritoneal epithelium, the gonads, and the longitudinal muscles of the adult. These results were supported by the independent observations of Bergh and Vejdovsky, showing that in leeches and earthworms also the circular muscles are of wholly different origin from the longitudinal ones, the latter alone arising from the mesoblast pole-cells.

In the present paper Meyer reenforces his position by a great number of new observations on many different annelids, of which the most thoroughly studied were *Polygordius* and *Lopadorhynchus*. Although both these forms had

already become classical objects through the earlier work of Hatschek, Fraipont, Kleinenberg and others, Meyer brings forward an almost bewildering profusion of new results for both, which sustain and extend his earlier conclusions on *Psygmobranchus*. In both forms primary and secondary mesoblasts are wholly distinct in origin and in fate; in both, the mesoblast bands (secondary mesoblast) give rise only to the peritoneal epithelium, the gonads and the definitive longitudinal muscles of the body-wall; in both there are several regions in which mesoblast (primary mesenchyme) is independently derived from the ectoblast. From the primary mesenchyme are derived not only the provisional larval musculature, but also an important part of the definitive musculature, namely, that of the gut, of the parapodia and cephalic appendages, of the dissepiments, and the circular and diagonal muscles (when present) of the body-wall. Meyer thus shows that although a part of the larval musculature (for instance, the prototrochal ring-muscle) is undoubtedly of a provisional character, yet a much larger part of it is retained in the adult than has hitherto been supposed. This part is assumed to have been derived from the platode parenchyma, which has, as it were, been carried over into the annelid organization. Among many interesting special points may be mentioned the discovery of a *paratrochal* ring-nerve; and the demonstration, both in *Polygordius* and in *Lopadorhynchus*, of numerous true neuromuscular foundations—*i. e.*, areas in which nerve-cells and primary muscle-cells are proliferated from common ectoblast areas, but it is also shown with perfect clearness that Kleinenberg was in error in maintaining the origin of the secondary mesoblast-bands and the ventral nerve-cords from such a common neuromuscular foundation. Interesting detailed studies are given of the larval nervous system; Kleinenberg is shown to have been in error in deriving the germ-cells directly from the ectoblast; and the existence of Hatschek's famous nephridial 'Längscanäle' is again denied.

Fortified by these new facts, Meyer reasserts and further extends his original hypothesis, giving a thorough and critical review of the

literature and putting forward many ingenious suggestions regarding the possible phylogeny of the coelome, blood-vessels and musculature, the origin of metamerism, and other deep-lying morphological problems. Phylogenetic speculations on embryological data are getting out of fashion, and some of Meyer's conclusions will doubtless meet with little sympathy on the part of those whose interest in the historical problems of morphology has suffered a temporary attack of paralysis through devotion to more 'modern' questions. Even the sceptical reader, however, who will take the trouble to examine Meyer's work with care, will not be able to deny that the theoretical views are everywhere held closely in touch with admirably thorough and extended observation, and constitute no mere inflated speculative system, but a natural working hypothesis growing directly out of the facts.

In the present paper Meyer considers only the larval development; and his results form a most important supplement to that of students of cell-lineage, who have not, in general, carried their work to a sufficiently late period to determine the real relation of the germ-layers to the adult body. It may be pointed out, however, that the comparative study of cell-lineage in platodes, annelids and mollusks has steadily added weight to Meyer's original contention of a double origin of the 'mesoblast,' for it has shown that in the two higher groups a 'larval mesenchyme' is often formed from cells of the ectoblastic quartets, which are quite distinct from the pole-cells of the secondary mesoblast, the latter (with the apparent exception of *Capitella*) being always derived from a cell of the fourth quartet (otherwise entoblastic). The cell-ancestry of the larval mesenchyme thus agrees in a general way, though with interesting modifications of detail, with that of the mesenchyme (mesoblast) of polyclades, which inevitably and independently suggests the same view as that of Meyer, though from a quite different point of view.* Meyer's observations render it in the highest degree probable that, as the writer has suggested, mesen-

chyme may arise from any of the three ectoblastic quartets; for (not to mention the so-called 'head-kidneys' of *Nereis*), such origin has already been observed in the second and third, and if the cell-lineage of *Polygordius* and *Lopadorhynchus* is of the same type as in other annelids, as can hardly be doubted, the umbrellar neuro-muscular foundations in these forms must be derivatives of the first quartet.

The gonad theory of the coelome, which Meyer has done so much to advance, has made a deep impression on morphology, as may be seen, for instance, by reference to the admirable review of the theories of the coelome by Ray Lankester in the second volume of his 'Treatise on Zoology,' which appeared last year; and it has made serious inroads on the widely accepted enterocœle theory. Whether the two views can be reconciled is not to be determined without further research; for some of the most important observations on which Rabl, Lankester and others have relied in attempting to trace the transition from the pole-cell type to the enterocœle type (*e. g.*, pole-cells in *Amphioxus*, gut-pouches in *Paludina*) have been shown to be erroneous. Meyer believes the enterocœle type to be secondary; Lankester accepts the reverse view. Others have suggested the possibility that the two types have been distinct from the beginning, and this has for years been held open in the writer's advanced lectures on zoology and embryology as a possible basis for a division of the 'triblastic' animals into two parallel but independent series that diverged further down than the platodes—a division which, though entirely provisional, and as yet without adequate basis, nevertheless brings into order a surprisingly large number of facts otherwise difficult to reconcile. This is a question for the future, and may be left with Lankester's significant remark, that "When the cell-lineage of mesenchyme and its tissue-products has been cleared up we may be able finally to put aside the hasty criticisms and phantastic assertions of those who have grown impatient over the slow and difficult task of cellular embryology."

EDMUND B. WILSON.

Publications of the University of Pennsylvania, Astronomical Series. Volume I., Part III.

The work before us is Part III., of the publi-

cations begun by the University of Pennsylvania for the new Flower Observatory, which was formally inaugurated with a public address by Professor Simon Newcomb in November, 1897. The Flower Observatory is widely known among astronomers as a new institution managed on a solid conservative basis, by a gifted and devoted staff of untiring workers. Though it has been in operation but a few years, it has already taken its place among the leading observatories of the country. It is distinguished by the care and accuracy of all its work rather than by the quantity of material turned out; and for that reason it has from the start taken rank with the best of modern observatories. The care and painstaking accuracy which characterized Professor C. L. Doolittle's work at the Sayre Observatory in Bethlehem, Pa., was at once recognizable in the spirit of the new institution under his direction at Philadelphia; and the results are now becoming apparent in the first volume of the 'Publications.'

Part II. of this volume appeared more than a year ago, and dealt in a characteristically thorough manner with the variations of latitude observed at Philadelphia, and with several determinations of the constant of aberration incidentally made in connection with the latitude work. This constant came out somewhat larger than the value which had generally been used by astronomers. The value found by Struve and Peters at Poulkova was $20''.44$, and for many years this was accepted as standard; but recent investigations by several authorities tend to increase the figure to about $20''.55$, which is the value found by Professor Asaph Hall, Jr., at the Detroit Observatory of the University of Michigan. Professor C. L. Doolittle's several determinations confirm this larger value; and on account of the care and precautions exercised in the work, there is little doubt in the minds of conservative astronomers that this new figure is much nearer the truth than that adopted in the nautical almanacs.

Part III. of Volume I. of the New Publications is devoted to the measures of 900 double and multiple stars made with the 18-inch Brashear refractor of the Flower Observatory, by Professor Eric Doolittle, son of the director

of the Observatory. This part consists of 146 large quarto pages of closely set matter, all beautifully and conveniently arranged. There is no defect in the conception or execution of the work, and it is not too much to say that this publication may be taken as a model for astronomers generally.

A concise introduction of eight pages deals with the constants of the equatorial, and with the micrometer employed in the measures. The latter is an ordinary filar micrometer, with the Burnham illumination. Its simplicity enabled the observer to center his whole attention on the work, and the result is a handsome volume of measures on 900 double and multiple stars, all made within the past four years. The stars are chosen mostly from the lists of Burnham, with occasional selections from the Struves and Dewbowski, and such modern observers as Hough and See. They represent in all cases objects requiring measurements. Though no special search was made for new double stars, a list of 22 such objects found in the prosecution of the regular work is given on page 8; all of them being close or interesting pairs which should receive the attention of future observers. The 900 stars measured are arranged in order of right ascension, with places referred to the epoch 1880.0. Their magnitudes and the several designations used by astronomers are clearly and accurately given in each case. The measures are nicely reduced and annual means are formed, according to the classic models of the Struves, Dewbowski and Burnham. The notes accompanying the measures are brief and to the point; no important matter is overlooked, and yet nothing superfluous is ever added. The total number of complete observations is about 3,700, representing something like 44,000 settings of the micrometer.

It should be pointed out that all these observations were taken and reduced by Professor Eric Doolittle alone, in addition to his teaching duties at the University, where he conducts advanced courses of instruction in celestial mechanics. In conclusion it may be noticed that publications dealing with the measurement of double stars are not merely of contemporary interest, but increase in value with time. Thus the work of the Herschels, the Struves and

Dewbowski are immensely more valuable now than when they were made many years ago, by reason of changes in the sidereal heavens which have since intervened; and all precise work such as that now being done at the Flower Observatory is assured of a lasting and honorable place in the history of science. Scientific research prosecuted for its own sake is among the most noble of intellectual pursuits, and the University of Pennsylvania is much to be congratulated on the distinguished place it is acquiring in the astronomical world.

T. J. J. SEE.

WASHINGTON, D. C.

A History of the Precious Metals from the Earliest Times to the Present Day. By ALEX. DEL MAR. Second edition, revised. New York, Cambridge Encyclopedia Co. 1902. 8vo. Illustrated. Pp. xxii + 480, 1-9.

The first edition of this remarkable work was published at London in 1880 and has long since been exhausted; meanwhile the author, in his profession of mining engineer, has visited many remote sources of the precious metals and has secured at first hand new material which has caused the volume to be entirely rewritten. This history is prepared by a profound student, from the point of view of the antiquarian, the archeologist and of the metallurgist, as well as the political economist, and deals with the exploration of the entire surface of the globe for gold and silver from the earliest record of mankind to the present day; copper, tin and the other heavy metals are only incidentally treated. The author is particularly well qualified for this vast undertaking, having already published several serious studies on money, its history, its science and its bearing on the progress of civilization, and having held positions of authority under the United States government, Director of the United States Bureau of Statistics, Mining Commissioner, and member of the International Congresses which met at Turin and at St. Petersburg. He is now engaged on 'The Romance of the Precious Metals' and 'The Politics of Money,' both of which are well advanced.

Mr. Del Mar maintains that the principal motive which has led to the dominion of the earth

by civilized races is the desire for the precious metals, rather than geographical research or military conquest; that the occurrence of gold has invited commerce, and the latter has been followed by invasion and eventually permanent occupation. With these facts in mind he portrays the stupendous power exerted by the quest for the precious metals from the beginnings of history in India, Persia, Egypt, Greece, Italy, Spain and the Western Hemisphere. He depicts very vividly the painful ways in which each gold-producing country has been mercilessly plundered by more powerful neighbors, saying that 'mining is slow work compared with plundering.' He also shows elsewhere that mining is generally more expensive than plundering, except where forced labor and slavery is employed. And to illustrate the latter point he claims that 'since the discovery of America the European world has acquired 19,500 and odd millions of dollars, of which 1,000 millions were obtained by conquest, 9,500 millions by slavery and 9,000 millions chiefly by free mining labor.'

Recognizing these sources of the precious metals he is decidedly opposed to the dictum of certain philosophers that the value of gold is its 'cost of production,' and says this formula does not take into account the 'millions of human lives, the rivers of human tears, the oceans of human blood, the immeasurable amount of human anguish.'

This aspect of the case is set forth in powerfully written chapters on the plunder of America (by the Spaniards), of Africa (from the Roman Emperors to South African War), of Asia (by the Romans, Portuguese and the British), and of China in all ages; chapters showing great historical research and learning. The author's arraignment of Spain is particularly interesting at this epoch: "Besides despoiling aboriginal America of her gold and silver, Spain accomplished nothing in the New World except extermination and destruction. She swept away half as many human lives as all Europe contained at the period of the discovery of America. She destroyed every memorial of the Aztec and Peruvian civilizations. She disfigured the entire face of Central and South America. And she planted nothing

in the place of what she destroyed save a race laden with disadvantages and a few mission churches crumbling to decay. The spoil she obtained amounted altogether to some seven thousand millions of dollars." And all this cost the conquerors practically nothing in comparison. And here again the author remarks, "the value of these precious metals is *not* due to the cost of production, but to their usefulness and their quality, to the relation of supply to demand."

It is gratifying to note that Christian civilization now adopts different methods and "the acquisition of the precious metals by means of conquest is virtually over."

The volume is so crowded with facts, as well as with the results of thought and argument, that no ordinary book review can do the author justice; in the words of those who reviewed the first (incomplete) edition, it 'abounds with vivid description and practical knowledge; it is replete with information, and evinces much care and study; it is able and exhaustive; of the highest scientific value, yet readable as a novel.'

In the chapter on 'Production, Consumption and Stocks of Metal' the author does not conceal his poor opinion of the 'defective and misleading statistics of the Mint Bureau,' supported in its methods by Congress, and reflecting 'the narrow views of the Mint Director.' Valuable features are the chronological summaries, the bibliography (with press marks of the British Museum Library) and the index. The volume is clearly printed on good paper, probably in England, as we observe the words 'honour,' 'labour' and 'negros,' instead of the more familiar 'negroes.' There are two illustrations, a mining scene in California and a portrait of General Nelson A. Miles, who is casually mentioned in the text.

The volume is of the highest value.

HENRY CARRINGTON BOLTON.

SOCIETIES AND ACADEMIES.

CALENDAR.

The American Association for the Advancement of Science. A meeting of the council will be held at the Quadrangle Club, University of Chicago, on the afternoon of January 1. Sec-

tion H (Anthropology) will meet at the Field Columbian Museum, Chicago, on December 31 and January 1. The next regular meeting of the Association will be held at Pittsburgh, Pa., from June 28 to July 3. A winter meeting is planned to be held at Washington, during the convocation week of 1902-3.

The American Society of Naturalists will hold its annual meeting at the University of Chicago on December 31 and January 1. In conjunction with it will meet the Naturalists of the Central States and several affiliated societies, including The American Morphological Society, The American Physiological Society, December 30 and 31, The American Psychological Association and the Western Philosophical Association, December 31 and January 1 and 2.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

THE 538th meeting was held October 12, 1901.

An obituary notice of Mr. C. A. Schott, for many years chief of the computing division of the Coast and Geodetic Survey, was read by Superintendent O. H. Tittmann; and Mr. R. A. Fessenden presented, through Mr. Winston, a paper on 'Progress in Practical and Theoretical Electricity' giving a rapid sketch of the condition of all the great branches of electricity.

The 539th meeting was held October 26, 1901.

Mr. Marcus Baker described 'A Dictionary of Alaskan Names,' now in press, to be published by the U. S. Geological Survey, pointing out its characteristics and the principles on which it is made. It will contain about 6,500 adopted names, 3,000 obsolete names and cross-references and 60 pages devoted to a catalogue of authorities with brief accounts of the explorers. Dr. Dall spoke appreciatively of the work.

Mr. C. H. Hinton, of the Nautical Almanac Office, then read by invitation a paper on 'A Fourth Dimension in Space demanded by Electrical Phenomena.' The paper cannot be summarized, but may be characterized as an attempt to apply to 4-space some principles of quaternions developed for 3-space.

The 540th regular meeting was held November 9, 1901, Vice-President Adler in the chair.

Mr. Hinton continued the presentation of his

views begun at the last meeting on an explanation of electrical phenomena by a fourth dimension in space.

Dr. G. M. Sternberg, Surgeon-general of the Army, reported on 'Health Conditions in the Philippines.' He finds that the health of the troops has been constantly improving; small-pox is practically stamped out; typhoid and malarial fevers and heat strokes are almost unknown. Dysentery is one of the most serious troubles; so at most barracks distilled or sterilized water is supplied. In the discussion that followed Dr. Dall called attention to the absence of malaria in Alaska, although mosquitoes of several species are very abundant.

Dr. Adler reported on the progress of the 'International Catalogue of Scientific Literature.' After conferences for several years, definite plans were settled on during the past summer. Owing to the failure of Congress to take action, the United States was not officially represented, but Mr. Herbert Putnam, Librarian of Congress, was in London and had some share in the negotiations. The plan adopted requires each country to index and classify the literature published within its borders pertaining to 17 branches of science, beginning with 1901; the Smithsonian Institution has temporarily undertaken this work for the United States. The material is then to be arranged and published by the Royal Society in 17 volumes annually; these will be sold separately. About 320 sets have been subscribed for, for 5 years, at £1 per volume; 65 sets are to come to the United States. The speaker described some of the difficulties met with in formulating the plans, gave various details regarding the work, and exhibited the schemes of minute classification to be followed by the indexers.

CHARLES K. WEAD,
Secretary.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 343d meeting was held on Saturday evening, November 16.

C. P. Hartley exhibited some malformed ears of corn, stating that their interest lay in the fact that they had been grown from seed taken from an ear similarly abnormal, the malformation having been reproduced.

H. E. Van Deman showed a specimen of the ripe fruit of the guava from Florida, and made some remarks on the extent to which this fruit was now being cultivated.

L. O. Howard announced that he had received a letter from Mr. C. L. Marlatt, announcing the discovery of the long-sought original habitat of the San José scale insect; this was found to be in China, in the region to the south of the Great Wall. The scale insect was preyed upon by a species of ladybird beetle, living examples of which were now on their way to the United States.

H. G. Dyar presented some 'Notes on Mosquito Larvæ,' being a summary of investigations made during the past summer and including the following species: *Anopheles crucians*, *punctipennis*, *maculipennis*; *Culex sollicitans*, *territans*, *pungens*, *confinis*, *canadensis*, *sylvestris*; *Stegomyia fasciata*; *Aedes smithii*; *Uranotænia sapphirina*; and *Psorophora ciliata*. The habits and habitats of these various larvæ were described, and it was pointed out that there was great diversity in the latter. Some species preferred clear water, others infested turbid pools, and still others were found in brackish water. The speaker showed drawings of the different larvæ and drew attention to their peculiarities and their distinctive specific characters. It was noted that a species of fresh-water hydroid was seen to feed on mosquito larvæ, while on the other hand one species of larvæ fed on bacteria and another fed on other larvæ.

C. B. Simpson gave some 'Observations on Jack Rabbits,' telling of their rapid increase in parts of the west and describing their runways among the sage brush and the manner in which they were hunted by their great enemies the coyotes.

Vernon Bailey described 'The Little Deer of the Chisos Mountains, Texas,' stating that the same species, *Odocoileus couesi*, was also found in Mexico, Arizona and New Mexico, so that their occurrence in this locality was an extension of their known range. Owing to the distance of the Chisos Mountains from the railroad and the unfitness of the country for grazing purposes, the deer were still to be found there in considerable numbers. The speaker said that an adult buck would weigh only one hun-

dred pounds, and a doe much less, and pointed out the differences between the color of the summer coats of this and the large white-tailed deer of Texas, *Odocoileus texensis*.

Barton W. Evermann spoke of 'Birds in the Dry Season,' stating that few realized how important to birds was a supply of water, nor the influence of drouth on the distribution of birds. During an unusually dry summer the California quails did not breed, but kept together in flocks as they did during the fall. The speaker gave a list of eighteen species of birds that were seen to resort to a single leaking water spigot and described the manner in which various species drank. In conclusion it was suggested that during dry seasons, or in arid regions, drinking places should be provided for the benefit of the birds.

F. A. LUCAS.

DISCUSSION AND CORRESPONDENCE.

METEOROLOGICAL OBSERVATIONS WITH KITES AT SEA.

TO THE EDITOR OF SCIENCE: On page 412 of SCIENCE I stated that meteorological observations were about to be attempted with kites flown from a transatlantic steamer. With the aid of my assistant, Mr. Sweetland, and through the courtesy of Captain McAuley, this was accomplished on board the Dominion steamship *Commonwealth*, which left Boston for Liverpool on August 28. During most of the voyage we were within an area of high barometric pressure that was drifting slowly southeastward and out of which light winds blew. Although these were insufficient to raise the kites, the ship's speed of 16 knots created a corresponding wind from an easterly direction that sufficed to lift the kites on five of the eight days occupied by the voyage to Queenstown. On one of the three unfavorable days, a following wind became too light on the ship for kite-flying, and on the two other days a fresh head wind, augmented by the forward motion of the ship, was so strong as to endanger the kites, but, had it been possible to alter the course of the vessel, a favorable resultant wind might have been produced every day. The maximum height attained was only about 2,000 feet, but with larger kites and longer wire this could have been greatly ex-

ceeded. Automatic records were obtained of barometric pressure, air temperature, relative humidity and wind velocity, which did not differ markedly from records obtained in somewhat analogous weather conditions over the land. The most striking feature was the rapid decrease of the temperature with increasing height in all but one of the flights. The fall of temperature was fastest in the first 300 feet, where it exceeded the adiabatic rate of 1° Fahrenheit in 183 feet, but in the last-mentioned flight the temperature rose 6° in 660 feet, and during the afternoon remained so much warmer than at sea-level. The relative humidity varied inversely with the temperature, the direction of the wind shifted aloft toward the right hand when facing it, and its velocity generally diminished with altitude. These are probably the first meteorological observations at a considerable height in mid-Atlantic, and have a special importance because they indicate that at sea high-level observations may be obtained with kites in all weather conditions, only excepting severe gales, provided the steamer from which the kites are flown can be so manœvered as to bring the wind to a suitable velocity.

As the basis of an appeal for the exploration of the atmosphere at sea, the records described were exhibited to the Geographical Section of the British Association at its Glasgow meeting, and the appointment of a committee, with a grant of money to undertake observations with kites in Great Britain, together with the interest manifested there and on the continent of Europe, encourages the hope that my project will be realized. The equipping of the English Antarctic vessel *Discovery* with meteorological kites, as mentioned on page 779 of SCIENCE, and a similar installation on the German Antarctic ship *Gauss*, are unlikely, for various reasons, to have yielded much data on their voyages across the equator. Although the United States has taken no part in this international undertaking, an opportunity is now offered, without material expense, danger or hardship, to cooperate in a study of the general atmospheric circulation, which is one of the objects of polar exploration. Indeed, for a naval vessel not actually engaged otherwise, the sounding of the atmosphere in the tropics, whereby the relation of the upper air

currents to the winds useful for navigation may be ascertained, would seem to be as legitimate a task as sounding the depths of the oceans and determining the currents and temperatures prevailing there. But if our Navy Department will not authorize this, a private expedition should be organized to investigate the questions mentioned in my letter to SCIENCE on 'A New Field for Kites in Meteorology.' Since then, Professor Hildebrandson, of Upsala, who is an eminent authority on the circulation of the atmosphere, writes me that a meteorologist on a steamship provided with kites, and also with small balloons to ascertain the drift of the upper winds when there are no clouds, by making atmospheric soundings between the area of high barometric pressure in the North Atlantic and the constant southeast trades south of the equator, and in this way investigating the temperature and flow of the so-called anti-trades, could solve in three months one of the most important problems in meteorology. If any of your readers will furnish the steamer required, I stand ready to carry out these investigations.

PERMANENT SKIN DECORATION.

IF Mr. H. Newell Wardle* had referred to Mr. H. Ling Roth's great compilation, 'The Natives of Sarawak and British North Borneo,' he would have found the Bornean process of tattooing described and the implements figured. From actual experience I can assure Mr. Wardle that in Sarawak, at all events, the pattern is gently printed on the skin from a wooden block and the pigment is driven into the skin by means of an ordinary tattooing needle which is hit by a slender iron rod. This is the typical Tahitian 'tatu.' Examples of the apparatus employed will be found in the splendid Furness-Hose collection in the Free Museum of Science and Art in Philadelphia.

A. C. HADDON.

LIFTING HOT STONES.

TO THE EDITOR OF SCIENCE: In the late number of *Nature* Professor S. P. Langley calls

* SCIENCE, Vol. XIV., p. 776.

attention to an old Tahitian priest who walked in bare feet over the heated stones of a pit prepared for cooking. Mr. Andrew Lang calls attention also to the fact that this was a ceremonial performance, preparatory to the cooking.

The United States National Museum is in receipt of a letter from Lieutenant Campbell E. Babcock, U. S. A., stationed at Vancouver Barracks, Washington State, enclosing a communication from Chief Peter Wildsho, of the Cœur d'Alene Indians in Idaho. Peter in his simple way is telling how fifty years ago his ancestors cooked their food in basket pots by means of hot stones. At the close of the description is the following in Peter's own words: "An amazing little story is connected with this basket for cooking food with hot stones. The medicine-man was considered a very powerful being by his tribe. He could take away the life of a man at his word or cure a sick or dying person. His power depended on the wild beasts that are fierce and powerful, and he carried constantly around his body some parts of the animal, such as a piece of the tail." This man to show his power stripped himself and painted his body. While he was singing and dancing, accompanied by all the Indians, he went to the basket containing cold water and sang, and, while all were watching him in awe, he slowly took the red-hot stones in both hands and dropped them into the basket of cold water. The water was heated and not a blister or burn was to be seen on his hands.

O. T. MASON.

THE HITTORF JUBILEE.

THE Academy of Sciences at Berlin has issued the following terse summary of the life-work of the venerable Hittorf:

HERRN JOHANN FRIEDRICH HITTORF zum Fünfsigjährigen Doctorjubiläum am XXI. October MDCCCLXXXVI.*

HOCHGEEHRTER HERR COLLEGE!

Indem die Königliche Akademie der Wissenschaften Ihnen zu der Jubelfeier Ihrer Promotion herzliche Glückwünsche sendet, erinnert sie sich dankbar des hervorragenden Antheils Ihrer Arbeit an dem Fortschreiten Ihrer Wissenschaften, der Physik und der

* Usually known as Wilhelm Hittorf.

physikalischen Chemie, in den verflossenen fünfzig Jahren.

In Ihrer scharfsinnigen Untersuchung des Selen und des Phosphors wiesen Sie den Zusammenhang der Allotropie mit der von dem Körper aufgenommenen Wärmemenge nach. Sie stellten die physikalischen Eigenschaften der Substanz in den verschiedenen Zuständen, insbesondere bezüglich der Dampfspannung fest und fanden merkwürdige Beziehungen der Allotropie zu dem elektrischen Leitvermögen.

Die Hauptarbeit Ihrer früheren Forschung aber war auf die Elektrolyse der Lösungen gerichtet. Es ist schwer zu sagen, ob die Bewunderung, zu welcher diese Arbeiten zwingen, mehr der Exactheit und Ausdauer bei der Bestimmung der Ionenwanderung entspringt, einer der mühsamsten, jemals angestellten experimentellen Forschungen, deren Resultate durch spätere Arbeiten nur bestätigt und kaum erweitert worden sind, oder aber der Folgerichtigkeit und Stetigkeit Ihrer Anschauungen über die elektrolitischen Vorgänge. Durch Sie allein sind wir an die richtigen Vorstellungen gewöhnt worden, welchen Sie gegen den Widerspruch selbst hervorragender Physiker Geltung verschaffen mussten, und von denen Sie später die Freude erlebt haben, dass sie das Fundament für einen grossen Theil der neueren physikalischen Chemie geworden sind.

Von ähnlicher grundlegender Bedeutung war die andere grosse Arbeit Ihres Lebens, die Erforschung der Vorgänge bei der elektrischen Entladung in Gasen. Schon in der ersten Entwicklungszeit der Spectralanalyse hatten Sie sich mit PLÜCKER an der verdienstvollen Classification der Spectra betheiligt. Ihre späteren grossen Arbeiten umfassten die Gasentladung in der Hauptsache nach allen Seiten ihrer Gesetze.

Sie waren der Erste, welcher einen der merkwürdigsten Vorgänge in der Natur dessen Fruchtbarkeit für die Wissenschaft und in der letzten Zeit auch für das Leben noch nicht bis zum Ende abgesehen werden kann, die Kathoden-Entladung im luftverdünnten Raume, in seiner vollen Entwicklung zur Anschauung brachte. Sie zuerst stellten das Vacuum in der hierzu nothwendigen und später nicht übertroffenen Vollkommenheit her und beobachteten und beschrieben die Ausbreitung und die vielseitigen Wirkungen der Kathodenstrahlen in musterhafter Weise. Zugleich gelang es Ihnen, diese Vorgänge der elektrischen Messung zugänglich zu machen und nach der Seite der Stromvertheilung wie des Leitungswiderstandes zu verfolgen. Dabei ergab sich, dass die Elektrizitätsleitung der Gase ganz anderen Gesetzen folgt, als diejenige in Metallen oder Elektrolyten. Grosse Dienste leisteten bei dieser Forschung Ihre, für die damalige Zeit im grössten Stile aus-

geführten Stromerzeuger, mittels deren Sie die intermittirende Entladung durch eine solche ersetzen, deren continuirliche Beschaffenheit, entgegen der verbreiteten Meinung, durch sinnreiche Hilfsmittel von Ihnen nachgewiesen wurde. Auch an den neueren Aufschlüssen über die Natur des Leuchtens im allgemeinen haben Sie bei diesen Gelegenheiten einen verdienstvollen Antheil genommen.

Ihre Arbeit, hochgeehrter Herr College, bildet ein classisches Beispiel für die Erfolge, welche durch die Concentration der Forschung erreichbar sind. Die Wissenschaft wird Ihnen für alle Zeiten zu tiefem Dank verpflichtet sein.

DIE KÖNIGLICH PREUSSISCHE
AKADEMIE DER WISSENSCHAFTEN.

The committee having the matter in charge purpose additionally to celebrate the fiftieth anniversary of Hittorf's doctorate by presenting him with a bust or a similar testimonial of their appreciation.

CARL BARUS.

SHORTER ARTICLES.

FUSARIUM EQUINUM (NOV. SPEC.).

AN epidemic skin disease among horses has appeared on the Umatilla Indian Reservation, Pendleton, Oregon. There are upwards of six thousand horses on the reservation, and of these more than sixty per cent. are said to be affected. The disease manifests itself through severe itching and loss of hair over almost the entire body. The animals remain around the rubbing posts all day, and a number of them die from starvation.

An examination of samples of the skin forwarded to the Pathological Division of the Bureau of Animal Industry demonstrated the presence of *Sarcoptes equi*. These parasites, however, were not present in sufficient numbers to account for the almost complete alopecia, and a careful examination of some samples, almost denuded of hair, failed to show their presence.

Microscopic examination of sections of the skin, stained with borax blue, or after Gram, showed the presence of large half-moon, spindle- or sickle-shaped bodies, deeply stained, in the hair sacs and sebaceous glands.

By pulling out one or more of the remaining hairs, clipping off the root with sterile scissors,

and shaking these roots up in melted agar and plating there develops, at 37° C., in the course of a few days, from one to five circular colonies of a fungus which grows rapidly and assumes a salmon-pink color. Cover-glass preparations made from these colonies contain numerous sickle-shaped segmented spores, characteristic of *Fusarium*.

There are, according to Dr. Erwin F. Smith, about twenty-five known varieties of this fungus. Some are strict saprophytes, others are parasitic on grains and plants, and others are pathogenic to plants. No *Fusarium* has, however, been known to be pathogenic to animals. I would, therefore, pending the present investigation, which will require some time, propose the name *Fusarium equinum* nov. spec.

VICTOR A. NÖVGAARD.

WASHINGTON, D. C.,

Nov. 14, 1901.

RHIZOCTONIA AND THE POTATO.

ATTENTION has been called recently to the parasitic nature of *Rhizoctonia* on various plants in the United States by Dr. B. M. Dugger and Professor F. C. Stewart. Observations at the Colorado Experiment Station on the relation of this fungus to the potato have brought out some interesting facts. During the spring months sclerotia develop freely on tubers and young sprouts in sacks and bins. A few affected tubers in a sack or bin of clean tubers, under favorable conditions, will spread the disease and in a short time render the entire lot worthless for seed. Affected tubers used for seed transmit the disease to the young plants, and these in turn to the following crop of tubers. Under proper conditions the fungus attacks all parts of the potato plant and in all stages of growth, but it is most destructive to the softer tissues. The weaker plants are often killed before they reach the surface of the ground. Those which are able to withstand its earlier attacks are apt to suffer more or less injury from it later in the season.

Little potatoes are produced by the fungus injuring the tuber stems in such a manner as to prevent free transportation of plant food between the main stem and tubers, or by completely cutting off the tuber stem while the

tubers are small. When the tuber stem receives an injury sufficient to check the free transportation of plant food, the food accumulates above the injury and soon excites the buds on the tuber stem above this point into growth. These buds develop into tubers. The fungus may continue its work and in time kill back the tuber stem, or it may cut off this stem above the newly formed tubers. If the tuber stem is attacked just as it grows out of the main stem adventitious buds may push out on the main stem around the injured point. These usually develop into short-stemmed or stemless tubers, forming bunches of small tubers. If the roots are badly injured the food supply is reduced and the plant puts out weak tuber stems. These stems are easily cut off by the fungus and the plant usually sets few or no tubers. The food which it is able to take up is used mostly in top development. The leaves become thicker, have a tendency to crinkle and take on a yellowish tinge. When the roots are less severely injured but the free transportation of food to the subterranean stems is interfered with, excessive top development is produced, and the axillary buds may develop aerial potatoes.

Aerial potatoes may be produced artificially: (1) By ringing the stem; (2) by tying a line firmly around the growing stem; and (3) by removing the subterranean tubers as soon as formed.

Sclerotia are often found on the surface of the larger tubers. Apparently these sclerotia do no injury, but experiments show conclusively that scabbing and browning of tubers may be produced by this fungus.

The corrosive sublimate treatment is promising as a preventive of this disease.

F. M. ROLFS.

FORT COLLINS, COLO., Nov. 11, '01.

THE WORK OF THE 'ALBATROSS.'

STUDENTS of marine zoology will welcome the appearance of the brochure just issued by the U. S. Fish Commission, compiled by C. H. Townsend, and entitled, 'Dredging and Other Records of the Steamer *Albatross*, with Bibliography Relative to the Work of the Vessel.' This useful paper contains in condensed form

the records of the work of the *Albatross* for eighteen years, for this vessel has never been out of commission since she was turned over to the Fish Commission, all necessary repairs having been made during intervals between the various cruises. The Bering Sea controversy and the war with Spain interrupted the regular work of the vessel for several years, but with these exceptions she has been almost continuously engaged in investigating fisheries and fishing grounds, in deep-sea sounding and dredging, and in other branches of hydrographic work.

The dredging and trawling records run from 1883 to 1900 and include data of 1,786 hauls of the dredge and trawl, from depths of less than 100 fathoms down to the maximum of 4,173 fathoms, the deepest water in which a dredge has been used. Three charts, bearing the serial numbers of stations, show the extensive area covered by these operations.

The record of hydrographic soundings shows the date, latitude and longitude, depth and character of bottom, in 4,032 soundings, but as the figures have been used in various charts no map of these is given.

Then follow records of the surface and intermediate tow nets, miscellaneous records and records of serial temperatures. All these will not only aid in identifying the large collections placed in the hands of specialists or deposited in museums, but make intelligible many references contained in papers on the *Albatross* collections in which localities are referred to by the station number only.

The chronological bibliography relative to the work of the *Albatross* between 1884 and 1901 comprises 233 titles, and a list is appended of 63 papers now in course of preparation. Finally we are given a list of something like 2,000 new species, largely of deep-sea fishes and crustaceans, which have been described from specimens obtained by the *Albatross* and which give some idea of the amount of material secured. Those who are familiar with the magnificent volumes of the *Challenger* report may be surprised to learn that the zoological material on which they are based is in every way much less than that procured by the *Albatross*, but the *Challenger* material has had the advan-

tage of being systematically worked up and published in consecutive volumes, and in a manner to show it to the best advantage. The *Albatross* has probably obtained a hundred deep-sea fishes where the *Challenger* obtained one, a statement that may be illustrated by saying that a single haul of her trawl brought up many more specimens of *Macrurus* than were secured by the *Challenger* in her entire cruise. In a way this wealth of material has been truly an embarrassment of riches, for its accumulation, and particularly its care, have occupied the time of those who might otherwise have been engaged in its study; nevertheless, we can but hope that the scientific work of the *Albatross* may proceed in the future as it has in the past.

F. A. L.

RICHMOND MAYO-SMITH.

THE Council of Columbia University adopted the following resolution on the death of Professor Mayo-Smith:

The members of the University Council have learned with profound regret and unfeigned sorrow of the sudden death of their long-time friend and colleague, Professor Richmond Mayo-Smith, the chief of the Department of Political Economy in this University.

During his zealous, devoted and successful service of twenty-four years in this institution, he founded the department over which he has presided and developed it to so high a point of excellence that it has few equals in this country or in the world. He was, moreover, the chief promoter, if not the founder, of the science of statistics in this country. His published works upon this most difficult subject have brought exact and orderly knowledge into a domain where, before, uncertainty and confusion prevailed, and have earned for him honor and gratitude from the scientific world.

His activity went, however, beyond the limits of his own department. As a member of the University Council from the date of its establishment to the moment of his death, and of several of its most important committees, he contributed largely and ably to the formation of the policies of the University as a whole, and to the present organization of this complex institution.

To all this must be added the influence of his personality. His thorough scholarship and his great modesty, his unwavering truthfulness and sound judgment, with his genuine deference for the opinions of others, his dignity of character and kindness of heart, and his manliness united with his gentleness, all conspired to make him a great intellectual and moral force, a noble example of high thinking and of simple life, throughout all branches of the University and wherever he was known.

Speaking for themselves and for the bodies which they represent, the members of the Council desire to enter on the records of the Council this minute, expressing their appreciation of the great merit of their colleague and their sense of the great loss which they individually, and the University as a whole, have sustained in the death of Professor Richmond Mayo-Smith.

SCIENTIFIC NOTES AND NEWS.

SECTION H (Anthropology) of the American Association for the Advancement of Science will hold its winter meeting at the Field Columbian Museum, Chicago, on Tuesday and Wednesday, December 31 and January 1, 1901-2. Members of the section who wish to present papers will please inform the Secretary, Mr. George Grant MacCurdy, Yale University, New Haven, Conn. Hotel del Prado, Midway Plaisance, will be the headquarters of the Section.

THE completion of fifty years since M. Berthelot began the teaching of chemistry at the Collège de France was celebrated on November 24. Addresses were made by scientific and public men, and a gold medallion was presented by President Loubet.

ARRANGEMENTS have been made to present the eminent French surgeon, M. Odilon-Marc Lannelongue, with a gold medal in celebration of his scientific jubilee.

THE Royal Society's medals will this year be awarded as follows: The Copley Medal to Professor J. Willard Gibbs, Yale University, For. Mem. R.S., for his contributions to mathematical physics; a Royal Medal to Professor William Edward Ayton, F.R.S., for his contributions to electrical science; a Royal Medal to Dr. William Thomas Blanford, F.R.S., for

his work in connection with the geographical distribution of animals; the Davy Medal to Professor George Downing Liveing, F.R.S., for his contributions to spectroscopy; and the Sylvester Medal to Professor Henri Poincaré, For. Mem. R.S., for his contributions to mathematical science.

IN celebration of the hundred and fifteenth anniversary of its foundation, the Göttingen Academy of Sciences has made the following elections: Honorary members: Professors Abbe (Jena) and Neumayer (Hamburg); non-resident members: W. Waldeyer (Berlin), Gaston Darboux (Paris), W. Zittel (Munich) and J. Wislicenus (Leipzig); corresponding members: Aurelius Voss (Würzburg), Hugo Seeliger (Munich), Max Planck (Berlin), Karl Runge (Hanover), Arthur Schuster (Manchester), Swante Arrhenius (Stockholm), Giovanni Ciamician (Bologna), Emil Fischer (Berlin), Wilhelm Ostwald (Leipzig), Walther Spring (Liège), Hermann Minkowski (Zurich), Charles Barrois (Lille), Lazarus Fletcher (London), Michel Levy (Paris), Victor Uhlig (Vienna), Friedrich v. Recklinghausen (Strassburg), Karl Chun (Leipzig), Giov. Batt. Grassi (Rome), Herbert Ludwig (Bonn), Edmond Perrier (Paris).

DR. SMITH ELY JELLIFFE has been appointed visiting neurologist to the New York Hospital, the position having been made vacant by the resignation of Dr. Frederick Peterson, recently appointed Commissioner in Lunacy.

DR. TARLETON H. BEAN has been recommended by the Fish and Fisheries Committee of the St. Louis Exposition as chief of that department.

THE lectureship in connection with the California Philosophical Union for the current year has been offered to, and accepted by, Professor R. M. Wenley, of the University of Michigan.

DR. CHARLES HERTY, adjunct professor in chemistry at the University of Georgia, has resigned in order to accept a position in the United States Department of Agriculture.

DR. NICHOLAS SENN, professor of surgery in the Rush Medical College of the University of Chicago, has returned home from a tour of the world, which included a trip across Siberia, *via* the new Russian railroad.

MR. JOSEPH W. T. DUVEL, who is holding for the third time the Ferry Fellowship in botany at the University of Michigan, spent the summer and fall in Europe, inspecting the several botanical experiment stations. He is again carrying on research work on the conditions affecting the germination of seeds, in the botanical laboratory of the University of Michigan.

DR. WILLIAM R. HARPER, president of the University of Chicago, has accepted the directorship of the educational congresses to be held in connection with the World's Fair in St. Louis.

MR. JOHN HYDE has resigned the editorship-in-chief of the *National Geographic Magazine*, which he has held since 1895, with a view to devoting so much of his time as is not occupied with his exacting duties as statistician of the U. S. Department of Agriculture to work in a much-neglected branch of economic science.

DR. REMLINGER, director of the Antirabic Institute at Constantinople, has been appointed chief of the Imperial Bacteriological Institute, replacing Professor Nicolle. Dr. Remlinger will continue also to hold his former post.

MR. ALFRED L. JONES, the originator of the School of Tropical Medicine at Liverpool, has been made a Knight Commander of the Order of St. Michael and St. George.

MR. WILLIAM MARCONI left London on November 25, for Newfoundland, where he will select sites for the erection of stations for his system of wireless telegraphy.

THE Berlin Academy of Sciences has made an appropriation of 3,000 Marks to Dr. Blanco for a continuation of his geological investigations, and of 1,500 Marks to Professor Boveri for investigations on the fertilization and early development of the egg.

WE regret to announce the death of the eminent magnetist, Professor Max Eschenhagen, at the age of 43 years. He has been in charge of the Royal Prussian Magnetic Observatory since its establishment in 1899, and he took a very active part in the planning of the magnetic work of the German Antarctic expedition and in arranging the international work to be carried out simultaneously over the entire globe during the period of the expeditions. His contributions to terrestrial magnetism are numer-

ous, his skill exhibiting itself especially in the improvement of magnetic instruments and in the designing of new ones. His light, convenient, portable magnetographs will be extensively used in the international work.

THE death is announced at the age of 59 years of Mr. A. H. Smee, author of valuable contributions to chemistry and physiology. He was the principal medical adviser of the Gresham Life Assurance Society, and his statistical reports on rates of mortality are standard authorities.

THE archeological field work, conducted in central New Brunswick during the past summer by Mr. Samuel W. Kain, yielded good results, but owing to Mr. Kain's ill health the report will not be published for some time.

THE Imperial Academy of Sciences of Vienna has received, according to *Nature*, intelligence of the botanical expedition in Brazil, from its chief, Professor R. von Waldheim, down to September 10, from São Paulo. The rivers Rio Branco, Rio Mambu and Rio Aguapiby, flowing through an almost unexplored country, had been navigated in canoes; and large consignments have already been sent to Vienna in the form of living plants and roots, herbarium specimens, preparations in spirit, woods, fruits and economic products.

REUTER'S AGENCY reports from St. Petersburg that uneasiness is no longer felt regarding the fate of the scientific expedition under Lieutenant Kozloff, which was reported some time ago to have been massacred by a band of Tibetans, as news has been received stating that the expedition left Si-ning-fu, which is near Lake Kokonor, on September 12, for Fushar. The expedition was escorted by Chinese soldiers, and further news has been received from the Russian Consul at Chuguchak, who had been informed by local authorities that the party had passed through Jan-lan and Datum.

THE Royal Geographical Society of Antwerp announces an exposition to be opened in that city in May next. The object is to popularize geographical sciences, to make those countries recently opened to commercial activity better known, and to contribute to the development of the mercantile marine and of maritime enter-

prises. There will be a section devoted to ancient and modern maps and globes, surveying instruments, etc., which will comprise also meteorological and ocean-sounding apparatus. The committee proposes to assemble important ethnographical collections, in view of the interest taken in them by the public in regard to trans-oceanic enterprises. The participation of the Kongo Free State will largely contribute to the success of this section. Besides the colonial section, there will be a department devoted to everything relating to the progress of navigation. Models of ships and of great maritime works, improvements in the art of navigation, and trophies of voyages of exploration will be exhibited. It is desired to give to the exhibition an international character.

THE subject for the Speniaroff prize of the International Geological Congress for 1893 is a critical review of methods of classifying minerals. Two copies of the paper must be sent before the next congress to the secretary of the last congress, M. Charles Barrois, 62 Boulevard, Saint-Michel, Paris. The value of the prize is about \$225.

THE November meeting of the Faculty Science Club of Wellesley College was addressed by Professor Cummings of the department of botany, to whom the lichens of the Harriman Alaskan Expedition were sent for identification. She showed on the map the region covered by this and former collecting parties, and stated that among the thousand specimens put into her hands three new species had been found and 76 not before known in Alaska.

The Botanical Gazette states that the herbarium of Theodor von Heldreich, professor of botany and director of the Botanic Gardens, Athens, is for sale. It contains approximately 20,000 species, and richly represents the floras of Greece, Asia Minor and Egypt. It contains also hundreds of types and authentic specimens of new species, described by Heldreich in the works of Bossier.

BY the will of the late Mrs. Charles E. Balch, of Manchester, N. H., the Manchester Institute of Arts and Sciences of that city is a beneficiary to the extent of \$50,000, in securities and real estate to the value of about \$30,000. The will provides that the bequest is to be ap-

plied to the purposes of the Fine Arts section of the Institute.

A COLLECTION of butterflies, containing over 5,000 specimens, has been given to the Art Gallery of the Plainfield, N. J., Public Library by Mr. Alexander Gilbert.

THE National Educational Association will hold its next annual meeting in Indianapolis, beginning on July 7.

THE twenty-second annual exhibition of the New York Microscopical Society will be held on the evening of December 6, at the rooms of the Society in the Mott Memorial Building, 64 Madison Avenue. The exhibition will be open to the public, but cards of admission will be necessary. These will be sent to those who apply by letter to Dr. George W. Kosmak, 23 East Ninety-third Street.

THE Imperial Leopold Caroline Academy of Sciences at Halle will celebrate the one hundred and fiftieth anniversary of its foundation on January 1, 1902.

As the result of a meeting held at Frankfort, under the presidency of Professor Edinger and addressed by Professor Hagen, it was decided to establish in that city a branch of the German Anthropological Society.

It has been previously announced in these columns that the *Botanische Centralblatt* has become the property of the Association Internationale des Botanistes. Arrangements for its transfer to the Association have been completed, and it will be published at Leyden beginning January 1, 1902, under the direction of an editor-in-chief appointed by the Association. Arrangements have been made for the appointment of a board of special editors in England, America and France, and reviews will henceforth be published in English, French and German. Beginning with the first of January, 1902, the *Centralblatt* will be sent gratis to all members of the Association. The annual fee for members is 25 shillings. The number of representatives on the general committee of the Association to which any country is entitled depends on the number of members living in that country. The names of previous subscribers to the *Centralblatt* are of course known to the editors in cases where the subscriptions were taken in the

subscribers' own names, but where copies were ordered through book sellers or other agents the subscribers' names or even the countries in which they reside are not known. In order, therefore, that the editors may be enabled to know the exact number of members residing in this country and thus ascertain the number of representatives on the committee to which we are proportionally entitled, all desiring to join the Association who have not already registered as members should send their names at once to the Secretary, Dr. J. P. Lotsy, care of E. J. Brill, Leyden, Holland. Any person may join the Association, and institutions, such as colleges, libraries, etc., are eligible to membership and can, by joining the Association, receive the *Centralblatt* on the same terms as private individuals. The subscription price of the *Centralblatt* to non-members of the Association is 28 shillings.

THE United States Coast and Geodetic Survey will have on January 1, 1902, four magnetic observatories cooperating in the international magnetic work to begin on that date and to continue during the period of antarctic exploration, viz: one at Cheltenham, Md., near Washington, D. C., another at Baldwin near Lawrence, Kansas, a third at Sitka, Alaska, and a fourth near Honolulu, Hawaiian Islands.

THE Göttingen Academy of Sciences has decided to establish and maintain at its own expense, during the period of the special international magnetic work, a magnetic observatory near Apia, in the Samoan Islands. The observatory will be equipped for observations in terrestrial magnetism, atmospheric electricity, meteorology and seismology. This observatory will be nearly magnetically south of the Honolulu observatory and about the same distance south of the magnetic equator as the latter is north of it. The two observatories will likewise use practically the same instruments and methods, so that interesting and valuable contributions may be expected from them. Mr. A. Nippoldt, of the Potsdam Observatory, will be in charge of the Samoan Observatory.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. F. A. SAMPSON, of Sedalia, Mo., has presented to the University of Missouri his library

of Missouriiana, a collection which is valued at \$25,000, and Professor Litton, formerly of Washington University, St. Louis, who died recently, bequeathed to the University a valuable collection of scientific apparatus and books.

THE sum of \$1,200 has been pledged with which to purchase books for an alcove in chemistry at Cornell College, Mount Vernon, Iowa.

It is stated in the New York *Evening Post* that it has been decided by the alumnae of Wellesley College to use certain funds in hand for an oil portrait of Helen A. Shafer, professor of mathematics in the college from 1877 to 1888, and president from 1888 to 1894, and for the purchase of books, models and other permanent equipment for the department of pure mathematics; and, in addition, to establish a fund of \$2,000 to be turned over to the trustees and invested by them as the Shafer Memorial Fund, the interest to be expended for the benefit of the above department.

THE trustees of Clark University, at Worcester, Mass., have voted to establish a collegiate department in accordance with the will of the late Jonas Clark. E. Harlow Russell, principal of the State Normal School at Worcester, has been selected for president of the department, which is to come into operation in October, 1902.

MR. REGINALD GORDON, instructor in physics in Columbia University, has resigned to enter a mercantile business. His place will be taken by H. C. Parker, now a tutor in physics, and Mr. Parker's tutorship will be filled by G. B. Pegram, now an assistant.

MR. H. O. JONES, Clare College, Cambridge, has been appointed Jacksonian demonstrator in chemistry in place of the late Mr. W. T. N. Spivey.

MR. H. S. DAVIS, graduate student in zoology at Harvard University, has been appointed instructor in vertebrate zoology at the Washington Agricultural Experiment Station, Pullman, Washington.

PROFESSOR PAUL KAUFMANN has resigned the chair of pathology in the University of Missouri.

THE MEETING OF THE AMERICAN SOCIETY OF NATURALISTS IN CHICAGO DURING CONVOCATION WEEK.

For the first time in its history the American Society of Naturalists, together with various affiliated societies, will hold its annual meeting in Chicago as guests of the University of Chicago during the week beginning December 30. A cordial invitation has been extended to the several societies by the Naturalists of the Interior and there is every reason to anticipate a large and successful meeting. It is greatly to be desired that naturalists in the east shall make a special effort to attend this meeting, as it is not likely that meetings of the American Society of Naturalists will often be held at a point so distant from the coast.

The American Society of Naturalists of late years has become chiefly a nucleus around which various affiliated societies of a more or less technical character are gathered, and the functions of the parent society have been reduced, to put the matter epigrammatically, to a discussion and a dinner. Those who have watched its progress most carefully believe that this evolution has been natural and logical. The time has clearly gone by when specialists

can be expected to listen with patience or with profit to the technical discussions of other specialists. But at the same time, as all biologists, at least, must recognize, differentiation with its inherent drawbacks must be corrected by some sort of careful cooperation of dissimilars, and it would appear that here, as in the bodies of living organisms coordination, though perhaps less conspicuous than the work of the specialized parts, is even more important.

The 'discussion,' which has become one of the two important features of the work of the Naturalists, has in the past generally proved useful and interesting. The subject chosen for this year is in no wise inferior to those of earlier years, namely, 'The Relation of the American Society of Naturalists to other Scientific Societies,' and it is likely that the whole subject of convocation week, winter meetings *versus* summer meetings, the proper function of the American Association for the Advancement of Science, and similar subjects of vital importance to the organization of American science in the future, will be thoroughly threshed out.

Hardly less important than the discussion is the 'dinner,' at which all members of all the affiliated societies should have an opportunity of becoming acquainted. It is greatly to be hoped that the *ménu* this year will be made simple and short and the service prompt, in order to allow time afterwards for making acquaintances, 'talking shop,' comparing notes, and the like. By fortunate custom all ordinary after-dinner speaking has been done away with, and in its stead with the sole accom-

paniment of coffee and cigars the president's address is given. This perhaps should be accounted the third feature of importance of the meeting of the Naturalists, and it ought to be distinctly understood that the president's address should not deal with technicalities within his own specialty but with some large subject of general interest or importance, if possible, to all naturalists and men of science. We are glad to observe that the address of the President for the current year seems likely to be of this character, the topic announced being the 'Modern Subjection of Science and Education to Propaganda.'

There is a strong feeling on the part of many men of science in America that summer scientific meetings ought to be given up, or at all events subordinated to a great winter meeting. It is argued that it is too much to expect of anyone who is comfortably resting or working in the mountains or by the sea that he shall expose himself to the fatigues and depression of tropical railroading, and the sometimes blistering heat of cities, in order to read or listen to scientific papers. A wise adaptation to the environment—when we cannot modify it—is a fundamental law of life, and it is urged with much force that the rapid growth in favor of winter meetings is simply a natural and inevitable adaptation of this kind to the environment. As our readers know, a large majority of the leading American universities and colleges have, at the instance of the American Association for the Advancement of Science, decided to set aside for the meetings of scientific and learned societies the week in which the first of January

falls. The meetings at Chicago of the Council of the American Association for the Advancement of Science and of the American Society of Naturalists and affiliated societies consequently mark the establishment of convocation week. This fact alone should make the approaching meeting one of unusual importance, and we desire once more to urge upon all naturalists who can possibly do so, and especially those in the east, the duty as well as the privilege of attending the Chicago meeting.

*EXTRACTS FROM PRESIDENT ROOSEVELT'S
MESSAGE TO THE CONGRESS.*

A SECRETARY OF COMMERCE AND
INDUSTRIES.

THERE should be created a cabinet officer, to be known as secretary of commerce and industries, as provided in the bill introduced at the last session of the Congress. It should be his province to deal with commerce in its broadest sense, including among many other things whatever concerns labor and all matters affecting the great business corporations and our merchant marine. The course proposed is one phase of what should be a comprehensive and far-reaching scheme of constructive statesmanship for the purpose of broadening our markets, securing our business interests on a safe basis, and making firm our new position in the international industrial world; while scrupulously safeguarding the rights of wage-worker and capitalist, of investor and private citizen, so as to secure equity as between man and man in this republic.

THE PACIFIC CABLE.

I call your attention most earnestly to the crying need of the cable to Hawaii and the Philippines, to be continued from the Philippines to points in Asia. We should

not defer a day longer than necessary the construction of such a cable. It is demanded not merely for commercial but for political and military considerations. Either the Congress should immediately provide for the construction of a Government cable, or else an arrangement should be made by which like advantages to those accruing from a Government cable may be secured to the Government by contract with a private cable company.

THE ISTHMIAN CANAL TREATY.

No single great material work which remains to be undertaken on this continent is of such consequence to the American people as the building of a canal across the Isthmus connecting North and South America. Its importance to the nation is by no means limited merely to its material effects upon our business prosperity; and yet with a view to these effects alone it would be to the last degree important for us immediately to begin it. While its beneficial effects would perhaps be most marked upon the Pacific coast and the Gulf and south Atlantic States, it would also greatly benefit other sections. It is emphatically a work which it is for the interest of the entire country to begin and complete as soon as possible; it is one of those great works which only a great nation can undertake with prospects of success, and which, when done, are not only permanent assets in the nation's material interests, but standing monuments to its constructive ability.

THE SMITHSONIAN INSTITUTION.

The advancement of the highest interests of national science and learning and the custody of objects of art and of the valuable results of scientific expeditions conducted by the United States have been committed to the Smithsonian Institution. In furtherance of its declared purpose—for the 'increase and diffusion of knowledge

among men'—the Congress has from time to time given it other important functions. Such trusts have been executed by the institution with notable fidelity. There should be no halt in the work of the institution, in accordance with the plans which its secretary has presented, for the preservation of the vanishing races of great North American animals in the National Zoological Park. The urgent needs of the National Museum are recommended to the favorable consideration of the Congress.

THE LIBRARY OF CONGRESS.

Perhaps the most characteristic educational movement of the past fifty years is that which has created the modern public library and developed it into broad and active service. There are now over five thousand public libraries in the United States, the product of this period. In addition to accumulating material, they are also striving, by organization, by improvement in method and by cooperation, to give greater efficiency to the material they hold, to make it more widely useful, and by avoidance of unnecessary duplication in process to reduce the cost of its administration. In these efforts they naturally look for assistance to the Federal Library, which, though still the Library of Congress, and so entitled, is the one national library of the United States. Already the largest single collection of books on the Western Hemisphere, and certain to increase more rapidly than any other through purchase, exchange and the operation of the copyright law, this library has a unique opportunity to render to the libraries of this country—to American scholarship—service of the highest importance. It is housed in a building which is the largest and most magnificent yet erected for library uses. Resources are now being provided which will develop the collection properly, equip it with apparatus and ser-

vice necessary to its effective use, render its bibliographic work widely available, and enable it to become not merely a center of research, but the chief factor in great cooperative efforts for the diffusion of knowledge and the advancement of learning.

A PERMANENT CENSUS BUREAU.

For the sake of good administration, sound economy and the advancement of science, the Census Office as now constituted should be made a permanent Government bureau. This would insure better, cheaper and more satisfactory work, in the interest not only of our business, but of statistic, economic and social science.

THE DEPARTMENT OF AGRICULTURE, FORESTRY AND IRRIGATION.

The Department of Agriculture during the past fifteen years has steadily broadened its work on economic lines, and has accomplished results of real value in upbuilding domestic and foreign trade. It has gone into new fields until it is now in touch with all sections of our country and with two of the island groups that have lately come under our jurisdiction, whose people must look to agriculture as a livelihood. It is searching the world for grains, grasses, fruits and vegetables specially fitted for introduction into localities in the several states and territories where they may add materially to our resources. By scientific attention to soil survey and possible new crops, to breeding of new varieties of plants, to experimental shipments, to animal industry and applied chemistry, very practical aid has been given our farming and stock-growing interests. The products of the farm have taken an unprecedented place in our export trade during the year that has just closed.

Public opinion throughout the United States has moved steadily toward a just appreciation of the value of forests, whether

planted or of natural growth. The great part played by them in the creation and maintenance of the national wealth is now more fully realized than ever before. Wise forest protection does not mean the withdrawal of forest resources, whether of wood, water or grass, from contributing their full share to the welfare of the people, but, on the contrary, gives the assurance of larger and more certain supplies. The fundamental idea of forestry is the perpetuation of forests by use. Forest protection is not an end of itself; it is a means to increase and sustain the resources of our country and the industries which depend upon them. The preservation of our forests is an imperative business necessity. We have come to see clearly that whatever destroys the forest, except to make way for agriculture, threatens our well-being.

The practical usefulness of the national forest reserves to the mining, grazing, irrigation and other interests of the regions in which the reserves lie has led to a widespread demand by the people of the West for their protection and extension. The forest reserves will inevitably be of still greater use in the future than in the past. Additions should be made to them whenever practicable, and their usefulness should be increased by a thoroughly businesslike management. At present the protection of the forest reserves rests with the General Land Office, the mapping and description of their timber with the United State Geological Survey, and the preparation of plans for their conservative use with the Bureau of Forestry, which is also charged with the general advancement of practical forestry in the United States. These various functions should be united in the Bureau of Forestry, to which they properly belong. The present diffusion of responsibility is bad from every standpoint. It prevents that effective cooperation between the Government and the men who utilize the resources

of the reserves without which the interests of both must suffer. The scientific bureaus generally should be put under the Department of Agriculture. The President should have by law the power of transferring lands for use as forest reserves to the Department of Agriculture. He already has such power in the case of lands needed by the Departments of War and the Navy.

The wise administration of the forest reserves will be not less helpful to the interests which depend on water than to those which depend on wood and grass. The water supply itself depends upon the forest. In the arid region it is water, not land, which measures production. The western half of the United States would sustain a population greater than that of the whole country to-day if the waters that now run to waste were saved and used for irrigation. The forest and water problems are perhaps the most vital internal questions of the United States.

Certain of the forest reserves should also be made preserves for the wild forest creatures. All the reserves should be better protected from fires. Many of them need special protection because of the great injury done by live stock, above all by sheep. The increase in deer, elk and other animals in the Yellowstone Park shows what may be expected when other mountain forests are properly protected by law and properly guarded. Some of these areas have been so denuded of surface vegetation by overgrazing that the ground breeding birds, including grouse and quail, and many mammals, including deer, have been exterminated or driven away. At the same time the water-storing capacity of the surface has been decreased or destroyed, thus promoting floods in times of rain and diminishing the flow of streams between rains.

In cases where natural conditions have been restored for a few years, vegetation

has again carpeted the ground, birds and deer are coming back, and hundreds of persons, especially from the immediate neighborhood, come each summer to enjoy the privilege of camping. Some at least of the forest reserves should afford perpetual protection to the native fauna and flora, safe havens of refuge to our rapidly diminishing wild animals of the larger kinds, and free camping grounds for the ever-increasing numbers of men and women who have learned to find rest, health and recreation in the splendid forests and flower-clad meadows of our mountains. The forest reserves should be set apart forever for the use and benefit of our people as a whole, and not sacrificed to the short-sighted greed of a few.

The forests are natural reservoirs. By restraining the streams in flood and replenishing them in drought they make possible the use of waters otherwise wasted. They prevent the soil from washing, and so protect the storage reservoirs from filling up with silt. Forest conservation is therefore an essential condition of water conservation. The forests alone cannot, however, fully regulate and conserve the waters of the arid region. Great storage works are necessary to equalize the flow of streams and to save the flood waters. Their construction has been conclusively shown to be an undertaking too vast for private effort. Nor can it be best accomplished by the individual states acting alone. Far-reaching interstate problems are involved; and the resources of single states would often be inadequate. It is properly a national function, at least in some of its features. It is as right for the National Government to make the streams and rivers of the arid region useful by engineering works for water storage as to make useful the rivers and harbors of the humid region by engineering works of another kind. The storing of the floods in

reservoirs at the headwaters of our rivers is but an enlargement of our present policy of river control, under which levees are built on the lower reaches of the same streams.

The Government should construct and maintain these reservoirs, as it does other public works. Where their purpose is to regulate the flow of streams, the water should be turned freely into the channels in the dry season to take the same course under the same laws as the natural flow. The reclamation of the unsettled arid public lands presents a different problem. Here it is not enough to regulate the flow of streams. The object of the government is to dispose of the land to settlers who will build homes upon it. To accomplish this object water must be brought within their reach. The pioneer settlers on the arid public domain chose their homes along streams from which they could divert the water to reclaim their holdings. Such opportunities are practically gone. There remain, however, vast areas of public land which can be made available for homestead settlement, but only by reservoirs and main-line canals impracticable for private enterprise. These irrigation works should be built by the National Government. The lands reclaimed by them should be reserved by the Government for actual settlers, and the cost of construction should so far as possible be repaid by the land reclaimed. The distribution of the water, the division of the streams among irrigators, should be left to the settlers themselves in conformity with state laws and without interference with those laws or with vested rights. The policy of the National Government should be to aid irrigation in the several states and territories in such manner as will enable the people in the local communities to help themselves, and as will stimulate needed reforms in the state laws and regulations governing irrigation.

The reclamation and settlement of the arid lands will enrich every portion of our country, just as the settlement of the Ohio and Mississippi valleys brought prosperity to the Atlantic States. The increased demand for manufactured articles will stimulate industrial production, while wider home markets and the trade of Asia will consume the larger food supplies and effectually prevent western competition with eastern agriculture. Indeed, the products of irrigation will be consumed chiefly in upbuilding local centers of mining and other industries, which would otherwise not come into existence at all. Our people as a whole will profit, for successful home-making is but another name for the upbuilding of the nation.

The necessary foundation has already been laid for the inauguration of the policy just described. It would be unwise to begin by doing too much, for a great deal will doubtless be learned, both as to what can and what cannot be safely attempted by the early efforts, which must of necessity be partly experimental in character. At the very beginning the Government should make clear, beyond shadow of doubt, its intention to pursue this policy on lines of the broadest public interest. No reservoir or canal should ever be built to satisfy selfish personal or local interests; but only in accordance with the advice of trained experts, after long investigation has shown the locality where all the conditions combine to make the work most needed and fraught with the greatest usefulness to the community as a whole. There should be no extravagance, and the believers in the need of irrigation will most benefit their cause by seeing to it that it is free from the least taint of excessive or reckless expenditure of the public moneys.

Whatever the nation does for the extension of irrigation should harmonize with, and tend to improve, the condition of those

now living on irrigated land. We are not at the starting point of this development. Over two hundred millions of private capital has already been expended in the construction of irrigation works, and many million acres of arid land reclaimed. A high degree of enterprise and ability has been shown in the work itself; but as much cannot be said in reference to the laws relating thereto. The security and value of the homes created depend largely on the stability of titles to water; but the majority of these rest on the uncertain foundation of court decisions rendered in ordinary suits at law. With a few creditable exceptions, the arid states have failed to provide for the certain and just division of streams in times of scarcity. Lax and uncertain laws have made it possible to establish rights to water in excess of actual uses or necessities, and many streams have already passed into private ownership, or a control equivalent to ownership.

Whoever controls a stream practically controls the land it renders productive, and the doctrine of private ownership of water apart from land cannot prevail without causing enduring wrong. The recognition of such ownership, which has been permitted to grow up in the arid regions, should give way to a more enlightened and larger recognition of the rights of the public in the control and disposal of the public water supplies. Laws founded upon conditions obtaining in humid regions, where water is too abundant to justify hoarding it, have no proper application in a dry country. In the arid states the only right to water which should be recognized is that of use. In irrigation this right should attach to the land reclaimed and be inseparable therefrom. Granting perpetual water rights to others than users, without compensation to the public, is open to all the objections which apply to giving away perpetual franchises to the public

utilities of cities. A few of the Western states have already recognized this, and have incorporated in their constitution the doctrine of perpetual state ownership of water.

The benefits which have followed the unaided development of the past justify the nation's aid and cooperation in the more difficult and important work yet to be accomplished. Laws so vitally affecting homes as those which control the water supply will only be effective when they have the sanction of the irrigators; reforms can only be final and satisfactory when they come through the enlightenment of the people most concerned. The larger development which national aid insures should, however, awaken in every arid state the determination to make its irrigation system equal in justice and effectiveness that of any country in the civilized world. Nothing could be more unwise than for isolated communities to continue to learn everything experimentally, instead of profiting by what is already known elsewhere. We are dealing with a new and momentous question, in the pregnant years while institutions are forming, and what we do will affect not only the present, but future generations.

Our aim should be not simply to reclaim the largest area of land and provide homes for the largest number of people, but to create for this new industry the best possible social and industrial conditions; and this requires that we not only understand the existing situation, but avail ourselves of the best experience of the time in the solution of its problems. A careful study should be made, both by the nation and the States, of the irrigation laws and conditions here and abroad. Ultimately it will probably be necessary for the nation to cooperate with the several arid states in proportion as these states by their legislation and administration show themselves fit to receive it.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

SECTION I, SOCIAL AND ECONOMIC SCIENCE.

OFFICERS for the Denver meeting were: *Vice-President*, John Hyde; *Secretary*, Raymond A. Pearson; *Member of Council*, E. T. Peters; *Sectional Committee*, C. M. Woodward, H. T. Newcomb, John Hyde, R. A. Pearson, Marcus Benjamin, F. R. Rutter and L. F. Schmeckebier; *Member of the General Committee*, F. H. Hitchcock.

Nine meetings were held and at each a full program was presented. Unusual interest in some papers was shown by the discussions. The average attendance was probably the largest in the history of the Section. The majority of papers treated of subjects which are of special interest in the West—one entire day, including an evening session, being given to the consideration of the economic and social aspects of irrigation.

The vice-presidential address of Professor C. M. Woodward, 'The Change of Front in Education,' was published in full in a recent number of SCIENCE. Other papers were as follows:

'Scientific Men of Colorado': DR. MARCUS BENJAMIN, Washington, D. C.

This paper had for its purpose the presentation to the Section of the records of various scientific men of Colorado, and consisted chiefly of summaries of the excellent work done by the graduates of the Scientific Department of Columbia University, formerly known as the School of Mines, towards the development of the mineral resources of Colorado, as well as of the improved methods in metallurgical science invented by them. The sketches were some twenty in number and included the careers of such men as M. W. Iles, M. C. Ihlseny, W. B. Devereux, H. V. Furman and Richard Pearce. Brief mention was also made of such scientists as the late Senator N. P. Hill, who was referred to as the only chemist ever elected to the United States

Senate ; Regis Chauvenet (a son of W. M. Chauvenet, who was president of the Association in 1870), president of the Colorado School of Mines, and others who have taken a conspicuous part in the development of scientific thought in Colorado. The paper closed with a brief appeal for the preservation in a suitable building of the remains of the former inhabitants of Colorado and the Southwest.

'Dangers from Inaccuracy in Presentation of Transportation Problems': JAMES H. BLODGETT, A.M. Division of Statistics, Department of Agriculture, Washington, D. C.

Projects for transportation of water, both for personal use and for irrigation of crops, are necessary on a scale requiring municipal or corporate association of effort. In transportation of food and other commodities the railroad and the steamship form the present culmination of carriers. Water-works for cities, or for agriculture, canal and ship enterprises call for government aid. Railroads once largely aided by public appropriations depend mainly on sales of bonds and stocks to investors. In some propositions to the public, error is combined with truth to a dangerous extent. Two groups of erroneous statements are now particularly prominent, even in school books, in regard to interior waterways: One relates to a presumed project for a ship canal between the Black and the Baltic seas, officially disclaimed by Russia; another as to interior waterways between Boston and Galveston, really no more than three feet deep in the shallowest part, and between the mouths of the St. Lawrence and the Mississippi, no more than six feet deep for long distances, with short narrow locks. The Chicago Drainage Canal has as yet no commercial relations. The limit of urban population is liable to be determined by the water supply. The extent of cultivation upon Western plains is already limited by

the availability of water. It is a question whether taxation does not tend to increase faster than average incomes or than market values of property. Municipal repudiation ought to be unknown. Many municipalities have reached the legal limits of taxation and of indebtedness, but under popular demand constitutions have been amended and new municipal organizations have been superimposed to place additional taxes on the property. In Illinois, for example, most of the following series of taxes may represent separate authorities levying independently.

(a) National, (b) state, (c) county, (d) township, (e) school district, (f) city, incorporated town, village, in addition to school tax, (g) township high-school district, (h) drainage district, (i) sanitary district, (k) townships or road districts, for hard roads.

Most of these separate agencies can incur debt not to exceed five per cent. of the valuation, making possible a very large aggregate obligation resting upon the taxable property. Township high-schools, drainage districts, sanitary districts, hard-road districts, are not numerous, but they are possible in any part of the State under general laws.

'The Census of Cuba': VICTOR H. OLMSTED, Assistant Director of the Census of Cuba.

The prospective establishment of an independent government in Cuba made information necessary concerning the numbers and distribution, the education, the racial divisions, etc., of its population. The American authorities, after deliberate consultation with eminent Cubans, decided upon a census of the island. The knowledge already had of the temperament of the people, and of the probable obstacles to speedy work, indicated that conditions in Cuba were unfavorable to census-taking on a scale so comprehensive as that of the United

States; hence only the more important data concerning population, education and agriculture were collected. The work was intrusted chiefly to Cubans. The prevailing idea was that the census was to be of Cubans, by Cubans and for Cubans, and that its successful accomplishment would indicate their capacity for the subsequent establishment and maintenance of civil government. This decision was enthusiastically received by Cuban press and public. President McKinley's proclamation, August 17, 1899, declaring the census a preliminary step towards the establishment of self-government, completed the obliteration of all suspicion of American motives theretofore prevalent throughout the island. The Assistant Director, who was placed in full charge of the census, reached Havana August 20, 1899, established a temporary office, and began dividing the island into districts, a task difficult and arduous, owing to a lack of accurate geographical data. By September 15 the island had been divided into 1,315 enumeration districts—afterwards increased to 1,607. Large numbers of educated Cubans, then out of employment, furnished an excellent field from which to select enumerators.

In cases of doubtful literacy, persons were required to read and write in the presence of the enumerator, and, as to illiteracy statistics, the Cuban census is probably the most accurate on record. The enumeration was fully completed by the time required, November 30, 1899. Delay in a few remote districts alone prevented a much earlier completion. The complete results are published in Spanish and English separately. The volume of 800 pages contains information not elsewhere obtainable concerning Cuba and the Cubans.

'Mechanical Tabulation of the Statistics of Agriculture in the Twelfth Census of the United States': H. T. NEWCOMB, Editor *Railway World*, formerly Expert Chief of the

Division of Agriculture in the Office of the Twelfth Census.

The public demanded of the twelfth census a more extended, elaborate and detailed investigation of American agriculture than had been undertaken by any of its predecessors. Previous censuses had collected the basic facts necessary to answer the inquiries of the public, but had never been able to undertake the complicated and extensive tabulation necessary fully to develop the information that they might have been made to supply. An investigation and tests prescribed by law finally led to the adoption of the Hollerith electrical tabulating machinery. This is controlled by cards to which the facts from the schedules returned by the enumerators are transcribed by means of perforations. Two kinds of cards were used: one providing for a description of single farms, and the other for the acreage, production and value of each of the separate crops raised on each farm. The facts indicated on these cards are all stated quantitatively and the perforations were made by machines somewhat similar in their manner of operation to a typewriter. About 115,000,000 crop cards and nearly 6,000,000 farm cards were necessary, and the former were punched at the rate of about 2,000, the latter at the rate of about 1,000, per day's work. These cards were fed into the tabulating machines, which consisted each of from three to ten connected adding machines impelled by electrical currents transmitted through the perforations. Several counting devices impelled in the same way were also added to the machines for different phases of the work; at one time as many as nineteen. In running cards through the machines an average of over 10,000 per day has been attained in the later months. The Division of Agriculture employs twelve of these tabulating machines for the farm cards and eighty-six for the crop cards.

The great advantage of the Hollerith tabulating machinery, aside from its precision, lies in the possibility of making a single transcription of data and but one handling of schedules serves for the most complicated tabulations and for those in which the same facts are classified and aggregated according to many different and conflicting elements. It also has the merit of simplifying the work of a large office and reducing the greater portion of it to the grade of factory work.

'The Single Tax': HON. JAMES CROSBY, Denver.

To the thoughtful mind the political outlook at the opening of the new century is profoundly interesting. The nineteenth century was a wonderful century, but in one sphere of human development it was a disappointment. With all our boasted progress, we have not made better citizens or a more contented people. Industrial slavery must be abolished before the social organism can be restored to health, and the single-tax philosophy contains the proper remedy. Single-taxers maintain that the reason the wages of labor do not increase as material progress advances is because rent, or the price paid for the use of land, is continually increasing. The land upon which Chicago now stands was not worth an old shoe one hundred years ago. To-day millions could not buy it. The land upon which Denver is built was valueless fifty years ago. To-day it is worth millions, and as the city grows, wages will not increase, but we all know that the value of land will. By collecting this ever-increasing rent and using it for the benefit of all the people we abolish land monopoly and solve the problem of the persistence of poverty amid an advancing civilization. This single tax is not a tax upon land, but upon land values, an entirely different matter. We are frequently told that the single tax would bear with great severity

upon the poor farmer. This criticism would be just if we proposed to tax land, but it is not true if land values are taxed. For while most of the land is in the country, most of the land values are in the city. Under the single tax system the farmer would pay very little tax. Land values are easily collected. Land cannot run away, nor can it be hid when the assessor appears. Everywhere, in all times, monopoly of the land upon which all must live and from which all wealth is produced, is the basis of social and political disorders. The single-tax system, if adopted, will destroy industrial slavery and will usher in a period of peace and prosperity for all.

'The Road Problem': JAMES W. ABBOTT, Special Agent U. S. Office of Public Road Inquiries for the Mountain Division, Denver.

The renaissance of road building began during the first half of the eighteenth century. Metcalf in England, and, contemporary with him, Tresaguet in France, were the pioneers in this movement, and were followed later by Telford and Macadam, whose methods, with slight modifications, are still used. It is a singular coincidence that correct road-building practices were evolved just before the beginning of the railway era. In the United States the first attempt at better roads was made by toll-road companies; later came the National 'Cumberland Road,' which was the beginning of an excellent system of government military roads constructed at public expense. While in Europe the railway and highway systems expanded together, in the United States the railway displaced the highway in public attention; and, with the beginning of the railway era, national appropriations for road building were discontinued. Then followed a very remarkable period of conquest of the wilderness, during which the highway question received almost no attention. The

period of awakening on this important subject began a few years ago, and probably received its first strong impulse from the League of American Wheelmen. Many states have appropriated money to aid in building state highways: New Jersey, New York, Rhode Island, Vermont, Maryland, California and many other states now have highway commissions. Wherever state funds are appropriated, the laws require the counties to share in the expense. The most striking feature of the reports of the highway commissioners is the demand for state highways, notwithstanding the requirement for contribution by the counties. The controlling reason for this demand appears to be the fact, now universally recognized, that the building of these improved State highways has vastly enhanced the values of contiguous and neighboring property. The United States Department of Agriculture, through its office of Public Road Inquiries, took up this matter a few years ago, and has been engaged in disseminating among the people information upon road conditions in Europe and America and in teaching improved methods.

'Farm Ownership and Tenancy in Delaware. A Study of Farm Tenancy': LE GRAND POWERS, Chief Statistician for Agriculture, U. S. Census.

The growth of farm tenancy, which has been noted in many States of our nation during the last thirty years, is a part of a social movement profoundly affecting the status of many families in the United States. It was the appreciation of this fact that led the government, by the tenth and subsequent censuses, to collect statistics relating to the subject. According to the twelfth census of the United States, there were in the state of Delaware, June 1, 1900, 9,687 farms. The number has steadily increased since 1850. In that year there were 6,063; in 1860, 6,568; in 1870, 7,615; in 1880, 8,749; in 1890, 9,381.

Of the farms of 1900, 4,876, or 50.4 per cent., were operated by tenants; 4,680, or 48.3 per cent., by individuals who owned the whole or a part of the land they tilled; and 131, or 1.3 per cent., were cultivated for their owners by salaried managers or overseers. A large number of the last-mentioned class were farms connected with public institutions, or the property of corporations, and most of the others were holdings of wealthy individuals and were operated as much for the pleasure as for the profit of the owners. During the last twenty years there has been a steady decrease in the number of farms operated by their owners, accompanied by a more marked increase of those operated by tenants. This actual and relative increase in the number of farm tenants has taken place under circumstances which have operated to assist a large number of families in rising from wage service to farm tenancy or ownership. None of the facts presented indicate the existence of a movement in Delaware toward the concentration of the ownership of farm property or its transfer to the hands of a fixed class of non-resident landlords. They lead to the conclusion that the titles to rented farms in Delaware are vested in a large number of persons, the majority of whom have, at some time in their lives, operated the farms now owned by them. This conclusion is warranted by the results of the investigation of the twelfth census concerning the ownership of rented farms. The ownership of rented farms is held under conditions that insure to capable and industrious wage-earners or tenants greater opportunities of becoming farm owners than ever existed in this country before 1850, or than is presented at this time in any other nation on the globe.

'What Next? Is it Socialism?' WALTER S. LOGAN, New York.

The present is industrial chaos. Where organization comes out of the chaos it is

warfare. On the one side are the employers of labor, on the other side the laborers; on the one side the people who receive dividends, on the other the people who receive wages. What is being fought over is the proceeds of labor. We have built up our economic civilization on the principle that the relation between one man and another should be dependent upon voluntary agreement between them. But now it has come to be a relation not between man and man, but a relation between class and class. The community founds itself upon the relationship. More men are now employed by single corporations than were working for wages in the whole United States a hundred years ago. Such is the present situation. It is admitted on all sides that it is intolerable. Socialism is defined to be the ownership and operation by the State of all cooperative industries within its jurisdiction—the industrial condition wherein the State is the only employer of labor and the only wage payer.

The advocates of socialism in picturing its blessings, assume that it is practicable—an assumption that has not been subjected to the test of trial. But great modern combinations have come upon the scene—so great and so extended that they approach in the complexity of their activities and the magnitude of their undertakings the functions of government itself. A paid servant only is watching other paid servants, and the eye of the master is almost as remote from the hand of the servant as it would be if the state itself were master. The success of the modern industrial combinations would seem to indicate that the state might succeed pretty well in operating its own industries. If socialism as a practical proposition is thinkable to-day, it is because these combinations have made it so. For good or for evil, they will leave us as a legacy the assurance that industrial operations approaching in extent the

operations of government itself can be successfully inaugurated and profitably carried on. As to the ultimate result, I have no opinion whatever to express. As to the immediate result, however, I have a very decided opinion. I believe we shall have, in the immediate future, not state socialism, but a more socialistic state. I agree that socialism must come if it is the only way to secure industrial peace and protect the masses of the people, but it is far from having been demonstrated yet that it is the only way to do this. I am not prepared to say that we have found another and better way, but I have confidence enough in our race's destiny to believe that we shall.

'Economic Work of the United States Geological Survey': L. F. SCHMECKEBIER, PH.D., United States Geological Survey, Washington, D. C.

The economic work of the United States Geological Survey consists of work in economic and mining geology, investigations relating to water supply and irrigation, the survey of forest reserves, the preparation of a topographical map of the United States, and the gathering of statistics relating to the mineral production of the country. In the field of mining geology the Survey works upon the general principle that it should endeavor to accomplish for the mining industry as a whole what the individual engineer or mine owner could not succeed in doing by his unaided exertions; in short the Survey undertakes to furnish the prospector and mining engineer with an accurate basis upon which their work may be founded. The hydrographic work falls into three general classes: (1) Work of a strictly engineering character, having to do with the measurement of surface streams and the conservation of water supply through the storage of flood water; (2) examination of the underground structure and the permeability of the water-bearing rocks; and (3) general reconnaissances for the pur-

pose of obtaining information as to the method of utilizing water supply for power, irrigation and domestic purposes. In the survey of the forest reserves every factor bearing upon the character and growth of the forest has been studied. The following points have been especially emphasized: The character of the soil; the forest litter; the depth of humus; the character and density of the underbrush and young growth; the range in size of trees of the principal species; the total height, clear trunk and apparent age and soundness; the effect of fires on reproduction; the proportion of dead standing timber; the character of the cutting; the means of transportation; the local demand for lumber; the effect of sheep pasturage; the use of water for irrigation and milling; and the extent and distribution of land more valuable for agriculture than for timber. The Survey is engaged in the preparation of a topographic map of the United States, which in addition to being a necessity for all other investigations undertaken in the field, has in itself a great economic value in all works of an engineering character. The statistics of mineral productions are compiled direct from reports made by the producers themselves.

'The Soil as a Social and Economic Factor': FRANK K. CAMERON, Ph.D. Soil Chemist, U. S. Department of Agriculture, Washington, D. C.

This paper was a presentation in general terms of the work which has been done and is being done upon soils from the point of view of the natural scientist. An outline of the work of the Bureau of Soils in the U. S. Department of Agriculture is given. The point is then made that such work can never, in itself alone, lead to the best development and management of soils, for it is in fact an economic problem, and the work of the physical scientist can only serve as a basis or point of departure

from which the economist may attack the problem. The causal relations between the character of the soil and the population it supports are brought out and the importance of the soil as a factor in the social and economic status of the community is insisted upon. A plea is made for more attention to the subject from experts in these lines.

'Woman's Suffrage in Colorado': J. E. LE ROSSIGNOL, Professor of Economics, University of Denver.

After the enactment of the Woman's Suffrage Law, in the year 1893, many women devoted themselves with enthusiasm to the theory and practice of politics, especially in the agitations concerning populism and free silver. Afterwards a number of leading women broke away from the regular political factions and formed organizations such as the Civic Federation, which took an active part in the municipal election of 1895, and in 1897 they secured the election of an independent ticket. Since then there has been a tendency for women to return to the regular party organizations. It is difficult to give an estimate of the value of woman's suffrage to Colorado, because of diversity of opinion on the subject, and because it is as yet impossible to prove either the success or the failure of the system from the point of view of social expediency. The woman vote is large. Women have not been injured by the franchise. The character of the leading women politicians is high. Women are not, as a rule, clamorous for office. Since 1894, ten women have sat as representatives in the Legislative Assembly, and three women have successively occupied the position of State Superintendent of Education. Women have also served acceptably as members of the various state boards. Women have exerted a civilizing influence upon the character of political meetings, and they have at times exerted an influence toward secur-

ing the nomination of respectable candidates. Some reforms have been accomplished, wholly or in part, through the influence of women. A considerable proportion of women voters are as yet somewhat independent of party control, forming an unknown quantity which disturbs the calculations of party managers, and whether called independence or fickleness, may be regarded as counting against rather than for political trickery and corruption. People who expected that society would be immediately regenerated through the influence of woman's suffrage have been grievously disappointed, and many of them, both men and women, consider the experiment a total failure. Such people have expected too much and are too impatient. No remarkable reforms have been accomplished, but it is safe to say that woman suffrage has done no harm, that it has done some good, and that it has been adopted by Colorado 'for better or for worse.'

'The World's Bread Supply': EDWARD T. PETERS, Division of Statistics, U. S. Department of Agriculture.

In his annual address as president of the British Association for the Advancement of Science, delivered at the Bristol meeting of that body in 1898, Sir William Crookes sounded an alarm as to the future of the world's wheat supply. He pointed out that the bread-eating populations, consisting of the people of Europe and of European settlers and their descendants in various parts of the world, are increasing in a geometrical ratio, and from the figures he presented, he reached the startling conclusion that, by 1931, the number of bread-eaters will have become so great as to require the produce of all the land in the world available for wheat-growing, unless there shall, in the meantime, have been an increase in the average production per acre, which, at the time of his address, he estimated for the world at large at 12.7 bushels per acre.

The conclusions reached by Sir William, as to the future wheat-exporting capabilities of the United States, have seemed to some writers to fall so far short of the truth as to make his conclusion in regard to the world at large seem unworthy of serious attention; but an article by Mr. John Hyde, statistician of the Department of Agriculture, published some time ago in the *North American Review*, if it does not entirely support Sir William's view, yet shows by an overwhelming array of well-considered facts and figures that the optimistic expectations of some of Sir William's critics are wildly extravagant. In considering the average capacity of the earth to support civilized populations, it is to be remembered that, with the rise in the general standard of living which was a conspicuous feature of nineteenth-century progress, bread became a smaller and smaller proportion of the total consumption of the people. Wants have greatly multiplied; and as these wants require the produce of land for their satisfaction, the average area required for the support of an individual is now much greater than it was one hundred years ago. Moreover, if the standard of living is to rise still higher, that average area must, in the absence of increased yields per acre, become greater still, and a still smaller proportion of it will be devoted to the production of bread. 'Man shall not live by bread alone' is receiving, with the advance of civilization, a more and more liberal interpretation, and this fact has a vital bearing on the capacity of the earth for supporting population. Population cannot increase beyond a certain point without arresting the improvement in the standard of living and starting a movement in the opposite direction, unless a means can be found of obtaining from the soil increasing yields. The point at which such increasing yields will become the only alternative to starvation may not be quite so near as Sir William

Crookes believes; but it is near enough to impress us with the vital importance of using to the utmost every agency by which skilled and scientific agriculture may be substituted for the loose and wasteful systems of the past, and also to emphasize the necessity of protecting the world's forests, conserving its waters and employing every other means by which the area of land available for productive purposes can be increased. Doubtless there is a limit to the number of human beings that the earth is capable of supporting in comfort, but science, skill and foresight may place that limit in a sufficiently distant future to remove all occasion for anxiety on the part of the earth's present inhabitants or their immediate posterity.

'The Interdependence of the Sciences': DR. MAX WEST, U. S. Industrial Commission, Washington.

This paper will be published in SCIENCE.

'The Present Status of Commerce in the Educational Policy and in the Administrative Organization of Modern Nations': JOHN FRANKLIN CROWELL, PH.D., Bureau of Statistics, U. S. Treasury Department.

This paper presented the results of an analysis of the courses of study of representative institutions, both in this country and abroad, in which higher commercial instruction has been given. In some respects our own schools are modeled after the institutions of continental Europe, but to a much greater extent they are the outgrowth of two tendencies in our national life—the expansion of our universities and the increasing influence of business men in public policy. A comparison of several of the more important higher schools of commerce in Europe and at home shows that there are five double groups of subjects regarded as essential to a comprehensive commercial curriculum of higher grade. These are: (1) Geography and history, (2) lan-

guages and methods, (3) science and technology, (4) economics and statistics, and (5) law and sociology. The preponderating influence of one or another of these groups is determined by the general character of the college. In some institutions the type of training offered is professedly technical, in others it is practically a commercial substitute for a liberal education. The liberal and the professional purposes are probably least dissociated in the curriculum of the Wharton School of Finance and Economy at the University of Pennsylvania, the oldest of the higher schools of commerce in this country.

The practice has prevailed of organizing a commercial curriculum of four years out of subjects hitherto taught in other departments. However necessary this may have been to meet a growing demand for special instruction of a higher commercial character, it has made the fundamental educational mistake of failing sufficiently to differentiate the field of commercial phenomena from that of industry on the one hand and finance on the other. There is accordingly much confusion, that must retard greatly the rate at which the field of commercial knowledge shall be reduced to scientific consistency. It is to the solution of the distinct problems of commerce that education must devote itself if it means to organize commercial experience for the aid of individual enterprise and of national prosperity. The scientific classification of commercial phenomena is preliminary to the solution of these inherent problems.

A truly scientific course in the study of commerce must fill four conditions:

1. The classification of the facts and methods of modern commerce.
2. The formulation and solution of commercial problems.
3. The grounding of the student in economic principles and in their ready application to commercial situations.

4. The mastery of knowledge relating to the history and development of commercial policy as embodied in the economic progress of modern nations.

This is the least that scientific thought can ask of higher commercial education.

'The Development of the Mineral Resources of Colorado': CHARLES W. COMSTOCK, Professor of Mining Engineering in the Colorado School of Mines.

The paper began with a few figures showing Colorado's position in the mineral-producing world, especially with regard to gold, silver and lead. The relative change in importance of silver and gold in the state's wealth was brought out. The figures showed that 49 per cent. of its production had been silver and 35 per cent. gold. The statistics of 1900 show 25 per cent. silver and 57 per cent. gold. The all-important point in the history of gold and silver production is the increased economy in the mining and the treatment of ores. This is indicated by the lower grade of the ore mined now as compared with earlier years. Even in Cripple Creek, the newest of the producing district, it is striking. The causes leading to these reductions are cheaper labor, cheaper fuel, lower freight rates, cleaner work and close attention to details. One of the potent factors in developing low-grade ores has been the improvement in ore-dressing machinery and methods, together with a more general dissemination of information with regard to this very important subject. The figures from one instance of actual practice show that proper mechanical preparation makes a change from a loss of \$5 per ton to a profit of \$2. The paper closed with a brief reference to the zinc problem which has been an absorbing one in Colorado for more than fifteen years.

'Protection of Communities by the Forest': GIFFORD PINCHOT, Forester, U. S. Department of Agriculture.

The relation of the forest to the community penetrates every portion of communal life on the material side. To follow it in detail would be to describe the modern community with a minuteness which has perhaps had little approach. For the general theme it is sufficient to say that the communal life of modern civilization as we know it would be impossible without the forest.

Forests protect communities especially by safeguarding the drainage systems on which they depend either for navigation or water supply, by fixing the drifting sands which have already overwhelmed so many towns and villages, by securing the prosperity of the tributary territory upon which the communal prosperity itself must hang, and finally, by providing the recreation grounds without which much of communal life must be flat, stale and unprofitable. The town or city forest is an institution of the highest beneficence which has yet only begun to appear in America. Examples are not uncommon abroad of towns free, either partly or wholly, from communal taxes by the revenues of their forests; and this is perhaps the least of the services which they render. Cheap and abundant supplies of wood come to the citizens from their forest lands, but best of all, the forest serves as a playground and breathing space whose influence penetrates to every portion of the community. Public spirit could take few directions more useful to the citizens, towns and villages of this country than to provide them with self-supporting recreation grounds of the forest type, for there is a quality of renewal inherent in play time in the forest which follows no other kind of rest from work.

'Leasing and Disposal of the Public Lands': C. E. WANTLAND, Denver.

The United States owns about half a billion acres, the net cost to date of the remaining lands being probably about \$250,000,-

000. To maintain the Land Department, an expenditure of about \$2,000,000 per annum is necessary. In the western states there are about 500,000,000 acres, about 400,000,000 million of which are used for grazing purposes by 25,000,000 cattle and sheep under conditions gradually growing worse. If leased, the revenue in ten years, in connection with the net receipts from sale of public lands, would double irrigated lands in the West now estimated at 10,000,000 acres. In the eleven western states we have only 250,000 farms, and 50 per cent. of the people live in towns and cities, while about 75,000,000 acres of public lands can still be reclaimed if the water which now runs to waste can be stored. Congress has failed to realize the great importance of the subject and very little constructive legislation has been secured. Forest reservations, the Carey Grant Act and the recent Free Homes Bill were secured after great difficulties. Public lands should be leased for short terms in limited quantities and at low rates. Owing to different conditions in the different states, leases should be issued on a county local-option basis, after careful classification of lands by commissioners and approval by stockmen. Funds should be used for reducing county taxes, for surveys and reservoir construction. The majority of stockmen are now in favor of a good lease plan, fair to all concerned. The Homestead law should be amended to enable settlers by a combination homestead and lease privilege to control enough land to make a living on, and the Government should advertise the facts about public lands for the benefit of people who want new homes. The Desert Land Law should be repealed. Forest protection and the reclamation of the arid lands will bring great prosperity to the country. The landless man of the east must be placed upon the manless land of the west.

'Irrigation': F. H. NEWELL, Hydrographer, U. S. Geological Survey.

The western half of the United States consists for the greater part of vacant land belonging to the nation and at the disposal of Congress. With this enormous area, aggregating fully one-third of the United States, it would be supposed that settlement would progress rapidly and population increase with stupendous strides. As a matter of fact, however, the past decade has not been marked by notable developments, but, on the contrary, it appears that the settled area has to a small extent actually diminished. As a rule the soil and climate are suitable for the production of large crops, were it not for the scarcity of moisture. The pioneers and their successors have taken out almost innumerable ditches and have diverted the smaller streams, demonstrating the practicability and profitable character of agriculture by the artificial application of water. In all, about ten million acres of land have been brought under cultivation by means of works built largely by farmers acting in partnership or in associations. Irrigation development when brought about in this manner has been extremely profitable. But, contrary to the experience of the farmers, large irrigation enterprises have almost invariably been financial failures. This anomalous condition, where enterprises succeed in a small way but fail financially on a large scale, merits careful consideration. There are upwards of seventy million, or even a hundred million, acres of arable land which might be reclaimed and made into homes by utilizing the waters of the large rivers or of the floods which now run to waste. The reason for the failure of the large enterprises lies for the most part in the difficulty of securing immediate settlement and of obtaining experienced farmers who can practice irrigation with success from the outset.

One of the great questions now before the people of the country is how to dispose of the crowded and surplus population around the great manufacturing centers and to render the idle laborers producers of wealth instead of helpless consumers. The public lands in the past have proved the great outlet for superfluous labor, especially at the periodical occurrence of hard times. Vast areas of fertile public lands still remain, but these cannot be utilized until the problem of supplementing the deficient water supply can be solved. This problem of water supply for the arid lands is one which must be taken up by the publicist and statesman. The engineering features are comparatively simple, but the great question to be solved is as to who is to pay for the original outlay. The public at large is undoubtedly the gainer, since by the creation of prosperous homes upon the public domain the commonwealth is strengthened, and commerce and manufacture increased. A similar question with regard to the building of light-houses and the improvement of harbors has been answered by the national government taking charge of the matter, and it is urged by many who have studied the matter thoroughly that Congress, the custodian of the public lands, must take cognizance of present conditions and not only modify the land laws to suit the conditions of the arid West, but also provide means by which large rivers may be made available and floods held so that the farmers by their own work may be able to utilize the waters, as has been done by their predecessors.

'The Scope of National Aid for Irrigation': FRED BOND, State Irrigation Engineer, Cheyenne, Wyo.

Irrigation laws are a necessary part of the statutes of every state any portion of which lies west of the 100th meridian, and they form a part of the statutes of those states. These laws are enacted for the

purpose of governing the diversion and appropriation of water and its use, and state codes and state statutes alone define water rights and provide for their determination and administration. The general government has never undertaken to exercise any authority over water used in irrigation, but has left the control of the water in the arid region entirely to the states wherein found. Whatever might have been originally undertaken with advantage by the nation does not change present conditions, and it is now too late, even were such action desirable, to undertake the enactment of laws which will come into conflict with the long-conceded rights of the states to regulate and control these matters; nor can the government determine future rights or undertake their administration without creating a conflict between those state and national authorities which have the diversion of water directly in charge. The funds for irrigation development must come from some national resource, for the states are financially unable to raise them, and no matter how willing many of them might be, they are precluded from the undertaking because the limits of taxation permitted by their respective constitutions has been reached in providing means to meet ordinary state expenses. They are, however, not only ready and willing, but entirely capable of prosecuting the work to a successful conclusion, the means being found. The funds should come from such a source as would bring about the least possible interference with present conditions, and the appropriation or setting apart of the receipts from the sale of arid lands seems most completely to fill these requirements. The volume of work undertaken in any state each year may be limited by the receipts from the sale of public lands in such state for the year previous, a plan commendable in that interests not benefited are not required to render any assistance in the work. The amount ob-

tained in this manner from any one state would not be large, but would enable a beginning to be made and at the same time give the state an opportunity to demonstrate its fitness to continue in the work of its own development under these conditions.

A part of the discussion which followed this paper is given :

F. H. Newell: The proposition presented by Mr. Bond is one which has been fully discussed by committees in Congress. The general conception is not new, but the point which he emphasizes, of the importance of state control of national funds in irrigation development, is one which, it is feared, will prove a stumbling-block to progress. Relatively few of the states would be benefited if the proceeds from the disposal of public lands in each state were devoted exclusively to works in that state. This narrowing of development is undoubtedly the outgrowth of an attempt made to cede the vacant public lands to the states to be disposed of by the legislatures. This has been shown to be contrary to the whole spirit of national administration of the public lands; these lands being held, not for the benefit of the states in which they are located, but for the making of homes by citizens. There is no apparent ground for the fear of conflict between national and state authority. There can be no question as to the importance of national development of vacant public lands, which still include nearly one-third of the United States. It is practicable for the government to erect storage reservoirs, and to divert large rivers to a point where settlers can take out the water and make for themselves homes as was done by the pioneers. The further limitation, however, which Mr. Bond seems to insist upon, that this work should be done by state officials, is one which is so opposed to all experience and precedents that it would doubtless weaken the movement in the minds of those who have studied the subject.

George H. Maxwell, Chairman of the Executive Committee of the National Irrigation Association, expressed the opinion that the paper by Mr. Bond tended to create an entirely wrong impression as to the relation of the national Government to irrigation development. No one, he said, contends or proposes that the national Government should undertake in any way to regulate the distribution of water in conflict with the laws of the state. It is proposed that the Government shall do two things: First, enlarge its policy of internal improvements to include water storage through appropriations under the river and harbor bill, the water so stored to be turned into the stream in the dry season and distributed under the state laws just as though nature had put it there. Second, build such reservoirs and irrigation works as may be necessary to bring water within reach of settlers on the public lands, reserving lands for which water is thus made available for actual settlers only, and charging the lands in proportion to benefits with the actual cost of the Government works. In carrying out this latter policy the Government occupies the relation to the states of a land owner, and will proceed just as any other land owner would do to accomplish the reclamation and settlement of his land. It is conceded in Mr. Bond's article that the national resources must provide the funds for this irrigation development. This being so, the national Government will administer their disbursement. It has steadily refused to cede the public lands to the states, because experience has shown that such a policy would result in the lands being improvidently administered or absorbed in large holdings by speculators. The same result would follow if the control of their reclamation were turned over to the states. The national Government will never appropriate money from any source for state engineers to spend to reclaim the public

domain. The sole ultimate object of the national irrigation policy is to make homes on the public domain, and when this has been done the national purpose has been accomplished. Until the home-builder is actually there, the national Government will never abdicate its functions or transfer to state politicians the administration of this great national trust.

'The Grand Canyon of the Gunnison.' Illustrated evening lecture by A. L. FELLOWS, Resident Hydrographer of U. S. Geological Survey, Denver.

Below the Black Canyon of the Gunnison, which is traversed by the D. & R. G. Railway in Western Colorado there remains still a portion of the Gunnison canyon which has been practically unknown, and a portion at least of which has never been explored until it was investigated by Mr. A. L. Fellows, resident hydrographer of the U. S. Geological Survey, and by one companion, Mr. Will Torrence, of Montrose, Colorado, in the month of August, 1901. This portion of the Gunnison Canyon is known in Hayden's survey as the Grand Canyon of the Gunnison, and although a number of efforts had been made to penetrate its secrets, these efforts have been without avail until the present attempt. This is the more extraordinary as there is no portion of Colorado that can compare with it in scenic grandeur, and the problems in geology that are presented are also of intense interest. The absolutely unexplored portion is of but a few miles in length, but there are some thirty-five miles of which very little is known. This is that portion of the canyon between the mouth of the Cimarron River at Cimarron and the mouth of Uncompahgre at Delta. The plateau which is cut by the Grand Canyon of the Gunnison is known as the Vernal Mesa, and appears to have been caused by an uplifting of the overlying strata by geological forces beneath. The sandstones

of the surrounding region were uplifted several thousand feet above the adjacent territory, but these sandstones have been eroded from the region traversed by the canyon, and the canyon itself is eroded into the metamorphic granite and through crystalline rocks to a depth at present amounting to about 2,000 feet on the average below the surrounding territory. The walls are in many cases very nearly vertical, and at times are strangely marked by gigantic veins of quartz. The flora and fauna of the canyon do not differ materially from those of other Colorado canyons, the stream being lined by spruce and cottonwood trees, and the canyon being occupied, to some extent at least, by the usual fauna of the wilder portions of Colorado. The investigation was made in the interest of a survey that is being carried on by the hydrographic division of the U. S. Geological Survey under the general direction of Mr. F. H. Newell, for the purpose of determining the feasibility of diverting the water of the Gunnison into the Uncompahgre Valley for the irrigation of its lands. The trip was made, commenced on the 12th and ended on the 21st of August, 1901. The investigation resulted in the obtaining of practically all the data desired, over a hundred excellent views of the canyon being taken, and copious memoranda made concerning the nature of the rocks and other features of interest. The trip was an excessively hard one, and was made with the lightest possible equipment, the explorers being obliged to take to the river and swim some seventy-odd times, besides scaling the sides of the cliffs times innumerable.

'The Development of Irrigation in Colorado': L. G. CARPENTER, Director of Experiment Station and Professor of Irrigation, Fort Collins, Colorado.

'The Social and Economic Aspects of Irrigation': GEORGE H. MAXWELL, Chairman

of Executive Committee of National Irrigation Association, Washington.

RAYMOND A. PEARSON,
Secretary.

AMERICAN ORNITHOLOGISTS' UNION.

THE Nineteenth Congress of the American Ornithologists' Union convened in New York City, Monday evening, November 11. The business meeting of the Fellows was held at the American Museum of Natural History, and the public sessions, commencing Tuesday, November 12, and lasting three days, were also held at the Museum.

Dr. C. Hart Merriam, of Washington, D. C., was reelected president; Charles B. Cory, of Boston, and C. F. Batchelder, of Cambridge, Mass., vice-presidents; John H. Sage, of Portland, Conn., secretary; William Dutcher, of New York City, treasurer; Frank M. Chapman, Ruthven Deane, E. W. Nelson, Witmer Stone, Drs. A. K. Fisher, Jonathan Dwight, Jr., and Thos. S. Roberts, members of the Council.

The ex-presidents of the Union, Dr. J. A. Allen and Messrs. William Brewster, D. G. Elliot and Robert Ridgway, are *ex-officio* members of the Council.

Outram Bangs, of Boston, Joseph Grinnell, of Palo Alto, Cal., Dr. T. S. Palmer and Professor F. E. L. Beal, of Washington, D. C., and Dr. Louis B. Bishop, of New Haven, Conn., were elected Fellows.

Montague Chamberlain, of Boston, was elected to corresponding membership. Fifty-five associates were elected to the new class known as members, and eighty-three new associates were elected.

By the adoption of certain amendments to the By-Laws, at the present Congress, the following classes of members are now recognized by the Union, viz., Fellows, Honorary Fellows, Corresponding Fellows, Members and Associates.

Dr. J. A. Allen, in his paper on 'The

Present Outlook for Stability in Nomenclature,' dwelt upon the American method and its gradual acceptance by foreign ornithologists as well as by workers in other branches of science.

Mr. E. W. Nelson described a collecting trip which he took through portions of Yucatan. In that country, occupied until recently by hostile Indian tribes, he discovered more than one hundred birds new to science.

Mr. Ruthven Deane exhibited books and other relics from his own library which were once the property of John James Audubon. What he had to say on 'Auduboniana,' was of historic interest.

The report of the Committee on Protection of North American Birds showed that satisfactory results had been obtained during the past year. Mr. Dutcher spoke of the great good for protection made possible by the 'Thayer Fund'—money raised through the efforts of Mr. Abbott H. Thayer. By its aid Dr. T. S. Palmer and Mr. Dutcher had been able to appear before legislative committees in many States, and new and better protective laws had been passed. Mr. Chapman referred to the present abundance of bird life on Gardiners Island, N. Y., the result of rigid protection.

Professor W. W. Cooke traced the routes of bird migration across the Gulf of Mexico, bringing out many new and interesting facts.

Excellent lantern slides from photographs of birds in life were shown by Rev. H. K. Job, and Messrs. Nelson, Chapman, Dutcher and Baily.

The New York Zoological Society invited the members of the Union to visit its park, and many availed themselves of the privilege November 15. Director Hornaday conducted the party through the grounds.

Following is a list of the papers read at the sessions.

'The Present Outlook for Stability in Nomenclature': J. A. ALLEN.

'The Plumages of the American Goldfinch (*Spinus tristis*): JONATHAN DWIGHT, JR.

'Routes of Bird Migration across the Gulf of Mexico': W. W. COOKE.

'On Methods in Museum Bird Exhibits': FRANK M. CHAPMAN.

'Ornithological Notes from Northern New Hampshire': JOHN N. CLARK.

'Some Impressions of Texas Birds': LOUIS AGASSIZ FUERTES and H. C. OBERHOLSER.

'The White-winged Crossbill in Captivity': JAMES H. HILL.

'The American and European Herring Gulls': J. A. ALLEN.

'Auduboniana': RUTHVEN DEANE.

'The Molts and Plumages of the North American Ducks (*Anatidae*): JONATHAN DWIGHT, JR.

'A Naturalist in Yucatan,' illustrated by lantern slides: E. W. NELSON.

'Photography in North Dakota Bird Colonies,' *et cetera*, illustrated by lantern slides: HERBERT K. JOB.

'A Reconnaissance in Manitoba and the Northwest,' illustrated by lantern slides: FRANK M. CHAPMAN.

'Are Humming Birds Cypseloid or Caprimulgoid?' HUBERT LYMAN CLARK.

'List of Birds of Wequetonsing, Mich.': OTTO WIDMANN.

'Notes on the Ornithological Observations of Peter Kalm': SPENCER TROTTER.

'Report of the Committee on the Protection of North American Birds': WITMER STONE.

'Results obtained under the Thayer Fund': WILLIAM DUTCHER.

'National Bird Protection—Its Opportunities and Limitations': T. S. PALMER.

'Gulls of the Maine Coast, and Miscellaneous Notes,' illustrated by lantern slides: WM. DUTCHER and WM. L. BAILY.

'Some Results of Bird Protection,' illustrated by lantern slides: FRANK M. CHAPMAN.

The next annual meeting will be held in Washington, D. C., commencing November 17, 1902.

JOHN H. SAGE,
Secretary.

JOSEPH HIRSCH.

THE biography of the late Joseph Hirsch, briefly sketched, is as follows:

Born May 22, 1836, of an old and well-known family, characterized in all its branches by taste, refinement, and ability, and with a strong proclivity toward both art and engineering, he studied at the *École Polytechnique* and became an engineer of the *Ponts et Chaussées*, standing at the head of his class in line of promotion from the first. He served in Marseilles, Algiers and Alsacia, and accepted missions in Germany and Austria. In 1861 he was engaged in the construction of the Houillères de la Sarre canal, inventing, meantime, the ingenious syphon arrangement by which its level is automatically maintained. In 1867 he was assigned to special service relative to the work of improvement of the navigation of the Saone, and presently, on his marriage with Mlle. Dreyfus-Dupont, whose distinguished relatives in this country are so well known to all engineers and army and navy men, he secured indefinite leave from the Government and devoted himself to the study and investigations which so liberally offered themselves in connection with the great iron and steel works of his father-in-law. After the close of the Franco-German war, one of these establishments, on then German territory, was sold, and Hirsch erected new and modern works at Pompey, near Fruard. In this construction he introduced every modern appliance and made it a model of its kind.

The children of this fortunate union growing up, it was decided to take up residence in Paris, and for many years, No. 1, rue de Castiglione, was a center of social,

scientific and artistic life. Meantime, his two brothers had become famous, the one as artist, the other as architect, and aided in making the new life beautiful and profitable.

In 1876 Hirsch was appointed to the chair of 'The Steam Engine,' at the *École des Ponts et Chaussées*, and, until his retirement at the age limit in 1898, he steadily added to the fame of that great institution. After those twenty-two years of service, the Inspector-General reported :

"To great scientific knowledge he added from the first extensive practical information, the fruit of personal experience, which enabled him to conduct his course as a practitioner, as well as a *savant*, and thus to give it the character most appropriate to the *École des Ponts et Chaussées*."

At his retirement he distributed a considerable sum, 10,000 fr. for ten years, in prizes for students '*les plus méritants et le moins fortunés*.' He 'gave much but with discretion; he took the trouble to give usefully.' Riches, in his view, created an indebtedness to his country and his people which he was always willing and glad to discharge.

Hirsch added to his work at the *Ponts et Chaussées* that of the department of Mechanics at the *Conservatoire des Arts et Métiers* (1886), and took great pleasure in directing its evening classes and teaching the crudely educated, as well as the well-prepared, pupils at the government school. In 1879 he was on the 'State Commission of Steam Engines'; in 1880 he had charge of the office of engineer-in-chief of the department of purchase and inspection of materials for the state railways. He was on the international juries of 1878, 1889 and 1900 in Paris, and in 1878 received the cross of *Chevalier de la Legion d'honneur* and, in 1900, that of *Officier*.

M. Hirsch published his course at the *Ponts et Chaussées* in the '*Encyclopédie des*

travaux publics,' and, in its first volume, on the steam engine, had the assistance of M. Debize. His reports upon the machinery exhibited at the International Expositions appeared in the volumes officially issued from the government press.

As M. Darlein says: "*Telles sont été les principales occupations et les travaux le plus notoires du savant ingénieur, du professeur accompli, du chercheur original, de l'homme de bien dans la plus haute acception de ce mot, qu'une mort subite vient d'arracher à la tendresse de sa famille et à l'affection de ses amis. * * * Adieu, camarade et ami, ou plutôt au revoir: ta mémoire nous demeurera chère et ton exemple nous restera utile.*"

An acquaintance of many years' duration permits the writer to speak with confidence in confirmation of the testimony given by his professional colleagues at the meetings of various societies after his death. In his home and in his private capacity he illustrated the noblest attributes of the gentleman and the scholar; serious yet always kindly and affectionate, giving and eliciting respect and affection, sweet reasonableness accompanying correct judgment and clear views of right and wrong, familiar yet dignified, provident yet liberal, as husband, father, friend, he was invariably and completely admirable. Professionally he was a leader. Practically experienced, technically learned, cultured and efficient, he was a reliable adviser and director in his whole wide field of special work. He was admired, respected and honored by every client, as by every colleague.

His record, official, professional and private, stands a permanent memorial to the man.

R. H. THURSTON.

SCIENTIFIC BOOKS.

Les Variations de Longueur des Glaciers dans les Régions Arctique et Boréales. By CHARLES RABOT. Archives des Sci. Phys. et Nat. Geneva, 1897, 1899 and 1900.

The literature of the variations of glaciers has been greatly enriched by the contributions of M. Rabot. He has brought together in a convenient form the observations that have been made on the northern glaciers, with references to his sources of information, so as not only to give an excellent review of what is known of these glaciers, but also to give the data for comparisons with future work. Many of the original publications which he refers to are in languages, such as Icelandic, Danish, Swedish and Norwegian, which are little known outside of the regions where they are spoken, so that his extracts and synopses bring before us important facts which could not be obtained otherwise without great difficulty. He does not confine himself to the variations of glaciers only, but also gives descriptions, measures of the motion, observations on melting, etc. Although he disclaims that his work is complete, it will be recognized that the incompleteness is not due to oversight on his part, but to paucity of exact information on the subject. One is surprised, indeed, that he has been able to collect so many facts regarding more than 250 glaciers, many in very remote regions.

M. Rabot divides glaciers into three classes: *inland ice*, such as the ice covering of Greenland with its great ice streams which reach tidewater, including smaller local ice-caps; *Alpine glaciers*, with which we are familiar in the Alps; and *composite* or *Alpine-Norwegian glaciers*, an intermediate form grading into each of the other two. Glaciers of the first class are the most common in the arctics.

In temperate regions, the variations of a glacier are easily determined by the change in the position of its end; but this is not so simple among arctic glaciers. Many of them end in fiords and the ice is continually breaking off as icebergs, so that the point where they end varies according as we observe them shortly before or after much ice has broken off. M. Rabot thinks the intensity of the calving is a better criterion of the state of the glacier; if much ice is coming off and at the same time the glacier is not materially receding, it is to be considered in growth; and *vice versa*.

M. Rabot reviews the observations of the

glaciers of Grinnell Land, Greenland, Jan Mayen's Land, Iceland, Spitzbergen, Francis-Joseph Land and Scandinavia, five of which regions he has himself visited, and brings out many interesting facts, but we can only notice the most important of his conclusions. Of the regions mentioned Iceland and Norway furnish the most detailed information for the longest time. It is well established that the glaciers of these two countries were much smaller before the eighteenth century than they are now, and that this smaller extension lasted for several centuries; that there was a great advance during the eighteenth century interrupted for a short time about 1750; that during the nineteenth century there has been a slight retreat marked by several minor variations, though the glaciers are still considerably larger than they were during and before the eighteenth century. A Norwegian document of the eighteenth century contains a general description of the Greenland glaciers which might apply to the country to-day, so we must infer that the extent of the ice did not differ very greatly then from what it is now. With the exception of this document all accurate information of the Greenland glaciers refers to the period since 1850. Observations since then are not at all concordant, but they seem to show in general a stationary condition or a slight advance. The natives are unanimous in asserting that the ice has been advancing within historic (?) times. The fewer observations in Jan Mayen's Land and Spitzbergen indicate that their glaciers have followed the same history as those of Iceland and Norway. The glaciers of Grinnell Land and Francis-Joseph Land appear to be retreating at present. Local ice caps, probably of comparatively recent origin, cover the islands which make up the latter.

M. Rabot mentions that the glaciers of south-eastern Alaska seem to have been at a maximum at the end of the eighteenth century; and it may be added that observations in Glacier Bay show that there was a long period in which the glaciers were much smaller than at present, followed by the comparatively short but strong advance which apparently culminated at the above date, and that since then there has been a general retreat; so that it seems quite probable that the Alaskan glaciers have experienced

variations synchronous with those of the Arctics.

The general conclusions are that in the Arctics the eighteenth century was a period of very marked advance of the glaciers, that this was preceded by several centuries of great retreat, and followed by a small retreat which is still in progress. Where the information is sufficient these conclusions are fully established; where it is meager they are partially confirmed or at least not contradicted.

M. Rabot points out certain resemblances and differences between the variations of the arctic glaciers and those of the Alps. Although, so far as can be made out, there seems to be a fair accord in the dates of the variations, there seems little relation between their respective intensities. The general advance of the arctic glaciers in the eighteenth century was not marked in the Alps; and the strong retreat of the second half of the eighteenth century in the Alps is but faintly shown in the Arctics. Moreover, it has not been possible to show a distinct relation between the variations of climate and the variations of the glaciers in the Arctics as has been done in the Alps.

M. Rabot has accomplished what must have been a laborious task, and deserves the thanks of all persons interested in the variations of glaciers.

HARRY FIELDING REID.

GEOLOGICAL LABORATORY,
JOHNS HOPKINS UNIVERSITY.

The Brain of Acipenser. A Contribution to the Morphology of the Vertebrate Brain. By J. B. JOHNSTON, Professor of Zoology, West Virginia University. Zool. Jahrb., Abt. f. Anatomie, Bd. XV., Jena, 1901, pp. 204, with 12 plates and 22 text-figures.

The application of the cell theory to the nervous system (for this is what the doctrine of the neurone amounts to in the upshot) has reached its consummation only within the past decade. Accordingly, the neurology of to-day, whether human or comparative, demands not merely topographic descriptions of the tracts and nuclei within the brain, but the precise relations between the two, stated anatomically in terms of cellular morphology as well as in terms of experimental pathology. This necessi-

tates the rewriting of some chapters in the standard text-books and the repetition of many classical researches upon the lower animals with 'modern neurological methods.'

Such, then, is the motive which has led Professor Johnston to attempt 'a complete study by modern methods of the brain of a lower vertebrate.' The type chosen, the sturgeon, was described in 1888 by Goronowitsch, and the present study aims to fill in the cellular details upon the basis of the topography as there laid down (with the result, we may add parenthetically, of correcting several errors both of fact and of morphological interpretation found in Goronowitsch's account). Standard histological methods—among which judicious staining with Delafield's hæmatoxylin is still unrivaled for lower brains—were, accordingly, supplemented by the use of methylene blue in various forms and by chrome silver impregnation. The author's results with the latter method are especially brilliant. He has succeeded in getting whole brains impregnated and cut into unbroken series of sections, so that the courses of the more important tracts could be controlled by the actual demonstration of the paths of individual fibers through them.

Of the 12 plates accompanying the paper, one is a chart showing all the more important fiber tracts in the brain of this fish elucidated by an ingenious color scheme, the reflex arc being represented as consisting of a chain of several links which are indicated by colors of the spectrum, sensory roots blue and motor roots red, with the connecting tracts in series between. The other plates (all photographic reproductions from untouched negatives) include seven views of the entire brain, 56 photographs of Golgi preparations, illustrating nearly all the important types of neurones in the brain, and 21 transverse sections from a series stained with Delafield's hæmatoxylin to illustrate the topography. The latter are accompanied by lettered outline drawings on transparent paper and incorporate also some results of the study of Golgi sections.

Dr. Johnston is one of the few neurologists who give evidence of an adequate appreciation of the importance of the peripheral nervous system as furnishing the key to the central, and

who accordingly have fully and sympathetically entered into the doctrine of nerve components as developed within the past decade. While he has not himself studied the peripheral nervous system of *Acipenser*, his analysis of the medulla oblongata has been made in the light of the facts of peripheral connections already known, and hence his results are of far-reaching importance to the major problems of the morphology of this confusing region. Into the details of these results we cannot now go, merely calling attention to the fact that in this connection he has made some observations of great importance to the phylogeny and organogeny of the vertebrate nervous system.

For instance, he confirms statements of previous writers that the communis, or visceral sensory, system of cranial nerves is related anatomically with centers both in the oblongata and in the spinal cord which are quite distinct from those of the tactile nerves (general cutaneous centers and dorsal horns). On the other hand, the acustico-lateral system of cranial nerves, innervating the ear and lateral line organs, is structurally very intimately related to the general cutaneous centers and dorsal horns. Johnston, in agreement with other very recent writers, finds the cerebellum directly related with the tuberculum acusticum, all the types of cells characteristic of the cerebellum being represented in the acusticum by transitional forms. From this it follows that the cerebellum and acustico-lateral nerve centers are phylogenetically derived from the dorsal horns of the spinal cord. It is important that this interesting conclusion be controlled by studies upon still more primitive vertebrates and by embryological studies upon the lower fishes, and that the succeeding steps in this evolutionary process be worked out in the types next above the ganoids. The first of these desiderata has already been met in large measure by an exhaustive study of the brain of the lamprey by similar methods, which Dr. Johnston has now in press in an American journal and by which the main theoretical conclusions of this paper are confirmed in a striking manner.

Another critical region upon which interesting conclusions are expressed is the pallium.

"There are found in *Acipenser* two sets of cells which seem to constitute the earliest representative of the cortex proper. One of these serves to connect the epistriata of the two sides by fibers through the anterior commissure. The other is found in the dorsal membranous roof of the fore-brain and probably corresponds to the dorsal or dorso-median cortex of reptiles. The transformation of a membranous pallium into a massive nervous pallium, which has recently been declared impossible, is seen in actual progress in its early stages in *Acipenser*."

In conclusion, we may add that, whether Dr. Johnston's theoretical conclusions stand or fall (and we think that for the most part they will stand), the cause of sound morphology is best promoted by just such exhaustive and painstaking researches as this one, by which a secure basis of positive fact is first laid down.

C. JUDSON HERRICK.

The Smithsonian Institution, Documents Relative to its Origin and History, 1835-1899. Compiled and edited by WILLIAM JONES RHEES. In two volumes. Vol. I., 1835-1887. Twenty-fourth Congress to Forty-ninth Congress. Washington, Government Printing Office. 1901. Pp. liii + 1044.

The Smithsonian Institution is taking praiseworthy pains to make permanent records of its origin, history and activities, so that the future historian of science in America shall be able to draw from authorized sources. Three volumes have previously appeared pertaining to the origin and history of Smithson's foundation, one bearing a title similar to that under review, one dealing with the 'Journals of the Board of Regents, Reports of Committees, Statistics,' and the third, the large, handsome work, 'History of the First Half Century,' edited by Dr. George Brown Goode and published in 1897. The volume in hand is compiled and edited by one who has been in the service of the Institution under all three secretaries, as chief clerk and now as keeper of archives, and whose familiarity with the life of the Smithsonian, together with painstaking research, has produced a valuable work.

The book is complementary to that issued in 1879, and contains in detail the history of the

relations of the Institution to Congress, as found in the volumes of the *Congressional Globe* and *Congressional Record*, the Journals of the Senate and House, and the Statutes at Large. Part I. contains the documents pertaining to the foundation, the will of James Smithson, the correspondence ensuing and statements of other bequests to the Institution; Part II. embraces legislation relative to the establishment of the Institution, 1835-1847; Part III. embraces the legislation in Congress from 1847 to 1887; and according to the table of contents of a second volume (printed in Vol. I.), that will contain details of legislation from 1887 to 1899.

These volumes will prove indispensable to those seeking full and accurate information of the Smithsonian Institution.

H. C. B.

Grds.
 A *College Text-book of Chemistry*. By IRA REMSEN. New York, Henry Holt and Co. 1901. Pp. xx + 689.

This book is intended to fill a place between the 'Inorganic Chemistry' and the elementary text-books by the same author. After an introductory chapter, in which some fundamental principles, including the laws of definite and multiple proportions, symbols, and equations, are discussed, six chapters are given to oxygen, hydrogen, water and the atomic theory. The remaining elements are considered in the following order of the families of the periodic system: Chlorine, nitrogen, carbon, lithium, glucinum, aluminium, copper, zinc, gallium, germanium, chromium, manganese, iron, platinum. Two short chapters on carbon compounds close the book. At appropriate points, topics pertaining to theoretical chemistry are taken up, such as the periodic law, mass action, dissociation, osmotic pressure, Faraday's law and atomic heats.

While President Remsen believes that 'the time has not yet come for the abandonment of the study of elements and their compounds in what some are pleased to call the old-fashioned way,' those subjects which pertain to what is commonly known as physical chemistry receive a fair degree of attention. Not only are the fundamental theories of solutions discussed in detail in two or three places, but several applications of the theory are considered in con-

nection with individual compounds. The great importance of such a reiteration of fundamental principles is, of course, clearly recognized by all successful teachers.

The laboratory study which the author intends should accompany the use of the text is indicated by a series of experiments at the close of the successive chapters. A few quantitative experiments are included. The subjects for experimental illustration are mostly well selected, but the addition of some work, demonstrating the fundamental properties of solutions is needed.

The book, as a whole, is written in that clear and fluent English which is so characteristic of the author and which has done so much to make him one of the greatest of the teachers of chemistry.

W. A. NOYES.

SCIENTIFIC JOURNALS AND ARTICLES.

The American Naturalist for November opens with an article on 'The Parasitic Origin of Macroergates among Ants,' by W. M. Wheeler, in which the writer describes the occurrence of certain monstrous workers of the genus *Pheidole* caused by the presence of a parasite of the genus *Mermis*. These macroergates are compared with phenomena observed among other species, the author concluding that the character of the adult ants is not due to the efforts of the attendant workers alone, but also to a certain amount of initiative in the larvæ. H. L. Osborn describes 'Some Points in the Anatomy of a Collection of Axolotls from Colorado, and a Specimen from North Dakota,' these points being wholly external and connected with the change of *Siredon* into *Amblystoma*. 'A Parasitic or Commensal Oligochæte in New England' is described in some detail by M. A. Willcox, and Albert C. Eycleshymer gives some interesting 'Observations on the Breeding Habits of *Ameiurus nebulosus*.' M. Louise Nichols considers 'The Spermatogenesis of *Oniscus Asellus* Lim., with especial reference to the History of the Chromatin,' and George H. T. Nuttall treats of 'The Formation of Specific Anti-Bodies in the Blood, following upon Treatment with the Sera of Different Animals,' giving the results of a series of investigations which

show that, although the bloods of various animals may be mixed, they may be detected and differentiated. The final paper, by W. J. Kent, is on 'The Colors of the Crayfish': red may be caused by exposure to sunlight or by environment, but all other colors are the result of environment and are protective in their nature.

The Osprey for September contains the 'Song Birds of the Kissimmee Valley, Florida,' by Wm. Palmer, 'A Visit to Otter Rock, Pacific Ocean,' by A. G. Prill; 'Notes on the Blue Grosbeak, *Guiraca cerulea*,' by John W. Daniel, Jr.; the tenth instalment of 'William Swainson and His Times,' by Theodore Gill; a second paper on 'The Cage Birds of Calcutta,' by Frank Finn; and the eighth and final chapter of 'The Osprey or Fishhawk: Its Characteristics and Habits,' by Theodore Gill. An editorial on 'Work and Worry for the Classicists' shows some of the numerous troubles in store for those zoologists who propose to abide by the decision of the majority, in regard to nomenclature, at the last international zoological congress.

The Plant World for October contains the second part of 'Notes on Trees of Cuba,' by Valery Havard; 'Some Interesting Cases of Plant Distribution,' by John M. Holzinger; 'The Knubble, Advice to Beginners in Botany,' by Walter Deane; and many briefer articles and notes on current literature. The supplement on the 'Families of Flowering Plants,' by Charles L. Pollard, is devoted to a continuation of the descriptions of the families of the order Sapindales.

The American Museum Journal for October should be in demand by ornithologists, for it has for supplement a twenty-four-page 'leaflet' devoted to the Bird Rock Group recently placed on exhibition. This is by Mr. Chapman, and is admirably illustrated by reproductions of the group and of the real Bird Rock whose bird life it so well represents. The *Journal* proper contains notes on the summer's work of the various field parties of the Museum, and on the recent acquisitions.

Journal of Physical Chemistry, October. 'On the First Plait in van der Waals's Free Energy

Surface for Mixtures of Two Substances,' by Ch. M. A. Hartman (Physical Laboratory, Leiden). This contains a review of the investigations referring to binary mixtures and a bibliography. 'A New Proof of the Formula $d = \frac{.02 T^2}{L}$,' by Felix Lengfeld. 'The Influence of Electrical Waves on Chemical Action,' by Felix Lengfeld and James H. Ransom. 'On the Dielectric Constants of Pure Solvents,' by Herman Schlundt. The work of Dr. Schlundt was carried out under the supervision of Professor Kahlenberg, of the University of Wisconsin, and while a number of new examples have been found which follow the Nernst-Thomson rule, that the greater the dielectric constant of a solvent the greater is its dissociating power, some striking exceptions have also been found, from which it is argued that the rule is inadequate.

SOCIETIES AND ACADEMIES.

CALENDAR.

The American Association for the Advancement of Science. A meeting of the council will be held at the Quadrangle Club, University of Chicago, on the afternoon of January 1. Section H (Anthropology) will meet at the Field Columbian Museum, Chicago (December 31 and January 1). The next regular meeting of the Association will be held at Pittsburg, Pa. (June 28 to July 3). A winter meeting is planned to be held at Washington during the convocation week of 1902-3.

The American Society of Naturalists will hold its annual meeting at the University of Chicago (December 31 and January 1). In conjunction with it will meet the Naturalists of the Central States and several affiliated societies, including The American Morphological Society (beginning on January 1; The American Physiological Society (December 30 and 31); The American Psychological Association and the Western Philosophical Association (December 31 and January 1 and 2); The Society of American Bacteriologists (December 31 and January 1), and The American Association of Anatomists (December 31 and January 1 and 2).

The American Chemical Society will meet at the University of Pennsylvania, Philadelphia (December 30 and 31).

The Society for Plant Morphology and Physiology will hold its fifth annual meeting at Columbia University, New York City (December 31 and January 1 and 2).

SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY OF THE NEW YORK ACADEMY OF SCIENCES.

THE Section met on the evening of November 4.

Dr. S. A. Mitchell gave a very interesting report of the recent Eclipse Expedition to Sumatra. Numerous lantern slides were exhibited, showing the arrangement of the apparatus at the different stations. The paper is given in full in SCIENCE.

Professor William Hallock gave a report of some recent work on underground temperatures.

Dr. L. Boroschek gave an account of some work he had undertaken in connection with Dr. Tufts on the absorption of light by some dyes of the fluorescein group. The dyes studied were fluorescein and a number of its nitro-derivatives. It was stated that Hewitt and Perkins (*Journal Chem. Soc.*, 1900, page 1324) claim that a double symmetrical tautomerism furnishes a satisfactory explanation for the fluorescence of fluorescein, and that in the case of dinitro- and tetra-nitro fluorescein this tautomerism is inhibited by a secondary tautomerism between the nitro and hydroxyl groups when in ortho position to each other. It was found that the mononitro-fluoresceins, obtained by condensing the 3-nitro- and the 4-nitro-phthalic anhydrides with resorcin, in which the nitro group is on a different benzol nucleus from the hydroxyl groups, show no fluorescence in alkaline solutions. According to the theory of Hewitt and Perkins alkaline solutions of such dyes should fluoresce. Photographs of the absorption spectra of alkaline solutions of the dyes were taken, and it was found that the substitution of nitro groups displaces the prominent absorption band of fluorescein towards the red end of the spectrum and increases the absorption in the ultra-violet. The absorption of light in the visible spectrum was studied by means of the flicker photometer.

The amount of light transmitted by equal thicknesses of solutions of different concentrations was measured for the different dyes. A relation was thus obtained between the absorption of light and the concentration of the dye. The work is still in progress. F. L. TUFTS,
Secretary.

SECTION OF ANTHROPOLOGY AND PSYCHOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

THE first sectional meeting of the season was held on October 28, Professor Farrand in the chair. The names of Robert MacDougall and J. E. Lough were proposed for membership.

Professor J. McK. Cattell made a brief report regarding psychology at the Denver meeting of the A. A. A. S.; and Professor G. G. MacCurdy, of Yale University, reported on anthropology at that meeting, and in addition described the explorations that are being carried on in the Mesa Verde of southwestern Colorado by the Colorado Cliff Dwellings Association.

Professor Franz Boas described the facilities for anthropological study in Berlin, as observed by him in a recent visit. Within the last 20 or 30 years, the anthropological equipment of Berlin has progressed enormously. The museum now contains better East Indian collections than can be found in England; and it is strong in nearly all departments, notably so in American and especially South and Central American anthropology. Fifty scientific workers are engaged on these collections, and 16 of these are at work on American subjects. Besides the museum, there are several other institutes in Berlin, such as the Anatomical Institute of Waldeyer and the Pathological Institute of Virchow, in which anthropological work is done.

The leader of German anthropology is Virchow. He disbelieves in the study of the variation of the whole body, and insists that only the study of the variation in the individual cells of the body can lead to fruitful results.

Reports of summer field work were presented by H. H. St. Clair, 2d, on his work in Wyoming and Oregon, and by William Jones, on his work in Iowa and Oklahoma. The work of Mr. Jones was carried on among the Sauks and Foxes, a people of Algonquin stock. One band of this

people is located in central Iowa, and another in Oklahoma. Both bands practice similar customs, live in much the same way, wear the same kind of dress, show similar physical types, and, with the exception of certain differences in idiom, and with the exception that the Iowa band have a slower, more deliberate pronunciation, they speak the same tongue. The Iowa band is the more conservative, and among them the law of the clans still holds. The education of the children is accomplished not by instruction but by imitation. The older boys imitate the men, and the younger boys imitate the older ones; and similarly with the girls. The life of the children is but a smaller edition of the life of the older people. R. S. WOODWORTH,

Secretary.

TORREY BOTANICAL CLUB.

At the meeting of the Club on November 12, the first paper was by F. S. Earle, on '*Asco-corticium* in North America,' correcting the current nomenclature as to this genus, details of which will shortly appear in print.

The second paper, by Dr. Britton, 'Remarks on the Flora of St. Kitts, British West Indies,' was a sketch of his recent observations there, with copious series of herbarium sheets, and of fruits and other specimens in alcohol. Scarcely any botanical work had been done on St. Kitts previous to its exploration by Dr. Britton and Mr. John F. Cowell last summer. In all they collected about 3,500 herbarium specimens, representing perhaps half of the flora. Many tree-ferns were brought which are now making good growth, and a great number of cacti which are already on exhibit in the succulent house of the New York Botanical Garden.

Dr. Britton spoke in particular of the great interest attaching to that purely tropical flora, its aspect wholly dissimilar from that of our Atlantic coast except only in the presence of the introduced Horseweed, *Leptilon*. St. Kitts is a volcanic mass, formed of a rugged central mountain rising to about 4,000 feet, dissected by radiating gorges which reach to the sea, and wholly surrounded by a fringe of arable land on the shore. Steep ravine-sides 300 feet deep were often completely covered with a prodigious growth of tree-ferns; there were four or five spe-

cies in the ravines and one or two more in the denser forests; some reached a height of 50 feet; another was chiefly prostrate. A good number of the filmy ferns were found; perhaps ten; and many *Gleichenias* at high altitudes, where ferns constitute the chief flora. No *Equiseta* were found; among the Lycopods, a species of *Psilotum* on tree-trunks, some large and handsome *Selaginellas*, and three *Lycopodiums* occur, of which one conspicuous species was known to the negroes as 'Staghorn.' The grasses number 30 or more, the largest a *Gynerium* known as Wild Cane or Dumb Cane. Guinea-grass, *Panicum maximum*, is the only source of hay. Sedges were few, for there is little standing water (except a littoral salt-marsh); only a little pond near a mountain summit at 3,500 feet, and a little lake in the bottom of the old crater of the volcano, Mt. Misery. *Sclerias* with saw-edged leaves were quite abundant and form an obstacle on mountain-trails.

Aroids are very conspicuous, and in great quantity, but only about eight species; two of *Anthurium*, climbing trees, two of *Philodendron*, one with perforated leaves; one *Dieffenbachia*; and a species known as Elephant's Ear, forming great masses, with leaves sometimes five feet long.

Only two palms were found, one, a *Bactris*, reaching 30 feet; two *Commelynas*; three or four *Tillandsias*; a *Dioscorea* with remarkable purple leaf, now growing in the propagating house; about sixteen orchids; and one gymnosperm, a *Podocarpus*, abundant high up, and known as 'wild rosemary tree.' Among higher plants the pepper peppers, the Papilionaceæ and allies, the *Euphorbia* and *Melastoma* families, are numerous. The Compositæ are numerous present, but chiefly as weeds; a handsome new purple-flowered *Eupatorium* was found on the top of Mt. Misery, forming a shrub, and eight to ten feet high. The alligator-pear, *Persea Persea*, is quite abundant. There are four species of *Ficus*, a wild cherry, a *Viola*, etc. A raspberry occurred in a mountain pasture at 2,000°. Among the more peculiar were the *Cecropia*, with white under surfaces of leaves, *Marcgravia* climbing appressed to trees to the height of 50 feet, and *Hillia*, interesting from its large lustrous white flowers.

The results of Dr. Britton and Mr. Cowell's expedition bid fair to prove of high economic importance aside from their scientific value. The expedition owed much to the kind assistance of the planters, who detailed their negroes and horses for the service of the explorers. Without such aid, it would have been difficult to penetrate the forest belt, through which trails had first to be cut.

Further remarks were added by Dr. Underwood regarding a dodder in tops of trees in Porto Rico; by Mr. J. H. Barnhart, on an epiphytic *Utricularia* among the specimens from St. Kitts exhibited; by Mr. F. S. Earle, on the few fungi collected; and by Mrs. Britton, on the other cryptogams, which numbered 81, and included a *Vittaria* prothallium.

EDWARD S. BURGESS,
Secretary.

ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

THE 321st meeting of the Society was held on November 5. Professor W. H. Holmes read a paper on the 'Discovery of Human Relics and the Bones of Extinct Mammals in a Sulphur Spring, Indian Territory,' an abstract of which will be published in SCIENCE. This paper was discussed by Dr. W. J. McGee, Jos. D. McGuire, F. W. Hodge, Francis La Flesche and others.

Miss Alice C. Fletcher gave an account of 'The Inauguration of the New Department of Anthropology, University of California,' through the munificence of Mrs. Phoebe A. Hearst. For ten years Mrs. Hearst has been gathering museum material, spending fifty thousand dollars a year on its acquisition and looking forward to a time when the collections might be housed in a museum building. Last summer the project took form, resulting in the establishment of the Museum at the University of California with a handsome endowment, the details of which appeared in SCIENCE, October 18, 1901.

WALTER HOUGH.

DISCUSSION AND CORRESPONDENCE.

THE GEOGRAPHICAL DISTRIBUTION OF FISHES.

IN SCIENCE for November 1, Professor A. E. Ortmann offers some very interesting notes on

my paper (in SCIENCE, October 11) on the geographical distribution of fishes. On the points raised I may add a word.

1. There is little or nothing in the present relations of the fish fauna of Japan to that of the Mediterranean to suggest a former connection through a warmer climate to the northward. The forms common to the two regions are chiefly of Indian and rather deep water distribution. One curious anomaly occurs, the existence of a second species of the large trout, *Hucho*, in Japan, the other known species being in the Danube.

2. The views of Dr. Ortmann as to the faunas separated by the Isthmus of Suez and the Isthmus of Panama seem to agree with those expressed by me. Of course, from the standpoint of ichthyology, no one could say when either oceanic connection actually existed. That is a matter for geologists.

3. The fish fauna of the Cape of Good Hope is imperfectly known, that of the southeastern coast of Africa still less. It is certain, however, that some tropical or semitropical genera do pass this barrier at present. In other ages the Cape might conceivably have been less of a barrier through less extension or through warmer climate at its extremity. This again rests with the geologists.

4. I am willing to accept the theory of the former extension of the continent Antarctica on geological grounds, and the known distribution of *Galaxias* would be explained by it. But the case of *Galaxias* would not of itself prove such extension, and the value of zoological evidence in such cases is easily overestimated.

DAVID STARR JORDAN.

PREGLACIAL DRAINAGE IN SOUTHWESTERN OHIO.

TO THE EDITOR OF SCIENCE: In his reply (November 15) to Mr. Miller's criticism of my papers on preglacial drainage conditions in the vicinity of Cincinnati, Professor Tight should have added that every one of the smaller streams mentioned by Mr. Miller, in proof of his theory, is of *postglacial* origin and consequently has no bearing on the question.

A view up and down the Ohio from the hill-top at either Madison or Leavenworth, Indiana,

will convince any one at all familiar with such features that he is on the crest of a high watershed which has been cut through in very recent times; recent, that is, in comparison with the period of the alluvial valleys up and down the stream from his point of observation.

GERARD FOWKE.

THE SENEGAL BAOBAB TREE.

It is said by travelers that the fruit of the Senegal Baobab tree is used by the natives to curdle milk. As it is also called 'sour gourd' and cream-of-tartar tree, the curdling is probably due to an acid; and other vegetable acids are also known to be so used. But it seems that other vegetable products that are not acid will also curdle milk. In northern Mexico I was once served with a palatable dish of cooked 'cheese' that the mistress of the house told me she had herself curdled with the juice of berries, some of which she showed me. They were fruit of a *Solanum*, apparently *S. heterodoxum*. She was an intelligent woman, and spoke of that use of the berries as a common custom in Mexican families. Like other fruits of the nightshade family, they had no perceptible acid taste; and the curd which they produced had a consistence similar to that which is produced by rennet. Possibly the action upon milk of the juice of that and other non-acid fruits is similar to the action of rennet, which is thought by some investigators to be a kind of ferment.

SHORTER ARTICLES.

THE LARGEST DEEP-SEA FISH.

DURING the cruise of the *Albatross* in 1888 in the Pacific Ocean, a fish nearly five feet long was hauled up in a trawl cast in water of the depth of over 1,000 fathoms. Unfortunately it was thrown overboard, but happily not before a photograph was taken of it. Mr. Townsend has ever since hoped to have another chance to secure the species, but without present hope. It became desirable to make allusion to the species at this time, and he has conferred with Dr. Gill and asked to indicate its probable affinities.

The species appears to be most nearly related to *Percophis*, and for the present it may be as-

sumed that such is the case, but it is by no means certain that it is. It is deserving of the generic name *Macrias* with reference to its length as well as bulk, and the specific name *amissus* is appropriate for it as an stray from its relatives as well as to indicate the loss of the type. It is definable as follows:

MACRIAS.

A genus of Percophoid fishes with moderately oblong head, eyes in the second fourth of the head's length, slightly projecting lower jaw, thick lips, small teeth, small jugular ventrals and anal with origin behind that of second dorsal.

MACRIAS AMISSUS.

The body is elongate and between five and six times longer than high; the head forms more than a fourth ($1:3\frac{4}{5}$) of the extreme length; the caudal about a seventh. The head is oblong conical in profile, with the forehead nearly rectilinear; the eyes are in the third eighth of the length, with the diameter equal to about an eighth of that length, and nearly midway between the preoperculum and the front of the jaw; the mouth is quite oblique and the supra-maxillary extends scarcely behind the front of the eye; the teeth appear to be cardiform; the lips thick. The dorsal rays are not sufficiently defined to count exactly, but they approximate the following formula: *DXI*—19.

The specimen was obtained at the *Albatross* dredging station 2788, off Chonos Archipelago, southern Chili, S. A. (Lat. S. $45^{\circ} 35'$, Long. W. $75^{\circ} 55'$), at the depth of 1050 fathoms; bottom green mud; bottom temperature, 36° F.; surface temperature, 58° F.; from an 11-foot beam trawl, Feb. 11, 1888. The dredge haul lasted three hours.

The fish was about five feet long, and is the largest deep-sea fish taken by the *Albatross*—probably the largest ever taken by beam trawl or dredge. Its color was grayish. It had the softness of flesh characteristic of deep-sea fishes, settling down on the deck so that its natural contour does not show in the large 8 x 10 photograph that was at once made of it.

There being no receptacle available for preserving it in alcohol, it was placed in a cask and salted. Later the cask and specimen were un-

fortunately thrown overboard with some rubbish from the ship laboratory.

The exact measurements of the specimen will be given later when the photograph is reproduced by the Fish Commission.

THEO. GILL,
C. H. TOWNSEND.

CURRENT NOTES ON METEOROLOGY.

HAIL PREVENTION BY CANNONADING.

THE hail prevention cannonading craze has gone very far in Windisch-Feistritz (Steiermark), the home of this newest undertaking for artificially controlling weather phenomena. In *Das Wetter* for October Dr. Friedrich Stengel, who has recently visited the locality, gives an enthusiastic account of the somewhat remarkable arrangements which have been made for this work. The huts containing the firing apparatus are 1 km. apart, in four long parallel rows, the rows also being 1 km. apart. There are three groups of stations, containing twelve, thirteen and fifteen stations each, respectively. Each section has a central station, under the charge of a *schliessmeister*, and each *schliessmeister* is directed by the general superintendent. Cannonading begins when a thunder-storm is within two or three kilometers. Sometimes only one of the sections fires; at other times all the stations participate. Firing continues until the sky begins to clear overhead, or, if this does not happen, until thunder and lightning cease and a general rain sets in. The central station of each section regulates the time of the beginning and ending of the firing, as well as the rapidity of the discharges.

THE DUST STORM OF MARCH, 1901, AND GLACIAL STUDIES.

In the October number of the *Meteorologische Zeitschrift*, Richter calls attention to the use that may be made of the fall of red dust which occurred over most of Europe on March 11 last. It was suggested some time ago that studies of glacial movements and phenomena might be facilitated by coloring a considerable portion of the surface of a glacier, and then noting the rapidity of movement, and the folding and fracturing of this particular colored stratum. The dust storm of last March colored the Euro-

pean glaciers on a grand scale, and thus an excellent opportunity of making critical studies of these glaciers has been provided, which could never have been brought about by artificial means.

THE CLIMATIC CONTROL OF GOVERNMENT IN THE TROPICS.

MR. W. ALLEYNE IRELAND, who is well known in this country through his writings on the settlement and government of tropical possessions, read a paper on the influence of geographical environment on political evolution before the British Association at its Glasgow meeting. In this paper the possibilities of native government within the tropics are discussed. The conclusion is reached that while the natives of the tropics are not deficient in intellectual power, their 'climatic discipline' renders them unfitted to play the part of legislators or responsible administrators, or to maintain a government sufficiently stable to admit of proper commercial development.

UNDERGROUND TEMPERATURES AT OXFORD.

THE volume containing the meteorological observations made at the Radcliffe Observatory, Oxford, from 1892 to 1899, presents some notable facts regarding soil temperatures. The observations were made with platinum resistance thermometers, placed at various depths. The thermometers on the whole were found to work much more satisfactorily than the common spirit thermometers with long stems. It appears that the annual variation in temperature is reduced to 0.1° at a depth of 45.3 ft., and to 0.01° at 66 ft. The semi-annual wave has these same limits at 21.4 and at 36 ft., respectively.

R. DEC. WARD.

BOTANICAL NOTES.

IMPORTANT PHILIPPINE WOODS.

UNDER this title Captain George P. Ahern, of the Ninth Regiment of United States Infantry, has issued a small quarto volume of 112 pages, illustrated with forty-two colored plates. The author, who is in charge of the Forestry Bureau at Manila, candidly states that it is a compilation undertaken in response to numer-

ous inquiries concerning the Philippine forests. In its preparation he has made use of the works of Blanco, Vidal, Delgado and Garcia. The translations are rather awkward, indicating a lack of botanical knowledge on the part of the translator. The plates are mainly from Blanco's 'Flora de Filipinas' and Vidal's 'Sinopsis de Familias y Generos de Plantas lenosas de Filipinas.'

More than six hundred species of trees are now enumerated for the archipelago, and it is estimated that there are from twenty to forty millions of acres of forests still standing, in which there are in many places trees one hundred and fifty feet in height. Gum, rubber, gutta percha and dye-producing trees occur in abundance, as also those producing timber, firewood, textiles, oils, tan-bark, medicines and edible fruits.

In many cases these forests are at present inaccessible on account of the lack of waterways and good roads. The methods of the natives are crude, slow and expensive. When good roads are made and better methods are introduced the islands will be able to supply a large amount of timber for construction, for which there is a great demand throughout the Orient.

RECENT ECOLOGICAL PAPERS.

THREE recent papers are noted here, the first of which is by Professor Doctor Bray of the University of Texas, on the 'Ecological Relations of the Vegetation of Western Texas,' published in the August, September and October numbers of the *Botanical Gazette*, in which the author points out the fact that the region is the meeting ground of no less than eight floral elements, and that the flora is one of xerophytic aspect. Excellent half-tone illustrations add much to the clearness of the text. The second paper is by A. J. Pieters, assistant botanist in the United States Department of Agriculture, on 'The Plants of Western Lake Erie,' in the *Bulletin* of the United States Fish Commission. Here it is shown that the vegetation may be grouped as follows: (1) Free-swimming, microscopic forms in the open lake—*i. e.*, the plankton; (2) other unattached species, mainly macroscopic, as *Lemna utricularia*, etc.; (3) attached submersed plants, as *Najas*, *Chara*, *Cladophora*, etc.; (4) attached plants with floating leaves, as

Nymphæaceæ and *Potamogeton*; (5) swamp plants. Here again excellent half-tone illustrations are used with good effect. The third paper is by Thomas H. Kearney, of the Division of Botany of the United States Department of Agriculture, on a botanical survey of that very interesting region, the Dismal Swamp of southeastern Virginia. After a discussion of such factors as climate, physiography, geology and soils, the plant covering is described at length, and the conclusion is reached that of the indigenous species (about 620) 'over five hundred are endemic in extra-tropical North America, the great majority in the country east of the Rocky Mountains.'

GOVERNMENT GRASS STUDIES.

THE Division of Agrostology was established in the United States Department of Agriculture in 1895 for the purpose of investigating the various problems relating to the grasses and forage plants of the country. After six years of existence a bulletin has been issued presenting a summary of the work accomplished, under the title of 'Field Work of the Division of Agrostology,' and prepared by Cornelius L. Shear. Maps show at a glance the territory covered by the various field workers, and no botanist can examine these without gratification that so much has been done in half a dozen years. The greatest amount of work has been done in the Gulf States from Florida to Texas, thence northward over the Great Plains and the eastern Rocky Mountain region to the international boundary. Twenty-seven different botanists have been engaged in these field studies.

In the Atlantic coast states the investigations included, in addition to the usual one of forage, the study of grasses as sand-binders, and much attention was given to this part of the subject. In the States of the Gulf coast the forage problems are more difficult of solution, the soil having been exhausted in many places, and the people having the impression that grasses for forage purposes cannot be grown here as well as in the North. The fact that between 300 and 400 species grow naturally in this region disproves the latter, and the results of experiments show

that on almost any soil some grasses may be grown with profit. On the Great Plains, although the region is so vast, the problems are less varied, since the conditions are more nearly similar throughout. Here to a great extent the problem is the preservation of the natural pastures and meadows, and their renovation where they have been injured by overpasturing or by the plow. Over a great part of this region the natural meadows should be allowed to remain, and the plow should not be permitted to disturb the well-set sod. In the Rocky Mountains the conditions are extremely varied, and the problems are accordingly more numerous. In many places the natural meadows must be preserved, while in others, as under irrigation, grasses especially suited to the new conditions must replace the scanty growth which preceded them. A new problem obtrudes itself here, viz., that of forage plants for the 'alkali soils.' The problems in the Northwest include the last mentioned (apparently solved by the growth of species of *Atriplex*), and the renovation of the natural pastures which have been overstocked. In the Southwest some interesting facts are brought to light, as that as soon as the prairie fires are stopped the mesquite tree (*Prosopis*) and the prickly pear cactus (*Opuntia*) increase very rapidly, while at the same time the extermination of the coyotes allows the rabbits and prairie dogs to increase to such a degree as to make them most serious pests. On the Pacific coast the work has included the problem of the control of shifting sands in addition to studies of pasture and meadow grasses.

In the course of these investigations much valuable material for scientific study has been obtained, and great quantities of seeds of the more important species have been secured for distribution and trial elsewhere in the country. Above forty bulletins have been issued by the division, ranging from quite popular to technically scientific. No one can look over the work done, as indicated in this bulletin, and not feel that Secretary Morton did a good thing when he established the Division of Agrostology, and that it has fully justified its existence.

CHARLES E. BESSEY.

THE UNIVERSITY OF NEBRASKA.

THE SOUTH AFRICAN MUSEUM.

THE report of the South African Museum for 1900 may be styled a record of good work performed under adverse conditions, for the war in South Africa has affected the museum in more ways than one, lessening not only the number of contributors to the collections, but the number of visitors. This falling off is the first break in a steady increase that has been going on for a considerable period. The accessions of vertebrates have been principally of birds, but one example of the young of the rare cat *Felis nigripes* was obtained in a rather curious way, it having run into the trenches at Zand River during a hot engagement.

Two of the contributors to the museum, Mr. Walter Francis and Dr. A. C. Stark, have been killed during the war; the latter was engaged in the preparation of a work on the birds of South Africa, the first volume of which had appeared. The second volume has been completed by the director, Dr. W. L. Sclater, and is now in press. Dr. L. Peringuey has sent to the printer the first part of a descriptive catalogue of the *Scarabeidæ*, and states that the manuscript of the second part is well advanced. The second volume of the *Annals* of the museum is well along and all the collections are said to be in good shape, and we hope with Sir David Gill that the time may soon come when it will be possible to increase the small appropriation made for the maintenance of this museum.

F. A. L.

SCIENTIFIC NOTES AND NEWS.

DIRECTOR W. W. CAMPBELL, of the Lick Observatory, was elected a foreign associate of the Royal Astronomical Society at the meeting of November 9.

MR. ALEXANDER AGASSIZ, accompanied by Mr. W. McM. Woodworth, has undertaken an expedition to the Maldiv Islands in the Indian Ocean, in order to study the coral formations. A steamboat for this purpose has been chartered at Ceylon.

PROFESSOR F. LAMSON SCRIBNER, chief of the Division of Agrostology of the United States Department of Agriculture, has been given charge of the Bureau of Agriculture which is to

be organized in the Philippines. Professor Lamson-Scribner will sail for the Philippines with his family on February 1.

MR. EDWIN REYNOLDS, of Milwaukee, has been elected president of the American Society of Mechanical Engineers.

DR. JOSEPH LARMOR, lecturer in mathematics in Cambridge University, has been nominated by the council as junior secretary of the Royal Society.

PROFESSOR WILLIAM B. SCOTT, Blair professor of geology at Princeton University, has returned from his visit to the Argentine Republic, where he spent six months in investigations preparatory to his work in publishing the reports of the Princeton Patagonian expeditions.

PROFESSOR E. W. MORLEY, professor of chemistry in Adelbert College, has returned from Paris, where he went to be present at the International Conference of Weights and Measures during October.

DR. MAXWELL SOMMERVILLE, professor of glyptology in the University of Pennsylvania, has returned from an expedition to the Orient. He has brought with him valuable collections, which will soon be added to the great collection which he presented to the museum several years ago.

D. I. BUSHNELL, JR., has returned from St. Louis, where he explored a number of small mounds in that part of Forest Park that is to be occupied by the Fair in 1903. A knowledge of them is thus secured before their total destruction.

AN oil portrait of Dr. Edward G. Janeway was unveiled at the anniversary meeting of the New York Academy of Medicine on November 26. An address was given by Dr. R. H. Fitz, of Harvard University, whose subject was 'Some Surgical Tendencies from a Medical Point of View.'

DR. HERMAN STRECKER, a sculptor and entomologist, died at his home at Reading, Pa., on November 30, aged sixty-five years. Dr. Strecker was the author of a work on 'Native and Exotic Butterflies and Moths,' and owned a collection, said to contain 375,000 specimens.

THE little son of Professor T. D. A. Cockerell died at East Las Vegas from diphtheria on November 25. Though only eight years old, he had made a number of little discoveries of his own. Thus he discovered the larva of *Picris occidentalis*, and raised the butterfly. He also found the first psocid recorded from New Mexico, and collected at least three new insects: a new bee of the genus *Epeolus*, described by Professor Cockerell; a new meloid beetle, now in the National Museum, not yet described; and a new grasshopper of the genus *Melanoplus*, described by Mr. Scudder, and about to be published.

SIR WILLIAM MACCORMAC, the eminent British surgeon, died on November 4, at the age of sixty-five years.

M. GUILLAUME TIBERGHEN, for fifty years professor of philosophy in Brussels University, died on November 28, aged eighty-two years.

THE death is also announced of Dr. Federico Horstman y Cantos, for forty years professor of anatomy in, and for a long time dean of the Medical Faculty of, the University of Havana.

AN examination will be held on January 21, to fill the position of assistant in the Division of Entomology, U. S. Department of Agriculture, at a salary of \$1,200 a year. The chief subject is the economic entomology of the orchard.

THE executive committee of the trustees of the Washington Memorial Institute met at Washington on December 7.

AT a meeting of the council of the Royal Society on November 7, the following resolution was passed: "That in the opinion of this council it is desirable that the secretaries should not be so re-elected as to hold office for a period exceeding ten consecutive years, this resolution not to apply to the present holders of office." A memorial supporting this resolution was signed by 130 fellows, a counter-memorial having the support of less than thirty.

THE twenty-fifth general meeting of the American Chemical Society will be held at Houston Hall, University of Pennsylvania, Philadelphia, Pa., December 30 and 31, 1901. The opening session will be called to order at 10 a. m., Monday, December 30. The visiting

chemists will be welcomed by Dr. J. Merritt Matthews, chairman of the Philadelphia Section; the provost of the University of Pennsylvania, and a representative of the City Government. President F. W. Clarke will address a few words in response. The remainder of the forenoon will be devoted to the reading and discussion of papers and general business. In the afternoon there will be visits to points of special interest under the direction of the local committee. In the evening the address of the retiring president will be delivered at the Acorn Club, 1618 Walnut Street, after which a reception will be given to the members of the Society and their ladies. On Tuesday, a session of the Society will be held in the forenoon. The afternoon will be devoted to visits and excursions, and in the evening there will be a subscription banquet. A meeting of the council will be held at such time and place as may be appointed by the president. The local committee expects to arrange a 'smoker,' if there is opportunity to do so. The committee has not been able to secure special transportation rates, but those who expect to attend may avail themselves of the regular holiday rates which prevail on some of the roads during this season.

DIRECTOR W. W. CAMPBELL, of the Lick Observatory, made public the following report on December 6: "On account of unfavorable conditions observations of the interesting nebula surrounding the new star in Perseus were not obtained for several weeks. The clear sky of last night, just preceding to-day's storm, was taken advantage of by Professor Perrine to secure a photograph of it with the Crossley reflector, exposure five and a half hours. The extraordinary motion in the nebula, discovered by him on November 10 and confirmed by Ritchie, of Yerkes Observatory, on the day following, continues unchanged for the two principal condensations. They have moved outward certainly more than half a minute of an arc in the last three weeks. The third condensation has greatly changed its form, but nevertheless its motion outward appears to continue. The strong mass of nebula nearest the star seems to remain unchanged, both in position and appearance."

A PEARSON CLUB has been organized recently by members of the faculty of the University of California for the discussion of fundamental problems of science suggested by Karl Pearson's 'Grammar of Science.' The membership of sixteen includes representatives from the departments of biology, geology, mathematics, philosophy and physics.

A DESPATCH to the London *Times* from Littleton, New Zealand, states that the National Antarctic Exploration ship *Discovery* arrived here November 29. All on board were well and in good spirits. They state that they entered the pack-ice in lat. 63.5 and long. 141 E., but pressure of time prevented a thorough investigation of the ice. Interesting collections were, however, made during the voyage. A party landed on Macquarie Island for a few hours, obtaining some live penguins, some eggs and some seals. The *Discovery* has been dry-docked for caulking, having sprung a leak, though not a serious one. When the *Discovery* continues her voyage, which will probably be in a fortnight, she will take with her a supply of meat presented by the Canterbury stock farmers.

THE Liverpool School of Tropical Medicine has sent a special expedition under Dr. Charles Balfour Stewart, to the Gold Coast and to the gold-mining districts of that colony, to conduct a series of operations there with a view to improving the conditions of health and sanitation.

THE Russian Pharmaceutical Society, Moscow, has celebrated with appropriate ceremonies the two-hundredth anniversary of the opening of the first free pharmacy in Russia.

THE courts have decided in favor of the ruling of the Treasury Department, which excluded an Irish immigrant suffering from tuberculosis.

THE egg of the great auk continues to bring a large price whenever chance brings one into the market, and the last was sold at the noted auction rooms of J. C. Stevens, London, for 240 guineas. This egg was the last of four owned by the late Baron D'Hamonville, and was peculiarly marked with inky lines and blotches. It was purchased by Mr. Massey, who some years ago paid the record price, 315

guineas, for what is thought to be the best egg of the great auk extant.

THE large tusk of an African elephant, recently noted in SCIENCE as having been purchased by the British Museum, is said to be one of the two shown by Messrs. Tiffany & Company at their rooms in New York. These tusks, whose measurements and weight were given in SCIENCE and have also been noted in Mr. Lucas's 'Animals of the Past' will probably continue to hold the record for elephant tusks.

PRESIDENT FRANCIS, of the Louisiana Purchase Exposition Co., states that the "Washington University site will be enclosed within the limits of the fair grounds, and all the new buildings will be used for the purposes of the exposition. The university grounds comprise about 110 acres, and upon them have been erected during the past two years educational buildings which have cost approximately \$1,000,000. None of these buildings is yet completed, but all now in course of construction will be finished within the next six months. The exposition company will give liberal compensation to the University for the use of its grounds and buildings, but the entire consideration for such use will be put into the erection of additional buildings, and into the embellishment of the grounds for the use of the exposition, thus affording unparalleled advantages for an educational exhibit."

At the meeting of the Zoological Society of London on November 19, Professor E. Ray Lankester, F.R.S., read a memoir on the new African mammal *Okapia johnstoni*. After an account of the history of the discovery of this remarkable animal by Sir Harry Johnston, Professor Lankester gave a description of its skull and skin, based upon the specimens forwarded to the British Museum by the discoverer, and compared its structure with that of the giraffe and the extinct member of the same family, *Helladotherium*. The nearest living ally of the Okapi was undoubtedly the giraffe. Mr. Oldfield Thomas read a paper on the five-horned giraffe obtained by Sir Harry Johnston near Mount Elgon. It was shown that, although the horns were unusually developed, the animal could not be specifically separated from the North-African giraffe, *Giraffa camelopardalis*.

This latter was believed to grade uniformly in the development of the horns and other characters into the South African form, which would therefore be only a subspecies, *G. c. capensis*. On the other hand, de Winton's *G. c. reticulata* (from Somaliland) seemed to be sharply separated, and therefore to be worthy of recognition as a distinct species, *G. reticulata*. With regard to the accessory horns, it was shown that they, or rudiments of them, existed in all male giraffes, even in the southern subspecies.

THE Davenport Academy of Sciences has arranged a course of popular scientific lectures as follows:

January 4—'The Snake Dance of the Mokis': DR. J. WALTER FEWKES, Bureau of Ethnology, Washington, D. C.

January 11—'The Degenerates of Animal Society': PROFESSOR HENRY B. WARD, The University of Nebraska.

January 18—'The Glacial Period in Iowa': PROFESSOR SAMUEL CALVIN, The State University of Iowa.

January 25—'Some Remarkable Members of an Ancient and Highly Distinguished Family': PROFESSOR THOMAS H. MACBRIDE, The State University of Iowa.

February 1—'The Aztecs of Ancient Mexico': PROFESSOR FREDERICK STARR, The University of Chicago.

— 'The Bottom of the Sea': PROFESSOR C. C. NUTTING, The State University of Iowa.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. ANDREW CARNEGIE has offered to give \$10,000,000 to the United States for the purpose of establishing in Washington a national university.

MRS. JANE L. STANFORD completed the transfer to Leland Stanford Junior University, on December 9, of property, consisting of stocks, bonds and real estate, said to be worth approximately \$30,000,000.

MR. JOHN D. ROCKEFELLER has offered to give Bryn Mawr College \$230,000 for the erection of a new dormitory building and a central heating and electric light plant, conditional upon the trustees of the College being able to secure by commencement day, in June, 1902, pledges for the additional sum of \$250,000 needed for a library building. The authorities of the College are taking steps toward raising

the required sum, and President Thomas has already received pledges amounting to \$40,000.

THE University of Pennsylvania has received \$25,000 from Messrs. Keasbey and Mattison for the new medical laboratories, and \$5,000 from Mr. John F. Wentz for the engineering department.

TUFTS COLLEGE receives \$50,000 by the will Mary F. Stearns. The Tuskegee Institute, the Hampton School and Berea College are to divide \$50,000 and the residuary estate.

MR. CARNEGIE promised recently to subscribe £25,000 to the building fund of the Glasgow Technical College on condition that an equal sum was raised from other sources. At the last meeting of the council the chairman announced that he had received two anonymous donations of £25,000 and £10,000 and other sums, making a total of £44,000. The fund, including Mr. Carnegie's subscription, now amounts to nearly £170,000.

THROUGH the generosity of the Frazer family a fellowship in physics (value \$10,000) has been established in the University of Pennsylvania in honor of John Fries Frazer, former professor of natural philosophy in that institution. This fellowship as well as the Hector Tyndale Fellowship in the same subject are now open for application.

THE Thaw fellowship in astronomy at Princeton University, carrying \$500 a year and open to any graduate of not more than five years' standing from an accredited American college, becomes vacant at the close of the present academic year. Applications for it should be sent in before the first of May, addressed to the professor of astronomy.

THE dedication of Cunningham Hall and the Van Wormer Library of the University of Cincinnati will take place in the spring. The building of the Technical School is nearing completion.

THE registration at Harvard University this year and last is as follows :

	1900.	1901.
Harvard College.....	1992	1983
Lawrence Scientific School.....	507	549
Graduate School.....	341	312
Total arts and sciences.....	2840	2844

Divinity School.....	28	37
Law School.....	648	627
Medical School.....	605	506
Dental School.....	126	105
Veterinary School.....	18	...
Bussey Institution.....	33	32
Total professional schools.....	1457	1308
Total University.....	4288	4142

There is thus an increase of 42 students in the Lawrence Scientific School, but a decrease in the other departments, except the Divinity School. The decrease in the Medical School is explained by the fact that this year the bachelor's degree or its equivalent is required for entrance. To the above figures should be added, in order to represent the entire university influence, the following :

	1900.	1901.
Summer schools.....	987	982
Radcliffe College (regular).....	323	334
Radcliffe College (special).....	126	116
Total teachers.....	496	487
Administrative officers.....	97	97
Total University influence.....	6317	6158

To the academic staff of the University of Cincinnati have been added :

C. W. Marx, C.E. (Washington Univ.), recently professor of mechanical engineering in the University of Missouri, professor of mechanical engineering and director of the Technical School.

C. H. Judd, A.B. (Wesleyan), Ph.D. (Leipzig), recently professor of experimental psychology, New York University School of Pedagogy, professor of psychology and pedagogy.

J. E. Ives, Ph.D. (Clark), instructor in physics.

J. F. Snell, A.B. (Toronto), Ph.D. (Cornell), recently assistant in the U. S. Department of Agriculture, instructor in chemistry.

L. L. Waters, A.M., Ph.D. (Columbia), instructor in chemistry.

J. M. Prather, A.B., A.M. (Harvard), Ph.D. (Chicago), recently assistant in Biological Laboratory of the University of Chicago, instructor in biology.

Wm. Osborn, A.M., instructor in biology.

D. T. Wilson, M.A. (Vanderbilt), recently instructor in astronomy in the University of Chicago, instructor in astronomy.

A. B. Griggs, B.S., C.E., instructor in civil engineering.

S. S. Bassler, lecturer on meteorology.

THE NAVAL OBSERVATORY REPORT.

No excuse is necessary for devoting the space we do to this important paper in our present number. We include with it only such portions of the reports of departments as seem to be of general interest. Among these is the very business-like report of the National Almanac Office.

Readers who have followed the discussions of the organization of the observatory which have appeared in our columns during the past year will be interested in this branch of the subject. We trust they will bear with us if we describe the spirit in which we have endeavored to carry on the discussion. We have taken as a fundamental principle that our remarks should be based on official publications and that no heed should be given either to gossip about the interior affairs of the observatory, which circulates so freely, or to supposed leaks through unofficial channels.

The case as thus presented has seemed to us too serious to admit of our indulging in carping, fault-finding or minor criticisms, even had we been disposed to do so. As presented in the report of the board of visitors for 1900 it took the following form : Our government has for more than half

a century been supporting a great national observatory for the promotion of astronomical science. During the last few years this has been done at a cost exceeding that of any other observatory, public or private, in the world. Even the great observatories of Greenwich and Paris, which the two governments have supported in friendly rivalry, do not approach ours in the matter of outlay.

The latter has, at various times during the past twenty years, been reported upon, officially and unofficially, by the highest scientific authorities in the land. Only one voice is heard in these reports. The work of our observatory, considered as a whole, does not come up to any standard of which our country can be proud. The Greenwich and Paris observatories are the pride of their respective nations; ours can inspire no such sentiment. On the cause of this failure the expressions are also unanimous. No reflection is ever heard upon the staff of the institution, which has always been and still is of the ablest. But this alone does not fulfil all the requirements of success. The best instruments and a well-arranged plan of work are also necessary. Above all, the work must be directed with that familiarity with the multifarious details of modern astronomy which our own good sense, as well as the experience and practice of all other nations, show to be necessary to success.

Secretaries of the navy have joined their voices with those of the scientific authorities in calling attention to this want, and asking that it be supplied. But Congress has never made provision for a director of the

observatory, and the work has suffered, and still suffers, in consequence.

Desirous of seeing to what extent the observatory had replied to all these criticisms, we made a careful study of its reports during the last ten years. It required no knowledge of technical astronomy to see that the most serious strictures seemed to be amply justified by them. Especially striking was the defense of the observatory in the report for 1900. A number of alleged weak points were pointed out in the report of the board of visitors, but the serious criticism was ignored, unless an implied denunciation of the whole body of astronomers of established reputation as men 'whose prejudices and animosities were mature and confirmed' could be regarded as a reply.

In our issue of January 4 last, we set forth the main points of the case against the observatory and earnestly invited their consideration by official authority. Our readers will be gratified to see that the head of the observatory has not thought them unworthy of attention. Desiring, as we do, in the interest of fairness and justice, to give the greatest publicity possible to every official defense of the scientific character of the institution, we invite attention to the following passages of the report, premising that we do not imply that this is or is intended to be the best that the author of the passages might say on the subject:

Critics who are in no way responsible for results, and who probably would not carry out their own suggestions if they were, have had a standing grievance against the observatory because it has not put its clocks underground. In point of fact very few

observatories do put their clocks underground. The notable exception is Pulkova.

I invite the attention of the Bureau to Mr. Hill's report, as evidence of the spirit in which the observatory has been (and still is) criticized by outside astronomers. Malice has dictated these criticisms, to my knowledge, for thirty years. In this instance ignorance becomes a valuable accessory.

Leniency in criticism of the quality of the work thus issued is not asked nor expected. Scientific work must stand or fall on its merits. But it would be an encouragement, little to be expected, if the scientific world of this country could appreciate or acknowledge the efforts to bring up to date work long in arrears. Appreciation from abroad is not wanting, and has been gratefully acknowledged.

The passage alluded to in the second extract is the following :

Before proceeding to report upon the observations secured with the instruments I desire to invite the attention of the superintendent to the following extract from SCIENCE for January 11, 1901, page 42 :

We find, also, that the total number of separate observations with the prime vertical transit was 164, less than one-half the number of nights in the year, while those with the altazimuth, used as a zenith telescope, numbered a little more than the days in the year. At the international geodetic stations the observers are expected to make about 16 double observations on every clear night.

Attention is also invited to this extract from the same publication, but of the date of January 4, 1901, page 4 :

There are also intimations that something is wrong with the prime vertical transit, and altogether the impression made on the reader is that, after seven years of effort to equip the observatory with the best instruments, it is doubtful whether a single one of real importance, except the great telescope, is in order for first-class work.

The writer of these editorials in SCIENCE clearly indicates that his conceptions of the amount of astronomical observing to be obtained with an instrument in the prime vertical are absurd.

This betrays a misconception so singular that we must correct it. In our strictures of want of continuity we expressly excepted the work with the prime vertical transit, which has been pursued with rare zeal and

diligence. The passage first quoted from our columns was intended only to show the difficulty that readers might feel in reconciling it with the following striking statement in the report for 1900, which was given a place of honor both there and in the report of the Bureau :

All the astronomical instruments of the observatory have been steadily and continuously in use during the year on every clear night and day.

In energetically showing that the instrument was out of use from April till June, Mr. Hill only impugns the accuracy of this statement, not the correctness of our remarks, which were mere condensations from the observatory report.

The intimations of our second extract comprised allusions to 'a systematic error whose origin still remains a mystery,' and reported efforts to locate this error found in the publications and reports of the observatory. Our 'grave doubts' may be justified by the facts now reported that three other instruments have been undergoing alterations and repairs since we wrote.

A statement has appeared in the public prints that the head of the observatory will reply to the board of visitors. If this is done SCIENCE will be glad, in the interest of fairness and justice, to bring into prominence whatever he can say in defense of his position.

*REPORT OF THE SUPERINTENDENT OF THE
NAVAL OBSERVATORY.**

THE 26-INCH EQUATORIAL TELESCOPE.

THIS instrument has been in charge of Professor T. J. J. See during the whole year. Owing to the death of Mr. George

* Condensed by omitting passages of less general interest than the rest.—EDITOR.

Anderson, who had been assistant on this instrument for twenty-six years, which occurred in November last, and to the absence after February 1 of the party sent out by the observatory to observe the eclipse of the sun in Sumatra, Professor See worked entirely alone for a part of the year. The manual labor alone in using this instrument is considerable, and I consider the showing made in Professor See's report as creditable. This instrument has been devoted to the same general line of work as in previous years, and has been maintained in good order. Professor See's report is herewith transmitted.

THE 9-INCH TRANSIT CIRCLE.

This instrument has been steadily employed on the regular sun, moon, and planet work, a revision of the *Astronomische Gesellschaft* Zones, and the Zone of Zodiacal Stars undertaken for the Paris Astronomical Conference of 1896. From long service this instrument is in need of important repairs. The pivots have become so worn as to need regrinding, and the illumination should be changed so that the reticule will be illuminated by a beam of light in the optical axis of the instrument, instead of a beam cast from one side, as at present. As soon as the alterations of the 6-inch transit circle, which are noted later, are completed, the whole staff for meridian observations will be transferred to that instrument, and the 9-inch transit circle will be put under repairs. The report of Assistant Astronomer King, in charge of the instrument at the close of the fiscal year, is transmitted herewith.

THE 6-INCH TRANSIT CIRCLE.

Since this instrument was mounted two years ago a serious defect in the form of a diurnal change in the constant of azimuth, following changes of temperature, has been a source of annoyance and embarrassment and a serious detriment to the usefulness

of the instrument. Since March last a systematic and patient investigation of this defect has been carried on by Professor Updegraff with the object of determining, and if possible, removing the cause. Successive changes have been made in the instrument and its supports as a result of this investigation, without in any way altering its form (which could not be done without entirely rebuilding it), and there is reason to believe that the success of these changes is already assured.

This instrument was built by Messrs. Warner & Swasey, of Cleveland, Ohio, from designs by Professor William Harkness, U. S. N., following closely the pattern of the latest instruments by Repsold, of Hamburg. It would be presumptuous to criticise the result of the experience of the oldest and most skilful instrument-makers in the world, and yet I can not believe that this form of instrument will ever be entirely free from uncertainty in the errors of azimuth or level, or both, for the reason that in order to assure precision in other respects a principle has been sacrificed which has been recognized as fundamental in the construction of astronomical instruments for at least two hundred years, viz., that the instrument itself should be directly supported on a substantial foundation of masonry. In this form of instrument the pivots are supported by a skeleton work of metal by which they are raised sixteen inches above the piers. Differences in the rate of expansion between the masonry of the piers and the metal support of the pivots become immediately apparent in the azimuth or level of the instrument, and some evidence of this will, I believe, be always apparent. If these errors can be reduced to something manageable under normal conditions, there will still remain the probability that abnormal conditions and sudden and excessive changes of temperature may still make them incon-

veniently apparent. In this connection I may observe that preparations have been made for a south meridian mark for both the 6-inch and 9-inch meridian circles, but no steps have been taken during the year to erect them.

THE CLOCK SYSTEM.

The effort to bring the department of meridian observations, which is the real *raison d'être* of the Observatory itself, to a state of the highest efficiency and up to the most modern standard of requirement, has included not only a thorough overhauling of both meridian instruments, but also an examination, and if possible an improvement in the clock system of the Observatory. Critics who are in no way responsible for results, and who probably would not carry out their own suggestions if they were, have had a standing grievance against the Observatory because it has not put its clocks underground. In point of fact very few observatories do put their clocks underground. The notable exception is Pulkova. It is difficult to maintain a clock underground and not ruin it by rust. The experiment was tried in the very early days of the Naval Observatory and abandoned after the valuable Kessels clock had been nearly sacrificed to the experiment. If, however, a clock can be inclosed in air-tight case from which the air has been partially exhausted, it should be entirely removed from the influences of temperature, pressure and humidity, and it should, theoretically, be as safe in a vault as above ground. This is the principle which has governed the construction of the clock vault of the Naval Observatory. The vault is dug in the basement of the clock house, which stands on the highest eminence in the Observatory grounds, a knoll of quite abrupt grades, of a gravel soil, and so situated that the natural drainage is away from the vault in all directions. The vault is

built with double walls and roof and thick concrete floor, the space between the walls being filled with nonconducting material. The air of the vault is dried by gas and proper provision is made for ventilation. The air-tight cases containing the clocks are of metal and glass, and in each is exposed in full view a rust gauge of bright steel, which is closely watched, and its condition reported to the Superintendent at frequent intervals. The Kessels clock, which is regarded as the standard, is regulated to mean time, and as it is not capable of sustaining the electrical connections necessary for chronometric connection on the clock circuit, it is compared with the sidereal sounder by coincidence of beats by the aid of a microphone. the beats of the clock being wholly inaudible to the unaided ear. So far the whole arrangement has proved on the whole satisfactory, and the rate of the Kessels clock reduced to a constant of almost 0. Some trouble has been experienced in making the clock case actually air-tight, and if the experiment (for I regard it as no more than an experiment) fails, it will be from this cause. Professor Updegraff's report is herewith transmitted.

THE 12-INCH EQUATORIAL.

This instrument has undergone extensive alterations during the year. It was remounted in April, and has been employed in charge of Assistant Astronomer Theo. I. King, since that time. This instrument is used for the benefit of visitors admitted to the Observatory at night.

THE PRIME VERTICAL TRANSIT INSTRUMENT AND 5-INCH ALTAZIMUTH.

These instruments have remained in charge of Assistant Astronomer G. A. Hill, in continuation of the observations for variation of latitude.

I invite the attention of the Bureau to Mr. Hill's report, as evidence of the spirit in which the Observatory has been (and

still is) criticised by outside astronomers. Malice has dictated these criticisms, to my knowledge, for thirty years. In this instance ignorance becomes a valuable accessory.

THE 40-FOOT PHOTO-HELIOGRAPH.

Photographs have been taken of the sun daily whenever the weather and other circumstances would permit. During the absence of the photographer, Mr. George H. Peters, on duty with the eclipse expedition, his place was supplied by Mr. E. A. Boeger, computer.

THE TOTAL SOLAR ECLIPSE OF MAY 18, 1901.

By virtue of a provision of the urgency deficiency bill of the last session of Congress, the Observatory was enabled to equip and put in the field an expedition to the island of Sumatra to observe the total eclipse of the sun of May 18, under charge of Professor A. N. Skinner, U. S. N. Professor Skinner's very interesting preliminary report of the expedition and its results is forwarded herewith. A detailed report will appear in conjunction with a report of the eclipse of May 28, 1900, in a forthcoming volume.

It may very reasonably be asked whether, in view of the meager results on account of cloudy weather on the day of the eclipse, the expense of sending an expedition to such a distance was a justifiable outlay of public money. The reply would be that a chance of failure on account of the weather was one of the conditions which attached unavoidably to the undertaking. Other expeditions were less fortunate and secured no results at all. But the real answer is that results, no matter how meager, fully justify the outlay, because such results are not to be judged by themselves, but are to be regarded as forming a part of the general sum of observations of this and other eclipses. The problems presented will be solved, not by the recorded observations of any one

person at any one time, but by the accumulation of such observations in the general account of human knowledge. From this point of view even one photograph, or a single observation of contact, would have fully justified the entire outlay. At Fort de Kock ten excellent negatives were obtained, which were acknowledged by foreign astronomers to be the best made by any party in the field, and at Solok, the Observatory's other station, contacts were observed and some photographs obtained. I am satisfied with the results.

A serious drawback to the expedition has been the withdrawal for so long a period of an important part of the Observatory's astronomical staff.

An acknowledgement is due the War Department for uniform courtesy to the expedition both on board the transports and at Manila, and to the commanding officer of the U. S. S. *General Alava* for much valuable assistance.

COMPUTATIONS AND PUBLICATIONS.

Since my last report the whole computing force of the Observatory has been assembled in one division, instead of being distributed to the various instruments as heretofore. This change has resulted in a decided economy of time and labor, and is generally in the interests of system and efficiency. All astronomical observations, by whomsoever made, are turned over to the computing division for reduction, it being understood that the author is consulted as to the methods of reduction and exercises a general supervision in cooperation with the officers at the head of the division. Professor Eichelberger has been placed in charge of this division, and in his absence with the Sumatra eclipse expedition his place was supplied by Assistant Astronomer King, up to the close of the fiscal year.

During the year the first volume of the new series of Washington Observations has

been published and distributed. The second volume is ready for the press and will be printed immediately. A third volume is nearly ready, and other volumes will follow as rapidly as the material can be prepared for the printer, and until the accumulation of unpublished work is exhausted. This breaks the long suspension of printing which has been a source of anxiety for several years. Leniency in criticism of the quality of the work thus issued is not asked nor expected. Scientific work must stand or fall on its merits. But it would be an encouragement, little to be expected, if the scientific world of this country could appreciate or acknowledge the efforts to bring up to date work long in arrears. Appreciation from abroad is not wanting, and has been gratefully acknowledged.

NAUTICAL ALMANAC OFFICE.

Professor W. S. Harshman was appointed Director of the Nautical Almanac March 28, 1901. Up to that time and since the retirement of Professor Simon Newcomb the direction had been in the hands of a professor of mathematics who held the post in addition to his regular duties at the Observatory. The Almanac demands the undivided time and attention of a competent director. This need had become imperative. Professor Harshman has had the advantage of long experience in the office in a subordinate capacity. He has systematized and regulated the office and brought the work up to date, the regular issue of the Almanac three years in advance having failed. The office is now in a high state of efficiency, and general harmony and enthusiasm prevail in its staff. The Nautical Almanac has been noted, since its foundation in 1849, for thoroughness and precision in its methods and for superior excellence in its personnel. That this quality is still dominant is shown by the high stand taken by several of its staff in the competitive ex-

aminations for professorships. The report of the Director of the Nautical Almanac is herewith transmitted.

THE BOARD OF VISITORS.

The Board of Visitors established by the naval appropriation act approved March 3, 1901, which went into effect on July 1, met in April, and since that time and prior to July 1, two duly constituted committees of the board have visited the Observatory officially. The law provides for one 'annual visitation to the Observatory at a date to be determined by the Secretary of the Navy, and * * * such other visitations, not exceeding two in number annually, by the full board or by a duly appointed committee as may be deemed needful or expedient by the majority of the board.' The board has already made the full number of visits allowed by law to any one year.

THE DEPARTMENT OF NAUTICAL INSTRUMENTS AND GENERAL STORE-KEEPER AND DEPARTMENT OF CHRONOMETERS AND TIME SERVICE.

By the detachment of Lieut. Commander Charles E. Fox in May, the last remaining officer of these departments was withdrawn, and both of these important departments left without any regularly assigned personnel whatever. The regulations for the government of the Observatory issued by the Department provide for three officers for this work. I believe this situation is unique in the public service. It is hard to make bricks without straw, but that is the situation of these departments at the present time.

As the work could not cease, a computer, previously detailed from the astronomical department has been put in charge of these departments, with one of the clerks of the Observatory in charge of the books. This arrangement is not only improper, but is prejudicial to the service and injurious to

the individual. I have in previous reports made specific recommendations looking to the establishment and maintenance of a permanent force for these departments. I renew these recommendations. The accompanying reports show the volume of business in these departments for the year.

THE PRIME VERTICAL TRANSIT AND THE
ALTAZIMUTH.

Sir: In compliance with paragraph twenty three of the regulations governing the United States Naval Observatory, I respectfully submit the following report of the operations in my department during the year ending June 30, 1901.

Before proceeding to report upon the observations secured with the instruments I desire to invite the attention of the superintendent to the following extract from SCIENCE for January 11, 1901, page 42:

"We find, also, that the total number of separate observations with the prime vertical transit was 164, less than one-half the number of nights in the year, while those with the altazimuth, used as a zenith telescope, numbered a little more than the days in the year. At the international geodetic stations the observers are expected to make about sixteen double observations on every clear night."

Attention is also invited to this extract from the same publication, but of date January 4, 1901, page 4:

"There are also intimations that something is wrong with the prime vertical transit, and altogether the impression made on the reader is that, after seven years of effort to equip the observatory with the best instruments, it is doubtful whether a single one of real importance, except the great telescope, is in order for first-class work."

The writer of these editorials in SCIENCE clearly indicates that his conceptions of the amount of astronomical observing to be ob-

tained with an instrument in the prime vertical are absurd.

Taking up the first extract, I wish to answer it. I was, by orders of the Department, as well as by yourself, detailed last spring as an observer in one of the parties sent south to observe the eclipse of the sun, and for six weeks I was detached from the instrument.

From April 15 to May 1, I was directed to give my whole time to preparing for shipment the apparatus to be used in the eclipse. From May 1 until June 1, 1900, I was at Griffin and Barnesville, Ga., engaged in preparing for the phenomena just mentioned. In addition, I observed at both places on fifteen nights, to determine their latitude and longitude.

The wisdom of the Observatory displayed in having those two fundamental positions determined is well illustrated by the misfortune that came to an observer who went to Africa. He trusted to an approximate latitude and longitude, and found at the instant of the eclipse he was entirely outside of the shadow line.

If the writer of the above extract was only superficially informed of the time necessary to secure a complete observation of a star across the prime vertical, he would not have attempted to make a comparison between the number of observations secured during the same period with the prime vertical and the zenith telescope. It will take about four hours per night to observe sixteen pairs of stars with the zenith telescope, the number usually obtained by those engaged in the variation of latitude work. In the same time it is impossible for anyone using the prime vertical to secure more than four or five, and had the writer consulted an astronomer he would have found that out.

During the past spring I observed practically all night on each in which the sky was clear, and over a tour of observing of

nine or ten hours the largest number of star observations I could possibly obtain was nine or ten.

As an additional answer to his senseless criticism, I would invite the attention of the superintendent to a comparison of the number of observations made with our instrument with that obtained by the only other astronomer who is now continuously observing with the prime vertical transit.

In 1900 I obtained in ten and one-half months observing 164 observations. The observer at Pulkova for the full year made 106. Since 1896 I have secured 1,150 observations. In the same time the prime vertical at Pulkova has yielded 755. This record will be found in Professor Albrecht's report on the variation of latitude for 1900, a copy of which is in the library.

The remarks contained in the second extract are equally absurd.

In justice to our prime vertical transit, I desire here to state that it is of a better form, it is built in a more symmetrical manner, and its mounting permits of determining the errors it may have in a more complete manner than any other now in use.

In 1898 I obtained about 125 observations of α Lyræ in the full daylight, as well as in the night. The range between the greatest and least declination for the whole year's work, including every observation made, and the good, fair, and poor seeing that obtained for each, was 1.44". If four observations are rejected, because they stand out so markedly from the others, made at a time when the seeing was very poor, and so noted in the observing book, the range is reduced to 1.04".

There is not in existence a meridian circle, vertical circle or zenith telescope that has been used to observe the same star or pair of stars, *throughout the year*, that has as small a range as that in the declination, or latitude secured with it. The

probable error of a single observation for that series, including the variation of latitude, is $\pm 0.16''$.

I have during the year made an investigation of the form of the two pivots attached to the instrument. I have examined each throughout the length of its bearing surface in the Y's, and the results, which will be printed in the volume containing the observations secured with the instrument, do not indicate that either pivot is out of parallelism with the cube, or that their departure from a true cylinder is of enough magnitude to affect an observation.

In the past year I have made 619 observations with the aid of both instruments. The reduction of the observations on the sheets, which have all been made by myself, are practically complete to the 1st of January, 1901.

Last fall I made a complete rediscussion of the prime vertical transit observations, basing the derived latitude upon the star places obtained from the New Catalogue of Fundamental Stars, prepared by Professor S. Newcomb. After it was finished the results were transmitted to Professor Albrecht, of the Central Bureau der Internationalen Erdmessung, Potsdam, Germany, to be used by him in his annual paper upon the 'Variation of Latitude.'

From that discussion the following mean yearly latitudes were obtained:

	°	'	"
1894.....	38	55	14.51
1895.....			.52
1896.....			.61
1897.....			.46
1898.....			.45
1899.....			.43
1900.....			.55
Mean.....	38	55	14.50
Reduction to the clock room.....			— .52
Latitude of Naval Observatory.....	38	55	13.98

The individual observations of all prime vertical transits up to December 31, 1899, are now ready for the printer. The intro-

duction to the volume to contain them is three-fourths completed, and will be finished in time to transmit it to the Government Printing Office by the last of July or middle of August.

The 5-inch altazimuth was used during the year principally as a zenith telescope, in connection with the prime vertical transit. I am not making zenith-telescope observations exclusively with it, but only of those stars that are observed with the prime vertical, and which permit of being observed by Talcott's method.

This observatory is the only one in this country equipped with a prime vertical transit and for that very reason the major portion of the data we are securing for the study of the variation of latitude is made with it.

GEORGE A. HILL,
Assistant Astronomer.

ANNUAL REPORT OF THE SECRETARY OF
AGRICULTURE, 1901.

THE Fifth Annual Report of the Secretary of Agriculture, Hon. James Wilson, is considerably longer than in former years, reflecting thereby the great growth and development which has attended this Department during his administration.

WEATHER BUREAU.

He announces an important extension of the forecast field of the Weather Bureau, which now includes reports from certain points in the British Isles and on the continent of Europe, from the Azores, Nassau, Bermuda and Turks' Island. The Atlantic forecasts based upon these reports now form part of the regular night forecasts issued in Washington. Three new forecast districts have been established—in Boston, New Orleans and Denmark. An extension of the forecast to farmers through the Rural Free Delivery is contemplated. Substantial improvements are reported in the De-

partment's system of wireless telegraphy, of which the Secretary states in conclusion :

While there is much experimental work yet to be done before the present system is reliable for inter-ship communication, or before any two systems can work within the same field without each rendering the other useless, such progress has been made by the Government experimenters that, with no interference by private systems, stations can be successfully operated over at least 150 miles of coast line, and they are now in operation on the North Carolina and Virginia coasts, and soon will be instituted between the Farallone Islands and the mainland and Tatoosh Island and the mainland, on the Pacific coast.

ANIMAL INDUSTRY.

A large portion of the report covers the subject of animal industry. The grand total of animals and animal products exported during the year exceeded \$250,000,000 in value. This vast foreign market is only preserved to our producers by the indefatigable efforts of the Department and the rigid inspection exercised through the Bureau of Animal Industry. This Bureau inspected for export 385,000 cattle, 228,000 sheep and 48,000 horses and mules, and nearly 1,000 vessels carrying live-stock. Imported animals were also inspected to the number of 342,000, and, where necessary, quarantined. The Secretary suggests that with the enormous interests our stock-raisers have at stake, and inspection or quarantine affording, after all, a relative, not an absolute guarantee of protection, it might be well for this country to follow the example of Great Britain and exclude live-stock from other countries entirely. The meat-inspection service involved the inspection at time of slaughter of nearly 37,000,000 animals. Of the more than 5,000,000 cattle inspected, the condemned carcasses were about one-fourth of 1 per cent. ; of the 6,500,000 sheep, one-tenth of 1 per cent. ; and of 24,000,000 hogs, one-third of 1 per cent. In the control of indigenous diseases, 1,500,000 inspections were made and over 45,000 cars disinfected in the Texas fever

service alone. In the repression of scabies in sheep nearly 8,000,000 animals were inspected and over 1,000,000 dipped under the supervision of the Department inspectors. In combating the disease known as 'black leg' the Bureau distributed over 1,500,000 doses of vaccine, the result being to reduce losses in affected herds to less than 1 per cent., where formerly it was in most cases about 10 per cent. To aid in detecting tuberculosis in cattle and glanders in horses, over 44,000 doses of tuberculin and 7,000 doses of mallein have been supplied. The Secretary points out the serious evil resulting from a system of State inspection, which, if it became general, would effectually prevent the marketing of live-stock in some sections, and would destroy much of the usefulness of the Federal inspection. He regards the present conditions as so menacing to the interests of the cattle industry in the West and Southwest, that he has requested the Attorney-General to cooperate in bringing the matter before the Supreme Court for decision as to the constitutionality of these State laws. This request has been favorably received and the assistance of the Department of Justice promised.

PLANT INDUSTRY.

The organization of the Bureau of Plant Industry is reported. It has brought together in one group investigations in plant physiology and pathology, botany, grasses and forage plants, pomology, and the experimental gardens and grounds including the experimental farm at Arlington, and the introduction of foreign seeds and plants.

Plant Physiology and Pathology.—Investigations in plant physiology and pathology have been lately devoted to the study of cotton diseases, diseases of orchard fruits, and of forest trees and construction timber. An interesting discovery to cotton-growers is reported of a cowpea resistant to the fungus that destroys the cotton roots. The

cowpea being used in rotation with cotton, the securing a resistant cowpea will be of the greatest possible value to cotton-growers. Remarkable success is reported in experiments in plant-breeding to secure samples of cotton resistant to wilt and other diseases. Numerous valuable hybrids have also been developed. One from an American upland cotton and an Egyptian variety promises to be greatly superior to either parent. The Department has been for several years trying to secure by breeding a race of oranges resistant to frost. A cross of hardy Japanese with the Florida sweet orange has resulted in the hardiest evergreen orange known, and there is promise of ultimately securing a fruit both hardy and of good quality. Considerable success has also been attained in breeding raisin grapes resistant to the disease known as 'coultre.'

Botanical Investigations.—In botanical investigations important work has been done on seeds, improvement of crops, and methods of crop production in our tropical possessions, and prevention of losses to cattle in the West from eating poisonous plants. The low germination of commercial samples of Kentucky blue-grass seed was investigated. It was found that there is a stage in harvesting this seed when heating takes place in the tops of the grass, piled in windrows, which tends to destroy the germination of the seed. This can be avoided by methods of handling the grass, but the Department is experimenting with machinery which will dry the moist seed without permitting it to heat. Comparative experiments regarding the relative value of American and European clover seed give results strongly in favor of the former, at least under conditions prevalent in this country. A remedy has been found which, when promptly administered, is effectual in the treatment of animals poisoned from larkspur and poison camas.

The agricultural conditions of our new possessions are being thoroughly studied, and special attention is being given to the production in these possessions of tropical crops, for which the United States pays out millions of dollars annually. Raising coffee in Porto Rico has been the subject of special study. Our annual importations of this valuable crop now amount to \$70,000,000. The Secretary asserts that much loss has resulted to the cattle industry in the West in recent years, owing to the injudicious management of ranges. The Department's experiments show that much could be done, under proper control, to restore the ranges to their original condition, and he recommends action by Congress, giving the President authority to secure for the experimental needs of his Department such tracts of public range lands as may be necessary.

Pomological Investigations.—The pomological investigations have been especially directed to the extension of the fruit markets abroad and to the encouragement of the domestic production of fruits hitherto largely imported. Prune-growing has been made the subject of special study; also the growing of European grapes in the South. Attention is called to the rapid increase in our exports of apples since the magnificent showing of this fruit made by this Department at the Paris Exposition.

Arlington Farm—Tea Experiments.—Progress is reported in preparing the Arlington farm to serve in conducting experiments, as an adjunct to the Department. The Secretary cordially commends the experimental work now carried on at Summer-ville, S. C., under the direct supervision of Dr. C. U. Shepherd. About 4,500 pounds of high-grade tea, which found a ready market, were produced here during the year.

Introduction of Valuable Seeds and Plants.—Great activity has characterized the intro-

duction of valuable seeds and plants from abroad, with most satisfactory results. The development of the rice industry in Louisiana and Texas since the introduction by the Department of the Japanese rice, during the past three years, has been remarkable. At the same time our imports of this product have decreased from 154,000,000 to 73,000,000 pounds. The United States imports yearly nearly \$800,000 worth of macaroni. Macaroni wheats have been introduced in the past two years very successfully into the Dakotas and also into Kansas and Nebraska. Fully 90 per cent. of the date palms introduced in recent years from Africa are now growing vigorously in Arizona and southern California. This year a collection of the choicest varieties in Egypt have been obtained. Progress is reported in the introduction of Egyptian cotton. The imports of this product now amount to about \$8,000,000 yearly.

Congressional Seed Distribution.—In regard to the Congressional seed distribution, the Secretary states that he has endeavored to meet the wishes of Congress in every way possible and to secure seeds of as high a character as can be obtained under the conditions under which the work is done. It has been arranged to send out cotton seed, tobacco seed, sorghum seed, and sugar-beet seed, and grasses and forage plants, under the direct auspices of the Department, and not through the contractor.

BUREAU OF SOILS.

The Division of Soils has recently been made a Bureau and has received increased financial resources, which enable it to extend its scientific investigations, as well as its practical operations.

Soil Survey.—An extensive review of the work of soil survey shows that the areas surveyed and mapped during the year exceeded 3,500,000 acres, making a total of nearly 6,000,000 acres surveyed during the

past two years. The field work, including preparation of reports, transportation and supplies, has cost an average of \$3.26 per square mile, or about 51 cents per hundred acres. A part of the expense has been paid by state organizations, and effective cooperation has been had with the stations. The demands for soil survey in various parts of the country continue to be received in excess of the ability of the Bureau to comply. The Secretary enumerates sundry important results in the work of the survey, but dwells especially upon what has been achieved in connection with tobacco. Especially successful have been the experiments made by the Bureau in the growing of a fine type of Sumatra leaf on certain soils in the Connecticut Valley. During the past year nearly 43 acres have been grown under the direct control of the Department experts. An interesting feature of the experiment is that the bulk of the cost, estimated at \$20,000, has been invested by the farmers themselves, and it is gratifying to record that their enterprise has been rewarded far beyond their expectations. The recommendations of the Department have also been followed in the methods of curing tobacco in Pennsylvania, with the result of effecting a saving from the ravages of the black rot, exceeding one-half million dollars. Urgent demands for assistance in the tobacco industry have reached the Department from New York, Wisconsin, Texas and Florida. Referring to the reclamation of alkali lands, to which attention has frequently been called in the reports of the soil survey, the Secretary says that he is more and more convinced that to carry the lesson home to the individual it will be necessary for the Department itself to undertake a practical demonstration of the efficiency of drainage. The necessity of a special study of climatology in connection with the soil work is pointed out. "The time has come," says the Secre-

tary, "when the work should be taken up on a scale commensurate with the extension of at least two or three crop interests. It is certain that the immediate benefit to the farmers will amply repay expenditure."

WORK OF THE BUREAU OF CHEMISTRY.

In this Bureau investigations into the composition, nutritive value and adulteration of food products have been continued. This work during the year was devoted particularly to the study of preserved meats, the composition and nutritive value of the preserved article being compared with the original, and the preservatives, if any were employed, determined. Food products imported into this country, and suspected of adulteration or of containing injurious constituents, have also been examined. The Secretary is authorized to inspect, through the Bureau of Chemistry, American food products intended for export. Unfortunately, Congress has not provided appropriations adequate to the proper execution of this law. The Secretary adds that it is important that our food products going abroad be pure and wholesome, and that we should protect our exporters against discrimination in foreign countries.

In connection with the Bureau of Forestry, the chemist is taking up the work of forest chemistry, and is studying forest trees in their relation to the soil and the products they yield. Among the chemical industries immediately dependent on forest productions are the tanning industry, manufacture of wood pulp, production of wood spirit, charcoal and other products. The sugar laboratory of the Bureau continues to study all the chemical problems relating to the production of sugar-producing plants and the manufacture of sugar. The chief part of this work is devoted to the study of sugar beets. The work that the Bureau of Chemistry is doing for other departments of the Government is considerable and con-

stantly increasing. By agreement with the Secretary of the Treasury, the chief of the Bureau has been designated as supervisor of sugar tests in the laboratories of the appraisers in the ports of New York, Philadelphia and Boston. The other departments to which the aid of the Bureau of Chemistry has been extended are the War Department, the Post-Office Department, the State Department and the Department of the Interior.

In cooperation with the Office of Public Road Inquiries, a laboratory for the study of road materials has been organized in the Bureau of Chemistry. The prime object of this laboratory is to aid road-builders in selecting the best available materials in their localities.

WORK OF THE BUREAU OF FORESTRY.

Another of the newly organized bureaus is that of Forestry. The Secretary reports that this Bureau is cooperating with the Federal Government, with several States and many private owners in handling their forest lands. Altogether, assistance has been asked for a total area of 52,000,000 acres, of which 4,000,000 are held by private owners. The work of forest management is reviewed in some detail. During the year nearly 800,000 acres under private owners were examined by representatives of the Bureau, and four detailed working plans, covering 226,000 acres, were prepared. The working plan for the Black Hills forest reserve was completed and working plans were undertaken for the Prescott and Big Horn and the Priest River reserves.

Forest investigations include the study of commercial trees and economic tree-planting, of forest fires, grazing, lumbering, forest productions, and other important lines. The region containing the proposed Appalachian forest reserve was examined in cooperation with the United States Geo-

logical Survey, and nearly 10,000,000 acres were mapped, lands classified and the forests carefully studied. The Secretary regards the creation of the proposed forest reserve as urgent in order to protect the headwaters of important streams, to maintain the already greatly impaired supply of timber and to provide a national recreation ground. Upon the request of the Secretary of the Interior, the effects of grazing and forest fires were investigated on twelve of the forest reserves.

In the study of economic tree-planting in cooperation with farmers and others in making forest plantations, 46,145 acres were examined and plans were prepared for nearly 6,000 acres, while 148,000 applications for tree-planting plans were received.

THE OFFICE OF EXPERIMENT STATIONS.

The Secretary reports, as the result of a broad inquiry made through the Office of Experiment Stations, that by far the largest part of the work of the stations has direct relation to the important agricultural interests of the communities in which they are located.

The work of the stations is becoming better understood by the farmers, and a broader, deeper foundation of scientific inquiry is being laid each year. Cooperation between this Department and the stations continues to increase, and the value of these cooperative methods to the agricultural interests are very generally acknowledged. As a result of the practical confidence so attained, Congress and the State Legislatures have shown a disposition to be liberal with this Department and with the stations. The movement for the separation of the office of director of the station from that of president of the college has advanced, and at present there are but eleven States and Territories in which the college president exercises the functions of director

of the station. At the same time, the amount of teaching required of station officers has been materially reduced.

The experiments of the station in Alaska, with headquarters at Sitka and subsidiary stations at Kenai, on Cook Inlet, and at Rampart, in the Yukon Valley, are regarded as distinctly encouraging. From all the evidence received at the Department, it seems clear that agriculture may be sufficiently established in this Territory to serve as an important aid to the mining, lumbering and fishing industries. During the year a station has been established in Hawaii. Among the first work at this station was the planting of taro, with the special object of studying the diseases seriously affecting that crop. Probably 50 per cent. of the working population in these islands depend on taro for their daily food, and, owing to these diseases and the attendant deterioration of the crop, the price of taro has increased 500 per cent. in the last decade. Some other diseases of fruits and vegetables call for study, and poultry experiments have been inaugurated with a view to increasing the supply of poultry. It is reported that live chickens sell in Honolulu at \$15 a dozen and eggs at 40 and 50 cents a dozen. Hogs bring from 10 to 17 cents a pound on the hoof, and experiments have been undertaken in the feeding of swine with various tubers and roots.

The station at Porto Rico has not yet been fully established, owing to the difficulty of securing suitable land for the purpose. In the meantime, such investigations will be undertaken as can be pursued on lands leased or loaned by persons ready to engage in cooperative work with the station director. Some preliminary investigations in coffee culture have already been arranged for.

The Secretary earnestly recommends that the annual appropriations for all these sta-

tions be increased to \$15,000, the same as the National Government contributes at present to all of the other stations in the various States and Territories.

The Philippines.—He regards it as extremely desirable that agricultural investigations should be undertaken in the Philippine Islands under the War Department and in cooperation with the Department of Agriculture. In furtherance of this work, the Secretary recommends an additional appropriation of \$15,000 for the ensuing fiscal year 'to institute agricultural investigations in the Philippines and, if feasible, to locate and maintain an agricultural experiment station there.'

Agricultural Education.—An increase in college-extension work in agriculture is noted and stress is laid on the movement for the establishment of secondary schools of agriculture and the introduction of the elements of agriculture into the rural schools, as hopeful signs of progress in agricultural education. The Secretary suggests that his Department, already giving aid to rural schools in various ways, should take a still more active part in encouraging this work. He recommends encouragement by distributing seeds and plants to establish school gardens, by furnishing schools with collections of specimens of insects, of plant diseases, and other illustrative material, and by supplying the teachers with such publications of the Department as may be useful to them.

Aid to Farmers' Institutes.—He reviews very fully the great development in the work of farmers' institutes. In 1899 over 2,000 farmers' institutes were held in this country, attended by over half a million farmers. These were held in forty-three States and Territories. The Secretary thinks that there is room for much useful work by his Department in aid of this and other movements for the education of our farmers in the improvement of our agriculture. He

has therefore asked for a special appropriation of \$5,000 to enable the Office of Experiment Stations to enlarge its work with a view to giving definite aid and encouragement to farmers' institutes in the different States.

Nutrition Studies.—The dietary studies and experiments in cooking, digestion and metabolism, have been conducted in various parts of the United States in cooperation with experiment stations, agricultural colleges and universities. The results of nutrition investigations already made should, the Secretary thinks, be practically and beneficially applied to the feeding of men wherever a considerable number of persons are to be fed on a systematic plan. He instances the hospitals for the insane in the State of New York, the annual cost of food for which is over \$1,000,000, and states that of the \$26,000,000 expended for 100,000 persons maintained in the public institutions in New York State alone, \$6,000,000 is expended for food. He urges investigations to determine the best dietary for the use of our soldiers and civil officers in tropical regions, and states that a special appropriation of \$5,000 has been asked for the study of the food supply and consumption of people living in the tropics.

IRRIGATION MATTERS.

The Secretary devotes a great deal of space to a discussion of irrigation investigations. These have been conducted through the Office of Experiment Stations, and embrace (1) studies of irrigation laws and the social and industrial institutions of irrigated agriculture; (2) investigations of the methods by which water is conserved, distributed and used.

Titles to Water.—In reference to the first subject the Secretary states that the character of the titles to water finally recognized will do more than all other influences combined to determine whether the Western

farmers ought to be tenants or proprietors. Naturally, this makes the disposal of the water resources of the West a matter of vital importance not only to the persons directly interested, but to the country at large. Every consideration which justified the general government in the control, the survey, and disposal of public lands, applies equally to the orderly and just establishment of titles to water by public authority, either state or national. He points out the confusion and trouble and almost endless litigation frequently attending the settlement of this question, and declares it to be absolutely necessary that some simple and final method of determining and protecting rights to streams should be provided. In the meantime the conditions, as they exist in arid states, are being carefully studied by the Department.

Improved Instruments.—Irrigation experts of the Departments have designed improved instruments for measuring water, by which registers are now furnished to irrigators at about one-half the cost of the foreign instruments.

Irrigation in Humid Regions.—Attention is directed to the growth of irrigation in the humid regions, and the remarkable fact is stated that in Louisiana more money has been expended on pumping-plants in the past two years than in any arid state. By irrigation, rice-growing in Louisiana and Texas has raised the price of land originally worth \$5 to \$10 per acre to \$50 and even \$100 per acre.

Legislation by Congress.—The Secretary expresses the belief that irrigation will, in the near future, become a subject for legislation by Congress, there being important reasons why it should have the attention of that body. At the same time, he says that those best informed believe that the uncertain character of water rights can only be remedied by a larger measure of public control and the making of certain classes of

irrigation structures permanently public works. These, it is urged, should not be owned by private parties, and the argument produced in favor of constructing reservoirs by act of Congress is the same which justifies setting aside forest reserves and the maintaining of a force to control them. On the other hand, the Secretary points out that an appropriation of money by Congress to construct such irrigation works will bring the country face to face with a new Government policy and will carry a larger measure of public control over the water resources of the West than has hitherto prevailed or been sanctioned by public sentiment.

Land Laws affecting Irrigation.—He reviews the influence of land laws on irrigation development, stating that laws which control the disposal of 500,000,000 acres of arid public lands must have a vital influence upon the success of irrigated agriculture. He condemns the desert-land act, stating that 640 acres is more land than a man of moderate means can cultivate under irrigation. Cutting down the entries from 640 to 320 acres is an improvement, but he believes in the entire repeal of the desert-land act and in requiring settlers or homesteaders to cultivate as well as live on their land.

The Grazing Lands.—Referring to the grazing lands, he says probably 400,000,000 acres of the public domain has no agricultural value except for pasturage. It is at present an open common, with no laws for its protection or disposal. He refers to the frequent conflicts of the farmers under irrigation with the range stockmen, and recommends, as a remedial and beneficial measure, the leasing of the grazing land in such a way as not to interfere with the homesteader. The rentals, he believes, would amount in the aggregate to a large sum, which could be appropriately applied to the reclamation of the irrigable lands.

He points out that such leasing is not an experiment, as it has been successfully tried, although in a limited way, in Colorado, Idaho, Montana, Nebraska, Utah and Wyoming. He winds up the discussion of this subject by presenting the following conclusions:

1. That private enterprise will have to be supplemented by public aid in the construction of certain classes of irrigation works if we are to secure the largest development of Western agriculture.

2. That reservoirs located in the channels of running streams should be public works.

3. That the first step toward national aid for irrigation should be the passage of enlightened codes of water laws by the States to be benefited.

4. That the land laws should be modified by repealing the desert act and by requiring cultivation as well as residence on a homestead.

5. That the non-irrigable grazing lands should be leased in small tracts so as to unite the irrigable and the pasture lands.

WORK IN ENTOMOLOGY.

Under this head the Secretary reports the successful introduction and establishment in California of the fig-fertilizing insect, with the result that it has been thoroughly established at several points, and that the Division of Entomology is now ready to supply fig insects to any grower after he has succeeded in raising to the bearing stage caprifig and Smyrna fig trees. The discovery is reported, by an expert of the Division sent to Asia for the purpose, that the San José scale is not indigenous to Japan, but that it is so in north China. It has been found in a section of that country where there have been no fruit importations, and all fruits are of native sorts. Further, in this district, it was found to have a natural enemy—a ladybird beetle,

of which the expert in question has collected many specimens and forwarded them to Washington, and steps will be taken to acclimatize this important species. This importation will doubtless prove of extreme value to fruit-growers in this country. Another valuable importation of the ladybird beetle was of one which feeds upon several distinct species of plant lice accidentally imported into this country from Europe.

BIOLOGICAL SURVEY.

The Survey is engaged in mapping the natural boundaries of the crop belts of the country. Its aim is to furnish farmers with lists of products likely to be successful, so far as climatic conditions go, in different parts of the country. During the past season the work of mapping the life zones and crop belts has been continued, particularly in Texas and California. A fiber plant, closely related to the Mexican istle or Tampico plant, is found growing in great abundance over a large part of the arid Sonoran zone. In view of the great quantity of fiber of other species of agave imported into this country (\$12,000,000 worth in 1900), the Texas species is likely to prove of great value.

In response to constant complaints, the Survey has prepared and distributed a circular of direction for the destruction of prairie-dogs, and is now conducting experiments in the Dakotas, Nebraska, Kansas and Texas, with a view to discovering remedial measures against this pest, cheap enough for general use. It has been discovered that the bullock oriole and the California least tit feed extensively on the orange and olive. In Texas, the large blackbirds, known as jackdaws, and which have been slaughtered in great numbers for the millinery trade, are particularly useful owing to their feeding habits in the rice and cabbage-growing districts. In addition to its other duties, the Survey is

charged with the general supervision of matters relating to game protection. In aid of the preservation of native birds and game it has published bulletins on the laws governing the transportation and sale of game, digests of State game laws, etc. Carrying out the provisions of the Lacey act, the Secretary acknowledges his obligations to three other executive departments, the Treasury, Interior and Justice, to several railroad and express companies, and to many State officials and individuals. Under the system of permits established for the transportation of foreign wild animals and birds, 186 permits were issued during the year, covering the entry of 350 animals and nearly 10,000 birds. Numerous violations of the laws regulating interstate commerce and game have been reported to the Department and in many instances it has been called upon to assist in prosecuting the offenders.

THE DIVISION OF STATISTICS.

The work of this Division consists largely in the preparation of reports relative to the principal products of the soil, including the extent and geographical distribution of the area of production, the condition and prospects of the crops during the growing season, and the quantity, quality and disposition of the products harvested. It has included also reports on various branches of rural economics, such as transportation, wages of farm labor, cooperation in agricultural industries, etc. An urgent demand exists for broadening the scope of the work of this Division. But this cannot be done without enlarging its appropriations. Telegraphic interchange of crop reports has been arranged for with the governments of some of the principal grain-growing countries of Europe. In furtherance of the plan to place the crop reports in the hands of the farmers as early as possible, a system of cards containing the most important

points of the statistician's monthly report has been adopted. These cards are mailed promptly after the publication of the telegraphic summary to postmasters throughout the country with the request that they be promptly displayed in their offices. The Secretary recommends the enlargement of the Division under Bureau organization.

PUBLIC ROADS.

In establishing an Office of Public Road Inquiries, the object was to promote the improvement of public roads throughout the country. Efforts were first directed to ascertain the condition of the roads, the state of public opinion in regard to their improvement, the obstacles in the way, and the best methods to be employed in securing better roads—such has been the work of this office up to the present. For spreading information and awakening interest, nothing has been found so effectual as the 'object-lesson,' or sample roads, which, during the past year, have been built in nine States under the advice and supervision of the office. In building these sample roads, machines have been loaned by manufacturers and carried free by the railroad companies, while the local community furnishes material and labor. During the year, for the better carrying out of the work of the office, the United States was divided into four divisions, the eastern, middle, western and southern, each under a special agent.

PUBLICATIONS.

In the performance of its duty to diffuse the information acquired through its several Bureaus, Divisions and Offices, the main dependency is upon the issue and distribution of publications. This work, therefore, affords a fair reflex of the intelligence and activity of the investigating branches of the Department. The Secretary deplors the fact that this condition has not been as fully recognized in the appropriations as

it should be, and the work of publication has, therefore, not kept pace with the wonderful growth and development of the Department. He deplors particularly the unavoidable suspension toward the close of the year of the work of both printing and distribution, and that no less than thirty-five worthy employees had to suffer distress by being furloughed through no fault of their own. Notwithstanding these restrictions, there were issued during the year 606 separate publications, aggregating nearly 8,000,000 copies. Nearly 3,500,000 copies were Farmers' Bulletins, of which two thirds in round numbers were distributed under Congressional orders. With the increased appropriation and the accumulated copies, this year's supply of these bulletins will, under the present law, which assigns four-fifths, instead of two-thirds, to the use of Congressmen, make the allowance of each Senator, Representative and Delegate 15,000 copies. A special building has been rented to be devoted exclusively to the storage and shipment of Farmers' Bulletins, of which not less than 7,000,000 will have to be printed this year. The amount provided, however, for material and labor in their distribution is quite inadequate and must be supplemented by a special appropriation, if the demands of Congressmen are to be met. Referring to the great demand for the Year-book and the growth of the Department, the Secretary points out the inadequacy of the quota assigned the Department. When the edition of this work was 300,000 copies, 30,000 were placed at the disposal of the Department, the same as now, notwithstanding that the edition to-day is half a million copies. The demand for the publications of the Department continues to be greatly in excess of its ability to supply. Many of these—over 24,000 copies last year—were sold by the Superintendent of Documents. This is almost three times as many as the

sales made by that officer of the publications of all other Departments of the Government. A special appropriation has been asked for to carry on more effectively the work of illustration, which the condition of the appropriations in recent years has caused to be somewhat neglected. Over 140 persons are employed, including editors, proof-readers, artists, clerks and laborers, in the work of publications, and these are greatly hampered, owing to their segregation in different buildings in crowded and inadequate quarters.

ACCESSIONS TO THE LIBRARY.

Over 4,000 books and pamphlets were added to the Library during the year. These included many books of special value in the work of the Department and a large number of scientific periodicals. Every effort is made in the Library of the Department to meet the demands occasioned by the constantly broadening fields of investigation entered upon by the Department, and to aid educational and scientific workers engaged elsewhere upon kindred work. The Department Library is regarded as the headquarters of agricultural literature, and should be able to meet demands from without as well as within the Department. The Secretary calls attention to the danger of destruction by fire of the 70,000 pamphlets and books now in the Library, owing to the character of the building at present occupied by the Department.

ACCOUNTS AND DISBURSEMENTS.

Congress appropriated \$3,303,500 for the United States Department of Agriculture for the fiscal year ended June 30, 1901, being an increase of \$558,920 over the appropriation for the preceding year. When all accounts shall have been finally settled the payments will amount to about \$3,220,000.

The regular appropriation of \$15,000 for

each of the 48 agricultural experiment stations in the several States was also made.

On June 30, 1901, the unexpended balance of the appropriations for the year 1899, amounting to \$28,899.27, were covered into the Treasury.

During the year \$6,340 was paid for rental of leased buildings in Washington. Owing to inadequate accommodations, Congress, at the last session, provided for the lease of additional buildings, and the rental for the fiscal year 1902 will exceed \$10,000.

EXPORTATION OF AGRICULTURAL PRODUCTS.

The highest record previously attained in the export of agricultural products—in 1898—was surpassed by over \$90,000,000 in the fiscal year of 1901, when a value of over \$950,000,000 was reached. Of the merchandise sent abroad during the year, 65 per cent. originated on the farm. Of foreign customers for our agricultural products, the United Kingdom stands first, taking over 50 per cent. The next most important markets are afforded by Germany, France, the Netherlands and Belgium, in the order named. The Section of Foreign Markets has begun the preparation of a most comprehensive report on the character of our agricultural importations received by the United Kingdom, from countries other than the United States. The importance of this report is evidenced by the fact that, large as were our exports to the United Kingdom, they comprised only one-third of the foreign farm produce purchased by that country. Special statistics have been compiled by the Section of Foreign Markets relative to our trade in farm products with our new insular possessions. Our agricultural exports to Cuba, Porto Rico and the Philippines during the year comprised about 53 per cent. of the domestic merchandise sent to these islands. Our imports of agricultural products from these islands exceeded our exports by just \$30,000,000.

CONCLUSION.

The report concludes with a review of the development of agriculture and commerce during the past twenty years, and of the contributions by the Department of Agriculture to the progress of events and the building up of domestic and foreign trade. The Secretary says that coincident with this growth numerous institutions have grown up in this country and abroad, devoted to the application of science to the service of agriculture, thus creating a great demand, at good salaries, for the right sort of men. Each nation is seeking to extend its productions, and is depending more and more upon the aid of science. Men combining knowledge with practical experience and ability are hard to get, and hence the Department has to face the necessity of paying much higher salaries, or of being compelled to either lose opportunities of getting the best men or to lose some of those who, under its training, have developed such qualities as make them exceptionally valuable.

He concludes by saying that he would urge upon Congress, in the strongest terms and for the best interest of the country, such liberality as will enable him to obtain and retain the best men that can be found to fill the important places at his disposal.

MEMBERSHIP OF THE AMERICAN ASSOCIATION.

THE following have completed their membership in the American Association for the Advancement of Science during the month of November:

Samuel L. Bigelow, Ph.D., Asst. Prof. Chemistry, University of Michigan, Ann Harbor, Mich.

Thos. A. Chittenden, Instr. in Mechanical Engineering, A. & M. College, W. Raleigh, N. C.

Patrick B. Delany, Electrician, Inventor, South Orange, N. J.

Wm. Fox, Asst. Prof. Physics, The College of the City of New York, New York, N. Y.

Manuel R. Gutierrez, Prof. Physics, Normal School, Calle de las Victimas, No. 1, Jalapa, Vera Cruz, Mex.

John J. Hollister, Mining Engineer, Gaviota, Santa Barbara Co., Cal.

John W. Leonard, Author-Lawyer, Wheaton, Ill.
Wm. L. Martin, Augusta, Ga.

George H. Maxwell, Chairman, Natl. Irrigation Ass'n, 1827 Phelps Place, Washington, D. C.

Charles P. Nott, Palo Alto, Cal.

C. Howard Parmly, Asst. Prof. Physics, The College of the City of New York, New York, N. Y.

Wm. B. Potter, Ch. Eng. Ry. Dept. G. E. C., Gen. Elec. Co., Schenectady, N. Y.

Ferdinand A. Schiertz, Rosario Mines Ltd., Guadalupe y Calvo, Chihuahua, Mexico.

Solon Shedd, Prof. Geology and Mining, State Agric. College, Pullman, Wash.

Dr. Edw. G. Spaulding, Instr. Philosophy, The College of the City of New York, New York, N. Y.

Dr. Edw. W. Taylor, Instr. Neuropathology, Harvard Medical School, Boston, Mass.

Jos. B. Tyrrell, Mining Engineer, 181 Metcalfe St., Ottawa, Canada.

SCIENTIFIC BOOKS.

Practical X-Ray Work. By FRANK T. EDDYMAN, B.Sc. (Lond.), F. I. C. London, Scott, Greenwood & Co.; New York, D. Van Nostrand Company. Price, \$4.00.

This little book, as the name indicates, seems to be a thoroughly practical guide for the beginner in X-ray work. As would be expected, the scientific knowledge to be gained by even a careful study of the treatise must be almost entirely empirical. The scope and purpose of such a book quite preclude treating the physics of the subject in any but a statement-of-fact way.

The work is divided logically into three parts; the first part, wisely brief, treats of the history of the development of X-ray practice; the second, of the apparatus and of its management; the third, of practical X-ray work.

It is to be noted that Mr. Eddyman is a physicist and presumably trained in the science of the subject; also that he has charge of the radiographic work in a large hospital, and so has had ample experience in the practical application of X-ray diagnosis in surgical and medical cases. Such a combination is almost necessary if one is to prepare a book of real value on this subject. The author seems to have succeeded admirably, giving only enough of the pure physics to make the application of it intelligible, and

going into the detail of manipulation with great care and thoroughness.

In Chapter II., dealing with sources of electricity, somewhat more space than is necessary seems to be given to primary batteries, since in this country at least such sources of current are seldom if ever found desirable. The use of the alternating-current supply is discouraged rather briefly (p. 42) when we consider that a motor-generator is known to be a very convenient and efficient method of deriving a low-voltage direct current from a higher-voltage alternating source.

A very important point in the design of contact breaks is emphatically presented (p. 66) and exceedingly well explained. It is very desirable that the duration of 'make' be long as compared with the time of 'break'; thus an interval is allowed long enough for the current to reach a maximum value before it is interrupted. Makers quite often pay too little attention to this, and writers frequently ignore it altogether.

The classification of breaks (p. 66) should, in the writer's opinion, include a fifth, viz., mechanical breaks. Such breaks have been used in this country with much success.

In the description of various tubes (Chap. 5), it is a cause of surprise and regret that one or two very effective American tubes are not mentioned. The automatic regulating tube invented by Sayen is used all over the United States and has been highly spoken of abroad by no less authorities than Lord Kelvin and Röntgen himself. The scope and plan of the book in general is such as to commend it to the writer as the best of the few that have yet appeared on the subject.

It should be a very valuable aid to all engaged in X-ray work who have not had much experience of their own, though, as the author clearly states, such personal experience is absolutely necessary to all who would produce reliable results.

Very little seems to be said in Mr. Eddyman's book about the use of X-ray methods in medical diagnosis, though that line has been considerably developed in this country. The results of investigators in all countries except in England seem to have been rather consistently overlooked.

ARTHUR W. GOODSPEED.

Lehrbuch der Meteorologie. Von DR. JULIUS HANN. Leipzig, Tauchnitz. 1901. Royal 8vo. Pp. xiv + 805. Pls. 8. Charts 15. Figs. 111.

That a text-book of meteorology from the hand of the leading meteorologist of the world would be a masterly presentation of the subject was a foregone conclusion. No one is better qualified than Dr. Hann to write such a book. As director of the Hohe Warte in Vienna; professor in the Universities of Vienna and of Graz; editor of the *Meteorologische Zeitschrift*; a life-long original investigator of the widest range of meteorological phenomena; an earnest student of meteorological publications in all languages, Dr. Hann has brought to his latest work a wonderfully rich experience and an amazing fund of knowledge.

The 'Lehrbuch der Meteorologie' is more than a text-book. It is rather a treatise on meteorology. It ranks as a worthy companion to the same author's 'Handbuch der Klimatologie.' The 'Lehrbuch' is not intended to be a 'popular' presentation for beginners, nor is it adapted for general reading. It is a systematic and concise review of the whole subject of meteorology, as complete as is possible within the limits of 800 pages. Nothing of any importance is omitted. Admirable brief historical summaries of the different topics are followed by references to the results of the most recent investigations. So many, so well selected, and so complete are the references, in text and footnotes, that the book is indispensable to every student of meteorology simply as a bibliography. In fact, teacher and student alike will want to have this volume always close at hand, on their desk, or on the nearest shelf of their bookcase.

Since Schmid published his classical 'Lehrbuch der Meteorologie,' in 1860, no author has attempted so complete a presentation of the subject as has been given by Dr. Hann. In its general plan the new 'Lehrbuch' is not unlike that of Schmid, allowing for the natural changes which have resulted from the advance of the science during the last forty years. Schmid's 'Lehrbuch' was a landmark in its time, and is so still, as a classic. Hann's 'Lehrbuch' now occupies, and will continue to occupy, a similar position. Schmid's book was overweighted

with tabular matter and with mathematical discussions. Dr. Hann has very wisely reduced his tabular matter to a minimum, and has devoted an appendix to the consideration of the more important physical theories which involve mathematical treatment. A few of the shorter and simpler formulæ only are included in the general text. By this arrangement the text is unencumbered, and the reading becomes easier and pleasanter. None of the modern text-books of meteorology, of which there are many, attempt to cover the field which Dr. Hann has so successfully covered. Hence no comparison of the new 'Lehrbuch' with these text-books is desirable, or even possible.

There is clearly no need to outline the contents of such a book as that now before us. Throughout, in the arrangement of the contents, the treatment of each subject, and the selection of the references, the hand of the master is clearly seen. If we were to single out one chapter which is likely to be of the most general interest to meteorologists at the present time, it would probably be that dealing with the theory of extra-tropical cyclones, a subject in the discussion of which Dr. Hann has taken a very prominent part, he being a strong advocate of the dynamic theory of the origin of these disturbances. In this country, Mr. H. H. Clayton, of Blue Hill Observatory, and Professor F. H. Bigelow, of the Weather Bureau, have made interesting contributions to this discussion. An excellent summary of the main facts in the case is given, and the position of the author is made clear by the statement (p. 586): "Es soll also hier die Ansicht vertreten werden, dass es zwar atmosphärische Störungen und damit Wirbelbildungen mannigfachen Ursprunges giebt, dass aber die Hauptursache derselben, namentlich aller grösseren und langlebigeren atmosphärischen Wirbel, in den Störungen der grossen atmosphärischen Zirkulation zu suchen sein dürfte."

Americans may well take satisfaction in noting the frequent references made by Dr. Hann to the work of Mr. H. H. Clayton and of his associates at Blue Hill Observatory, and also to that of the Weather Bureau. For a book of the size of this 'Lehrbuch' there are comparatively few illustrations in the way of charts and

weather maps. Since the publication of Bartholomew and Herbertson's new 'Atlas of Meteorology,' however, there is not much need of introducing charts into text-books of meteorology, especially when the books are of such a grade as the present one. There are four half-tone views of clouds; one of lightning; two of hail-stones, and one of a waterspout. This waterspout is the one which occurred off the southern coast of New England on August 19, 1896 (see SCIENCE, N. S., Vol. IV., 1896, p. 718). Isothermal, isanomalous, isobaric, wind and rainfall charts are included.

It is seldom that a reviewer has so pleasing a task as that involved in writing a notice of Hann's 'Lehrbuch der Meteorologie.' The book is a masterpiece.

R. DEC. WARD.

A Manual of Determinative Bacteriology. By F. D. CHESTER, Delaware College Agricultural Experiment Station. N. Y., The Macmillan Co. Price, \$2.60.

Systematic bacteriology is the *bête noir* of the bacteriologist. The amount of confusion which exists in literature regarding the description of species is hardly conceivable. The descriptions are found scattered through an extensive literature; they are sometimes verbose and extended, and at other times brief and insufficient. Anything which looks toward a simplification of this complex problem will always be received with relief by bacteriologists.

The work of Professor Chester is a somewhat modest attempt to give a little assistance in this realm of confusion. It does not pretend to be a study of systematic bacteriology, but rather, as the name indicates, of *determinative* bacteriology. The author has endeavored to collect all species of bacteria which have been sufficiently described for even moderately satisfactory determination, and to arrange these within the limits of one medium-sized book in such a way that they can easily be found. By the use of artificial analytical keys, based upon simple, but important characters, the bacteria which the author includes in his list have been classified into easily distinguishable groups.

The amount of labor which has been involved in the collection and tabulation of these numerous species, about 800 in all, is very great.

Inevitably, also, the work is very uneven. Professor Chester has been obliged to use as his data the descriptions published by the numerous bacteriologists, and inasmuch as these descriptions vary so widely in their accuracy and in the extent of the details given, there is considerable difference in the completeness of the descriptions of species listed. But this, of course, cannot be laid to the fault of the author, but rather to the incompleteness and irregularity of the original descriptions.

Two phases of this work are of especial value, and bacteriologists will owe a debt to Professor Chester for introducing them. The first is the substitution of a new, descriptive word for the long, frequently verbose descriptions which have been widely used by bacteriologists. The single word 'arborescent' is quite as descriptive as the long phrase commonly found in bacteriological descriptions. A careful study of the essential characters of colonies, gelatin growths, etc., has enabled Professor Chester to select a comparatively small number of words which are distinctively characteristic, and which can almost always be used in place of the long paraphrases. This makes it possible to reduce the length of descriptions and to give them in the form of terse sentences, with a few characteristic adjectives. The work of describing species is thus immensely simplified. The second important addition is the arrangement of analytical keys. This, in itself, is one of the most important phases of the work. By the use of these analytical keys it is quite easy to trace any unknown species of bacterium very quickly to its proper place in Professor Chester's list, and then, by further study of a few carefully drawn descriptions, to determine whether the unknown species corresponds with any of those previously described. It is hardly necessary to emphasize the immense value it will be to bacteriologists to have all the known species of bacteria systematically arranged and traceable by means of a skilfully devised key. In these two respects the work of Professor Chester will be of the utmost assistance to bacteriologists.

The author adopts Migula's classification, based upon flagella, and this inevitably makes a part of the arrangement of species uncertain.

A large majority of the descriptions of bacteria in literature contain no reference to flagella. In many cases, therefore, Professor Chester has been forced to infer the presence or absence of flagella, and to classify the organisms to a certain extent in this way by guesswork. Without attempting to criticise the value of a classification based upon flagella, one cannot but deplore the fact that the classification must be based upon characters so difficult to determine. Most bacteriologists are more interested in the physiological aspects of bacterial action than in their structure, and it will be a long time before the students of bacteria will become so familiar with microscopic methods as to be able to describe the distribution of flagella. For species described in past years, and for those described by many bacteriologists for years to come, we must expect that the distribution of flagella will be a subject not attended to with sufficient accuracy to make possible a grouping of the species according to Migula's classification. At all events, in this determinative list of Chester's many of the species are classified without any knowledge of their flagella, and their arrangement into groups, as Professor Chester has arranged them, is, in many cases, therefore, a pure matter of inference.

One other point may raise more criticism. The author has taken the liberty to give names to unnamed species. Where an author refers to a bacterium by number, Chester has given it a name. The original author will, therefore, frequently quite fail to recognize an old friend under a new name. The use of synonyms and a good index of names, however, relieve some of the difficulties arising from this wholesale use of new names.

It is, of course, inevitable that in a work of this sort there will be some omissions. Each bacteriologist who is particularly well acquainted with a certain group of bacteria will, naturally, be able to look through the treatment of Professor Chester and find many points to criticise. Each specialist will, doubtless, find some omission and be inclined to differ with the author in regard to the proper relationship of the species. This, however, is inevitable and does not at all detract from the usefulness

of the work. The work is at best a provisional one, and one which will require constant modification and perfection in future years. On the whole, the work is of a high character and must hereafter form a part of the library of every bacteriological laboratory.

H. W. CONN.

Das Wirbelthierblut in Mikrokristallographischer Hinsicht. Von DR. H. U. KOBERT, mit einem Vorworte von PROFESSOR DR. R. KOBERT. Stuttgart, Ferdinand Enke. 1901. Pp. 118, mit 26 in den Text gedruckten Abbildungen.

The reviewer does not recall any monograph since Preyer's 'Die Blutkrystalle' (1871) which presents the literature on the crystalline derivatives of the blood in the manner of this little book. In view of the medico-legal importance of the microchemical methods for the detection of blood, Dr. Kobert has given in detail numerous directions for obtaining various blood-pigment derivatives in crystalline form; many of these have originally been suggested by the well-known pharmacologist and physiological chemist, Professor R. Kobert of Rostock, to whom the author—his nephew—is largely indebted. While the monograph is intended for physicians and chemists rather than for the crystallographer, purely chemical methods of examination are only considered incidentally. Each chapter concludes with an historical summary of the literature on its subject. Among the topics treated are hemocyanin, in connection with which the reader may now consider the very recent paper by Henze (*Zeitschr. f. Physiol. Chem.*, XXXIII., 370), arterin and phlebin, to prove the independent existence of which (in distinction from oxyhæmoglobin and hæmoglobin) the author devotes considerable space; methæmoglobin and similar compounds; hæmatin and hæmin, with many (in part unpublished) data regarding the so-called Teichmann's crystals; hæmochromogen, of the crystals of which several photomicrographs are reproduced and form a useful addition to the usual textbook description; hæmatoporphyrin, melanins, serum-proteid crystals, hæmosterin and a few other crystalline derivatives.

Dr. Kobert's monograph may properly be studied in connection with Schulz's 'Die Krys-

tallisation von Eiweissstoffen' (reviewed in SCIENCE of November 1, 1901), which likewise deals with the blood proteids.

LAFAYETTE B. MENDEL.

SHEFFIELD SCIENTIFIC SCHOOL
OF YALE UNIVERSITY.

SCIENTIFIC JOURNALS AND ARTICLES.

The Popular Science Monthly for December has for its first article 'A Mechanical Solution of a Literary Problem' by T. C. Mendenhall, this being the noting of the relative frequency with which words of a given number of letters occur in the writings of various authors as compared with Shakespeare. The results were plotted in curves, and the curve derived from the plays of Marlowe was almost identical with that derived from the plays of Shakespeare. Sir Robert Giffen discusses 'The Importance of General Statistical Ideas,' showing the application of Statistics to the solution of such questions as the probable increase of population, food supply, commerce or manufactures. R. T. Glazebrook describes 'The Aims of the National Physical Laboratory of Great Britain' and under the title 'Cement for a Modern Street' S. F. Peckham treats of the progress that has been made in the manufacture of good cements. In 'The Influence of Rainfall on Commerce and Politics' H. Helm Clayton shows that there is a certain periodicity in years of abundant rainfall and consequent plentiful food supply and general prosperity. The political party which chances to be in power during these seasons of plenty assumes the credit for them which is really due to weather conditions. William L. Poteat tells of 'Lucretius and the Evolution Idea' and D. T. MacDougall briefly describes 'The Sensory Mechanism of Plants.' Finally, under the caption 'The Reception of the Origin of Species,' we have a reprint of some of the more noted reviews which appeared shortly after the publication of that work.

Bird Lore for November–December completes the third volume of this magazine, and contains the index for the past year. The number comprises 'Recognition Marks of Birds,' by Ernest Seton-Thompson; 'A Bird of the Season,' by

C. William Beebe; 'Mocking-bird Notes,' by Lucy Gould Baldwin; 'A New Device for Securing Bird's Pictures,' by Frank M. Chapman; 'Bird Life in the Klondike,' by Tappan Adney, and a poem 'On Hearing a Winter Wren Sing in Winter,' by Lynn Ten Sprague. 'Birds and Seasons' now gives place to 'How to Name the Birds,' studies of the families of Passeres, by Frank M. Chapman, the first of a series of papers on identification. In the Department for Young Observers, E. W. Sinnott tells of 'My Bird Restaurant,' while many notes and reviews and an account of the New York meeting of the American Ornithologists' Union complete a large and well-illustrated number. The frontispiece of a ptarmigan on its nest deserves particular mention as a fine example of protective coloration.

The Museums Journal of Great Britain contains a brief but suggestive article by F. W. Rudder 'On the Registration of Type Specimens by Local Scientific Societies,' showing the desirability of having published records of types in the possession of societies or individuals. E. M. Holmes contributes a paper 'On the Arranging and Indexing of Scientific Pamphlets in Museum Libraries,' a subject which has been pretty well worked out in the United States. D. P. H. discusses 'Hygiene as a Subject for Museum Illustration' and there are a large number of notes from many museums in various parts of the world.

SOCIETIES AND ACADEMIES. CALENDAR.

The American Association for the Advancement of Science. A meeting of the council will be held at the Quadrangle Club, University of Chicago, on the afternoon of January 1. Section H (Anthropology) will meet in the Field Columbian Museum, Chicago (December 31 and January 1 and 2). The next regular meeting of the Association will be held at Pittsburg, Pa. (June 28 to July 3). A winter meeting is planned to be held at Washington during the convocation week of 1902-3.

The American Society of Naturalists will hold its annual meeting at the University of Chicago (December 31 and January 1). In conjunction with it will meet the Naturalists of the Central States and several affiliated societies, including the American Morphological Society (beginning on January 1); The American Physiological Society (December 30 and 31);

The American Psychological Association and the Western Philosophical Association (December 31 and January 1 and 2); The Society of American Bacteriologists (December 31 and January 1), and The American Association of Anatomists (December 31 and January 1 and 2).

The Astronomical and Astrophysical Society of America will meet in Washington (beginning on December 30).

The Geological Society of America will meet at Rochester, N. Y. (December 31 and January 1 and 2).

The American Chemical Society will meet at the University of Pennsylvania, Philadelphia (December 30 and 31).

The Society for Plant Morphology and Physiology will hold its fifth annual meeting at Columbia University, New York City (December 31 and January 1 and 2).

WINTER MEETING OF SECTION H, ANTHRO- POLOGY, OF THE AMERICAN ASSOCIA- TION FOR THE ADVANCEMENT OF SCIENCE.

THE Secretary has received the following titles of papers for presentation at the meeting to be held in Chicago, December 31, 1901, and January 1-2, 1902:

'The Beginnings of Anthropology': W J MCGEE.

'Twenty Years of Section H': GEORGE GRANT MACCURDY.

'The Exhibit of Hopi Ceremonies in the Field Columbian Museum': GEORGE A. DORSEY.

'On Some Painted Stone Slabs from the Graves of the Ruins of Walpi': C. L. OWEN.

'Basketry Designs in Northern California': ROLAND B. DIXON.

'Pueblo Indian Settlements near El Paso, Texas': J. WALTER FEWKES.

'Field Work in Arizona, 1901': WALTER HOUGH.

'The Anthropological Work of the Hyde Expedition': ALES HRDLICKA.

'Some Observations concerning the Navaho Blanket Industry': FRANK RUSSELL.

'Certain Forms of Winged-Perforated Slate Objects': WARREN K. MOOREHEAD.

'The Variability of Anthropometric Types': FRANZ BOAS.

'A Voice Tonometer': C. E. SEASHORE.

'The Psychological Elements of Visual Space Orientation About a Horizontal Axis': ROBERT MACDOUGALL.

'The Sherman Anthropological Collection, Holyoke, Mass.': GEORGE GRANT MACCURDY.

'The Significance of the Cross': PAUL CARUS.

SECTION OF ANTHROPOLOGY AND PSYCHOLOGY
OF THE NEW YORK ACADEMY OF SCIENCES.

A MEETING was held on November 25, with Professor Farrand occupying the chair.

Professor Robert MacDougall stated some of the conclusions of an investigation into the 'Combination of Simple Rhythm Groups in Higher Syntheses, and their Equivalences.' He has found that the simplest rhythmic units are always combined into larger groups, provided only the units succeed each other with sufficient rapidity. And these larger groups may be combined into others still larger—a process to which no definite limits can be set. The simplest group of rhythmic units is the pair or dipody, which appears in every rhythmic series that admits of such grouping. The means by which this coupling of the units is accomplished in poetry are: Subordination of the accent of one unit to the accent of the other, differentiation in the intervals, introduction of mid-line and final pauses, catalexis and rhyme. In any sort of rhythm that is objectively expressed, the first unit of a dipody receives the major accent, and also occupies more time than the second unit. Even in a long rhythmic series, there is properly no mere reduplication of units, but each unit fulfils a unique function in the series, in virtue of which it is differentiated from all the other units, in emphasis and duration and also in its internal configuration.

Professor Edward L. Thorndike spoke of some general aspects of the investigation which he is at present carrying on into the correlations amongst mental abilities. He found that regular correlation, where each degree of one function involves a similar degree of the other, is by no means the rule in the case of mental abilities. The relationships are often extremely irregular. For instance a high degree of one ability may go with a high degree of another but all other grades may involve no similarity in the other. A single coefficient of correlation in such cases is of course an absurdity. Correlations seem more marked between complex than between simple abilities. A variation of the Pearson method was outlined, which is well adapted to work with mental correlations and especially with studies involving few cases.

As samples of his results, Dr. Thorndike demonstrated the absence of correlation between certain motor and mental tests, the pronounced correlation between ability to spell and ability to notice the structure of words, the pronounced correlations between school marks in different subjects and the lesser degrees of correlation in the case of objective tests in the same subjects.

Mr. J. Franklin Messenger outlined an 'Experimental Study of Number Perception.' His experiments had reference to the so-called space threshold in tactile sensations, to the fusion of touch sensations, and to the perception of number through touch. The validity of a threshold determined only by the distance apart of the two points applied to the skin was denied, because distance is only one of the elements on which the perception is based, and often not the most important element. The fusion of two tactile sensations was also denied because of such facts as the following, that two points, *one on each hand*, may be perceived as one point when the hands are close together.

The speaker offered a theory of the tactile perception of number. Number is not directly sensed by touch, but is inferred from various peculiarities of the tactile sensation, such as the geometrical arrangement of the stimulating objects, the distance apart of these objects, the contour of the surface stimulated—and also from the preceding sensation and the attitude of the subject.

R. S. WOODWORTH,
Secretary.

TORREY BOTANICAL CLUB.

AT a meeting of the Club at the College of Pharmacy on October 30, the scientific program was opened by a paper by Dr. D. T. MacDougall, entitled, 'Some Characters of Alpine Vegetation.' The paper was illustrated with numerous sheets of mountain plants from Montana, many of them with attached photographs showing the habitat. In the Missoula region where Dr. MacDougall was working this summer, the growing season for many plants was about 40 days only, but the actual light reaching the plants may have been 30 to 40 per cent. greater than at sea level, and with a larger

proportion of blue rays. These mountain tops may be among the driest places on the continent or may contain swamp pockets. There is no distinct type of Alpine vegetation as such; but Alpine plants are really xerophytes, being such plants as have adapted themselves to an insufficient water supply.

Our Alpine plants are often thought to be identical with polar plants. But the polar plant receives light continuously through a long period, though the light is of little intensity. The polar plant has an atmosphere of much greater humidity, but a much colder soil. Polar plants develop much greater thickness of leaf. Alpine plants abound in more numerous protective devices, as waxy coatings, hair, thicker stems, and modes of propagation without seeds. *Poa alpina*, for example, in many mountain regions is never known to flower.

Remarks followed regarding the viviparous state of *Poa alpina*, Dr. Rydberg observing its abundance in Greenland and Spitzbergen, and Miss Isaacs remarking on her collecting it at 7,500 feet altitude during the last summer in Switzerland.

Dr. Underwood called attention to the relative amount of sunlight in tropical and in northern regions, showing that the amount of light is much greater north of the tropics, though more oblique.

Discussion followed regarding relations of moisture. Dr. Schoeney referred to the peculiar erect and densely appressed stems assumed by a cespitose *Opuntia* about Boulder, Colorado. Dr. MacDougal spoke of the remarkable degree to which many of the *Cacti* have adapted themselves to xerophytic conditions, so that they lose water less than $\frac{1}{300}$ as readily as in ordinary plant structures in similar positions.

Dr. Rydberg referred to the permanent moisture found within ten or twelve inches of the surface in the dry sand hills of Nebraska.

The second paper was by Dr. P. A. Rydberg, 'Revisions of *Limnorchis*,' being a study now printing in the *Bulletin*, treating of the former genus *Habenaria* and of segregations accepted from it, including the new genera *Limnorchis*, the green and swamp orchids of the Eastern United States, *Piperia*, *Lysiella* and *Gymnadeniopsis*; and the revival of the genus *Blephari-*

glottis of Rahneseque. The first *Limnorchis* described was Koenig's '*Orchis hyperborea*,' often found in Iceland and Greenland, but rare in America, though sometimes occurring in the cold upper region of New York and Canada. Discussion of synonymy and illustration by numerous specimens accompanied the paper. The diagnostic characters were drawn from the spur, lip and stamens, 24 species of *Limnorchis* and 9 of *Piperia* being recognized.

Reference was made by Mr. G. H. Watson to a remarkable growth near Ellenville, New York, where two trees not only different in species, but in family had so twisted together as to become incorporated, and in response to remarks appreciating its significance, he promised further investigation and a photograph of the trees.

EDWARD S. BURGESS,
Secretary.

SCIENCE CLUB, UNIVERSITY OF WISCONSIN.

AT the November meeting of the University of Wisconsin Science Club, Professor C. S. Schlichter presented a paper on 'A New Method of Determining the Size and Velocity of Underground Streams,' and A. H. Pfund discussed 'The Dispersion and Absorption of Selenium.'

During the past summer Professor Schlichter made preliminary tests, for the Hydrographic Division of the U. S. Geological Survey, of the movement of streams percolating through sands and gravels beneath rivers like the Arkansas and Platte, which, across the semi-arid plains in western Kansas and Nebraska, entirely disappear during the months of July and August. The method devised for these tests was an electrical one which permitted rapid and extensive surveys to be made at low expense. A double row of one and one-half inch drive wells was sunk across the channel of the river. The upstream wells were charged with a strong electrolyte, which dissolved and passed downstream with the underground water. When the chemical reached the lower wells its presence was shown by the deflection of a needle, and the rate of movement was then easily calculated. The underground flowage at the places tested was found to range from 3 to 15 feet per day, and to be fairly constant, not

varying more than 10 per cent. The gradient at such places is 8 to 10 feet per mile.

Professor Schlieter's paper was discussed by Professors C. R. Van Hise, J. B. Johnson, F. W. King, F. E. Turneaure and E. A. Birge.

Mr. Pfund discussed the 'Dispersion and Absorption of Selenium.' By devising a new method for depositing films of the aniline dyes on glass and for photographing the interference fringes produced by a Michelson interferometer, the dispersion of amorphous selenium, a comparatively opaque substance, has been success-fully studied. The refractive index of selenium rises with extraordinary rapidity until at the limit of the photographic field it reaches a value of 3.13, one of the very highest known. In general, the light-absorbing power of selenium lies between that of the aniline dyes and that of the metals. With a small concave grating, it has been found that selenium absorbs light more and more strongly as the end of the ultra-violet spectrum is approached, instead of there being a region of retransmission.

C. K. LEITH.

DISCUSSION AND CORRESPONDENCE.

THE MATHEMATICAL THEORY OF THE TOP, SIMPLIFIED.

TO THE EDITOR OF SCIENCE: Professor A. G. Greenhill has been good enough to show me his terse method of treating the top integrals. As this is a subject on which Professor Greenhill speaks authoritatively, and will interest a number of your readers, in particular his many friends in Sections A and B of the American Association, I suggest that it be published in SCIENCE.

CARL BARUS.

Brown University, Providence R. I.,
November 20, 1901.

Let the vector OH represent the resultant angular momentum of a symmetrical top; spinning about its point O is a small smooth fixed cup, as in the Maxwell top.

Since the axis Og of the torque of gravity is always horizontal H will describe a curve (a Poinso't herpolhode), in a fixed horizontal plane at a height OG above O , the vertical vector OG representing the constant component G of angular momentum about the vertical.

We assume that the component G' of the angular momentum of the top about its axis OC remains constant, as there is nothing to alter it, if the top is symmetrical.

FIG. 1.

Expressed by Euler's angles θ and ψ the vector OH has the components (Figs. 1 and 2)

$$(1) \quad OC = G', \quad CK = A_1 \sin \vartheta \frac{d\psi}{dt}, \quad KH = A_1 \frac{d\vartheta}{dt},$$

A_1 denoting the moment of inertia of the top about an axis through O perpendicular to OC .

The velocity of H is equal to the torque of gravity $Wgh \sin \vartheta$, so that, denoting the polar

FIG. 2.

coordinates of H in the horizontal plane GHK by ρ and π , and resolving in the radial direction GH .

$$(2) \quad \frac{d\rho}{dt} = Wgh \sin \vartheta \cos GHK = Wgh \sin \vartheta \frac{KH}{\rho}$$

$$(3) \quad \rho \frac{d\rho}{dt} = A_1 Wgh \sin \vartheta \frac{d\vartheta}{dt},$$

and integrating,

$$(4) \quad \frac{1}{2} \rho^2 = A_1 Wgh (E - \cos \vartheta).$$

To make the equations homogeneous, put

$$(5) \quad OG = \delta, \quad OC = \delta', \quad 4A_1 Wgh = k^2,$$

so that

$$(6) \quad \rho^2 = \frac{1}{2} k^2 (E - \cos \vartheta).$$

Now denoting the perpendicular GK from G on the tangent at H by p ,

$$(7) \quad p \sin \vartheta = \delta' - \delta \cos \vartheta,$$

so that, eliminating ϑ ,

$$(8) \quad p^2 = \frac{[\delta' k^2 - \delta(Ek^2 - 2\rho^2)]^2}{k^4 - (Ek^2 - 2\rho^2)^2},$$

and this is the characteristic geometrical property of a Poinsoth herpolhode; it also defines the trace of a rolling line of curvature, the intersection of an ellipsoid and a confocal hyperboloid of two sheets, and then δ is the angle between the generating lines of the confocal hyperboloid* of one sheet through H (Darboux).

Since

$$(9) \quad KH^2 = GH^2 - GK^2,$$

$$(10) \quad A_1^2 \left(\frac{d\vartheta}{dt} \right)^2 = 2A_1 Wgh (E - \cos \vartheta) - \frac{(G' - G \cos \vartheta)^2}{\sin^2 \vartheta};$$

and putting $\cos \vartheta = z$, $\frac{Wgh}{A_1} = n^2$,

$$(11) \quad \left(\frac{dz}{dt} \right)^2 = 2n^2 Z,$$

$$(12) \quad Z = (E - z)(1 - z^2) - \frac{(G' - Gz)^2}{2A_1 Wgh} \\ = (E - z)(1 - z^2) - 2 \left(\frac{\delta' - \delta z}{k} \right)^2.$$

Denoting the roots of $Z = 0$ by z_1, z_2, z_3 , and arranging them so that

$$(13) \quad z_1 > 1 > z_2 > z > z_3 > -1,$$

then with $\frac{d\vartheta}{dt}$ positive, $\frac{dz}{dt}$ negative, as in Fig. 1,

$$(14) \quad nt = \int_z^{z_2} \frac{dz}{\sqrt{2Z}},$$

an elliptic integral of the first kind; and, by inversion, z is an elliptic function of t .

To make the reduction to Legendre's standard form, put

* Proc. London Math. Society, XXVI., XXVII.

$$(15) \quad z = z_2 \sin^2 \phi + z_3 \cos^2 \phi,$$

$$(16) \quad z - z_3 = (z_2 - z_3) \sin^2 \phi,$$

$$(17) \quad z_2 - z = (z_2 - z_3) \cos^2 \phi,$$

$$(18) \quad z_1 - z = (z_1 - z_3) \Delta^2 \phi,$$

$$(19) \quad k^2 = \frac{z_2 - z_3}{z_1 - z_3}, \quad k'^2 = \frac{z_1 - z_2}{z_1 - z_3};$$

then

$$(20) \quad nt = \sqrt{\left(\frac{2}{z_1 - z_3} \right)} \int_{\phi}^{\frac{3}{2}\pi} \frac{d\phi}{\Delta \phi} \\ = \sqrt{\left(\frac{2}{z_1 - z_3} \right)} (K - F\phi),$$

$$(21) \quad F\phi = K - mt, \quad mt = \sqrt{\left(\frac{z_1 - z_3}{2} \right)} nt.$$

Then, in Jacobi's notation,

$$(22) \quad \phi = am(K - mt),$$

and in Gudermann's notation,

$$(23) \quad z = z_2 \operatorname{Sn}^2(K - mt) + z_3 \operatorname{Cn}^2(K - mt),$$

the expression of z or $\cos \vartheta$ by elliptic functions of t .

Next, denoting the angle KGH by χ ,

$$(24) \quad \tan \chi = \frac{KH}{GK} = \frac{A_1 \sin \vartheta \frac{d\vartheta}{dt}}{GK \sin \vartheta} \\ = \frac{\sqrt{(2A_1 WghZ)}}{G' - Gz} = \frac{\sqrt{2Z}}{2 \frac{\delta' - \delta z}{k}},$$

$$(25) \quad \sin \vartheta \cos \chi = \frac{G' - Gz}{\sqrt{[2A_1 Wgh(E - z)]}},$$

$$\sin \vartheta \sin \chi = \frac{\sqrt{Z}}{\sqrt{(E - z)}}.$$

Resolving transversely to GH , or rather, taking the moment of the velocity of H round G ,

$$(26) \quad \rho^2 \frac{d\pi}{dt} = Og \cdot GK = Wgh \sin \vartheta \cdot GK \\ = Wgh (G' - G \cos \vartheta)$$

so that, from (6),

$$(27) \quad \frac{d\pi}{dt} = \frac{G' - G^2}{2A_1 (E - z)}$$

$$(28) \quad \pi = \frac{Gt}{2A_1} + \frac{G' - GE}{2A_1} \int \frac{dt}{E - z}$$

$$= \frac{\delta}{k} nt + \frac{\delta' - \delta E}{k} \int_z^{z_2} \frac{dz}{(E - z) \sqrt{2Z}},$$

involving an elliptic integral of the III. kind, and then

$$(29) \quad \psi = \pi - \chi.$$

But the component of the angular momentum round the vertical

$$(30) \quad OC \cos \vartheta + CK \sin \vartheta = G' \cos \vartheta + A_1 \sin^2 \vartheta \frac{d\psi}{dt} = G$$

so that

$$(31) \quad \frac{d\psi}{dt} = \frac{G - G' \cos \vartheta}{A_1 \sin^2 \vartheta} = \frac{G - G'z}{A_1 (1 - z^2)} = \frac{G - G'}{2A_1} \cdot \frac{1}{1 - z} + \frac{G + G'}{2A_1} \cdot \frac{1}{1 + z}$$

which gives ψ as the sum of two elliptic integrals of the III. kind, their addition into a single integral (Legendre) is shown by (23), (29).

The reduction to the Weierstrassian form is effected by putting

$$(32) \quad p\mu - e_a = s - s_a = \frac{1}{2}M^2(z - z_a),$$

where M is a homogeneity factor at our disposal ; and now

$$(33) \quad nt = \int_{s_3}^{s_2} \frac{M ds}{\sqrt{S}}, \quad S = 4(s - s_1)(s - s_2)(s - s_3),$$

$$(34) \quad p'^2 \mu = S = \frac{1}{2}M^2 Z,$$

$$(35) \quad \frac{nt}{M} = \int_{s_3}^{\infty} \frac{ds}{\sqrt{S}} - \int_{s_2}^{\infty} \frac{ds}{\sqrt{S}} = \mu - \omega_2.$$

If v, σ, Σ denote the corresponding values of μ, s, S when $z = E$,

$$(36) \quad pv - p\mu = \frac{1}{2}M^2(E - z)$$

$$(37) \quad pv - e_a = \sigma - s_a = \frac{1}{2}M^2(E - z_a)$$

$$(38) \quad ip'v = -\sqrt{(-\Sigma)} = M^2 \frac{\delta' - \delta E_1}{k}$$

$$(39) \quad z_1 > E > z_2 > z > z_3, \quad s_1 > \sigma > s_2 > s > s_3,$$

so that

$$v = \omega_1 + \psi \omega_3 ;$$

and (28) becomes

$$(40) \quad \pi = \frac{\delta}{k} nt + \frac{1}{2} \int \frac{ip'v dn}{pv - p\mu}$$

with the elliptic integral of the III. kind in the standard form of Weierstrass.

In the steady motion of the top, $\frac{d\vartheta}{dt} = 0, \frac{d\psi}{dt} = \mu$, a constant, H and K coincide, and

$$(41) \quad \rho = GK = OC \sin \vartheta - CK \sin \vartheta = G' \sin \vartheta - A_1 \mu \sin \vartheta \cos \vartheta,$$

$$(42) \quad Wgh \sin \vartheta = \rho \mu = \sin \vartheta (G'\mu - A_1 \mu^2 \cos \vartheta),$$

and dropping the factor $\sin \vartheta$,

$$(43) \quad A_1 \mu^2 \cos \vartheta - G'\mu + Wgh = 0.$$

A. G. GREENHILL.

ORDNANCE COLLEGE,
WOOLWICH, ENG.

CURRENT NOTES ON PHYSIOGRAPHY.

NEW ORDNANCE MAP OF ENGLAND.

THE 'Colored One inch Map of England,' now in process of publication, marks a great improvement on both the old and the new series of the earlier ordnance survey inch-to-a mile maps. Relief is shown by brown hachures, drawn with much accuracy of expression, and by red contours at intervals of 100 feet. Water is in blue, with blue contours in the sea for every 25 feet of depth near shore ; the chief roads are in ochre, woodland on some of the sheets is green, and culture is black. Most of the sheets represent quadrangles measuring 18 miles east and west by 12 miles north and south ; but for southern England the sheets frequently include larger areas, according to some system that is not immediately apparent. Some 130 sheets have now been published, the standard sheets costing a shilling each. While looking over them, local geographical features are brought vividly to mind. The Falmouth sheet, Cornwall, includes the typical drowned valleys of Fal and Helston rivers, open to the sea on the east side of the even uplands back of the Lizard, and of Loe river, closed on the more exposed western coast by Portleven sands, one of the few beaches of this ragged shore line. The contours along the valley sides here and on the neighboring Ivybridge and Boscastel sheets are of much smoother curvature than those that follow the coast, thus showing that the shore line in this district of resistant ancient rocks is in that immature stage of development when its irregularity of detail has become greater than it was in the initial stage. Where the coast consists of weaker Mesozoic rocks, as shown on the Exeter and Sidmouth sheets, a smoother shore line of greater retreat and more mature expression is found. A little further east, where the Bridport and Weymouth sheets join, the long sweeping curve of Chesil bank is finely displayed.

The relations of rivers to their valleys offer some interesting problems. In certain meandering valleys the rivers sweep around the valley curves in a most competent fashion, pressing against their outer banks and demanding an increased breadth of meander belt ; the Torridge in Devonshire (Chulmleigh sheet) and the

Tamar in Cornwall (Tavistock sheet) are of this kind. But it is more common to find the streams incompetent to swing steadily around the curves of their meandering valley floors; the headwaters of the Thames in the Cotswolds offer striking illustrations of this sort. The Evenlode (Oxford sheet) and the Cherwell (Chipping Norton sheet) are typical straggling streams, meandering on so much smaller a scale than their valley that they seem to wander aimlessly about its curving floor. The chief cause of the incompetence of these streams is probably to be found in their loss of volume, from having been beheaded by the (Stratford) Avon; yet some additional cause must be looked for, inasmuch as the Avon, which should be gaining in volume as its obsequent branches increase in length with the retreat of the Cotswold escarpment, is also somewhat incompetent to follow the pattern of its distinctly meandering valley (Worcester and Stratford-on-Avon sheets). No general climatic change towards less rainfall can be appealed to, for the streams cited in Cornwall and Devonshire, as well as certain others in Wales, show no signs of diminished volume by shrinking from the curvature of their valleys. The meanders of the Torridge, above mentioned, are remarkable for their large arc, and for the associated interlocking or dovetailing of the upland spurs that enter the valley meanders. The spurs that enter the meanders of the Evenlode valley appear to have been trimmed and steepened on their up-valley side, the result of the systematic down-valley migration of the river meanders before the decrease of volume took place; the distinctness with which this delicate detail of form is shown being a high tribute to the accuracy of the topographer's work.

HYDROGRAPHY OF THE PARIS BASIN.

The geological structure of the Paris basin has been minutely studied by Dollfus, who makes application of his results in a discussion of the 'Relations entre la structure géologique du bassin de Paris et son hydrographie' (*Ann. de Géogr.*, XI., 1900, 313-339, 413-435, map). The Cretaceous and Tertiary strata that occupy most of the basin have been gently undulated in late Tertiary or in post-Tertiary time; the shallow

synclines and low anticlines generally run northwest-southeast, in accordance with the trend of the more closely folded underlying Paleozoic strata, which appear in Brittany and elsewhere. The author recognizes several classes of streams: consequent, inconsequent, obsequent (the definition of this term does not agree with that given by others) and secant (traversing an anticline); subsequent streams are not explicitly noted. He then shows that many streams of the Paris basin are consequent, inasmuch as they follow synclinal troughs. The Somme is a good example of this class, although it does not drain the whole length of its syncline (p. 317). The eastern part of the syncline is occupied by the Aisne, which is led southward

by the Oise, away from what appears to have been its original westward extension to the Somme; the Oise being secant to several anticlines on its way to the Seine just below Paris. This diversion is ascribed to capture (p. 318), though the causes and proofs of capture are not clearly set forth. The diversion might possibly be consequent on a rise in the floor of the syncline between the Oise and the head of the Somme.

While many examples of consequent synclinal streams are indicated, they are usually of relatively small volume. A number of the larger streams frequently follow oblique courses, seemingly indifferent to the anticlines that lie across their way, and for this inconsequent behavior no full explanation is offered. The antecedent origin of the Meuse through the Ardennes is discarded (p. 330) on what seems insufficient evidence; its gorge is explained as the result

of retrogressive erosion by a Belgian stream, which is thought to have captured the Meuse from an assumed westward course south of the uplands, a process that seems inadmissible in view of the continuity of the Ardennes as a divide elsewhere. The numerous subsequent streams in the eastern part of the Seine system are not recognized as such; and the subsequent valley-lowlands, opened on weak strata, between the cuestas that are maintained by stronger strata, are not regarded as certainly due to differential erosion (p. 326), although no specific reasons are given to justify this scepticism. The Loire, whose former northward course from the Central plateau to the Seine is proved by the distribution of crystalline gravels, is explained as having been turned to its present westward course past the site of Orleans by one of the chief anticlines of the region; but its extension southwest past Blois and Tours seems to have been taken with little regard to the numerous anticlinal and synclinal axes mapped there.

The former northward course of the Loire, as above stated, may perhaps give explanation to the peculiar westward deflection of the Aube, upper Seine and Yonne along a subsequent valley south of the cuesta of *calcaire grossier* to the point where the Loing, a smaller stream, turns their united waters through the cuesta towards Paris. The Loing seems to represent the former course of the Loire. While that large river ran here, one of its subsequent branches might, with more or less aid from differential elevation, naturally enough have captured the Yonne, upper Seine and Aube, which then continued in their deflected course after the Loire had been turned away to the west.

HERCEGOVINA.

A students' excursion from the University of Vienna through Bosnia, Hercegovina and Dalmatia, under Penck's leadership, in the spring of 1899, led that geographer to prepare two essays on the physical features of the region visited ('Geomorphologische Studien aus der Hercegovina,' *Zeitschr. deutsch.-oesterr. Alpenvereins*, XXXI., 1900, 25-41, 'Die Eiszeit auf der Balkenhalbinsel,' *Globus*, LXXVIII., 1900, 133-136, 159-164, 173-178). Strongly folded Mesozoic limestones occupy most of the country traversed.

They have been extensively denuded and in some areas reduced to plains, while elsewhere mountains of strong relief still remain. Some of the latter possess well-defined cirques and moraines of former local glaciers. Large sink-holes abound in the highlands. Much of the upland surface exhibited bare limestone ledges, the typical Karst landscape. The lower course of the Kerka river lies across one of the plains of denudation whose surface evenly truncates the inclined limestone strata; but the plain is now elevated and trenched by the river, and in the young gorge thus formed extensive travertine deposits have produced a beautiful group of falls, back of which stretches a narrow, branching lake. In other cases, dislocation is believed to have accompanied elevation. Many streams that flowed on the surface of the lowlands before their elevation now escape to the sea from enclosed basins by underground passages, reappearing further on in great springs, and thus leaving the uplifted land forms more than usually intact. The undersigned also, as a member of Penck's party, has written a brief account of this 'Excursion in Bosnia, Hercegovina and Dalmatia' (*Bull. Geogr. Soc. Phila.*, III., 1901, 21-50).

W. M. DAVIS.

NOTES ON ENTOMOLOGY.

WITH the coming of the new century we have two new entomological journals. One, entitled *Revue Russe d'Entomologie*, is issued bimonthly by a committee of six editors, several of whom are well known to entomologists. It is a general journal, containing descriptions of new species, synopses, etc., but most of the articles are devoted to the Russian fauna. Each number contains a bibliography of current entomologic literature appertaining to the Russian fauna. The other journal is the *Zeitschrift für systematische Hymenopterologie und Dipterologie*, published by F. W. Konow, of Teschendorf, Germany. Six numbers are to appear each year. Its title indicates its intended scope, but several biologic articles have already appeared in its pages.

It has long been known that the species of *Orina*, a genus of Chrysomelid beetles, were viviparous. Recently Mr. Champion and Dr.

Chapman have investigated this matter,* confirming the previous knowledge, and discovering that one species is ovo-viviparous. They find that the eggs develop into larvæ in the ovarian tubules, and increase in size during their progress down the oviduct. This indicates that fecundation in these insects is not by the usual method; but how is as yet unknown.

Part I., 1901, of the journal of the Hungarian National Museum, *Természetrázi Füzetek*, contains world catalogues of two families of insects. One is 'Catalogus Pipunculidarum,' by C. Kertész, pp. 157-168. It brings the subject down to 1901, and includes 4 genera and 110 species. The other is a 'Catalogus Endomychidarum,' by E. Csiki. It is published as a supplement to the journal, and contains 78 genera and 585 species.

Brauer has issued another part of his 'Beiträge zur Kenntniss der *Muscaria schizometopia*.' † This deals with the synonymy of many species described by Bigot, Macquart and others that belong to genera allied to *Calliphora*. It is prefixed by a table to these genera. Nearly twenty of the species come from the United States, and many more from Mexico. Of especial value are his determinations of the Bigot material.

E. Wasmann has concluded his paper on '*Termitoxenia*,' ‡ in which he deals with the systematic position of the genus. In a previous part he thought it would go in the Stethopathidæ, but now he concludes to erect for it a new family, Termitoxenidæ, intermediate between the Eumyidæ and the Pupipara. It thus falls into Coquillett's superfamily Muscoidea.

An interesting contribution towards the life-history of an eastern mosquito has been published by Miss Nelly Evans.§ She has studied *Culex fatigans*, one of the species known to

* 'Observations on some Species of *Orina*, a Genus of Viviparous and Ovo-viviparous Beetles,' *Trans. Ent. Soc., Lond.*, 1901, pp. 1-19. 2 plates.

† *Sitzungsber. Akad. Wissensch.*, Wien, 1899 (1901), pp. 495-529.

‡ '*Termitoxenia*, ein neues, flugelloses, physogastres Dipteren-genus aus Termitennestern'; part II. *Zeitschr. f. Wissensch. Zool.*, 1901.

§ 'Some Observations on the Life-history of *Culex fatigans*, the Common Grey Mosquito of Lower Bengal,' *Proc. Asiat. Soc. Bengal*, Aug., 1901, pp. 65-67.

attack birds. Specimens were kept a month on fruit; but will not deposit eggs until they have had a meal of blood. Fertilization normally occurs after feeding, but one specimen laid eggs that had been fertilized only before feeding. Egg-boats are laid about four to six days after meal of blood; if the mosquito is again fed, it will deposit again, and some specimens laid five egg-boats. The larval stage lasts twenty days; the pupal stage four days.

Dr. F. Dahl has given an account of the habits of the ants of the Bismarck archipelago.* It is preceded by a systematic article by Professor Forel. Dahl, however, gives tables to the genera and species, both according to structure, and according to nesting habits. He compares the fauna to that of north Germany, and tabulates the species of the latter region according to nest habits. The plates illustrate two remarkable nests. One is of *Camponotus quadriceps* in the stems of a plant. The pith is partially excavated; at places the cavity is enlarged, and there are simple openings to the outside. This does not affect the plant or cause any abnormal growth. The other is a greatly enlarged stem of a plant in which there are many channels and cavities caused by *Iridomyrmex cordatus*.

Dr. G. Enderlein has written on the breathing apparatus of the Gastridæ † (more commonly known as Cæstridæ). In these larvæ, which infest various large animals, respiration is often performed under difficulties, and results in considerable modification of the breathing apparatus. These modifications, which the author describes in considerable detail, are summed up as follows:

1. Complication of the closing apparatus of the stigmata.
2. Elongation of the stigmal cleft.
3. The beginning of air reservoirs.
4. Development of the terminal tracheal structures for the reception of oxygen by the blood.

* 'Das Leben der Ameisen im Bismarck-Archipel,' *Mitt. Zool. Mus. Berlin*, II., hft. 1, pp. 1-70, 2 pls., 1901.

† 'Die Respirationorgane der Gastriden,' *Sitzungsber. Akad. Wiss.*, Wien, May, 1899 (1901), pp. 235-302, 3 pls.

Karl Verhoeff has recently added another number to his series of articles on palæarctic Myriopods.* This part deals with certain points in the morphology, classification and distribution of the Chilopoda. He makes out four pairs of mouth-parts, and five segments in the chilopod head. The systematic part treats of the genera *Bothriogaster*, *Geophilus*, *Cryptops* and *Lithobius*.

Probably no one has studied the varieties of a moth so closely as has Mr. J. A. Clark, who, in a recent article on '*Peronea cristata* Fabr. and its aberrations,' † has elucidated and named no less than sixty-two forms of this British moth. Twenty-five of these aberrations are here described for the first time.

Monographiæ Entomologiæ, No. II., is to be 'A Monograph of the Membraciæ' of the world, by G. W. Buckton. The first part has been issued, is a quarto in size, and contains fifty-six pages and eight colored plates. It is, however, far from a 'monograph'; there are descriptions of many species, but there are many other species listed but not described, and often without reference as to where they were described. One of the new species is from New York. The plates are rather crude.

Every coleopterist should be interested in Mr. H. C. Fall's recent list of Coleoptera from southern California. ‡ Apart from the fact that, next to the New Jersey list, it is the largest local list yet issued, it is of great value because of the notes on habits and variation of the species mentioned. The total number of species runs up to 2,197, included in 826 genera. The long lists of Malachiidæ and Tenebrionidæ are especially marvelous to an eastern collector. Eighty-seven new species are described, and many others indicated, but not fully studied.

Nuttall and Shipley in continuation of their investigations on the structure and habits of

*Anopheles** have given many interesting observations. The recent parts relate to the pupa and imago, and will be of particular value to those interested in the external anatomy of insects. The detailed descriptions of the emergence of the fly from the pupa and of the feeding habits of the imago are especially interesting. In the description of the thorax the authors have followed Brauer in the nomenclature of parts. They consider that the first thoracic spiracle belongs to the mesothorax and not to the prothorax, as several authors have claimed.

Major Ross has issued his 'First Progress Report of the Campaign against Mosquitoes in Sierra Leone.' † This crusade was largely in the nature of an experiment to prove that tropical towns, notorious for mosquitoes and malaria, could be largely freed from these plagues by the adoption of certain sanitary measures. It is almost needless to say that it was successful. Empty tin cans, buckets and broken bottles were gathered, pools and puddles in streets and back yards were drained, and in a few weeks mosquitoes were rarities in Freetown.

NATHAN BANKS.

THE GEOLOGICAL SOCIETY OF AMERICA.

THE fourteenth winter meeting of the Society will be held at Rochester, N. Y., beginning on Tuesday, December 31, in the Geological lecture room, Sibley Hall, University of Rochester. The meeting will be called to order at 10 o'clock a. m. by President Charles D. Walcott. The annual address of the retiring president will probably be given Tuesday evening. The Council will hold an informal session on Monday night to open and count the ballots for officers and fellows, and will meet in formal session at 9 o'clock Tuesday morning. If the weather is favorable short excursions may be planned; one to see the Niagara strata of the Genesee gorge in the northern part of the city, and another to the Pinnacle moraine in the southern edge of the city. Ward's Natural Science Establishment, which is across the street from the University, will provide a lunch

for those Fellows who may wish to visit the Establishment during the noon recess. The president of the University, Dr. Rush Rhees, and the Trustees will tender a reception to the Fellows of the Society at the president's house on Thursday evening, January 2. The customary dinner will be arranged, probably for Wednesday evening.

No special reduction of railroad fare can be secured for the meeting, but during the holiday season reduced rates can usually be obtained from important railroad centers.

*PROGRAM OF AMERICAN SOCIETY OF
NATURALISTS.*

Tuesday, December 31, 1901.

8.00 P. M., Kent Theater, University of Chicago.—Address of welcome, by President W. R. Harper. Lecture by Dr. Leland O. Howard. Subject: 'International Work with Beneficial Insects.'

9.30 P. M., the President's House.—A Reception to all the Societies, by President Harper.

Wednesday, January 1, 1902.

2.00 P. M., Kent Theater.—Business meeting.

3.00 P. M., Kent Theater.—Discussion. Subject: 'The Relation of the American Society of Naturalists to other Scientific Societies.' Charles Sedgwick Minot, Harvard Medical School; C. B. Davenport, University of Chicago; W J McGee, Washington; William Trelease, Washington University, St. Louis; E. A. Birge, University of Wisconsin; J. McKeen Cattell, Columbia University.

6.45 P. M., Auditorium Hotel.—Business meeting.

7.00 P. M., Auditorium Hotel.—Annual dinner. Address of the President, Professor William T. Sedgwick, 'The Modern Subjection of Science and Education to Propaganda.'

LOCAL COMMITTEES.

Executive.—C. B. Davenport, Chairman; E. O. Jordan, Secretary; W. A. Locy, Treasurer; L. F. Barker, C. R. Barnes, John M. Coulter, John Dewey, H. H. Donaldson, G. A. Dorsey, F. R. Lillie, Jacques Loeb, E. P. Lyon, C. O. Whitman.

Reception.—H. H. Donaldson, Chairman; C. W. Andrews, Miss Helen Culver, W. R. Harper, Mrs. Martin A. Ryerson, G. C. Walker, Mrs. Coonly-Ward, C. O. Whitman.

Transportation.—Frederick J. V. Skiff, Chairman; G. A. Dorsey, F. R. Lillie, Willard A. Smith.

General.—C. M. Child, C. B. Davenport, George Dreyer, John Dewey, H. H. Donaldson, G. A. Dorsey, W. S. Hall, L. Hektoen, E. O. Jordan, F. R. Lillie, W. A. Locy, Jacques Loeb, A. P. Matthews, A. R. Reynolds, C. O. Whitman.

RAILROADS.

The New England Passenger Association, the Trunk Line, the Central and the Western Passenger Associations have granted the usual reduction (one and one third fares for the round trip) to those attending the meeting and provided with 'certificates.' The certificates, not transferable, must be obtained from the ticket agent at the starting-point (or, if the starting-point is not an important station, at the nearest station issuing certificates) to the place of meeting, at least thirty minutes before the train leaves. The going ticket may be purchased not earlier than December 26 or later than December 31. The certificate must state that the object of making the journey is to attend the meeting of the Affiliated Scientific Societies at Chicago, and they must be signed on December 31, January 1 or January 2, by Dr. L. W. Williams and by the special railway agent in attendance at the meetings on these three days.

SCIENTIFIC NOTES AND NEWS.

It is announced by cablegram from Stockholm that the Nobel prize in medicine has been awarded to Professor Behring, the prize in physics to Professor Röntgen and the prize in chemistry to Professor Vau't Hoff. The value of each of the prizes is about \$40,000. The prize for the promotion of peace has been divided between Dr. Dumant and M. Passy, and the prize in literature has been awarded to M. Prudhomme.

THE Symons gold medal of the Royal Meteorological Society has been awarded to Dr. Alexander Buchan, F.R.S.

PROFESSOR ALFRED C. HADDON, of Cambridge University, lectured before the New York Academy of Sciences and the American Ethnological Society on December 11, his subject being 'The Ethnography of British New Guinea.' Professor Haddon sailed for England on December 14.

THE Academy of Natural Sciences of Philadelphia, has nominated Professor E. G. Conklin, of the Biological Department of the University of Pennsylvania, for vice-president; and Dr. J. P. Moore, of the same department, for corresponding secretary.

SIR WILLIAM ROBERTS-AUSTEN, K.C.B., F.R.S., will deliver the tenth 'James Forrest' lecture at the Institution of Civil Engineers on April 17, 1902, the subject being 'Metallurgy in Relation to Engineering.'

DR. N. SIEBER-SCHUMOW, a woman, has been temporarily appointed to fill the place of the late Professor Nencki as head of the Department of Biological Chemistry in the Imperial Institute of Experimental Medicine, St. Petersburg.

THE Board of Overseers of Harvard College has voted that 'a joint committee of the corporation and this board be appointed to confer with Mr. Alexander Agassiz and request him to sit for a portrait to be placed in the museum as a gift from friends of his and of the university, there to remain a memorial of the great service rendered by Professor Agassiz to that department.'

AN oil painting of Professor John Johnson, LL.D., who was professor of natural science at Wesleyan University from 1837 to 1879, has been presented to the library.

As a memorial of the late Professor Dickson, there have been presented to the Glasgow University library 388 volumes of Migne's 'Pathology,' a work which Dr. Dickson long desired to acquire for the library.

A PORTRAIT of Mr. G. D. Liveing, professor of chemistry at Cambridge University, was presented to St. John's College on December 7, as a testimonial in recognition of his valuable services to science, to the university and to the town. The portrait, which is by Sir George Reid, is of three quarters length. Arrange-

ments have also been made for a bronze bust of Professor Liveing, by Miss Edith Bateson, which will be placed in the chemical laboratory during next year.

DR. CHARLES J. ESSIG, professor in the dental department of the University of Pennsylvania, has died at the age of seventy-four years. In 1878 he organized the dental department of the University of Pennsylvania, and was for many years its dean and secretary. He was the editor of 'The American Text-Book of Prosthetic Dentistry,' and the author of a well-known treatise on dental metallurgy.

MR. WILLIAM RICH HUTTON, a well-known civil engineer, died on December 11 at the age of seventy-five. He was a member of the American Society of Civil Engineers, the Institution of Civil Engineers of London and of the Société des Ingénieurs Civils de France.

MISS H. M. GOULD has given \$5,000 to New York University for the establishment of a museum of pedagogy, with the understanding that this should be applied in the first place to an exhibit of the work done for education by New York University, and that this should form an exhibit at the World's Fair at St. Louis in 1903, and afterwards become the property of the School of Pedagogy.

THE Association of American Universities will hold its annual meeting at Chicago, during the last week of February next.

AN election for officers of the Botanical Section of the Academy of Natural Sciences of Philadelphia, December 9, 1901, resulted in the choice of the following persons: *Director*, Benj. H. Smith; *Vice-Director*, Joseph Crawford; *Corresponding Secretary*, John T. Pennypacker; *Recorder*, John W. Harshberger; *Treasurer and Curator*, Stewardson Brown; *Directors*, Benj. H. Smith, Joseph Crawford, Stewardson Brown, Ida A. Keller, John T. Pennypacker.

MR. FREDERIC A. LUCAS, curator of the Division of Comparative Anatomy at the U. S. National Museum, lectured before the Woman's College of Baltimore, December 3, on 'Dinosauria.' Sir Robert Ball, of the University of Cambridge, Eng., lectured on December 6, his subject being 'Other Worlds than Ours.'

AMONG the lecturers before the Technology Club of the Massachusetts Institute are Dr. Ira Remsen, president of the Johns Hopkins University (Dec. 12); Professor George E. Hale, director of the Yerkes Observatory (Jan. 3); Professor Arthur A. Noyse (Feb. 18); Mr. William Barclay Parsons, chief engineer of the New York subway (Feb. 26); Mr. F. H. Newell, chief hydrographer, United States Geological Survey (Mar. 3).

THREE additional lectures on archeology have been arranged for December at the University of Pennsylvania. The first one will be on 'The Archeology of Michigan,' by Mr. Harlan I. Smith, of the American Museum of Natural History, New York. The second by Stewart Culin on 'Archeological Notes on the John Wanamaker Expedition of 1901.' The last lecture before the holidays will be on 'The Cliff Dwellers and their Relations,' by Dr. J. Walter Fewkes, of the United States Bureau of Ethnology, Washington, D. C.

It is announced that Boothia Felix has been chosen as the headquarters for Professor Amundsen's three-year magnetic pole expedition. Boothia Felix is a peninsula, and is the most northern part of the mainland of North America, having east, Boothia Gulf; north, Bellot Strait, and west, Franklin Channel. The magnetic pole is in this peninsula, the northern point of which is in about latitude 72 degrees north.

AN assistant is wanted for the respiration calorimeter experiments and other nutrition investigations in the chemical laboratory of Wesleyan University and for work in the collating of results of foreign inquiry and preparing reports for publication. A chemist or physiologist, or better, a physiological chemist, of university training, preferably a Ph.D. or M.D., is desired. Scholarly spirit, ability for independent research, familiarity with German, French and other chemical and physiological literature, or, at least, the capability of becoming familiar with such literature are important. A man capable of becoming a university professor or director of a scientific establishment is desired. The salary at the outset will be from \$1,000 to \$1,500, according to the qualifications, with the

chance of increase to that of an associate professorship or professorship. There may also be a second position for a man of similar abilities and academic training but with less experience and correspondingly smaller salary, very probably the equivalent of a fellowship, with opportunities for study and advancement. The work is connected with the inquiries regarding the food and nutrition of man which is being carried on under the auspices of the U. S. Government in universities, colleges and experiment stations in all parts of the country and has its headquarters at Wesleyan University. The association with a number of trained specialists, the atmosphere of research, unusual library facilities and opportunity for experimental inquiry, study and advancement make the positions very desirable for young and ambitious men. Applications for either of the above positions may be made to Professor W. O. Atwater, Wesleyan University, Middletown, Conn.

THE United States Geological Survey has in press a work entitled 'Bibliography and Catalogue of the Fossil Vertebrates of North America,' by O. P. Hay. It contains a list of about 4,100 papers which bear on the fossil vertebrates of North America and a systematic list of all the species that have been described. Furthermore, there goes with each species citations of all the works in which it has been described and discussed. An estimate shows that there are altogether about 40,000 citations. The book forms bulletin No. 179 of the Survey, and will be issued probably early in the coming year.

HENRY S. CARHART, professor of physics in the University of Michigan, and Horatio N. Chute, instructor in physics in the Ann Arbor high school, are writing a new work on physics, which will be completed in about two months. The work will be called 'High School Physics.'

THE London *Times* states that Dr. Charles Balfour Stewart has proceeded to Sierra Leone under the auspices of the Liverpool School of Tropical Medicine to study the methods successfully utilized by Dr. Logan Taylor in dealing with malaria. Dr. Balfour Stewart has had considerable experience in India, and the knowledge he there acquired proved very ser-

viceable on the recent appearance of plague in Liverpool. Now he intends to commence his attack on malaria at Cape Coast Castle, where there is great mortality among Europeans. Under Major Ross he will have the general direction of operations for improving the drainage and general sanitary conditions of Cape Coast Castle, clearing away the stagnant pools which are breeding-places for the *Anopheles* mosquito. Though Dr. Balfour Stewart has been engaged for a year by the Liverpool School of Tropical Medicine, he will, it is expected, remain on the West Coast while his help is needed to place the sanitary conditions of the colony on a satisfactory basis. He also contemplates operations in the mining districts, but will be guided by the advice of the Governor of the Gold Coast. Thus the sanitary crusade against malaria will shortly be in operation on the whole coast from the Gambia to Lagos.

MR. A. MONTEFIORE PRICE writes to the *London Times* as follows: "Now that the more serious work of the British Association is over it may perhaps interest your readers if I draw attention to some curious examples of science adapted to heraldry. I derive them from the banners and bannerets which have been hanging up in the reception room of the British Association at Glasgow during the past week. The banner, for example, of Sir William Huggins, who was president at the Cardiff meeting, 1891, shows the solar spectrum for a crest and the constellation of Orion for a coat of arms. That of Sir William Crookes presents a radiometer and three prisms, together with the quaint motto 'Ubi crux ibi lux.' Herschel was president of the meeting at Cambridge so long ago as 1845, and on his arms there appropriately appear the sun in the chief and a telescope in the base. Sir William Turner, who presided last year at Bradford, bears as a charge a wheel; Siemens blazons what is apparently a beetroot—he was interested, I believe, in sugar produced from that source, and Sir Roderick Murchison, who was president at Southampton so long ago as 1848, a pecten shell—suitably enough for so a great geologist. Sir William Flower's banner shows a coat bearing a cinquefoil and the punning motto 'Et flores et fruches.' Lord Lister (Liverpool, 1895) blazons the staff

and serpent or Æsculapius; Dawson, who presided at Birmingham in 1886, has three daws on his coat; and Sir George Airy (Ipswich, 1851), Sir Henry Roscoe (Manchester), and Sir Michael Foster (Dover) display the arms of those towns and presumably did not possess personal arms."

WE learn from the *London Times* that the business and finance committee of the general council of Edinburgh University has prepared a report on the subject of the Carnegie Trust. It says that chairs in the University founded long ago embrace nominally many subjects which, if they are to be followed beyond their elementary stages cannot profitably be now taught by one man. It may be possible for a professor to give systematic instruction over the whole subject to ordinary students, but for the purpose of higher study and research by the professor and the advanced students there is now great urgency, if not for splitting up the subject, at least for the creation of junior associate professorships to relieve the pressure and to enable more personal practical instruction to be given to the students. Any such professorships instituted by the Carnegie Trust might, therefore, with great advantage be attached to the four universities in common, subject to some new arrangement. Many benefits, besides the obvious one of economy, would accrue from the introduction of community and reciprocity as working ideas into Scottish university life. One of the foremost claims upon the trustees will be to strengthen the modern language departments in each of the universities. Traveling scholarships would be a great incentive and benefit to students. Research in medicine and science demands a large portion of the immediately available income in the hands of the Carnegie trustees. What have been required for long are special research laboratories in which higher students would in the first instance be trained in the methods and apparatus of research. Mr. Carnegie's position as a founder of libraries is a guarantee that the University libraries will receive adequate consideration at the hands of the trustees. With regard to the payment of University class fees the report says that the scheme should give a great impetus to education throughout the country. Some such

stimulus has been needed, as of late the number of university students has tended to decrease. The committee further presents an interim report on the decrease of students pending a fuller investigation which is to include the other Scottish universities and English and foreign schools. In Edinburgh the number of students continuously decreased from 3,576 in 1889-90 to 2,825 in 1895-96, above and below which figure they have fluctuated but slightly.

THE Royal British Commission on Tuberculosis is now sitting in London. The experimental part of its work will be carried out near Stansted, in Essex, on two farms that have been placed at the disposal of the commission by Sir James Blyth.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. JOHN D. ROCKEFELLER, has made a further gift of \$1,250,000 to the University of Chicago, making the total amount given by him \$10,251,000.

By the recent death of Mrs. Anne Wentworth, of Lowell, Mass., Dartmouth College will, it is said, come into the possession of an estate worth about \$500,000, bequeathed to it by Tappan Wentworth.

WESLEYAN UNIVERSITY has secured \$100,000 which will be used for an administration building, and \$25,000 toward a fund for the building of an observatory and scientific laboratories.

It is reported that Mr. Carnegie will liberally endow the Carnegie Laboratory of Engineering of the Stevens Institute on the occasion of the dedication on February 6.

DR. PURDIE, professor of chemistry in St. Andrews University, has offered the University a gift of £5,000 for the purpose of building and equipping a small chemical research department at St. Andrews. In his letter to Principal Donaldson intimating the gift, Professor Purdie says that their universities are very poorly provided for research when compared with those of foreign countries, and that scientific industries suffer in consequence.

THE physical laboratory of the University of Michigan will be enlarged next year by taking in the third floor of the building, which has

hitherto been devoted to bacteriology, and possibly by the addition of a large lecture room to seat 300 persons. The present capacity of the building is insufficient to accommodate the 500 students who are taking courses in physics.

FIRE of unknown origin destroyed the main building of the University of Wooster. The loss is estimated at \$250,000, with insurance of about \$70,000. It is supposed that an explosion of chemicals in one of the laboratories was the cause.

THE registration at the Sheffield Scientific School of Yale University this year and last is as follows:

	1900-1901	1901-1902
Graduate Students	105	133
Seniors	134	128
Juniors	143	143
Freshmen	199	245
Special Students	29	26
	<u>610</u>	<u>675</u>

There is thus an increase of 65 students, especially noticeable being the increase in the number of graduate students and of the Freshman class.

The number of dental students in America from foreign countries is increasing every year. In the dental department of the University of Pennsylvania this year 80 of the 364 registered students are foreigners, representing a large number of nationalities.

MR. JOHN A. BRASHEAR has been elected Chancellor of the University of Western Pennsylvania. Mr. Brashear was last year vice-president of the American Association for the Advancement of Science and chairman of the Section of Mechanical Science and Engineering.

DR. HENRY LEFAVOUR, professor of physics at Williams College, and dean of the faculty, has been elected president of the newly-organized Simmons College for Women at Boston.

PROFESSOR E. G. HARRIS, of the Missouri School of Mines, has been elected professor of civil engineering in the University of Pennsylvania.

DR. THEODORE W. RICHARDS has been elected full professor of chemistry at Harvard University. It will be remembered that Professor Richards was recently called to a chair of chemistry at Göttingen.

REPORT OF THE COMMITTEE ON CONVOCATION WEEK.

THE Committee on Convocation Week has continued its work and has secured the allegiance of a large number of important educational institutions to the plan. The proposal has been so generally accepted and has met with such cordial approval that the committee regards its permanent success as secured.

It will be remembered that the first step taken was to communicate to the Association of American Universities, on behalf of the American Association for the Advancement of Science, the proposition to establish the week in which the first of January falls as Convocation Week, to be set aside for the meetings of national scientific and learned societies. The Association of Universities formally recommended by a unanimous vote the adoption of this proposition, and it has since been adopted by nearly all the universities belonging to that association.

A report of the progress made was published by the committee in SCIENCE, N. S. Vol. XIII, p. 641, and in the same journal, Vol. XIII, p. 996, appeared an editorial article advocating the plan for a convocation week, and defining some of its advantages. The Committee has had its report and the

editorial reprinted for its use, and has distributed copies to the governing bodies of numerous universities and colleges.

At its recent Denver meeting the American Association voted to hold its next meeting at Pittsburg, beginning June 28, 1902, but to hold a special meeting of the Council at Chicago during Convocation Week, 1901-02, and to authorize any section of the Association to organize a meeting at the same time and place. This was the first formal adoption of Convocation Week for scientific meetings. The Association further voted to recommend to its present Council to hold a regular meeting of the Association during Convocation Week, 1902-3, at Washington. Since then important advances have been made in the development of the plan in two ways:

First, it is to be reported that Convocation Week this year will be immediately utilized for the meetings of national societies, the following having already voted to hold their meetings during that period:

The Council of the American Association for the Advancement of Science.

The American Society of Naturalists.

The American Morphological Society.

The Association of American Anatomists.

The American Physiological Society.

The American Psychological Association.

The Western Philosophical Society.

The Society of American Bacteriologists.

The Botanists of the Central and Western States.

The American Folk Lore Society.

Section H (Anthropology), American Association for the Advancement of Science.

The American Chemical Society.

The Astronomical and Astrophysical Society of America.

The Geological Society of America.

The Society for Plant Morphology and Physiology.

The American Historical Society.

The American Economic Association.

Second, it is to be reported that the Committee has sent a formal communication to the president of every university, college and technological school included in *Minerva*. The total number of these is 50,

to which must be added the fourteen universities which had been previously communicated with, making a total of 64 institutions. The formal communication was addressed to the president or corresponding officer of each institution, and read as follows:

BOSTON, September 15, 1901.

Dear Sir:

The American Association for the Advancement of Science has the honor to request the cooperation of your college in setting aside the week in which the first of January falls as 'Convocation Week' for the meetings of learned societies.

At the New York meeting the Association appointed a Committee, consisting of its President, R. S. Woodward; its Permanent Secretary, L. O. Howard; of Professors J. McK. Cattell and E. L. Nichols, and of the undersigned as Chairman, to take charge of the matter. The Committee presented the plan to the Association of American Universities, which body, at its recent meeting, voted unanimously to recommend the adoption of the plan by the universities. Since then, the following twelve universities, members of the Association, have acted favorably upon the recommendation:

The University of California.

The Catholic University of America.

Clark University.

Columbia University.

Cornell University.

Johns Hopkins University.

Leland Stanford Junior University.

The University of Michigan.

The University of Pennsylvania.

Princeton University.

The University of Wisconsin.

Yale University.

For your further information the accompanying documents are enclosed, both reprinted from *SCIENCE*. The first gives the general arguments for the proposed 'Convocation Week,' the second indicates the various plans of cooperation adopted by the different universities, all intended to secure the essential point—releasing the teachers of the university from their official duties to enable them to attend the meetings of 'Convocation Week.'

It will give me pleasure to furnish any further information in my power, should you desire it.

Permit me, on behalf of the Committee, to express the hope that your institution will be able to give its support to the project to establish 'Convocation Week,' for we believe that no more important meas-

ure for the promotion of learning in America has ever been proposed.

I have the honor to remain,

Yours, with the highest respect,

CHARLES S. MINOT,

Chairman.

President A. A. A. S.

Harvard Medical School,
Boston, Mass.

Replies, in every case favorable, have been received from the following institutions :

Woman's College of Baltimore.
University of Buffalo.
Case School of Applied Science.
University of Colorado.
Columbian University, Washington.
Hamilton College.
Knox College, Galesburg, Ohio.
Massachusetts Institute of Technology.
Michigan College of Mines.
University of Minnesota.
University of Nebraska.
New York University.
College of the City of New York.
Northwestern University.
Oberlin College.
University of Syracuse.
Tufts College, Boston.
Vassar College.
Wellesley College.
Wesleyan University.
Western Reserve University.
Williams College.

The action has not been uniform, for in a few institutions no change in the vacation was necessary, but several institutions have changed the dates of their vacation to allow the necessary time for Convocation Week to become free. A small minority of the institutions have voted to allow their teachers leave of absence to attend meetings during Convocation Week. Almost every reply has included an expression of cordial approval of the plan.

The Committee hopes to continue and extend its correspondence with those universities and colleges which have not yet taken action, and to be able later to report their adhesion.

The facts above reported seem to the Committee to justify the expectation that the proposed Convocation Week will be permanently established through its formal acceptance by all the leading higher educational institutions of the country.

CHARLES S. MINOT, *Chairman,*

R. S. WOODWARD,

E. L. NICHOLS,

L. O. HOWARD,

J. MCK. CATTELL.

A CENTURY OF PROGRESS IN ACOUSTICS.

IN selecting the 'Progress of Acoustics,' on its experimental side, as the subject for this year's presidential address, I am fully alive to the fact that this branch of science has been comparatively neglected by physicists for many years, and that consequently I cannot hope to arouse the interest which the choice of a more popular subject might command. It is, however, just because of this neglect of an important field of science that I conceive it to be my duty to direct some attention thereto. This duty I can best perform, it seems to me, by taking a survey of the work accomplished in this particular field during the century that has just closed. Such a survey will make it evident not only that the science of acoustics has made immense progress during that time, but also that many of the experimental methods in use in other branches of physical science were invented and first employed in the course of acoustical research. This latter fact, though not generally recognized, furnishes an illustration of the interdependence which exists between the various branches of physical science, and suggests the probability that the work of acoustical research in the future may be advanced by experimental methods specially designed for investigation in other fields. A revival will, of course, come in time for acoustics, as it has recently come for electricity, and it ought to come all the

sooner because of the cooperation which physicists may naturally look for from those who are cultivating the new fields of experimental psychology.

In order to avoid the tedium of a bare enumeration of discoveries arranged chronologically, I propose to refer in the first instance to the invention of the various experimental methods which have been employed in acoustical research. A separate reference to these methods will enable us to appreciate their potency in the advancement of this science.

The earliest of these methods is due to Chladni, whose work, 'Die Akustik,' appeared in the form of a French translation in 1809, under the title 'Traité d'Acoustique de Chladni.' In this work were collected all the researches on the vibrations of bodies which Chladni had conducted with the aid of the new method (*méthode de sable*). This method consists in distinguishing, on the surfaces of vibrating bodies, the parts which are vibrating from the parts which are in repose, by means of the sand which is driven from the former to collect on the latter. In these experiments of Chladni on plates, etc., the violin bow was used for the first time to produce the necessary vibrations. The bow had previously been used only for vibrating cords, the 'violon de fer,' and other musical instruments. Chladni made his discovery of sand figures in 1787, having been led thereto by Lichtenberg's discovery of electric figures.

The transversal nodal lines given by Chladni's method in the case of rods vibrating longitudinally were readily explained. Not so, however, the complicated nodal lines presented by vibrating plates, or the alternate lines which appear on the two sides of rods vibrating longitudinally, and which sometimes also appear on rods vibrating transversally. It was not until 1833 that an explanation of the former of these phenomena was offered by Wheat-

stone's theory that the nodal lines were due to the superposition of transversal vibrations, corresponding to sounds of the same pitch coexisting with respect to different directions in the plate. This theory was confirmed experimentally in 1864 by Rudolph Koenig, who constructed rectangular plates giving unison notes corresponding to different sets of nodal lines parallel to two adjacent sides of the plate. The theoretical figure results when the plate is vibrated so as to produce the coexisting unison notes.

The alternate nodal lines given by vibrating rods were also explained by the theory of the coexistence of two sounds near unison in the same vibrating rod. In this case, however, one sound corresponds to longitudinal, and the other to transversal vibrations. This explanation was first given by Augusta Seebeck in 1849, whose theory was confirmed in 1859 by Terquem in a very important paper 'Sur les vibrations longitudinales des verges libres aux deux extrémités.'

In 1807, five years after the publication of Chladni's 'Akustik,' appeared Dr. Thomas Young's 'Course of Lectures on Natural Philosophy and the Mechanical Arts' in which we find the earliest description of the graphical method, including its application to chronography. This description is as follows:

"By means of this instrument we may measure, without difficulty, the frequency of the vibrations of sounding bodies, by connecting them with a point which will describe an undulated path on the roller. These vibrations may also serve in a very simple manner for the measurement of the minutest intervals of time; for if a body, of which the vibrations are of a certain degree of frequency, be caused to vibrate during the revolution of an axis, and to mark its vibrations on a roller, the traces will serve as a correct index of the time occupied by any part of the revolution, and the motion

of any other body may be very accurately compared with the number of alterations marked, in the same time, by the vibrating body." Notwithstanding the clearness of this description, the graphical method remained for a long time unknown, and when it was developed later, in 1862, the original discovery was incorrectly attributed to Wilhelm Weber (1830). Between these dates slight applications of the method had been made by Savart, Duhamel, Lissajous and Desains, Wertheim, and others; the most important of such applications being that of Scott, who in 1858 applied it to his phonautograph. Finally, from 1858 to 1862, Rudolph Koenig devoted himself specially to the perfecting of this method, and exhibited the results of his labors at the Exhibition in London in 1862, in the form of a large collection of phonograms. This collection in its seven sections comprises all the applications of the method which have so far been made in acoustics. Whilst the progress of this method was thus slow before 1862, its use from that time onward became general, especially in physiological researches, in connection with which it received its widest development in the publication by M. Marey of his splendid work, 'La méthode graphique' in 1878. Parenthetically I might remark that Edison's phonograph (1877) was doubtless suggested by Scott's phonautograph.

As with the graphical method, the earliest suggestion of an optical method of studying vibratory movements came from Dr. Thomas Young, who in 1807 gave the construction of curves resulting from the composition of two rectangular vibratory movements. The practical realization of these curves was effected in 1827 by Wheatstone in his kaleidophone. The most important advance, however, in the development of this method was made by Lissajous, who, after some preliminary work in 1855, published in 1857

his great paper entitled 'Mémoire sur l'étude optique des mouvements vibratoires.' The optical effects produced by Lissajous' method, especially when the curves were projected on the screen, were so beautiful that the method obtained general recognition, and became immediately popularized. The chief merit of the method, however, does not lie in the beauty of the effects thus obtained, but rather in the fact that by this means we are enabled to determine with facility and with the utmost accuracy both the interval and the difference of phase between two vibratory movements. It is this fact which renders the optical comparator one of the most important instruments at the disposal of the acoustician.

A second optical method we owe to Biot, who in 1820 showed that the changes in density at the nodes of a transparent body vibrating longitudinally could be exhibited when the nodal line of the body is placed between the crossed mirrors of a polarization apparatus. During the continuance of the vibrations the image is highly illuminated in the analyser and becomes darkened when the vibrations stop. This method was developed much further by Kundt in 1864, and by Mach in 1873.

A third optical method was devised by Toepler and Boltzmann in 1870 for the purpose of exhibiting the changes which take place at a nodal point of a vibrating column of air. This method consists in producing interference bands by means of two rays of intermittent light from the same source, one of which passes through the air in its normal state, and the other through a nodal point of the vibrating air column. A vibratory movement of the interference bands results—a movement which can be made as slow as we please, thus rendering it possible to deduce by stroboscopic methods exact measurements as to the movement of the air at the nodal point.

The object of the method of manometric

flames, invented by Rudolph Koenig in 1862, is to furnish an ocular proof of the variations in density at a point of the air traversed by waves originating in another body or in the air itself. A short description of the first apparatus based on this method appeared in Poggenдорff's *Annalen* in 1864. Between that year and 1872 the method was applied to a series of instruments, the experiments being described in the same journal in a long memoir entitled, 'Les flammes manométriques.' Although this method is extremely sensitive and capable of furnishing very accurate results, it has been prevented for a long time from rendering more efficient service on account of two causes: first, the want of sufficient brightness in the reflected images of the jumping flames, and second, the difficulty of observing the details of these images owing to their momentary appearance in the mirror. The former of these difficulties has now been overcome by the employment of acetylene and other gases, which at the same time allow admirable photographs of the flames to be taken, thus obviating the second difficulty also. We owe an important paper on this subject to Professors E. L. Nichols and Ernest Merritt published in 1898 in the *Physical Review*.

In 1865, Kundt published his method of using light powders for the purpose of exhibiting the vibratory character of stationary air waves in columns and plates of air. During the existence of these vibrations the light powders arrange themselves in transversal striæ which collect around the loops, and are wanting at the nodes. As in the case of the nodal lines on Chladni's plates, a satisfactory explanation of these striæ was for a long time wanting. In 1890 Professor Walter Koenig showed, from hydrodynamical considerations, that the particles of the powder necessarily arrange themselves in planes at right angles to the direction of the vibratory movements, and that their

observed distribution at the loops and nodes is in accordance with the same laws.

Before the invention of the preceding methods the acoustician occasionally resorted to the device of deducing the vibrations of a sounding body from the behavior of a similar body whose movements were of sufficient amplitude to be seen by the eye, and so slow that they could be readily counted. In this way Mersenne counted the vibrations of a cord 15 feet long under a stretching force of 7 pounds, and found them to be 10 per second. In shortening the cord to $\frac{1}{20}$ of its length, he obtained an audible sound whose pitch, he concluded, corresponded to 200 vibrations per second. In the same way Chladni employed a long and thin metal rod, which gave in the first instance only 4 vibrations per second. He then shortened the rod until it gave an audible sound whose pitch he determined from the law expressing the relation between the length and the number of vibrations. This method, however, which appears so simple in theory, is subject to large errors and gives in practice very poor results.

Mersenne's and Chladni's method has accordingly given place to another—the stroboscopic—which allows the vibrations of the sounding body to be viewed directly, its movements relatively to a vibrating eyepiece being rendered as slow as we please. The first use of stroboscopic discs for the purpose of observing very rapid periodic movements was made by Plateau in 1836. His discovery, however, remained unnoticed, for Doppler, in 1845, published a note on the same subject, without referring to Plateau's discovery. It was Toepler who first made the method generally known by employing it in a series of acoustical experiments which he published in Poggenдорff's *Annalen*, Volume 128. In the earlier applications of this method, the view of the vibrating body was rendered intermittent by looking through slits which were opened

and closed in rapid succession. This plan was modified by Mach who caused the vibrating body to be illuminated by intermittent light.

If now we allow the stroboscopic images of a moving body to fall on a photographic plate, giving the plate a movement of translation which is arrested before each appearance of the image, we thereby obtain a series of photographs of the successive positions assumed by the body. If, further, matters are so arranged that the beginning and duration of the phenomenon are traced on the images, we have a new method, which is called chronophotography. It was M. Janssen who first conceived the idea of taking automatically a series of photographic images in order to determine the successive positions at different times of the planet Venus in its passage across the sun. It was Janssen also who, in 1876, first suggested the idea of applying successive photographs to the study of animal locomotion. The analyzing of such movements was first accomplished by Muybridge, of San Francisco. The method has been largely extended and perfected by M. Marey, who has employed it in studying the locomotion of all sorts of subjects, from men to insects.

The last of the methods to be noticed is that employed by Rudolph Koenig in his wave-siren. In this instrument a metal band or disc with curvilinear edges passes before a narrow slit from which issues a current of compressed air. By means of these discs we can produce either simple sounds, or sounds of various timbres, containing such harmonics as we please, the intensities and phases of the latter being varied at will. The first wave-siren was constructed in 1867, and the account of the first series of experiments was published in 1881.

The mere enumeration of the methods of acoustical research which have been de-

vised since the days of Chladni is an indication of the enormous advances which have been made in this branch of science. It remains now to state more particularly what these additions to our knowledge of acoustical phenomena have been. This can be most conveniently done under the following heads, viz. : The velocity of sound ; its pitch, intensity and timbre ; and the phenomena produced by the coexistence of two or more sounds.

THE VELOCITY OF SOUND.

Long before the beginning of the last century it had been observed that the propagation of sound was not instantaneous. Mersenne in fact had tried to estimate the velocity by experiments on echoes, and by counting the time which elapses between the flash of a gun and the report. The latter experiments were also repeated by Kircher as well as by the Academy of Florence in 1660. The same experiments were subsequently, in 1738, undertaken by members of the Academy of Sciences at Paris, by savants, such as Kaestner, Benzenberg, Goldingham and others, but the results obtained did not gain the confidence of the scientific world. A new series of experiments was accordingly undertaken in 1822, on the suggestion of Laplace, by members of the Bureau des Longitudes, to determine the velocity in air and other media. These experiments, which were the beginning of truly scientific work in this subject, were performed by Prony, Arago, Mathieu, A. de Humboldt, Gay-Lussac and Bouvard, between Monthéry and Villejuif, cannon being fired at both stations. The result obtained was 331 m. at zero temperature, with an increase of 0.6 m. for each degree above zero. In the course of these experiments it was observed that the cannon fired at Villejuif were all distinctly heard at Monthéry, whilst the reciprocal reports were so faint that only a

small number were heard. Tyndall long afterwards, in 1875, explained this curious phenomenon, attributing it to the existence at Villejuif of a heterogeneous atmosphere, caused by the heated air which came from Paris.

Since the memorable experiments of the Bureau des Longitudes of Paris, various individuals have from time to time undertaken to solve the same problem. Among these may be mentioned Moll and van Beck (at Utrecht), Gregory Woolwich, Stone and Captain Perry in his voyages to the polar regions in 1822, 1824, and Kendall in the Franklin expedition in 1825. In some of these experiments the temperatures ranged from 2° to -40° , the results obtained according with the theoretical values. In 1823 Stampfer and Myrback conducted experiments between two stations in the Tyrol at a difference of level of 1,364 m.; a similar experiment being undertaken in 1844 in Switzerland by Bravais and Martin with a difference of level of 2,079 m. Both experiments confirmed the law that the velocity of sound in air is independent of the pressure.

In all these experiments the exactness of the results was affected by the difficulty of estimating accurately the time between the perception of the flash and that of the report. Different observers of course gave different estimates. This source of error was first eliminated by Victor Regnault, who in his long series of researches between 1860 and 1870 made use of the graphical method and electric signals to measure time intervals. Regnault's experiments were conducted in seven tubes (part of the Paris sewers) varying in length from 70 m. to 4,900 m., and of diameters from 0.11 m. to 1.10 m. Experiments were also conducted in the open air by means of reciprocal shots fired from two stations at a distance of 2,445 meters. The number of shots fired was 334. These researches

of Regnault represent such an enormous amount of work that I shall attempt to give only the principal conclusions deducible from them:

1. In a cylindrical tube the intensity of the wave varies, diminishing with the distance. The narrower the tube, the more rapid is the diminution.

2. The velocity of the sound decreases as the intensity diminishes.

3. The velocity approaches a limiting value, which is higher, the greater the diameter of the tube. The mean value in dry air at 0° in a tube of diameter 1.10 m. is 330.6 m.

4. The velocity is not affected by the mode of producing the sound wave.

5. The velocity in a gas is independent of the pressure.

6. The ratio of the velocities in air and any other gas is $\sqrt{\frac{1}{\rho}}$, where ρ is the density of the gas, supposed perfect.

7. The average of the results of all the experiments in the open air is 330.7 m. at 0° .

Regnault was also the first to attempt direct experiments for determining the velocity of musical sounds. In this case, however, the electric signals and the graphical recording apparatus were not sensitive enough to respond to the front of the wave, and it became necessary to resort to the ear alone. In these experiments Regnault had the cooperation of Koenig as observer, with whose assistance it was shown that:

1. A note does not change sensibly when it traverses long distances in tubes of large diameter.

2. When the sounds are observed by the ear the velocity of high notes appears to be less than that of low ones. This may be due to the more ready response which the tympanum makes in the case of low notes.

3. In traversing tubes of great length, a

note does not preserve its timbre, being resolved into simple components.

Regnault's experiments have recently been repeated by M. Violle in the large sewers near Grenoble and Argenteuil, some of Regnault's apparatus being employed for the purpose. The results of these experiments have not, however, been yet published.

PITCH.

Before the last century, as already mentioned, Mersenne had attempted to determine the vibrations of a cord by deducing them from very slow vibrations of the same cord when lengthened. Cheadni's tonometer, which consisted of a vibrating metal rod of variable length, was based on the same principle. In 1819 Cagniard de la Tour invented the siren, a much superior instrument, but incapable of giving very exact results, notwithstanding the simplicity of its mechanism. The same remark may be made of the toothed wheel invented by Savart in 1830.

A most important step in advance was made in 1834 by Henri Scheibler, of Crefeld, who in that year invented his tonometer, consisting of a series of 56 forks going from A (440) to its octave (880), the vibrations increasing regularly by differences of eight, any two adjacent forks thus giving four beats per second. Curiously enough, although Scheibler went to Paris and exhibited his tonometer there, he was unable to interest savants in his discovery; and it was not until the London exhibition of 1862 that the attention of physicists and musicians was directed to the value of the instrument by Koenig. The apparatus in its new form contained 65 forks going from C₃ (512) to C₄ (1024).

Notwithstanding the great utility of this tonometer to the acoustician, it still left undetermined the absolute pitch of the fundamental note, and hence of the whole series. This problem of realizing a stand-

ard of pitch remained practically unsolved, even after the French Government in 1859 decreed that the standard should be A = 870 v. s., at 15° C. The standard then constructed by Lissajous was found, in 1880, to be too high by $\frac{9}{10}$ of a vibration. The standard employed since 1880 by Koenig is C = 512 v. s. at 20°. The acoustical standard before that date was in reality 512.35 at 20°. The problem of realizing a standard fork, which had given rise to much controversy among physicists, was finally solved in 1880 by Koenig, who in that year published his paper 'Recherches sur les vibrations d'un diapason normal.' In this paper Koenig describes how by means of a clock-fork (horloge à diapason comparateur) he established a standard fork, the error of which did not exceed $\frac{1}{60000}$ of a vibration. The clock-fork method enables us at the same time to determine readily the variations in the number of vibrations due to a rise or fall of temperature. Having established in this way an absolute standard of C₃ = 512 v. s. at 20° C., Koenig commenced the construction of a universal tonometer based thereon, a colossal undertaking which he finished in 1897, after working a score of years. This tonometer, which has a range from 32 to 180,000 v. s., consists of the following:

1. 4 forks giving vibrations from 32 to 128, with differences at first of $\frac{1}{2}$ v. s. and afterwards of 1 v. s.

2. 132 large forks, tuned to give (without the sliders) the 127 harmonics of C₁, C₂, C₃, C₄, C₅, C₆, being in duplicate.

Each fork can be lowered, by means of sliders, to unison with the fork next below.

The differences immediately obtainable by sliders are:

- 1 v. d. between C₁ and C₃; 2 v. d. between C₃ and C₅; 4 v. d. between C₅ and C₇.

3. 40 resonators to reinforce forks of 2.

4. One large resonator of diameter 0.48 m. and of length varying from 0.30 m. to 2.30 m.

5. 18 forks for notes from C_7 to F_9 .

6. 15 forks for notes from Sol_9 to 180,000 v. s.

Under the head of pitch come two very difficult questions relating to the audibility of very low or very high sounds. With regard to the former Helmholtz has shown that if the vibrations are very slow and do not follow the pendular law (the fundamental being thus accompanied by a series of harmonics), the fundamental may be quite inaudible, whilst the harmonic is heard distinctly. In such a case the harmonic is often mistaken for the fundamental. On the other hand, if we employ large tuning forks, vibrating rods, or the wave siren, for the purpose of obtaining pendular vibrations, we are still met with the difficulty of determining accurately the limits of audibility, owing to the fact that it not only depends on the intensity of the vibrations, but varies from one observer to another. In general it may be stated that it requires from 60 to 80 v. s. to produce a sound perfectly continuous and possessing a musical character. In using very powerful high forks to produce beats, which were gradually diminished in number, Koenig found that the sensation of a continuous low sound ceased when their number did not exceed 26.

As to the high notes above $C_7 = 8,192$, the amplitudes of the vibrations are generally so small that the ordinary methods no longer serve to determine the pitch. For this reason it was at first the practice to tune forks above C_7 by means of the ear. The high forks constructed by Marloye and presented to the Academy of Sciences at Paris, in 1848, by Depretz, were constructed in this way. In 1858, however, Koenig showed that even in the upper half of the octave $C_8 - C_7$, the best musicians ceased

to judge the intervals accurately, a fact which seemed to show that it was extremely unlikely that forks giving notes two octaves higher could be tuned accurately by the ear. For this reason Koenig effected the tuning of very high forks by means of the sounds resulting from their beats. The first series of forks tuned in this way were made by Koenig in 1876. A set of similar forks constructed about the same time by Preyer, and going, as he alleged, as high as E_{10} were shown by Melde, in 1894, to be greatly out of tune, the intervals being wrong by as much as a third, and even an octave. In 1897, Melde's results were confirmed by Stumpf and Meyer.

In 1899 Koenig published his researches on very high notes. In this memoir, after showing the exactness of the tuning attained by the sounds of beats in forks between C_7 and F_9 , he proceeds to state that, by means of Kundt's method of using light powders, he had constructed a series of high forks accurately tuned and proceeding according to the intervals of the perfect (major) scale, from C_7 to the enormous pitch of 180,000 v. s., and that without reaching a limit to the number of such vibrations.

As to the audibility of these high forks, it has been remarked by Koenig that those between C_7 and C_9 are generally audible, whilst C_{10} and those above are entirely inaudible. He further remarks that the limit of audibility, which thus lies between C_9 and C_{10} , largely depends, as in the case of low sounds, on the intensity, and varies with the individual.

INTENSITY.

With regard to the question of intensity of sound, it is only necessary to say that there exists here a great lacuna in our acoustical knowledge, as we do not yet possess a means of measuring the physiological intensity of sound.

TIMBRE.

To Helmholtz belongs the credit of first elucidating the question of timbre by showing that the timbre of a sound depends upon the number and intensity of the harmonics accompany the fundamental. The question of timbre is thus intimately connected with the study of the phenomena produced by the coexistence of two or more sounds. With regard to such phenomena, it was stated by Helmholtz that when two notes of different pitch are sounded together, they give rise to two other sounds, the pitch of which is measured, the one by the difference, and the other by the sum of the vibrations of the two primary sounds. Further, that these resultant sounds are not due to beats.

These propositions of Helmholtz are controverted by Koenig, who, on the contrary has proved that the sounds actually heard accompanying two primary sounds are always due to beats. Koenig asserts, moreover, that the sounds referred to by Helmholtz, even if we could prove that they had a real existence, would always be inaudible, and therefore without effect on the acoustical phenomena. He further establishes the curious fact that even interruptions of a sound give rise to another sound.

As to timbre, Helmholtz's theory was that it depended solely on the number and relative intensities of the harmonics which accompany the fundamental, and that it is not affected in any degree by differences in the phases of these components. This latter proposition is combated by Koenig who holds that differences of phase as regards harmonics exercise a very important influence on the timbre of a sound, so that according to him timbre depends on the number, relative intensities and differences of phase of the harmonics which accompany the fundamental. Koenig's experiments on this disputed point were performed with his large wave-siren. Even this wider defini-

tion of timbre is, however, according to Koenig's most recent view and experiments, insufficient, as not being applicable to certain classes of timbres—for example, those produced by most musical instruments, especially stringed instruments. In these cases the fundamental is accompanied not only by harmonics, but also by other sounds which are not harmonic, the superposition of which produces series of waves which change their form successively. These wave forms have been investigated by Koenig in a paper, 'Sur les timbres à ondes de formes variables,' in which he determines the conditions under which such timbres may be considered musical, and concludes that in these cases the fundamental is accompanied by harmonics which continually change their relative intensities and their phase-differences.

In conclusion I may state that, according to Koenig, the fact that differences of phase amongst harmonics produce differences of timbre is explained for the first time by his recent discovery that the intensity of a sound can be increased by the addition of another sound, when the maxima of intensity in the vibrations in the two cases correspond more or less exactly, and that several sounds produced together may reinforce a sound of lower pitch than any of them. For example with the same six primary sounds, by changing their phases only, he produces not only timbres differing in intensity and in richness, but timbres in which, at one time, the octave (2) and at another time the fifth above (3) are heard. The difference between these two timbres is, indeed, so great that when heard in succession, there appears to be an interval of a fifth between them, although their fundamentals are exactly the same. These experiments may be said to be the last on this difficult subject in the years of the century which has just closed. JAMES LOUDON.

UNIVERSITY OF TORONTO.

CURRENT QUESTIONS IN ANTHROPOLOGY.*

No idea is more firmly fixed in the mind of the average man than that of monogenesis—*i. e.*, the idea that all mankind sprang from a single pair, and hence came up in a single center. Nor is the prevalence of the idea surprising; engendered by the associations of family life, fostered by honorable regard for worthy ancestors, and nourished by tradition, it grows into a natural intuition; and when intensified by the teachings of biology (whence most modern thinkers derive early lessons), it readily matures in a postulate so simple and so strong that few anthropologists take the trouble to question its validity. Yet once the question is raised, the postulate is seen to be gratuitous; in the present state of knowledge it may not be either affirmed or denied with confidence; but it must be recognized that the intuitive idea of monogenesis is not supported by a single observation in the domain of anthropology, and is opposed by the great body of observations on human development. The first corollary of the monogenetic postulate is that mankind differentiate—that they differentiated in the beginning, that they are differentiating now, or that they differentiated at some intermediate stage, one or all; in any event, that the course of human development is one of progressive differentiation. Of course, if the postulate were a direct inference or a generalization, this mode of statement would be reversed; in that case it would be necessary to say that certain observed facts of differentiation lead to an inference of differentiation in general, and point to a law of monogenesis; but it cannot be too strongly emphasized that the notion of monogenesis in the human realm does not represent observation, generalization, inference or other inductive procedure from

fact to interpretation—it is a pure assumption, imported into anthropology from other realms of thought, introduced as a full-grown foundling, and ever at war with the legitimate offspring of the science of man.

The great fact attested by all observation on human development, and susceptible of verification in every province and people, is that mankind are not differentiating in either physical or psychical aspects, but are converging, integrating, blending, unifying, both as organisms and as superorganic groups. The population of the world is steadily increasing, but the number of races is not; while the number of distinct peoples is progressively decreasing and the racial boundaries are slowly but surely melting away. This present condition is in accord with the past so far as history runs; races have not come up, tribes have not multiplied, but distinct peoples have coalesced, dialects and languages have blent into common tongues, throughout the known world—indeed, the processes of integration have been so characteristic of human progress throughout the historical period that it is now possible to enounce, if not to establish, the proposition that peoples are preminent in proportion to the complexity of their blood and culture. These salient facts of the present and of the recorded past fall naturally into a generalization of integral or convergent development, which in turn points toward a hypothesis of polygenesis. The major indications are supported by minor ones too numerous for easy counting; and the burden of the testimony is amply sufficient to compel the open-minded anthropologist to tolerate the polygenetic hypothesis, if not to accept it as a working platform alternative with that of the monogenesis so long yet so gratuitously assumed.

Several students, like Keane in recent publications, have, indeed, held that the black, brown, yellow and white races cannot have sprung from common parents;

* Abstract of address before Section H, Denver Meeting, American Association for the Advancement of Science.

yet it may be questioned whether even this position is not merely a stepping-stone toward a more general view of humanization beginning with many varieties of the unknown prototype in different regions, coming up through the multifarious tribes of scientific record, and approaching the dominant types of to-day. Certain it is that when a race or congeries of tribes measurably similar in physical features—*e. g.*, the Amerinds—are considered with respect to the intertribal relations established by record and tradition, their history is found to be one of coalescence, through the growth of stronger groups and the assimilation or elimination of weaker, through the interchange (whether inimical or amical) of artifacts and industrial processes, through more or less frequent intermarriage, through the giving and taking of linguistic elements, through the interchange of custom, faith, ceremony, law and other factors of culture which react on mental and bodily exercise and thus shape development; the interchange and coalescence may be slow and incomplete, as between the Seri and Guayaqui tribes and their respective neighbors, or rapid and comprehensive, as in the Iroquois and Dakota confederacies, yet it is ever-present, and when the lines of development are traced backward they are invariably found to diverge more or less widely and point toward more or less distinctive origins.

What is true of the Amerind tribes in this respect is even more conspicuously true of the African tribes, ranging from the pigmy Akka to the gigantic Zulu and other widely diverse physical and cultural types; most of these tribes, too, have been observed in actual coalescence with their neighbors, while not a single satisfactory indication of differentiation or increasing distinctiveness has ever been detected; so that here, too, the developmental lines traced backward are found to diverge and

multiply up to the very verge of the unknown—the prehistoric, or at least the scriptless, past. And what is true of America and Africa is more or less conspicuously true of other continents and other peoples; everywhere the developmental lines converge forward and diverge backward, just as the lines of biotic development diverge forward and converge backward. How this discrepancy is to be removed is a question whose importance increases with every advance in the science of anthropology.

It seems not too much to say that the leading question before the anthropologist of to-day is that relating to the trend of human development and its bearing on the alternatives (postulate and inference, respectively) of monogenesis and polygenesis; for it is easy to see that most of the other questions are affected by this primary one. The definition of race, the discussion of human antiquity and various civil problems of the day are all involved; and while it is too much to hope for general agreement concerning the fundamental question at any early day, it is none the less desirable to note the trend of multiplying facts and observe their steady set toward the inductive hypothesis of polygenesis rather than toward the deductive assumption of monogenesis.

BUREAU OF AMERICAN ETHNOLOGY.

THE ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS.

THE eighteenth convention of the Association of Official Agricultural Chemists held its meetings in Columbian University, Washington, D. C., November 14, 15 and 16, 1901, under the presidency of Dr. L. L. Van Slyke, Chemist of the New York Agricultural Experiment Station, at Geneva. The attendance at this meeting was the largest in the history of the Association, reaching 118 members, representing nearly all the States and Territories of the Union.

A notable change has taken place in the character of the meetings of the Association of Official Agricultural Chemists, which at first was organized chiefly for the unification of methods of the analysis of commercial fertilizers. This branch of the work has now reached such perfection as to require little or no attention. The great work of the Association is now directed to other subjects, especially to investigations, researches and studies of foods and food adulterants.

The two most important events of this meeting were the reports of the committee on uniform methods of food investigation, of which Dr. W. D. Bigelow, of the Bureau of Chemistry, of the U. S. Department of Agriculture, is chairman, and of the committee on food standards, of which Dr. Wm. Frear, of the State College of Pennsylvania, is chairman. Since nearly all the States have pure food laws, it is of the utmost importance, from both a scientific and a legal standpoint, that uniform methods of investigation be followed and that some definite standards may be fixed whereby the court and jury may follow a uniform method in determining variations from the normal.

The officers elected for the ensuing year are Dr. H. J. Wheeler, Chemist of the Rhode Island Experiment Station, Kingston, R. I., president; Professor R. J. Davidson, Chemist of the Virginia Agricultural Experiment Station, Blacksburg, Va., vice-president; Dr. H. W. Wiley, Chief of the Bureau of Chemistry, U. S. Department of Agriculture, Washington, D. C., secretary; Dr. C. G. Hopkins, Chemist of the Illinois Agricultural Experiment Station, Urbana, and Mr. Fred. D. Fuller, Assistant Chemist at the Agricultural Experiment Station of New York, at Geneva, additional members of the executive committee.

The next meeting of the Association will be held in Washington, at the call of the executive committee, probably in November, 1902.

H. W. WILEY.

SCIENTIFIC BOOKS.

Tierleben der Tiefsee. Von OSWALD SEELIGER, Professor der Zoologie an der Universität Rostock. Leipzig, Verlag von Wilhelm Engelmann. 1901. Pp. 44.

While it can hardly be claimed that this work is a distinct addition to our knowledge of deep-sea life, it nevertheless serves an important purpose in presenting a compact resumé of the more notable facts relating to the animals of the deep and the conditions under which they exist. The author has been fortunate in his method of treatment, which is popular rather than technical, and covers the field as well as could reasonably be expected in the space occupied. There is hardly any 'padding,' and the more technical parts of the work are wisely segregated under the heading 'Anmerkungen' at the end.

An introductory sketch of the development of deep-sea investigation, from the ancient pearl fisheries of the Indian Ocean to the recent German deep-sea expedition, includes notices of the work of John Ross, Edward Forbes, Michael Sars, Lovén, the cable surveys and the resultant discoveries of animal life in abyssal regions, and the expedition under the direction of the naturalist Chun. It is, to say the least, unexpected to find no mention whatever of such notable expeditions as those of the *Porcupine*, *Challenger*, *Travailleur*, *Blake* and *Albatross*. A similar surprise awaits the reader who peruses the pages devoted to a description of methods and instruments of deep-sea research without finding the slightest mention of the many instruments of precision invented by British and American investigators, such as Sir William Thomson, Alexander Agassiz, Professor Brooke, and Captains Sigsbee and Tanner of the U. S. navy.

The discussion of the physical conditions of the deep sea includes a presentation of the more important facts regarding temperature, but presents to greater length the matter of pressure. The author estimates that the total pressure exerted on a human body, if sunk to a depth of 4,000 m., would equal the weight of ten loaded freight trains, each consisting of an engine, tender and 32 cars. The American reader should remember, however, that these are con-

tinental, and not American trains. As a matter of fact, this pressure has little effect on the organisms inhabiting the depths on account of their being themselves so largely composed of and permeated by sea water. But the release of pressure experienced by individuals suddenly transferred from deep to shallow water is most disastrous in its effects, as illustrated by the fate of deep-water fishes when brought to the surface.

In discussing the chemical composition of sea water the author states that the oxygen is derived from the atmosphere, and that the carbonic acid increases with the depth, and that this latter fact explains the lighter calcareous skeletons of deep-sea forms as compared with their shallow-water relatives. On the other hand, silicious skeletons from great depths are proportionately heavier than those from shallow water, although actually smaller. In this connection the point might well be raised that the heavier calcareous skeletons are not needed in the depths for weight or protection against waves or currents, and that their comparative fragility could be accounted for on other grounds than the solvent action of carbonic acid.

The problem of the penetration of sunlight is treated at considerable length. This subject has been made a matter of investigation by means of experiments with sunken photographic plates, the greatest depth at which even the most sensitive are in any degree affected being 500 to 550 m., according to Fol and Sarasin. Red rays, however, might still be present without affecting the photographic plates, and the reddish yellow twilight of Agassiz and Haeckel might result.

Professor Seeliger denies the red-light theory, and maintains that the blue or blue-green rays penetrate most deeply. He substantiates his argument by an ingenious reference to the well-known and beautiful illumination of the famous 'Blue Grotto' of Capri, where the light penetrates a considerable depth of sea water and is reflected upward into the cave. Spectroscopic investigation confirms this blue-light theory, which appears to be now well established by the arguments here recorded. The author believes that no light from the sun reaches the greater depths, and says that no

conditions of existence in the deep sea have so strongly influenced the organization and manner of life of animals as the absence of sunlight and heat.

The coloration of deep-water forms is regarded as protective in the main. In explanation of the red color so often found, the claim is made that this color would be protective, on account of its being inconspicuous in a blue light. This point is debatable, in the opinion of the reviewer, as any neutral tint would be just as inconspicuous as red, and thus the utterly useless production of such quantities of bright pigment be avoided. After noting the frequency of dark-colored or black hues among the abyssal fishes, and the contrast between this rich pigmentation, on the one hand, and the bleached, often colorless condition of cave animals on the other, the author fails to grasp the significance of the contrast. He doubts the effective presence of attractive coloration as an aid to sexual selection in the deep 'wo die tiere gar nicht oder nur unvollkommen sehen' (*sic!*). Indeed the discussion of the coloration of deep-sea forms is the most unsatisfactory part of the work.

The loss of sight in abyssal animals is frequently compensated for by the special development of other organs, usually tactile, such as the extremely elongated spines of certain fishes, the immensely lengthened antennæ of crustaceans such as *Nematocarcinus gracilipes* and *Sergestes magnificus*. Such structures are often coordinated with degenerate eyes. Sense hairs are sometimes greatly developed in deep-sea annelids and on the lengthened legs of certain crabs.

The author claims that a light, aside from that of the sun, is found in the depths in the form of phosphorescence, and this he discusses in a very interesting manner. The fisherman at night draws up his net filled with 'tausenden glühender Fünckchen.' The light-emitting forms increase in the deeper waters, "Hier finden sich zeitlebens festgeheftet am Meeresgrund lebhaft phosphoreszierende Rindenkoralen, stark bläulich leuchtende Seefedern. Hier leben zahlreiche leuchtende Würmer und Protozoen, prächtig glühende Seesterne (*Brisinga*) und Cephalopoden."

Light-producing organs may be found, often in great numbers, in various parts of the body. Often such organs are coordinated with eyes, and in some cases—*e. g.*, *Ipnops**—the eye itself has become degenerate and replaced by a phosphorescent organ. Among the crabs, as well as fishes, the light-emitting organs serve as dark-lanterns to illuminate the immediate surroundings, and also as lures to attract the prey. The author claims that there is, in general, a decreasing degeneration of the eye with increasing depth. In *Ethusa granulata*, a crab, specimens from shallow water have good visual organs, while those from 900 to 1,300 m. are usually blind. It appears to be a fact that the eyes of deep-sea forms tend either to a great increase in size, on the one hand, or degeneration on the other, as ordinary eyes are of little use in the depths.

The possession of light-emitting organs in blind animals is explained on the ground of utility in terrifying hostile animals or alluring the prey.† There are also instances in which very similar light-producing organs have been developed by widely differing animals by a process of approximation.

In discussing the systematic relationships of deep-sea animals the author states that they do not differ among themselves more than do shallow-water forms. It was at first thought that the abyssal region would yield many ancient types, and, indeed, this is in a measure true. It appears that the older forms were often driven to the depths to escape competition with newer and more specialized rivals. Many deep-sea sponges and echinoderms resemble cretaceous and jurassic types. It can be stated as a generalization, however, that deep-water ani-

* It should be noted, however, that the eyes of *Ipnops* still appear to be functional, although exceedingly modified to form the immense phosphorescent lantern that occupies about half of the dorsal surface of the head.

† In the discussion of phosphorescence in the deep sea, the conclusions of Professor Seeliger are so nearly identical with those presented by the present writer in the number of SCIENCE issued May 31, 1901, that attention should be called to the note at the bottom of page 852, referring to a previous article on 'The Utility of Phosphorescence in Deep-sea Animals,' published in the *American Naturalist*, Oct., 1899.

mals are no nearer mesozoic forms than are those from lesser depths. In sustaining this latter claim the author cites the many cases of so-called 'living fossils' among shallow water mollusks, and also the old-fashioned mammals still existing, such as the proboscidiens. On the other hand, deep-sea animals can often, indeed usually, be referred to existing genera of shallow-water forms, and the author claims that the former were originally derived from the shallow-water inhabitants of the past. The conditions of life in the abyssal regions are not conducive to developmental changes, neither are they such as to favor the evolution of the organic from the inorganic.

Professor Seeliger, like most other writers on this subject, cannot refrain from having his fling at the '*Bathybius* theory' of Huxley, which was exploded through the chemical researches of Buchanan, who demonstrated that the apparently vital movements of '*Bathybius*' were purely physical.

Our author believes that animal life becomes less abundant in the greater depth, but that there is no zone that is entirely uninhabited, a conclusion directly opposed to the one so thoroughly demonstrated by Alexander Agassiz, who maintains that there is an intermediate zone which is practically lifeless. The argument against the existence of an uninhabited zone is based on considerations affecting the food supply. In shallow water the food basis is largely vegetable, but plant life becomes sparse below 200 m. and practically vanishes below 400 m. But the inhabitants of the underlying zone ascend to what may be called the plant zone for their nourishment, and then retire satisfied to the deep. The bottom-inhabiting species, whether free-moving or fixed, are nourished by the organic substances sinking, in changed form, to the bottom.

The bottom deposits are briefly described as diatom ooze, radiolarian ooze, globigerina ooze and red clay.

The author concludes by emphasizing the intimate connection between the animal inhabitants of the upper and deeper zones, and the dependence of the abyssal forms upon the upper regions for their food supply. The animal world of the deep is in general a reflected rep-

resentation (Spiegelbild) of that of the upper waters.

The last sentence in the body of the work is well worth quoting for the beauty and grandeur of the conception involved:

“Denn alles, was oben im Spiel der Wellen und im Sonnenlicht lebt und vegetiert, muss endlich doch noch in irgend einer Form zur Tiefe gelangen, um in der dunklen, von keiner Welle erregten Riesengrabstätte des Meeresgrundes den Kreislauf des Stoffes zu vollenden.”

Following the body of the work are twenty closely printed pages of notes of a more technical character, embodying the actual facts which form the basis for the statements and conclusions of the author. These are of real value to those who study more carefully the fascinating problems of the deep.

The work as a whole will form a welcome addition to the library of the general student, and the specialist will find it well worthy his careful perusal and frequent consultation.

Agricultural Bacteriology: A Study of the Relation of Bacteria to Agriculture with special Reference to the Bacteria in the Soil, in Water, in the Dairy, in Miscellaneous Farm Products, and in Plants and Domestic Animals. By H. W. CONN, Ph.D. Philadelphia, P. Blakiston's Son & Co. 1901. Pp. 412. Figs. 40.

This is a new book on a new subject. There have been books treating of separate phases of the subject, as dairy bacteriology, but heretofore no book has been issued in English which has attempted to cover the whole range of bacteriology in its relations and applications to agriculture. As the sub-title explains, it has special reference to the bacteria in the soil, in water, in the dairy, in miscellaneous farm products and in plants and domestic animals.

Professor Conn shows that while in the popular mind bacteria have come to be almost synonymous with disease, they are intimately associated with many normal processes which are going on in the soil, water and elsewhere, and are important and very often essential factors in the operations of farming as well as in every-day life: “From beginning to end the

occupations of the agriculturist are concerned in the attempt to obtain the aid of these micro-organisms when they may be of advantage, and in preventing their action in places where they would be a detriment”; and he adds that “farming without the aid of bacteria is an impossibility.” As yet only a beginning has been made in studying their application. In the section on bacteria in the soil, the author shows that they have important relations to agricultural processes in at least five different directions, namely, in the decomposition of rocks, the fixation of free atmospheric nitrogen in the soil, the decomposition of all complex organic bodies and compounds in the soil, the formation of nitrates, and, in connection with the legumes, in reclaiming nitrogen from the air. He prophesies that “in the future the problem of the proper treatment of soil for the use of agriculture will be, in a very large degree, a problem of the proper control of bacteria. Agriculturists must learn to stimulate the bacterial actions which are advantageous, and check those which are disadvantageous, if they would insure the continuance of soil fertility.” There is perhaps no phase of agriculture where bacteria play such an important part as in the dairy. It is appropriate, therefore, that this subject, to which Professor Conn has himself been an important contributor, should receive quite extended treatment. The advances made in the control of bacteria in milk, as a result of better understanding of their sources and of pasteurization, have contributed to a better milk supply of cities, as well as to superior quality of the butter produced. The author contends that the introduction of pure cultures for ripening the cream in butter-making has resulted in improving the general quality of butter and has led to greater care in the preparation of the ‘starter’ where pure cultures are not employed. The part played by enzymes, especially galactase and rennet, in the ripening of cheese is pointed out, but the author is inclined to ascribe considerable importance to lactic bacteria in this connection. Elsewhere the importance of enzymes in explaining various phenomena formerly ascribed to the direct action of bacteria is discussed at some length. This opens up an interesting

line of study in a field where comparatively little beyond the result is known at present. The book is written in a clear and entertaining style that should commend it to the general reader as well as the student. It is an important addition to our agricultural literature, and will be welcomed by many who have felt the need of a general treatise on the subject.

E. W. ALLEN.

The Feeding of Animals. By WHITMAN H. JORDAN. New York, The Macmillan Co. 1901. Pp. 450.

This book by the director of the New York State Experiment Station, is the latest contribution to the excellent Rural Science Series. Several books on feeding have been published by American writers, but in some ways this is the most systematic and comprehensive treatment of the subject, especially as adapted to the needs of the student. While the teachings of European experiments and experience are taken account of, American conditions are kept constantly in mind, and this gives the book a distinct advantage over some which have adhered too closely to the German feeding methods. Dr. Jordan has combined a quite thorough review of the important scientific teachings on the subject, with a plain and clear statement of the application of these facts in practical feeding. He has digested the investigation relating to feeding at home and abroad, and gives the reader the benefit of his judgment and insight into the subject in interpreting and applying them. The applications which he makes of the science of feeding to practical conditions show that he is not bound down by any theoretical ideas or teachings but is thoroughly familiar with the standpoint of the practical feeder. He breaks away, in a measure, from the mathematical doses of nutrients prescribed in feeding standards, but at the same time he admits the value of these formulas as an aid in selecting adequate, uniform and well-proportioned rations. The first part of the book is taken up with the principles of feeding, the relations of plant and animal life, the composition and digestibility of feeding stuffs, the function of nutrients and the laws of nutrition; while the second part considers the practice of feeding, the selection and compounding of rations for

maintenance, for milk and meat production, for growing animals and for work, as well as questions of general management. The arrangement of the book is logical and orderly, and it is well suited to the needs of the student and the class room; in fact it may quite possibly prove more popular as a text-book than as a manual for the farmer or practical feeder, and for such a text-book there is perhaps the greater need at present.

E. W. ALLEN. w.

A Text-book of the Physics of Agriculture. By F. H. KING. Second edition. Madison, Wis., Author. 1901. Pp. xvi + 604. Figs. 276.

In this book, which is by the professor of agricultural physics in the University of Wisconsin and physicist of the experiment station, "the aim has been to present to the student who expects to be a farmer some of the fundamental principles he must understand to become successful." The author states that it is his purpose to present these principles from the physical rather than from the chemical or biological standpoint, and from that of the general student and farmer rather than from that of more technical scientific agriculture. Nevertheless, the book will be found to be a notable contribution to the literature of scientific agriculture in a field which has not heretofore received the attention its importance demands. The introduction deals briefly with certain general physical principles, laws and factors, a knowledge of which is necessary to an understanding of their subsequent practical application. Other chapters deal with the nature, origin and waste of soils; chemical and mineral nature of soils; soluble salts in soils; physical nature of soils; soil moisture; physics of plant breathing and root action; movements of soil moisture; conservation of soil moisture; relation of air to soils; soil temperature; objects, methods and implements of tillage (especially the plow); ground-water, farm wells, and drainage; principles of rural architecture, including strength of materials (posts, barn frames etc.), warmth, light and ventilation, principles of construction, construction of silos; farm mechanics, including principles of draft, construction and maintenance of country roads, farm motors (animal power, steam and gasoline

engines and windmills); farm machinery (general principles, belting, farm pumps, hydraulic rams); principles of weather forecasting, including discussions of the atmosphere and its movements and weather changes.

W. H. BEAL.

Chemische und medicinische Untersuchungen.

Festschrift zur Feier des sechzigsten Geburtstages von Max Jaffe, mit Beiträgen von M. ASKANAZY, P. BAUMGARTEN, M. BERNHARDT, R. COHN, TH. COHN, W. ELIASSOW, A. ELLINGER, J. FROHMANN, P. HILBERT, LASSAR-COHN, D. LAWROW, E. v. LEYDEN, W. LINDEMANN, W. LOSSEN, H. MEYER, E. NEUMANN, H. NOTHNAGEL, E. SALKOWSKI, W. SCHEELE, L. SCHREIBER, A. SEELIG, S. STERN, O. WEISS, R. ZANDER. With 8 plates. Pp. 472. Braunschweig, Friedrich Viewig und Sohn. 1901.

Such volumes as this 'Festschrift' are always of interest in recalling definitely the position and achievements of the scientist to whom they are dedicated, since they come at a time when his great creative work is generally completed. They reveal also something of that side of scientific investigation, unnoticed in the journals and text-books, but of so much importance in the development of thought, the personal relations of the investigators, their influence upon each other, and the inspiration derived by both from the association of teacher and pupil. The papers contributed to volumes of this character are, indeed, frequently distinguished for kindliness of intention, rather than for intrinsic merit. Such is not the case in this volume. Most of the papers are the first presentation of important investigations, which might take their place worthily in any scientific or medical journal. The remaining articles, although presenting no new facts, are interesting on account of the ability and reputation of their writers, and afford suggestive discussions of some of the problems which are of special importance at the present time.

This volume is in every respect a fitting tribute to Jaffe. Although, of course, no word of it was written by him, there is throughout a tone which clearly reflects his influence. The firm grasp of the purely chemical aspects of the problems, even when dealing with clinical or

pathological subjects, the definiteness of the problems set before the investigator, and the clearly devised and vigorously executed experiments employed for their solution, show in the pupils the imprint of the teacher; in the friends, the influence of the coworker. It is one of the most hopeful signs for the future of medical investigations that they are adopting from chemistry and physics that habit of measuring without which science would be mere empiricism. If that quality be sought in Jaffe's researches which most entitles them to their place, it would probably be found in the exactness of the chemical methods employed. They are excellent examples of the application of pure chemistry to the problems of biology. Jaffe has rarely left an investigation of the complex organic substances, whose origin or influence in the animal body he has discovered, without having established also their structural formulæ. He seems to possess the even rarer gift of impressing this trait on others.

The contents of the volume are arranged in three parts, of which the first is devoted to clinical medicine. In the opening article, v. Leyden, as the oldest friend and coworker of him in whose honor he writes, reminds the reader that they two were the first to introduce into medicine, as long ago as 1866, the use of oxygen gas. After reviewing briefly the opposition or rather indifference with which this method of treatment was long regarded, especially in Germany, the writer dwells with just pride on the universal acceptance at the present day of the value of oxygen inhalation, not only in cases of morphine, strychnine and carbon-monoxid poisoning, extreme chloroform narcosis and dyspncea from many other causes, but also as a therapeutic agent in several of the diseases of the respiratory organs. Following this paper are articles by Nothnagel on 'Intestinal Hemorrhages,' Scheele on 'Subphrenic Abscesses,' and Frohmann on 'Primary Sarcoma of the Intestine.' To these are added a report and discussion by Eliassow on 'Three Cases of Degenerative Chorea,' and by Bernhardt three reports upon cases of 'Localized Convulsions in the Upper Extremities,' 'Localized Convulsions in the Lower Extremities,' and 'Infantile Facial Paralysis.' To

this section also Stern contributes an interesting description of a case of 'Traumatic Neurosis and Simulation,' which, after being diagnosed repeatedly by others as simple imposture, the writer was led to regard as the manifestation of real suffering and deficiency. He closes a discussion of the views of Charcot and others on hysteria, hypnotism and allied phenomena, with a plea for a more sympathetic attitude on the part of physicians toward patients so affected.

The second part of the volume is devoted to morphological subjects, and contains an article by Schreiber, which is in the main a review of the recent work on the so-called 'Clasmatocytes' and an investigation of their probable origin and purpose. This is followed by Zander on 'Schistosoma in Man—A Contribution to the Mechanics of Development under Normal and Pathological Conditions,' and Askanazy on the 'Pathology of Bone' in cases of grafting and in the stump of a bone at the point of amputation.

The third and by far the largest part of the volume contains investigations in pure chemistry, physiology, toxicology, experimental pathology and bacteriology. The first of these subjects is represented by Lossen on 'Phthalylhydroxylamin and Related Compounds,' and 'An Improved Nitrometer' by Lassar-Cohn. On the side of physicochemical methods in physiology and medicine, Baumgarten discusses 'Hæmolysis' from the standpoint of the changes in the osmotic pressures of the blood; and Th. Cohn advocates the introduction to clinical use of the freezing-point method for the determinations of alterations in the fluids of the body.

By investigations on 'The Influence of Alterations in the Kidney (either spontaneous nephritis or from cantharides) on the Course of Pancreas-Diabetes in Dogs' Ellinger and Seelig find that the elimination of sugar falls both absolutely and relatively to the nitrogen, but that this diminution in the glycosuria in no wise diminishes the hyperglycæmia, since it is accompanied by an increase in the sugar content of the blood. From experiments, also on dogs, 'On the Functional Capacity of the Heart in Fatty Degeneration' induced by 'Pulegon'

(a substance like phosphorus in its effect on metabolism, but without direct influence on the heart) Lindemann finds the force and rhythm of the beat to remain long unaffected, and concludes that the abnormalities which ultimately result are due to the alterations in the cardiac muscle itself, and not to any influence on its nervous connections.

Four articles represent physiological chemistry. Salkowski contributes an analysis of the 'Hydrocephalus Fluid,' in which, like other observers, he finds an extremely small content of solids (100 cc. containing only 0.43 gram organic substances, mainly urea and dextrose, and 0.77 gram inorganic); Lowrow reports a study of the 'Decomposition Products of the Hæmoglobin of the Horse'; and Weiss the 'Separation of Methylpentose from White of Egg,' its presence or absence depending upon the food of the hen. In a study of the 'Glycocol Supply of the Animal Organism,' by R. Cohn, the methods used are essentially the same as those employed by Lusk in this country, and the results confirm the conclusions of the latter.

In one of the two papers devoted to bacteriology Hilbert is led by his experiments (on white mice) to answer the question, 'Are Toxic or Immunizing Substances Recognizable in the Filtrate of Streptococcus Bouillon Cultures?' in the negative. Finally, in perhaps the most valuable contribution in the volume Hans Meyer, on the basis of experiments performed by him in conjunction with J. T. Halsey and Fr. Ransom on 'Localized Tetanus,' shows that the toxin when injected into a nerve acts not only more quickly, but also more intensely, than when injected subcutaneously, since by the former method the spinal cord is reached more completely and in more concentrated form by the poison. It is further shown conclusively that the action of tetanus is entirely central, and that the greater part of the time of incubation is consumed in the slow passage of the poison to the central ganglia, and only a brief period in the performance of the chemical reaction in the cells affected. Finally, Meyer concludes that the neutralizing action of the antitoxin must occur outside the nervous system, since this substance never penetrates into either the peripheral or central ganglia, and

that the tetanus poison reaches the ganglia of the central nervous system, not by way of the circulation, but along the peripheral nerves.

YANDELL HENDERSON.

YALE UNIVERSITY.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *Botanical Gazette* for November contains the following leading articles: G. T. Moore has published, with three plates, his second paper entitled 'New or Little Known Unicellular Algæ,' giving a detailed account of the life history of *Eremosphæra viridis*, and coming to the conclusion that for the present, at least, the genus should be classed with the Protococcoideæ; and also describing as a new genus a form which has been confused heretofore with *Eremosphæra*, and naming it *Excentrosphæra*. T. C. Frye has published, with one plate, an account of the development of the pollen in certain Asclepiadaceæ, his investigation having been suggested by the record that in certain members of this family there is no tetrad division. The development of the sporangium was found to be of the general type, the primary sporogenous cells passing over directly into pollen-mother cells; these latter divide in the usual tetrad manner, but subsequently through mutual adjustment the four spores are arranged in a linear series. Miss F. Grace Smith has published the results of a large number of observations upon the distribution of red color in vegetative parts in the New England flora. A general conclusion is reached that the statistical observations obtained fit no one theory of color in all particulars. Mr. George A. Shull has published, with illustrations, the results of observations upon 'Some Plant Abnormalities.' He records instances of fasciation in *Erigeron canadense* and *Echium vulgare*; abnormal foliage leaves in *Pelargonium* and *Hicoria*, and abnormal floral organs in *Lathyrus odoratus*, as well as in certain species of *Clematis*. Under the head of 'Briefer Articles,' E. B. Copeland has discussed Meissner's paper on evergreen needles, answering certain criticisms of the author, and presenting new observations; M. L. Fernald publishes a final paper upon the instability of the Rochester nomenclature, being an answer to papers of Messrs. C. L. Pollard, L. M.

Underwood and N. L. Britton; and Charles Robertson has published a third set of observations of flower visits of oligotrophic bees.

ANNOUNCEMENT has been received of the establishment of a new scientific journal entitled *Archivio Italiano di Anatomia e di Embriologia*, under the editorship of Professor Chiarugi, of Florence, already favorably known as the editor of the excellent little journal, the *Monitore Zoologico*. It is published with the cooperation of the professors of anatomy of Pisa, Padua, Sienna, Perugia, Ferrara, Genoa, Catania and Bologna. There has been a great awakening of anatomical and embryological study in Italy, but it has long been a matter of regret that although many important investigations have been published they have appeared in the proceedings of societies or in journals of very limited circulation, so that it has been very difficult for foreigners to secure access to this Italian work, much of which is extremely valuable. We shall, therefore, welcome a journal which will gather together and render more thoroughly accessible the results of anatomical and embryological research in Italy. The list of supporters of the new enterprise is a guarantee of its high character so that we may reasonably expect the new journal to rank as the equal of the best French and German journals. The subscription price for America is 31 francs, 50 centimes. The publisher is Luigi Niccolai, Via Faenza 44, Florence, Italy.

SOCIETIES AND ACADEMIES.

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

THE 322d meeting was held November 19. Dr. Walter Hough occupied the session with an account of the explorations among the ancient pueblos of northeastern Arizona, carried on by him last season. The paper was illustrated with maps and selections of artifacts from the two thousand specimens secured during the work. The paper was discussed by F. W. Hodge, J. D. McGuire, Hon. H. M. Baker, Mrs. Matilda C. Stevenson, and President W. H. Holmes.

The 323d regular meeting was held December 3. Mr. S. P. Langley presented a paper on 'The Fire Walk of the Tahitans.' Mr. Langley

gave an interesting account of his voyage to the Society Islands. A number of lantern views of the scenery of Tahiti, the natives, their houses and their arts, were thrown on the screen, accompanied by instructive remarks. The incidents leading up to the ceremony of walking over the heated stones of the taro oven were detailed and a series of instantaneous views on the screen showed graphically the fire walk in progress. Mr. Langley dissipated the mystery that has enveloped this startling ceremony since it was first described. Briefly, his investigations show that the volcanic rocks employed are non-conductors, and though very hot on the under surface, are cool enough above to be walked upon with bare feet.

The paper was discussed by Mr. Townsend, W J McGee and Walter Hough. A vote of thanks of the Society was tendered to Mr. Langley for his valuable paper.

Dr. John E. Walsh, of the Peary Relief Expedition, read a paper, entitled, 'The Eskimo, their Country and Habits.' Dr. Walsh gave an account of the environment of the northern Eskimo as affecting their mode of life, their dwellings and arts. He found no evidences of social organization or religion among these Arctic Highlanders beyond certain minor customs. Dr. Walsh's paper was favorably received. In reference to the tattoo marks of the women spoken of by Dr. Walsh, W J McGee discussed the kinship of the Eskimo, adducing evidence that these marks were for the purpose of indicating relationship. Dr. D. S. Lamb and Dr. Frank Baker remarked upon the series of Eskimo skulls presented by Dr. Walsh. These skulls are notably scaphocephalic. Dr. Walsh also exhibited a number of ethnological specimens from his collection.

WALTER HOUGH.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

THE 541st regular meeting was held November 23, 1901. Dr. W. H. Dall spoke on 'The True Nature of Tamiosoma,' a fossil found in California in 1856 and described by Conrad. Its nature has been much discussed for nearly half a century and there has been great diversity of opinion as to its relationships. The speaker has recently acquired sufficient material to

show that some former studies were based on broken specimens, and some on an inversion of the object. It is now clearly seen to be a barnacle.

Mr. J. F. Hayford discussed the question, 'What is the Center of an Area or the Center of a Population,' with especial reference to the general popular notion that the latter is the point which has as many people on one side of it as on the other. The difficulty with this definition is that the point varies according to the direction chosen; the only point that remains fixed, whatever fundamental directions are chosen, is that analogous to the center of gravity of an area; the sum of the squares of the distances from *this* center to all the elements of the area (or population) is a minimum. An ingeniously cut figure showed at a glance the absurdity of the popular idea. Mr. O. H. Tittmann read from an article written by Professor Hilgard in 1872 giving predictions on the movement of the center of population of the United States.

The 542d meeting was held December 7, 1901, Vice-President Gore in the chair.

Mr. Radelfinger presented a curious series that he had met with in differentiating a complex variable.

Professor T. J. J. See, of the Naval Observatory, presented the results of his recent measures of the diameters of the planets by daylight: the observations were made near the close of the day, when the sky was sufficiently lighted to prevent or at least to diminish the error from irradiation. Professor Campbell had made daylight measures on Mars in 1894, but all other published diameters are based on night work. The daylight observations are remarkably consistent, so that the speaker thought the results on Jupiter and Saturn might be relied on to 1 part in 1000. All the results are sensibly lower than former measures gave, *e. g.*, Jupiter, 38".40 by night, 37".65 by day; Neptune, 2".25, and 2".00, respectively. The densities of the planets as computed from these new values of the diameters are much increased. Similarly the diameters of Jupiter's satellites and Titan were measured. (The paper will appear in the *Astronomische Nachrichten*.)

Dr. A. F. A. King read a paper on the 'Etiology of Intermittent Fever,' in which he discussed *sunlight* as a factor in promoting sporulation of the malarial parasite, which he maintained would not take place in continued darkness. Hence 'chills' do not occur at night; races with non-translucent skins are immune; sunshine increases fever, cloudiness decreases it; spontaneous cures were explained by the shade of hospitals; the red light of the blood promoted the vital activity of the parasite, violet light restricted it, hence the cure by Prussian and methylene blues; quinine cured by its fluorescence accentuating the violet rays. (The paper will appear in the *American Journal of Medical Sciences*.)

CHARLES K. WEAD,
Secretary.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 344th meeting was held on Saturday evening, November 30.

William Palmer read some extracts from an illustrated article in one of the Sunday papers, on the alleged occurrence of toads in solid rock, and exhibited plaster molds from which some of the illustrations had been made. One of these molds, made over a dead frog, appeared in the picture labeled, 'a mold in which a frog lived for four days,' while the cast of a salamander was figured as 'a salamander emerging from a plaster mold in which it had remained for several days.'

E. W. Nelson presented a paper entitled 'A Naturalist in Yucatan,' describing the country and its flora, touching also on the ruins at Chichenitza, Uxmal and other points. The little known east coast was partly explored and Cozumel Island visited during Mr. Nelson's trip, and a number of colored lantern slides illustrated some of the most interesting features of plant and animal life observed.

H. J. Webber spoke of 'Strand Flora of Florida,' illustrating his remarks with many views of both the eastern and western coasts and describing the manner in which certain plants aided in forming sand dunes, and others such as the mangroves, in making small islets which later on were added to the mainland. The characteristic plants of various portions of the

coast were noted, and the speaker drew attention to the marked difference shown by some plants, the grape nut for example, according as they grew inland or were exposed to the salt winds from the ocean.

F. A. LUCAS.

THE AMERICAN CHEMICAL SOCIETY, NEW YORK SECTION.

AN unusual degree of interest has been manifested in the work of the Section during the present season. Very full programs have been offered at every meeting, and the attendance has been unprecedented. It has been necessary to hold a special meeting in order to dispose of the great number of available papers, and other special meetings will probably have to be held in the spring. The membership of the Section has increased steadily, and is now over four hundred and fifty. The committee to secure funds for the endowment of the research medal and for the encouragement of research among the members of the Section consists of Mr. Clifford Richardson, Professor C. F. Chandler, Mr. Maximilian Toch, Dr. Theron C. Stearns and Dr. William Jay Schieffelin. It shall be the endeavor of this committee to secure a large endowment fund and to suggest an appropriate name for the Section medal, as well as the detailed conditions governing its award. Since the last report of our meetings appeared in SCIENCE, the following papers have been presented:

Special Meeting, November 1.—Edmund H. Miller, 'On the Composition of the Ferrocyanides of Cadmium'; Marston Taylor Bogert and David C. Eccles, 'On the Production of the Imides of Succinic and Glutaric Acids by the Partial Hydration of the Corresponding Nitriles'; W. G. Lindsay, 'On a Colorimetric Method for the Estimation of Sulphur in Pig-iron'; Thomas F. Hildreth, 'On the Determination of Manganese in Spiegel'; John A. Mathews and William Campbell, 'The Alloys of Aluminium.' This paper was profusely illustrated by lantern photographs. It was presented in two parts. The first part being a review of recent work upon the constitution of alloys, with explanation of the nature of solid solutions, eutectics, pyrometric and metallographic methods of alloys, research, etc., the second part embodied the results of the re-

searches of the authors while in Professor Sir William Roberts-Austen's laboratory.

Regular Meeting, November 8. C. W. Volney, 'The Decomposition of Sodium Nitrate by Sulphuric Acid,' in which he showed that the reactions were much more complicated than has been generally supposed. Martin L. Griffin, of Mechanicsville, N. Y., 'The proximate analysis of the spent alkali liquor from the reduction of poplar wood for paper stock by the soda process, with a description of the method.' Mr. Griffin said that these liquors contain nearly 10 per cent. of acetic acid. The possible recovery of this great quantity of acid offers an interesting problem for chemists. Phoebus A. Levene's 'Preliminary Communication upon Glucoposphoric Acid' was read by the secretary. William Campbell, of London, gave an illustrated talk upon his studies of the constitution of 'The Alloys of Copper and Tin.' Daniel D. Jackson, 'The Photometric Determination of Sulphates,' with exhibition of the apparatus. John A. Mathews, continuing his talk upon the constitution of alloys begun at the meeting of November 1, spoke upon 'Alloys and the Phase Rule.' This paper was illustrated with lantern diagrams and showed how the phase rule may be of use in explaining problems of equilibrium in such complex substances as alloys.

Regular Meeting, December 6. W. H. Birchmore presented an introductory paper, 'Notes and Studies on Molds and their Allies,' accompanied by an exhibit of many specimens. Professor Edgar F. Smith spoke on 'The Value of Electrolytic Methods in Chemical Analysis,' urging upon chemists their use or at least a fair trial of them. He contrasted the advantages of the electrolytic methods with the usual gravimetric methods. Professor Smith stated that twenty-five of the seventy elements could be conveniently determined in this way, and that more than one hundred and fifty separations were possible. Particular mention was made of the electrolytic determination of copper, mercury, bismuth, cadmium, molybdenum and uranium. He also mentioned a rapid electrolytic method for the oxidation of sulphur in natural sulphide minerals, by means of a current of ten or fifteen volts and one ampere. The sulphide is

mixed with fused caustic potash in a nickel crucible which is made one of the electrodes, and a stout rod dipping into the fused caustic alkali is the other electrode. Fifteen minutes serves to oxidize completely the sulphur in pyrites, and most other natural sulphides require less time. Professor Wilder Bancroft read a paper upon 'Analytical Chemistry and the Phase Rule Classification.' Dr. Francis G. Benedict, in a paper upon 'Some Aspects of Ventilation,' gave experimental evidence to show that the high temperature and excessive humidity of expired air is a more potent factor in producing discomfort among those who have to breathe it, as, for example, the inmates of a crowded and ill ventilated room or hall, than is the presence of a high percentage of carbonic acid. The experiments were made with human subjects in Professor Atwater's laboratory, and the results are interesting in that they are very much opposed to general ideas upon this subject and to the results which have been published by previous experimenters as well.

JOHN ALEXANDER MATHEWS,
Secretary.

THE NORTHEASTERN SECTION.

At the last regular meeting of the Section held on November 19, 1901, the following officers were elected for the year 1901-1902: President, L. P. Kinnicutt; Vice-President, Charles R. Sanger; Treasurer, B. F. Davenport; Secretary, Henry Fay.

Professor A. A. Noyes addressed the Society on the 'Importance of Catalytic Agents in Chemical Processes.' The lecture was illustrated by numerous experiments, and was discussed under the following headings: (1) Catalytic Action in which the Catalyser Combines Temporarily with one of the Reacting Substances. (2) Catalytic Action by Absorbent Contact Agents. (3) Catalysis by Electrolytic Agents. (4) Water as a Catalyser. (5) Catalytic Action of Acids, Bases and Salts. (6) Catalysis by Enzymes. (7) Colloids.

At the next regular meeting to be held December 17, Professor C. F. Chandler will address the Section on 'Electro-Chemical Industries at Niagara Falls.'

HENRY FAY,
Secretary.

THE LAS VEGAS SCIENCE CLUB.

THE usual monthly meeting was held November 12. Mr. Cockerell briefly reviewed the work of the members during the past summer. At the end of June the top of the Las Vegas Range (11,000 feet) was revisited, and a considerable collection was made, including a number of species of insects new to New Mexico. The insects of this collection are now being recorded in *Psyche*. Mr. Cockerell exhibited two stone spear-heads, which he found on the top of the Las Vegas Range. Seven members of the club spent a part of the summer on the coast of California, where special attention was paid to the Mollusca. Mrs. Cora W. Hewett exhibited a series of shells which she had collected at Coronado, Point Loma and La Jolla. Mr. Cockerell exhibited the internal shell of *Tethys* (*Neaplysia*) *ritteri*, a new species which he found at San Pedro, and named after the director of the University of California Marine Station at that place. This *T. ritteri* was about 21 cm. long, and differed from *T. Californica* in wholly lacking the bars of white and dark brown on the inner surface of the swimming lobes, these parts being of a pale seal green; it also differed in having oblique, flame-like, blood-red markings on the sides of the body. Outside of the Mollusca, some study was made of the insects of the California coast, and several new species of bees were obtained. Mrs. Cockerell found at San Pedro the hydroid *Aglaophenia octocarpa* Nutting, new to the United States.

Mrs. W. P. Cockerell described how she had succeeded in obtaining the eggs of *Argynnis nitocris nigrocærulea* at Beulah. The larvæ which hatched from them had gone into hibernation without feeding. A communication by Mr. Cockerell and Miss Mary Cooper on the genus *Ashmunella* was presented, and a series of the shells was exhibited. The most interesting was a new species, proposed to be called *Ashmunella antiqua*, found fossil in the Pleistocene beds of Las Vegas, N. M. It resembled in most respects *A. thomsoniana*, but wholly lacked the parietal tooth. Miss Ada Springer exhibited the vertebra of a bison which she had found in the charcoal zone of the Las Vegas (Arroyo Pecos) Pleistocene.

Mr. Emerson Atkins showed a series of drawings of the mouth-parts of wasps and bees. The series indicated an evolution from the type with six-jointed maxillary palpi and four-jointed labial palpi, the joints in each case about equal in length, to forms with five-, four-, three- or two-jointed maxillary palpi, and labial palpi with the joints much elongated and very unequal. It was remarked that the maxillæ increased in size, while their palpi diminished. Mr. John McNary communicated a series of drawings illustrating the venation of the middle of the tegmina in various genera of grasshoppers, viz., *Trimerotropis*, *Leprus*, *Arphia* and *Dissosteira*. It was possible to recognize the same veins as are found in the upper wings of Lepidoptera, but whereas in the Lepidoptera they are very constant and very useful for generic classification, in the grasshoppers, which are more primitive insects, they are found to be extraordinarily variable. If one were to depend on the venation for generic characters in Orthoptera to the same degree that one does in Lepidoptera, *Trimerotropis laticincta*, for example, could be split into three genera.

T. D. A. C.

THE TEXAS ACADEMY OF SCIENCE.

THE first regular meeting of the Texas Academy of Science for the present academic year was held in the chemical lecture room of the University of Texas, at Austin, on the evening of October 26, 1901, when Professor J. C. Nagle, of the Agricultural and Mechanical College of Texas, the newly elected president of the Academy, presented his inaugural address on 'The Influence of Applied Science.'

"My purpose," he said, "is to touch upon a few only of the general features of the world's progress, in which applied science has been an aid not only to material development, but to researches in pure science as well, and to suggest, if possible, some means by which the workers in applied science may be brought to contribute more largely towards advancing the purposes and aims of the Texas Academy of Science."

Continuing, the speaker said: "If the recorded history of the world's progress in thought and material prosperity for the last

two thousand years be roughly divided into two parts—the latter one dating practically from the beginning of the nineteenth century—and if the causes making for the amelioration of man's condition during these two periods be examined, we shall see that a single century of applied science has done more for the world's direct advancement in enlightenment, tolerance and real culture, as well as in material progress, than was accomplished in the preceding nineteen hundred years. Furthermore, a comparison of the opportunities and advantages possessed by man at the beginning, the middle and the end of the nineteenth century will show how much the rate of progress was accelerated during the latter half of the century, and if, judging by this, any prediction for the future may be ventured, we may gain some faint idea of the place applied science is destined to fill in the next fifty years."

Among the subjects dwelt upon somewhat in detail were astronomy, physics, especially electricity, civil engineering, chemistry and biology, with special reference to bacteriology. This address will appear in full in Part II. of Volume IV. of the *Transactions* of the Academy soon to be published.

The second meeting for the year was held on November 22. Mr. T. U. Taylor, professor of applied mathematics in the University, read an abstract of his report to the Hydrographic Division of the United States Geological Survey on the 'Water Power of Texas.' In this report he treats of the water power of the State, both existing and prospective, with special reference to that of the following rivers: Pecos, Devils, San Felipe, San Antonio, Guadalupe, Comal, San Marcos, Colorado and tributaries, Brazos and tributaries. The potential water powers at Llano and Marble Falls are considered in detail, and the latter is pronounced as having the grandest possibilities of any place in Texas. Llano and Marble Falls are in the heart of one of the finest granite regions of the country, and every unit of power could be made to pay in that industry alone.

A translation of a part of the introduction to Dr. Ferdinand Roemer's 'Kreidebildungen von Texas,' by Dr. Frederic W. Simonds and Edmund Wild, was read by the latter. 'Die Krei-

debildungen von Texas' contains observations upon the geology of the State made fifty years ago. It is, in fact, the foundation of Texas geology, and won for its writer the title 'Father of the Geology of Texas.' This work has been a fruitful source of inspiration to later writers upon the geology of this region, and it is now the intention of Messrs. Simonds and Wild to make it accessible to all by means of a carefully prepared English translation.

The midwinter meeting of the Academy will be held simultaneously with that of the State Teachers' Association in Waco during the holiday recess.

FREDERIC W. SIMONDS,

Secretary.

UNIVERSITY OF TEXAS.

THE BOSTON SOCIETY OF NATURAL HISTORY.

At the meeting of the Society, held November 6, 1901, Professor William Morris Davis spoke on 'River Terraces in New England,' with a view to supporting a recent theory to account for the successive stair-like terraces with concave fronts found in many New England valleys. A buried ledge of gradual slope encountered by a meandering stream in its sidewise swingings, throws the stream to one side, and prevents its further cutting action at that point. When the stream, in subsequent swinging across the valley floor, returns once more to the attack, it encounters the ledge at a lower level, and is again turned back; thus the terraces as formed are protected from erosion.

At the meeting of November 20, 1901, Professor E. S. Morse presented the results of his researches on living Brachiopoda. He gave an account of the habits of *Lingula* and *Glottidia* and called attention to their marvelous vitality. He described in detail the structure of the leading forms and announced for the first time the œsophageal glands in *Lingula*. A correlation was shown between the presence or absence of setæ and the development of the pedicle; the errantian forms and those moving freely on the pedicle having the setæ greatly developed, those more restricted in their motion having shorter and fewer setæ, while those with lower valve fixed to the rock, such as *Mergerlia*, *Crania*, etc., are without setæ. In the young of all forms studied, the setæ were present, and of great

length. The cœcal tubes, which Dr. Sollas has shown to be probably organs of tactile impression, were wanting in the errantian forms, more or less abundant in those moving freely on a fixed pedicle, and in those fixed by the lower valve, abundant, and in *Crania* even branching. He described the external glands of *Terebratulina*, as well as the strand-like bundle of sperm cells. He insisted that the Heart of Hancock was not a pulsating organ, and was inclined to believe that the 'accessory hearts' were genital in their nature.

GLOVER M. ALLEN,
Secretary.

DISCUSSION AND CORRESPONDENCE.

CONNECTICUT RIVERS.

IN the issue of SCIENCE of November 29, 1901, Professor W. M. Davis reviews my paper on 'The River System of Connecticut' (*Journal of Geology*, IX., 1901, pp. 469-485) and expresses his doubt respecting the principal thesis of the paper; namely, that Connecticut rivers betray by their orientation a controlling influence of joint or fault planes. The subject of stream orientation is a large one and the explanation offered a somewhat new one for American rivers at least. The thesis is one not easily demonstrated as respects the larger area treated, and the review seems to me to be in the main an eminently fair one. From it I infer, however, that my paper may in some particulars be susceptible of misinterpretation, and, therefore, take this opportunity to correct certain impressions which appear in the review, so as, if possible, to prevent further misunderstanding.

If I have omitted to speak at length of the particular controls of stream orientation other than by joint and fault planes, it has not been because I would ascribe little importance to them, but because in a general paper dealing with a special kind of control it was obviously impossible to treat all at length. On page 474 it was stated:

"It is not to be expected that the actual course of a stream will now be coincident with or even absolutely parallel to any fault direction, for there have unquestionably been many local conditions which have produced larger or smaller migrations of the river channels. Their

general direction has, however, it would seem, been maintained despite the minor accidents which have marked their life histories, and even under so revolutionary a change as complete reversal of drainage."

I should certainly agree with Professor Davis when he says that, "it is inherently improbable that the Pomperaug fault lines possess an extension all over the State in systems so rigid as are here postulated." And it was a matter of some surprise to me when the natural trough lines were found in so many instances to correspond to known fault directions of the Pomperaug Valley. Some explanation of this may, however, be found in the fact that the lines noted for the master streams of the State correspond in direction, not to the prevailing faults in the Pomperaug Valley, but rather to the exceptional ones. In the Shepaug Valley immediately adjacent to the Pomperaug, however, the only control observable is from the four directions of faulting which prevail in the Pomperaug Valley. It is my anticipation that when the theory is applied in detail to the broader area of the Connecticut Valley, and the directions of streams carefully compared with the directions of the actual *minor* as well as major faults of that Newark basin, a control will be recognized to have gone out from the planes of faulting. That the directions which were discovered in the Pomperaug Basin will be found to be the only ones I do not of course expect, and it is quite likely that in certain areas they may not appear at all. That an elaborate system of joints and faults, analogous to that of the Pomperaug Valley exists and is accountable for the zigzag outlines of the trap hills scattered over the Connecticut Valley seems to me, however, hardly to admit of doubt. That such a system ceases to exist beyond the border of the Newark is, in my view, inherently improbable.

I should be the last to wish to push the theory of control of streams by fault and joint planes beyond what the facts warrant. In the Pomperaug Valley itself the faults supposed to control the drainage were in the majority of instances discovered. In the near-lying area, *e. g.*, the Shepaug river basin, where the rivers adhere to the four prevailing fault directions of the Pomperaug Valley, this explanation seems

almost a necessity. As regards, however, the extension of the system throughout the State, where individual work in the field should be done in order to familiarize the worker with special and local conditions, I fully recognize the incompleteness of the evidence. It deserves to be emphasized, however, that the student of a carefully prepared map has always at hand the accumulated knowledge acquired by the corps of topographers whose painstaking labor it represents—labor which the modern school of physiographers has been quick to use as the basis of their conclusions. It is not assumed that along every trough line of the map lies the course of a fault. In my article it is stated (p. 478):

“The term ‘trough lines’ * * * may, for the present, be given no further signification than lines so favored by nature that the waters of the region have been induced to adopt them for their channels over longer or shorter distances. On a map of this scale the trough lines, if rectilinear, should be slightly curved, but inasmuch as the present river courses, because of the many accidents of their history, can only roughly approximate to the directions initially given them, it would be an over refinement to introduce a correction of this nature.”

Evidence obtained from the examination of a map by this method can only be of value when cumulative. A single stream which persists in a given direction even for a long distance affords little support to the theory, when compared with that yielded by a number of smaller streams each approximating to a rectilinear course for a shorter distance, *provided the rectilinear courses are parallel*. A harder layer of rock, or a barrier of drift may conduct one stream or the other in its course, but it is inherently improbable that one of these causes or the other, or both combined, have controlled the parallel river series in an area of such geological structure as we find in the State of Connecticut. As was pointed out in the paper, it is worthy of note that so few of the master streams of the area follow the slope of the plain of erosion. As regards the larger area of the State the theory may, perhaps, as Professor Davis says, ‘be regarded as standing in an interrogative rather than in a demonstrative at-

titude,’ but it would be doing injustice to the facts to consider the trough lines as isolated lines while ignoring their arrangement in parallel series.

WM. H. HOBBS.

PHYSIOLOGICAL EFFECT OF DIMINISHED AIR PRESSURE.

TO THE EDITOR OF SCIENCE: The interesting communications of Messrs. Clayton and Ward upon the physiological effects of the diminished air pressure due to mountain climbing recall some records which I made in 1896 during an ascent of El Misti, Peru, similar to that described by Professor Ward. As the effect of the high altitude upon my condition was in part different from that experienced by him, it may be of interest to describe it. The journey from the observatory at Arequipa, elevation 8,050 feet, to the summit of El Misti, elevation 19,200 feet, was made on four occasions. The distance is about 25 miles. It is possible to ride on horseback or muleback to the very summit, following a caravan trail across the pampa to the base of the mountain, and ascending by a winding path constructed with great skill by Professor S. I. Bailey when the meteorological station was established. The journey from the observatory to a hut at an elevation of about 15,400 feet occupies one day, during which the rider is usually obliged to endure the scorching rays of the sun. The night is passed at the hut, and the final ascent to the summit made on the second morning. This occupies several hours, as the animal stops to rest every fifteen or twenty feet at this altitude. On two occasions I was obliged to walk a short distance to cross snow which had drifted across the path, and realized the extreme difficulty of breathing during the exertion required. The return from the summit to the observatory is easily made on the second day, but on two occasions I spent a second night at the hut.

The effect of the altitude upon me was chiefly to cause headache, sleeplessness and partial loss of appetite. On one occasion while at the summit I experienced a decided feeling of faintness for a short time. During the nights at the hut the temperature was about 32° Fahr., but it seemed impossible to keep the body warm, in

spite of arctic sleeping bag and blankets and overcoats so numerous that one could hardly lift the weight in breathing. On the trips in which a second night was passed at this height, more sleep was secured, indicating that the body was getting adjusted to the altitude. The headache disappeared and the appetite revived on the return trip. On the first of these trips, records were made of the pulse and respiration, as accurately as could be made by a person upon himself. They are as follows: Aug. 18, 10 p. m., at observatory on retiring, pulse 80, respiration 16; August 19, 6.00 a. m., on rising, pulse 80, respiration 16; 3.30 p. m. at *tambo de los huesos*, elevation 13,300 feet, pulse 96, respiration 12; Aug. 20, 6.25 a. m., at hut 15,400 feet, on rising, pulse 90, respiration 12; 12.30 p. m., at summit, 19,200 feet, pulse 86, respiration 11; Aug. 21, 10 a. m. at hut, 15,400 feet, pulse 86, respiration 11. The rather small increase in the pulse and the decrease in the respiration are noteworthy. While I made no records on other trips, I noticed frequently that my tendency was to breathe more slowly than usual, except when moving about.

WINSLOW UPTON.

PROVIDENCE, R. I.,
December 7, 1901.

SCIENTIFIC ORNITHOLOGY.

THE following remarkable misuse of terminology occurs in Mr. Robert Ridgway's 'Birds of North and Middle America,' Part I., The Finches, just from the press of the Government Printing Office. He says in his Introduction: "There are two essentially different kinds of ornithology: *systematic*, or *scientific*, and *popular*. The former deals with the structure and classification of birds, their synonymies and technical descriptions. The latter treats of their habits, songs, nesting, and other facts pertaining to their life-histories." And he continues: "Popular ornithology is the more entertaining with its savor of the wildwood, green fields, the riverside and seashore, bird songs and the many fascinating things connected with out-door nature. But systematic ornithology, being a component part of biology—the science of life—is the more instructive and therefore the more important." And are, indeed, life-habits and life-history not biology, not, if scientifically

studied, science of life, not more important than the mere forms which result from this part of bird biology? Could there be found a worse misconception of where science and popular writing differentiate!

X.

SHORTER ARTICLES.

THE RESULTS ATTENDING THE EXPERIMENTS IN LOBSTER CULTURE MADE BY THE UNITED STATES COMMISSION OF FISH AND FISHERIES.

IN April, 1900, the United States Commission of Fish and Fisheries appropriated several thousand dollars to be used in devising, if possible, a practical method of artificial lobster culture, and the undersigned was appointed to take immediate charge of the experiments.

The breeding period of the lobster, continuing as it does only through a few weeks of the late spring and early summer, is so brief that extended experiments have been impossible, but the experiments that have thus far been made (during the spring of 1900 and of 1901) would indicate that very large numbers of lobsters may be hatched and retained in captivity until they have reached an age when they are well able to take care of themselves. Indeed, it would seem that the enormous mortality among lobster young (which results either from boiling females 'in berry,' or stripping the eggs from the female as the lobsters are taken from the traps) may not only be lessened, but that the young enclosed in these eggs may, with very little expense, be hatched in the more important fishing ports and hamlets and protected until they have passed through the critical stages.

It seems advisable to defer the rendering of the final report until the Commission has profited by the experiments of another season. Inasmuch, however, as the problem is of considerable economic importance, it would seem desirable to make some report at the present time, although only a report of progress.

In the spring of 1900 a number of experiment stations were established along the New England coast, namely, at Orrs Island, Freeport, Annisquam, Gloucester, Woods Holl, Naushon and Wickford. Experiments had been made previously at Woods Holl, but without encour-

aging results, and it was thought that the establishment of several stations might result in the discovery of some locality having physical and biological conditions more favorable than those found at the government laboratory. The officers of the stations at Gloucester and Woods Holl and the officers of the *Grampus*, *Fish Hawk* and *Phalarope* cordially cooperated in the work of the special committee, but the experiments at all the stations excepting that at Wickford were discouraging. The lobster fry, even in the cold clear water of the Gulf of Maine, would soon become covered with a chenille-like growth of diatoms and would die, no matter what kind of enclosures were used.

At Wickford, however, where the Rhode Island Commission had courteously given the use of their floating house-boat, the fry seemed to find a more congenial environment. In what respects the water and the plankton at Wickford were more favorable to the fry cannot at the present time be stated; it was, nevertheless, a fact that the young taken from the hatchery at Woods Holl would quickly perish when confined at various localities near Woods Holl, but would thrive when placed in the same kind of enclosures at Wickford. The water at Wickford is rather fresh and of high temperature (often ten degrees higher than at Woods Holl). It is charged with vegetable and animal life, and the current is sufficiently strong to assist materially in the aeration of the water in the enclosures.

Many different devices for enclosures were adopted and tried. Large salt-water ponds, smaller pools, artificial pools made by the building of dikes, enclosures made of wire screen and floated and wire screen and submerged, huge canvas boxes and cars, cars of scrim floated and anchored at the bottom, glass jars of various sizes, running water in vessels of wood, metal, glass, porcelain and stone, and various rotary devices, all proved efficient agents for the killing rather than for the rearing of lobster fry.

The only enclosures which gave encouraging results were made out of scrim in the shape of huge bags some sixteen feet in diameter and several feet in depth and so leaded at the bottom that they would rise and fall with the current and agitate the enclosed fry. But the current

was not sufficient at all times to keep the young lobsters from settling to the bottom, devouring one another and gathering into a confused mass of maimed and struggling individuals. At these times it was necessary for the staff at Wickford to agitate the water artificially, and this was done by the use of paddles.

To Dr. A. D. Mead, who was the director of the Wickford laboratory, is due the credit of having demonstrated the importance of keeping the young lobsters from the bottom of the enclosure, by either natural or artificial means.

Under favorable conditions the growth of the young fry is phenomenal. The first molt takes place about six days after the young have left the egg, the second molt some six days later and the third about five days later still. The third molt takes the fry into the fourth stage, when they assume the characters and habits of the adult. Under the most favorable conditions this fourth stage may be reached in nine days from the time the lobsters are taken from the hatching-jars, but under less favorable conditions, within the same enclosures, certain individuals may be found in the second stage after a lapse of several weeks. In both structure and habits the young that have reached the fourth or 'lobsterling' stage are very different from those of the previous stage. These older individuals (known at the laboratory as 'four-ses') are provided with pinching-claws, hardened shell and vigorous muscles. They are very active, have a voracious appetite, and are pugnacious and secretive.

It is well known that the planting of a few young trout in the fingerling stage will accomplish much more toward restocking our streams than the planting of many thousand fry, and I think it safe to conclude that the planting of many thousands of lobsters in the 'lobsterling' stage would do much more toward rehabilitating the waning lobster industry than the planting of many millions of helpless fry as they leave the hatchery.

No special effort was made in 1900 to treat the fry after they had reached the fourth stage, but a few were retained. Those of the United States Fish Commission office at Washington have been obliged to endure the more artificial environment of an aquarium. Those at Wick-

ford have had a somewhat more natural environment, having spent the winter in a submerged crate. They are hardy, voracious and seem to thrive.

The plans for the second year were based on the successes and failures of the first, and it was thought best to take advantage of the favorable environmental conditions at Wickford, to discontinue the work elsewhere, and to put all the energy into devising some economical contrivance for keeping the water so agitated that the fry would not and could not settle to the bottom.

After many experiments, a relatively simple and inexpensive device was adopted. Several bags of scrim about three feet in diameter and four in depth were so suspended in the pool of the floating laboratory that the current could not change their general shape or cause them to collapse. In each bag was placed a dasher, the blades of which in rotation would constantly lift the water through the mesh at the bottom of the bag and urge it with obviously less velocity through the pores of the vertical walls. The dashers were kept in motion by means of a small gasoline engine, the motor apparatus as a whole having a striking resemblance to the aerating equipment of a second-class restaurant. The scrim bags looked like so many vertical cylinders. We found that when the mechanism was in actual operation the current in rising through the bottom of the bag brought with it large numbers of pelagic animals, while the reduced current of the water passing through the greater expanse of the vertical walls was not sufficient to carry this living material out of the bags; thus the apparatus sufficed not only for keeping the fry and artificial food from the bottom, but it also provided the fry with living natural food. To Mr. George H. Sherwood is due the credit of devising and installing this aerating and feed apparatus.

In practice it was found that the eggs stripped from the abdomen of the female would hatch in these scrim enclosures under much more favorable conditions than in McDonald jars. Indeed, I am inclined to believe that a far higher percentage of eggs would hatch in these bags than in the McDonald jars, and I am sure that the young are in a much more healthy condition

than when hatched by the older method. Even a superficial examination of the young that have spent some hours in the trituration of the McDonald jars will show that a large proportion of them have the appendages broken, bent or indented.

The number of fry that were available for the purpose of experimentation during the first season was considerably less than in 1900, and the period of experimental work was also materially reduced. Nevertheless, Dr. Mead, who had the work immediately in charge, reports that by actual count in no case was the number of lobsters that reached the fourth stage less than 16 per cent. of the number of fry originally placed in the enclosure. In a few cases it was above 40 per cent. and in at least one case it was as high as 54 per cent. In previous years no experiments had yielded more than a fraction of one per cent. The total number of lobsters raised to the fourth stage during the season of 1901 (in the twelve cylinders) was a little more than nine thousand.

Encouraged by these results, the United States Commission of Fish and Fisheries is now planning to equip one or more stations with the aerating, hatching and brooding apparatus above described, and to actually test the feasibility of raising large numbers of fry to the fourth stage, and I feel convinced that the liberation of large numbers of these more hardy young will result in the restocking of our depleted waters.

H. C. BUMPUS.

AMERICAN MUSEUM OF NATURAL HISTORY.

ON THE STRUCTURE OF THE MANUS IN BRONTOSAURUS.

During the past season, while engaged in collecting vertebrate fossils for the Carnegie Museum, Mr. Charles W. Gilmore had the good fortune to discover in the Jurassic exposures on Sheep Creek, in Albany Co., Wyo., a very considerable portion of the skeleton of *Brontosaurus*.

This skeleton was very carefully taken up by Mr. Gilmore and has been received at the museum. Among the more important parts secured was a nearly complete fore limb and foot with the different elements for the most part still retained in their normal position, making it possible for the first time to definitely deter-

mine most of the more important points regarding the structure of the manus in this genus of the Sauropoda.

The entire limb and foot were taken up in two sections, in one of which was the humerus, while the other contained the radius, ulna, and such portions of the manus as were preserved, consisting of the supposed scapholunar, the complete series of metacarpals, the five proximal phalanges, and the ungual of the first digit. All these elements when found, except the scapholunar, lay in approximately their normal positions, with reference to each other, and thanks to the skill and care of Mr. Gilmore, they were so taken up and packed that their original positions had not been disturbed when the limb and foot were unpacked in the laboratory.

The radius, ulna and manus have already been partially freed from the matrix by Mr. Gilmore, and throw considerable light upon the structure of the latter.

The limb when found lay with the palmar side up. The proximal end of the radius lay in the radial groove on the anterior surface of the ulna, these bones still articulating with the distal end of the humerus. Lying between and upon the palmar side, near the distal end of the radius and ulna, was a large flat bone presenting on one side a gentle but regularly convex surface, and on the other two flat, subequal surfaces separated by a low ridge. This bone I have interpreted as the scapholunar, and it seems to be the only carpal element retained in the *Brontosaurus* manus.

Metacarpals I., II., III., IV., V. were in regular order at the distal extremity of the radius and ulna, though the first and fifth were closely applied to the external lateral surfaces of the distal ends of the radius and ulna, indicating that in life they articulated directly with these bones, perhaps through the intermedium of heavy cartilaginous pads, while the three median metacarpals were a little more removed in order to accommodate the scapholunar mentioned above.

The proximal phalanges of all the digits were present and nearly in their normal positions with relation to their respective metacarpals. That of digit I. was in contact with its meta-

carpal, but shifted from its normal position so that its external lateral surface was opposed to the distal end of the metacarpal, with its proximal articular surface turned inward toward the median axis of the foot, and the distal outward. The proximal phalanx of digit II. was in position at the extremity of metacarpal II., but very much flexed, so that its longitudinal axis lay almost at right angles to that of metacarpal II. It is much the larger and stronger of the series of proximal phalanges, and has the distal articular surface deeply grooved for the keel of the second phalanx. The first phalanx of digit III. is much smaller than that of the second, and presents distally a small, but well-formed and slightly grooved, surface for the articulation of the succeeding phalanx. It (the first) was found in its proper position at the extremity of metacarpal III., and there was on the palmar side, interposed between it and that bone, a small rounded sesamoid. The proximal phalanx of the fourth digit was in position articulated with metacarpal IV. It is the smallest of the series and presents distally an ill-defined articular surface. That of digit V. lay at the extremity of its metacarpal, but with its external lateral surface opposed to the distal end of the latter. This phalanx is slightly larger than the corresponding one of digit IV., but its distal extremity scarcely shows any trace of an articular surface for a succeeding phalanx. These were the only phalanges found with this foot except the ungual of the first digit, which lay in its normal position with reference to that of the first phalanx as the latter has been described above, except that it was turned on its side and had been moved slightly backward, and lay with its articular surface abutting against the external border of the distal articular surface of the first phalanx and the external lateral surface of metacarpal I.

There was a slight vertical displacement in the carpal region, so that the distal ends of the radius and ulna were a little lower than the metacarpals. Metacarpals I. and V. lay in such position with reference to II., III. and IV. as to indicate that the proximal ends of these bones were arranged in the arc of a circle, and not horizontally.

From the above brief description it will readily appear that the Sauropod manus in *Brontosaurus* at least was like the pes, arranged on the entaxomic plan, and not mesaxomic as Professor Osborn was led to believe from a study of the abundant but isolated material in the collections of the American Museum of Natural History.

This foot and limb will be more fully described and adequately illustrated in the coming number of the *Annals* of this Museum.

J. B. HATCHER.

CARNEGIE MUSEUM,
December 2, 1901.

GOLDFISH AS DESTROYERS OF MOSQUITO LARVÆ.

IN Professor L. O. Howard's recent excellent volume on 'Mosquitoes,' etc. (p. 161), reference is made to a reported employment of 'carp' as destroyers of mosquito larvæ and doubt is expressed as to the facts in the following words:

"It was stated a number of years ago in *Insect Life*, that mosquitoes were at one time very abundant on the Riviera in South Europe, and that one of the English residents found that they breed abundantly in the water tanks, and introduced carp into the tanks for the purpose of destroying the larvæ. It is said that this was done with success, but the well-known food-habits of the carp seem to indicate that there is something wrong with the story. If top-minnows or sticklebacks had been introduced, however, the story would have been perfectly credible, and it points to the practical use of fish under many conditions."

An examination of *Insect Life* (Vol. IV., p. 223) and also of *Nature* (Vol. XLIV., 1891, p. 591)—the original source of the statement in question—fails to reveal the precise species of 'carp' here referred to, but if, as seems likely, it was the common goldfish, *Carassius auratus*, I happen to be in a position to confirm the general truth of the story.

About six years ago at my home in Belmont, near Boston, Massachusetts, I constructed a small artificial pond in which to grow water-lilies and other aquatic plants, and also to breed, if possible, some varieties of goldfish—though the latter object was a secondary consideration.

The advisability of making this pond had been somewhat questioned on account of its close proximity to my house and the fact that such ponds are likely to become excellent places for the propagation of mosquitoes. Nevertheless, the plan was carried out and the pond was stocked with goldfish taken from natural ponds in the vicinity where they had been living and breeding, to my personal knowledge, for a number of years.

The aquatic garden has proved a success and the goldfish have meantime thriven and multiplied. Moreover, no mosquitoes attributable to the pond have appeared and I have been unable to find any larvæ in it, although I have searched repeatedly and diligently for them. I have always believed that the absence of mosquito larvæ from this pond was due to the presence of the goldfish, and I have so stated in a paper 'On the Drainage, Reclamation and Sanitary Improvement of Certain Marsh Lands in the Vicinity of Boston' in the *Technology Quarterly*, XIV., 69 (March, 1901), as follows: "In the water [of this pond] are hundreds of goldfish that feed upon the larvæ of mosquitoes and serve to keep this insect pest in check."

On observing the statement referred to in Professor Howard's book I determined to make careful observations, to settle the point in dispute. Within fifty feet of the pond in question stands a large tank which for a long time last summer was filled with rain water. Here I found constantly large numbers of mosquito larvæ, of both *Culex* and *Anopheles*. Between this tank and the pond runs a cool brook, fed by a spring. Here also I found abundant mosquito larvæ, those of *Anopheles* being more prevalent than those of *Culex*. Reflecting upon this fact it seemed more probable than ever that the goldfish were holding the mosquitoes in check in the artificial pond while in the brook the insects were breeding in comparative safety.

To test the correctness of my theories I took from the pond a small goldfish about three inches long and placed it in an aquarium where it could, if it would, feed upon mosquito larvæ and still be under careful observation. The result was as I had anticipated. On the first day, owing perhaps to the change of environment,

and to being rather easily disturbed in its new quarters, this goldfish ate eleven larvæ only, in three hours; but the next day twenty were devoured in one hour; and as the fish became more at home the 'wrigglers' disappeared in short order whenever they were dropped into the water. On one occasion twenty were eaten in one minute, and forty-eight within five minutes. This experiment was frequently repeated, and to see if this partiality for insect food was a characteristic of those goldfish only which were indigenous to this locality, I experimented with some said to have been reared in carp-ponds near Baltimore, Maryland. The result was the same, though the appetite for mosquitoes was even more marked with the Baltimore fish than with the others. This was probably due to the fact that they had been in an aquarium for a long time before I secured them, and had been deprived of this natural food. I also tried the experiment of feeding commercially prepared 'goldfish food' and mosquito larvæ at the same time, and found that in such a case the goldfish invariably preferred the larvæ.

It is not as generally realized as it should be that goldfish will thrive in our natural northern waters. In my experience they can easily be bred in any sheltered pond where the water is warm and not fed by too many cold springs, and form any years they have been breeding naturally in many small ponds in the vicinity of Cambridge, Massachusetts.

When it is once understood that these fish are useful as well as ornamental and comparatively hardy, it is to be hoped that they will be introduced into many small bodies of water where mosquitoes are likely to breed, and thus be employed as a remedy for mosquitoes sometimes preferable to kerosene.

WILLIAM LYMAN UNDERWOOD.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY, November 27, 1901.

NOTES ON INORGANIC CHEMISTRY.

NEW WORK ON RADIUM.

A NEW series of experiments has been carried out by Berthelot on radium, with reference to its chemical action, as shown upon several compounds. The radium used was enclosed in one sealed glass tube within another, and in

some of the experiments within a third, so that its influence was much weakened and some of the active rays were altogether cut off. The action took place in the dark and was exceedingly slow. Iodin pentoxid was decomposed by the radium rays just as by light, and the same was true of nitric acid. Since both of these reactions are endothermic, the rays must furnish chemical energy. The change of rhombic sulfur into the insoluble variety, an exothermic reaction which is effected by light, was not affected by the radium rays. The rays have no influence upon acetylene, which is very sensitive to the action of the electric current but is unaffected by light. Oxalic acid also was not changed, though it is readily oxidized even in diffused light. The glass tubes in which the radium was contained were blackened, owing probably to a reduction of the lead. A purple color was also noticed in the glass near the blackened portions, which was attributed to an oxidation of the manganese present.

In this connection it may be noted that the existence of the radio-active lead, recently described by Hofmann and Strauss, is denied by Giesel. He considers it to be a mixture of lead with a little radium. He confirms, however, the observation of several workers, that water can be rendered strongly radio-active by radium. He enclosed half a gram of radium-barium bromid in one arm of a sealed U-tube, distilled the water of crystallization over into the other arm, and then sealed it off by fusion. Both the water and the air in the sealed tube were strongly active, more so indeed than the original salt. That this was not due to minute particles of radium which had been driven over mechanically was proved by the fact that the radio-activity disappeared within a few days.

AMMONIA ON METALS.

IN endeavoring some years since to find a metal which would withstand the action of ammonia gas at high temperatures, G. T. Beilby noted the fact that every metal tested soon become brittle and spongy. In conjunction with G. G. Henderson, Mr. Beilby has now investigated the phenomenon more closely and the results are published in the last number of the *Journal of the Chemical Society* (London). It has

long been known that ammonia is rapidly decomposed into nitrogen and hydrogen by the action of red-hot iron, but the effect upon the iron has attracted less attention. The authors find that whatever the metal used, it becomes changed in its appearance and very brittle. With some metals, as iron, the action is very rapid, with others slower, but even gold and platinum cannot resist this action of ammonia. Under the microscope the metal gives evidence of having been fused or semi-fused, and of bubbles of gas having escaped through the fused metal. The authors conclude that under the influence of the ammonia a nitrid of the metal has been formed, which is stable only within narrow limits of temperature, and which is fusible at the temperature of its formation. At slightly higher temperatures than that of its formation, it is decomposed into the metal and the escaping nitrogen gives the peculiar appearance to the metal. Pure iron was found to be rendered hard and brittle by the absorption of small quantities of nitrogen and a rod of charcoal iron was made so hard that it could be used as a drill. The thought naturally suggests itself that the presence of nitrogen may play some part in the manufacture of cement steel. The results of this investigation make it clear that there is no metal of which pipes can be made for the conveyance of ammonia at high temperatures, and that porcelain is the only available material for this purpose.

FITTICA'S LATEST TRANSMUTATION.

PROFESSOR FITTICA has been heard from again, and this time he claims to convert boron into silicon, or rather he considers boron to be an oxid of silicon, contaminated perhaps with carbon. By heating boron in a silver dish with sodium or potassium or their hydroxids, he obtains a dark, oily mass, from which carbon can be isolated by acidifying. The chief constituent of this mass, however, is silicic acid, as shown by familiar tests. The alkali was proved to be originally free from silicic acid, but no evidence is presented that the boron used did not contain silicon. Other methods for effecting this conversion were successful, but all seem to be open to the same criticism.

J. L. H.

CIRCULAR OF INFORMATION OF THE NATIONAL BUREAU OF STANDARDS, NO. 1.

ANNOUNCEMENT OF ORGANIZATION.

By an act of Congress approved March 3, 1901, the Office of Standard Weights and Measures of the Treasury Department was, on July 1, 1901, superseded by the National Bureau of Standards, the functions of which are as follows: The custody of the standards; the comparison of the standards used in scientific investigations, engineering, manufacturing, commerce, and educational institutions with the standards adopted or recognized by the Government; the construction, when necessary, of standards, their multiples and subdivisions; the testing and calibration of standard measuring apparatus; the solution of problems which arise in connection with standards; the determination of physical constants and the properties of materials, when such data are of great importance to scientific or manufacturing interests and are not to be obtained of sufficient accuracy elsewhere.

The Bureau is authorized to exercise its functions for the Government of the United States, for any State or municipal government in the United States, or for any scientific society, educational institution, firm, corporation, or individual within the United States engaged in manufacturing or other pursuit requiring the use of standards or standard measuring instruments.

For all comparisons, calibrations, tests, or investigations, except those performed for the Government of the United States or State governments, a reasonable fee will be charged. Provision is also made for the purchase of a site and the erection of a suitable laboratory, its equipment with the most improved facilities and the personnel necessary for the organization of the Bureau.

A suitable site has been selected in Washington in a locality free from mechanical and electrical disturbances, and yet easy of access. Plans are being prepared for a physical laboratory which will be equipped with apparatus and conveniences for carrying on investigations, and for testing standards and measuring instruments of all kinds. Also a somewhat similar building, to be known as a mechanical labora-

tory, which will contain the power and general electrical machinery, the instrument shop, refrigerating plant, storage batteries, dynamos for experimental purposes, and laboratories for electrical measurements requiring heavy currents.

The construction of the buildings will be pushed as rapidly as possible, and it is expected that they will be ready for occupancy by January 1, 1903. For the present, additional quarters have been secured in the building occupied by the former Office of Standard Weights and Measures, with a view to the organization of the bureau and the immediate development of the more needed extensions of the work heretofore carried on, such as photometric measurements, the testing of instruments for determining high or low temperatures, clinical thermometers, chemical glass measuring apparatus, electrical apparatus used to measure alternating currents, pressure gauges, and meteorological instruments.

For the present, however, the work of the bureau will be limited to the comparison of the following standards and measuring instruments, either for commercial or scientific purposes:

Length Measures.—Standard bars from 1 to 10 feet, or from 1 decimeter to 5 meters; base bars; bench standards; leveling rods; graduated scales; engineers' and surveyors' metal tapes 1 to 300 feet or from 1 to 100 meters.

Weights.—From 0.01 grain to 50 pounds, or from 0.1 milligram to 20 kilograms.

Capacity Measures.—From 1 fluid ounce to 5 gallons, or from 1 milliliter to 10 liters.

Thermometers.—Between 32° and 120° Fahrenheit, or 0° to 50° centigrade.

Polariscope Apparatus.—Scales of polariscopes, quartz control plates, and other accessory apparatus.

Hydrometers.—Alcoholometers, salinometers and saccharometers whose scales correspond to densities between 0.85 and 1.20.

Resistances.—Coils of the following denominations: 1, 2, 5, 10, 100, 1,000, 10,000, 100,000 ohms; low resistance standards for current measurements of the following denominations: 0.1, 0.01, 0.001, 0.0001 ohm. Coils of resistance boxes; potentiometers; ratio coils.

Standards of Electromotive Force.—Clark and other standard cells.

Direct Current-Measuring Apparatus.—Millivoltmeters and voltmeters up to 150 volts; ammeters up to 50 amperes.

It is the desire of the Bureau to cooperate with manufacturers, scientists, and others, in bringing about more satisfactory conditions relative to weights and measures in the broader meaning of the term, and to place at the disposal of those interested such information relative to these subjects as may be in possession of the Bureau.

S. W. STRATTON,
Director.

WASHINGTON, D. C.

*MEETINGS OF SCIENTIFIC SOCIETIES AND
CONVOCATION WEEK.*

WE call special attention to the calendar of the meetings of scientific societies which begin shortly after the issue of the present number of SCIENCE. They are as follows:

The American Association for the Advancement of Science. A meeting of the council will be held at the Quadrangle Club, University of Chicago, on the afternoon of January 1. Section H (Anthropology) will meet in the Field Columbian Museum, Chicago (December 31 and January 1 and 2). The next regular meeting of the Association will be held at Pittsburg, Pa. (June 28 to July 3). A winter meeting is planned to be held at Washington during the convocation week of 1902-3.

The American Society of Naturalists will hold its annual meeting at the University of Chicago (December 31 and January 1). In conjunction with it will meet the Naturalists of the Central States and several affiliated societies, including the American Morphological Society (beginning on January 1); The American Physiological Society (December 30 and 31); The American Psychological Association and the Western Philosophical Association (December 31 and January 1 and 2); The Society of American Bacteriologists (December 31 and January 1), and The American Association of Anatomists (December 31 and January 1 and 2).

The Astronomical and Astrophysical Society of America will meet in Washington (beginning on December 30).

The Geological Society of America will meet at Rochester, N. Y. (December 31 and January 1 and 2):

The American Chemical Society will meet at the University of Pennsylvania, Philadelphia (December 30 and 31).

The Society for Plant Morphology and Physiology meets at Columbia University, New York City (December 31 and January 1 and 2).

The American Mathematical Society and the American Physical Society meet at Columbia University, New York City (December 27 and 28).

SCIENTIFIC NOTES AND NEWS.

DR. ADOLF MEYER has been selected as director of the Pathological Institute of the New York State Hospitals. Dr. Meyer is at present director of the clinical work and laboratory of the Worcester Insane Asylum and docent in psychiatry in Clark University.

THE Paris Academy of Sciences has filled the vacancy in the section of physics, caused by the death of Dr. Raoult, by the election of M. Gouy, of Lyons, to corresponding membership.

LORD AVEBURY has been elected a foreign member of the Swedish Academy of Sciences.

PRESIDENT REMSEN, of the Johns Hopkins University, was entertained by the alumni in Boston on December 16. Speeches were made by President Remsen, President G. Stamley Hall, of Clark University, Professor A. L. Kimball, of Amherst College, Professor L. P. Kinnicut, of the Worcester Polytechnic Institute, Professor W. T. Sedgwick, of the Massachusetts Institute of Technology, and others.

PRESIDENT ELIOT, of Harvard University, has planned a trip to the Pacific Coast and the South, during which he will make many addresses. He will leave Cambridge about February 20, and will return the latter part of April.

PRESIDENT HARPER, of the University of Chicago, has declined the directorship of the International Congress at the St. Louis Exposition.

PROFESSOR W. W. ROWLEE, of the botanical department of Cornell University, and Professor J. C. Gifford, of the College of Forestry, have gone on an expedition to Cuba to study the forests and botany of western Cuba and the Isle of Pines.

PROFESSOR JOHN MACFARLANE and a party of students from the University of Pennsylvania are spending the Christmas holidays in botanical field work in Florida.

M. IZARE WEILLAR has come to the United States commissioned to study the organization of our technical schools and business methods.

DR. L. O. HOWARD, chief of the Division of Entomology, Department of Agriculture, lectured before the Biological Club of the Woman's College of Baltimore last week, on 'Mosquitoes and their Relation to Disease.'

PROFESSOR F. W. CRAGIN has recently obtained a new Colorado meteorite. It is from the eastern part of the State, and, like the three or four others hitherto found in Colorado, is an iron; the date of the fall is unknown. It is of square-lenticular form, strongly pitted, and weighs forty-two pounds.

DR. SVEN ANDERS HEDIN, the Swedish traveler, who has been exploring in the Gobi Desert and Thibet, has reached Ladakh, Kashmir, on his way home.

BARON TOLL says that his winter quarters have been established on the Nerpenskiye coast, in the neighborhood of the Lena Delta, and that an observation station has been opened at Kotelnys Island. During the summer the expedition reached latitude 77 degrees 32 minutes, in New Siberia.

THE memorial to Robert Fulton in Trinity Churchyard, New York City, to which we have already referred, was unveiled on the occasion of the recent meeting of the American Society of Mechanical Engineers.

A BUST of Alphonse Milne-Edwards has been completed by the sculptor Marqueste and will be placed in the Hall of Zoology in the Paris Museum of Natural History.

AT the anniversary meeting of the Royal Society, held on November 30, attention was called to the deaths of the following fellows and foreign members. The deceased fellows were Sir John Conroy, died December 15, 1900, aged 55; Lord Armstrong, died December 27, 1900, aged 91; Dr. William Pole, died December 30, 1900, aged 86; Professor George Francis Fitzgerald, died February 22, 1901,

aged 50; Dr. George Mercer Dawson, died March 2, aged 52; John Christian Malet, died April 9, aged 53; Professor Henry G. Hennessy, died March 8, aged 76; Professor John Viriamu Jones, died June 2, aged 45; Dr. Charles Meldrum, died August 28, aged 80. The foreign members were Charles Hermite, died January 14, 1901, aged 78; Henry A. Rowland, died April 16, aged 53; Henri de Lacaze-Duthiers, died July 21, aged 81; Professor Aleksandr Kowalewski, died November 22.

PROFESSOR HENRY FULTON, dean of the School of Applied Science of the University of Colorado at Boulder, died on December 7, aged 55 years. Dean Fulton was prominent in educational affairs of the State for many years. By his death the University loses an able professor and valued administrative officer.

PROFESSOR ALEKSANDR ALEKSANDROVIC KOVALEVSKI, professor emeritus of zoology at the University of St. Petersburg, died in that city on November 22.

DR. ARTHUR KÖNIG, associate professor of the physiology of the sense organs at the University of Berlin, and director of the physical section of the Physiological Laboratory, died on October 26 at the age of forty-five years. Dr. König was an assistant of Helmholtz's and aided in the preparation of the second edition of the *Physiologische Optik*. He had carried out important researches on vision, and, with Professor Herm. Ebbinghaus, edited the *Zeitschrift für Psychologie und Physiologie der Sinnesorgane*.

THE death is announced of Dr. A. A. Tokasky, head of the Moscow Physiological Laboratory.

JACOB HEINRICH KRELAGE, a Dutch botanist and horticulturist, died on December 1, at the age of seventy-six years. He was head of a well-known firm engaged in the growing of bulbs.

REPRESENTATIVE WOODS, of California, has introduced a bill in the House creating a department of mines and mining. The department would have a secretary with a seat in the cabinet.

THE recent changes in ownership and plans of the *Botanisches Centralblatt* have already been referred to in these columns. The Committee of the Society for Plant Morphology and

Physiology, to which the selection of American editors for that journal was entrusted by the officers of the International Association, will make a full report to the Society at its Columbia meeting on December 31, and the substance of the report will also be announced to the botanists at the Chicago meeting. In the meantime we are authorized to announce the names of the American editors already chosen, who, with their respective departments, are as follows:

Phanerogams (systematic), and Chairman of the American Board, Professor William Trelease, Missouri Botanical Garden.

Morphology, Professor D. H. Campbell, Leland Stanford University.

Physiology, Professor D. T. MacDougal, New York Botanical Garden.

Cytology, Dr. C. J. Chamberlain, University of Chicago.

Paleontology, Professor D. P. Penhallow, McGill University.

Fungi, and Secretary of the American Board, Dr. Hermann von Schrenk, Shaw School of Botany.

Algae and Archegoniata, Dr. G. H. Moore, of Washington, D. C.

Further announcements as to the organization of this board, etc., will later be made, but in the meantime it is desirable that the authors of all papers published in America should send separates directly to the respective editors. It is expected also that at the Columbia meeting nominations of the two members of the General Committee, to be voted for by the American members of the International Association, will be suggested.

THE sixth annual meeting of the New York State Teachers' Science Association will be held at Syracuse, N. Y., on September 27 and 28. A full and carefully selected program is offered including papers and discussions interesting to all teachers of science.

SENATOR WM. A. CLARK has made a donation of \$250 to facilitate the work of the University of Montana Biological Station at Flathead Lake. This is the fourth contribution from Senator Clark for this purpose.

ONE of the American delegates to the Pan-American conference in Mexico City has presented a plan looking to the creation of an inter-

national sanitary commission to be composed of not more than five members of each government, this commission to hold annual or periodical meetings, probably at Washington. At its meetings it would discuss and make recommendations on sanitary matters in general, particularly on the condition of dangerous or infected ports and other places, and the means of improving them.

THE Bibliographical Society of Chicago, an organization founded 'to encourage and promote bibliographical study and research,' has requested the Committee on Education of the St. Louis Exposition to appoint a Commissioner of Bibliography for the Louisiana Purchase Exposition whose duties shall be: (1) To have supervision and final control of all bibliographical publications that may be issued in connection with the Exposition, and to undertake, for his own part, the editing of a series of bibliographies of subjects relating to the Louisiana purchase, and the political, industrial and intellectual development of the territory concerned, and other subjects that may prove pertinent. (2) To collect a complete set of all printed matter relating to the Exposition and to compile an accurate catalogue thereof, and (3) to arrange for an international bibliographical exhibit, with the idea of keeping the same intact after the close of the Exposition as a permanent bibliographical library.

WE have already called attention to the Yellow Fever Institute, organized under the direction of the supervising surgeon general of the U. S. Marine Hospital Service. The work of the Institute has been divided into four sections by which the following topics will be investigated:

SECTION A.—HISTORY AND STATISTICS.

- Topic 1. The early history of the disease.
- Topic 3. History of recent epidemics (since 1850).
- Topic 4. Relation to modern sanitation, especially paving, drainage, etc., in cities.
- Topic 5. Why did not New Orleans have it in early times while Boston did?
- Topic 6. Mortality statistics.
- Topic 7. Maps showing yellow fever zones.
- Topic 8. Maps showing the infectible territory in the United States.

SECTION B.—ETIOLOGY.

- Topic 1. The cause of the disease.

SECTION C.—TRANSMISSION.

- Topic 1. The transmission of the disease by the mosquito.
- Topic 2. Can any other mosquito than the *Stegomyia fasciata* carry the infection?
- Topic 3. Is the progeny of the mosquito also infected?
- Topic 4. How many generations?
- Topic 5. Can the mosquito become infected by any other means than by sucking the blood of a patient sick with the disease?
- Topic 6. Can the mosquito become infected by contact with the dried blood discharges or other infected materials upon fomites?
- Topic 7. Can the disease be transmitted by any other means than through the mosquito?
- Topic 8. Can the disease be conveyed by fomites, or through the air, soil or water?
- Topic 9. The geographical distribution of *Stegomyia fasciata* in relation to the disease.
- Topic 10. Is the immunity enjoyed by certain localities due to the absence of this variety of mosquito?
- Topic 11. A study of the life and habits of the *Stegomyia* and allied species, especially with a view to their extermination.

SECTION D.—QUARANTINE AND TREATMENT.

- Topic 1. Is disinfection of baggage necessary to prevent the spread of the disease?
- Topic 2. Is any treatment of baggage necessary?
- Topic 3. Mosquitoes in baggage, in merchandise, in cars, in ships.
- Topic 4. Treatment of the patient.
- Topic 5. Guards against mosquito bites.
- Topic 6. Immunity of individuals, of races.
- Topic 7. Individual prophylaxis.
- Topic 8. Communal prophylaxis—sanitation.

THE Academy of Natural Sciences at Philadelphia announces the following Ludwick Institute Courses of Free Lectures. Each course contains five lectures and they are given in the evening. The courses are as follows:

Course I., Physiology and Hygiene, Seneca Egbert, A.M., M.D., professor of hygiene, Medico-Chirurgical College, Philadelphia. On Thursdays, beginning on November 7.

Course II., Entomology, Henry Skinner, M.D., conservator of the entomological section, Academy of Natural Sciences, Philadelphia. On Mondays, beginning on November 11.

Course III., Parasites and Parasitism, J. Percy Moore. On Thursdays, beginning on January 2.

Course IV., Structure and Life Histories of Some Common Birds, Witmer Stone, M.A., Conservator of the ornithological section, Academy of Natural Sciences, Philadelphia. On Mondays, beginning on January 6.

Course V., Sedimentary Rocks, their Origin and Formation, Amos P. Brown, Ph.D., professor of mineralogy and Geology, University of Pennsylvania, Philadelphia. On Thursdays, beginning on February 6.

Course VI., The Principles and Methods of Zoology, Philip Calvert, Ph.D., instructor in zoology, University of Pennsylvania. On Mondays, beginning on February 11.

Course VII., Studies of Plant Life in the Vicinity of Philadelphia, Stewardson Brown, conservator of the botanical section of the Academy of Natural Sciences, Philadelphia. On Thursdays, beginning on March 13.

Course VIII., Mollusks, Henry A. Pilsbury, conservator of the conchological section of the Academy of Natural Sciences, Philadelphia. On Mondays, beginning on March 17.

UNIVERSITY AND EDUCATIONAL NEWS.

A MEETING has been held in Halifax to consider a plan for the affiliation of the colleges in the provinces of Nova Scotia, New Brunswick, and Prince Edward Island, and the establishment of a university in the maritime provinces.

THE American residents of Montreal have given the sum of \$9,000 to McGill University to found a political science fellowship in honor of the late President McKinley.

THE Berlin correspondent of the London *Times* states that the estimates for the army include a vote for the new military technical college which the Government proposes to open in the course of next year. The necessity for some such institution has been impressed upon the military authorities by the advancing scientific requirements of modern warfare, which are now too numerous and too varied to be adequately provided for by the resources at the command of the existing Staff College. There are branches of technical knowledge which, although they cannot strictly be classed as military, are, nevertheless, indispensable for the soldier. Among such subjects are steam-power,

electricity, mechanics, the construction of boats and bridges, and the establishment of means of communication. In recognition of this fact the college which is shortly to be opened will have for its objects the extension of general technical knowledge in the army and also the special technical training of engineer officers, as well as of those officers who desire to prepare themselves there for a career in the railway, ballooning and other special departments of the service. The college will provide for the instruction of 200 officers, the course of study will be completed in three years, and the students will pass through three grades. One hundred officers will take the first year course, and of these 50 will subsequently proceed to the second and third grades. It is expected that the college will be opened on October 1, 1902. The ordinary annual expenses are estimated at 300,000 Marks.

PROFESSOR ADRIAN J. BROWN, director of the British School of Malting and Brewing, of Birmingham University, has issued a report in which he says that they have now more students than the laboratories ought to accommodate, and he has been compelled to refuse others who have applied for admission. There are 18 students at present working in the school, and of these 16 devote their whole time to their work.

FOUR students of the University of Pennsylvania have been awarded scholarships by the Institute for Medical Research, founded by Mr. John D. Rockefeller. Those receiving the scholarships are Dr. George H. Gildersleeve, of the hygienic laboratory, and E. B. Vedder, C. M. Duval and Dr. F. P. Gray, of the pathological laboratory.

MR. WILLIAM MAXWELL REED has been appointed assistant professor of astronomy at Princeton University to fill the position left vacant by Mr. Taylor Reed.

MISS EDITH M. TEWKESBURY, B.A. (Wellesley), has been appointed instructor in chemistry at Wells College.

THOMAS SHAW, professor of animal industry at the Minnesota State Agricultural College, has resigned to become editor of an agricultural journal.
