Years ago, when I first began to keep bees, I used a few box hives for two years, which had, as a top, a board $\frac{1}{4}$ inch thick. In this top were slots cut, 1 inch wide by $5\frac{1}{2}$ inches long, running across the combs, for entrances to the 6-pound boxes, which were then used. The combs in the brood-chamber were expected to be built in a certain direction; guides of thin wood, brought to a sharp edge on the under side, were used to secure this object, and these slots in the top were so spaced that three openings between the combs below were to come into the slot; thus giving the bee a passage way of about 3 inches by $\frac{3}{8}$ of an inch from the brood-chamber to the boxes. The boxes had slots in the bottom to correspond with the slots in the top of the hive, and were set directly on top of the thin slotted board.

This gave a space of but $\frac{3}{8}$ of an inch, which separated the main combs in the hive from the boxes, as the bottom to the box was but $\frac{1}{8}$ inch thick. At the same time I was using the Langstroth hive, which had 5-16 inch bee-space between the frames and honey-board, which was $\frac{3}{8}$ of an inch thick. Over the slots in the honey-board were placed the boxes, the bottoms of which were $\frac{1}{8}$ of an inch thick, which gave a space of a 3-16 of an inch through, which the bees must pass before entering the boxes when coming from the combs below. As a consequence, the bees would enter the boxes in the box-hives much the quicker; the result of which was, that all things being equal, I could get the most surplus honey from the box-hives. But as I could not keep the bees equal as to numbers in the box-hives with those in the others, and for other reasons too numerous to mention, which makes the movable frame hive so much preferable, I decided to do away with the box-hives, after which I began to study how I could do away with the honey-board and bee-space in the Langstroth hive; thus making the top similar to the box-hive. At first I left the bottom of the box entirely off except a thin strip at each edge to hold the box in shape, setting the boxes directly on top of the frames; but as the combs in the filled boxes would be attached to the frames below, so as to nearly spoil them by removing, I soon gave it up.

Next I set the boxes directly on the frames, using them with full bottom,

as they were used on the box-hives. This plan gave good satisfaction as to the product of honey, but it was slow work putting on the boxes, as the bees must all be driven from the top of the frames before the boxes were put on, as many would be crushed and killed underneath them. At about this time I adopted the wide-frame system, or case-and-separator system, as I prefer to call it, which did away with the honey-board entirely; so that I have not had a honey-board in my apiary for nearly 12 years.

To prevent the killing of bees, I gave a scant $\frac{1}{4}$ inch space between the bottom of the cases and the tops of the frames. This worked so well that I have used it mainly till the present time, with the exception of some few hives where the cases rested on tacks to keep them $\frac{1}{4}$ of an inch above the frames. These tacks got pulled out of a part of the hives, which let the cases down on the frames, in which shape I have used them with good results, except that some bees would be killed in handling them. The past season I used several hives with only six brood-combs, as has been explained elsewhere, in which case it became necessary to set the cases directly on top of the frames.

To prevent the killing of the bees, was the question which now came up. To accomplish this, all I had to do was to raise the frames so that the tops of them came even with the top of the hive, when I could slide the cases along on the top bars of the frames; thus pushing the bees out of the way as the case was put on. In this way, I was master of the situation, and had the difficulty solved, regarding how I could use my sections to the best advantage. It will be understood that on these hives my cases and entrance to the sections go cross-wise of the frames, and not parallel with them, as do the sections in most hives. I expected that these cases would be so glued down with propolis, that it would be hard work to remove them; but in this I was mistaken, for I can remove them much easier than I can those cases which have comb and honey put between the bottom of them and the frames of the hive; and also much easier than I could a honey-board fastened in the same way, where it is desirous to use sections $1\frac{1}{2}$ inches in width, without separators running parallel with the brood-frames.

Dr. Tinker's plan of continuous passage ways, is an excellent one. In this way a number of very thin slots, a little wider than the top of the frames, are so fastened together that each slot comes over the top-bar of each frame; thus making a rack covering the top of the hive. This rack is to be slid on top of the frames at the beginning of the honey harvest; and so left till fall, unless the brood-chamber is to be opened. Immediately on top of this is placed (by sliding on) an intermediate rack which is very nearly like the first. Upon this the rack of sections is placed so that to remove the sections or replace them, all there is to do is to slide this intermediate rack back and forth on the first; or the rack of sec-

tions can be slid on the first rack if desired, and the intermediate rack be used in tiering up. By either of these plans the objectionable shallow bee-space is overcome, and the sections placed as near the brood as possible, without danger of killing bees; thus securing a greater yield of honey, which yield is what we are all after. If a greater yield of honey can be obtained by the above plan (which I have been studying on for over 12 years), and that with the same amount of labor or expense to the apiarist, I cannot see how it can "retard progress."

Will Mr. Heddon please tell us what his reasons are for preferring the shallow space; and also his objections to the above plans for doing away with it, if he has any such objections?

I also notice on page 58, an allusion to Italian bees objecting to this shallow space. In all my experience I have failed to note any reluctance on the part of Italian bees to enter the sections, whether this shallow space was used or not. I have often seen it stated that the hybrids and black bees would enter the sections much more readily than the Italians; but from close watching since 1871, I could not see but what colonies of different strains of bees would enter the sections at about the same time; providing that the brood-chamber was contracted so that little or no empty comb was therein at the time the honey harvest opened.

The greatest advantage, in my opinion, which the Italian bees possess over other strains, is in their producing a large amount of brood in May and June; thus getting plenty of workers to gather the harvest, and then slackening up in brood-rearing during the harvest; thus avoiding a needless consumption of honey during the honey harvest, and after it is passed.

That an Italian queen mated with a black drone will produce workers of the best type to produce comb honey, I am well aware; for a direct cross always produces vigor; but how shall we get such workers without the Italians to start with? I really hope none are talking of breeding from hybrid stock, for the purpose of being able to sell all the queens they rear with no fear that any one can have any claims on them for purity.

To the honey-producers of this country, the Italian bee is an indispensable thing as a starting point; and those who ignore this point, are "off the track," according to my views, after an experience of 12 years with both Italians and hybrids in my yard. The result of trying to build up a stock of bees by breeding from a hybrid mother, has proved in all cases, which I have tried, that every generation grows poorer and poorer, instead of proving any better.

Borodino, N. Y.

The bee-keepers of Tuscarawas County will meet in the Town Hall at Port Washington, O., on Thursday, May 15, 1884, to organize a bee-keepers' association. All are earnestly invited to attend.

Facts in Wintering Bees.

O. E. COOLEY.

As the subject of wintering bees successfully seems to be as far from satisfactory solution as ever, I will give my experience of 13 years.

I began with the box-hives, occasionally getting a few pounds of surplus honey. When putting them into the cellar for the winter, I placed the hives bottom up; the bottom being left entirely open all winter. I lost only one colony in that condition, and that died of starvation. I have used a hive similar to the Langstroth.

I prepare bees for wintering as follows: As soon as the clover and basswood season is over, examine every colony; remove the supers from all the colonies not having honey enough to carry them through the winter; and if at the end of the season they still have not stores sufficient for winter, feed immediately of good extracted clover honey. This is all the preparation for winter that I ever make. I never extract the honey and feed sugar; never make holes through the combs for winter passage ways; never take out frames and put in division-boards; and never use cushions, chaff, or packing of any kind, but simply let them remain just as they stood on the summer stands. The tops of the frames come nearly flush with the tops of the hives. I spread a sheet of cotton cloth over the top, upon which the board cover is placed. The cover is simply a flat board that tightly covers the top of the hive. The bees soon wax the cloth tightly to the tops of the frames, leaving but little or no upward ventilation, and no chance for the bees to pass over the tops of the frames at all. If any one should ask how the bees could pass from one frame to another as their honey is consumed, I would reply, by going around between the outside of the frames and the inside of the hive, which has an open space of nearly $\frac{3}{8}$ of an inch wide, which makes just as convenient a passage way as one would be over the top of the frames.

The entrance to most of my hives is $\frac{3}{8}$ of an inch wide, running the whole width of the hive, and is left open in winter the same as in summer. This is all the ventilation they have. The cellar used for 11 years was 13x20, and 7 feet high, dug in dry ground. It never froze, and had no ventilation, except what was given by opening the door occasionally. The temperature was usually about 35°. What was the result? I never have lost but one colony of bees that did not starve to death, and that had been queenless so long that half the colony died before putting them into the cellar. The average number of colonies I have wintered for the past 11 years, was about 50. In the winter of 1879-80, I wintered 103 colonies, and all came out alive, and all but 3 were in good condition. Two years ago I wintered 14 colonies in a cellar 10x12x6 feet high, and lost none. In the same cellar, the year 1881, I wintered 32 col-

onies without loss. Although the winter of 1882 and 1883 was the coldest for years, and the temperature for weeks, in my cellar, being 12° to 15° below freezing, yet my bees wintered without loss.

I have given as briefly as possible my method of wintering bees, also the result. I have no theories to advance on the subject, nor any pet hobbies to ride; but I will just say that my opinion is that our bees would often give us very much more satisfactory results both during the honey season and in wintering, if we would just let them alone.

What Causes Bee-Diarrhœa?

JAMES F. WOOD.

This question yet remains unanswered. Many say that dampness is the cause; others claim that it is pollen eating. I do not believe that dampness, cold or confinement causes it; and as to the pollen theory, I cannot give any facts at all. I have always wintered my bees in the cellar, without the loss of a single colony from disease, until this winter. I believe the cause of bee-diarrhœa, in many cases, is in the kind of honey that the bees have for winter stores.

In support of the above, I will first give the condition of my own bees. Last spring I removed one colony to a location about 5 miles from my home apiary, where bees gathered much more honey than in my location; but usually the bees died with diarrhœa in its worst form, in early winter. As I never had a colony suffer from the disease, I thought I could winter them on this honey, if I prepared them as I did the rest of my colonies. I moved this colony home in October, and to my surprise, before any of the colonies were put in the cellar, it and all its increase had the diarrhœa, while the others were free from the disease. I brought one of the afflicted colonies from the cellar a few days ago; the bees had nearly all left the hive, and lay dead in front of it. I shook what remained, from the combs, and on examination, found the combs perfectly dry, and very little pollen in the cells. What pollen there was, was all in the outside comb, and the honey was removed from over it; but it did not appear to have been removed. The honey was very black, and tasted much like cheap molasses.

Mr. Heddon will attribute my loss to pollen, but I shall keep this honey and give it to colonies that will not have to be moved, and I shall be very careful that it contains no pollen. I shall also take more bees to this place another season, and remove the pollen from some, and hope to get at the truth of the matter another winter. I do not think that moving bees in the fall causes disease.

To illustrate this, take the experience of W. W. Cary & Son. They are situated in a poor location for honey-producing; move a great many colonies away during the latter part of

the summer and early fall, to secure stores for winter. In the fall, they are all moved home and wintered in the bee-cellar. I never heard of them losing a colony until last winter. Then they lost only two. These were away in a location where they gathered a peculiar kind of honey. I saw the hives in the spring; they were daubed with excrement, while the remainder of his apiary was free from disease. It could not have been from moving them, as a large portion of his colonies were moved at the same time.

I saw an apiary of over 100 colonies in which about half were Italians, and the rest blacks. The blacks wintered very well, while the Italians had the diarrhœa so as to seriously reduce their numbers. They were wintered in a bee-house. The Italians gathered a superior article of honey; and hence, had white honey for winter, while the blacks had black honey.

In view of these facts, it appears to me as if the kind of honey the bees have for winter, has something to do with successful wintering. I do not see how dampness had any thing to do with my colony, as the hives were dry; besides, they were diseased before winter came. How can I apply the "pollen theory" to these cases?

North Prescott, Mass.

Northeastern Kentucky Convention.

This convention was held at Covington, Ky., for the purpose of organizing a bee-keepers' association. Quite a number of bee-keepers from surrounding counties were in attendance. Mr. Peter McVean was chosen chairman, and Geo. W. Cree, secretary *pro tem*.

Upon taking the chair, Mr. McVean stated that the object of the meeting was the organization of a bee-keepers' association, the better to secure a general co-operation by which the individual members would be able to secure readily the benefit of the general experience. He was confident that the interests of those engaged in bee-culture in the northern part of Kentucky would be forwarded.

After the preliminary work of organization, the meeting adjourned till 1 o'clock.

On re-assembling, the chairman called for an expression of opinions, and a number of members discussed the best form of organization, and the most suitable plan of operation. The general drift seemed to be that the association would be highly advantageous, and all were confident in the assertion that its establishment would be permanent and popular.

It was accordingly decided to make a permanent organization, and the balloting for officers resulted as follows: President, Peter McVean; Secretary, G. W. Cree; Vice-Presidents, Rev. C. Johnson, Jacob White, A. B. Hymer, Alex. W. Stith, N. B. Wilson, W. T. Gibson, John T. Conley, C. Riggs, W. C. Phillum, W. F. Coffin.

On motion, Messrs. G. W. Cree, Alex. W. Stith and T. A. Crigler were appointed a committee for the purpose

of drawing up a constitution and by-laws, to be submitted at the next meeting of the association.

In the choice of a suitable name, it was decided that the association should be called the Northeastern Kentucky Bee-Keepers' Association, and the membership fee 50 cents.

Messrs. Colonel Adie O. Robertson, W. G. Gosney and T. L. Thornton were chosen as the executive committee.

It was decided that one part of the association's programme at each meeting, should be the reading of essays, and the vice-presidents were appointed to prepare them for the next meeting.

The vice-presidents were also intrusted with the duty of calling upon the bee-keepers of their respective counties for the purpose of securing their co-operation with the association.

It was decided that the next regular meeting of the association should be on the second Wednesday in August; but in order to secure a discussion of points of special interest for that time, it was voted that an intermediate meeting should be held in Covington, on May 7. Adjourned.

For the American Bee Journal.

Pollen or Ventilation.

H. S. HACKMAN.

Has the truth been arrived at in regard to bee-diarrhoea? Is it the pollen, or the want of proper ventilation that causes the diarrhoea?

My experience leads me to think it is the want of proper ventilation. A year ago last fall I wintered 230 colonies of bees, all fair and strong ones. 105 were in two-story hives; 125 were in one-story hives; and all packed alike in leaves on the summer stands, facing the south. The two-story hives had both entrances open. By two-story, I wish to be understood as being two one-story hives setting on top of each other. Bees almost always clustered in the upper story; the lower story, in many cases, had only foundation starters, and sometimes were full of comb.

Of the 125 in the one-story hives, I lost 100 by the middle of April; while of those in the two-story hives, I lost 5; but from this date until June, 18 more in the two-story hives were lost by spring dwindling. Nearly all of the one-story hives contained frost or ice during the cold weather. This was proven by the presence of broken comb, and the water running out of the entrances when it became warm enough to thaw. The bees in these hives had diarrhoea.

The colonies in the two-story hives were free from diarrhoea, ice, moisture, and broken comb, and the bees were as bright as could be. I paid no attention to the pollen in these colonies, so there was not as much doubt in those of the one-story hives as in those of the two-story hives; and I, therefore, conclude that it was the air-space under the cluster, and the circulation of the air through the open entrances.

Two of my neighbors, the same winter, had about the same number of colonies—25 or 30 each. No. 1 had his packed in corn fodder. His hives being part frame and part box, and all one-story. He lost all except 2 colonies. No. 2 had all box-hives, and every box raised an inch from the bottom-board. Quite a number of his hives had openings in the top, from 3 to 4 inches square, and were left open all winter. His bees came through all alive and bright. Take this for what it is worth. The man who lost all but 2 colonies, told me the above, and I have no doubt but that it is true; so what do we know about wintering bees?

Peru, Illinois.

For the American Bee Journal.

Capturing Queens.

W. H. STEWART.

On page 103, Rev. P. W. Archer claims to be able, by locating himself beside a colony of bees, within a few minutes, to cause the queen to come out and allow herself to be captured.

When I first read the statement, I was inclined to doubt its truthfulness; but after thinking the matter over, I believe that I understand the manner, or at least one way, in which it can be performed.

Perhaps it may be done at any time during warm weather; but I doubt whether it could be successfully performed at any time, except during the swarming season. It is well known to all close observing bee-keepers, that when a plurality of queens is hatching in the hive, the queens will, at twilight, utter several monotonous sounds, very much like the sounds produced by the mason-wasps while building their mud nests. This noise made by the queens, is believed by most bee-keepers to be a challenge for the deadly combat that often ends in the destruction of all the queens in the colony except one.

If I am not badly mistaken, one could seat himself near the entrance of the hive containing a strong colony, in this climate during the months of June and July, and (with the queen-mocker that I to-day send you, to be placed in your museum) produce an imitation of the piping of the queen; thus causing her to believe that a rival queen is near the entrance, challenging her to combat. I think when she hears the challenge, she would present herself at the entrance for the purpose of fighting; and while under the excitement, could be captured.

If the queen-mocker can be made to work well, it will be very useful while moving brood-combs with adhering bees, from strong colonies, for the purpose of using them to build up those that are weak; or, in other words, building up nuclei.

It is sometimes quite a task to hunt up a queen while doing this work, as the colony from which we wish to take the brood-combs are very populous; and it is desirable to know just where the queen is, in order that we

may be sure that we do not carry her to the nuclei, with the other bees adhering to the brood-comb.

Whether the plan that I propose is the same as that practiced by Mr. Archer or not, we are indebted to him for the idea of thus getting at the queen. We may, however, find by practice that any plan will end in disaster. I have thought that, perhaps, a queen thus enraged would be balled or killed upon returning to the colony in that excited condition.

For the American Bee Journal.

Honey Fermenting.

R. R. MURPHY.

I see a great deal in the BEE JOURNAL about the pollen theory, the humidity theory, the poor honey theory, and a great many other theories to account for the loss of the bees in winter.

My experience has been, if I could keep the moisture out of the hives, and had a good strong race that bred young bees until late in the season, and if the honey was all right, there was not much trouble. I think one of the greatest troubles, or, at least it has been in this section, where otherwise cared for, has been in the honey, and that, generally, in the early honey. For this section I would rather chance the late honey for wintering than the clover and basswood honey; for the reason that the early honey in the body of the hive, and occasionally the surplus honey, if left in the hive too long, seems to ferment the same as good yeast will. I have had a piece as much as 3 inches square of the caps of the cells, tear loose from the cells in a body and raise up $\frac{1}{8}$ of an inch or more in the centre from the cells; and the space beneath, on top of the honey, full of small air bubbles; and colonies with such honey in variably wintered poorly, or died during the winter, according to the amount of such honey in the hive.

I cannot give any reason for the honey apparently fermenting (as it does not sour). Whether it is bacteria or fungi that causes it, or not either, I am unable to say; but I have found that when I discovered any of it in a colony, if I would extract it and let them fill up on late honey, they were all right for the winter; and I found by experimenting, that if the old bees were fed on this honey in the fall, after the honey season is over, they would begin to die off and dwindle the same as spring dwindling. I have thought many times that spring dwindling was caused by this kind of honey, even when it had not developed enough to show it to the naked eye.

There has been more or less of this kind of honey in some of my hives nearly every year since 1871 or 1872, and it was thought by some of the bee-keepers of Kentucky and Tennessee, about that time, that this kind of honey was the cause of such heavy losses in those States from 1867 to 1869. If my memory serves me right,

there was said to be whole apiaries where the bees had deserted their hives and left them full of honey.

Gen. Adair, of Kentucky, was the first one I ever talked with that called my attention to this kind of honey as being injurious to bees. I think it was in the year 1869 or 1870, that I met him, and we talked about the losses of Kentucky bee-keepers; and he told me that whatever it was that caused it, he had not been able to control it, and that the malady was traveling northward gradually, and that if it got as far north as where I lived, that with our long cold winters, it would destroy our apiaries if it was as bad as it was with them. He had a sample of the honey with him, showing how it looked; and the next week, when I reached home, I examined my colonies, but found nothing of it then, and did not for three years afterward.

It first shows itself by the caps of the cells here and there being convex instead of concave; and as the disease, or whatever it may be called, progresses, there are more cells affected, and the cappings of the first ones begin to possess yellowish tinge; and honey that a few days before was of a heavy body, is, after being affected, rather thin and watery. Immediately under the cappings are fine air bubbles.

If none of the bee-keepers recognize the disease, or whatever it may be, if I find any of it this coming season, I will send a sample to the editor of the BEE JOURNAL, if I do not forget it. I did not find any of it the past season, and but little the year before; but the two seasons before that there was plenty of it in my yard.

Garden Plains, Ill.

For the American Bee Journal.

Stimulative Spring Feeding.

W. J. DAVIS.

I have read with care and much interest the able article on "Spring Management of the Apiary," by Mr. Allen Pringle, in No. 13.

He advocates the feeding of substitutes for natural pollen, in early spring, and I have no doubt that for his latitude he is right; but for *this* locality, I am forced by actual experience to consider the practice of doubtful utility. I have often thought that there is no legitimate pursuit of man, that demands the exercise of more discretion and good common-sense, than that of bee-keeping; nor is there any class of men, to whom prescience should be given, to say, "What will the morrow be," more than to bee-keepers.

To those of limited experience, many of the articles in the BEE JOURNAL appear very contradictory; but it should be remembered that this JOURNAL is Continental in its character. While in one part of its heritage, the bees are closely clustered and packed in cellars and wintering houses, or snugly tucked under warm blankets, in other parts honey and pollen are coming in rapidly, and

drones are on the wing. Hence, the locality of each writer should be carefully considered; while the honey-bee of low or high northern latitudes may be the same, and its instincts the same, its management will of necessity be very different in many respects. That is to say, the management of bees must vary to suit the climate, or kind of weather that prevails in any locality. With this introduction, I will proceed to give an index of our spring weather, and my experience in stimulative feeding.

Our bees generally have a cleansing flight about the middle of February. They are then re-housed for about 4 weeks. For several years I have supplied them with unbolted rye meal, thoroughly cleaned and ground finely, or wheat flour mixed with bran or corn meal. This I fed by placing in clean barrels in a warm, sheltered place on the south side of a building, placing from 2 to 3 pecks of meal in each barrel, and inclined them toward the sun at an angle that would not allow the bees to blow out the bran with their wings; and as they would work out the flour, roll the barrels about $\frac{1}{4}$ over, and the bran would slide down and give the bees a chance to cull the finest parts, which they readily work into nice pellets on their thighs, and go home rejoicing.

If there is anything worker bees delight in, it is feeding their babies. A strong mark of their feminine character. We see in this the wisdom of Him who created all things. Had the workers been males, there would have been more failures in the bee business than there is, provided the same number engaged in it.

Now for the result. The taking in of pollen stimulates to breeding, just as we expected and desired, and from the middle to the last of April the bees have about as much sealed brood in their combs as they can cover when the weather is mild; then a "cold wave" comes along; the wind blows cold, and it freezes. I have known it so cold here in the middle of April, that blue birds were frozen to death. Where are our bees? The cells within the cluster are all occupied with brood. The vitality of the old bees is severely taxed in producing the brood. Not an empty cell in which an adult bee may enter to get warm. They are of necessity spread in thin layers between the combs. By physical exertion they do all they can to resist the cold. They strive to keep themselves and their brood warm. But there is a limit to their endurance; the cold continues for about 3 days; for 2 days of which time the bees will be dropping to the bottom-board, half of the old bees be dead, and a large amount of the brood chilled beyond recovery. How much have we gained?

Another item of my experience may not be without interest. Several years ago I read in the BEE JOURNAL a suggestion of a British bee-keeper, to stimulate breeding even before the bees were able to fly, by mixing flour and honey in the form of paste, and pressing it into the combs. I tried it on 3 colonies. They did start a large brood, but the result was far from

being satisfactory. The first of June found them the poorest colonies in my yard.

One year ago I fed rye meal as usual, and I observed 2 colonies that worked with greater zeal than any of the others. I was pleased with their conduct; but in May there was a greater mortality of old bees in those two, than in any of my other colonies; and in their summer's work, they fell below most of the others. In this locality a large supply of pollen is usually secured from the blossoms of the soft maple, which bloom from the 20th to the last of April. I am going to wait for natural pollen this year, and if I make a mistake by so doing, I will frankly acknowledge it. In higher northern latitudes, spring may not throw out her promises so early, but when it comes, it comes to stay. The days lengthen with greater rapidity; and, hence, are not liable to the backsets of this latitude. Therefore, stimulative feeding may be an advantage in Mr. Pringle's locality; but to resist cold, bees must have empty combs to cluster in, whether it be in December or April.

Our 122 colonies have wintered without loss, and in fine condition. We are looking with all our old enthusiasm for a good honey season.

Youngsville, Pa.

For the American Bee Journal.

Surplus Arrangements.

WM. M. BARNES.

A great deal has been said on this subject to the end that a standard shall be fixed for hives and honey-racks, for the easy and successful manipulation of bees. We all have our choice so far as what already exists in the line of inventions pertaining to the above subject will allow. I will describe the surplus arrangement I use, so the more experienced honey-producers will have a chance to point out my errors.

I take a board $\frac{1}{4}$ of an inch thick, and just as large as the top of the hive. Across the ends nail cleats $\frac{3}{4} \times 2$ inches; then nail this board to the top of the hive, so that the cleats will be above the top. Draw a line lengthwise in the middle of the board; then 3 inches on either side of this line will be the centre of a row of slot holes cut crosswise of the board 2 inches long and $\frac{3}{8}$ of an inch wide, and measuring $1\frac{1}{4}$ inches from the centre, measuring lengthwise of the board. This is then the bottom of the rack.

The separators I use are made of basswood, $6 \times 1\frac{1}{2} \times 3-16$ inches, with insets $\frac{1}{2} \times 2$ inches cut in both edges the same distance from the middle, so as to just match the holes in the board. Then directly between these insets, I bore in each end one $\frac{3}{4}$ inch hole; this completes the separators.

My sections are $6 \times 6 \times 1\frac{1}{4}$ inches, and the same width all around. To set these up, I have glass cut just the size of the separators. I then put one glass on its edge against the cleats across the board; then put on 2 sec-

tions against the glass, and then more glass and more sections, until full; wedging them tightly inside of the last cleat. They can be tiered up if desired.

I find by actual experiment, that my sections of honey are freer of propolis with the use of this rack than they are with any other. I can easily take hold of them, as it is impossible for the bees to touch the edge only where the insets are in the separators; and the holes in the separators allow the bees passage ways from one section to another.

I do not see any detriment to the appearance of the honey, arising from these holes; but it is the cause of quite an ornament being built on the surface of each comb in the shape of a little mound. I have never had a section of honey that could not be placed by either side of any other section, and yet the honey not come in contact.

Boaz, Wisconsin.

Clipping the Queen's Wing.

DR. I. S. M'ALLISTER.

Mr. Stewart, on page 576 of the BEE JOURNAL for 1883, after leading the reader along, wishes some bee-keeper to answer his question; and says that all will agree with him, that a mother cannot transmit to her off-spring that which she does not possess. I do not agree with him on this point, and would as soon have queens from the one as the other (all things being equal); for I have been in the medical profession for over 23 years, and have had occasion to perform and witness many amputations of limbs, and never saw any off-spring from said parents, that was minus any limb; or, that seemed at all affected thereby. I have watched the progeny of queens, whose wings have been clipped, and I fail to see any difference from those bees that their mother did not have her wing clipped; and on several occasions, I have clipped a wing so close to the body, that the queen would curl down close to the comb, and show signs of pain for a moment; then go quietly about her business as though nothing had happened.

Of course such close clipping was an accident; as there is no need of clipping more than one-third of one wing. I think the comparisons are not parallel; for it is not supposed that a queen has occasion even to leave the hive, after she has once mated, except in swarming; and I doubt very much whether it would improve her generative powers, to have her tossed up and compelled to fly; though it would be likely to interrupt her laying ability, besides the risk of otherwise injuring her.

They are apt to be altogether too handy with their wings; and it is no pleasant thing to have a valuable queen and a large swarm of bees abscond, just for the simple neglect to clip a wing. It has been proven by years of practical experiments by many able bee-keepers, that it is in

no way detrimental to the well-being of the bees; and it saves the loss of many a valuable swarm. Years ago, I, too, was opposed to the plan, but now it is only a piece of carelessness with me if I fail to clip a queen's wing, after she is mated and has commenced to lay.

As far as hybrids are concerned, if they could be made a fixed type, they might be improved; but as it is, I fear it will be difficult to send for pure stock before long, as there are so many bees "bred for business." I prefer to keep my stock of Italians pure.

For the American Bee Journal.

The Use of Comb Foundation.

E. P. GIBBS.

On page 25, Mr. J. V. Caldwell takes up the subject discussed by Mr. Doolittle in regard to the necessity and profit of using comb foundation. I am glad to see this question agitated; for I have been a heavy consumer of foundation, and for the past two years, I have been of the opinion that it was made unnecessarily heavy for use in the brood-chambers.

The past season has caused some doubts in my mind as to the utility of using foundation in the brood-chamber for any other purpose than as a starter in the frames. My observation is, that a great many of the thick sheets of wax are not drawn out at all, but simply built upon; and I believe that the 10 sheets of foundation ordinarily put into a brood-chamber, weighs three times as much as ten frames of new empty comb. The greater part of last season the price of foundation was about 65 cents. Now, nearly four sheets of common-weight foundation for Langstroth frames, make a pound. Hence, to fill a 10-frame hive, it requires 2½ pounds; and at 65 cents per pound, would cost \$1.62½ instead of 75 cents, as Mr. C. says.

Mr. C. says we cannot get a hive full of worker comb if we do not use foundation. That is true. Neither can we if we do use it. He says further, if we do not give them drone foundation, how can they get drone comb? If they have no drone comb, and want some, they will build drone cells on the worker foundation. In my earlier days of bee-keeping, I used to cut out the drone-brood and throw it away; but the bees would just as often rebuild it. I finally came to the conclusion that it was wasting too much of their time to build drone comb for me to throw away.

I do not wish to be understood that I prefer a brood-chamber with ½ or ⅓ drone comb; but they will have some any way. I have combs made on foundation that have not a worker cell in them, but all drone cells. I am not prepared to say that it is best to entirely discard foundation in the brood-chamber, but I am satisfied that it is made twice as heavy as need be; and that every consumer should insist on a much lighter weight per foot, or make his own.

Lyndon, Ill.

For the American Bee Journal.

Success in Wintering for 21 Years.

IRA BARBER.

By all the methods except one, that I wintered bees, I could not bring 50 per cent. of them through the winter in as good condition as when placed into winter quarters. That one was by burying them in trenches in a light gravelly soil, entirely below the surface, and covering them about 10 inches deep with the same. In this way, nearly all came out as strong as when put in.

I tried burying them in clamps above the ground, but sustained heavy losses. I built a house in which to winter them, but this proved too cold for them, and was abandoned after using it for two winters. In all the cold rooms in which I have wintered bees, diarrhoea appeared; the worst case destroying ¾ of all my apiary.

During all this time I had a good cellar, but it was wet, and I was afraid to risk my bees in it, for it was generally believed that bees would not do well in damp cellars. Having 130 colonies, I concluded to chance them, thinking they could do but little worse than heretofore.

About Nov. 15, I placed my bees in that cellar, keeping a close watch of their condition. One-third of the hives were provided with chaff cushions, and the rest were ventilated at the top by raising the top board. In the spring all were alive, but in only fair condition. After three winters of experimenting, I found that those which were ventilated at the top of the hive were in much the best condition; I might say that they were just as strong as when put in for the winter. By thus wintering them I have had no trouble since.

I do not think it is necessary to keep the temperature in the cellars as high as 65° to 90° above zero; but I know that bees will stand that degree of heat and come out all right, with my way of preparing them. My hives are 12x19½ inches, inside measure, and 12½ inches high, with two entrances, one at the bottom and the other in the centre of the front end. For coverings, I use felt and burlap, putting them on when I take off the sections. I also use a top-board 1 inch thick; the bees having all the fall to glue them fast. I pile them up in the cellar in columns of 4 or 5 high, very closely together. The lower tier rests on caps taken from the hives, and are raised ½ inch from the bottom to prevent molding, and all are left with entrances open.

For ventilating the cellar, I use a 3-inch pipe 24 feet long, which enters the cellar window and extends up on the outside. My cellar is 17x19 feet, and 7 feet high, and contains 225 colonies, they furnishing all the heat. In November the mercury stood 12° above zero on the outside, and 65° above on the inside. In April it stood 60° outside, and 90° inside. Bees cannot be wintered in a very dry cellar at so high a temperature.

The walls of the cellar are made of stone and mortar, and are 2 feet thick. I never open it from the outside from the time the bees are put in until taken out. I do not see that bees breed any more in a warm, damp cellar than they do in a cool, dry one. The old colony of bees I purchased of Mr. M. Quinby in 1863, is still alive, and has been wintered all these years in a warm, damp cellar.

I have never used a subsoil cooler, but intend to put one in sometime, just to cool off the bees when I set them out. I would not ask for bees to winter better than they have on the foregoing plan for 21 years, for I find them uncomfortably lively when putting them out.

De Kalb Junction, N. Y.

For the American Bee Journal.

The Improved Section Case.

E. P. CHURCHILL.

The article by Mr. G. F. Williams, on page 39, agrees with views that I have entertained for sometime. I was glad, indeed, to learn that others see some of the difficulties of rapid work of bees in the sections.

I have always used Root's Case, and I think it combines many good features; but as they are made, the outside sections are so near the glass that the bees must pass up between them and the next tier of sections; and as there is only $\frac{1}{2}$ bee-space at the outside, or next to the glass, the comb must be shortened just $\frac{1}{2}$ bee-space, and the bees must have holes through the combs in order to get through.

This trouble has bothered me about as much as it has the bees, I think; but after studying over the matter, I have finally overcome the difficulty, to my satisfaction, as well as to the satisfaction of others.

As the Root Case is made to hold 28 sections, $1\frac{1}{8}$ inches wide, there is a little play between all of them, so as to allow them to be closed up about $\frac{3}{8}$ inches. I tack strips up and down across the glass stays, so they rest against the edges of the sections. These strips are $\frac{1}{8}$ of an inch thick, and $\frac{3}{8}$ of an inch wide. I place the section rests so as to agree with the sections, and nail them there to remain. I use no spaces nor strips across the rests to be glued down by the bees. The Cases can be made one row of sections shorter, and I think they would be advisable, as they can be made as narrow and as short as one may desire.

I have always believed that the boxes were too wide, so I have been making some only 1 inch for top and bottom, with ends about $\frac{3}{8}$ of an inch wider. I think, as they are so much like natural comb as to thickness, the bees will like them much better. Of course they will not weigh a pound, but I have no fears but that they will sell.

I have gone a little farther and made sections of the same thickness, and depth $4\frac{1}{2} \times 5\frac{1}{2}$ inches long, to hold a pound. This size gives more room

for bees in a clump, and 3 lengths fill the common crate, by using a $\frac{1}{2}$ inch strip at the ends. On the lower edge of these I nail strips of tin just wide enough, so the ends of the boxes can rest on them; thus doing away with the wood rest the whole length of the boxes; and also the killing of so many bees when removing and replacing the boxes.

I allow $\frac{3}{8}$ of an inch space between the bottom of the sections and the frame, because where they rest on the frames, they are gummed down, and with a $\frac{3}{8}$ inch space, they are only waxed. I know it takes some wax; but it takes some lives of bees to set a crate right down on the frames. The queen is more likely to enter the sections where there is no space; but if one desires them to rest on the frames, he can leave off the rim or edge of the case, and down they go. In fact, this crate can be made almost any size; and as there are partitions between each tier of boxes, we can leave out one set, and cover their places with cloths, etc., and the remaining boxes will stay in place. Of course the strips are used at the outside as with the wide sections, which offers a nice free passage way for the bees, and right where they are most needed.

I am satisfied we all have lost by allowing only this seemingly trifling thing to pass without a remedy; and I also believe we have more crooked combs in the sections by allowing too many at once, than from any other cause. Why? Because where there are more sections than the bees can fill plumb full, they take the centre first; and where one side of the foundation is drawn at a time, it is nearly always crooked; but if we use just what they can fill and work out altogether, we have a nice straight lot of comb, if the foundation was properly set and left straight, from our own hands.

I shall use no more hives without a firm strip of woolen cloth between the two stories, tacked on the upper one with a heavy coat of new paint first; then they are all hasped together, and the bees will not leave the outside sections nearly so much as otherwise. And when we lift a hive, it will not fall apart, nor will the upper story rise up when we press down a cushion.

I make the cases with a roof, and pack with hay, and tack on burlap; then these are hasped to the upper story. I have a ventilator at each end of the case. I believe the packing cools in hot weather, and warms in cold. It also presses the enameled cloth down smoothly on the frames, when in the upper story, and, in short, it is just complete.

As I have no patent on this, I have no ax to grind; but I am interested in improvements in bee-keeping. I can get double the extracted honey that I can of comb, but many will have box honey. It seems strange that any one chooses to let it remain in the hive till capped before extracting, because it causes the bees just so much waste to cap it to be cut off so soon. I choose to extract it soon after it is

gathered, and do the evaporating myself, and put on caps if I wish. In many things, it is good that we do not think alike; but we ought to agree that bees cannot work in a $\frac{1}{2}$ inch space and do a fair job.

Auburn, Maine.

Read at the Ohio Convention.

Spring Management of Bees.

DR. H. BESSE.

I use a one-story hive similar to the Langstroth, and I use 9 Langstroth frames in each. Usually, about the first week in March, I put my bees on the summer stands, after which I clean out all the dead bees and close the entrances to within an inch, and examine thoroughly as to stores, and if such are about exhausted, I feed them at once by putting a comb of honey as near to the cluster as possible; or, if I have no comb honey, I fill an empty comb with sugar syrup and give it to them. They should have enough feed at this time to last until about April; and after this all colonies, whether they have enough to carry them through to fruit bloom or not, should be fed a little every day to stimulate the queen.

Early in May, every hive should be full of bees and brood, in order to get the best results both in honey and increase. If some colonies are yet weak, I give them 2 or 3 frames of hatching brood; giving the strong colonies empty combs, or foundation in their place.

I am ready, as soon as the honey flow commences, to put on honey-racks filled with one-pound sections; or, if for extracted honey, upper stories. These I have full of empty combs, which have been selected from colonies that have much drone comb and old combs that are unfit for brood-rearing. I also put one frame of brood in the upper story; this causes the bees to work there at once.

For increase, I set apart about $\frac{1}{3}$ of my best colonies, and from these I select 2 or 3 for queen-rearing, and a like number for drone rearing. This I do about the middle of May, as I believe that nothing is gained by commencing this too soon; as colonies are weakened, brood chilled, and the young queens reared are more frail and less prolific than those reared after warm weather is fully established.

The first step in rearing queens, is to select a last year's light-colored worker comb, and put it in the centre of the colony that I wish to breed from. In 3 or 4 days this comb is usually filled with eggs; the oldest of which is beginning to hatch into larvæ. Then remove the queen and the brood from some strong colony, shaking the bees from the brood-combs back into the hive, and divide the brood among weak colonies; the old queen can be given to a queenless colony, sold, or given to a nucleus, prepared on purpose for her. This comb of larvæ, from the choice queen, is given to the queenless colony prepared for it. Some recommend trim-

ming off the lower edge of the comb to where the eggs are beginning to hatch, or cutting a few holes into it in different places, so as to give the bees a better opportunity for building queen-cells.

I mark the date upon a slate, which I have hanging on each of my hives, thus knowing when the cells are ready for use. This date should also be written in a memorandum book kept for the purpose, and which should be consulted each day. All hives should be numbered, and their numbers recorded, with any facts about them you wish to remember. By strictly following this rule, your queen-cells will not be forgotten and neglected until one of the queens is hatched and has destroyed all of the queen-cells and unhatched queens.

From 9 to 10 days is the proper time for removing cells thus prepared; and at the time marking it on the slate. I usually leave in the hive one cell or more if they cannot well be separated. These cells should be handled with care, so as not to injure them. After removing the comb of eggs from the selected queen, it should be replaced by another comb, and in about three days this will be filled with eggs, and can be given to another queenless colony. We should not allow a colony to build more than 1 or 2 lots of queen-cells; after which it should be given a laying queen.

A day or two before I expect the first lot of cells to hatch, I divide as many colonies as there are cells, by taking out about 3 or 4 combs with brood, examining them carefully so as not to get the queen; then I put these into an empty hive, removing the part containing the queen into a new place, and putting the new hive on the old stand. This should be done in the middle of the day, while the bees are busy at work. In a day or two I take out one of these combs and engraft a queen-cell, which is nearly ready to hatch; then in 6 or 8 days I examine the new colony, and if I find eggs, I know they are all right; if not, I give them a laying queen or another queen-cell. This method does not apply to those who rear queens to sell; they form smaller nuclei, or give a mature queen-cell. It is very convenient to have queen-cells ready, or nuclei with laying queens.

About the time I make the first arrangements for starting queen-cells, I select 1 or 2 of the best colonies for drone rearing. Select a comb filled with drone cells, remove one of the outside frames, spread the combs apart, and insert the new comb in the centre of the cluster; feeding these colonies a little every day to stimulate the queens, also feeding those colonies which are to rear queen-cells.

Introducing queens is an important item to those who buy them for a good price. G. M. Doolittle says: "I always liberate a choice queen, as late in the evening as I can see to do it. A queen can be quietly dropped into a prepared colony with but little danger, if put in so late that the bees cannot see to fly, and so quietly as not to arouse them." He further says: "I used to do it by a round wire cage,

with a plug at each end, a string tied to each plug, and the ends of the string brought out from under the quilt cover; then pull the strings gently till something separated."

This process, I think, would be the safest, providing the cage is left under the quilt from 24 to 48 hours, and then operated as described, after dark.

The apiarist should watch the bees, and give all necessary care at the proper time. The successful apiarist will always have his apiary in a neat condition, with "a place for everything, and everything in its place."

Delaware, Ohio.

For the American Bee Journal.

Shade for Bee Hives.

M. BRAY.

When I said by having my bees well shaded (page 441 of 1883), I did not intend to convey the idea that the bees of J. D. Enas had suffered from lack of being properly shaded. What I meant by being well shaded, was that I was giving them more shade than usual. I use Langstroth hives; they front to the east; my shade-boards are 2x3 feet; I place them a little to the front, and a little to the north; then set 3-foot stakes about 2 feet from the hive, leaning against it along the south side and across the west end. This kept the sun off the hive and ground near it. This extra shading saved my bees, but when the mercury gets up to fever heat, as Mr. Enas says, shade does but little good, for the wind blows as hot as if it came from a fire.

I use a double-walled hive, and think it will prevent injury from heat. It produces a draft between the brood-chamber and the outer case, taken from an underground pipe made of lumber. I have conductors made of lumber one inch square, inside measure, that connect with holes bored through the box under ground, and holes bored through the bottom-board of the hive. I have two of these conductors to a hive, one at each corner of the back part of the hive. The space between the brood chamber and outer case should be 2 inches at the back, to give room for holes to connect with the pipe below. The cover is made something like the cover of a trunk, with a 1½ inch hole bored through the front, and wire cloth nailed on for ventilating.

I drive two pickets for the front of the hive to rest on, which gives the hive the appearance of resting on 4 short posts. The head of the pipe should be laid about level with the top of the brood-chamber. This gives a constant draft of cool air, and the warmer the day the stronger the draft. The brood-chamber and outer case are not fastened to the bottom-board. Nail small blocks to keep them in place. I would not dare to trust to a dead-air space, as this would confine the heat generated in the brood-chamber. Besides preventing over-heating, this hive is as near a robber-proof hive as it can be made.

SELECTIONS FROM OUR LETTER BOX

Bees in California.

My apiary of 200 colonies produced 14,000 pounds of honey during the last season, principally from blue sage. The coming season I intend locating an apiary of 100 colonies in the north part of San Diego county. I find a great many small apiaries along the coast range of mountains, badly managed. Some of the queens are from 3 to 5 years old. I think if the BEE JOURNAL could be placed in those apiaries, they would soon present a brighter aspect. JOSEPH SAYLER.
Pleito, California.

Bees in Missouri.

One month has passed since I moved my bees from the cellar, to let them have a cleansing flight, which they needed very much. Some of them had diarrhoea badly, and I was glad when good weather came, so as to move them out-of-doors. The weather has continued fair up to this date. Out of 60 colonies, I lost 1; 20 had diarrhoea. Those which were affected with diarrhoea, were mostly of those I had built up from nuclei, and had only fall honey in their hives, and plenty of pollen. From those that had diarrhoea, I removed the honey last summer. After taking them from the cellar, I found that one colony had nothing but pollen in the combs, and not a drop of honey. I removed the combs that were the most besmeared, and gave them three frames partly filled with honey, which brought them out all right, and they

are now doing well. Of the other infected colonies, there has, up to this time, 6 swarmed out and joined other colonies. I fear that I will lose several more, as many are so weak and dwindled down, that they can hardly hold out much longer, and soon will have to give up the battle. I have wintered 14 colonies out-of-doors on the summer stands; 9 packed in chaff, and 3 without any protection; they all came through the winter in good condition. Two colonies I had covered up with ground, only leaving the front open, and they wintered the best of all; one of them had drones flying to-day. Experience teaches me that colonies from which honey is removed during the summer, will have diarrhoea; while those worked for comb honey show no signs whatever, and are strong and healthy.

JOHN NEBEL.

High Hill, Mo., April 14, 1884.

The Weather and Bees.

The weather has been cloudy and cold for the past ten days. With only a few exceptions, bees have been confined during that time. It is still cloudy, and the indications are that we will have some snow. Bees are getting short of stores.

C. THEILMANN.

Theilmanton, Minn., April 15, 1884.

My Affliction, etc.

I have been compelled to neglect my correspondents on account of my suffering with an unfortunate eye, and finally submitting to the removal of the lens. The operation was painful but short, and my progress towards recovery is exceptionally good. My confinement in a dark room for almost two weeks was a greater torture to me than the operation itself. In a week from this date I hope to be myself once more. My bees seem to have wintered better than usual. From reports, I judge that a larger interest than ever will be manifested by bee-keepers the coming season.

CHAS. F. MUTH.

Cincinnati, O., April 12, 1884.

Bees Confined 149 Days.

I believe that bee-diarrhoea is caused by dampness in the hive; and that dampness is produced by the breath of the bees and damp air collecting on the combs. What is found in the intestines of the bee after death by diarrhoea? We find $\frac{1}{2}$ part pollen, and $\frac{3}{4}$ parts water. I think if the inside of the hive be kept dry, there would be no bee-diarrhoea. The bees become damp and cannot fly, and death is the result. Was there ever a colony lost by diarrhoea, when the combs and hive were dry? My bees were put into the cellar Oct. 26, and taken out March 25, being confined 149 days. I found 4 dead colonies; 1 starved, having no honey but plenty of pollen; 3 that had diarrhoea were wet and moldy. The hives had been near the bottom of the cellar, and the cap fitted tightly. Sixty colonies came out in fine condition; but they

are light in honey. I have never had bees eat so much honey in the cellar as was eaten during the past winter. One wintered out-of-doors came through nicely; it was a Syrian colony, and the hive is full of bees. They endured 40° below zero. Syrians are always on the alert, and a robber-bee stands no show if it makes an appearance at the entrance of the hive. When the Syrians will not produce 75 pounds of honey per colony, spring count, I will try some other race of bees. Location has something to do with the yield of honey; it is not all in the race of bees.

Cokato, Minn. FAYETTE LEE.

Valuable Instruction.

The books, "Bees and Honey," and Prof. Cook's Manual, I have studied very carefully, and find both of them invaluable to bee-keepers. The BEE JOURNAL is indispensable to any enterprising bee-keeper. Every number contains one or more articles that are worth as much, or more than the subscription price for one year. Leaflet No. 1, and "Honey as Food and Medicine," are just what is wanted.

C. E. CANNADAY.

West Berne, N. Y., April 12, 1884.

Winter Losses Slight.

Bees in this section are in good condition. The winter loss is but slight, compared to some years. I did not lose a colony, and I am feeding but one, which was left unpacked as a test. All were on the summer stands, packed with chaff and dry leaves.

II. D. CUTTING.

Clinton, Mich., April 14, 1884.

Still Cold in the Pineries.

After 159 days confinement, I took my 108 colonies out of the cellar, and found 100 live ones. Three had starved, 3 had lost their queens, and 2 died with diarrhoea. The ice has not yet thawed in the bay, and the ground is covered with snow. It looks pretty gloomy for a specialist in bee-keeping this far north.

C. CASE.

Petoskey, Mich., April 17, 1884.

Pollen and Fermented Honey.

On opening one hive about the middle of January, I was struck by the peculiar condition of one of the frames. The caps were bursted off of about one-half of the cells, and a yellowish substance protruding from them. I removed the frame and carried it to a neighboring bee-keeper, where we examined it together. We found it to be pollen and honey fermented; which, acting the same as anything else in the same condition, generated gas which probably bursted the caps off the cells. Now, why was the honey and pollen in the same cell? A bee-keeper tells me the honey was put over the pollen to keep it moist. I claim the bees were crowded for space to store their honey, and so placed it over the pollen; and, consequently I am ridiculed, but still I hold the same opinion. If bees placed

honey over pollen to keep the latter moist, why would they leave $\frac{2}{3}$ or $\frac{3}{4}$ of it uncappped? If it preserves $\frac{1}{3}$ of it, the bees surely ought to know that it would also keep the other $\frac{2}{3}$. We all know the use of any liquor in a state of fermentation, is very little to give the person the dysentery who uses it; and is it not reasonable to suppose that honey and pollen, in a state of fermentation, would do the same thing with bees? This is no fancy sketch, but facts as I saw them.

FRED C. HATHAWAY.

Portland, Mich., April 16, 1884.

Bees in Nebraska.

My bees are in the cellar yet. I think they have wintered all right, and are now beginning to wake up to a sense of their duty. I will have to set them out before long. We are having a very wet, backward spring, but everything works for the best.

G. W. STARK.

Holmesville, Neb., April 11, 1884.

Moving Bees on the Railroad.

I moved 29 colonies of bees March 10, from Illinois to Iowa. The weather was so cold, and so much snow on the ground when I arrived, that I could not put them out. Ten colonies starved; the remainder are in good condition.

DAVID WATTERSON.

Benzette, Iowa, April 6, 1884.

Poor Honey a Cause of Disease.

Out of 66 colonies put up for the winter, 11 died of diarrhoea. I think poor honey was the cause of it. They were last year's swarms, and did not work in the sections. Those that did work in the sections are in fine condition; have plenty of honey and bees. Those that died had from 16 to 30 lbs. of honey left; about $\frac{1}{2}$ down from the top was white clover honey; the rest was of a pinkish color. The bees that stored the poor honey in the sections are all living, while those that stored late honey below and had to eat it first, are all dead. On Oct. 7 a swarm of black bees came to my yard. I hived them in a box, captured the queen, and put the rest of the bees with a nucleus of Cyprians that had a young queen. I fed these about 12 lbs. of the best white sugar, and now they are doing nicely; of those that died, 9 were Italians and 2 blacks. I wintered my bees on the summer stands in Simplicity - Langstroth hives. We had very cold weather the past winter, 30° below zero at one time; but the cold weather in March was the most detrimental to the bees.

Casey, Ills. D. R. ROSEBROUGH.

Fruit Bloom is Backward.

The weather is cold and the spring is backward. Bees have dwindled badly. Loss, 25 per cent.; cause, dysentery, resulting from poor honey, gathered mostly from honey dew and from yellow willow, late in the fall. White clover looks promising; fruit bloom is backward.

S. COULTHARD.

Preston, O., April 15, 1884.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Questions by a Beginner.

I bought a colony of bees in December; moved them a mile in a lumber wagon. February 19, shipped them on an emigrant train, and then hauled them 5 miles, on a load of goods, over rough roads. They have been out all winter, and are in fine condition; also, are at work every favorable day. They are in a Langstroth hive.

1. When is the time to put on sections?
2. About what time, generally, do bees swarm?
3. Can I do without a smoker?
4. How long after a swarm is hived, do you put on sections, if at all?

J. N. CAST.

Lincoln, Neb., March 6, 1884.

ANSWERS.—1. When the bees begin to build bits of comb about the tops of the frames.

2. Bees usually swarm from 1 to 3 weeks after the building of new bits of comb.

3. If you have plenty of tact, you can do without a smoker; but it will pay you better to purchase one, even with one colony.

4. If the swarm is hived on full sheets of foundation in the brood-chamber, and is a large one, you can put the sections on at the time of hiving; otherwise from 5 to 10 days afterward.

Italianizing.

Will Mr. Heddon, in "What and How," please answer the following: What would be his method of getting Italian queens in colonies in box hives which are to be transferred in fruit bloom, so as to get all the benefit possible from the Italian colony this season? I practice transferring without drumming out.

W. G. FISH.

Ithaca, N. Y.

ANSWER.—My method would be to purchase untested queens, and place one at the head of each colony, after destroying the black queen, at the time I did the transferring.

Losses of Bees in Winter.

The past winter has been very hurtful to the bee interests in this section. As far as I can learn every person in this vicinity has lost all, or nearly all of their bees. Those wintering in bee houses faring alike with those wintering on the summer stands. Out of 100 colonies on the summer stands, I have only 9 remaining; 80 colonies were in the Fisher chaff-hive, which contained the remnant left alive; 20 colonies in the Heddon hive, all died. As I cannot use all of my old hives and combs, this summer, can I keep them free from moths until another year, the comb all being built since

1880? Bees did very poorly here last year; storing very little surplus honey. They did not pay expenses, the season being so wet and cold. Cold and dysentery, I think, caused our losses. We miss our little pets very much, and shall try and retrieve our losses.

WM. SHIER.

Marlette, Mich., April 10, 1884.

ANSWER.—You can keep your comb over another year by boxing them absolutely moth-tight, provided they have been exposed to a temperature as low as 14° above zero; if not, I would fumigate them with sulphur, and hang them in a cool, airy room, so as not to touch each other. I once kept a lot in the cellar, hung between the joists overhead, about an inch apart, and leaving the cellar windows out (screening the same); thus allowing a circulation of air which is most detrimental to the development of the moth larvæ. Protection in winter acts as a preventive to diarrhoea. Had you protected your hives, the death rate would have been the same as with the chaff hives. We have tried the experiment several times.

Moving Bees.

Please answer through the BEE JOURNAL the following questions:

1. I have my hives on a bench very close together, and wish to put them in better position; say, scatter them over a flat of ground 15 yards square. How can I remove them without losing bees? They have been wintered on the summer stands, and need transferring also.

2. How can they be removed half a mile without loss of bees?

Please do not refer to any back numbers in your answers, for I have not got them.

A. J. BROWN.

Cockeysville, Md., April 9, 1884.

ANSWER.—At the first period, when they will be most likely to be shut in for a few days by cool weather. When you move them, or just when they are about to fly from the new stands, smoke and jar the hives, and put boards before the entrances, so that they will bump noses, or have to fly out sidewise around it, and remove any fixtures from the old quarters that may make them "look like home."

Convention Notices.

A bee-keepers' association is to be organized in Western New York on Tuesday, May 6, 1884, at Randolph, Cattaraugus County. In this southern-tier district there are a large number engaged in bee-keeping, and an association of this kind has long been needed. A general invitation is extended to all interested in bee-keeping.

W. A. SHEWMAN.

The Progressive Bee-keepers' Association will meet for their spring meeting May 3, 1884, at the apiary and residence of J. B. Haines, Bedford, Cuyahoga County, O. All interested are invited.

J. R. REED, Sec.

The Northwestern Illinois and Southwestern Wisconsin Bee-keepers' Association, will be held at Rockton, Winnebago Co., Ills., on May 20, 1884.

JONATHAN STEWART, Sec.

The Bee-keepers of Tippecanoe and adjoining Counties, will hold their regular quarterly meeting at room No. 3, in Purdue College, in the city of Lafayette, Ind., on May 6, 1884. All lovers of the honey bees are respectfully invited to be present and take part in the discussions.

MRS. JAS. L. HAVENS, Sec.

DR. L. SNYDER, Pres.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
Monday, 10 a. m., April 21, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—There is no life in the market. Extracted honey sells in its regular way and to its wonted channels, without any speculative feeling about it, and brings 7@10c on arrival. Comb honey sells slow at 15@16c a lb. from store for choice.

BEESWAX—Is in good demand; choice yellow brings 35c a lb. on arrival.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@18c. Dark and second quality, 15c.; extracted white clover in kegs and barrels, 9@10c.

BEESWAX—Prime yellow, 34@35c.
H. K. & F. B. THURMER & CO.

CHICAGO.

HONEY—Of late receipts of comb honey has been scattered amongst many firms, and as all are desirous of realizing on their receipts at as early a day as possible, prices have been irregular and low, some lots being offered from 5c to 7c per lb., less than 30 days ago.) quote white comb 13@16c; fancy 18c. Extracted honey—demand light, 7@9c.

BEESWAX—30@37c.

R. A. BURNETT, 161 South Water St.

KANSAS CITY.

HONEY—Demand for comb honey good, with lower prices: 15@16c for choice 1 and 2 lb. sections. Dark and broken or irregular comb, slow at 10@12c. The liberal receipts of comb honey from New York State have cast much Western honey in the shade, and our Western producers will have to look to their laurels. There have been thousands of pounds of Eastern honey marketed here this season, and almost every comb has been perfect in every respect. It is hard to sell the unsightly stuff that I am receiving daily from other sources, by the side of this handsome honey from the East. Extracted in fair demand, at 8@9c, according to quality and color.

BEESWAX—None in this market.

JEROME TWICHELL, 514 Walnut Street.

SAN FRANCISCO.

HONEY—We again advise our shippers not to put their extracted honey in old or second-hand tins and cases. The wood of old oil cases is saturated with oil, the nails will not hold, and the cases often arrive in a broken and dilapidated condition. They smell of coal oil, look roub, and are not as salable as good, clean, new packages.

White to extra white comb, 15@18c; dark to good, 10@13c; extracted, choice to extra white, 7@8c; dark and candied, 5@—

BEESWAX—Wholesale, 27½@30c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@16c per lb., and strained and extracted 6@8½c.

BEESWAX—Firm at 32@32½c. for choice.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is unchanged with us. There is a continued steady demand for choice white 1 lb. sections at 18c; 2 lbs. move more slowly at 16@17c; but for second quality there seems to be no demand. Our supplies of 1 lb. are kept well down. Extracted does not sell at all at any price.

BEESWAX—Wanted at 35c.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Demand light. 1 lb. sections comb honey, 14@20c.; 2 lb. 16@18c. Extracted, 9@11c.

BEESWAX—35c.

BLAKE & RIPLEY, 57 Cbatham Street.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

We are now preparing a new book for the pocket, to be called "The Bee-Keepers' Convention Assistant." It will contain a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making reports for statistical information—and much other useful matter for those who attend Conventions. One of the latter will be a suitable Programme of questions for discussion at such meetings, model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs; a few blank leaves for jotting down interesting facts, etc. We shall aim to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world. It will be of a size suitable for the pocket, nicely bound in cloth, and the price will be 50 cents.

We can supply photographs of Rev. L. L. Langstroth, the Baron of Berlepsch, or Dzierzon, at 25 cts. each.

DUNHAM COMB FOUNDATION MACHINE.

TESTIMONIALS.

Mrs. FRANCES DUNHAM, De Pere, Wis.
Dear Madame:—We have made about 38,000 lbs. of foundation on your mills this year, and the
foundation has given universal satisfaction; so much so, that several manufacturers have stopped
manufacturing to supply their customers with our foundation. We have also manufactured about
100,000 lbs. of this foundation on the Vandervort machine for surplus boxes, and it has been equally a
success, but for brood chamber foundation, yours is still unexcelled.
Yours,
CHAS. DADANT & SON.
Hamilton, Ill., Dec. 10, 1883.

Mrs. FRANCES DUNHAM, De Pere, Wis.
Dear Madame:—I have made over 100,000 lbs. of foundation on one of your machines, and would
not now take double the price I paid for it.
Yours very truly,
D. A. JONES.
Beeton, Ont., Dec. 10, 1883.

Mrs. FRANCES DUNHAM:
All prefer the foundation I manufacture on one of your mills, to that made on any other machine
I have no difficulty in rolling it from 10 to 12 feet to the pound for sections.
Yours respectfully,
J. G. WHITTEN.
Genoa, Chryga Co., N. Y., Dec. 12, 1883.

Mrs. FRANCES DUNHAM:
After using one of your foundation mills for the past 3 years, we can't say too much in its favor
And for brood foundation, it stands head and shoulders above all.
Yours,
SMITH & SMITH.
Kenton, Ohio, Dec. 29, 1883.

Mrs. FRANCES DUNHAM:
I made all brood on Dunham mill, and that I believed it by far the best for that purpose, and as
further proof, instance the testimony of E. Kretchmer, of Cohurg, Iowa, and L. C. Root & Bro., of
Mohawk, N. Y. Messrs. Root & Bro. have only used brood foundation of me, and in a later communi-
cation say: "It (our foundation) gave the best results of any tried." I write this that you may have fair
play, which is me always a jewel. You are at liberty to publish this. Yours truly, **T. L. VON DORN.**
Omaha, Neb., Jan. 18, 1884.

1868. 1884.
HEDDON'S
COLUMN.

My New Langstroth Hive.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

One Hive complete for comb honey. .\$.300
(The above will contain two cases complete with sections).

The above Hive complete for extracted honey. .\$.300
The above Hive complete for both in one. .450
One Hive in the flat. .200
Five or over, each. .150

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddson Hives, that in no wise embrace my principles. Judge only by those purchased from me.

Given Comb Foundation, after having been thoroughly tested by many of our most experienced, most successful and most extensive bee-keepers, now stands, at least, second to none. I have on hand a large and choice stock of pure, domestic wax, together with improved facilities for making an article of that Foundation excelled by none.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4 1/2 x 4 1/2 x 6, 7 and 8 to the foot, per 1,000, \$6.50; 5 x 6 x 2, per 1,000, \$8.00. All shipped from here.

STUDENTS OF APICULTURE

Will receive terms for 1884 on application.

BEES and QUEENS.

If you contemplate the purchase of Bees in any shape, tested or untested Queens, it may pay you to send for my

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.

Address,

JAMES HEDDON,
DOWAGIAC, Cass County, MICH.

BEE-KEEPERS' SUPPLIES.

Send a postal card for my Illustrated Catalogue for 1884.

COMB FOUNDATION.

On account of the prevailing scarcity of beeswax the price of comb foundation is now advanced 3 cents per pound above the price quoted in my Catalogue for 1884.

BEE SWAX.

I pay 32c. per pound delivered here, for yellow Beeswax. To avoid mistakes, the shipper's name should always be on each package.

CLOVER SEEDS.

The present prices are as follows:

White Clover, \$15.00 per bushel, \$4.00 per peck, or 30 cts. per pound.
Alsike Clover, \$12.00 per bushel, \$3.25 per peck, or 25 cts. per pound.
Sweet Clover, \$10.00 per bushel, \$2.75 per peck, or 20 cts. per pound.

NO. 30 TINNED WIRE For Brood Frames.

One ounce spools, each, - 4 cents. Postage, 2 cents extra.
One oz. spools, per dozen, 40 cents. Postage, 13 cents extra.
One pound spools, each, 40 cents. Postage 18 cents extra.
One pound will wire about 175 frames.

Eureka Wiring Tool,

For pressing Foundation into wired frames. Something entirely new. Price, 50c. by mail; 40c. by express.

WIRE NAILS,

On account of a decline in the price of Wire Nails, I will make a discount of 15 per cent. from the prices quoted in my Catalogue, until further notice.

CHEAP FOUNDATION MILLS.

These Mills will make Foundation of any desired thickness, for either Section Boxes or Brood Frames.

PRICES:

4 inch Rolls. .\$.10.00
6 " " .15.00
10 " " .25.00
12 " " .40.00

CHICAGO, ILLINOIS.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most money in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pultusk, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style and is cheap at the price.—Farmer, Cleveland, O.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.

A very valuable work for those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the most important in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

VALUABLE

ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that the original Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, and only a little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but if these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To

BOOKS!

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates, on larger quantities, given upon application.

Dzierzon's Rational Bee-Keeping.—A Translation of the Masterpiece of that most celebrated German authority, by H. Dieck and S. Stutter, and edited, with notes, by Charles N. Abbott, *Ex-editor of the "British Bee Journal."* Dr. Dzierzon is one of the greatest living authorities on Bee Culture. To him and the Baron of Berlepsch we are indebted for much that is known of scientific bee culture. Concerning this book, Prof. Cook says: "As the work of one of the great masters, the Langstroth of Germany, it can but find a warm welcome on this side of the Atlantic." Mr. A. I. Root says of it: "Old father Dzierzon... has probably made greater strides in scientific apiculture than any one man... For real scientific value, it would well repay any bee-keeper whose attention is at all inclined to scientific research, to purchase a copy. Cloth, \$2."

Queen-Rearing, by Henry Alley.—A full and detailed account of TWENTY-THREE years experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price, \$1.00

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.—This manual is elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means can afford to do without. Cloth, \$1.25; paper cover, \$1.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Fourth Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 5c.; per dozen, 40c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. This is a chapter from "Bees and Honey." Price 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Bee Pasturage a Necessity, by Thomas G. Newman.—Giving advanced views on this important subject, with suggestions what to plant, and when and how to plant. This is a chapter from "Bees and Honey." Price, 10c.

Bees in Winter, with instructions about Chaff-Packing, Cellars and Bee Houses, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heads, bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price 35 c. postpaid.

Fisher's Grain Tables for Farmers, etc.—192 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measure, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. 6 cents.

Moore's Universal Assistant, and Complete Mechanic's Companion.—100 Indispensable Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Brazers, Gliders, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

The Hive I Use.—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Foul Brood; its origin, development and cure. By Albert R. Kohnke. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. 15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Dzierzon Theory;—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Apiary Register, for SYSTEMATIC WORK in the APIARY. The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book. Prices: For 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Deutsche Buecher, Ueber Bienenzucht.

Biene Kultur, oder erfolgreiche Behandlung der Biene, von Thos. G. Newman. Dieses Pamphlet enthält Belehrungen über folgende Gegenstände—Der Tlichkeit des Bienenstandes—Honig pflanzen—Erziehung der Königin—Füttern—Schwärmen—Ablegen—Versezen—Italienisieren—Zufetzen von Königinnen—Ausziehen—Biene behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschrieben ist. Preis 40 Cents.

Honig als Nahrung und Medizin—von Thomas G. Newman. Dieses enthält eine klare Darstellung über Biene und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angehend wie man Honigkuchen, Formkuchelchen, Puddings, Schaumfoncet, Weine, u. s. w. zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Conumenten bestimmt, und sollte vieltausendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Pferd und seine Krankheiten—Von V. J. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniß der verschiedenen Pferdekrankheiten, jammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Recepte. Preis 25 Cents.

Premiums on Bees and Honey.

The following is the Premium List on Bees and Honey as secured by the Executive Committee of the Iowa Bee-Keepers' Association, as mentioned on page 277 of this JOURNAL. These premiums amount to \$175.00, and Iowa bee-keepers should make a success of the apiarian department, by arranging such a display as will create astonishment. It can and should be done. Let every bee-keeper in Iowa read over the List, and then work for the premiums there offered.

| | First | Second |
|---|---------|---------|
| Best Italian bees in observatory hive. | \$ 5.00 | \$ 2.00 |
| Best Cyprian bees in observatory hive | 5.00 | 2.00 |
| Best Syrian (Holy Land) bees in observatory hive. | 5.00 | 2.00 |
| Best black (German) bees in observatory hive. | 5.00 | 2.00 |
| Best and largest display of different races of bees, in observatory hives | 20.00 | 10.00 |
| Best and largest number of Queen-cells on one frame of comb as actually built by the bees, shown with bees in observatory hive. | 5.00 | 2.00 |
| NOTE.—In awarding the premiums on the different entries of bees, the qualities of Queens and Bees will be considered. The Bees and the Queen-cells should all be shown in observatory hives with glass on both sides, so arranged that both sides of the comb can easily be seen. | | |
| Best comb honey, white clover or linden, not less than 20 lbs. | \$ 5.00 | \$ 2.00 |
| Best comb honey, fall flowers, not less than 20 lbs. | 5.00 | 2.00 |
| Best and largest display of comb honey | 25.00 | 10.00 |
| Best extracted honey, white clover or linden, not less than 20 lbs. | 5.00 | 2.00 |
| Best extracted honey, fall flowers, not less than 20 lbs. | 5.00 | 2.00 |
| Best and largest display of extracted honey | 25.00 | 10.00 |
| Best beeswax, not less than 10 lbs. | 4.00 | 2.00 |
| Best display of honey plants, pressed, mounted, and labeled. | 4.00 | 2.80 |

NOTE.—In awarding the Premiums on all the different entries of honey, the committee will give equal consideration to the quality of the honey, and to the style of the packages in which it is exhibited, as regards beauty and desirableness for purposes of marketing.

Bees and Honey are the great attraction at all the fairs which have given prominence to this industry, and we are glad to note the increasing interest year after year in the matter, as well as the increased size of the Cash premiums offered by the wide-awake managers of local, district and State fairs.

There are many good reasons for making magnificent honey exhibits, but the chief one, perhaps, is that those who produce honey for the market, may be induced to present it in the most marketable shape; for the new methods and new ideas of practical management must take the place of the old and undesirable ones.

It should be our aim to make honey a staple product. To this end, let all endeavor to popularize the consumption of honey by the masses, as well as to raise the standard of production, by applying correct principles and progressive art to the management of the apiary.

If there is one thing of more importance than another to the honey producer, it is that of popularizing the consumption of honey. These "shows" are the best educators of the masses that have yet been devised. In an article concerning the Toronto Bee and Honey Show, Mr. Wm. F. Clarke says:

"Under the stimulus of the liberal prize list, there was a magnificent array of honey. The directors appropriated an entire building to the use of bee-keepers, and for the first time at a great exhibition on the American continent, "honey hall" advertised itself side by side with horticultural hall, dairy hall, etc. Honey was displayed in every form, calculated to make the mouths of spectators water. The tin packages and cans were gorgeously colored and labeled; the glass jars were in various beautiful shapes, and even the wooden boxes displayed a wonderful diversity of taste. In the center was a miniature church, ingeniously built of honey-comb and wax, with pinnacles and spire. A smashing trade in honey was done at the exhibition. Thousands of people might be seen with gay-looking tin cans dangling from their fingers, or with pretty glass jars in their hands, or nice boxes under their arms. They bought and carried them home very much as is usually done with toys and trinkets on such occasions. The success of this show awakens great expectations as to the future of bee-keeping in this country.

Of the Honey Show in San Francisco, Cal., the *Semi-Tropic* said:

"The attractive display of bees and honey formed a centre around which

apiarists literally swarmed. One hundred and two varieties of honey-producing flowers, formed a novel and interesting feature of this exhibition. The decorations of white sage were tasteful and appropriate, and the nectar itself, in jars arranged in pyramidal shape, clear as crystal, supported by frame after frame of comb honey, snowy and inviting, made a picture which cannot be photographed except by the artist memory. There were samples of excellent honey vinegar, almost colorless, and above average in acidity; several samples of fruit preserved in honey with undeniable success, and three kinds of honey cake, which elicited the warmest praise from those who were fortunate enough to secure a sample. Fruit cake made with honey is richer, and retains moisture much longer than that made of sugar."

The Fremont, Mich., *Indicator* of last week, has the following:

George Hilton will attend the bee-keepers' meeting at Berlin, 24th, and also endeavor to have the next meeting of that association held here. It would pay any one interested in that line of business to come to Fremont and look through George's apiary; it is a very well regulated affair.

This is praise worth having. How much better than to say his apiary was a disgrace to the neighborhood.

Spider Plant.—Mr. S. F. Daily asks how large the spider plant grows; how far apart the plants should be, etc.?

Its botanical name is *Cleome pungens*, and it thrives best in rich, damp clay soil. It grows to the height of 5 or 6 feet. Plant them about 3 feet apart each way.

It commences to bloom about June 25th, can easily be propagated from the seed, and is an excellent honey-producer.

Balmy spring weather has come at last, and soon the flowers will bloom and all nature will look gay, clad in its rich garb of loveliness.

We have received the Bee-Keepers' Price List for 1884 of Thos. L. Thornton, Dividing Ridge, Ky.

For the American Bee Journal.

Comb Foundation in Brood Frames.

G. M. DOOLITTLE.

On page 672 of the BEE JOURNAL for 1883, I promised to discuss the matter regarding the economy of comb foundation, as Mr. Chas. Mitchell seems to think (page 362 of the BEE JOURNAL for 1883) that my plan of getting the bees to build 4 or 5 nice combs before helped by empty combs or foundation, to be "mistaken economy."

I have reason to doubt Mr. Mitchell's following out the plan as I gave it on page 80. of the BEE JOURNAL for 1883; for he does not even allude to that way of working, but tells us of giving his bees frames half filled with foundation, which was placing them in just the condition I cautioned against, viz.: a condition tending toward the production of drone comb in the brood frames. The object of the plan I gave on page 80, was to have this drone, or store comb, built in the sections, if any such was built at all.

The majority of the bee-keepers of the United States seem to have gone crazy over the using of comb foundation in the brood frames; so it appears to me. This is causing all, whether rich or poor, to believe it necessary to invest a large sum of money in comb foundation, or mills to make it. To those who have plenty of money to use lavishly, I have nothing to say; for it is their privilege to use it as they please; but to those who must deprive their families of the necessities of life, in order to purchase foundation for their bees, I say do not do it; for in my opinion natural comb can be built just as cheaply as we can bother with foundation.

I realize that this assertion will call down many hard thoughts, if not hard words upon myself; but I desire that those who think otherwise, will follow my plan on one or two hives before they are too severe in their criticisms.

The plan I wish them to follow, and the one which has led me to the above opinion, is this: Wait till natural swarming has fully commenced, when two swarms are to be hived on the same day, each being as near equal as possible; one is to be treated to foundation the same as you formerly have done, and the other is to have empty frames given them, each frame having a nice starter of worker comb, or a wax guide the whole length of its top bar, or a strip of foundation $\frac{3}{4}$ of an inch wide in place of the comb or guide, as you prefer. Place as many frames in the hive thus prepared as it will contain except one; and in place of this frame use a division-board coming within $\frac{1}{2}$ of an inch of the bottom-board, having this

division-board in the centre of the hive.

Now, hive the swarm, and in 36 to 48 hours see on which side of the brood the bees have commenced to build comb the most largely; for there is where the queen will be; take out the frames on the other side of the brood from where the queen is, and over the part having the frames now left, place a set of sections which are filled with the thin foundation. Leave them (frames and sections) thus, till the bees begin to be crowded for room, when you are to put two or three of the empty frames you removed, in the brood-nest, placing them between those already built, so that each empty frame will come between two full ones. At the same time raise up the partly filled sections, putting another one, prepared the same as the first, under them; if you use the tiering-up plan, or place the sections at the side if you use the side storing plan.

By this plan I get combs built which are all straight worker combs just as good as can be prepared when built of foundation; and also get the foundation thinned and drawn out in the sections; while, if I hive the bees on empty combs or foundation, they use their secretion of wax by placing it upon the foundation in the sections; and thus we have the thick, hard, side walls of the foundation in our section honey, as I have repeatedly proven by scraping the honey off and washing the foundation, when I had a piece that no one could tell from the original.

Did Mr. Caldwell (see page 25) try the above plan in his experiment? or did he hive the bees, giving them the full hive? If he gave them the full hive, of course they would not go into the sections till the hive was all filled below.

The idea is, that a swarm of bees are going to build comb somewhere, or the wax secretion taking place at the time, must go to waste; and if you give them comb foundation in the brood-chamber, they will use their wax in the sections on the foundation. If you give them only a part of the hive, as I have given above, they will use their wax in making nice worker comb below, instead of wasting it by adding it to the foundation given them, as I have described above.

Again, at all times of a heavy yield of honey, the bees secrete wax whether any combs are to be built or not; and if the sections are all supplied with foundation, and the hive filled with comb, this wax is wasted, or else the foundation given is wasted; have it which way you please.

The past season I had several hundred sections placed side by side on colonies hived on a full set of combs; one-half of which had a starter of natural comb, and the other half filled with foundation, and all were ready to come off together; thus proving that in such times of plenty the foundation was simply thrown away, when a full hive of comb was used below. To remedy this waste, I use the $1\frac{1}{2}$ and 2-pound sections containing only starters, upon colonies whose hives

are full of comb (except to have 3 or 4 sections full of comb foundation, as a leader into the boxes), and place sections filled with foundation in colonies which are building comb. With the one-pound and smaller sections, foundation seems to be a necessity; for the bees seem averse to building comb in so limited a space.

To show that I am not alone in this matter regarding the waste of wax, I wish to quote from two or three of our best apiarists: the first is Prof. Cook, and no one will say that he is not good authority. He says, on page 103 of the latest edition of his Manual, "But I find upon examination that the bees, even the most aged, while gathering, in the honey season, yield up the wax scales the same as those within the hive. During the active storing of the past season, especially when comb-building was in rapid progress, I found that nearly every bee taken from the flowers, contained wax scales of varying size, in the wax-pockets."

This is my experience during "active storing," and the wax scales are to be found on the bees just the same whether they are furnished with foundation or not; and I can arrive at no other conclusion than that arrived at by Mr. S. J. Youngman, when he says, on page 103: "The bees secrete wax during a honey flow, whether they are building comb or not; and if they are not employed in building comb, this wax is most certainly lost."

Once more, on page 93, of the *American Apiculturist*, Mr. G. W. Demaree says: "Observation has convinced me that swarms leave the parent colony better prepared to build comb than they ever are under other circumstances; and if they are not allowed to utilize this accumulated force, by reason of having full sheets of foundation at hand to work out, there will necessarily be some loss; and I think that when the matter is computed, to find the loss and gain, the result will show that the foundation really costs the apiarist double what he actually pays for it in cash."

One more point and I will close. In our locality there is very little white clover, as this is mostly a grain raising district, so the land is plowed so often that white clover cannot get a foot-hold. Thus our bees generally get only enough honey during the month of June to keep up brood-rearing, while our swarming commences from June 15 to 20.

Now, I have often noticed, and especially in looking back over the last year, after reading Mr. Mitchell's "Mistaken Economy," that swarms hived in June would fill their hives full of nice straight worker combs, and the combs would be filled with brood during the first two weeks after hiving; while a colony not casting a swarm would not make a gain of a single pound of honey; nor would a swarm having a full set of combs given them, or the frames filled with foundation, be a whit better off at the end of two weeks.

Mr. P. H. Elwood has noted the same thing; thus proving that the theory that it takes 20 pounds of

honey to produce one pound of comb, will not hold good in cases where bees desire comb and have free access to pollen.

As most of my comb is built at this time, the reader will readily see that the combs cost me but little, save the looking after the colony once or twice while building comb, which is far cheaper than buying foundation, or fussing with a foundation mill.

As I said in a former article, I have never used 10 pounds of foundation in the brood-chamber; yet, I have experimented with it every year, and those experiments have led me to consider it an expensive luxury compared with natural combs, where the above plans are adopted.

In conclusion I will say that if this article shall lead any reader to have his combs built by the bees, thus saving the loss of wax, which must arise from using foundation in the swarming season, and also saving his hard-earned pennies, which he would pay out for foundation, and lay them out for the comfort of his family, this article will not be in vain. As I said at the outset, those having plenty of money to use, as they please, can pass this by unheeded; for, without doubt, they will enjoy the luxury of foundation, or modern transferring, better than to encourage and give the benefits of such economy to some poor neighbor.

Convention at Franklin, Ind.

In response to the call, a number of bee-keepers met at the Court House in Franklin, on April 5, and organized a bee-keepers' association. The meeting was called to order by Mr. L. R. Jackson, and the object of the meeting stated.

Mr. H. H. Luyster, of Franklin, was chosen temporary chairman, and L. R. Jackson secretary *pro tem*. On motion, the chairman appointed L. R. Jackson, J. T. Ragsdale and Mrs. Hannah Barlow as a committee to draft a constitution and by-laws, and to report at the afternoon session. The meeting then adjourned.

At 1:30 p. m., the chairman called the meeting to order, and asked for the report of the committee on constitution and by-laws. On motion of Mr. Frank L. Dougherty, the secretary was instructed to read the report, by sections, and the same to be discussed as read. After a few changes, the constitution and by-laws was adopted, and signed by 21 members.

On motion of Mr. John Beard, Mrs. Cass Robbins, President; Mr. Frank L. Dougherty, Secretary; and Mrs. Lizzie Stout, Treasurer, of the Indiana State Bee-keepers' Association, and Mrs. Robt. A. Kelly and Mrs. H. Delano, of Franklin, were made honorary members.

The following officers were then elected: Prof. C. H. Hall, of Franklin, President; Mrs. Hannah Barlow, of Rocklane, Vice-President; Mr. L. R. Jackson, of Urmeville, Secretary;

and Mrs. Phoebe J. Kelly, of Franklin, Treasurer.

Mr. F. L. Dougherty, of Indianapolis, being called for, made a few remarks, and was subjected to a running fire of questions, for half an hour, which he answered in an able manner. Questions were then asked of others.

Mrs. Robbins urges all, and especially the ladies, to attend the State Association, and to take a more active part in bee-keeping. She is a very enthusiastic bee-keeper, and encouraged our lady bee-keepers very much.

The next meeting will be held at Franklin, Ind., on Saturday, May 3, at 1 p. m.; at which time a much larger, and a very enthusiastic meeting is anticipated.

Mrs. Ella Jackson will read an essay to encourage the ladies in bee-keeping. Topic: "Bee-keeping, a Profitable Business for Ladies."

L. R. JACKSON, Sec.

PROF. C. H. HALL, Pres.

For the American Bee Journal.

To Iowa Bee-Keepers.

Your attention is called to the fact that at the State Fair in Des Moines, last September, an "Iowa Bee-keepers' Association" was formed to advance the science of bee-keeping, and to further the interests of bee-keepers. It is very desirable that this association have the friendship and co-operation of every bee-keeper in Iowa.

It is proposed to have a large meeting of bee-keepers on the Fair grounds in Des Moines next fall, Aug. 29 to Sept 5. Bee-keepers are invited to come with their wives and families. Bring tents and other essentials for camping out, and camp on the Fair grounds during the whole time of the Fair. Many people do camp on the grounds every year, and find it a pleasant, interesting, and an inexpensive way of spending Fair week. No charge is made for the privilege of camping on the ground.

It is proposed to have meetings of bee-keepers on the Fair ground, every night during Fair week, for mutual benefit. Experiences will be related, and methods of management discussed. Short papers will be read by practical men and women on important points in connection with bee-keeping. Perhaps some lectures may be given fully illustrated with materials and charts. Hives and other bee-keeping materials will be brought to the meetings and exhibited and discussed. It is believed that these nightly meetings, during Fair week, will be a source of much interest and profit to all. All bee-keepers are urged to come with their families and friends, and encamp near each other in a "bee-keepers' village," and so have a real "school of bee-keeping."

In aid of these nightly meetings, it is proposed to have a good tent bought and owned by the Bee-keepers' Association, and used as headquarters for all bee-keepers during the Fair week. Such a tent would serve for these large evening meetings, and as a reading

room and committee room during the day. Men who bring blankets with them, will find it a good place to sleep in.

The executive committee of the State Agricultural Society dealt generously with bee-keepers in the premiums offered in our department in 1883. They are still more generous the present year, having increased the aggregate of premiums offered last year by about 60 per cent. This year the premiums amount to \$175. If the bee-keepers of Iowa and the West respond by coming out in force and making a good show, we can, next year, get another advance in premiums.

It will be at once noticed that the premiums, this year, are confined to bees, honey, beeswax and honey plants. Nothing on hives or other bee-keeping implements and materials. This is done by the decision of the executive committee of the State Agricultural Society. They say that in other departments, they give no premiums on tools, implements, machines, etc.; and, hence, it is not consistent for them to offer premiums on these things in bee-keeping. Nevertheless, they have large and profitable exhibits of tools and machinery in all departments, and they invite and expect a large exhibit of the same from bee-keepers.

In bees, honey, beeswax, and honey plants, we believe that the premiums are, on the whole, the best ever offered in America. It is hoped that the bee-keepers from all parts of our State will heartily respond to this generous treatment by coming out in large numbers, and bringing their articles for competition and exhibition. By co-operation among our bee-keepers, we can have a very large, important, and instructive exhibit next fall.

Will you not begin the season with a determination to exhibit at the Fair? Then manage your bees so as to have something good to show, and so plan your work in the fall as to go to the Fair for the whole week if possible, and take your articles with you.

Every bee-keeper in Iowa is invited to interest himself or herself in the prosperity of the State Bee-keepers' Association. Join it yourselves, and ask your neighbors to join. Attend its meetings, and use your voice and influence to make the meetings valuable. L. E. Cardell, of Malcom, is the secretary. Send him your names, and the annual fee, one dollar, and be enrolled as members. Get your friends to do the same. The money so obtained will be used, this year, for the purchase of the tent, in which all members will have an equal share and right.

The next annual meeting of the State Bee-keepers' Association will be held on the Fair grounds in Des Moines during the next Fair. All members, men and women, have equal rights and privileges in these meetings. At the next meeting, officers will be chosen for the ensuing year, and the general work and policy of the Association will be decided upon.

While this circular is addressed specially to the bee-keepers of Iowa,

it must be remembered that our Association is open to all from every State who come in and pay the small fee of one dollar. Our Iowa State Fair is open to the world. All competitors from every State and Nation are heartily invited, and their exhibits welcomed to competition on equal terms with those from Iowa.

It is very desirable that all parties, intending to make an exhibit at the Fair, should send a correct list of their proposed entries to Hon. John R. Shaffer, Secretary of the State Agricultural Society, Des Moines, some days before the opening of the Fair. Their entry cards will then be made out, and will be ready when they call for them. This greatly facilitates the labor of all parties.

O. Clute, Pres., Iowa City.

L. E. Cardell, Sec., Malcom.

M. Sorrick, Treas., Des Moines.

O. O. Poppleton, Williamstown,
Executive Com.

For the American Bee Journal.

Foundation in Wired Frames.

C. M. RULAND.

One of the main things that is attracting the attention of bee-keepers at the present time, is wired frames; and the fact that one dealer buys No.

How to use my Wiring Tool.

30 tinned wire by the ton, to supply his customers, and that another states that his sales have increased ten-fold each year, and the large quantities sold by others, indicate the magnitude of its use.

We have yet to hear of the first bee-keeper who has tried wired frames and then abandoned them. I think that it is only a question of knowing their advantages, when all will use them. By their use you are sure of straight combs right where you want them; and, if the wire is properly pressed into the foundation, it saves fastening it to the top-bar; if it is left an inch below it, the bees will extend it the very first thing they do. If a swarm is hived on sheets of foundation, there is no danger of the sheets pulling loose from the top-bar, and falling down, and then there is no sagging.

There is great need of instruction as to the proper manner of wiring them. Only a day or two ago one of my neighbors told me that not knowing the right way, he had put one wire lengthwise of the frame, about half way down; and, although, that

was better than none at all, he was very sorry that he did not put them in right. I would like to give directions for placing the wires, and, from the engraving, I think it will be plain. I have carefully investigated the matter, and I believe the best authorities will bear me out in it.

First, bore 7 holes in each top and bottom bar, the first hole about one inch from the end of the frame, the others about equal distances apart. Commence at one end and sew the wire through the holes, draw it tight, and fasten at each end with a tack driven into the frame with the wire wound around it. Draw the wire tight enough to spring up the bottom-bar slightly, and spring in a stiff stick long enough to draw the bars straight, and the wires will be as straight and tight as a fiddle string. After the wire is pressed into the foundation, this stick can be removed and the foundation will hold the wires straight. I take no stock in top-bars so light that they need diagonal wires and a brace to hold them up. Make the top-bar at least $\frac{1}{2}$ of an inch thick, and it will never sag.

Over a board the size of the inside of the frame, place the foundation; on this, place the wired frame and press in the wire. Here trouble often occurs; for of all the things that bother bee-keepers in using wired frames, pressing the wire into the wax is the worst. I tried the button-hook process, a small wheel in a handle, a clock-wheel, and numerous other ways, but found them all slow, tedious, and unsatisfactory. They marred the foundation by plowing through it, and left the wire just stuck on, instead of embedded in the wax; so I was compelled to make a tool that would work better.

I first made it of wood; but that got wet, and warped and split; so I cast one of block tin, which has an advantage, as it keeps bright, is very strong, and will last forever.

This tool only touches the wire at intervals of $\frac{1}{2}$ an inch, and scarcely mars the wax at all. The wire cuts down to the centre of the foundation, and holds almost as strongly as if it were put in with a Given press.

The engraving shows the shape of the tool, and the manner of using it. The directions are for the Langstroth frame, and can be modified to suit any other. I hope that this will help the multitude of seekers for information; and if I have succeeded, I shall be pleased indeed.

Rockton, Ill.

For the American Bee Journal.

Selling Unripe Honey, etc.

JOHN WITSCHY.

"When shall we extract honey?" is the subject of an article on page 215, in which the writer says it is a question of importance; but I think the answer is still more important.

All are aware of the low price paid for extracted honey; and just as long as bee-keepers practice Mr. Balch's teachings, it will not be any higher.

Mr. B. makes a poor comparison in comparing a bee-hive to a cow stable. All who are acquainted with bees know that there is nothing cleaner than a healthy colony of bees in time of the honey flow. The aroma of the honey indicates the kind, even without opening the hive.

I think we should be satisfied if we save the bees from building comb without bothering about the capping of it. If we considered the quality of honey instead of the quantity, we should soon find the prices increasing. One who sells unripe honey is as dishonest as one who sells unripe fruit. My highest endeavor is not to sell the most honey, but the best. The reason we hear of so much candied honey, is because it was extracted before being ripe, thus the aroma escapes and leaves nothing but a sweet mass unworthy the name of honey. The presence of the aroma is required to preserve it in its natural state. For the past 5 years, I have had no honey granulated before spring.

People will be cheated; for the butter and cheese must be yellow, and the honey white, all contrary to nature; but this is no reason why we should use adulterations. We should aim to keep everything as nearly in its natural condition as possible. Take no honey from the hive before it is capped, and we shall soon have a good demand for extracted honey.

Morrill, Kans., April 14, 1884.

For the American Bee Journal.

Italian vs. Brown Bees.

H. V. TRAIN.

About 20 years ago I started with a brown race of bees, found in great abundance in the woods along the Kickpoe river, some 25 miles southwest of this place. I kept them apparently pure until 1878 or 1879, when yellow bands began to appear in some colonies; doubtless from Italian drones two miles away. As so much was said in favor of the Italian bees, and they looked so nice, I determined to introduce more Italian blood, and I bought 13 dollar-queens and introduced them.

At the time I introduced these queens, I had 108 colonies; but when white clover bloomed, there were 24 colonies too weak to work in supers; and among them 4 of the Italians. I doubled the 24 down to 12, and gave each of the 4 Italians another colony of bees and brood.

I run all for comb honey, and the result was as follows: Twelve colonies did not swarm; 3 of these were Italians and 9 natives. From 33 Italian colonies, I took from No. 1, 35 lbs.; from No. 2, 35 lbs.; from No. 3, 37 lbs. From the 9 native colonies, I took from No. 1, 42 lbs.; from No. 2, 75 lbs., and so on up to No. 9, 108 lbs. From the Italian colonies that did swarm, I obtained no surplus honey; from the natives that swarmed, I got some surplus from nearly all, and from many over 40 lbs., and from one, 80 lbs. I had 58 young colonies besides nuclei built up. Of these, 20

were pure Italians, and only 5 of them gave any surplus, and the best only 14 lbs.; while nearly all the young natives gave some surplus; many over 40 lbs., and one 65 lbs. But about one-half of those 1 call natives, had more or less yellow bands, but native queens.

The native queens, which were put into the nuclei, filled their hives of 13 frames, and one of them made 22 lbs. of surplus, and another 10 lbs. I noticed another fact: We could take the honey from 2 native colonies while we were taking the same amount per colony from one Italian. But a friend says Italians can reach deeper into flowers than blacks can. Perhaps they can; I have had no experience with blacks; but here are some more facts: My apiary, in September, was about half and half brown and yellow bees; and about the first of September, being anxious to know where a flow of honey was coming from, I visited some red clover fields near by. The first time, I went in the afternoon, the fields were buzzing with bees, but they were nearly all brown bees.

As I was anxious for facts, I counted, and proved that there were 12 brown bees to one yellow on the red clover blossoms. I went again, and found the same result. Afterwards I went in the morning, and found three brown bees to one yellow bee. These figures surprise me, but they represent facts. I am satisfied that all Italian bees are not superior to some brown bees.

It cannot be that these Italians fairly represent their race, or else they are compared with something more than an average of the German race. With these facts in mind, I, for one, shall go slow in taking a bee merely because it is yellow.

Mauston, Wis.

[Had you purchased good tested queens, probably the result would have been different. Buying poor untested queens may have been the cause.—ED.]

Bees as Property, etc.

E. B. SOUTHWICK.

Mr. Pond has corrected my statement that "bees are not property under the law;" and for proof, cites a case where a man's bees came out of the hive, and he watched them until they went into his neighbor's enclosure, and there secured them, taking them away, and the law bore him out in it. It would be the same if he had a deer, wild turkey, bear, or any of that class of animals. If they had escaped from his enclosure, and he had followed them, keeping in sight of them, as they are required in case of the bees, and the animal goes into his neighbor's barn, and he secures it there, he has the same right to take it away as he had the bees. I once knew of a board of supervisors who voted that they would assess bees \$2 a col-

ony; but some of the more cautious ones concluded they would inquire of some competent lawyer about it, and the result was that the assessing of bees was abandoned in that county. I noticed Mr. Pond's attempt to ridicule the idea of bee-keepers having the right of priority in territory. I think, if a man has discovered a good locality in which to keep bees, and that is unoccupied, and spends his time and money to test and occupy it, he has just as much right, in justice, to it as though it had been some new-fangled tooth-pick he had invented and patented.

Sherman, Mich., April 15, 1884.

For the American Bee Journal.

Something About Patent-Rights.

JAMES HEDDON.

What is a patent-right? It is simply an exclusive right given to any inventor who will pay for the patenting expenses, as a reward of merit offered for the purpose of stimulating improvements in all the implements and devices used by man.

There have been so many worthless devices patented and sold, that it seems as if, on the whole, the patent-system had been more of an injury than a benefit. Just how much our Nation owes its great advancement in "Yankee invention" to our cheap patent-system, we are hardly able to judge.

Mr. A. I. Root is opposed to patents; at the same time he favors a reward for meritorious inventions, as is proven by the money credits he often gives to some who send him some improvements or new and useful devices.

Be that as it may, we have such a government system created and sustained by the will of the majority, and if we are good citizens, we are bound to obey and help sustain it. There are some good things that grow out of the patent-system, good for the patentee and public.

Mr. Brown discovers a new way to construct a honey extractor, so that it will accomplish much more with less labor and time than any of the past will do. No one knows so well as Mr. Brown just how good all the parts must be made and adjusted to make his invention give that satisfaction that is expected of it, and which he claims for it. He gets a patent on the machine. He begins their manufacture and sale, and fixes a price that will always allow him to make a good article. By thus turning out an honest job, he soon builds up a reputation for his new extractor. This advertises in a very extensive and substantial manner. He thus makes a paying business, and benefits every customer at the same time.

Now, let us suppose that there is no patent-system. Just as soon as Peter Funk finds out that the valuable discoveries and genuine workmanship of Mr. Brown has gained a reputation, out he comes with a little cheap circular, making a specialty of "Brown's honey extractors." But Mr. Brown's good work and square

dealing has turned the whole volume of trade Brown-ward. Very soon Mr. Funk realizes this disagreeable fact, and the next thrust, he cuts prices, and then comes the inevitable cut in the quality of the goods. It is then that Mr. Funk takes a hand in manipulating the reputation of the "Brown extractor." Soon the implement begins to lose reputation. Even Mr. Brown does not make them as good as he used to. He is trying to hold his trade and keep the price as low as that quoted by Mr. Funk, and degeneration in quality is the result. Mr. Brown is damaged. The public are injured, and no one but Mr. Funk is benefitted; and he only until the less enlightened portion of the public can understand that cheap prices mean cheap material and cheaper workmanship.

I believe that a man has a moral right to the exclusive manufacture and sale of the fruits of his mental industry, so long as he is engaged in supplying the public with them of good quality, at a reasonable price. I do not believe in exorbitant prices. I am, however, a stickler for good goods, and detest shoddy wares, as well as moral thievery.

Patent-law, as well as all other law, is made to compel those to act honorably who will not do so of their own free will; then let us truthfully say that we will act honorably, and do not need its restraint.

I think I have never sold any article of another's invention while the inventor was supplying it; except as I purchased of him. Our pursuit has been seriously damaged by the manufacture and sale of shoddy wares. These goods were the necessary result of a cut-under in prices, which was indulged in by some one who had no other means of getting any trade.

By the way, this brings me to a point that I have often thought upon. At present there seems to be a perfect mania for dealing in bee-keepers' supplies. I know there is no bonanza in the supply business. Are not most of those taking to it illy situated and little known; possessing so little enthusiasm in the business of producing honey, that they are led to the new departure? In other words, is the honey business so poor a one that something else must be done, or had better be done? I firmly believe that many are making a mistake in entering the trade at all. Let us see if the future does or does not sustain me in this opinion.

But to return to the patent question. Perhaps no class of business men have been more assiduously worked upon to prejudice them against patents, than have bee-keepers; and all this because our business is surrounded with worthless patents. This is all wrong. When you defame patents and patentees indiscriminately, you are attacking without cause or provocation some of the grandest principles and grandest men that have ever existed.

In our own line, let us look at the Langstroth hive and its inventor. Was it a crime for Mr. Langstroth to patent his valuable discoveries? Was

it wrong for him to charge you \$10 for what was worth to you more than ten times that amount? Did not your \$10 pay for an individual right, and help Mr. L. to enlighten others to the fact that he had hundreds of dollars worth for them for only ten dollars.

"Some people, if they had their pleasure,
Because silly bargains are made;
Would deem it a rational measure,
To lay an embargo on trade."

Patent or no patent, we should avoid buying worthless goods. Worthless either in principle or construction. We should respect the inventor who patents his inventions. We should respect and help to protect him who does not patent his inventions, as long as he deserves it. The question is a simple one; there is nothing mysterious about it.

Dowagiac, Mich., April 2, 1884.

Fixed Frames.

A. WEBSTER.

One writer says: "The nearer we come to nature, the nearer we are to right."

I do not now propose to tell any one how to make bee-hives, or how to construct frames, which, in advanced bee-keeping, are considered the most important feature of hives, but to briefly discuss principles and seek the teachings of nature which are right for a guide in constructing the frames and hives of the future.

The chief advantage of comb frames, to the bee-keeper, is the facility they offer for manipulating in various ways. This has been made much of, while the relations of frames to the natural instincts and working habits of the bees has been neglected.

Frames in their relations to the bees may be considered as follows: 1. As fixtures to which to attach the combs and hold them in place. 2. As bounds to the separate cards or curtains of comb; determining their shape and size, both absolute and relative. 3. As a means of expanding or constructing the hive at the will of the bee-keeper, to meet the requirements of either large or small colonies at all seasons and in all climates. 4. Collectively, as a nucleus about which to arrange surplus receptacles.

1. No one will question that in a natural state bees always select fixed objects to which to attach their combs; or that when put into hives with loose bars or frames, they will fix them in the most thorough manner, which the means at their command will admit; or that any jar or disturbance of their combs, as a whole, or in their relations to each other, is distasteful to the bees. Therefore, we say frames should be fixed firmly in place, but easily detached for necessary manipulation. Safety and convenience unite in requiring it. Thus, only can we come near to nature and to right without sacrificing the requirements of art.

2. As bounds to the cards or curtains of comb, etc. It is pertinent

here to inquire how bees develop their combs in a state of nature, or when their natural working instincts and habits have free and full play uncontrolled by confinement of any kind.

This is sometimes seen even at the North, where bees have been known to establish homes in the open air, or in buildings, attaching their combs to a branch, log, ceiling, or other objects. The operation of comb-building is very interesting.

Having located, clustered, and provided wax to begin with, one comb is started and soon another beside it, which are rapidly extended outwards and downwards until two more are needed, one on each side to fill the circle. And so the work goes on to the close of the season, or until as many combs are provided as the colony can occupy with brood and stores. The depth of the two central combs will equal or exceed their length. The side combs gradually recede in depth and length in about an equal ratio.

If, now, a cylinder of suitable diameter, and of a length equal to its diameter be placed around these combs, and the bees allowed to fasten and complete them, we shall have a hive well suited to the wants of the bees, but not of the best form for the bee-keeper. Trim these combs to a square form; place a square box of suitable size around them, and we have a hive better adapted to the requirements of the bee-keeper, and not objectionable to the bees. Divide this box into diagonal sections corresponding to the curtains of comb, taking out the bee-space between each, and you gain an idea of frames constructed on scientific principles, coming near to nature and near to right.

3. Fix these frames to the bottom-board in a proper manner, and any even number will form a complete skeleton hive, which may be enlarged or contracted at will "on all sides alike," by the addition or removal of frames. Is not this near to nature and near to right?

4. This skeleton hive may be covered with sections or frames on top and on all sides, and thus "supplying abundant room for surplus storage as near as possible to the brood combs, with free continuous passages." Is any system nearer nature,—nearer right?

This is a great subject, a full discussion of which would require a volume, or a series of articles, and must wait. If what I have written shall excite and direct thought and investigation, it is all I have aimed at.

South Northfield, Vt.

For the American Bee Journal.

Artificial Comb Honey.

A. J. HATFIELD.

On reading an article, on page 87, by C. R. Isham, I was reminded of several instances while attending the Northern Indiana Fair, last fall, and on different occasions since, when in conversation with persons in regard to honey, of being asked: "How is artificial honey made?" I assured

them that it was an impossibility to make artificial comb honey; but they invariably replied that it must be manufactured, for they had read of it in the papers. In some instances it was impossible to convince them otherwise. As this false impression prevails all over the country, it is working serious damage to the honey trade; and as it seems impossible to induce the press, generally, of the country to correct the lie, the thought is suggested that the only way to set the matter right, would be for the bee-keepers of America to bring suit against Prof. Wiley for libel. This suit to be brought about by the North American Bee-Keepers' Association, or in any other way that might be thought best; and in any case supported by contributions from \$1 to \$5, by bee-keepers. Although no damages might be collected, the matter could thus be set right before the public. I give this as a suggestion to those who are better posted than myself, to think of.

New Carlisle, Ind.

For the American Bee Journal.

Brown Bees vs. Italians.

GEORGE B. PETERS.

In the "Hive and Honey Bee" of our Nestor, will be found a comparison of the different qualities of the Italian and black bees.

In this climate we have a native bee, which has a well defined brown color when in cluster, and so different in character from the "little black bee" described by authors, that I suppose the brown bee is as little like it as the Italian; and, therefore, I assume the brown bee is as much a distinct species as the black, Italian, or Cyprian bee.

Believing Mr. Langstroth has faithfully delineated the characteristics of the two races, I will mention the different habits of the brown bee as distinguished from the Italian.

1. IRASCIBILITY.—The brown bee, when handled with the same care as the Italian, is decidedly more docile and harmless. I have kept bees for 50 years, and as long as I had only brown bees, I never knew what a bee veil or gloves were; never used smoking wood, or any other defense until within the last 20 years, since I, in part, adopted the Italian bee, during which time I have found all of these articles of defense absolutely necessary. I can truthfully assert that I have been more sorely punished in one day by ill-natured Italians than I ever was in the 50 years of intercourse with the brown bee, all put together.

2. QUIETUDE IN HANDLING.—The brown bee is much more restless during work in the interior of the hive, and will not adhere to the combs nearly so steadily as their Italian cousins, making it more difficult to find a brown queen than an Italian one, whose workers remain steadfast on the combs during the examination.

3. ABSCONDING PROPENSITY.—The brown bee is decidedly less disposed to abscond than the Italian bee.

The latter is restless during the swarming impulse, and continues so for some time after they are hived; and their restless disposition causes them to scout for a new home sometimes, even after they are hived and placed on their stands. I have witnessed some facts which warrant this conclusion.

4. HONEY GATHERING.—The brown bee is greatly superior to the Italian as a honey gatherer during the spring and early summer; but after July 1, or about that time, they become comparatively indolent; while the Italian continues her vocation with unabated energy, and stores perhaps more honey in September than during any other month in the year, in this latitude. It is during September, with us, that the Italians, on account of bountiful stores, are apt to exhaust their hives by over-swarming; and the vigilance of the bee-keeper is never more in demand to prevent it. On the contrary, the brown bee rarely, if ever, swarms after the first month of summer has passed; no late robbing, or taking away of surplus sections, will induce them to equal their spring work.

5. COMB BUILDING.—The combs built by the brown bees in the spring of the year, is much more abundant and more regular than those built by Italians; and when filled with honey, is decidedly white and more beautiful; but in the fall months the tables are turned, except as to regularity and beauty.

6. WORKING IN SUPERS.—Every producer of comb honey knows how difficult it sometimes is, to get Italian bees to build in surplus sections. He also knows that the brown bee will begin work in them just as soon as the nursery department can detail a force sufficient to carry on the work. This quality alone, with the producer of comb honey, makes the brown bee pre-eminent, and unequalled by the Italian or any other known race of bees.

The foregoing characteristic features of the two races of bees are clearly marked in this latitude, if in no other region; and I doubt not that every bee-keeper of ordinary powers of observation, has witnessed these traits over and over again.

I have many grades of mixed blood in my apiary, and I think the mis-named hybrid, having about $\frac{1}{4}$ Italian and $\frac{3}{4}$ brown-bee-blood, makes the best honey-producers that the new industry has yet developed.

Some eminent apiculturist advocates the culture of the most energetic and prolific queens and their progeny. That is a declaration that some queens are indolent and worthless. Some emblazon their favorites with "bloated promises," but too soon these are followed by "lank performance." Our leading idea should be to investigate, and adopt the truth in whatever habiliments we find it, and to improve and foster everything that promises to advance the prosperity of apiculture.

Peters, Ark.

[Many confound the brown and black bees, calling them "natives."—ED.]

For the American Bee Journal.

Northeastern Michigan Convention.

The Northeastern Michigan Bee-Keepers' Association held its second annual meeting March 5, at Lapeer. The meeting was an interesting one, and for a local gathering, well attended. Thirty-six members paid their annual dues. The display of apianian implements and products, although not quite so large as that shown at the first meeting of the society, was very creditable.

The convention was called to order at 10:30 a. m. by President Taylor. The Sec. and Treasurer's reports were read and accepted. The President then called upon members to give their experience in wintering bees.

August Keoppen: Have a good warm hive, and the bees will winter all right.

Byron Walker: I am using some hives, this winter, that have a removable, protective, outer shell of a peculiar kind of building paper; but I think that the character of their winter stores has more to do with the successful wintering of bees than any thing else.

W. F. Card: Bees in box-hives full of cracks and openings, often winter better than those in well-made and painted, movable comb hives.

Sec. Hutchinson: For two winters I have successfully wintered bees by burying them below the frost-line. I simply dig a trench on a sandy hill-side, fill it with dry straw, lay fence posts across the trench, then boards upon the posts, and place the hives in rows upon the boards. Straw is then placed around the hives; fence posts placed with their upper ends together, like the rafter in a building; over the hives, straw a foot deep is put over the posts, and then earth is shoveled on to the depth of two feet. No opening is left for ventilation.

W. Wray: I buried 2 colonies one year ago; gave them a little ventilation, and they wintered well. Last fall I buried 54 colonies; but, of course, I cannot tell now how they are wintering.

C. E. Rulison: I once buried 6 colonies, and only 3 lived. There was but little ventilation, and the combs were very moldy. I have tried extracting all the honey in the fall, from a few colonies, and feeding them a syrup made from granulated sugar. Three colonies were left unprotected. The bees scarcely flew during the winter, but came through in the best condition.

M. D. York: I am satisfied that bees in chaff hives can be shut up too close. Bees that were too warm, and so uneasy that they hung out at the entrance, I have quieted by simply raising the chaff cushions over them. I have one colony in the cellar that is in good condition.

Ira Green: To one man, who once successfully wintered his whole apiary, while others met with heavy losses, I paid \$500 to learn the secret of his success. It was this: plenty of upward ventilation.

Secretary: If ventilation is so essential to success, how did Prof. Cook

succeed so admirably when he hermetically sealed up 2 colonies by pouring water over the hives and allowing it to freeze?

Adjourned until 1:30 p. m.

The President called to order at 1:30 p. m. The Secretary read an essay by Dr. L. C. Whiting. Subject: "The Production of Comb Honey," which will appear in the next BEE JOURNAL.

Mr. Walker: I shall, this season, use a case having glass on one side only, to determine if bees object to working next to glass.

L. D. Gray: By sawing empty sections into several pieces, and putting 3 pieces between the bulged sections, I can crate them without trouble.

C. E. Rulison: For several years I considered separators a necessity, but the experiments of the last year or two, have compelled me to admit that they can be dispensed with.

Mr. York: I have found, by experiment, that bees do not commence work so readily when separators are used. I used separators one year on part of my hives. Those without separators commenced work in the sections, and the combs were partly completed before those with separators had commenced work. I then gave some of the partly-finished sections to those having separators, which started the bees to work; but those without separators finished new sections given them at the time of the removal, sooner than the removed and partly filled sections were finished between separators. I shall also discard the wide frames. The sections are difficult of removal. An upper story filled with wide frames is too much room to give at one time. The lower tier of sections is filled, and becomes travel stained before the upper tier is completed. Of course if wide frames only one tier of sections high are used, this trouble is obviated; but such a course brings in too much complication, and too much manipulation.

The President had laid aside wide frames for the same reason. He had tried different styles of cases, but preferred the Heddon case.

Mr. Walker preferred a combined ease and shipping crate of his own make that could be used either in the middle of the brood-nest, at one side, or over it.

The Secretary preferred the Heddon hive, case, and system of management. He objected to Mr. Walker's ease upon the grounds that sections of different widths could not be used; that an outer case must be used over it; and that a cheaper shipping crate could be furnished. He also thought that, in order to secure the highest price, propolis should be scraped from the sections, and honey should be graded; and unless removed from the crate, some of the honey would be of a mixed character. He saw no necessity of ever placing sections inside of the brood-nest; if the brood-nest was of such a size that the queen could keep it filled with brood; and if it was full of bees and brood when the honey harvest opened, and boxes were placed upon the hive, the honey would of necessity be stored in the boxes.

"Cane sugar for winter stores," was the title of an essay read by the Secretary. He had experimented several years in substituting a syrup made from granulated sugar for natural stores. Some years the bees wintered all alike; in others there was a decided superiority in favor of the sugar.

R. L. Taylor: Mr. D. A. Jones feeds the syrup as early as he can in order that it may be sealed before cold weather. To retain the heat inside the hive as much as possible, he keeps the entrances nearly closed during the day, and entirely closed during the night.

Mr. Keoppen: What is the use of extracting the honey in the fall and feeding sugar, when it is so difficult to sell the honey? The sugar costs as much, if not more than the honey, and is no better.

President: It is of no use to those who never lose any bees in wintering them; but for those who do, and who can save them by so doing, it is a profitable operation.

Mr. Rulison: I have extracted 100 pounds of fall honey, and sold it at 12½ cents per pound; bought granulated sugar at 9 cents per pound and made 3 pounds of syrup from every 2 pounds of sugar, making a profit of \$6.50.

Mr. Wray: If it is improper food that kills the bees, why is it that bees in the same apiary with the same stores, and the same treatment, stand the winter so differently?

Secretary: How can we know that all the colonies of one apiary have the same kind of stores?

Mr. Wray: If the bees gather from the same localities, why is not the honey the same?

Secretary: It is seldom that all the colonies of an apiary are of the same age. Some of the older colonies may have stores 2 or 3 years old, and, consequently, of a different character. Each colony of an apiary does not always gather from exactly the same source as the others. Italians will gather from red clover, while, perhaps, the blacks are working on buckwheat. In some such manner as this a slight diversity of stores may be accounted for.

Mr. Wray: Why is it that bees in old box hives full of cracks, and left with no protection, so often come through all right; while those in well-made hives do not?

Mr. Walker: These old box-hives usually contain an abundance of old stores. In movable comb hives the best of the honey is often removed each year.

Ira Green: As the spokes in a wheel all point to one common centre, so do the facts in wintering bees all point to ventilation as the one thing needful.

Mr. Rulison: I think the facts point to the food. With movable comb hives we take away the best honey, and let the bees fill the combs with fall honey for winter stores.

Mr. Taylor: Bees in box-hives fill up their hives with good honey, and we cannot get it away from them.

M. S. West: In the statistical table published in 1881, in the BEE JOURNAL, the bees in box-hives came out far behind the movable comb hives.

Mr. Wray: I think that moisture is often the cause of bee-diarrhœa, and lack of ventilation is the cause of moisture.

Mr. York: It is my belief that with our movable system of management, we "wear the bees out" more than with box-hives.

M. D. York read an essay on "What varieties of bees shall we keep?" which will be published next week.

Mr. Rulison: I prefer the pure Italians for all purposes. They are the best honey gatherers; they are peaceable, and "death on moths." I can, by using the extractor, prevent their swarming; but I have never found anything that would keep the Syrians from swarming. I have entirely discarded the Cyprians; they are too cross for me.

Secretary: I agree with Mr. York, inasmuch that were I obliged to choose any pure race for the production of comb honey, I should choose the blacks; but I cannot afford to discard the industry and extra length of tongue of the Italians. We had a dozen or more colonies of hybrids last season, and when the Italians were swarming, they (the hybrids) were working away steadily, with a sort of quiet determination, and storing honey in combs built in the sections, without separators; but nearly as true as so many bricks. My brother or myself could quickly distinguish a case of sections that had been filled by the hybrids.

The discussion on comb foundation was prefaced by the making of foundation by Pres. Taylor, upon a Given press. Mr. Taylor preferred the press because of the thinness of the base, and the softness of the walls of the foundation made upon it; also because the foundation could be made directly on wired frames.

The President's address was excellent and appropriate, being chiefly devoted to the subject of "How to Begin Bee-Keeping." Only those who are energetic, prompt, industrious and persevering, and have a love for the business, should engage in bee-keeping. A location not already stocked with bees should be chosen, and it should be one having an abundance of those blossoms which furnish the main honey crops of the country. He advised the Langstroth hive and frame, and for the production of comb honey, the Heddon case. Beginners, to have Italians, should begin with 2 or 3 colonies, and, by practice, aided by a bee-book and paper, learn the principles of bee-culture.

Secretary: With wired frames there is certainly no necessity of having the combs fastened to the bottom bars any more than the bees do fasten them without inverting. Would it not be better to make the brood-nest of such a capacity that the queen would keep it full of brood? And then the honey will of necessity be placed in the sections. It is no trouble

to keep the combs so full of brood that, were it not for the projecting ends, no one could tell the top from the bottom-bars.

The committee on exhibits made their report, then came the report of the committee on statistics; the report was as follows: Number of colonies spring of 1883, 577; fall count, 987. Number of pounds of extracted honey, 9,585; number of pounds of comb honey, 9,778; number of pounds of wax, 260.

Adjourned until 7 p. m.

The meeting was called to order at 7 p. m., by the President. Considerable time was spent in discussing foul brood, but nothing new was brought out.

Upon request, the Secretary described the method employed by Mr. D. A. Jones in securing the building of large numbers of queen-cells under the swarming impulse.

Pres. Taylor: Are not the so-called artificial queens just as good as those reared under the swarming impulse, provided the conditions are such that queen-cells are plentifully supplied with royal jelly?

Mr. Rulison: They are just as good. "How to Prevent Swarming," was the next topic of discussion: Mr. Rulison? I prevent it by spreading the combs and using the extractor.

Secretary: Before discussing the question of how to prevent swarming, there is another question I should like to have settled, and that is: "Is it Desirable to Prevent Swarming?" I get more honey from a colony (and its increase) that swarms, than from one that does not. If I could have my choice I would have one swarm from each colony, and by practicing the plan given by Mr. Heddon, on page 126 of the BEE JOURNAL for 1883, I succeeded so well that I had only one after-swarm out of 25 swarms.

Question: "Can the Crystallization of Honey be Prevented by Heating to a High Degree?" Secretary: I saw the above inquiry in the last number of the *Country Gentleman*, and would like the opinion of the convention.

Mr. Rulison: By heating honey very hot, it can be prevented from again crystallizing; but the degree of heat required, is so high that if the honey is not burned, the essential oils are dispelled, and the flavor impaired. If the temperature is not raised above that of the boiling degree, the honey will not be injured. By applying a gentle heat for a long time, honey may be evaporated to about the consistency of dried pitch; it will remain in this state a long time, but will eventually crystallize.

The election of officers resulted as follows: President, R. L. Taylor, Lapeer; Vice-President, M. D. York, Millington; Secretary, W. Z. Hutchinson, Rogersville; Treasurer, Byron Walker, Capac.

Adjourned to meet at Vassar, the first Wednesday in February, 1885.

W. Z. HUTCHINSON, Sec.

R. L. TAYLOR, Pres.

The Lucas Co. Ass'n. will meet on Saturday, May 3, at the Court house, at Chariton, Ia., at 1 p. m. A. REUSCH.

**A Visitor from England.**

I hope to have the pleasure of a visit to Montreal, in August next, when the British Association meets; and after the work of the society is over, I should much enjoy a visit to some large apiaries. As I do not happen to know any one interested in bees in America, might I ask some one to send me a list of apiaries which are worth seeing; indeed, any information on this subject will be thankfully accepted by

C. P. OGILVIE, F. L. S.,
Sizewell House, Leiston, Suffolk,
England.

Wintering without Loss.

On April 17, I took my 20 colonies of bees out of the cellar, in excellent condition, without a loss of more than 4 quarts of dead bees. Every colony lived through the winter all right.

A. L. P. LOOMIS,
Rosendale, Wis., April 21, 1884.

Unsealed Sour Honey.

I removed my bees from the cellar during the latter part of March. Out of 29 colonies put into it, I have left 20 strong ones, 4 weak, and 1 bushel of dead bees. I wintered one on its summer stand without any protection save an enameled sheet over the frames, and during the extreme cold weather, shoveled snow over the hive. This colony is the only one free from diarrhoea. I removed as much pollen as possible in the fall. There was no signs of brood in any of those which died, but there was some brood-rearing going on in those which came through all right. Those having the most capped honey fared the best,

while all that died had unsealed sour honey. I think sour honey is the cause of all the trouble about bee-diarrhoea; and bees will eat it even though they have plenty of capped honey. Bees are doing very well, considering the cold, wet weather we have been having. I tried feeding rye and Graham flour, but the bees would not touch it. They gathered plenty of pollen from elm trees during the past few weeks. Fruit bloom opened up on the 18th, but it was too cold for the bees to improve it, the temperature being as low as 42° above zero all day.

RICHARD GRINSELL,
Baden, Mo., April 21, 1884.

Aged Queens.

On page 104, I see a statement about a queen being 11 years old. This reminds me of an old man in this county who has kept bees all his life, and who had a queen 16 years old. While exhibiting an Italian queen at our County Fairs, in 1864 and 1865, he wanted to see the new kind of bees and queen. I had heard of him before, so I told him to go to the observation hive and see if he could find the queen. He did so, and soon found her. He then told those standing around, that he had kept a queen until she was 16 years old; that he had kept track of her from the time she came off with a second swarm; and the 16th year she began to fail so much that he killed the bees with brimstone, and hunted out the old queen to see what she looked like; and he said that she was so old she was as black as his hat; and that she was the blackest queen he had ever seen.

R. R. MURPHY,
Garden Plains, Ill.

Bees in Good Condition.

My 27 colonies of bees came out in good condition. Three are queenless, but full of bees. I wintered 14 colonies out-of-doors in chaff hives, and 13 colonies in the cellar. The 14 consumed from 30 to 40 pounds of honey per colony; and the 13 from 10 to 15 pounds per colony.

C. W. JOHNSON,
Norwood, Mich., April 17, 1884.

Wintering on Unsealed Honey.

Myself and son began the season of 1883 with 80 colonies in fair condition; and by feeding honey in combs saved from the previous season, they became very strong by the time of white clover bloom, which was quite abundant; but the weather was too cold for the secretion of honey in quantity, and as basswood was nearly a failure, and fall flowers withered on account of dry weather and early frosts, we got but 2,500 pounds of extracted honey, and 1,000 pounds of comb honey; having to feed back 500 pounds for winter stores; so that our average per colony, spring count, was but about 37½ pounds. In 1882, our average yield, per colony, was 120 pounds, spring count. Dec. 3, we put into the cellar 133 colonies, and packed 9 in sawdust on the summer stands outside; so far all are doing nicely.

Those outside had a flight Feb. 2. Our cellar has ranged in temperature from 34° to 39°; the bees are very quiet, and but few dead ones are found on the floor. The entrances are open full width; no cover except quilts, and they are so arranged that there is ½ inch opening at the back of each hive. The hives are tiered up 4 high, with strips of wood between at each end for ventilation. One year ago we wintered our bees in the same manner, without loss, though a few old queens died after they were taken out of the cellar April 10. Many of our colonies had quite an amount of unsealed honey in the hives when put away, owing to the cool weather preventing the bees from evaporating and sealing it after breeding; but so far no bad effects are apparent from it. In preparing our bees for winter, combs with a very large proportion of pollen were removed, and replaced by others with little or none in them.

A. J. HATFIELD,
New Carlisle, Ind., Feb. 7, 1884.

No Diarrhoea.

On April 16, after a confinement of 156 days, I placed my bees on the summer stands. All the colonies are strong, and no signs of diarrhoea. The spring bids fair to be an early one, and every thing is looking well for this time of the year.

F. M. TAINTOR,
Elm Grove, Mass., April 17, 1884.

Testing Thermometers.

Thermometers are extensively used to indicate the state of the temperature in bee-repositories, cellars, etc. Are thermometers correct instruments with which to test an element so changeable as air? When the weight and measure inspector tests scales, some draw quicker and sharper than others, and do not weigh alike. I think the thermometer, to a certain extent, resembles the scales in correctness. On Niagara Peninsula are vast variations in the temperature as shown by different thermometers; so much so, that at times it is difficult to ascertain which one is correct. On Sept. 15 and 16, 1882, at one time, thermometers indicated all the way from 90° to 104° above zero. On Jan. 22, 1884, within a radius of 16 miles, thermometers indicated from 14° to 42° below zero. Why this variation? Suppose a poultry-keeper hatching eggs in an incubator, was depending on his thermometer to indicate 103° above zero (the proper temperature at which to hatch eggs), and it happened to be 8° too low, making the real temperature 111° above zero, the eggs in the incubator would be scalded, and thus worthless. Will some one who thoroughly understands thermometers, explain how we can know when they are correct?

JOSEPH M. WISMER,
Jordan Station, Ont.

☛ For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Questions about Foundation.

Will Mr. Heddon please answer the following:

1. How is the lye, that adheres to the sheets when using the Given press, best removed from the foundation?
2. Is it in any way detrimental to the foundation if not removed?
3. What is the best method of lubricating the dies with concentrated lye?
4. Is the die-book less inclined to stick to the foundation if kept bright?
5. Is it an easy matter to keep the dies so they will press all parts of the sheet exactly alike, so that no difference in thickness of base can be seen?

SUBSCRIBER.

Pine Plains, N. Y., April 10, 1884.

ANSWERS.—1. By passing the sheet through water.

2. If not removed, it will precipitate, leaving a white powder that will lose all its strength in a few days, and be quickly brushed off by the bees, doing no harm whatever, except to frighten the inexperienced.

3. We used to use the lye so strong that it would very quickly eat up a brush, or other substance used to distribute it. We used to wish for a very fine wire brush. We now use sal-soda or lye so very weak that it does not eat a common brush.

4. Yes, generally; though I have known the book to work quite nicely when the dies were black.

5. Yes; by tacking on strips of tin over the places where the impression is dull till the impression all comes alike.

Abnormal Swarming.

1. What causes bees to swarm out of the hive during this month?

O. CROWELL.

Hamlet, N. Y., April 15, 1884.

ANSWER.—1. Perhaps all the causes are not clearly understood by any one. Some have ascribed it to lack of pollen; but our 45 colonies entirely destitute of pollen, have offered no such antics; but remain in their hives clean and beautiful to look upon. I have found that any animal in trouble is liable to seek relief by a senseless change of base; and my opinion is, that most of such cases result from intestinal inflammation. It is wholesale spring dwindling; in other words, the milder form of bee-diarthæa.

Is that Queen Idiotic?

I have a queen which, I think, Rev. Mr. Langstroth would term "idiotic." She has the appearance, in depositing her eggs, of a laying worker, viz: depositing more than one in a cell; however, the cells seem to be uniformly occupied; and her eggs, when hatched, produce worker larvae.

1. What is the cause of this state of affairs?

2. Would it do to leave her alone until later in the season, and then supersede her? If not, what would you advise doing?

3. About what do you consider an average yield of honey in a fair locality, in about your latitude, for a colony of bees in a movable comb hive, and receiving what attention they require? From reports, I find this rather a difficult matter to ascertain.

A. E. HOSHAL.

Allanburgh, Ont.

ANSWERS.—1. To account for and find first causes for such actions is quite difficult. We have had such queens afterwards to become all right, but none of such late years.

2. I would advise trying her a while before superseding.

3. It is well-nigh impossible to give a sensible answer: for there is so much difference in seasons and colonies. I have obtained as much as 40 pounds of surplus honey from one colony that did not swarm; 48 pounds of which was comb, and the balance extracted. I took 29 pounds 13 ounces of extracted honey (not ripe) from one colony; all stored in empty combs in 24 hours, or about 14 working hours; all from basswood, and was mostly gathered 4 miles distant. These, however, are only possibilities. The proper question, however, is not "how much surplus honey per hive;" but how much surplus per field, or area; and how much capital and labor to get it, the best number of colonies, etc.

Convention Notices.

A bee-keepers' association is to be organized in Western New York on Tuesday, May 6, 1884, at Randolph, Cattaraugus County. In this southern-tier district there are a large number engaged in bee-keeping, and an association of this kind has long been needed. A general invitation is extended to all interested in bee-keeping.

W. A. SHEWMAN.

The Progressive Bee-Keepers' Association will meet for their spring meeting May 3, 1884, at the apiary and residence of J. B. Haines, Bedford, Cuyahoga County, O. All interested are invited.

J. R. REED, Sec.

The Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association, will be held at Rockton, Winnebago Co., Ills., on May 20, 1884.

JONATHAN STEWART, Sec.

The Bee-Keepers of Tippecanoe and adjoining Counties, will hold their regular quarterly meeting at room No. 3, in Purdue College, in the city of Lafayette, Ind., on May 6, 1884. All lovers of the honey bees are respectfully invited to be present and take part in the discussions.

MRS. JAS. L. HAVENS, Sec.

DR. L. SNYDER, Pres.

The bee-keepers of Tuscarawas County will meet in the Town Hall at Port Washington, O., on Thursday, May 15, 1884, to organize a bee-keepers' association. All are earnestly invited to attend.

A. A. FRADENBURG.

The Kentucky Bee-Keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed).

N. P. ALLEN, Sec.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
Monday, 10 a. m., April 28, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—There is no life in the market. Extracted honey sells in its regular way and to its wonted channels, without any speculative feeling about it, and brings 7@10c on arrival. Comb honey sells slow at 15@16c a lb. from store for choice.

*BEESWAX—Is in good demand; choice yellow brings 35c a lb. on arrival.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 14@16c. Dark and second quality, 13@14c; extracted white clover in kegs and barrels, 8@9c.

BEESWAX—Prime yellow, 34@35c.

THURBER, WHYLAND & CO.

CHICAGO.

HONEY—Of late receipts of comb honey has been scattered amongst many firms, and as all are desirous of realizing on their receipts at as early a day as possible, prices have been irregular and low, some lots being offered from 5c to 7c per lb., less than 30 days ago. 1 quote white comb 13@14c; fancy 18c. Extracted honey—demand light, 7@9c.

BEESWAX—30@37c.

R. A. BURNETT, 161 South Water St.

KANSAS CITY.

HONEY—Demand for comb honey good, with lower prices: 15@16c for choice 1 and 2 lb. sections. Dark and broken or irregular comb, slow at 10@12½c. The liberal receipts of comb honey from New York State have cast much Western honey in the shade, and our Western producers will have to look to their laurels. There have been thousands of pounds of Eastern honey marketed here this season, and almost every comb has been perfect in every respect. It is hard to sell the unsightly stuff that I am receiving daily from other sources, by the side of this handsome honey from the East. Extracted in fair demand, at 8@9c, according to quality and color.

BEESWAX—None in this market.

JEROME TWICHELL, 514 Walnut Street.

SAN FRANCISCO.

HONEY—Market is dull, offerings being small, and the demand light. Not until there are free arrivals of new is it likely that the market will present any specially noteworthy features. White to extra white comb, 15@18c; dark to good, 10@13c; extracted, choice to extra white, 7@8c; dark and candied, 5@6c.

BEESWAX—Wholesale, 27½@30c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@8½c.

BEESWAX—Firm at 32@32½c for choice.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is unchanged with us. There is a continued steady demand for choice white 1 lb. sections at 18c; 2 lbs. move more slowly at 16@17c; but for second quality there seems to be no demand. Our supplies of 1 lb. are kept well down. Extracted does not sell at all at any price.

BEESWAX—Wanted at 35c.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Demand light. 1 lb. sections comb honey, 18@20c; 2 lb. 16@18c. Extracted, 9@11c.

BEESWAX—35c.

BLAKE & RIPLEY, 57 Chatham Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 17@18c; extracted, 7½@8½c.

GEO. W. MEAD & CO., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a continual statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an additional present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

We are now preparing a new book for the pocket, to be called "The Bee-Keepers' Convention Assistant." It will contain a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making reports for statistical information—and much other useful matter for those who attend Conventions. One of the latter will be a suitable Programme of questions for discussion at such meetings, model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs; a few blank leaves for jotting down interesting facts, etc. We shall aim to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world. It will be of a size suitable for the pocket, nicely bound in cloth, and the price will be 50 cents.

The first edition of the "Apiary Register" having been exhausted, we have just issued a new edition, elegantly bound in Russia leather, with a large worker bee and "Apiary Register" in gold on the side. It forms not only a Register of both Queens and Colonies, but has also an Account Book at the back, in which to keep a record of all the receipts and expenditures of the apiary, which will be found exceedingly valuable. We have also reduced the prices, as will be seen on another page.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

 Cook's Manual in cloth and the Weekly BEE JOURNAL for one year will be sent for \$3. Manual and Monthly, \$2.00. We have no more of the old edition left, and, therefore, the club price of that edition at \$2.75, is withdrawn.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

 Letters for publication must be written on a separate piece of paper from items of business.

 We have a few photographs (cabinet size) just taken, of the Rev. L. L. Langstroth, which we can send to those desiring them, for 50 cts. each postage prepaid.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold; we send for 10 cts. each, or \$8 per 100.

WE CALL

the attention of all wanting A No. 1 BEES, Italian, Cyprian or Hybrids, to the following, from one well-known to the readers of this Paper:

"I have never seen a case of foul brood; my bees are entirely healthy, and have always been so, and are O. K. in every respect."
Geo. B. PETERS, M. D.

We can furnish any number of Colonies of the above Bees, and will warrant safe delivery and satisfaction.

N. II.—No Bees will be sold by us, for any consideration, from any apiary that has ever had a case of foul brood in it. For prices and particulars, send to

18A1t **HENRY ALLEY,** Wenham, Mass.

STANLEY'S AUTOMATIC

HONEY EXTRACTOR.

Reverses the combs without the aid of the hands; the reverse motion of the crank is all that is required. No time is lost, as we provide every machine with a brake to stop the motion, and the combs are half reversed when the motion stops. Can be used for 2 or 4 combs, as desired. No chance for combs to fall or get injured. The Comb Baskets always stop in the most convenient position for removing or putting in combs. We use XXXX Tin or Galvanized Iron for Cans. The Cylinder of Can is all in one piece. We challenge any Extractor, taking any number of combs, to do one-half the work of our 4-frame Machine. Prices reasonable.

 We want to employ good live Agents everywhere. Address,

G. W. STANLEY & BRO

1868.

1884.

HEDDON'S COLUMN.

My New Langstroth Hive.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

One Hive complete for comb honey...\$3.00

(The above will contain two cases complete with sections).

The above Hive complete for extracted honey...\$3.00

The above Hive complete for both in one... 4.50

One Hive in the flat... 2.00

Five or over, each... 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

COMB FOUNDATION.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8x16 1/4, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. My Circular gives prices.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4 1/4 x 4 1/4 x 6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

STUDENTS OF APICULTURE

Will receive terms for 1884 on application.

BEEES and QUEENS.

If you contemplate the purchase of Bees in any shape, tested or untested Queens, it may pay you to send for my

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.

Address,

JAMES HEDDON,
DOWAGIAC, Cass County, MICH.

BEE-KEEPERS' SUPPLIES.

Send a postal card for my Illustrated Catalogue for 1884.

COMB FOUNDATION.

On account of the prevailing scarcity of beeswax the price of comb foundation is now advanced 3 cents per pound above the price quoted in my Catalogue for 1884.

BEE SWAX.

I pay 32c. per pound delivered here, for yellow Beeswax. To avoid mistakes, the shipper's name should always be on each package.

CLOVER SEEDS.

The present prices are as follows :

White Clover, \$15.00 per bushel, \$4.00 per peck, or 30 cts. per pound.

Alsike Clover, \$12.00 per bushel, \$3.25 per peck, or 25 cts. per pound.

Sweet Clover, \$10.00 per bushel, \$2.75 per peck, or 20 cts. per pound.

NO. 30 TINNED WIRE

For Brood Frames.

One ounce spools, each, - 4 cents.

Postage, 2 cents extra.

One oz. spools, per dozen, 40 cents.

Postage, 13 cents extra.

One pound spools, each, 40 cents.

Postage 18 cents extra.

One pound will wire about 175 frames.

Eureka Wiring Tool,

For pressing Foundation into wired frames. Something entirely new.

Price, 50c. by mail.; 40c. by express.

WIRE NAILS,

On account of a decline in the price of Wire Nails, I will make a discount of 15 per cent. from the prices quoted in my Catalogue, until further notice.

CHEAP FOUNDATION MILLS.

These Mills will make Foundation of any desired thickness, for either Section Boxes or Brood Frames.

PRICES :

CHICAGO, ILLINOIS.

BEEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiculturist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keltshburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style and is cheap at the price.—Farmer, Cleveland, O.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utah, N. Y.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apilary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE.

PATENTED, MAY 20, 1879.

The Original
BINGHAM
Bee Smoker

Patented, 1878.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of smoke and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 50,000, there is evidence that 1884 with us is likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates, on larger quantities, given upon application.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Sixth Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 220 pages, and is profusely illustrated. Price, bound in cloth, \$1.00; in paper covers, 75c., postpaid.

Dzierzon's Rational Bee-Keeping—A Translation of the Masterpiece of that most celebrated German authority, by E. Dieck and S. Stutter, and edited, with notes, by Charles N. Abbott, *Ex-editor of the "British Bee Journal."* Dr. Dzierzon is one of the greatest living authorities on Bee Culture. To him and the Baron von Berlepsch we are indebted for much that is known of scientific bee culture. Concerning this book, Prof. Cook says: "As the work of one of the great masters, the Langstroth of Germany, it can but find a warm welcome on this side of the Atlantic." Mr. A. I. Root says of it: "Old father Dzierzon... has probably made greater strides in scientific apiculture than any one man... For real scientific value, it would well repay any bee-keeper whose attention is at all inclined to scientific research, to purchase a copy. Cloth, \$2."

Queen-Rearing, by HENRY ALLEN—THREE years experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price, \$1.00

Bee-Keeper's Guide, or, Cook's Manual of the Apiary. This Manual is elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Honey, as Food and Medicine, by Thomas G. Newman. This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be read by every one. Published in English and German. Price for either edition, 5c.; per dozen, 40c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. This is a chapter from "Bees and Honey." Price 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how; 26 engravings. This is a chapter from "Bees and Honey." Price, 10c.

Bees in Winter, with instructions about Chief-Packing, Cellars and Bee Houses, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages. 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price 45 c. postpaid.

Fisher's Grain Tables for Farmers, etc.—192 pages, pocket form; full of useful tables for casting up grain, produce, hay, cost of pork, interest; wages tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. 40 cents.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer, and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Quinby's New Bee-Keeping, by L. C. Root—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Novice's ABC of Bee-Culture, by A. I. Root—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, 50c.

Bleasod Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Foul Brood; its origin, development and cure. By Albert H. Kohnke. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. 15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Dzierzon Theory—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Apiary Register, for SYSTEMATIC WORK in the APIARY. The larger one can be used for a few colonies, give room for an increase of numbers, and send up the record all together in one book. Prices: For 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Deutsche Buecher, ueber Bienenzucht.

Bienen Kultur, oder erfolgreiche Behandlung der Bienen, von Thos. G. Newman. Dieses Pamphlet enthält Belehrungen über folgende Gegenstände—
—Der Tlichkeit des Bienenstandes—
—Honig pflanzen—Erziehung der Königin—
—Füttern—Schwärmen—Ableger—
—Versehen—Italienisiren—Zufetzen von Königinnen—Ausziehen—Bienen behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschrieben ist. Preis 40 Cents.

Honig als Nahrung und Medizin—von Thomas G. Newman. Dieses enthält eine klare darstellung über Bienen und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angebend wie man Honigkuchen, Formkucheln, Puddings, Schaumconfect, Weine, u. s. w. zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Consumenten bestimmt, und sollte vieltausendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Bier und seine Krankheiten—Von B. J. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniß der verschiedenen Pferdekrankheiten, sammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Rezepte. Preis 25 Cents.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Foul Brood and the Neb. Convention.

At the last meeting of the Nebraska Bee-Keepers' Association, as reported in the BEE JOURNAL for Jan. 23, a committee was appointed to investigate the cause of the existence of foul brood in that State, and to confer with the Authorities in regard to its suppression by legal measures. The Committee, after much deliberation and correspondence, have made the following report, which has been adopted by the State Association:

To the President and members of the Nebraska Bee-Keepers' Association.

LINCOLN, Jan. 10, 1884.

WHEREAS, The disease of bees known as foul brood, is regarded as one of the most malignant of bee maladies, often destroying whole apiaries despite the efforts of the apiarists, and

WHEREAS, The disease is known to be in our state in at least three counties, and

WHEREAS, Flanagan & Illinski, of Belleville, Ill., have shipped bees to M. L. Trester, of our State, affected with foul brood, and

WHEREAS, The disease is known to be a fungus growth, and also contagious. Therefore, be it resolved by the Nebraska State Bee-Keepers' Association:

1. That the bee-keepers be earnestly requested to examine their colonies closely, whether they suspicion foul brood or not.

2. That those who expect purchasing either bees or queens, first satisfy themselves that the party from whom they purchase has not the disease in his apiary.

3. That we would recommend the most rigorous method of destroying the disease wherever found, even to the total destruction by fire of bees, comb and hives.

3. That a copy of these resolutions, together with a concise statement as to what foul brood is, be published in

the leading dailies of the State, with a request that the county papers please copy, and that copies be sent to the leading bee papers and periodicals of the United States.

(Signed.) R. V. MUIR,
G. M. HAWLEY,
H. CULBERTSON,
Committee.

LINCOLN, Neb., March 1, 1884.

To the Executive Committee of the Nebraska State Bee-Keepers' Association, and all other Apiarists.

The undersigned, a committee appointed at the last annual meeting of the Nebraska State Bee-Keepers' Association to investigate the transactions in bees diseased with foul brood, beg leave to make the following report, without malice to any one, but in justice to all.

We find that foul brood has made its appearance in the central part of our State, but up to date, we have not been able to discover its origin.

We also find by the written records and correspondence of M. L. Trester, late of Greenwood, and now of Lincoln, Neb., that on July 20, 1883, he received 20 nuclei of Flanagan & Illinski, of Belleville, Ill., which has proven to have been diseased or infected with foul brood when shipped from Belleville, as shown by the following facts:

When the bees were received, each nuclei was transferred, and a written statement of the condition of each sent to the shippers, and as shown by the duplicate copy numbers 3, 7 and 11, were marked as having rotten brood; but not knowing foul brood at sight, it was watched with suspicion until Sept. 17, when it began to develop, showing it to be foul brood, when a lengthy correspondence between the receiver and the shipper was carried on (which we abbreviate as much as possible) as follows:

FLANAGAN & ILLINSKI: The bees I bought of you were infected with foul brood, and it has spread in my apiary. I expect you to make the damage good. Let me hear from you immediately. Greenwood, Sept. 20, 1883. M. L. T.

M. L. TRESTER: Yours received, and is a great surprise to us. Trust you are mistaken; but if not, what is the damage and mode of reparation? F. & I.

P. S.—We ought to say in self-defense, that we never saw a case of foul brood in our hives until this spring, and then it was instantly suppressed by cremating every hive. F. & I.

Belleville, Oct. 5, 1883. M. L. T.: One of us will try and meet you at the bee-keepers' meeting in Chicago, on the 17th and 18th. Please act with caution, as any damage to our credit makes it less in our power to settle to your and our own advantage. We want to see you and talk the matter over and settle it in a friendly way. F. & I.

Belleville, Oct. 13, 1883. F. & I.: Yours of 5th received. I want \$1,000 damages, and want to see one of you in Chicago on the 17th or 18th inst. M. L. T. Greenwood, Oct. —

Mr. Trester's memorandum here shows that he met Mr. F. in Chicago, Oct. 16 or 17, and almost F's first words were, "be cautious," as any injury to F. & I. would make them unable to pay. F. also stated that he knew that they had foul brood in their apiary during the spring of 1883, but thought that they had eradicated it. F. told T. he could prove nothing at law, when T. told F. that he would bring the men who worked for and helped destroy the infected colonies, to prove that F. knew the dreadful tendency of the disease. F. also told T. that he had come to Chicago on purpose to see him to keep from being exposed. F. also stated that he had also sent foul brood bees to Mr. —, Mass., who knew the disease when he saw it, and returned the bees.

T's memorandum shows that the matter must be made public, and insisted that F. remove his advertisement from the bee-papers and insert one in the same place, notifying the public that he would have no bees for sale for two years on account of foul brood. T. then made the following propositions:

First—That if F. & I. would pay him \$500 he would call the matter settled between them.

Second—T. offered to sell F. & I. every colony of bees that may be alive April 15, 1884, also applies on hand, value to be fixed by arbitrators.

Third—T. offered to take any amount of damage was agreed by the arbitrators. Said arbitrators in the above cases to be chosen as follows: One by F. & I., one by T., one by the president of the N. W. B. K. A.

Mr. F. then made a proposition that if F. & I. accept one of T's propositions, T. was to bind himself to keep the transactions a secret, which T's memorandum shows he would not agree to.

M. L. T.: After due consideration, we have concluded to send you in a few days, in cash, the amount we think is fair and right in regard to bees sent you last July. F. & I.

Belleville, Oct. 18, 1884.

F. & I.: At the time I bid adieu to Mr. F. in Chicago, I was of the understanding that as soon as he arrived at home, and you consulted together, he would write and accept one of my propositions, but all I have heard is a line saying you would send me some money to pay damage. I write this to remind you that I expect the \$500 in full before the 20th of this month. M. L. T. Greenwood, Dec. 13, 1883.

M. L. T.: You are, no doubt, tired of waiting on us. Have a little more patience. We will send you in a few days the amount we think fair and right. F. & I.

Belleville, Dec. 15.

M. L. T.: We will send you at the earliest opportunity the amount we believe to be fair and right. If you can wait until we can do this, which, we hope, will not exceed ten days, well and good. If not, all right; do as you think best in regard to the matter. F. & I.

Belleville, Dec. 31.

F. & I.: Yours of 31st inst. received. Let me hear from you before our State meeting, which convenes on Jan. 9. I am ready to place this matter in the hands of arbitrators at any moment. Lincoln, Neb., Jan. 3, 1884. M. L. T.

M. L. T.: We send you to-day, per express, \$95, which we tender you as in full of all demands to date for damage (if any) done you. Please sign the enclosed receipt and return per express ad oblige. F. & I.

Belleville, Jan. 14, 1884.

Mr. Trester informs your committee that he did not accept the money on its arrival, on account of the case being placed in the hands of a committee, and in a short time F. & I. telegraphed for it to be sent back to them; but that he is still ready and willing to place the matter in the hands of arbitrators to be chosen similar to the mode proposed by him in Chicago.

Desiring to do exact justice in this very unpleasant affair, we sent the proof of the above to Flanagan &

Illinski, and asked them if they had anything to say. If so, to send it on and have it published in the same paper, so that our readers would not be troubled with a prolonged personal controversy. The following is their reply:

The best and most careful of us are liable to blunder, and do, unintentionally, that which we would not knowingly do for any consideration. We can truthfully say that we never saw (to our knowledge) a cell of foul brood until last May. When the discovery was made, prompt and efficient measures, as we then thought, were taken to eradicate it. We were mistaken, however, as events proved, for as seen above, Mr. Trester claims that we sent him 20 nuclei, some having foul brood, and demanded the *modest sum* of \$1,000 damages. At a personal interview with him at Chicago, in October, he moderated his claim to \$500. On asking him, if we paid the sum demanded, whether that would be the end of the matter, he answered, "That he would not forego the pleasure of exposing us, if we paid him \$1,000." All this because, by accident or oversight, we had unfortunately sent him a few (2 or 3 perhaps out of 20) nuclei (taking his word for it) infected with foul brood.

After consulting some of the best bee-keepers of our country, who had been troubled by this disease, and had been successful in getting rid of it, and after carefully weighing the whole matter, we deemed it fair and right to return the purchase money, and we sent him \$95, the full amount received from him for 20 nuclei. This money he refused to receive, but tried to levy on, or attach it, so that he may obtain it without giving us a receipt in full of all damage; but the money was returned to us before he could accomplish his design.

At the meeting, where the foregoing resolutions were passed, his denunciations, etc., were so violent, that when strangers to us, who did not like such unfair treatment, tried to take our part, they were speedily "sat down on." These facts are susceptible of proof; and show, better than any words of ours, the spirit which actuated him.

Any man of business can see that, to knowingly sell diseased bees would be suicidal, and would justly result in utter ruin, financially and otherwise. We have too many thousands of dollars invested in this business, and our reputation is too dear to us, to be guilty of such folly. We certainly are as much interested in the suppression of this pest as any one can be, and perhaps more so, as our interests are larger. It is very unjust to report that we are scattering it through the land. FLANAGAN & ILLINSKI.
Belleville, Ill., April 25, 1884.

P. S. I wish to add that if any one has blundered, any mistake made, or any one wronged, that I alone am to blame for it, and that my partner, A. X. Illinski, M. D., is not responsible for my mistakes, as I have had the

entire control and management of the business, and if any are blame-worthy, it is I. I make this statement without the Doctor's knowledge, because I deem it but just. I will also say that had I acted with ordinary judgment, I would have laid the whole matter before the Northwestern Association, held in Chicago last October, and I regret exceedingly that I did not do so. I have tried to act fairly, and have nothing to take back or deny. E. T. FLANAGAN.

Having given both sides of this controversy, we cannot consent to burden our columns with any arguments *pro* or *con*. The disease is much to be dreaded, and the action of the Convention in taking measures to "stamp it out," is praise-worthy, and in the interest of the bee-keeping public. To do this, and still preserve friendly feelings on all sides, is quite an undertaking—perhaps an impossibility. The only way to arrive at an amicable adjustment, is for each one interested to do exactly as he would be done by; and when stipulating for that adjustment, to "put himself in the other's place."

SELECTIONS FROM OUR LETTER BOX

Dry Sugar for Bees.

On page 245, Mr. H. Richey has credited me with a wrong statement. He quoted me thus: "Mr. Henry Alley thinks dry sugar is the best food for bees, if water also be given." If Mr. R. will read my article again, he will see that I made no such statement. Mr. R. recommends syrup made from granulated sugar and water, for wintering bees. Well, I know that is good, and said so, certainly 20 years ago, as Mr. R. will find if he will look over the BEE JOURNAL as far back as that time. If it were not for sugar, I could not winter my bees sometimes. That is all the food they have had here for the past two years. HENRY ALLEY.
Wenham, Mass., April 23, 1884.

My Bees are Booming.

The bees in this locality are doing splendidly now. I put into the cellar, last fall, 54 colonies, some of them rather scant in stores. This spring I took out 51 alive, and 3 of which were quite weak. Of the 3 I lost, the rats destroyed 1, and 2 starved. There was no diarrhoea, except a little in 2 colonies, which have done well since they were set on the summer stands. I have sold 8 colonies, leaving me 40 in healthy condition, and which are now booming. The prospects are splendid for a general good time with the pets this year. H. J. SCOLES.
Knoxville, Iowa, April 26, 1884.

Bees Separated all Right.

The bees which were so heated in March, separated all right, and came out without the loss of a colony, that had a queen when put into the cellar. I found 5 in the lot of 225 that did not have a bee in their hives, and in each case they had not had a queen since last June. IRA BARBER.
DeKalb Junc., N. Y., April 26, 1884.

Bee-House Burned.

On April 23, my bee-house containing some fixtures, was destroyed by fire. If the wind had been in the south, my bees would have been burned, as they were within 10 feet of the house. On the same evening they were gathering pollen as if nothing had happened. Box-elder is in full bloom. H. CLARK.
Palmyra, Iowa, April 25, 1884.

Dearth of Honey in Cuba.

We are having a slight dearth of honey now, the first in six months, and yet it is not what we used to experience in California; for, now the bees begin work in the morning just as soon as there is a bit of light, and work till about 8 a. m., then lay off till about 5 p. m., when honey flows again, and continue until it is so dark it would seem impossible for them to find their hives. They work with great ambition, so they are holding their own, and want does not stare them in the face very badly yet. The honey flow for the last six months has excelled any thing I ever saw in any country. I am not yet prepared to tell the readers of the BEE JOURNAL what we have done in the way of modern bee-keeping in Cuba; but if Providence spares my health till the year is up, I will then tell to the world, through the columns of the BEE JOURNAL, what I know about bee-keeping in the West Indies. The weekly visits of the BEE JOURNAL are refreshing to one so far removed from home and friends, and the perusal of its pages is a rare treat; and one pleasing feature is, it never fails to come when it is due. A. W. OSBURN.
San Miguel, Cuba, April 16, 1884.

Cold Spring.

Spring is backward and cold. I put 450 colonies into winter quarters, last fall. I have not yet set all of them out, and so cannot say how they have wintered, but I think the prospect is good. J. R. TURNCLIFF.
Van Hornersville, N. Y., April 23.

Wintered without Loss.

Our bees wintered without loss; also those we had taken out of trees and transferred to movable comb hives, wintered all right. One was taken out and transferred as late as September. Some of my neighbors have lost heavily, and some lost all. We use chaff protection. Drones are flying to-day. N. E. COTTRELL.
Burdick, Ind., April 24, 1884.

CORRESPONDENCE

For the American Bee Journal.

Anti-Monopoly.

WM. F. CLARKE.

That it is possible to overstock an apicultural area is readily admitted; but how many colonies of bees are sufficient to do it, is a point on which there is difference of opinion. I have an impression that Mr. Heddon underrates the honey-yielding capacity of his own locality, and that, while there is a substratum of truth in what he says, he betrays the over-sensitiveness of a professional specialist, and is too much enamored with the charm of monopoly. But, be this as it may, I wish to submit to Mr. Heddon and others of his way of thinking, that "locating and occupying a field" by no means covers the whole ground of this discussion. It also embraces the important point of enlarging a field by providing bee pasturage.

Mr. Heddon's article assumes that a field is to be estimated according to its honey resources as developed by accident. It does this by implication rather than by direct assertion. But, next to the question how much honey a locality will yield left to chance, there arises the question what more it may be made to yield by a judicious provision of plants that produce the luscious nectar which bees love to gather? This question has not escaped Mr. Heddon's attention. Few things do that have any bearing on apicultural success. He has bought a tract of land out of the profits of bee-keeping, and is growing a variety of honey-yielding plants. He has sown the waste places around Dowagiac, even the gravel-pits with mellilot, and shows visitors, with pride, the rapidly-increasing breadth of this and other bee forage.

This may be done to almost an unlimited extent. There are districts in Germany where bee-keeping is the leading industry, and where the farming is carried on with a special eye to providing for the bees. "God bless the bees" is a common petition in the public prayers of the pastors in those localities, and as we should always try to answer our own prayers when we can, the people sow honey-producing plants, by means of which both the bees and the bee-keepers are blest. Bee-keeping is yet in its infancy in many respects, in this matter of providing bee forage among the rest, and by-and-by we shall not only ask, Is this a good field for honey-gathering, but is it capable of being made one? Or, being already good, can it be made better?

Mr. Heddon looks at this matter too exclusively from the stand-point of bee-keeping as a specialty. Now, while I believe it absurd to expect every man to be his own honey-producer, and hold that none should keep bees but those who have natural and acquired qualifications for so

doing, I consider that there is a legitimate sphere for bee-keeping in a small way, in the case of many persons who are not professional apiculturists. The old British idea that bees are properly part of the livestock of the farm, and that no farm is completely stocked unless it can boast a few hives, is, to a certain extent, correct. A mixed husbandry is the true theory of farming. There are cases in which a farmer may wisely devote his attention to some agricultural specialty, but they are few and rare, compared with those in which the true policy is to raise a variety of products. As a rule, a farm should produce not only milk, but honey. A well-managed bee-hive is as profitable as an average cow. Make allowance for the proportion of farmers who have no natural aptitude for bee-keeping, or will not qualify themselves for taking intelligent care of bees, and still there are a large number left who might easily keep 10 or 12 colonies of bees each, and find the profit of so doing a helpful item in the yearly income. Usually, there is a member of the family whose duties lie in the house, who could have a swarm of bees; or, at any rate, watch at swarming time, and blow the horn to call the farmer up from the field when there is living to be done.

Besides the farmers who might keep bees on a limited scale to advantage, there is the village shoemaker who would find it a pleasant change from his bench to look after a few colonies. The woman who takes in washing, the poorly-paid school-master or minister, and a host of others. The professional gardener does not argue that because he has started a market garden in a neighborhood, others must keep out the business and people in general abstain from making gardens. Even at horticultural shows, there is a distinction recognized between the amateur and the professional, and the legitimacy of gardening on a small scale, and as a side-show, is admitted.

A woman, compelled by circumstances to wash for a living, could make more money with less toil and far more independence, by keeping 10 colonies of bees, provided she has, as many women have, a natural aptitude for bee-keeping, with the addition of the acquired knowledge and experience, and much as I like a well-ironed shirt, I should rather see her a bee-keeper than a washer woman; not because I think the latter calling menial, but because the former is less laborious, and gives more scope for intelligence and the indulgence of a lady's tastes and instincts. Mr. Heddon will, perhaps, reply that he had not these classes in view when he penned his article, but whether intended or not, it seems to me that the whole tenor of his argument is calculated to discourage the small bee-keeper; and, looking at the matter from the broad standpoint of the apicultural interest at large, I do not think it is good policy, or strict justice, to do this even undesignedly.

Well, then, to join issue fairly and squarely, let us look at the Kendall

illustration. It proceeds on the assumption that where one bee-keeper (professional) locates, according to the old Scotch song, "There's nae room for twa." The same ground might be taken as to village store-keeping. It is a small place, and a merchant is already in the field. He is doing a good business. Another spies out the spot, and thinks he too will open out there. "My friend," says number one. "I can do all the trading needed here. If you start business beside me, you will seriously lessen my profits, and make very small ones yourself. I calculate to enlarge my store if necessary, and to keep pace with the growth of this village. I want to make a big thing of it, and if you commence, I will undersell you, and drive you out of the field." "Sir," says number two, "I shall be satisfied if I can make a comfortable living, and save somewhat. I like this place, believe it will grow, and think there is enough for two of us, if we are not over covetous and ambitious."

It is not a case of "the survival of the fittest," but a question whether number one shall permit another to "share in his good fare." They go to work, each having his business wits sharpened up to the keenest possible edge. Both become shrewder merchants because of the competition, both are more anxious to build up the place that each may do a better business, and after a little unfriendly rivaling, both learn to "live and let live." Human nature likes to take the cake and eat all of it; but it is often unavoidable and always benevolent to let somebody else have part of it. That we should respect the rights and interests of others, is most true, but it is not always easy to define those rights and fix those interests. It would be a long time before a village would have a second store, if the prior consent of merchant number one must be had before starting it. The fact is, there are many positions in life which can only be held by the personal ability of the occupant. Rivalry and competition cannot be prevented. We must accept the challenge of Rhoderick Dhu to Fitz James:

"For this is Coil-and-tangle-ford,
And thou must keep it with thy sword."

The village doctor, the village backsmith, the village hotel keeper, and last, but not least, the village clergyman, are in the same fix as Mr. Heddon. If they are as competent as he is in their several walks of life, they will hold their own as he has done, or move to "fresh fields and pastures new," as he will doubtless do, when another Heddon mightier than he shall get a footing in Dowagiac. There is too much of the white feather about this "keep-away-from Dowagiac" proclamation. I would rather hear Mr. Heddon exclaim with Fitz James:

"Come one, come all, this rock shall fly
From its firm base, as soon as I!"

Mr. Heddon says: "Never locate in a field already occupied," and he explains "occupied" to mean that it has already in its limits a bee-keeper who

either has stocked it to its utmost capacity, or intends doing so. "Let us figure," as Mr. Heddon observes. In a given locality there is a bee-keeper who has 200 colonies, and considers that about enough for the field. This, I think, is not far from the average which Mr. H. thinks sufficient for Dowagiac. Another bee-keeper comes along. For reasons cogent to his own mind, he would like to settle in that particular spot. He surveys the field, and concludes that it is rich enough to give 500 colonies all the work they can do. Certainly he is not "mean," because he honestly holds that opinion, and if it turns out correct, he is not "mistaken." But Mr. Heddon, in advance, assigns this man a place in "the ranks of the mean or mistaken." Or, to suppose another case. In a particular spot, there is a bee-keeper with 50 colonies. These give him a better living than the mass of farmers get off 100 acres of land. Another bee-keeper, who would like to settle there, talks with this man, and finds that as fast as his means allow, he intends to increase the number of his colonies until he has fully stocked the field. Bee-keeper No. 2 reasons "thusly:" This man is making a comfortable living now. He can double or treble his present colonies, and still leave me scope enough. I can keep 100 or 150 colonies, quite as many as I care to be bothered with, and not interfere with him. Is he a very near relative "to the knave or fool" if he decides to locate there? So Mr. Heddon affirms. But I fail to see the justice of this opinion, and I think the great mass of common-sense bee-keepers will agree with me. Mr. Heddon says, "there are plenty of unoccupied areas." But there are thousands of instances in which people want to live in a particular locality. It matters nothing that "there are plenty of unoccupied areas" elsewhere. "The world is all before us where to choose," and if a man honestly believes that there is an opening for him in a place where he wants to be, and that he can settle there without improperly trenching on the rights and interests of his neighbor, is it right to hurl such epithets as "knave," "fool," "mistaken," "usurper," "mean," at his luckless head? I venture to think it is not.

I do not know where Mr. Heddon will rank me after he has read this article, whether among "the froth of the profession," the "self-interested," or the "honest and sincere," but I do know that I have written from the best of motives, and with no other wish than to benefit the interests of bee-keeping and bee-keepers. While I do not wish to blow a trumpet for the purpose of rallying a multitude of recruits, who, when gathered, will only increase "the awkward squad" of unsuccessful bee-keepers, I do want to see more general attention directed to bee-keeping, not only for the sake of adding to the already large army of specialists, but in order to increase the means, and add to the comforts of multitudes of people whose incomes are scanty, and who might easily supplement them by be-

taking themselves to bee-keeping in a small way. I will also own that I greatly prefer to have a large number of those who keep about so many bees as they can personally manage well, rather than a comparatively few monopolists who have to depend largely on hired help with the attendant disadvantages admitted by Mr. Heddon in the article I am criticising.

I prefer this for reasons similar to those which lead me to prefer the state of things on this continent, where a large number of farmers each owns his 10¹ acres or thereabouts, to the state of things in Britain, where a few own the entire public domain. "The greatest good to the greatest number" is what I desiderate. Speedside, Ont.

For the American Bee Journal.

New Races of Bees—Fertile Workers.

JOHN HEWITT.

Mr. G. M. Doolittle, in the BEE JOURNAL for 1883, page 500, gives his opinion regarding these bees, and after reading his letter very carefully, I came to the conclusion that he is very much mixed about these bees, and that the new races of bees he has, are mixed also; and as there are many more people in America who have mixed bees, and are entirely in error regarding their true character, I write this hoping that it may be of some use in removing the errors and putting these bees in their true position.

The Eastern bees, bred and sent out by Mr. Benton, consist of the Cyprian, Palestine and Syrian races. Mr. D. speaks of Syrian and Palestine as identically one; but this is not so; there is more difference between them than between hybrids and Italians, both in color and disposition. How these bees came to be considered as one, I am puzzled to find out; but the error applies not only to America, but to some extent to England also.

In *Gleanings* for 1883, page 169, II. B. Harrington says: "We reared quite a number of queens from Mr. A. I. Root's Mount Lebanon queen, and as we took great pains to secure drones from our Bethlehem queen, we think we have as pure Holy Land bees as can be found."

Now, if it is remembered that Mt. Lebanon is in Syria, where Mr. Benton rears his Syrian queens, and that Bethlehem is in Palestine, where he also has an apiary, it is plain that Mr. H. reared only cross-breed queens. As to that part of his statement which I have italicized, I have no doubt he is quite correct; though I think he would have found that there was a great difference, had he reared some Syrian drones as well; but this he, no doubt, prevented in order to avoid the chance of in-and-in breeding.

Prof. A. J. Cook, in the *Bee-Keepers' Magazine* for 1883, page 223, very fairly describes the Syrians; but at the end of his article, the "Ed." says: "If the word 'Syrian' is altered into 'Holy Land,' all confusion will be

avoided." And so the error has spread from teachers to pupils. The Syrian bees are so much like Cyprians, in fact, very much more so than Palestines, that I think it highly probable that they have been taken for each other, and so mixed up.

To describe and compare these bees one with the other, in every particular, would make this article a very long one; but to give a few features, will be advisable.

For instance, all 3 races are smaller bees than either blacks or Italians; but when crossed with either kind of drones, the offspring are of the same size, and the Syrians show the 3 yellow bands; though in the black cross the shade is darker; but still they are all evenly marked like pure Syrians. The queens of the 3 races seem duplicates of each other, and I cannot tell one from another; so I think if all 3 races were mixed and bred into each other, the queens would still look like pure ones of either race.

The Syrian drones carry an orange-colored band, but the Palestine bees do not; in fact, if it were not for the gray, fuzzy hair on them, they would pass very well for black drones. Then if you open a hive containing Syrians, when the sun shines, you may do so with impunity, without any protection, preparation, or attempt to quiet them whatever, providing they are not jarred, smoked or allowed to smell it. This is a fact which smokers cannot comprehend, thinking they must require some kind of "doctoring" to be able to manipulate them; but this is not so, for unlike blacks or Italians, they are naturally very tame, as may be proved by sitting close to a hive entrance at any time, to watch them; while the Palestines must be smoked, and then the manipulations must be quietly and quickly performed, as they quickly empty their sacs of honey, and they cannot be made to regorge themselves; at least I never could make them do so.

I will now describe the Syrian bees, as it is with these I have had the most experience. They are the ones I like the best, and they will yet make their mark. They are the most peaceable bees I have ever seen, and I should have no hesitation in placing 50 or 100 colonies around my house door without the slightest fear of any one ever being stung.

In opening them (which I always do while the sun is shining), I draw the quilt off diagonally, very gently, when up comes some bees, trying to feel the sky with their lances, and stretching upwards as much as possible to accomplish it. They are not cross when in this condition, nor if they take wing. I then commence immediately to remove the combs; and if it is June or July, I find in a full colony 28 square feet of combs full of brood in one stage or another. This brood is all in one compact mass, completely filling the frames, which are 14x10 $\frac{3}{4}$ inches. The bees will be quietly sitting on it, as if nothing were going on, and being smaller than blacks, and never gorging themselves with honey, they look like a

host of beautiful little flies. Those which do take wing, just buzz about without any inclination to sting, and if a comb is wanted out, all that is needed is to give it a shake, and the bees drop off into the hive bottom, and run up amongst the other combs.

The hive or combs must never be jarred; but if you want to see them savage, just smoke them, and jar the hive (like you would blacks or Italians), and I do not care how you are dressed or protected, you will be well stung.

They are the most energetic workers I have seen, and this trait is improved when a Syrian queen is mated with a black drone; but the character of the Syrian is changed with the cross, for they require a dose of very dense smoke to quiet them, but on no account must they be jarred; for when roused they are worse than pure Syrians at stinging, besides they sting deeper, draw blood, and it is much more painful. They rear and pack brood just the same, and collect more honey.

I think this will reconcile some of the very conflicting accounts of these bees, and I should think some of the bees which have been sent out for the Cyprians and Syrians, have had a fair share of Italian blood in them to stand the smoking with which Mr. D. doses them.

All my Eastern queens have been obtained direct from Mr. Benton, and every one came from her native land; so I speak with confidence as to their purity.

In the second part of Mr. D.'s letter, he condemns their brood-rearing powers, and says the secret of honey getting is to have the bees just in the niche of time. I think here he is quite at sea as to their real best nature. There have been proposals enumerated to get two queens to lay at one time in the same hive, so as to get an enormous population and economize the heat. Here the problem is practically solved; for we have one queen capable of laying double the quantity of eggs of an ordinary good one, or 26,000 per week.

Let us go a little farther. On page 69 of *Gleanings* for 1883, he writes, "Mr. Betsinger says, and I agree with him, that if we had the same number of bees in a hive in apple-bloom that we do in basswood bloom, the yield would be as great. I once had 8 pounds stored in one day with not over one-third the bees I have in basswood bloom." Is it not possible with these bees to get a colony up to its full strength in time for apple bloom?—78,000 unhatched bees, with more than twice that number in the wing state; surely they would gather much honey.

Then there is the sycamore bloom just after, which I consider the king of all in honey-producing plants; after which they might be divided for the clover, and divided again for the basswood. Some have 4 enormous colonies for that harvest, instead of one.

Suppose, for argument, that they are so savage as to be unmanageable; have not bee-keepers who keep Italians always some rather weak colo-

nies when spring comes? And does it not strike one to exchange the queens of these, so that these savage bees can be replaced by Italians in time for the honey harvest (for he admits they winter well, and are very strong in the spring), and let the savage lot build up another colony for winter? I think the secret is, they have not been allowed sufficient room to breed in, so as to reach their full strength.

In the third paragraph, he makes an assertion, which, I am afraid, he has never proven by actual fact, but is reasoning from analogy, viz: "That fertile workers kill the young queens."

It is a fact that a large quantity of fertile workers appear in the hives after any attempt at queen-rearing. I might say hosts of them; for I have had 8 square feet of comb, egged in every cell, and some cells had upwards of 6 eggs in them, within 24 hours, with these workers; but the only serious drawback is, that no queen-cell is allowed to hatch out, being destroyed when about 14 days old. I think by reasoning on this fact, he has gotten wrong, or very likely missing the cells and finding no queen, he thinks she was killed as soon as hatched.

I find no difficulty in introducing queens to such, or uniting them with other colonies. I have never known them to kill a queen, but this I have proved; they will live on peaceably and lay their eggs side by side with a laying queen, as I have shown in the *British Bee Journal* for 1883, page 66.

What bee-keeper has not noticed a number of drones in worker cells, when a young queen commenced laying! Why? These have been laid by fertile workers only. I may here remark that some think a young queen ought to begin laying before 10 days after hatching; but this is an error, as the best queens I have had, have been those which longest delayed laying.

I once had a black queen hatched in July, which did not lay until March; and last year I had a Syrian hatched Aug. 9, which did not lay until the end of February; and both of these were fertile. I have several times found the cells filled with the production of fertile workers before the queens commenced to lay; and, no doubt, many a fine queen has been condemned as a drone layer on this account; and many a queen has been thought to have begun laying when only the workers had begun.

I had hoped, during the past summer, to be able to encourage the use of these fertile workers; but the weather spoiled my experiments.

If people will consider that every time a queen of these races is reared in their native colonies, a lot of fertile workers are also reared, and that the queens, whether virgin or mated, are not destroyed by them; or these bees would have been extinct hundreds of years ago; in fact, would be in less than five years. It will be plain that Mr. Doolittle has made a mistake in saying that they are.

As I have hinted that many of the queens doing duty for these Eastern bees, may only be mongrels, and some

may think I mean to advise getting rid of them, but I do not; for no matter how they may be crossed, if they have only the Eastern blood in them, they will pay for keeping, at least until an unquestionably pure one can be afforded, and when one can be got from a source which can be depended upon for getting a genuine Simon-pure, it would be as well to compare the bees from her carefully with those already in the apiary, particularly as to size and disposition to sting when handling them; for peradventure these you have may be pure ones, and it would be a loss to throw them away.

Palestines are better than Italians, but do not come up to the Syrians; while for profit in honey, give me a Syrian queen mated with a black drone; but never attempt to keep these bees unless you are prepared to let them have sufficient breeding space. They ought to have at least 16 Langstroth frames to breed in; though if the Langstroth is used, I should prefer two rows of frames placed over each other for a brood-nest; making it really two stories high; then with a good locality, a good season, and good management, the Carroll record could be outdone in most places, for I see nothing extraordinary in it with these bees.

Sheffield, England.

For the American Bee Journal.

Supers for Surplus Comb Honey.

E. P. CHURCHILL.

I am surprised to see how any one can advise a $\frac{5}{8}$ inch space between the top of the frames and the section case, unless he has strips to rest on the top-bars; for if there is nothing but the rim to the case, the bees must of a necessity go up only about the edges. I prefer a case to rest at the sides on a chamfered edge thin enough so that the bees can pass from the side of the hive, as they crawl up on the inside combs, which is $\frac{3}{8}$ of an inch from the side of the hive; and unless the side of the case is beveled down to at least $\frac{1}{8}$ of an inch, the bees are obliged to leave a passage from the outside comb.

I used them a long time before I discovered this fault. My case is a little like Root's. I use glass only on one side, and a solid $\frac{3}{8}$ inch wood on the other, and to stiffen the rests under the boxes. I use a partition $\frac{1}{4}$ inch thick, and the bottom of the ends are $\frac{1}{2}$ inch thick, and are beveled from $\frac{1}{2}$ inch at the bottom to 5-16 inch at the top, so that two lengths of $4\frac{1}{4}$ boxes just fit each side of the partition; thus I can have half a case or a whole one.

I rabbet 3-16 of an inch at the ends, and $\frac{1}{2}$ of an inch deep for box rests; these are 3-16 of an inch thick, and are nailed to the partition, which makes a stiff, good case, and leaves very little surface to stick to the frames. At each end of the top of the crate is a wedge to tighten the boxes; there is a bee-space of 5-16 of an inch, which is enough for a free

bee-space, and they can reach the sections anywhere on the frames.

I want no more cases the full width of the hive, especially where 10-frame hives are used; but I do want a 10-frame hive for many reasons. One very important thing is to have no air-space between the two stories, as it is sure to drive the bees away from the sections. One will say it is too expensive to make a hive air-tight; but it can be made so, simply by painting the edge of the upper story and tacking on firmly 1 or 2 thicknesses of woolen cloth. I want a narrow rim around the upper story to shut down $\frac{3}{8}$ inch over the lower story; then, with the cloth, the bees take to the outside boxes far more readily. On the case, I prefer a cushion made of leaves; for I know by experience that it is cooler on a hot day and warmer on a cool night; in short, it is a very good regulator.

I find that where no cushion is used, bees do double the gummying about the sections, especially at the sides and top next to the cloth; because nature tells them it is too cold. The hive should have not only heat but moisture to a certain extent; and a cushion supplies both.

The best cover for a hive is roofing with ventilator at each end close to the roof. Strips are tacked on the inside along under the roof, 1 inch or more down, and 5 or 6 inches wide. Burlap is tacked all around inside of the cover, but in one end in which I pack hay or excelsior; finally fastening the open end. This gives a circulation of air, and affords shade; and when a cloth is spread on the frames or cases, in the upper story, neatly tucked down (with a cushion below in winter), I have a perfect bee-home, and on a hot day the bees are far more comfortable.

The question of getting bees into the boxes is one of much importance. I have tried many ways, and will describe the one which I consider the best. I aim at early breeding, so as to have a good force about apple-bloom. I even up all colonies, so as to have a strong force from all; and it can be done in no way but by early feeding and proper care.

I add frames as needed till I have 9 Langstroth size. These I spread so as to fill the hive and let the bees build and fill out the combs just as much as possible; and as there are 9 instead of 10 frames, there is room for a lot of bees that are not really needed, but yet are just what I want at surplus time.

When honey comes in freely, and the frames are bulged and crowded, I shake off the bees and shave the honey off even with the frames, and place the ones with the least brood in the centre of the hive. I set first one $\frac{3}{8}$ inch frame from the side of the hive, and the others only $\frac{1}{2}$ inch from this, and so on to the ninth, which is within $\frac{3}{8}$ of the $\frac{1}{2}$ inch division-board. I now put on a case with the beveled edge over the first frame close to the side of the upper story. This case is one box narrower than the inside of the hive, which covers the 9 frames; but instead of a full case, I take out

half the boxes and fill the space with cloth, etc., and set the case with the boxes at the back part of the hive, covered with enameled cloth and cushion.

I add twice as much water as honey to the honey shavings, and mash all together and strain through a cloth; this I set on the section case in a feeder, and apply the same covering.

Now, as the frames are closed up, and as the honey is above the sections, the bees are encouraged to take to them. I reduce the honey as it obliges the bees to provide a place for it. As soon as the honey is all taken down, remove the feeder, replace the packing, and when the boxes are fairly started, one row is set forward, and a row of boxes with foundation put in its place. I do not alternate one of started and one of raw foundation; for the started ones are almost sure to be bulged into the new ones; but with a whole row it is all the same.

We have room for one more set of boxes, which may, in time, be given; and as more bees are hatching, raise this case and set another with foundation, under; following up and removing as fast as they are finished. Some one may say, why use so few boxes. If he has measured a 28 one-pound case, he will see that to fill one requires 16 quarts. Where is the colony to do this, which will rear a large number of workers and leave wax-workers and nurses in the hive?

Add the large crate to an open, airy hive, and we may easily account for poor box work. If they show signs of swarming, take a frame of brood and bees from a number of hives, and give them a laying queen; carry them away 2 miles, and in a short time there will be a good colony. Of course I replace with a frame of comb or foundation.

We must keep in mind that shade of some sort is indispensable; and evergreens are good and last some little time if only set in a can of water deep in the ground.

I believe much spring dwindling can be avoided by handling the bees at the proper time. While we are feeding in cold and chilly weather, the bees will get excited, and it is natural for a bee to load up and fly out, even if only a few feet from the hive, and return. However, if we manipulate, feed, etc., about dark, much of the excitement is avoided, both by the feed and handling. Clear honey is the worst thing to excite them. Bees suffer for water, and after much thought, I have invented a feeder, waterer and passage way over the frames, all in one. I changed a colony of Italians into a clean, dry hive, and they showed some uneasiness. I put on the feeder (which covers the length of the frames), and in one apartment I gave syrup, and the next close by I gave water with a bit of salt in it; and immediately they quieted down.

This arrangement is so made that the bees cannot get drowned or fly out; yet we can see them, and it does not shut off ventilation. It can and should remain on the hive all through

cold weather, for a passage way if for nothing more. For shipping bees it has no equal; by opening it and packing the feed boxes with moss and inverting on the frames, the moss being wet, the bees have a perfect life preserver.

North Auburn, Maine.

Improved Foundation Fastener.

W. H. SHIRLEY.

After experimenting with several methods of fastening foundation, I find that the Parker foundation fastener does the best work. On account of its sliding motion, I could rely upon doing a good job.

After using it a while, and putting the lubricants on the fastener with a knife, I decided that that was too dauby and slow; so I have improved it, as will be seen in the accompanying engravings, and have sent one to be placed in the BEE JOURNAL museum.

The improvement consists of a tin cup, made to put on the bottom piece of the fastener, which holds the lubricants. To use it when the top piece is back, lift up on it, and that forces the front end down into the cup, and you are ready to go ahead. To prevent the lubricants from running down the underside of the top-piece, cut a little notch in the underside of the top-piece, as seen in the engraving.

Any one who desires to improve the Parker fastener thus, can have any tinsmith make one at a cost of about 10 cents; and when put on and used, it will save time and daubing, and work like a charm.

Our plan, last year, was to cut a cup into the bottom piece of the fastener. This necessitates the use of a larger size fastener than the sections. This plan, I think, would pay any man who had 500 sections to fill with foundation. It was too costly for those who already had the Parker fastener; for all know it is very difficult to make people see a good thing when it affects the pocket-book.

Glenwood, Mich.

[The fastener is placed in the Museum for the inspection of visitors.—Ed.]

Read at the N. E. Michigan Convention.

How to Begin Bee-Keeping.

R. L. TAYLOR.

[The following is the President's address, delivered at the Northeastern Michigan Convention at Lapeer, March 5, 1884, as mentioned on page 282.—Ed.]

1. The first and one of the most important questions which one proposing to enter upon the business of bee-keeping is: Am I fitted for it by nature? Unless one has a genuine love for the business, and can keep alive some degree of enthusiasm, I doubt if he can attain real success. Though the fear of stings seems to the tyro a very formidable difficulty, it is really the least of all; a taste for apiculture will speedily overcome it. If one has, in addition to this quality, promptness, industry and practical energy in attention to details, with a determination to persistently labor to overcome difficulties, and never to yield to discouragements, he may well hope for fair success.

2. The first thing to be observed in deciding upon the territory to be occupied by an apiary, is that a country already stocked with bees must not be entered. To do so means a blasting of the hope of success at the outset. Then, the greatest care must be taken to occupy a place well supplied with all the honey plants necessary to make as complete a succession as possible, from early spring to the frosts of autumn; and especially should I insist upon an abundance of all those which are the source, generally, of the surplus crop, which are in this part of the State raspberry, white clover, basswood, and fall flowers.

3. The apiary should be placed upon a plat of ground which cannot by any possibility be flooded at any time of the year, and which has sufficient natural drainage to enable it to absorb quickly what little water remains upon it after a rain. It should, I think, be level, clean, smooth, and covered with a greensward kept closely mown, except where the hives are to stand, where some preparation to wholly prevent the growth of vegetation would be well, particularly about the entrance of the hive, which should also be so fixed that heavily laden and partially chilled bees that fall to the ground before reaching the entrance, can readily regain the hive without again taking wing. The hives are to be so disposed as not to hinder the work of the apiary, and so as to aid the bees in distinguishing, and so in finding their own honey. I prefer some shade, if it be not dense; for no shade at all is better than such as would create or retain dampness. A wind-break on the north and west is desirable, and should be early provided.

4. Before obtaining bees, determine satisfactorily to yourself the hive to be used, and that depends largely upon the size of the frame preferred. It is very desirable to use a frame exactly of the same size, as that mostly in use among those with whom you are likely to have dealings, either by

way of buying, or of selling. Colonies upon frames, such as the purchaser desires to use, are worth more to him by a large percentage, than are those upon frames different in dimensions. Perhaps there is nothing about which the beginner is so likely to be careless as in this matter of looking to the size of frames in the hive he procures; and for the amount invested in it, there is nothing so important. The Langstroth frame so-called, which is $9\frac{1}{8}$ inches by $17\frac{5}{8}$ inches is, I believe, in more general use than any other, and I advise its selection always. It may not be better than any other, but all things considered, I think it is at least the equal of any. For one who for any reason wishes a shorter, deeper, and somewhat lighter frame, the American or the Gallup is the alternative. When once a frame is selected, adhere to it undimly.

5. The hive itself should be a plain box without top or bottom. In depth $\frac{3}{4}$ inch greater than the depth of the frame selected. One of the other dimensions must be $\frac{3}{4}$ inch greater inside measure, than the length of the frame; and the remaining dimensions must be graduated to accommodate the number of frames desired, allowing about 17-16 inches for each frame. There must be a rabbet cut at the top of the ends, or of the sides, as the frame requires, upon which the arms of the frame are to rest; the rabbet must be just deep enough so that when the frame is put in position, the space above and the space below the frame are just equal. Some prefer tin rabbets; but I doubt whether their advantages balance the outlay. The cover should be a plain board simply cleated at the ends. The bottom-board is to be 4 inches longer than the hive, fastened to two pieces about 2 inches square; out of the upper side at the front end should be cut a triangular piece $\frac{3}{8}$ inch thick. Two of the angles of the triangular piece are at the front corners of the bottom-board, and the third angle should be about 5 inches back of the middle of the front end of the board. With a circular saw this can easily be taken out. When this is taken out, the space left becomes the entrance to the hive, and this entrance may be enlarged or diminished, or entirely closed by simply moving the hive forward or backward. The hive on the outside, and the cover upon both sides, should, of course, be thoroughly painted with two coats of the best white paint. I should have said, that after the sides and ends of the hive are cut, each piece should have a hand-hole cut into it with a wabbled saw, for convenience in handling. For a second story, if it were desired to produce extracted honey, I should use a body precisely like that of the lower story, with a flat honey-board between the two; preferring the use of the honey-board to the disadvantage of having bodies of two styles. For comb honey use the Heddon case. A sufficient amount of foundation should be had for use in the building of all the comb, and that for brood-frames and extracting should be put upon wires.

6. It must be remembered that what I am saying is for those who have never handled bees; particularly when I say that the bees to be procured should be the Italian, on account of their peaceable character; for this quality will enable the beginner the sooner to divest himself of all fear when handling bees; and the number of colonies should be no more than 2 or 3. A good work on apiculture, and one or more of the bee-periodicals, which should have been already obtained and well studied, should now be kept in constant requisition. These colonies, and largely the time of the learner, should now be given to investigation, practice and experiment. The incense of the smoker, which should of course be provided, should seldom fail to arise on the incoming of every warm day.

The object the first year should be to obtain practice, and a good degree of familiarity with bees, and with the various manipulations employed in their management. How to rear queens? How to divide colonies? How to hive swarms? Can a colony that has begun to prepare for swarming be induced to yield that disposition successfully? are only a few of the many points that should be studied and experimented upon remorselessly.

Let the beginner sacrifice his colonies, if need be, in order to become thoroughly grounded by practical experience, in as many as possible of the underlying principles of successful apiculture. I could not have gone into details and thus filled out the outline I have drawn, without trespassing on your time; nor can I take your time to touch on other matters of interest and consequence, but will leave the subject here, believing that the above suggestions followed out with a thoroughness which is begotten of genuine interest, will fit the beginner to care for an apiary of a moderate number of colonies, with satisfaction and success.

Lapeer, Mich.

For the American Bee Journal.

Students in Apiculture.

DORA HYDE.

If bee-keeping is a science and to be learned by an apprenticeship, it seems to me there ought to be some uniform system agreed upon by the teachers for the students. Now, there are as many "terms to students," as there are bee-keepers who teach, or propose to teach bee-keeping.

We understand an apicultural school somewhat on the plan of the "Business Colleges," was discussed by some of our leading bee-men last summer; but no terms could be agreed upon. The exact nature of the school I did not learn, but I have been informed that it was to have had a teacher or "professor," who would give instructions in the theory in general, and another, a practical honey-producer, who would furnish a few colonies, hives, sample fixtures, etc., and give a short practical illus-

tration of his method each day during a term of five months.

The school was given up, because one of its projectors now receives students and teaches them practically in his shop and apiary, and in a manner which he considers far superior to any school where theory alone is taught.

I was lately talking with a gentleman who had spent several weeks with each of four different parties, who take annually from 4 to 20 students; and his opinion was that some of those who propose to teach the business, seek in this way to get cheap labor only, and give as little attention as possible to the instruction of the students; giving some of the students work in the apiary, and others work in the shop, or, perhaps, even in the office at matter entirely disconnected with apiculture.

As a matter of business, this may be a good method; but the other side has rights which, in common justice, we should consider. The moment we accept the application of a student, and he places himself under our instruction, it is our duty to him, to our profession, and to ourselves, that he is directed each day where to look for instruction. If he is not already familiar with the operations of the apiary, and has not learned just what he needs to know, and where and when to find it, he will be just as liable to spend the most important part of the season in the shop, "driving sections," as out in the apiary, learning to handle swarms. The fact that he has placed himself under instruction is evidence of his ignorance of the business, and our accepting him as a student binds us as an honest teacher to instruct him in all the branches of the business, to the best of our ability. The selection of those who already know the most about the business to do the work in the apiary, and sending others who have some mechanical skill, to the shop, is an injustice to both classes.

We believe that young men who can spare the time, and who wish to engage in apiculture as a vocation, cannot do better than to spend a season with an experienced apiarist. We would advise them, however, to be sure they find one who will instruct them in all the details of the business, at a fair price for such instruction, rather than to give their time and labor for the crumbs that may accidentally fall in their way.

Cane Sugar for Winter Stores.

W. Z. HUTCHINSON.

In so many instances have bees died under circumstances in which the cause of their death could scarcely be attributed to anything except the improper quality of their food; diarrhoea has occurred under so many apparently conflicting conditions, and these apparent contradictions could only be explained upon the hypothesis

that the food was of an unsuitable character; and in so many instances has the superiority of sugar stores been demonstrated, that, three years ago I began to experiment by extracting the honey, in the fall, from the combs of a few colonies, and feeding the bees a syrup made from granulated sugar. Some of the sugar-fed colonies were left out-of-doors, some placed in the cellar, and others buried in a "clamp."

The first winter all came through alike. The honey of that season and locality was exactly as good for winter stores as was sugar. The same experiments were repeated the next season with marked results in favor of the sugar. The only colonies wintered in the open-air that lived until spring, were those having sugar stores. All of the colonies in the cellar, not having sugar for food, suffered from dysentery, and $\frac{2}{3}$ of them died; while those having sugar stores showed no symptoms of dysentery, and were dry, sweet, and clean, even the bottom-boards not being covered with dead bees. The bees in the "clamp" had wintered much the best: 15 per cent. of those with natural stores had died from diarrhoea, and most of the remainder, except those with sugar stores, had suffered more or less by the same disease.

Last fall I removed all the honey from about 20 colonies, and fed them sugar. About 50 colonies were each fed from 5 to 15 pounds of sugar. I theorized as follows: The bees will store the sugar in the empty cells in the centre of the hive, where they will be most likely to cluster in the winter; while the honey that is in the upper part and corners of the combs will not be consumed until spring, when frequent flights will prevent diarrhoea. About 15 colonies were left with natural stores.

If the 57 colonies in the clamp are in the same condition as the 13 in the cellar, they are in fair order. Fifteen colonies were left out-of-doors; 10 of them packed with chaff and sawdust in large boxes, while 5 were left with but slight protection.

I have about decided that bees require protection of some kind. I have, for several winters, left a few colonies unprotected; but in only one winter, and that was a warm one, have they wintered so well as those that were protected.

So far this winter I have lost 2 colonies, and they were from among the 5 that were unprotected. Each had been fed about 12 pounds of sugar, and the remainder of their stores, about 8 pounds each, was honey. One of them starved to death. It was not a very strong colony, and the continued, exceedingly cold weather prevented the bees from moving along in quest of food. There was not the slightest sign of diarrhoea; but the other colony died of it, and for awhile I was puzzled; but, at length, I remembered that this was the only colony in which the bees had clustered upon the upper part of the combs, and, consequently, they had fed upon natural stores.

Rogersville, Mich.

Production of Comb Honey.

L. C. WHITING.

The first point aimed at is to have the colonies strong in numbers and in the right condition to spare the field-bees to do their work. I have seen no plan that suits me better than the one recommended by Mr. Doolittle, which can be found in the bee papers of last year.

Have your racks and sections ready to be put on as soon as the flow of honey commences. Have, if possible, a few sections in each rack that are partly built out. These can be obtained by placing frames of sections filled with foundation in the brood-nest of strong colonies when fruit trees are in bloom, removing them as soon as they are well drawn out.

Place them in your honey racks to be ready for the main crop. Put the sections over the brood-nest as soon as you see a streak of white, new wax being added to the top of the brood frames between the combs. Then open the hive and reduce the size of the brood-chambers with a division-board to the capacity of the colony, or enough to crowd the bees into the sections. If it is a small or weak colony, put a frame of sections in the brood-chamber behind the main part of the brood, and keep one frame of open brood behind the frame of sections, changing this frame to the centre of the brood-nest as soon as capped over; never allowing the bees to hatch out behind the sections, but keep this space filled with eggs or open brood.

Should the bees swarm from a strong colony, place the swarm on the old stand, and give the rack of sections from the old hive. The swarm should have at first as few frames as they will cluster upon, so as to force a large portion of the bees into the sections, giving new frames as fast as those in the hive are filled with eggs.

Give the parent colony a frame or two of sections to draw out in the brood-nest, and when the queen is hatched, give them brood or bees enough to make a good colony, or double up with other colonies. Always keep the brood-nest crowded with bees, and you can have the honey stored when you want it.

Every colony can be made to gather its share of comb whether it is a nucleus with one comb, or a large one with 8 or 10 frames.

The wide frame I use has no top-bar, which enables me to take out the partly filled sections and replace with empty ones with little labor.

All sections should be finished over the brood-chamber and removed as soon as well sealed. If a colony is strong enough to work in the sections and does not, transfer a few sections, bees and all, from other colonies, and uncap some of the honey in the centre of the brood-nest. Full combs of honey can have the caps broken and placed in the centre of the brood-nest one at a time, and if conditions are favorable, it will be mostly taken up

into the sections. Reversible combs should be turned over whenever there is too much honey between the brood and the sections, and especially a few days before the close of a honey flow.

Always keep the brood-nest within the capacity of the queen. Handle the frames often, as it induces the bees to feed the queen, and she will lay the more. All caps and racks should be made strong, and so arranged that separators can be used or not, at the pleasure of the operator. The most profitable time to put in separators is after the bees are well at work in the sections and before the combs are built out too far. Look over the sections often in the early part of the season, and put in place any combs that are not straight, or as you wish them. It will save much disappointment when you harvest the crop. Use comb foundation for starters in all cases, and have at least half-inch openings between the sections. No more room should be given in the sections than the bees can keep warm, or they will waste much wax.

The Best Strain of Bees.

M. D. YORK.

The Italian bee is greatly magnified by many; even people who know nothing about the honey bee, have come to think that if one is keeping Italians, he is sure of success.

After studying their character closely for the past five years, I find that the queens are very prolific, more so than the blacks, and produce a larger amount of bees. This trait is all right for some purposes. I once thought a large amount of bees in a hive, and a prolific young Italian queen meant lots of honey; but I have found this to be a mistake. I generally get the best results in comb honey from those which are less prolific; and, consequently, less inclined to swarm.

I said this trait of prolificness is all right for some purposes. It answers well if one is working the business of rearing bees to sell; and also for the one who is just commencing in the business; and calculates his success by the number of swarms he can get from one colony. This is all right, if he could only stop when he wishes to, or rather when he has all the bees he wants, and desires to work for honey; but he is very much disappointed to find that they keep right on swarming, regardless of his wishes, and he has to let them spend their swarming energy in building brood-combs instead of storing surplus honey.

Again, it is all right if we wish to work for extracted honey, for the extractor is, without doubt, the best non-swarming apparatus ever invented; but I cannot yet believe that extracted honey ever will take the lead in our markets.

I can work the blacks with $\frac{1}{4}$ more bees in the hive, for comb honey, than I can the Italians or hybrids, with far less danger of their swarm-

ing. This swarming mania can be controlled to a certain extent, we all know; but I would rather have one colony to work for comb honey that swarms naturally the forepart of June, and then is satisfied, than two that you have to keep taking brood from, or swarm them artificially.

I was very much pleased to see how emphatically Mr. Hutchinson came out in his article in *Gleanings*, in favor of natural swarming; but I was very much surprised when he also came out in favor of the hybrids. Although Mr. H. is one of our most successful queen breeders, it is his first year's work for comb honey; and now Mr. H. should next season try some pure blacks for comb honey, and report.

Now, to sum up the whole matter, if it is desired to produce comb honey, the common black or brown bee is the best, in my opinion. It is the general verdict of those who have produced both comb and extracted honey, that the comb honey finds the most ready sale. I claim that the producer of comb honey from Italians, or their crosses, cannot compete in the same market, at the same time, with the one whose honey is produced by blacks. The honey of the former is not so nicely sealed, which gives it a darker and rougher appearance. I have never been able, as a rule, to get them to fill out their combs so nice and smooth next to the wood as do the blacks.

It is my opinion that the black bee will be much sought after in the near future; and I think there is nothing gained in crossing them with the Italians, unless making them more cross and vicious to handle is an advantage.

Millington, Mich.

For the American Bee Journal.

Wabash County, Ind., Convention.

The bee-keepers of Wabash County met at the Court House in Wabash, Ind., on April 11, for the purpose of organizing a bee-keepers' association.

Mr. A. Singer was chosen chairman, and Mr. H. Cripe, Secretary *pro tem.* of the meeting. The chairman then explained the object for which they had met; after which a committee was appointed to prepare a constitution and by-laws. Adjourned till 1 p. m.

At 1 p. m. the chairman called the meeting to order, and the committee on constitution and by-laws reported, which report was unanimously adopted, after changing the membership fee from 50 cents to 25 cents. Eleven names were then enrolled.

The election of officers was next in order, and resulted as follows: Mr. Aaron Singer, President; Mr. J. C. Zimmerman, Vice-President; Mr. H. Cripe, Secretary, and Mr. G. D. Lowman, Treasurer.

Two hundred fifty-six colonies of bees were represented by the members. After some discussion the convention adjourned to meet at the same place Oct. 5, 1884.

H. CRIFE, Sec.

AARON SINGER, Pres.

For the American Bee Journal.

Improved Bees—Comb Foundation.

JAMES HEDDON.

In reply to Mr. Doolittle's question on page 260, top of third column, let me say that I have several times in this JOURNAL, stated my objections to such complications as he, in that article, describes; and why I consider the shallow-chamber indispensable. I now refer him to page 637, for 1883, to quotations from Mr. Langstroth.

Mr. D.'s attack upon the efforts to improve bee stock is very well answered by two articles on pages 278 and 280. I wish to present just one among many refutations to his article against that greatest boon to scientific apiculture—comb foundation. Formerly, from 8 to 12 days of the best of the honey harvest was granted to a colony to get the brood-chamber ready for surplus boxes. Now, we give them just 48 hours to accomplish the same, and they do it in very much better shape. About 2 to 3 tons of fine wire are now used annually; and actual experiment has led to this wholesale use. Please let me be remembered as one who plead for the shallow-chamber between the brood and surplus apartments, and full sheets of comb foundation above and below, with wax and honey at present prices.

Owing to the backward spring, I think it better to postpone my report on wintering until about May 15. My bees are not yet out of the winter packing; they are in excellent condition as a whole. My past winter's loss is small for this county.

Dowagiac, Mich.

For the American Bee Journal.

Western Michigan Association.

According to appointment, the bee-keepers of western Michigan met at Berlin, on April 24. In the absence of the President, Vice-President Thos. M. Cobb, called the meeting to order.

The minutes of the previous meeting, and the Treasurer's report being called for, were read and adopted. The election of officers then took place, resulting as follows: For President, Thos. M. Cobb, of Grand Rapids; for Secretary and Treasurer, Geo. E. Hilton, of Fremont Centre; for Vice-Presidents, Ottawa Co., Jno. Slabbekoorn; Kent Co., Lewis Woodman; Muskegon Co., G. C. Young.

It was decided to annex the counties of Oceana and Newaygo; their Vice-Presidents to be appointed by the Secretary. By request of the Secretary, it was also decided to hold the annual meeting at Fremont, on the last Tuesday in November next.

Topics relating to bee-culture were then discussed by all the members. Colonies represented were, fall 480, spring, 441. Only 58 colonies being wintered in cellars. Although the meeting was small, much interest was manifested by all. Adjourned.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Essentials in Queens.

On page 234, Mr. Heddon, in reply to "Tommy Dodd," says: "Not one-half of the queen-cells usually built, would please me from which to rear a first-class queen."

1. What does Mr. H. call a first-class queen-cell?

2. What standard point does he require in a virgin queen to prove satisfactory?

3. After being fertilized, will she always prove a regular layer, or deposit her eggs in proper order?

JOSEPH M. WISMER.

Jordan Station, Ont.

ANSWERS.—1. There is no way to decide regarding cells, that I can readily describe here.

2. Virgin queens are too young to test for qualities.

3. Not always; but she will, as a rule, if nothing unnatural happens to her.

Italianizing, etc.

1. I have one colony of bees on a box-hive that is very strong; turn the hive up when I will, warm or cold, every inch of space in the hive seems to be crowded with bees. The combs are full of brood to the very bottom. There are no queen-cells that I can see, but there are lots of drones hatched and flying. Will they throw off a swarm soon, or what is the best to do with them? I have set the hive on top of a Langstroth hive, next to the frames full of comb and honey.

2. How can I tell worker combs from store combs?

3. How is the surest and best way to tell when robbing is commencing?

4. What time of the season is the best to introduce young (not virgin) queens to Italianize black bees?

I had a lively time with robbing one day. I carried some into the cellar; covered others with blankets;

and closed the entrance to all the weakest colonies. I did not get control of them until I closed up my strong colony. Then they stopped in a few minutes. DAVE H. LISLE.

Chebanse, Ill.

ANSWERS.—1. You must either give them surplus room above, artificially swarm them, or wait for natural swarms.

2. Worker comb has about 5 cells to the inch; store or drone comb about 4.

3. By the actions of the bees trying to enter the hive, robbers appear in a suspicious manner flying to-and-fro, alighting cautiously, and often arising instantly, re-alighting, repeating this several times before entering the hive. If the robbed colony is protecting itself, you will see the bees clinched and fighting.

4. June and July usually.

Bees and Peaches.

I live just across the road from a peach orchard of about 20 acres, and there are many others near.

1. Would it be wise or otherwise to attempt bee-keeping as a specialty in my location?

2. Would the sour juice from rotten and broken peaches injure the honey, or cause the death of colonies in wintering?

3. We do not know whether the bees would gather the juice or not; but if they should, would it injure the surplus honey? JAMES SMITH.

Willoughby, Ohio.

ANSWERS.—1. The peach orchard will be no objection.

2. I had my whole apiary once store large quantities of cider in each hive. They wintered tip-top all the same.

3. I think you need have no fears of any juice injuring the surplus honey.

Pollen in Abundance.

We are having a perfect avalanche of pollen; almost half filling some of the hives, and still it is coming in rapidly from soft maples, and dandelions to come yet. 1. Will not so much pollen prove to be a nuisance filling the combs so that brood cannot be reared? Bees are breeding finely now, and have wintered well. 2. Can the Langstroth hive be used without honey-board, and not have the queen bother by getting into the sections? Hillsdale, Mich. W. B. DRESSER.

ANSWERS.—1. You need have no fears regarding clogging the combs with pollen at this time of the year.

2. Yes.

The Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association, will be held at Rockton, Winnebago Co., Ills., on May 20, 1884. JONATHAN STEWART, Sec.

There will be a meeting of the Northeastern Kansas Bee-Keepers' Association, at Hiawatha, Brown Co., on May 16, 1884. A general attendance of bee-keepers is expected. Granada, Kan. L. C. CLARK, Sec.

The Kentucky Bee-Keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed). N. P. ALLEN, Sec.

The bee-keepers of Tuscarawas County will meet in the Town Hall at Port Washington, O., on Thursday, May 15, 1884, to organize a bee-keepers' association. All are earnestly invited to attend.

A. A. FRADENBURG.

The Cortland Union Bee-Keepers' Association, will hold their spring meeting May 13, 1884, at Cortland, N. Y. M. G. DARBY, Sec.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
 Monday, 10 a. m., May 5, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—There is no life in the market. Extracted honey sells in its regular way and to its wonted channels, without any speculative feeling about it, and brings 7@10c on arrival. Comb honey sells slow at 15@16c a lb. from store for choice.

BEESWAX—In good demand; choice yellow brings 35c a lb. on arrival.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 14@16c. Dark and second quality, 13@14c; extracted white clover in kegs and barrels, 8@9c.

BEESWAX—Prime yellow, 34@35c. THURBER, WHYLAND & Co.

BOSTON.

HONEY—Demand light. 1 lb. sections comb honey, 18@20c; 2 lb. 16@18c. Extracted, 9@11c. BEESWAX—35c.

BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—Of late receipts of comb honey has been scattered amongst many firms, and as all are desirous of realizing on their receipts at as early a day as possible, prices have been irregular and low, some lots being offered from 5c to 7c per lb., less than 30 days ago. I quote white comb 13@16c; fancy 18c. Extracted honey—demand light, 7@9c. BEESWAX—30@37c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Only in a small jobbing way is there anything doing. Market is easy at the quotations, holders being anxious to close out stocks. White to extra white comb, 15@18c; dark to good, 10@13c; extracted, choice to extra white, 7@8c; dark and candled, 5@.

BEESWAX—Wholesale, 27@30c. STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—Demand good for this time of the year. Prices unchanged. Choice comb, 2 lb. sections, 15@16c; 1 lb. sections, none in market; dark and irregular, 10@12½c. Extracted, in better demand for dark honey at 7@8c; white dull at 8@9c. I could sell a few thousand pounds of dark honey very readily at above figures. Stocks are low.

BEESWAX—None in this market.

JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@6½c.

BEESWAX—Firm at 32@32½c. for choice. W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Market continues very fair, particularly for choice 1 lb. sections, which are in good demand at 18c; 2 lbs. do not sell so readily, but in the absence of 1 lb. it moves at 17c. Second quality is very slow at 14@15c, and extracted not wanted at all in any shape.

BEESWAX—Very scarce; would bring 35 cts. on arrival for choice yellow.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 17@18c; extracted, 7½@8½c.

GEO. W. MEAD & Co., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a continual statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an additional present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price still lower, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

SOMETHING NEW!

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is NOW published SEMI-MONTHLY, at Seven Shillings, per annum, and contains the best practical information for the time being, showing what to do and when and how to do it. Rev. H. R. PEEL, Editor. We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.50 a year.

Bees! Queens! Nuclei!

INSTRUCTION IN BEE-KEEPING.

BEES.—I offer For Sale 100 colonies of Italian Bees, in good, new, well-painted Hives, Gallup Frames, 12 frames to a hive; every comb straight and good; and most of the combs built on foundation. One colony, \$9.00; 10 or more colonies, \$8.00 each.

QUEENS.—I breed Queens by the best methods, and from the best stock. Queens ready after May 20th. Untested, \$1.00; tested, \$2.00; selected tested, \$3.00.

NUCLEI, with untested Queen, \$3.50; with tested Queen, \$4.50; with selected tested Queen, \$5.50.

INSTRUCTION.—July 7, 1884, I shall begin instructing a class in bee-keeping—class for men and women. Full course in Theory and Practice. For Circulars of information as to this class, and Price List of Hives, Frames, Sections, Implements, Books, etc., address, **O. CLUTE,**
10Dtf IOWA CITY, IOWA.

BEE HIVES!

Simplicity, Langstroth and Chaff Hives, Section Boxes, Brood Frames, and Comb Foundation. Send for Price List. The successors of A. B. Miller & Son.

MILLER BROS.,

51DSt NAPPANEE, Elkhart County, IND.

Syrian & Italian Queens

Syrian Queens bred from Queens imported from Mount Lebanon. Italians bred from best imported and selected home-bred. Tested Queens of either race before June, \$3.00 each; in June, \$2.50; after June, \$2.00. Untested before June, single Queen, \$1.25; 6 or more, \$1.00 each; after June, single Queen, \$1.00; 6 for \$5.50; 12 for \$10.00, or "Cook's Manual of the Apiary," cloth only 90 cents with order for Queens.

NEW INVENTION.

Patented Oct. 17, 1882.

Bees forced to leave their surplus honey before removing it from the hive. Saves valuable time and labor; prevents robbing, and the liability of being stung. The Bees are first cut off from the brood hive, by closing the openings in a slat honey board; the conductor is then placed in position, which connects bees in surplus honey with brood hive. They soon find that they are imprisoned, and being anxious to escape, pass out through the Conductor into the brood hive. It also prevents their return.

Conductor and Langstroth hive complete.....\$6 00
Conductor and Honey Board, any size, and Sections to fill, which shows all the improvements..... 1 50
Conductor, by mail..... 50
Send for Circular giving full particulars.

Italian Bees and Queens For Sale.

Tested Queens, May, \$3.00; June, \$2.50; after July 1, \$2.00 each. Untested, after June 1, \$1.00; 6 for \$5.40. Full colonies in May, \$7.00; 2 for \$13.00; 10 for \$60.00. After June 1, \$1.00 less each colony Satisfaction guaranteed. **L. S. CROWFOOT,**
12A8t Hartford, Wis., April 1, 1884.

STANLEY'S AUTOMATIC

HONEY EXTRACTOR.

Reverses the combs without the aid of the hands; the reverse motion of the crank is all that is required. No time is lost, as we provide every machine with a brake to stop the motion, and the combs are half reversed when the motion stops. Can be used for 2 or 4 combs, as desired. No chance for combs to fall or get injured. The Comb Baskets always stop in the most convenient position for removing or putting in combs. We use XXXX Tin or Galvanized Iron for Cans. The Cylinder or Can is all in one piece. We challenge any Extractor, taking any number of combs, to do one-half the work of our 4-frame Machine. Prices reasonable.

Stanley's Dollar Smoker, \$1.25 by mail. Address,

HEDDON'S

COLUMN.

My New Langstroth Hive.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

One Hive complete for comb honey... \$3.00

(The above will contain two cases complete with sections).

The above Hive complete for extracted honey... \$3.00

The above Hive complete for both in one... 4.50

One Hive in the flat... 2.00

Five or over, each... 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

COMB FOUNDATION.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8 1/4 x 16 1/4, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. My Circular gives prices.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4 1/4 x 1 1/4 x 6, 7 and 8 to the foot, per 1,000, \$6.50; 5 x 6 x 2, per 1,000, \$8.00. All shipped from here.

STUDENTS OF APICULTURE

Will receive terms for 1884 on application.

BEEES and QUEENS.

If you contemplate the purchase of Bees in any shape, tested or untested Queens, it may pay you to send for my

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.

The *Monthly Bee Journal* and any of the above, \$1 less than the figures in the last column.

Best Advertising Medium.

Having advertised in the *AMERICAN BEE JOURNAL* quite extensively for the past two years, I would say (without solicitation) that it has sold more queens for me than any other three periodicals I have ever tried.

My bees are in fine condition this spring. I have lost but 4 out of 182 colonies. The outlook is fine for a good season. L. J. DIEHL.

Butler, Ind., May 7, 1884.

☞ The Lucas County Bee-Keepers' Association will meet at A. Reusch's apiary on Saturday, May 17, at 10 a. m. Bee-keepers are cordially invited. Bring your dinners, and have a basket picnic among the bees. A. REUSCH, Sec.

☞ Letters for publication must be written on a separate piece of paper from items of business.

VALUABLE ORIGINAL PATENTS.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and the only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Sixth Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 220 pages, and is profusely illustrated. Price, bound in cloth, \$1.00; in paper covers, 75c., postpaid.

Dzierzon's Rational Bee-Keeping.—A Translation of the Masterpiece of that most celebrated German authority, by H. Dieck and S. Stutterd, and edited, with notes, by Charles N. Abbott, *Ex-editor of the "British Bee Journal."* Dr. Dzierzon is one of the greatest living authorities on Bee Culture. By him and the Baron of Berlepsch we are indebted for much that is known of scientific bee culture. Concerning this book, Prof. Cook says: "As the work of one of the great masters, the Langstroth of Germany, it can but find a warm welcome on this side of the Atlantic." Mr. A. I. Root says of it: "Old father Dzierzon... has probably made the greatest strides in scientific value, it would well repay any bee-keeper whose attention is at all inclined to scientific research, to purchase a copy. Cloth, 82c."

Queen-Rearing, by Henry Alley.—A full and detailed account of TWENTY-THREE years experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price, \$1.00

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.—This Manual is elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means can afford to do without. Cloth, \$1.25;

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 5c. per dozen, 40c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. This is a chapter from "Bees and Honey." Price 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Bee Pasturage a Necessity, by Thomas G. Newman.—Giving advance views on this important subject, with suggestions what to plant, and when and how: 26 engravings. This is a chapter from "Bees and Honey." Price, 10c.

Bees in Winter, with instructions about Chaff-Packing, Cellars and Bee Houses, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price 35 c. postpaid.

Fisher's Grain Tables for Farmers, etc.—12 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measurer, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. 40 cents.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 20,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Golders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

The Hive in Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, 52c.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Foul Brood; its origin, development and cure. By Albert K. Kohnke. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. 15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 52 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Dzierzon's Theory—presents the fundamental principles of bee culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Apiary Register, for SYSTEMATIC WORK in the APIARY. The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book. Prices: For 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Deutsche Buecher, Ueber Biencenzucht.

Biencen Kultur, oder erfolgreiche Behandlung der Bienen, von Thos. G. Newman. Dieses Pamphlet enthält Belehrungen über folgende Gegenstände—Derlichkeit des Bienenstandes—Honig pflanzen—Erziehung der Königin—Zütlern—Schwärmen—Ableger von Königinnen—Zalenißen—Zuleker von Königinnen—Ausziehen—Bienen behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschriebem ist. Preis 40 Cents.

Honig als Nahrung und Medizin—von Thomas G. Newman. Dieses enthält eine klare darstellung über Bienen und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angehend wie man Honigkuchen, Formföckelchen, Puddings, Schaumkonfekt, Weine, u. s. f. m zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Conumenten bestimmt, und sollte vieltausendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Pferd und seine Krankheiten—Von B. J. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniß der verschiedenen Pferdebkrankheiten, sammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Recepte. Preis 25 Cents.

No. 20.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The Honey Crop of California.

We have received the following explanatory letter from Messrs. Geo. W. Meade & Co., of San Francisco, Cal., dated April 29, 1884. They say:

In the BEE JOURNAL of April 23, we notice that Messrs. Stearns & Smith, of this city, dispute the figures we gave in our annual review, as a close approximation of the California honey crop of last year, in which we set forth the total production at 960,000 lbs. The firm above referred to, place the quantity at 1,387,000 lbs.; in other words, an excess over our figures of 427,540 lbs.

Our figures were compiled, as they always are, from the only reliable sources in all the honey sections of the State; and, in making figures, we deal with *weights* only, and not cases, as both the cases used for comb and extracted honey now differ in size and quantity of honey contained therein.

Let us analyze the figures as given by Messrs. S. & S. They state the receipts at 8,456 cases extracted honey, which, it seems, they figure at 120 lbs. net weight each. Allowing that the number of cases is correct, although it is not known where they obtained their information, it is a fact well known to large honey dealers here that fully *one-half*, if not more, of this honey was packed and received this year in cases of *one-tin* each, which hold only about 70 to 75 lbs. net of honey. Deduct, therefore, 50 lbs. each on, say 4,500 cases of honey, and we have a deficiency on the start on extracted honey alone of 225,000 lbs. from their figures.

The same authority also places the production of comb honey at 4,228 cases, which they figure at 60 lbs. net each, or 253,480 lbs., an equivalent of 12 to 13 cars of comb honey; when from the most reliable sources in the whole State, our own purchases, as the largest dealers, and inquiries with commission dealers, we cannot learn that the entire product of comb honey the past year exceeded from 125 to 150,000 lbs. all told; and these figures

we believe to be correct enough for all practical purposes.

Deducting, therefore, 125,000 lbs. of comb honey from their figures, we have a further deficiency in their comb honey estimates of 128,480 lbs.

Taking up their figures on "shipped from interior," all of which were included in our original estimates, and working on the same basis, fully one-half in *one-tin* cases, we can easily make a deduction of 50,000 lbs. from their estimate of 118,340 lbs., thus reducing the quantity to 68,340 lbs.

In conclusion, therefore, we beg to recapitulate as follows:

| | |
|----------------------------------|-----------|
| Estimate made by S. & S. | 1,387,540 |
| Less deficiency extr. | 225,000 |
| " " comb. | 128,480 |
| " " Int. ship. | 50,000 |
| | 403,480 |

| | |
|-------------------------|---------|
| Net production. | 984,060 |
| Our figures. | 960,000 |

Difference. 24,060

While these figures, as given by us, are not claimed to be *absolutely*, yet we know them to be *approximately* correct; and we again assert, without any fear of successful contradiction, that the total honey crop of California for the past year, according to our original figures, was somewhere between 950,000 and 1,000,000 lbs.

An Apostle in days of old said:

"Without controversy, great is the mystery of godliness." After reading the foregoing, we may remark: Without controversy, great is the honey crop of California!! While, perhaps, neither the figures of Messrs. Meade & Co. or Stearns & Smith, are *absolutely* correct—they show most plainly that the honey crop of last year was quite satisfactory, taken as a whole, and has been shipped to all quarters of the globe.

We are glad to get these figures from the two rival honey merchants of San Francisco, for they show conclusively that there is no collusion, and the figures are near enough for all practical purposes, no matter which are the nearest to the exact amount.

While we thank both firms for their interesting figures, we think there is no need of further dispute concerning the small discrepancy between the two estimates. We only wish we

had two such firms in every large city of the East; for competition is the life of trade—especially the honey trade. What is needed more than anything else, is men who will push the sale of honey and thus create a market for the product.

Prof. Cook writes us that he has sold 2,000 copies of his Manual during the past year. The twelfth thousand being just published. The Manual is a deservedly-popular book, and we congratulate the Professor upon his success with it.

We have received a pamphlet of 44 pages, by Mons. Ed. Bertrand, of Yvon, Switzerland, entitled "The Care of Colonies of Bees; or a calendar of apiculture, with advice for beginners, in the management of bees." It consists of a detailed system of management of bees for each of the months of the year, and covers the entire ground of manipulation. It is published in French; and is scientific, progressive and practical.

Mr. I. V. McCagg, President of the Eastern Iowa and Western Illinois Bee-Keepers' Association, has sent out postal card blanks to each member, and desires that they all be filled out and returned to him, so as to enable him to make a complete report to all the members, before the swarming season commences.

Mr. F. A. Chapman wishes to correct the statement concerning the 800 pounds of honey on page 215. He exhibited it at the Industrial Exhibition held in Cobourg last October, instead of at the Industrial Exhibition in Toronto last September, as there stated.

Mr. Ira Barber desires to correct his article concerning ventilation, in the middle of the third column of page 264. He meant that those *not* ventilated at the top of the hive were in just as good condition as when put into the cellar, and that all upward ventilation was abandoned.

CORRESPONDENCE

For the American Bee Journal.

Controlling a Field.

G. M. DOOLITTLE.

I read with much interest the article found on page 86, by James Heddon, upon the subject of "Locating and Occupying a Field;" and I agree with his views, providing the occupant is a person who is about to change his location in search of a better or different field. In this case, a man who would locate near another apiary to the disadvantage of both himself and the owner thereof, must be so bereft of reason and the spirit that would "do unto others as ye would that they should do unto you," that any course of getting rid of the intruding party would be justifiable. But there is another side to this question, which I wish to speak of, to which Mr. H. does not allude, purposely or otherwise.

It so happens the oftener that the person who will injure the occupant of a field the most, is one who is already an owner of a large property near you, who, from poor health, jealousy, or your reported success in bee-keeping, desires to try his hand at the business. This person, perhaps, is a farmer, a merchant, or a lawyer, who does not want to leave his present location to start an apiary, neither could he well do so if he chose. He starts out with the desire to keep but a few colonies for his amusement, and a little honey for his family, thinking that this will not harm you in the least. After starting, he has a good year as well as you, and he becomes enamored with the pursuit. He falls to reasoning, and says: "I own a large farm, producing plenty of plants and trees which produce honey. Is not this mine by priority, and is there any reason that I should not keep all the bees I wish on account of Mr. — wishing his bees to monopolize my fields? No, sir; I will keep all the bees I wish, and if Mr. — thinks he will crowd me from the field by putting in more bees than I have, I will show him that I can put in 10 colonies to his one." Thus our bee-keeper, by using Mr. Heddon's advice on this man, has "cut off his own nose to spite his face."

What I want to get at is the right of the thing, and for this reason I am going to give a little personal history.

I was born and brought up within 50 rods of where I now live. Father kept bees when I was a small boy, getting as high as 60 colonies in box hives. These all died when I was about 10 years old, of that dreaded disease, foul brood. When I became of age there were about 250 colonies within two miles of us, kept by 3 or 4 persons. From reading King's Bee-Keepers' Text Book, a desire sprang up for bees. Father and I talked the matter over, and the result was we

purchased 4 colonies when I was 22 years old. That fall he gave me his, and I started out alone in the bee business.

I am often amused now, as I look back, at the ideas I then entertained. My highest aim was 20 colonies, and I hoped to secure an average yield from them of 20 lbs. each, or 400 lbs. total; this, at 20 cents per pound, would give \$80. Eighty dollars would give me quite a lift, and I could care for the bees and the farm at the same time, without extra help.

After I had increased to about 30 colonies (did not stop at the 20, you see), the man living about one mile from me, and having the largest number of bees of any one (120 colonies), came to me and talked quite similarly to what Mr. H. advocates, saying I was injuring his business, and as he had a large apiary before I began to keep bees, I ought to quit the business and leave the whole field to him.

I told him that father had kept bees long before he ever thought of keeping them, and that I expected to keep at the business as long as it was profitable, as we had a farm, and I did not see why my bees did not have as good a right to visit the clover and basswood on that farm as any body else's bees. The result was that he felt that I was wrong, and I felt justifiable in the course I pursued.

I wish here to ask Mr. Heddon if he does not think I had a right to keep bees under the circumstances? Well, right or wrong, with the 250 colonies against our 4 to start with, I have lived to see the time when not one of the parties who then kept bees have a bee at the present time. This shows that some man smarter than I may yet start in bee-keeping in my field, and cause me to move out or quit bee-keeping; so Mr. Heddon's "neighbor Jones" may yet cause "Mr. K." to relinquish his field in spite of Mr. Kendall's priority and additional numbers.

But to return to my story. When I had increased to about 100 colonies, a colony of bees was given by a friend to a neighboring farmer, whose land joined with my father's. As we were good friends, he often came to see me and talk bees, which I was always free to do.

He came out the next spring with one weak colony, which did not seem to build up any. He desired me to go and see it one day, which I did. I told him to come over on a certain day and I would show him how to fix his colony. He came, and I gave him a frame of brood just biting the covers to the cells, and told him to take it home and place it in the centre of his little cluster of bees. He did so, and from this he now has nearly 40 colonies. He often says if it had not been for Doolittle, he would never have had a bee, while I realize (knowing the man) that had I not done this, or rather had I shown the spirit toward him, "Kendall" did toward "Jones," in Mr. Heddon's articles, he would have been the worst rival in bee-keeping I could possibly have. As it is, he is contented to double back his bees to 20 colonies each spring, and

keeps them for pleasure, and profit also; for he secures nearly or quite as good results from his bees as I do from mine.

Two other neighbors starting in bee-keeping (one living a mile away, and the other $2\frac{1}{2}$ miles), I have treated as friends, telling them how I worked bees, and showing them freely all I know of the business, till to-day one has 45 colonies and the other 80, each expecting to make a specialty of bee-keeping. In this I have only done as I would be done by, were I starting again, whether Mr. H. thinks it right or wrong.

Now, as I said at the outset, I believe Mr. H. to be right (as long as there are plenty of unoccupied fields) in his advice regarding bee-men who are changing their location; but I cannot think the same course applied to friendly neighbors is a correct one. I believe in letting live as well as living; and if my neighbor desires to start in bee-keeping, there is no law, moral or legal, to hinder him from so doing. After he has once determined to start, I believe he will cause me less trouble if I treat him in a neighborly way, than he would were I to try to show him that I thought he had no business keeping bees.

But perhaps Mr. Heddon thinks as did my good friend Elwood, who once told me that he thought I was doing the bee-fraternity much harm by writing so much information to the bee-papers, and reporting my yields of honey; for, said he, "by so doing you are enticing thousands into our ranks, through your articles, only to be a curse to us by causing lower prices for our honey from an over-production of the same."

Perhaps I am wrong, and mistook my calling when I left farming to enter bee-keeping. Be this as it may, I have never written with but one object in view; namely, that of benefitting others by my experience, as I have been benefited by the experience and writings of such men as Gallup, Quinby, Langstroth and hosts of others. I have only told of bee-keeping as I found it to be, without fear or favor.

Borodino, N. Y.

For the American Bee Journal.

Assorting and Grading the Honey.

JOHN G. SMITH.

How to grade the honey, has for a long time perplexed my mind, and is still unsolved. No doubt there are very many others who are questioning the feasibility or practicability of the apiarist to grade or classify the particular kinds of honey, save two grades; viz., spring honey and fall honey.

In my opinion the true source from which the honey is gathered by the bees at any particular time, cannot be ascertained, from the fact that we have so very many different flowers in bloom at the same time.

I have kept bees on the improved plan for 5 years, and my observations have been that bees of the same col-

ony do gather honey from various kinds of flowers all at the same time; and that each bee gathers a particular kind of honey. For instance, if a bee starts out in the morning and works on a particular flower, it will invariably gather from that same source all the day, and perhaps for several succeeding days, while another bee will visit some other flower in like manner.

At this time we have, in this locality, many thousands of different flowers in bloom, with our bees gathering from every source. It is simply spring honey. My neighbors say that I have my bees so well trained that I can handle them as though they were flies; but I have yet to see the colony of bees so well trained that they will all gather one kind of honey at the same time.

New Canton, Ill.

For the American Bee Journal.

A Bee-Keepers' Union Wanted.

R. J. KENDALL.

Every article in any number of the BEE JOURNAL, dealing with the question of marketing honey, I always read with interest—and I read too few. I entirely agree with Mr. H. O. Edwards, that this subject does not seem to receive enough attention. To me it seems that the cause of the present low rates for honey is very much the fault of bee-keepers themselves.

Mr. Geo. W. House, "from time immemorial" almost, has been preaching up co-operation; but no one appears to pay much attention to him, if we may take actions as evidence of attention. Yet in co-operation, undoubtedly, lies the real secret of success. We want co-operation in communities, in counties, in States, and throughout the whole country. About a year ago I showed how, by co-operation, any section could educate the honey consumers of that section to take either extracted or comb honey; but my article fell as flat as ditch water, on the community; no one apparently took any notice of it, and we are still going on in the same old rut.

I believe that by combination and study, bee-keepers could net \$1,000 per year as an average income; and this amount is by no means high. If a man runs an average of 100 colonies, he ought to get an average of 100 pounds per colony, and this would give 10,000 pounds of honey, which, at 10 cents per pound, would give \$1,000. Is 10 cents per pound too much? Is 100 pounds per colony too much? Surely not. Yet we see extracted honey quoted at $6\frac{1}{2}$, 7, and $7\frac{1}{2}$ cents per pound. Honey sold at retail at 15 cents per pound is cheap; and a 5 cent margin should pay all expenses from producer to retailer; and I believe by right management it could be done.

This method of shipping honey indiscriminately to commission merchants is bad, and tends directly to lower prices, as any one who has lived in a large city will testify; *i. e.*, if he has had experience with commission

merchants. The better way would be to either select some one man to handle all the honey, or else establish our own agency on the co-operation plan. To such a central depot, honey could be shipped in bulk, and be there bottled, labeled, etc., and sold to retailers at not less than a certain price; or it could be sent already bottled, labeled or canned ready to retail. But I hear some one say, "if such a course were adopted, some firm would start up to cut prices." Not postively. For in the first place, with unity amongst honey-producers, such a firm would be unable to get honey at less than 10 cents per pound; or if it did, it would get inferior honey from persons who produced it incidentally, and were simply bent on getting something for an article upon which they had bestowed little or no care. The consequence in the end would be increased repute for the honey produced by the union men, and their brand would become the staple brand.

Now, to prove that my idea is sound, I may say that the honey dealers, Messrs. W. H. Hoge & Co., of London, are now advertising the formation of a honey-producing and honey-selling company, with a capital of £80,000 (nearly \$400,000) in 80,000 shares, of £1 each. They propose to purchase 10,000 colonies of bees in California; ship the honey produced to England, and sell it in the London market, both wholesale and retail. They say, as one inducement to speculators to join them, "the monopoly is complete." If a number of capitalists can do that, surely a number of honey-producers can also do it.

Now, if every legitimate honey-producer was to become a member of our union; and every union a member of a central union, they could control the honey market. They could keep an even supply in all the markets, so that St. Louis should not be glutted and Chicago short, or *vice versa*. Every producer would know just where to send his honey, and by a little organization, we could get regular honey railway cars, with an attendant who could travel with it, to collect the honey, once, twice, or three times per year, and so get better and safer carriage, delivery, etc. I believe the saved burstage and leakage would pay the extra expense of all this. In fact, it would seem that things have all the room to improve, and very little to go the other way.

When at a convention of honey-producers, a leading apiarist gets up and says they cannot calculate on getting more than 5 cents per pound net for honey, honey-producing is below par; for a man, if he is intelligent, desires something more than a bare existence, and that is about all honey at 5 cents per pound will give him. As to local honey markets' of course no man will sell in them at less than 10 cents per pound, and he would always be at liberty to sell at more. If every honey-producer were to decide that he would not sell at less than 10 cents net, in the city market, and 11 or 12 cents in the local market, but keep it first, honey would fetch higher prices. But just so long as men act on the princi-

ple of "every one for himself, and the devil take the hindmost," so long will the foremost not fare so well as he would if he co-operated with his fellows.

Again, we do not want to try to induce every body to become bee-keepers. Any person who really desires to become a bee keeper, by all means help him by advice, etc., but this trying to induce everybody to keep bees, I am convinced is going to benefit nobody. The idea I urge, will benefit alike all good bee-keepers, whether they combine bee-keeping with any other business or not; and it will cause a wide gulf between them and those who let the "bees work for nothing and board themselves," and whose only care is to get the honey every fall.

Finally, bee-keepers who agree with me in the above, do not let this matter rest by your simply saying, "That's a good idea;" but keep up the agitation until we get a "Bee-Keepers' Trade Union." No doubt many will read this article, look at the name of the writer, and say, "Kendall! who's he? He's nobody;" and so pass it by. Never mind who Kendall is, or who he is not. Call him Jones if you like, but consider the idea, which is not original with me, on its merits. If it is bad, give us a better. That "in union there is strength," is as true of bee-keepers as of others; and if we are wise we will work on it.

Austin, Texas.

Improved Section Case.

FRANK A. EATON.

I have sent you one of my Section Cases to be placed in the BEE JOURNAL Museum. I believe the points of most importance in a section case are:

1. To have a case that the bees will enter and work in the most readily.
2. One from which the sections can be removed with ease, and that will keep the sections clean.

These are what I claim for my Case. The bees can enter all parts of it as readily as in any Case I know of. The sections can be removed at all times of the year with ease, and without reversing the Case (as with the Heddon Case), and driving them out, thus breaking out some of the honey.

The Heddon Case has some few points of merit, but they are so few that I would not use it. In the first place there is valuable space taken up with partitions; there is no protection from propolis and wax, to the bottom of the sections, and they are difficult to remove when full. These objections are all overcome in my Case.

I prefer, for the most of the comb honey, sections $4\frac{1}{4} \times 4\frac{1}{4}$, and 7 to the foot. My Case is to be used without separators, and by using sections with narrow tops and bottoms, the bees will seldom bulge one comb into another.

In this Case the sections set perfectly compact, which economizes all

of the valuable space above the brood-chamber. One or two tiers of sections can be used, as desired, in the same Case, by covering it with burlap, or any kind of cloth. With narrow top sections, it is very easy to tell when the bees are at work in them, or when they are full, by raising it.

It can be used to great advantage in out-door wintering, by leaving it on the hive and placing your cloth in the bottom and filling with chaff or leaves, which will make ventilation enough, and absorb the moisture during confinement, thereby preventing diarrhoea in winter. I do not claim that my Case is perfection itself, but I believe it to be practical, and in advance of any Case I know of.

Bluffton, Iowa.

[The Case is placed in the Museum for the examination of visitors.—ED.]

For the American Bee Journal.

Surplus Cases—Bee-Diarrhoea.

JAMES HEDDON.

I have tried very hard to make some improvement upon my surplus comb honey Case. I cannot do it. I do not think that Mr. Dibbern has done it. I do not think that he is using my Case. I think my claims would not be broad enough to call his changes a Heddon Case. I have no claim upon the tin T.

I have never considered my Case best adapted to separators, though its solidity, cheapness, lightness and simplicity are such that I am not at all sure but that short separators going between the wood partitions of the Case just as it is, would be better, involving less complication taken all in all, than the Case described by Mr. Dibbern.

I am glad that he is not so far "off" as to throw away the invaluable beespace. Our bee-spaces, however, never enlarge.

I will now mention what I believe two serious disadvantages with Mr. D.'s plan. 1. As his rows of sections are separated from each other at their bottoms by the thickness of the T, the same opening must exist at the top, with nothing but glue to fill it. 2. It always has been a fact, and will soon be more fully appreciated, that it is of great importance that we have, and stick to a standard size of brood frame and section.

Practically we have their measurements before us in the shape of standard Langstroth, and $4\frac{1}{4} \times 4\frac{1}{4}$.

Now, I cannot make a light, strong, simple case to suit me; that is of a neat proper outside fit for the length of the standard Langstroth hive, and an inside fit for any given number of $4\frac{1}{4} \times 4\frac{1}{4}$ sections. If all the wood in my divisions were in the end pieces, the case would be no heavier, but not as strong.

Mr. D. says that many cannot dispense with separators. By the way they rose up at the last Northwestern Convention in Chicago, it would seem that many can and are dispensing

with them. I do not believe that many will wish to use them after using the $1\frac{1}{2}$ inch section in my original Case.

I have never had any trouble in variation in size of sections. A section would need be exceedingly plump to refuse to go between the partitions; but I can readily see that 4 such plump sections might amount to a misfit in Mr. Dibbern's style of Case.

I do not think it advisable for us to change our sizes of sections except in width; and this we do, keeping that width always such that some whole number of sections will measure one foot. The 2-inch section is 6 to the foot; $1\frac{3}{4}$ scant, 7 to the foot; $1\frac{1}{2}$, 8 to the foot. We can use all 3 sizes in one case at a time; and all 3 sizes fit the shipping crates equally well.

I have tried hard, and have come to the conclusion that for a surplus case without separators, the one I use cannot be improved. If I am mistaken, time and experience will show it.

I wish to say to Mr. Shepherd, with whom I well know how to sympathize, that my apiary has suffered with the ravages of that disease, more radically than his of last winter; and that, too, when not one drop of fall honey was in the hives, and the combs being well filled with rich, ripe basswood honey, well sealed, in a large, dry, warm cellar, and out-doors the same way. I have also, at other times, had excellent success when wintering almost exclusively on honey from the fall flowers he mentions.

Mr. Woodward is coming pretty near to the mark on page 249. His final conclusion, however, will not do. While it is true that brood-rearing is a friendly partner with bee-diarrhoea, it cannot be looked upon as the first cause, or more than one of the favorable conditions or aggravations, because many can testify to the disease in radical form with no attempts at breeding, present.

For the American Bee Journal.

Introducing Queens.

D. R. ROSEBROUGH.

A great many queens are lost when introducing them; but I have not lost one of the 25 I introduced the past year. My method is as follows: First find the queen you wish to supersede, cage her, and place the cage above the bees. It is better to have a one or $1\frac{1}{2}$ story hive. I then move the quilt, put the cage with the wire down, and leave it in that position about one hour, by that time all the bees will learn that their queen is imprisoned. Now remove her, and put the new queen in the same place, leaving her until sundown, when she may be liberated, after which the work is completed.

The old way of caging the queen for 3 days, is a failure; for in that time the bees very often take up with a drone-laying queen, and the new queen is killed, and the colony about ruined.

Do the work in the morning, but if you cannot readily find the queen,

close the hive again and wait; do not be in a hurry, for you can keep the new queen a week or more if necessary.

I would ask Prof. Cook why he objects to the use of oil-cloth in the place of a honey-board. I notice that he condemns the use of it, but gives no reason. I had concluded that it was the best thing to use, but if any thing else is better, I would like to find it out. Others besides myself are interested in this matter.

For the American Bee Journal.

Winter Stores, Pollen, etc.

H. V. TRAIN.

Mr. A. A. Fradenburg, on page 76, asks me to explain, 1. Why his bees had diarrhoea when fed on clover honey. I did not intend saying that bees never would have diarrhoea while eating clover honey; but that clover honey is less apt to sour than late honey; and hence, is safer for winter food. There is no honey that will not sour under certain conditions; and even sugar syrup will sour sometimes and cause diarrhoea; but it is less apt to do so, if made thick, than fall honey, and hence, is safer for winter stores; and the same is true of clover honey. In question No. 2, he asks if I ever knew of a colony to have the diarrhoea when there was no pollen in the hive. I answer no; for the reason that I never knew of such a colony; and it is very difficult to get a colony in that condition. If we feed pure sugar syrup at any time when there is pollen in the fields, or its substitute to be had, the bees are sure to store either the pollen or its substitute, while storing the syrup. They will do this for the reason that it is a necessary article in their household operations.

Bees get a substitute for pollen from various sources. My kind of meal will do; and they get it even from sawdust. I have often seen them loading their baskets from sawdust heaps; and, unless, we give them combs which have never been in a brood-chamber, there will surely be some pollen in the combs. I have never yet succeeded in getting a colony into the cellar without some pollen, or its equivalent in the hive. Others may have done so, but unless they have examined very carefully, I should be inclined to doubt.

Honey will sour in one colony when it does not in another at its side, and in the same temperature. In one, the honey may be riper than in the other; or there may be more bees in the one than in the other, and hence, the difference.

Honey will not sour while covered with bees, or as warm as the bees' breath; but when honey outside of the cluster gets cold enough to condense their breath, or rather the vapor therein, it becomes wet, and if this is long continued, the honey will sour.

See Mr. Heddon's remark on page 74, under "Frost Proof House." "But when below (that is the temperature),

dampness will injure the honey at once." Every body knows if you breathe upon any cold non-conducting substance, it becomes wet at once; and every honey-producer is aware that if honey is kept wet, it will soon spoil.

Mauston, Wis.

Mahoning Valley, O., Convention.

The annual meeting was held at Newton Falls, O., on Thursday, April 10, 1884.

Pres. Carson asked, "What is peavine clover, its habits and growth?"

Mr. Page: It is a very rank-growing clover. Its seed matures from the first growth of the season, and I think, secretes a large quantity of sweets.

Mr. Ovitt asked, if a double-walled hive with a dead-air space was not preferable to packing with chaff, and said: I have noticed that those who pack with chaff are no more successful than others. I fear that the chaff will gather dampness and engender disease, while with the air-space, the natural warmth of the bees will dry this portion of the hive. I notice the most of my loss in wintering, is by not having proper ventilation; they smother, or there is not enough circulation.

Mr. Langton: I have tried for the last three years the dead-air packing, and my bees came through well. I have tried two methods of wintering in clamps, out-door and in a cellar. My way of out-door wintering is as follows: I dig a trench some 4 inches wider than the hives, and 8 inches deep on ground, well drained. Fill this space with chaff or fine cut straw, lay a plank lengthwise on the straw, place two strips 2 inches square running parallel with the plank; take the bottom off of the hives, and place them on these strips; then take boards and form an inverted-shaped covering; cover with straw a few inches deep, then with about 8 to 10 inches of soil. At one end of the clamp I put in a small ventilator; take four laths and nail them together, and let it reach down near the bottom of the hives. At the other end I put in another one lying horizontally and protruding through the bank of earth, and running through under the first hive, covered with a little straw to exclude the light. With this system of packing, I have never lost a colony. By it the bees are kept dormant, and there is a proper circulation of air. Bees kept in this way consume but little honey, compared with the old way of keeping them. My method of cellaring bees is as follows: I stand the hives 2 feet from the cellar wall, pack one tier above the other, if the room is limited; and ventilate as in the clamp process, by perpendicular ventilators run up into the room above. The percentage of loss is small by this process. As to giving bees a flight in winter, I do not practice it. If I find that they are uneasy and make a rumbling noise, I water them by placing an empty section inverted on the cap of the hive just un-

der the carpet. They will drink readily, and then it is all quiet.

Mr. Page: I am aware that we can overdo the chaff packing. We pack too closely, and do not properly ventilate.

Mr. Bowman: The dead-air space is preferable to close chaff packing.

Mr. Ovitt: I tried the feeding of a colony which had no pollen, with sugar syrup, and was successful. For extracted honey this is a good process.

Mr. Bowman: If honey gathered late in the fall is not fit to winter bees on, is it right to offer it on the market?

Mr. Langton: We would be killing our own market; always sell a first-class article.

Mr. Paine: I have a quantity of not first quality of honey gathered late in the fall; what can I do with it?

Mr. Langton: Feed it in the spring when the bees are gathering pollen.

Adjourned till the afternoon.

First on the afternoon programme was the election of officers, which resulted as follows: For President, Leonard Carson; for Vice-President, S. S. Ovitt; for Secretary, E. W. Turner, Newton Falls; for Treasurer, H. A. Simmons; and an executive board of three, C. D. Kistler, C. R. Page, and C. G. Beardsly.

The subject of queen rearing was then discussed.

Mr. Bowman: First have a strong colony; remove the queen; examine the frames and find a nice frame of eggs, and watch carefully the hatching of each, or give a frame of eggs to a small nucleus, and let it rear a queen from this frame of eggs; as to testing of queens, I let them remain with the nucleus.

Mr. Page: I wish perfect cells. To do this I draw a knife across the top of the cells, sometimes cutting the comb in two, say 4 inches from the top of the frame.

Mr. Langton: I use a strip of foundation and destroy every other cell, so as to enlarge the distance between the cells.

Mr. Page: I use new combs.

"How early in the spring is it admissible to commence to feed your bees to stimulate brood-rearing?"

Mr. Langton: I take my bees out of the cellar as soon as it is safe to do so. I thoroughly clean out the hives, insert the division-board, and commence to feed as soon as the bees commence to gather pollen.

Mr. Hammon: I live close to a flour mill; my bees have no trouble in gathering pollen.

Mr. Page: I clean out the hives; put the bees on as few frames as possible; feed pure honey, and about the first of May I go over the hives again, give them more frames, and get ready for business.

Mr. Langton: I even up my colonies about May 1; take frames from a strong colony and insert it into a weaker one, and work up a strong force in this way. Some colonies gathered as high as 120 pounds of honey last season.

Mr. Bowman: I put my bees into winter quarters, and do not disturb them until apple-bloom is over.

Mr. Simmons: I commence to feed early by giving them flour and granulated sugar. Maple syrup is one of the best sweets to feed bees.

Mr. Hammon: I prefer pure Italian bees.

Mr. Bowman: The Italians are the standard bees for gathering honey; the Cyprians are a good breed, especially the American bred.

Mr. Simmons: I think the Langstroth hive is preferable for all purposes; at least it is my choice.

Mr. Langton: The Simplicity-Langstroth hive is my preference.

Mr. Hammon: I have used all the modern hives, and find the Langstroth the least trouble.

Mr. Simmons: Millet clover is one of the best honey-producers; it blooms all the season.

Mr. Page: In my section of the country basswood abounds in the woods.

Mr. Bowman: I would plant locust and the tulip. Melilot clover is one of the best honey-producing plants.

It was moved that a vote of thanks be tendered Mr. W. Z. Hutchinson, and others for their able articles.

The President then appointed Mr. Hammon and Mr. Page as essayists for our next meeting.

Adjourned to meet in Newton Falls, on June 6, 1884.

Priority of Location.

J. E. POND, JR.

Mr. Heddon, in his article which he holds out to be an answer to myself, either misunderstands my position or forgets the nature of the article to which I replied; for he nowhere touches upon my own position in regard to the question. This being so, I should not feel called upon to reply further, were it not that Mr. H. claims that because I am a lawyer, I am not the best qualified person to decide the matter in dispute.

Now, without contending to boast of my intellectual qualifications, I fail wholly and entirely to see why the fact that I am a lawyer disqualifies me in any sense from forming and expressing a correct opinion.

But what is this question that a lawyer is not able to decide? Simply this: Mr. H., in the original article which drew a reply from me, assumed that no one had a right to locate an apiary in a field already occupied. To this position I demurred, and I still demur; and claim that one person has the same right as another to locate an apiary wherever he chooses.

As well might "the butcher, the baker, and the candle-stick maker" claim right of priority in a certain town, as for an apiarist so to do. Mr. H.'s whole article is an attempt to prove a matter which is not disputed by me, and one that I did not suppose was even a question of dispute, viz: that a fully occupied field cannot be further sub-divided without causing loss to all its occupants. This matter

I admit; but the question of priority of location giving a person any exclusive right of occupancy I deny, both as a lawyer and a man; and fail as yet to see any good reason why my denial is entitled to less weight because I am a lawyer.

Foxboro, Mass.

For the American Bee Journal.

Diarrhœa—Marketing Honey.

J. E. CADY.

Of the many causes producing disease in bees, I think worry is the main one. I have seen bees spot the hive in a few minutes after I had removed their queen, on a beautiful summer day. In winter frequent disturbance, even if they have the best of honey, will cause them to spot the hive. Scarcity of honey, either from granulation in the cells or by becoming sour, or in any way unsuitable for the sustenance of bee-life, and long confinement will bring on the disease.

I do not think cold has any direct cause, but indirectly by causing honey to granulate, gather dampness, and sour. Pollen has nothing to do with it, except when it gathers dampness, ferments and mixes with the honey, then it has the same effect as sour honey, having lost its proper element as bee-food. We might as well exclude the honey from the hive for fear of its souring, as to exclude pollen. If bees are forced to eat pollen from a lack of honey, they will starve, and all will become sick if starved. Old bees cannot live a great while in the winter, even upon the nicest quality of pollen.

To supply proper food in sufficient quantities, is a long step in the right direction; but time will change the quality of honey in any cellar. My cellar is so dry that when I sweep up the bees, it raises a dust; and yet it is no place to keep honey in first-class condition, even in the summer. There are two outside hatchways to it, and it can be ventilated in a few moments, making it as nice as an upper room.

When brood-rearing begins in the spring, bees want water, especially if they are in a dry cellar; this causes a worry that makes them spot the hive. All hives should have a hole within easy reach of the bees, above the entrance that cannot be clogged with bees. In colonies which worry, the bees will come to this hole. Now, with an awl make a small hole about 1 inch above and a little to the right of the first one; press a tack into it, then hang a small wet cloth on the tack, so it will hang down by the opening in the hive; keep this cloth wet, and your bees will not suffer much from worry. If the honey has granulated, the water will assist them to eat it. If they still worry, it is evident that sour honey or a scarcity of stores is the cause. I have stopped 2 colonies with water alone, this spring. Towards spring keep the temperature down as low as possible; take every block from the entrance, give each colony plenty of ventila-

tion, but on bright, warm days, close the ventilation of the cellar, and open it at night.

There will be a general worry towards spring that you can do nothing for except to sprinkle the fronts of the hives with water, or keep a wet cloth on the tack. The first pleasant day, when the temperature is 40° or 45° in the shade, set them out. If you use loose bottom-boards, clean off the dead bees as you set them out; then keep the entrances closed to within $\frac{1}{2}$ an inch, to keep them from swarming out. Watch them closely to prevent accidental loss of swarms. Be sure to commence watering them the next day with warm water, at some convenient place near the yard. This will save many thousands of bees. Continue it all the spring, for it is one of the greatest helps in the business.

I have had 10 years experience in selling honey. When I began, I found comb honey, from the body of the hive in Langstroth frames, on the market at 30 cents per pound, and extracted honey was unknown. I run my apiary for both comb and extracted honey; about $\frac{3}{4}$ extracted. I began by convincing the druggists that my extracted honey was pure, and succeeded in selling them 500 pounds of white clover honey, at 25 cents per pound. It saved them 5 cents per pound, and the trouble of getting it from the comb themselves. I then sold my basswood honey from house to house, at 20 cents per pound, and I soon found that it was necessary to have a wholesale price, which I fixed at 16 $\frac{2}{3}$ cents a pound, and succeeded in selling my whole honey crop (over 3,000 lbs.) in my home market. I sold 800 pounds of comb honey in two-pound sections at 25 cents per pound; this I have kept up with slight variation, and a steady decline in prices, till comb honey retails slowly at 20 cents; wholesale, good at 15 cents. For extracted honey, wholesale, 10 cents, and retail 12 $\frac{1}{2}$ cents, with demand good. Almost a fabulous amount of pure honey was sold in this market, last year. My sales are, up to date, 6,000 pounds during the past year. I have used the pamphlet, "Honey as Food and Medicine," also a card of my own get up. I find these gives me a vantage ground; save much time, tell the people at a glance with whom they are dealing, save mistakes, bring me many orders and sales that I should not otherwise get, and hasten acquaintance. It takes years to establish a business integrity, which these help to gain more quickly. That is the foundation of success; it is our capital, and should be valued highly. I use these cards in the cities near me, deliver the honey in person when I get orders enough to pay me to go, but always take along more honey than is ordered. I receive but few orders for less than 25 pounds, and often 50 and 100 pounds. I sell a little cheaper by the hundred, but make no difference on 25 or 50 pounds.

To get the full advantage of circulars, a first-class quality of honey has to be delivered in every case; if not,

the advertisement proves a damage; but now honey has to be a thoroughly good article, and well ripened in the hive.

Medford, Minn.

For the American Bee Journal.

My Report on Wintering.

JOHN YODER.

I put 53 colonies into the cellar Nov. 13, 1883, and took them out April 18, 1884. My cellar is 25x16 feet, made of stone and brick; and under the kitchen a 3-inch ventilating pipe reaches down from the chimney, then along the cellar floor to a little room 16x8, partitioned off one end of the cellar. Into this room I put the 53 colonies in 2 rows 4 deep; the bottom row standing on empty bee-hives. Each hive was setting on its own bottom-board, and each had an oat-hull cushion on the top, and also contained 30 pounds of good white honey. During all the forepart of the winter, the thermometer ranged from 42° to 46°, and the latter part 49°.

About Feb. 1, the bottom rows commenced to show signs of diarrhœa, and a little later the second row showed the same, and soiling the entrances of the hives badly. So the disease spread upward slowly. I could not well put them out without disturbing the top rows, which were as clean as when I put them in. When I put them out, I found the bottom rows had used nearly all their honey, the top rows using the least; but all quite clean inside. One had starved to death after using at least 30 pounds of good honey. One out of 53 is not bad I think. I took up 2 bushels of dead bees.

The last 2 winters my bees were in the same cellar, prepared the same way, and were in about the same length of time, and only consumed on an average 9 pounds of honey. I think my cellar was too warm, and there must have been some difference in temperature between the bottom and the top of the cellar, to cause the difference in the keeping of the bees; at all events I think the bottom rows commenced to breed, then commenced to eat pollen, thus causing diarrhœa. They must have bred a lot somewhere, and the old ones "jumped off the stage," or where would all the dead bees come from?

I hear of a great many bees dying in Elgin county and elsewhere. I use the Quimby hanging-frame hive with no division-boards, nor holes in the comb. I cannot see but what empty comb or combs, in a hive with a small colony in the centre, is not as well protected as though they had a division-board in them. The season is late, and there is not much pollen yet. It is very dry here. A little rain would make it jubilant for the bees.

Springfield, Ont., April 28, 1884.

☞ The Kentucky Bee-Keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed). N. P. ALLEN, Sec.

For the American Bee Journal.

Description of my Hive.

G. I. WILLIS.

I make my hives about 3 inches deeper than the frames, which are 10x15 inches, inside measure. I nail on the side of the hive, in each corner, 1 inch strips 10 $\frac{1}{4}$ inches high. To these strips I nail laths about $\frac{1}{4}$ inch apart, and then fill with straw or chaff back of this, putting on a plate or strips reaching from one corner post or strip, to the other, thus making a 4-inch, permanent, chaff wall. Then put metal rests on these end plates for the frames to rest upon. My frames run lengthwise of the hive. I make a passage way for the bees under one of the chaff walls.

For winter preparation, I take out all of the frames except 5 or 6, and put them in the centre of the hive, and slip my division-boards upon both sides of the frames, which leaves about 4 inches on either side. These spaces I fill with chaff or straw, and also on top of the frames. Thus the bees are completely encased in straw or chaff.

It is considerable work to prepare them in this way; but then, I think it pays every time. It is a great satisfaction to me to see my 28 colonies so snugly packed in this way. They all came through this extreme cold winter so nicely. Packed in this way, the brood-chamber is kept perfectly dry and warm.

My frames are closed ends, and top and bottom narrow, so they can be slipped up snugly together for packing, and yet not crush the bees. I have in my mind a device that can be used with narrow frames, to prevent them from coming together and crushing the bees.

The advantages of this hive for summer use is: 1. In the spring, as soon as the weather becomes warm, I take out the straw or chaff on the top and sides, and enlarge my hive to the capacity of 10 frames, as the bees need them.

2. It is so much easier to get to the frames than in a hive where they come up flush to the ends, and are stuck fast with propolis. With the frames resting on metal rests on the end plates, 3 inches from the ends of the hive, it is impossible for the bees to fasten them.

3. With the walls of the hive running 3 inches above the frames, and the roof made with a 3-inch strip on the sides, it gives plenty of room for a case of sections inside, without adding a second story; though if it is desired to add a second set of frames, I only need to put on a super or large section, and I have a complete two-story hive for extracting. The Root chaff-hive, as I understand it, is always a two-story. This, I think, would be an objection. Another advantage in having the sides, and ends also, run 3 inches above the frames, is that it gives room for chaff for winter packing.

I have always had a great deal of trouble in fastening foundation in the

brood frames. Last season I experimented by putting it down to the bottom-bar, and leaving the space above; in this way it needs no rubbing down to the frame, or melted wax, or any fastening at all, other than the wires. The bees will run little fastenings along the wires at the top, and fasten them to the top bar, and then fill the spaces between. In this way I get a solid comb for extracting.

I slant the roof of the hive like that of a house, and use shingles, double course, painting them well. This makes a roof that will not crack or leak, and will last for years.

Farmer City, Ill.

Woodstock, Ont., Convention.

The bee-keepers of Oxford County, Ont., held their first general meeting at Woodstock, on Saturday, April 19, at 10:30 a. m. After the routine business was disposed of, President J. B. Hall gave a report of his visit to Toronto in reference to the passage of a Bill relative to bees affected with foul brood.

A motion was passed authorizing the secretary to correspond with the secretary of the Ontario association, with a view to bringing about such united effort as will result in the passage of such a law.

The meeting adjourned till 1 p. m.

After the calling of the roll in the afternoon, the question of spring management of bees was taken up.

Dr. Duncan said that, as a rule, strong colonies will take care of themselves if they have sufficient food.

Mr. Hall said that weak colonies seldom paid for building up with brood taken from stronger colonies; while to stimulate with feeding would induce robbing to a great extent. As a rule he believed it best to let each colony stand on its own strength and resources, and if any failed to come up to the standard of excellence desired, double up and introduce a new queen, or give a queen-cell.

Mr. Frith said that management should begin in September, as the condition of the bees in the spring depended on that they were in when put into winter quarters.

Mr. Elpore did not favor building up weak colonies, by taking bees or brood from stronger ones.

Mr. Emigh said he thought plenty of food and heat were the principal requisites to secure strong colonies in the spring.

The question of spring feeding, or stimulation to induce breeding, was taken up, when the general impression seemed to be, that it did not pay until the weather became warm, and the season pretty well advanced.

Mr. Shannon said that bee-papers advanced the idea that as a general thing bees wintered inside were more subject to spring dwindling than those wintered out-of-doors; but he would like to hear the subject discussed.

Mr. Hall thought the cause for the idea being entertained, was due more to the fact that when colonies were taken out in the spring, they usually were very full of bees, a large portion

of which were old and ready to die, while those wintered out-of-doors allowed the old bees more opportunity to come out, hence the dwindling was less perceptible.

Mr. Emigh said he found that late feeding was sure to induce dampness.

Mr. Frith spoke on the meteorological effects of air, showing that when a current of cool air was allowed to pass through a bee-house or cellar, when it came in contact with the warm air inside, it expanded, thereby absorbing dampness, leaving the house in a dry and proper condition.

A high temperature was considered far preferable in wintering, as there was less danger from diarrhoea by honey that was not sealed or ripe when going into winter quarters. From 55° to 60° was considered the most desirable temperature.

Mr. Tennant said his bees had eaten an unusually large quantity of honey in wintering. The temperature of his cellar averaged less than 45°, but he thought if the temperature had been higher, less honey would have been consumed.

Mr. Hall thought pollen was very useful, and served as an important factor in successful wintering.

The disease of foul brood in bees was next discussed.

Dr. Duncan made a clear and intelligent exposition of the disease and its cure. When the question: "Is there any known cause for foul brood?" was elicited, Mr. Hall replied that there were many theories, but no positively known cause.

It was considered best to destroy bees affected with foul brood rather than attempt a cure, as it would in all probability be the cheapest in the end.

The best method of increase was the next subject discussed.

Mr. Emigh thought if the colonies were doubled, that would be a sufficient increase, and would advise increase by natural swarming.

Mr. Malcolm said for those wishing increase, rather than take off honey, it would be safe to increase two, or even three fold, if the season were favorable.

M. S. Schell explained his method of securing an increase of colonies during the last season, which was simply by making nucleus taken from the strongest and giving them capped queen-cells or young queens reared from the best colonies, taking special precautions to keep the nucleus warm.

The following question was next placed on the table by Dr. Duncan: From which colonies will we receive the most honey; the ones that are prevented from swarming as much as possible, or those that are allowed to increase a reasonable amount?

Messrs. Hall and Emigh were both of the opinion that taking the average season, the most honey would be received from the colonies that were allowed to increase; of course the honey taken from the new colonies being included with the old one.

In reference to making a display of honey at the fall Agricultural Exhibition, it was resolved that the ex-

executive committee make such arrangements as may be deemed best.

Adjourned to meet on the 3d Saturday in next August, at 1 p. m.

Review of Unsettled Points.

EDSON J. SMITH.

No report of a trial with comb foundation should be given to the world by one who has made such advancement in bee-culture as has Mr. Heddon, when such comb foundation as the Vandervort and Olm are left out; both of which are equal, if not superior to any which were used in his trial; and it does the manufacturers of both of the machines great injustice. The Vandervort is the leading machine in this vicinity, getting nearly all the wax to make up, in preference to other machines.

Last year I used over 600 frames filled with the Vandervort foundation, and but 4 of them sagged. I use no wire, as I consider it useless when foundation is fastened in as it should be.

Double-walled hives are taking the lead in this county. At least $\frac{3}{4}$ of the apiaries contain them, and the last year over 70 tons of comb honey was produced in them, in one and two-pound sections, and all being first-class honey. Though the losses were heavy in some localities last winter, here it was scarcely anything.

In the spring of 1881, my bees had come through the winter very strong, and bred up fast. About May 1 they commenced to bring in honey and pollen from the woods. The sun shone out in the morning very warm, there was no wind, and the bees went to the woods in large numbers; about 10 or 11 a. m., the wind blew up from the north very cold; and the bees on their return to the hives, became chilled, dropped on the ground and died. You could pick them up everywhere, loaded with pollen; and the consequence was that the colonies were not nearly so strong by May 15 as they were on April 1. Now, I know they were well wintered, and had the weather kept warm, they would not have dwindled; and yet, Mr. Heddon, on page 578 of the BEE JOURNAL for 1883, in reply to Mr. Mitchell's question, says: "It is my opinion that no bees ever spring dwindled that could rightfully be called well wintered."

If the wind comes from the north and blows hard and cold when the sun crosses the equinoctial in March, the bees will dwindle badly in the spring; but if the wind comes from the south, or if the weather is calm and the wind changeable, the effect on the bees will be opposite from the former condition.

Bees will not dwindle as badly in double-walled hives packed with chaff, or feel the excessive heat of summer, as in single-walled ones.

The black bees are the best to go to work in the sections, and build white comb which will take the first premium every time over that made by the Italians. The blacks are a hardier

race of bees, less liable to swarm or abscond, do not breed so fast after the honey season is over, and will not cling to the comb nor rob as quickly as the Italians.

I cannot agree with Mr. H. in regard to separators being cheaper. I am getting out 2,000 of them for one-pound sections, each one being long enough for two sections, and 500 for two-pound sections; the whole cost of which will be \$6.50, besides my own work, and I think they will last a lifetime.

Wood is preferable to tin for separators, as it is warmer and easier for the bees to cling to or climb on. As nearly all the honey in this county is glassed, we shall continue using separators, for we believe it pays to glass it when we can make \$6 per day for washing and glassing; and then the dealers demand it. As a proof of this, one firm in this vicinity bought over 7 tons of honey last fall, all of which was glassed.

New England.

For the American Bee Journal.

Seneca County, O., Convention.

Met on Saturday, April 29, at Tiffin, with President Troxel in the chair.

"Early Spring Treatment" was the first topic discussed. Mr. Overmyer, of Sandusky county, advocated letting bees remain quiet, not disturbing them too much. After an examination sufficient to see whether they need feeding, and to see that none are motherless, they should then be left to themselves—no opening and breaking their clusters out of simple curiosity. Have a purpose when you open a colony, and when you do so, perform the operation as rapidly as possible, and then quit. They need to be kept warm so that breeding may go on rapidly. He advised using a division-board, and contracting the brood-chamber to the number of combs that the quantity of bees will cover and no more. As the weather gets warmer, and the bees increase in number, give more combs. Usually one comb at a time is sufficient, and always put the comb you give them in the centre, and not on the outside of the hive. In describing the different qualities of honey, he gave a description of a dark-colored honey the bees had gathered at his apiary in Ottawa county late in the season, from the tall cane growing on the low lands along Lake Erie. He found that any colonies going into winter quarters with any of this quality of honey uncapped, was fatal to the colony. The bees gathered this from the blades of the cane, and he believed, upon examination, that it was the product of a plant louse. He doubted very much whether there was any such thing as "honey dew."

Mr. Feasel thought it unnecessary to contract the space in brood-chamber, believing that the bees would see to that, and generate heat sufficient to protect and mature the brood. He had read in a bee-paper of a case where bees had generated heat sufficient to melt down their combs when the thermometer was below zero. He

was quite sure that there was such a thing as honey dew when the conditions were favorable for its formation.

Mr. Martin did not believe in any such reports that bees could generate heat sufficient to melt down combs, when the thermometer was below zero. Bees, he said, had no nose, and did not breathe by means of lungs as animals do, nor yet by gills as fish do, but through small holes called spiracles under their wings. It was simply an impossibility for 40,000 bees—a strong colony—to inhale sufficient oxygen to produce that amount of heat. He believed that bees frequently, when severe cold continued for an unusual length of time, exhausted their physical strength and died from over-exertion, in their efforts to keep warm, by their rapid breathing, as that is the only means they have of increasing the temperature in their hives. We all know that one way to warm up, when very cold, is to breathe rapidly for a short time.

Adjourned till 1 p. m.

At 1 p. m. the association met with an increased attendance. A general examination of honey, hives, etc., took place.

"What kind of hive shall we use?" and "Bee Pasturage," were the topics for the afternoon session. Mr. Overmyer explained his process of transferring. He said he used two kinds of hives, the Langstroth and the Gallup. He believed in having large hives, so as to give plenty of room, and when any colony weakens from any cause, contract space by a division-board. He explained extracting honey, and said that last summer he obtained 41 barrels of honey from 175 colonies—spring count, in 9 days—mostly from linden, as white clover was very scarce in this locality.

Mr. Martin explained, for the beginners, the process of transferring and putting a new swarm into the hive. Would not transfer too early; not before the fruit trees are in bloom, and not then on any day when the bees could not fly in safety from cold blasts of wind. He preferred the standard Langstroth hive.

Mr. Feasel said he used the Langstroth hive and worked for comb honey; explaining fully his mode of securing honey in sections. He said if he obtained 25 pounds as an average from all colonies, old and young, it was equal to the large yields from spring count. Can take one good strong colony in his apiary, in early spring, and increase to 10 or 12 good colonies by the time white clover and linden open.

Mr. Troxel gave his experience with the Langstroth hive. He said he worked for both comb and extracted honey. He exhibited some very fine specimens of comb foundation, of his own manufacture.

The subject of "Bee Pasturage" was postponed until the next meeting.

Several new names were added to the membership list of the association, and the next meeting promises to be one of unusual interest.

Adjourned to meet May 17.

E. J. C. TROXEL, Pres.

J. T. MARTIN, Sec.

SELECTIONS FROM OUR LETTER BOX

White Clover Looks Promising.

My bees are all in fine condition; no loss in wintering. This is the fourth winter I have packed my bees in chaff out-of-doors without loss, and I am still satisfied with chaff packing. Bees are now gathering honey rapidly, and building comb. Everything bids fair for a good honey crop. White clover never looked better at this time of the year, and this is from which we get our honey, if we get any surplus at all. The Langstroth hive is taking the lead in this locality, and the deep frame is becoming a thing of the past. Bees suffered terribly during March and April, where they were not protected; many have lost all either by spring dwindling or robbing. J. G. NORTON.
Maeomb, Ill., May 1, 1884.

Bees Starving in June.

I think there is no foul brood in this section of the State. There are many who keep a few colonies, and some lose all by starvation in June. I live in the Blue river valley, and in the spring the bees work on maple, willow, gooseberry and raspberry blossoms; but in June, for about three weeks, nothing blooms, and the bees have to be fed. After July 1, comes sumac, heart's-ease, snowdrop, catnip, etc., until frost, and bees do well during this time. I have 15 colonies of hybrid bees, which I expected to increase to 50, but the weather has been very cold and wet.

DAVID M. IMLAY.

Seward, Neb., April 28, 1884.

All is Lovely with my Bees.

My bees wintered well in the cellar. In 30 colonies there is not one moldy comb. The tops of the hives were all removed, and the honey boards left open. I am satisfied that more bees die from lack of ventilation than from any other cause. The first fruit blossoms have just appeared, and today the cherry-trees are alive with the busy workers. We are expecting a good honey season.

I. P. WILSON.

Burlington, Iowa, May 2, 1884.

Bees Swarming.

Bees have been doing nothing up to the 25th, but stock up in brood. For the last few days they have been doing finely; accomplishing more in the last four days than in all the rest of the spring put together. It has been cold and wet all through April. Not many colonies have swarmed, and those which did so, took to the woods. The first swarm from a colony would stay and do finely, then the weather turned cold, the young queens all hatched out, and when they would come out, the bees would follow them and all make for the woods. I suppose it was owing to

their coming out to be mated, and the bees would follow them. If I am not correct in this, will some one give me the reason? I had as many as 3 swarms from one colony in the same day. I examined and cut out all the cells except one, and stopped the swarming. Hope I will not have many swarms this season.

DR. H. M. WILLIAMS.

Bowden, Ga., April 30, 1884.

Wintered Well.

Bees in Central Ohio wintered well. The colonies are now strong in numbers. White clover is promising. I think we shall have an abundant honey crop. AARON BENEDICT.

Bennington, O., May 6, 1884.

Moving Bees 200 Miles.

For 4 years I have been engaged in bee-culture; but I have been residing in a rather unfavorable location (Bates Co., Mo.) for the business, until April 3, 1884, when I shipped my 50 colonies to Carrollton, Mo. They were in the car about 30 hours, and were moved a distance of over 200 miles. In these colonies are 600 nice, straight combs in movable frames, and all came through with the loss of only 3 combs broken; but the bees were in fine condition after their trip. My bees are nearly all Italians. I am very much interested in bee-culture, and shall continue making it a study.

ELI E. STARKEY.

Carrollton, Mo., May 5, 1884.

Heavy Losses of Bees.

Our bees at the College are doing well. I am sorry to learn that the losses have been heavy in many parts of the country. The time when ignorant bee-keeping would succeed, is gone by.

A. J. COOK.

Lansing, Mich., May 7, 1884.

Fruit in Bloom, but no Nectar.

Ninety out of 96 colonies came through the winter. Sixty, which were covered with fodder, did not winter as well as the 36 in double-walled hives on the summer stands. The 6 lost were among those covered, and 2 of them were unusually strong when covered last fall. Some drone brood is now sealed with a few drones out of the cells. Some drones were kept through the winter. Wet, cool weather has delayed breeding, and bees are still inclined to rob, with a profusion of fruit-bloom open; but the cool nights prevent a secretion of nectar. Some colonies have too much honey left. Figwort has come up very thickly where the plants were cultivated among the corn last year. The prospect is good for a fine honey-crop. WILLIAM CAMM.

Murrayville, Ill., May 4, 1884.

Bees Gathering Honey.

Bees are gathering honey rapidly from the early yellow flowers. I do not know their name.

WICKLIFF FISHER.

Hamlar, O., May 5, 1884.

Smart-Weed Honey.

On page 267, D. R. Rosebrough complains that his bees did not winter well on late honey. I want to ask him if there was any smart-weed bloom in his locality. A few years ago, in this locality, we had no honey crop until smart-weed bloom; it was thick all over the country; and bees were in need, and worked it very greedily; and the result of this honey (or something else it may be), was that nearly all the bees died during the winter, or left the hive the first warm days of spring. I think I am safe in saying that not one colony in 10 survived to May 1. They left the hives full of honey, but filthy. I received one dissatisfied colony three times, but could not make it stay. I am satisfied that the trouble was in the honey, and have about condemned smart-weed as unfit for winter stores. If I am wrong, I would like to be convinced, for we can nearly always depend on a crop of smart-weed here.

J. B. MILLER.

Montezuma, Iowa, May 1, 1884.

Bees Confined 161 Days.

My bees wintered nicely; part of them being in the cellar and the rest on the summer stands. One colony did not have a flight for 161 days, and it came through in good condition.

G. W. DUNBAR.

Embsen Centre, Me., May 5, 1884.

Small Loss in Wintering.

Bees in this section are in for a big boom this season. I never saw them in as fine condition at this time of the year, and the loss of the past winter will not average 1 per cent. The greatest loss was with myself. I have only a very small portion of my apiary left, but hope for the best.

J. H. ROBERTSON.

Pewamo, Mich., May 6, 1884.

Good Increase.

I started one year ago with 3 colonies, and now I have 10 strong ones. I lost one colony by not giving it enough bees last fall. There was not more than 1 pint of bees in the hive, and they froze to death. I use the Armstrong hive. I wintered my bees out-doors on a north slope of ground, fully exposed. The trees are just commencing to bloom, and the bees are beginning to work, but I have not the time to manage them as they should be. P. E. VANDENBURG.

Jerseyville, Ill., May 3, 1884.

Juneberry.

For more than 10 days past the bees have been diligently at work among the Juneberry (*Amelanchier canadensis*) blossoms. In this vicinity these little trees are very abundant along the creeks and rivers, and are always white with blossoms long before the apple and plum trees bloom. In favorable weather it yields honey profusely; and up to date the bees here have stored from 3 to 8 pounds per colony, and are still at work. The

honey is of a light brown color, several shades lighter than buckwheat honey. Coming early into bloom as it does, and at a time when there are no other honey-bearing flowers to speak of, the Juneberry occupies an important place among honey plants. The Juneberry tree is receiving considerable attention at present among horticulturists, for its fruit. A number of cultivated European varieties are now being tested in our College nursery.

F. A. HUNTLEY.
Ames, Iowa, May 6, 1884.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Wax, Queens, Out-Door Feeding, etc.

1. What is the degree of temperature above which wax should not be heated?
2. How shall I dispose of the cappings, and rid them of the adhering honey, when I extract? I have purchased an extractor, but never used one, or saw one in operation.
3. Is it better to let colonies rear their own queens, or to give them cells from choice stock, or a thoroughbred queen?
4. Will out-door feeding stop robbing?
5. How are wax comb-guides made?
6. Do bees produce wax at pleasure?
7. Will mixed races of bees degenerate if allowed to rear their own queens?

DAVID M. IMLAY.
Seward, Neb., April 28, 1884.

ANSWERS.—1. It should not be heated sufficiently to scorch it. My experience has led me never to heat it to a higher degree than is absolutely necessary.

2. Cappings should be first scraped into a receptacle with a coarse wire cloth bottom, till drained all thoroughly. Then place them loosely in flat pans, which put into an oven up from the bottom, with one of the oven doors a few inches ajar. Watch closely, and just as soon as all is

melted, set it out to cool. The wax will cake over the top, and while the honey below is yet warm, tap the wax cake at its edge, tip up the pan, and as nice honey as you ever saw will flow all clean from below the wax cake.

3. No; do not let the divided bees rear their own queen. Give them either a fully developed queen-cell or young queens.

4. Out-door feeding at certain times, if done just right, might stop robbing, but would need be persisted in till the natural honey flow took its place. With the inexperienced there will be great danger of encouraging robbing, and that, too, to a demoralizing extent.

5. Wax comb guides are things of the past. They were never practical, as they were not positively successful. Narrow strips of comb foundation (I would advise them not over $\frac{3}{4}$ of an inch wide), are the very best comb guides known. What is still better and more economical, in the end, is full sheets of comb foundation not too heavy, and in brood frames, pressed upon wires.

6. My opinion is that the production of wax is optional with the bees.

7. No. No race or mixture of races will degenerate by raising their own queens. My opinion is that many breeders do not get as good queens as the bees would rear if left to themselves. The bee-keeper has this advantage; he can rear all queens from a few colonies of superior traits of character, thus improving his stock from year to year. Breeding in the good and out the bad qualities of his stock. He can rear at will as good queens as are ever produced, if he knows how, and takes the pains.

Convention Notices.

The Mahoning Valley Bee-Keepers' Association will hold its next meeting at Newton Falls, O., on June 6, 1884. It is desired that a display of apiarian supplies and samples of honey be made at that time. Mr. Hammon, of Bristolville, and Mr. C. R. Page, of Streetsborough, will read practical essays on topics pertaining to bee-keeping.

E. W. TURNER, Sec.
LEONARD CARSON, Pres.

The Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association, will be held at Rockton, Winnebago Co., Ills., on May 20, 1884.

JONATHAN STEWART, Sec.

Under a resolution adopted at the last meeting, an extra session of the Northeastern Kentucky Bee-Keepers' Association is called to meet at Covington, Ky., on Saturday, May 17, 1884, at 9 a. m., for the purpose of transacting such business as may come before it. It is hoped there will be a full attendance of the bee-keepers of Northeastern Kentucky. Membership fee, 50 cents.

ADIE O. ROBERTSON,
Chm. Ex. Com.

There will be a meeting of the Northeastern Kansas Bee-Keepers' Association, at Hiawatha, Brown Co., on May 16, 1884. A general attendance of bee-keepers is expected.

Granada, Kan. L. C. CLARK, Sec.

The bee-keepers of Tuscarawas County will meet in the Town Hall at Port Washington, O., on Thursday, May 15, 1884, to organize a bee-keepers' association. All are earnestly invited to attend.

A. A. FRADENBURG.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
Monday, 10 a. m., May 12, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—There is no life in the market. Extracted honey sells in its regular way and to its wonted channels, without any speculative feeling about it, and brings 7@10c on arrival. Comb honey sells slow at 15@16c a lb. from store for choice.

BEESWAX—In good demand; choice yellow brings 35c a lb. on arrival.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 14@16c. Dark and second quality, 13@14c; extracted white clover in kegs and barrels, 8@9c.

BEESWAX—Prime yellow, 34@35c.
THURBER, WHYLAND & CO.

BOSTON.

HONEY.—Demand light. 1 lb. sections comb honey, 18@20c.; 2 lb. 16@18c. Extracted, 9@11c.

BEESWAX—35c.
BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—Extracted honey is a drug here. Very little of it is being used for manufacturing or baking purposes. Parties who last season used from 500 to 600 pounds, have for the past winter, bought not to exceed 100 pounds in a like period of time. Many producers are anxious to realize on their last season's product, but it is impossible to find purchasers, even at the low price of 6 and 7 cents per pound. Comb honey, stocks well reduced, but prices are low for anything short of fancy, quotable at 8@16c per lb.

BEESWAX—Scarce at 30@37c.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Only in a small jobbing way is there anything doing. Market is easy at the quotations, holders being anxious to close out stocks. White to extra white comb, 15@18c; dark to good, 10@13c; extracted, choice to extra white, 7@8c; dark and candied, 5c.

BEESWAX—Wholesale, 27@30c.
STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—Demand for choice comb still good, and moving freely at 15@16c for 2 lb. sections. Market bare of 1 lbs. at present, with considerable inquiry for them. Extracted in fair demand at 8@9c for white, and 7@8c for dark. Very little of the latter now in this market, and a few thousand pounds would meet with very ready sale.

BEESWAX—None in this market.
JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@8c.

BEESWAX—Firm at 32@32½c. for choice.
W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Market continues very fair, particularly for choice 1 lb. sections, which are in good demand at 18c; 2 lbs. do not sell so readily, but in the absence of 1 lbs. it moves at 17c. Second quality is very slow at 14@15c, and extracted not wanted at all in any shape.

BEESWAX—Very scarce; would bring 35 cts. on arrival for choice yellow.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 18@20c; extracted, 7@8c.

GEO. W. MEADE & Co., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a continual statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an additional present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price still lower, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

"STUFF FOR STINGS."

Will cure all kinds of Bee-Stings. No more swelled Fingers and Faces. Will refund money if it fails. Per bottle, 25c. in stamps.

Sixth Thousand Just Published!

New and Enlarged Edition

OF

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit: sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure.
T. F. BINGHAM.
Aronia, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.
I. H. BROWN.
Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ills.

A Liberal Discount to Dealers by the Dozen or Hundred.

SECTION BOXES!

HEDDON'S COLUMN.

BEST GIVEN COMB FOUNDATION.

Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8½x16½, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

One Hive complete for comb honey. .\$.3.00

(The above will contain two cases complete with sections).

The above Hive complete for extracted honey. .\$.3.00

The above Hive complete for both in one. .4.50

One Hive in the flat. .2.00

Five or over, each. .1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4½x4½x6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

STUDENTS OF APICULTURE

Will receive terms for 1884 on application.

BEEES and QUEENS.

If you contemplate the purchase of Bees in any shape, tested or untested Queens, it may pay you to send for my

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.

Address,

JAMES HEDDON.
DOWAGIAC, Cass County, MICH.

DUNHAM COMB FOUNDATION MACHINE.

TESTIMONIALS.

MRS. FRANCES DUNHAM, De Pere, Wis.
Dear Madam:—We have made about 38,000 lbs. of foundation on your mills this year, and the foundation has given universal satisfaction; so much so, that several manufacturers have stopped manufacturing to supply their customers with our foundation. We have also manufactured about 10,000 lbs. of thin foundation on the Vandervort machine for surplus boxes, and it has been equally a success, but for brood chamber foundation, yours is still unexcelled.
Yours,
CHAS. DADANT & SON.

Hamilton, Ill., Dec. 10, 1883.

MRS. FRANCES DUNHAM, De Pere, Wis.
Dear Madam:—I have made over 100,000 lbs. of foundation on one of your machines, and would not now take double the price I paid for it.
Yours very truly,
D. A. JONES.

Beeton, Ont., Dec. 10, 1883.

MRS. FRANCES DUNHAM:
All prefer the foundation I manufacture on one of your mills, to that made on any other machine I have no difficulty in rolling it from 10 to 12 feet to the pound for sections.
Yours respectfully,
J. G. WHITTEN.

Genoa, Cayuga Co., N. Y., Dec. 12, 1883.

MRS. FRANCES DUNHAM:
After using one of your foundation mills for the past 3 years, we can't say too much in its favor. And for brood foundation, it stands head and shoulders above all.
Yours,
SMITH & SMITH.

Kenton, Ohio, Dec. 29, 1883.

MRS. FRANCES DUNHAM:
I made all brood on Dunham mill, and that I believed it by far the best for that purpose, and as further proof, instance the testimony of E. Kretschmer, of Coburg, Iowa, and L. C. Root & Bro., of Mohawk, N. Y. Messrs. Root & Bro. have only used brood foundation of me, and in a later communication say: "It (our foundation) gave the best results of any tried." I write this that you may have fair play, which is to me always a jewel. You are at liberty to publish this.
Yours truly,
T. L. VON DORN.

Omaha, Neb., Jan. 18, 1884.

Send for description and Price List to

Best Advertising Medium.

Having advertised in the AMERICAN BEE JOURNAL quite extensively for the past two years, I would say (without solicitation) that it has sold more queens for me than any other three periodicals I have ever tried.

My bees are in fine condition this spring. I have lost but 4 out of 182 colonies. The outlook is fine for a good season.
L. J. DIEHL.
Butler, Ind., May 7, 1884.

The Mahoning Valley Bee-Keepers' Association will hold its next meeting at Newton Falls, O., on June 6, 1884. It is desired that a display of apiarian supplies and samples of honey be made at that time. Mr. Hammon, of Bristolville, and Mr. C. R. Page, of Streetsborough, will read practical essays on topics pertaining to bee-keeping.

E. W. TURNER, Sec.
LEONARD CARSON, Pres.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XX.

CHICAGO, ILL., MAY 21, 1884.

No. 21.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Convention Hand-Book.

This is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

A Canadian wishes us to state in the BEE JOURNAL, whether we take Canadian money for subscription or books. We do; and for fractions of a dollar, Canadian postage stamps may be sent.

Mr. Geo. E. Hilton was married on Thursday, May 15, 1884, to Miss Lizzie Copeland, at Fremont, Mich. The BEE JOURNAL extends its compliments, and hopes that life's journey will be a pleasant one to the happy couple.

The World's Exposition to be held at New Orleans, La., next winter, is engrossing considerable attention, and Mr. Paul L. Viallon, of Bayou Goula, La., writes us as follows concerning it:

Do you not think it advisable to have a grand meeting of the bee-keepers of the United States, at New Orleans, during the Exposition? Would it not be possible for the North American Bee-Keepers' Association to have their convention in New Orleans during the Exposition—say in March or April next?

It would be a grand thing for the Southern bee-keepers to assemble and have a rousing time. The National Society might appoint the next meeting at New Orleans, in April, 1885, as suggested by Mr. Viallon, and afford an excellent opportunity for many to attend who have heretofore never done so.

The article on page 313 was written by the Rev. G. T. Willis, of Hoopston, Ill., and not G. I. Willis, of Farmer City, Ill. The initial was written very indistinctly, and no address was given. We put on the only P. O. stamp readable—supposing that was right, in the absence of the address by the writer. It is very annoying to find a name written so that it is difficult to read, but many write it more indistinctly than anything else in a letter; it is so familiar to them that they take no pains in writing it. We wish every one would bear in mind the fact that the name and address should always be written plainly.

It is extravagant economy to delay ordering hives, sections, foundation, etc., till the last moment, or till they are needed for use; for frequently a dealer finds it impossible to fill orders promptly when they are all held back till the last moment. Then, in the rush, many are disappointed. Therefore we would say to all, order early, and save yourselves much vexation and disappointment.

Surely the world moves! In a circular on our desk, issued by a commission merchant, we find this explanation concerning the granulation of honey:

"By simply placing the can or glass in warm water, the honey will return to its liquid state. The honey is in nowise injured by its candying. Our large English and German orders for California honey, nearly all now explicitly state: 'Candied honey preferred,' as they well know that the very fact of its candying is one evidence of its purity."

It is but a short time ago that candied honey was condemned as sugar—and thought to be worthless by merchants who happened to have it in stock.

We have received these late Price Lists of bee-keepers' supplies:

T. Pierce, Gansevoort, N. Y.
W. C. R. Kemp, Orleans Ind.
W. T. Stewart, Eminence, Ky.

"EVERYBODY'S PAINT BOOK," a complete guide to the art of out-door and in-door painting, designed for the special use of those who wish to do their own work, and consisting of practical lessons in plain painting, varnishing, polishing, staining, paper-hanging, kalsomining, etc.; as well as directions for renovating furniture, and hints on artistic work for home decoration, together with a full description of the tools and materials used. Precise directions are given for mixing paints for all purposes. Illustrated. By F. B. Gardner.

We acknowledge a copy of this book from the publisher. It should be in every household. We can supply it. Price, \$1.00.

Some whose subscriptions ran out with last month, are disappointed because we cannot supply any more back numbers. All should renew as soon as they receive their Journal marked on the first page with a blue pencil, and thus save annoyance; or have their papers marked to continue without being stopped at all. We wish all who desire it continuously, would notify us to mark it so on our books.

For the American Bee Journal.

Queens—Diarrhœa.

A. R. KÖHNKE.

If, as Mr. Doolittle admits, that hybrid queens "will produce workers of the best type to produce comb honey," because "a direct cross always produces vigor," why should a cross of the second degree, when queen and drone are bred from such vigorous colonies, deteriorate? Should they not, according to the claims of the advocates of pure-bred stock, produce a still more vigorous type of bees?

Taking the dollar queen, as bred and sold by reliable breeders, as representing the real unit-value of a queen, how does it increase the value of that queen, to the buyer, by being kept by the breeder long enough to test her?

It may be said, the breeder charges that much more for his trouble, for which he should be paid; but that is not the question. I am asking this question with reference to the buyer, not the seller. Is a tested or any other queen worth more than one dollar to the honey-producer? It is my experience, and I believe that of most honey-producers, that individual queens and their offspring are changeable?

Mr. Heddon is reported to have put the question in some convention, like this: "Why will a colony one season out-do all the rest, and the next do almost nothing; and then again in another season excel all others in furnishing a surplus, and all this takes place when the colony is of apparently the same strength one season as well as another?" Does it not prove that queens are not at all reliable? May not a dollar queen produce a colony of excellent workers, and a select tested one prove to be worthless to the honey-producer? It cannot even be said, the chances are against the former. I am quite confident that no breeder of high-priced queens will guarantee the amount of honey the offspring of his queens will gather in a good locality.

It appears that some bee-keepers suppose that some of the fraternity think pollen to be the first, last, and only cause of the bee-diarrhœa. I do not know, nor have I read of a single bee-keeper who has expressed his belief to that effect. But one thing is certain, if the bees had no pollen to eat, then their evacuation could not be largely composed of undigested pollen, of which it does, and thus constitutes the disease.

I lost 10 per cent. during the past winter, by different causes, among which some died of diarrhœa. Two of them had it as early as November, when we had several days of quite warm weather each week. One of the two was the strongest and heaviest colony I had. I think, when preparing them for winter the latter part of Sep-

tember, I may have killed the queen, and instead of clustering, the bees kept up a continual turmoil, not keeping warm enough.

I have noticed in all my colonies thus affected, two conditions which precede or accompany the disease. 1. A colony thus affected, or very nearly so, presents to a hand held above the cluster on top of the cover, a sensation which I cannot compare to anything better than the body of a person about to die—cold and clammy. 2. The degree of the disease with my colonies seemed to be in an inverse proportion to the size of entrance, though I had all of them entirely open; they varied in height nearly $\frac{1}{4}$ of an inch. I have made them all now a full $\frac{1}{2}$ inch.

Insufficient ventilation may be a factor to be taken into consideration in accounting for the cause of the disease; but when some one says, it is caused by "inflammation," that word cannot be used regarding any conditions to which bees may be subject.

Nor do I believe they are ever troubled with consumption or neuralgia. If bees were nearer related to mammals, than they are, we would be better enabled to understand their body, and the causes and conditions producing disease or health; but as it is, we cannot know much, and the little we do know we acquire not by comparison to other animals, but by experiment with the bees themselves.

Those two colonies first affected, I took into the kitchen, made a rousing fire, heated the room up to 90°, and had them fly for about 6 hours. Then I examined both and found no queen in the stronger colony; but the weaker pulled through without losing many more bees. The stronger one lived until nearly the end of March; and I then examined the combs and found the two frames in the center almost a solid mass of pollen, having been covered with honey which had been eaten, of course; this honey, as also that in all my colonies, had been gathered from white clover. No fall honey around here; hence fall honey cannot be a cause of the disease as some one seems to believe. The dead colony previously exhibited a most voracious appetite, having consumed all the honey, 24 lbs., and had not reared any brood either, as they had no queen; consequently brood-rearing cannot be a cause, as some one suggests.

In fact, I found in the several colonies that I lost by diarrhœa, only one, which had a patch of brood of about the size of a silver dollar; thus, I think, proving quite conclusively that brood-rearing has nothing to do with it.

It may be, that anything which makes the bees uneasy, may be the first cause or starting-point, in causing the bees to move about too much, instead of clustering quietly; such cases may be queenlessness, lack of ventilation, or rather, a lack of sufficient fresh air, frequent disturbance or jars; all this causes them to eat more than is necessary, partake of pollen also, and the result is overloaded intestines. My lighter colonies wintered best; some came through all right on 6 lbs. of honey, by actual weight.

Youngstown, O.

Utah Convention.

At the late convention held in Tooele City, Utah, the interests of bee culture were represented by the following encouraging reports:

C. Conley, from Box Elder county, stated that there were some 700 colonies in the county, and that about 30 colonies were lost during the winter. He had examined some 500 colonies, and found them in good condition. But little foul brood in the county. Some little chill brood had been discovered. His 50 colonies had wintered well. Last season he took 1,000 pounds of honey.

German Ellsworth, of Payson, said there were over 700 colonies in Payson. He had lost only about 3 per cent.,—wintered on summer stands. He commenced in the spring of 1883, with 30 colonies, 2 of which were queenless. He had increased them to 60 colonies, taken from them 4,000 pounds of honey and 40 pounds of wax. He explained how they successfully managed foul brood for the last 4 years, which, he maintains, is in the honey, and does not attach to the bee. Bees bred in September all die before the following May.

O. B. Huntington, of Springville, stated that they had no organization at that place, where there were several old-fashioned bee keepers, who would not adopt modern methods in bee-culture. He owns 27 colonies, which wintered without loss. Last season he took 1,300 pounds of honey and 79 pounds of wax. He uses the patent extractor, and has sent for a foundation machine. There is foul brood now in the place, which has 427 colonies, averaging 70 pounds of honey to the colony.

Simon Noall, of this city, commenced in the spring of 1883 with one weak colony. He subsequently bought 2 heavy ones. From the 3 he procured 300 pounds of honey. There was some foul brood in his section.

Mr. Welch, from Morgan county, last spring started with 6 colonies, which he increased to 14. Lost one during the winter; took but 300 pounds of honey. There were 72 colonies in the county; some 14 perished during the winter. One man had 30 colonies in old-fashioned bee-gums. He lost a good many. The altitude is great and seasons short. There is no foul brood in the county, and no bee association. He likes the Simplicity hive, and when his bees need food, he feeds them mill dust through a 15-inch tin tube.

John Morgan, of Salt Lake county, believes that the smelter fumes and foul brood caused the great mortality among his own and other apiaries in the county. Last spring he captured a deserting swarm by clodding them. These he increased to 3 colonies. Bees should not be overhauled too early, lest they become chilled. He found great prejudice against honey extractors, which is because of ignorance and in over-using. Bee inspectors are not encouraged by the County courts, who pay them grudgingly.

W. M. Egan, of this city, said he was sorry to learn that there are still

some in Utah who stick to the old methods of bee-culture. From 15 to 20 lbs. of honey can be saved to every pound of comb foundation artificially made and introduced into the hive. Each society should take at least one bee-paper, and profit by the experience of others in the East and elsewhere. An experienced expert can cure foul brood, but inexperienced persons should not tamper with it. He strongly recommended the two-story hive. Take honey from the upper story only, and you can readily change frames from one to the other story.

The feeling of the meeting was strongly in favor of organizing bee-societies in every settlement in Utah where bees are kept. A President, Vice-President, Secretary and Treasurer, are all the officers usually considered necessary. The Secretary and Treasurer may be united in the same person. It is hoped the friends of bee-culture everywhere will appreciate the importance of this suggestion and act upon it without delay.

The convention recommended the AMERICAN BEE JOURNAL, published in Chicago at \$2 per annum; and *Gleanings in Bee-Culture*, published at Medina, O., \$1 a year, as the best papers for bee-keepers.

Messrs. Morgan, Cowley and Ellsworth agreed to prepare an article, each, on the best management of bees for May, June and July respectively.

From written reports received and read, the following are extracts:

Tooele City last fall had 230 colonies; this spring 200 colonies; loss 21. Some of the colonies are weak, but on the whole we have had good success in wintering, considering the severity of the winter. T. W. LEE, *Pres.*

JNO. DUNN, *Sec.*

Manti, about 850 colonies in the county (Sanpete). On the average took about 50 lbs. of honey from each colony. Many of those who wintered on the summer stands sustained heavy loss. Those who used chaff as a protector succeeded well. The interest in apiculture was appreciably on the increase. WM. BRAITHWAIT, *Pres.*

WM. BENCH, *Sec.*

Eli Bell, of Logan, writes: "The bee interests in this county (Cache) are reasonably good this spring. All that I have seen are in good condition. Our method of wintering is to pack the hives in sawdust or shavings and put them under good sheds. We remove the upper frames or honey boxes and put in straw cushions. Last year our yield of honey was very good.

Secretary S. Worthington, of Payson, writes: "The number of colonies of bees in Payson last fall was 738. During the winter lost 25 colonies, or 3½ per cent. of the whole. All were wintered on the summer stands. Total amount of honey taken, 38,158 pounds, and 296 pounds of wax."

A. P. Winsor writes from St. George: "140 colonies; honey yield light; but little wax; wintered on summer stands; no foul brood; but little loss or gain in numbers of colonies. Drouth and frost have contributed largely to the partial failures."

Thirty-five colonies were reported at Santa Clara, near St. George. Win-

tered well; loss under 2 per cent. No foul brood.

Edward Stevenson, secretary of the Parent Society, but now in Canada, writes: "I can report 50 colonies in good condition, the last I knew of them. Some of them are in two-story chaff hives. Last season I took 60 pounds of honey from each colony at one extraction, without troubling the lower story at all. The lower story has 9 frames; the upper has 14 to 15 frames. The lower hive has 2 inches of chaff under it, and 3 inches at each end, making the upper story 6 inches longer than the under one. The frame of the lower part being lengthwise, will fit the upper one crosswise. In the fall the frames should be taken out of the upper part, and a sack of chaff put into it. I made one of these hives for a friend here, which he values very highly. There are not many bees in Canada, the winters being too severe. But few patent hives are in use."—*Tooele City Daily.*

For the American Bee Journal.

Observations in Cellar Wintering.

C. W. DAYTON.

In colonies first afflicted with diarrhoea I have found but few of the bees with distended bodies, and where they were dead the colony appeared to be free from disease. By close watching, colonies beginning to show the common signs were detected several days before. Either strong or weak colonies which clustered low on the combs were all more or less afflicted with diarrhoea.

I have tried acid and sugar which I believed to check it, but found afterward that it was increased ventilation or settlement of the cluster. Five colonies wintered perfectly on wholly uncapped honey.

I once put 7 colonies whose brood-chambers were covered with wire cloth, in the cellar, alternately with 12 whose brood-chambers were covered with chaff cushions; and after a confinement of 156 days, in a temperature ranging between 32 and 50 degrees, the 12 were found nearly dead with diarrhoea and of the 7, 6 were in good condition, and one weak, without diarrhoea. I have known in several instances voidance of feces to resemble water.

When I moved 60 colonies to their summer stands this spring, after a confinement of 145 days, 11 of the 15 diarrhetic colonies were amongst the 44 having no brood. During the last winter the temperature of my bee-cellar never was below 43°, or above 45½°; and there was a patch of brood in one comb in each of 16 colonies when set out.

In the winter of 1882-3 the temperature varied from 32° to 50° and there was brood in from one to three combs in every live colony. I have known several colonies in deep hives, in a warm cellar, and clustered low on the combs, to keep dry and quiet from 50 to 100 days, when the accumulation of moisture on the combs or material about the brood-chamber, became

visible, without the aid of brood-rearing; and the honey being consumed near the cluster, to cause a move of the cluster which was generally followed, but sometimes preceded, by the very sudden appearance of distended bees which remained in the cluster, unless so exhausted as to exhibit their well known conduct; and in the spring the hive and combs near the cluster were found to be dry, and a part of the remaining bees found with distended bodies and the cause of diarrhoea (unless it should be found to be pollen) disappeared.

Since examining, without injurious disturbance, 30 colonies twice each day, on more than one hundred days during one winter, and also 50 diarrhetic colonies in the spring, I believe there is but little to be learned from the tracks of the disease.

While successfully wintering a reasonable number of colonies with the right upward ventilation, and a like number supposed to be hermetically sealed above, I have found that a medium preparation has fixed the price of my experimenting.

My experiments thus far have been made with natural stores gathered before July 25; and my idea is that 10 colonies in a diarrhetic test are better than a larger number.

Bradford, Iowa.

For the American Bee Journal.

Des Moines Co., Iowa, Convention.

The Des Moines County Bee-Keepers' Association, held its last session at Middletown, Iowa, on April 22, 1884. The meeting was called to order by the President, Geo. Bischoff.

The committee appointed to wait upon the Agricultural Society reported that the following premiums would be offered at the Fair next fall.

- Best display of Italian bees.....\$3.00
- Best display of black bees..... 5.00
- Best imported Queen..... 3.00
- Best display of comb honey, not less than 25 lbs..... 5.00
- Best crate of honey, not less than 25 lbs..... 3.00
- Best hive for all purposes, best honey extractor, best wax-extractor, best bee-smoker, and the best bee-veil..... Diploma.
- Best display of apiarian implements..... Dip. and \$5
- 2d best display of apiarian implements..... Dip. and \$3

NOTE.—All hives must be securely closed while on exhibition, and no bees allowed at large.

The foregoing report was adopted, and hearty thanks expressed to the Agricultural Society.

Nine names were added to the list of membership; 16 members represented 564 colonies, fall count; spring count, 491. The subject of wintering bees was then discussed.

Henry Breder winters them in a cellar, and uses the Langstroth hive. Adjourned.

After dinner the same subject was continued.

Jno. Nau winters them in an arched cellar, with sufficient ventilation to keep the temperature ranging from 40° to 46°. A. M. Baldwin, on their summer stands without any protection. W. R. Glandon, in an old ice-house. F. F. Melcher, on their summer stands with straw packed on the sides and back, and in the cap of the hive. Others in his neighborhood packed in the same way, but lost

heavily. A. Zackmeyer, on their summer stands and in the cellar, with canvas on the top, and straw in the cap of the hive; 2 colonies he left without any protection, and both were lost.

"Handling and Transferring" was next discussed. Henry Smith gave a practical explanation of his method. Messrs. Bell, Bischoff, Smith and others discussed "Spring Management of Bees."

The following resolutions were adopted:

Resolved, That we meet on Sept. 17, 1884, at 10 a. m., on the Des Moines Co. Fair Grounds, for the exhibition of honey and apiarian implements and supplies.

Resolved, That we hold our next annual meeting at Burlington, Iowa, on the 4th Tuesday in April, 1885, at 10 a. m. sharp.

Uniform prices for honey was considered very desirable.

The Italian bees were most favored, but hybrids were considered the best workers. Queen-rearing was briefly discussed by many of the members. The next subject that received special attention was "Natural Swarming" vs. Dividing. The latter method was not approved except for rapid increase; but nearly all expressed themselves as believing that natural swarming is the most preferable.

Adjourned to meet Sept. 17, 1884.

JOHN NAU, Sec.

GEO. BISCHOFF, Pres.

For the American Bee Journal.

Southern Wisconsin Convention.

The Convention met at Janesville, Wis., May 6, and was called to order by Pres. C. O. Shamon, who briefly stated the object of the Association.

After the reading of the minutes of the previous session, and the constitution and by-laws, new names were added to the roll.

The exhibit of apiarian implements was not as large as expected. The discussion was of a miscellaneous kind. Questions which seemed most imperative were discussed.

Wintering was briefly considered, some preferring the cellar, if dry, with the honey-board moved forward $\frac{1}{4}$ inch; others choosing to winter on the summer stands, packed in chaff. The great advantage of this is in allowing them to remain in winter quarters until cold nights are past. The losses in wintering will probably not exceed 5 per cent.

Supers were discussed at some length. Those most in favor were 1 and 2-lb. sections in frames.

How to use comb foundation to the best advantage, wiring in frames, etc., was well agitated.

A discussion among a few, during recess, on the relative size of the different kinds of bees, resulted in the conclusion that, since the cells are the same size, there can be no material difference in the size of bees, except as the cells become smaller with age.

The next meeting of the Association will be held in Janesville, Wis., Sept. 23, 1884.

J. T. POMEROY, Sec.

For the American Bee Journal.

Wide Frames vs. Cases.

W. H. SHIRLEY.

On page 198 Mr. Burrell gives his experience with cases and separators. I endorse all of his article except where he says, "I will not use wide frames. They are an abomination."

I can hardly agree with him there. I have never used any case-method in my own apiary yet. I have produced comb honey 2 years without separators. In the spring of 1883 I determined to run about $\frac{1}{2}$ of my apiary for comb honey, put up in those naughty $\frac{1}{2}$ lb. sections, and the other $\frac{1}{2}$ for comb honey, put up on the old plan, in 2 lb. sections.

I used the clamp-method that Mr. Heddon has described in the BEE JOURNAL, for the 2-lb. sections. For the $\frac{1}{2}$ -pound sections I procured 150 supers, each holding 6 one-story wide-frames with wooden separators, and I kept looking, all through the season, for the wide frames to prove "an abomination"; but they did not. I much prefer the one-story wide-frame system to any case-method I have ever yet seen. My reasons are these:

1. Wideframes keep the sections nice and clean all through the season, and when you crate them, it is not one half the work to clean them for market, and when cleaned, they are not stained as sections are where they come in contact with the bees, as they do with the case-method.

2. Often I have gone to a hive and found the sections in the middle wide-frame nearly full of honey and the outside ones hardly touched. All I had to do was to slip out my wedges, put the outside wide-frame into the middle of the case, and in a few days there would be a nice case of finished sections. The foregoing manipulation is more than the case-method will let you do.

3. When one wishes to use the same sections, 7 to the foot, or $1\frac{1}{4}$ inches without separators, all you have to do is, to put them into the wide frame with the separators out, clamp them tightly together, and you have a case that goes far ahead of Mr. Burrell's. I have seen one of Mr. Burrell's cases, so I am not speaking at random.

By using my wide-frame case-method, I am able to use the 1-lb. sections or the $\frac{1}{2}$ -lb. without extra cost, as either size will fit into the wide frames.

It is a fact among bee-keepers, as in all other branches of trade, that he who invents certain things or adopts certain methods and becomes wedded to them knows best how to manipulate them. With me, Mr. Burrell's case would be too much of a complication; too many loose sticks and boards to look after; and in the make up of it, iron as well as wood has to be used, which adds to the weight, cost, etc. It also destroys the bee-space above the frames, and between the cases when tiered up, which I consider is of vital importance.

I procured my one-story wide-frame supers of Mr. Heddon, who used them in equal numbers with his cases; and

while he and his students prefer the case, I prefer the shallow wide-frames, though I have never tested the case-method the season through.

I am sure I should prefer Mr. H.'s case without separators, to Mr. Burrell's with them. Mr. Heddon agrees with me that of all the plans for the use of separators, he prefers this neat little one story wide-frame super; and also, that he does not consider his case any better than the super for all persons in all locations.

With 8 sections to the foot, or $1\frac{1}{2}$ inch sections, I am inclined to think 95 per cent. of them would be perfect, where full sheets of foundation are used without separators. Of course the wide frame if used would have to be made narrow to correspond with the sections.

But why dispense with separators when by their use the honey is all built nice and perfect? I am satisfied that I can get as much honey stored in sections with separators as without them; for last year I tried quite a number of wide frames filled with sections, which when finished weighed only 4 ounces; and the bees finished them just as quickly as any other size. All things being equal, I think it makes but little difference with the amount of honey stored, with separators or without; but all things considered I can say from my experience, "give me separators."

Glenwood, Mich., May 2, 1884.

For the American Bee Journal.

Western Bee-Keepers' Association.

The fourth semi-annual meeting of the Western Bee-Keepers' Association was held in the Court House at Independence, Mo., April 24.

At 2 o'clock, owing to the unavoidable absence of the President, the meeting was called to order by the Vice-President, Dr. G. W. Young.

The minutes of the previous meeting were read and approved. The committee on "Marketing Honey," reported that they had visited Kansas City and that with only one exception all the leading honey-dealers preferred their honey unglassed. The committee recommended unglassed honey in 1-lb. sections, in crates of from 12 to 20 lbs. each.

On motion a committee of three was appointed to prepare a list of subjects for discussion.

Mr. P. Baldwin in an able manner addressed the convention in regard to preparing honey in the finest possible condition for market.

The first question discussed was: "What is the best spring management to bring bees up to proper working condition in season for the honey harvest?"

B. Baldwin: My opinion is that all that is required is to see that the bees have plenty of stores ahead, so that they never will be short, and let them alone. I have tried tucking them with blankets, closing down on two or three frames, carrying them in and out of the cellar every cold spell, and with no better results than with present management.

J. H. Jones: Weak colonies must be cared for. I am strongly in favor of blanketing and closing down to four or five frames early in the spring.

A. A. Baldwin: I think all that is needed in the spring is to see that the bees have plenty of stores within reach of the cluster at all times; and then leave them alone, and they will prepare themselves for summer work. The bees that I moved from New York last fall were wintered in the cellar. When spring came I tucked all but 4 with blankets. Those which I left alone are as far advanced as the others. I have had 4 of those first mentioned swarm out and desert the hive. I would repeat that plenty of stores close to the cluster and brood, is about all the spring management bees require.

L. W. Baldwin: I think a weak colony is better off closed down to two or three frames. Do not be in a hurry to spread them out. Wait till they are crowded before giving more room.

P. Baldwin: I believe that a colony which has been wintered on the summer stand will be more gritty, and will build up quicker and get strong, and ready for the honey harvest sooner than one wintered in the cellar. I advocate uniting all weak colonies.

Mr. J. F. Myers, of Wyandotte, Kas.: I believe in putting on quilts and keeping the bees shut down close. Do not give them any more space than they can occupy. I think it better to build up all the weak colonies. I often find them as profitable for honey as some that are strong in early spring.

A. A. Baldwin: I do not double them up till later in the spring. Wait till they are gaining fast in numbers then select the best queen, kill the other, put two together, and then they will go ahead and make a strong colony that will pay better than the two which are weak.

J. D. Meador: My experience is that it pays better at the end of the season to build up all weak colonies. I think I make more in that way than I would by uniting them. I am satisfied that a large amount of the fussing and fooling done with bees in the spring is unnecessary. The main thing is a close hive and plenty of stores that the bees can get at in all weather.

The next subject was, "What is the best management to prevent too much swarming?"

A. A. Baldwin: My plan is: wait until the colony is nearly ready to swarm, then take away the old queen and either kill her, or give her about a quart of bees, and frames of foundation. If you desire increase, that would be the best way to get it. Then give the colony a cell and let them rear a young queen. They seldom swarm with a young queen.

J. F. Myers: Plenty of room will prevent swarming, in a great measure. It cannot entirely be prevented.

P. Baldwin: I have tried Doolittle's plan and it failed. Bees in New York are not like western bees; ours have broader views; are more like the inhabitants; have more enterprise and go-aheaditiveness. My method to prevent too much increase is, to let the

colonies all swarm once; put two or three swarms into one hive, and put on all the sections they can occupy. I cannot prevent swarming, but I can prevent too much increase.

The next question was, "Which is the better method of increase, dividing or swarming?"

L. W. Baldwin: I am strongly opposed to dividing. It is strictly opposed to nature. A colony of bees knows better than we when it is ready to swarm. A colony left to swarm naturally will begin to build comb 3 or 4 days sooner than one which is made by dividing. Then another strong argument against it is: A man will double up his bees and if from any cause the flow of honey should cease, he would be left with all his bees, or a great many of them, in a starving condition.

J. W. Hart: I do not believe that one can become well enough skilled so as to know just when to divide a colony, and have it go ahead like one that chooses its own time and gets ready in its own way. I have tried both methods and have come to the conclusion that the best way is to let nature take its course.

P. Baldwin: I have tried all the new theories that have been advanced. I am strongly in favor of natural swarming.

J. F. Myers: I am an advocate of dividing. It is the only safe way of guarding against swarms going to the woods. I start nuclei early in the season and rear queens to give the old colony; for it will swarm and become so light in bees, that, at times, I would have to strengthen it.

A vote was taken on the question which resulted in a majority of 4 to 1 in favor of natural swarming.

"Which is the best plan of rearing queens?"

Jas. A. Nelson: I think queens reared in good nuclei, are in every respect equal to those reared in full colonies. Those queens reared early in the season, or late in the fall, may not be so good.

J. C. Batch: I am satisfied that queens reared in nuclei are superior, or at least ought to be, to others; for you have a chance to rear from the best colonies.

A. A. Baldwin: I am satisfied that a queen is far better reared in a full colony with the natural impulse of swarming, than one reared in a small nucleus. I have bought a great many forced queens, or queens not reared under the swarming impulse, and never had one to live more than 6 months. I would rather pay \$3 for a queen reared naturally than \$1 for a forced queen.

P. Baldwin: I think a queen reared in a capped cell taken from a full colony is as good as any, no matter where reared or hatched.

J. W. Hart: I know that a queen reared from a cell that was capped in a full colony, is just as good, if reared in a small nucleus, as if it had been left to hatch in the parent colony.

J. H. Jones made a strong argument in favor of queens reared naturally.

A. A. Baldwin: I have always noticed that a cell produced in a full col-

ony has plenty of food left in the base of it; while a cell produced in a nucleus is generally left without any.

Adjourned till 7:30 p. m.

At 7:30 the meeting was called to order by Vice-President Young. The Secretary was ordered to have 500 copies of the constitution and by-laws printed and distributed. A motion was carried that the President appoint two committees on the fall meeting of the association.

The convention then took up the question of the relative profit of producing comb and extracted honey.

Mr. P. Baldwin said that he had always produced comb honey, and of course he knew but little of the relative profits of the two.

L. W. Baldwin: I extracted 2,000 to 4,000 lbs. each year and am strongly in favor of comb honey for profit and quick sales. When my comb honey is all sold I have the most of the extracted on hand. That has been my experience, and I am bothered to sell the extracted. I think more bees die from the use of the extractor than from any other cause. Bee-keepers will extract late and the consequence is, bees go into winter quarters with unsealed honey, it sours and causes disease, when if sealed stores had been left them to winter on, they would have done well.

J. H. Jones: I am of the same opinion as Mr. Baldwin. I think of giving away my extractor. I think it would be money in my pocket to never use one again.

Dr. J. G. Meador: I produce extracted honey exclusively; have no trouble to sell it. I can dispose of the extracted as soon as I could the same amount of comb honey. The most of my customers would rather have it, at the same price. I believe I can get 3 pounds of extracted to one of comb.

W. B. Thorne: I have found it more profitable to produce extracted honey. It is easier handled, less trouble to store it, and quick sales. I could always sell my extracted honey as fast as the comb. The most of my customers take the extracted in preference to comb honey if put up in glass. I think that is the only way to put up honey to sell direct to the consumer.

E. J. Baxter, of Nauvoo, Ill., said that he had handled a large amount of both comb and extracted honey, and that there was more money in the extracted. A good colony will produce three times as much extracted as comb honey, in 2-lb. sections. Last year he produced 2,100 lbs. and had no trouble to sell it.

J. W. Hart: I think that the best results can not be obtained from either one by itself, but recommend that a bee-keeper must produce both in order to make a success of the business.

Adjourned till Friday morning 9:30 a. m.

The convention was called to order at 9:30 a. m. by the Vice-President.

The first question: "Is the traffic in the dollar-queens any benefit to the bee-business?"

P. Baldwin: I do not use dollar-queens, and I am not in favor of the traffic.

L. W. Baldwin: I do not handle dollar-queens, but I am satisfied that it is an injury to the bee-business. I know that good queens cannot be reared and sold for one dollar. A great many ship old and inferior queens to their dollar-customers and keep the best for better prices.

J. A. Nelson: I think that as good queens are sent out by the dollar-queen breeders as those sent out as tested. I take as much pains in breeding as others, and my queens are as long lived. There are irresponsible queen-breeders, as well as in any other business. I have had better queens that I bought for \$1. than many I have paid \$3 for.

A. A. Baldwin: I have bought a great many dollar-queens and never had one to live over 6 months. A great many of them were nothing but dwarfs. Some never laid an egg after being introduced.

J. C. Batch: I have bought dollar-queens with good results; they lived as long as any, and I am well pleased with them.

W. B. Thorne: I have bought several dollar-queens and have been in every instance, well pleased.

P. Baldwin: I have always observed that the most of those who bought dollar-queens were not experienced bee-keepers, but beginners who want something cheap, and consequently the breeders should be very careful what they send out.

J. A. Nelson: I have noticed that a great many beginners buy dollar-queens of me, but they generally buy more the next year and often send for tested queens. I have customers who have bought queens for 8 years, by the dozen. They say they can buy them cheaper than they can rear them in their own apiary.

The next question was, "What is the best method of wintering bees?"

E. J. Baxter: I winter them on summer stands in a double-walled hive; have 8 frames in the hive, pack one side with leaves, put a mat of grass 1 inch thick on the top of the frames, then fill the cap with chaff and tack on a piece of oiled muslin to keep the leaves in. I leave the front entrance open, make sure that they have plenty of sealed stores within reach of the cluster, and leave in plenty of honey to last them till the first of May. The past two winters I have lost less than 2 per cent. I much prefer this mode of wintering to putting them into a cellar.

A. A. Baldwin: I am very much in favor of a double-walled hive with side and top-packing, for out-door wintering. I think that is the best way a colony can be wintered; and it will build up in less time in the spring than one wintered in the cellar.

P. Baldwin: I am in favor of a single-walled hive for out-door wintering, with the cap packed with chaff to absorb moisture. I think I can winter more successfully on the summer stands in this climate.

J. F. Myers: I winter my bees in the cellar, with less loss and a great saving of honey. Last fall I put 88 colonies in and took out 87 this spring in good condition.

L. W. Baldwin: I have been in the business 16 years, and have always wintered my bees in the cellar when I could. It saves a large amount of honey and I find it less trouble to carry in and out of the cellar than to pack them for out-door wintering. And it saves the expense of mats and quilts.

J. W. Hart: I have wintered bees on the summer stands, and in the cellar, with about equal success; but I prefer the cellar, for I save from 8 to 10 lbs. of honey to the colony.

J. D. Meador: I prefer a cellar to winter in, if I have one that is suitable; but if it is not dry and so fixed that the air can be kept pure, the bees had better be left on the summer stands.

Adjourned till 1:30 p. m.

At 1:30, after calling the meeting to order, the President introduced Mr. Jerome Twichell, of Kansas City, Mo., who addressed the convention in a very able manner on the subject of marketing honey. Mr. Twichell showed the convention that he was master of the situation, and well up with the times in regard to the best manner of packing and shipping honey. There has been sold in Kansas City, the past season, 70,000 lbs. in 2-lb. sections, 4-5 of which was glassed; 13,000 in 1-lb. sections, 2,000 of it glassed; and about 6,000 lbs. of comb honey; in irregular shapes, about 18,000 or 20,000 lbs. The honey from New York was mostly in 2-lb. sections glassed. The extracted was nearly all from California, Iowa, and Illinois.

He says: I have received comb honey from New York City in good shape. It came by freight. I consider Kansas City one of the best of honey markets. There is no danger of overstocking the market. I have a large trade in Colorado and New Mexico, and have shipped there with very satisfactory results. For the home trade I prefer honey unglazed; but for shipping a long distance I strongly favor glassing it. My advice to bee-keepers is not to use dovetailed sections. I have found on arrival 90 per cent. of the broken combs of honey in dovetailed sections. I do not think $\frac{1}{2}$ -lb. sections would pay. I have had but little shipped to me this year. The bulk of the extracted honey, I have sold for manufacturing purposes. The cry of adulteration deters many of my customers from dealing in it. All dark extracted honey should be shipped in large packages, for the manufacturers prefer it in that shape. The average price in Kansas City this season was: No. 1, comb, 17 $\frac{1}{2}$ cents; irregular box-honey, 14 cts.; extracted, No. 1, 9 $\frac{1}{4}$ cts., No. 2, 8 $\frac{1}{4}$ cts.

Independence, Mo., was selected as the place of next meeting; the time to be fixed by the executive committee. The following was adopted:

Resolved, That the Western Bee-keepers' Association extend a vote of thanks to Mr. J. Twichell for his able and instructive address.

The query-box was opened at this time.

The report of the committee on statistics is summed up thus: 23 members represented 1,938 colonies; fall

count; 1,609, spring count.—loss 329 colonies.

A large number of very prominent bee-keepers from abroad were in attendance.

Adjourned to meet at Independence, Mo., upon call of the Executive Committee.

C. M. CRANDALL, Sec.
DR. G. W. YOUNG, Vice-Pres.

For the American Bee Journal.

The Production of Drones.

D. K. BOUTELLE.

On page 594 of the BEE JOURNAL for 1883, Mr. Thielmann refers to the statements of Messrs. Youngman and Trussell, in the Northern Michigan Convention (page 542 of the BEE JOURNAL for 1883,) that they have had queens, drones, and worker bees, all from the same larvæ. He then relates an experience of his own, from which he seems disposed to conclude that queens, drones and workers may be reared from eggs laid in worker cells.

On page 568 of the BEE JOURNAL for 1880, may be seen an article from me relative to this same subject, giving an account of my experience in 1878. It seemed to be so much at variance with the Dzierzon theory, and all popular writers upon bees, that I did not venture to offer it for publication until I experimented more. This I did in the two following years; and, by these experiments and my former one, I became fully convinced that there is no difference in the eggs from which the three classes of bees are produced; but that different treatment and conditions cause the different effects.

I did not then venture, seemingly against all the bee-world, to express this conviction very strongly, but simply gave my experience, hoping to draw out others and more experienced bee-keepers on the subject; but it seemed to attract no attention, and I concluded I had made a laughing-stock of myself among bee-keepers, and that I would better have kept still. So, when the "parthenogenesis" discussion came round, I shrugged my shoulders and kept quiet; but I thought it was all *no genesis*.

But finally Dr. A. B. Mason, in the *Bee-keepers' Instructor*, makes allusion to my article, and the BEE JOURNAL of 1882 quotes from him on page 37. The Editor, after quoting from my article, pays me the following compliment: "The experience that this correspondent gives, is worth more than all the theories of learned and experienced apiculturists." While of course I am thankful to the Doctor for his compliment, if he means it, yet, it seems to me like the boy's "boo," that made the colt run away with his father; entirely "too big a boo for such a little colf."

Let us think a little more about this subject, sex in bees. It seems to me one worth investigating; and, after all, what is there so very incredible in the idea that the different sexes of bees should be developed from the same kind of eggs?

What absurdity is there in the supposition that different conditions, different surroundings, different treatment, and different influences produce the difference of sex? No doubt there is a natural and adequate cause for this effect; but we possess very little, if any, definite knowledge as to what the immediate cause is.

So far as we know, in all animated nature, except bees and a few other insects, every individual, male or female, requires both a father and a mother in order to gain an individual existence.

After understanding this great general law, is it not more incredible, more irrational, seemingly more absurd that these insects are an exception to the law? Do not both male and female chicks hatch from the same kind of eggs?

Aye, is not this also true of the ova of all known animals? To me, it does not seem rational that the bee should be an exception to this great law, that requires both male and female to reproduce their kind.

But, says one, "if this be so, then what becomes of parthenogenesis which the great bee-scholars of Germany have so ably defended; can we ignore what these great men have verified?" And farther, "do we not see that eggs laid by unmated queens always produce drones?" So too, I would answer, a few hundred years ago everybody could see that the earth was flat, and that it was the center of the universe; the sun, moon and stars all revolving around it every day; and the learned astronomers had verified these facts. Now, I am unable to account for the at-present-seeming-fact that virgin queens lay eggs that produce drones; but it does not therefore follow that it cannot be done.

When Copernicus published his theory of the solar system, and was summoned before the authorities, he was told that if his theory was true, the planet Venus ought to show phases like the moon. He thought and answered, "yes, it ought; I had not thought of that before. I cannot explain it, but I believe it will be explained."

A little later, when Galileo constructed his telescope and looked through it at Venus, there she was a half moon. So too, I have faith enough in *law* and *science* to believe that it will yet be demonstrated that all reproduction of kind comes under one law, and that parthenogenesis is a myth like the Ptolemaic system of astronomy, a chimera like the fabled Centaur—a monster of imagination.

Let us hear from others. I like the way Mr. Heddon treats most questions; he is a great skeptic; he doubts or has doubted nearly all that has ever been said or written of bees. He doubts and then goes for investigation to either verify or prove the falsity of the hypothesis, which have been assumed. Doubt is the harbinger of knowledge; and then he owns up so candidly when he finds he learns his mistakes, and never calls his opponents fools or knaves, because they disagree with him.

Surplus Receptacles.

JOHN LONGMATE.

I have been very much interested in the articles on the subject of surplus receptacles, and have made some experiments, with a view of ascertaining the best method of producing surplus comb honey.

I have tried side-storing in boxes and in frames, the same as the brood frames, and in sections with and without brood frames; also top-storing in the various modes, endeavoring to find the best and most practical method of storing honey, in the best marketable condition.

I consider it settled beyond controversy, that the best form in which to have it, either for home market or for shipment, is in sections not to exceed 2 lbs. in weight, and these should be well filled and smoothly capped, in such a manner that when packed, the honey does not touch the sides of the case, nor any portion of any other section, so as to chafe the cappings and cause leakage.

After long experimenting, I hit on the plan of broad frames of the same form and size as the brood frames. These I could use in the side next to the brood combs, and by placing a hive just like the lower one on top of it, use them as an upper story; placing them all on at once, or by the use of division-boards and cushions on the brood frames, commence with a few and increase as needed.

When I had this plan perfected in my mind, and adapted to the size of the hive I said, "I have it"; and thought, "now that is perfect. That is splendid. I shall have no more trouble with bulged combs, or waxed sections, for the outside of the sections will all be protected by the brood frames, and the thin wood separator tacked to the side of the frame will compel the bees to build all the combs straight, and not bulge them beyond the edges of the sections."

So in the winter I made a lot of broad frames, and tacked on the wooden separators and had them ready for the honey flow. When the time came I put them into the hives, and with eager expectation watched the result. It soon became time to take them out, and great was my disappointment. While some of them were as nice as I could wish for, many of the combs were built crosswise and attached to the division-boards, or to the separators on each side, and could not be removed without first cutting loose from the separators of the adjoining frame.

And then came the difficulty of getting the bees from between the combs and separators, and of removing the sections from the frames, for the bees glued them to each other and to the frames.

The edges of the sections were as much daubed and discolored as those where the bees were allowed to run over the whole outside. It is the edge of the section which we wish to keep clean and white, for they are the parts exposed to view, when packed in cases.

If I were satisfied that there is no better way, I could endure these vexations, thinking they were a part of the business, and must be endured; for by "the sweat of the brow" and the sting of bees we shall eat honey.

I find I have not the number of the BEE JOURNAL containing Mr. Heddon's description of his honey-board; but I can see very little benefit derived from the use of a honey-board. I think the best way to place sections on a hive, is to take two strips of wood $1\frac{1}{2}$ inches wide, and $\frac{1}{4}$ inch thick, and as long as the inside of the hive, or enough to take in as many sections as you wish to set side by side; take 2 strips of the same width, $\frac{3}{8}$ inch thick and $\frac{1}{8}$ inch longer than the sections, nail the long strips to the ends of the short ones, and you have a case in which to set the sections. Place this crosswise on the brood frames on the back side of the hive. On the inside of this, along each side, place a strip 5-16 of an inch thick, $\frac{1}{2}$ inch wide, and as long as the case. Now place the sections in this case, resting them on the strips, close the ends with wood separators and key them tight with pieces the same as the top of the section. Two of these cases of sections cover the brood frames, and when more are needed, lift them up and place empty ones under.

This is, in my mind, the simplest, cheapest, and most readily manipulated case I have ever seen or heard of. Any one section, or the whole case, can be removed and returned with perfect ease.

The top and bottoms of the sections are $\frac{1}{4}$ or $\frac{3}{8}$ inch narrower than the sides, leaving room for the ingress of the bees, and a good opportunity to see the condition of the combs, by simply laying back the cloth a little. The 5-16 inch strip between the sections and frames, admits of the passage of the bees between them, and where they are properly put on, the bees do not wax them as much as in broad frames.

Three-eighths of an inch is too much space. The bees will sometimes bridge up between, and $\frac{1}{4}$ inch is not quite enough. They sometimes wax them fast.

In putting the sections on I find it best to place the case on first, then the narrow strips, and then the sections one at a time. In this way I kill no bees and when one gets a little used to it, they can be put on very quickly.

I have been using sections $1\frac{1}{2}$ inches wide, with separators, and thought separators indispensable; but since reading Dr. Tinker's article on page 545, and considering the idea of sections occupying the same space as the brood combs, and continuous passages up into the sections, I have concluded to try it this summer, and have made sections with sides $1\frac{1}{2}$ inch wide, and top and bottom $1\frac{1}{8}$ inch. These I can use on my present rack, and if I can obtain all, or nearly all straight and smooth combs without separators, I shall consider that a very great advance has been made in scientific apiculture.

There is one point upon which I wish our practical bee-men would

throw the light of their experience. The division-board, I consider an almost indispensable article in the apiary, but I experience some difficulty in preventing the bees sealing the ends to the sides of the hives. I have tried cutting the boards $\frac{1}{4}$ inch shorter than the width of the hive, and tacking strips of woolen cloth on each end, to fill the space. I have tried glazed cloth, put on in such a manner as to form a half-circle tube, between the end of the board and the hive. This last I consider the best for the end of the board.

Then to make it easy to remove the boards, I cut them in the center, or make them of two pieces, and hinge them with small staples. Then to remove the board, push the center from the comb. This shortens it and it is easily taken out or moved back. If any of our bee-men have a better way, will they please describe it in the BEE JOURNAL?

Farmer City, Ill.

For the American Bee Journal.

"Who Should Keep Bees?"

JOHN YODER.

So much has been said and written about the art of bee-keeping, that the novice may say, "I can never learn"; and yet the "half was never told," and that which has been told should never have been told.

Too much is said on the bright side of the bee-business; it makes the hundred resolve to "embark" when only one will succeed. It is very nice to visit a practical bee-man and see him handle his bees, taking off 20 or 30 lbs. of pure honey per colony; yes, so the 99 resolve to get "just a few for our own use." They do so and the few gather perhaps 20 or 30 lbs. of honey during the summer and then their bees die from the carelessness or malpractice of their keeper. No one should attempt to keep bees unless he knows "what manner of man he is"; if every man before starting in the business would first commit to memory W. F. Clarke's paper, "Who should keep bees," read at the Toronto Convention, and ask himself, am I naturally qualified? if so, can I attend to it? and then give an honest answer and act accordingly; if every one would do that, I am sure there would not be so many *bee-killers*.

It is really surprising how many there are who undertake, and do keep bees without having one book or paper on the subject; or who do not read an article in a whole year, unless they borrow or hear a short lecture while on a visit to some live bee-man.

This is the advice I gave to a bee-man the other day when talking to him about his bees: "If you want to make them pay you a handsome profit and do not wish to take from them what honey they have, or do not desire to sell them, set them out from under that old shed, pile those old rails on them and set fire to them." Now I know that was good advice under the circumstances; and there are very many more who might "go

and do likewise". What I mean is this: There is lots of honey wasted by every body who keep bees, to their own loss and the loss of the *one* practical man. However, this is a free country. A locality can be easily so overstocked that very little honey will come on the market.

Now as to spreading a knowledge of bee-keeping by getting subscribers to the BEE JOURNAL (and I know no better way of doing it), I can say, it is not beneficial to me; though I have tried it, talked it up, and lent my paper for miles around, and never took a subscription. You see if all my bee-keeping neighbors would get enthusiastic on the subject (and no one should keep bees unless they do) it would be bad for me; but Darwin says, "The fittest will survive." In this village I am almost "monarch of all I survey"; but in a village 6 miles from here, there is at least 6 enthusiasts that are going to make a specialty of the business, and run it into the ground. Now you may think me selfish, but there is something not right; perhaps that something is myself.

I have wintered my bees for two winters in the cellar, very successfully; and 22 colonies consuming, on an average, in 158 days last winter, a little less than 9 lbs. of honey; or rather they lost in weight less than 9 lbs. including the dead bees. All of them soiled the outside entrances of the hives; some of them so badly that I really was afraid they would die.

On April 2, I set out 7 colonies for a fly; they spotted everything within reach, so I set them back the same evening. On the 14th I set them all out; they did not spot anything. How was that? And most of the hives were very clean inside; while bees wintered on summer stands were very much soiled inside. I think when bees are in a warm, dark place they will come out to void themselves. In the cellar I pile the hives 3 deep, the first resting on an empty hive, a cushion made of oat-hulls over the frames of each, and let the cross pieces of the bottom board span the hive below, resting on a slat nailed on the end of the hive $\frac{1}{2}$ inch below the top.

I have 53 colonies with those cushions on most of them. The bees cluster immediately under the cushion; but those without the cushion cluster lower down, thus showing that the cushion is warm and agreeable to them. Spring dwindling is what I fear most, although I have not had much trouble in that way. I use the large hanging, 8-frame Quinby hive.

How would heavy pasteboard do for division boards? When a colony is strong enough in the spring to cover only 5 or 6 frames I think such a board would be just thing. Let the board fit tight all around. Some use a hanging-board the same size as the frames; but I do not see that they would be any better than an empty comb, or a full one either.

Here is a recipe for the prevention of bees' stinging, as told me by an old Irishman. He said there was a gentleman in the old country who kept 40 or 50 colonies, and before going to handle his bees he would first make a

soap lather on a hog's back and smear his arms, hands, neck, and face with it. The bees would not sting him for a week, unless he washed himself; for a bee would not sting a hog or any thing that smelled like one. Try it. Springfield, Ont.

For the American Bee Journal.

Bee-Feeding in the Spring.

W. A. SHEWMAN.

In all the bee-periodicals one reads much on the subject of feeding in the spring; and it well pays all who are engaged in keeping bees, as very many new ideas are brought forth, which a careful reader and sound reasoner may turn to advantage and profit. The success of the season, in a great measure, depends on the success of spring management; and in that there are many different theories.

To an apiarist of experience, or to those having a large number of colonies, the articles published in the newspapers are more especially directed; and the amateur or the possessor of a dozen colonies hardly finds in them the intelligence just suited to his case in order to make matters the most practicable. Experience is a valuable teacher, but practicability must go hand in hand with it, in order to be successful. With me success is to succeed with the least expense and labor—reasonably so.

But spring feeding is my theme, and I am on the amateur side. I read various ways of feeding, but the many different feeders advertised, are unavailable, so I use a method of my own, which I find is successful.

No doubt Messrs. Heddon, Doolittle, Hutchinson, etc., will smile audibly; but it will contrast with the "old fogies" who "pool" at their fancy methods. When I first examined my colonies in March, I found them all as strong, apparently, as when packed, in the fall, and as bright as a new silver dollar; but some had very little honey. How to supply it, was a question, as my time was limited. So I procured several small wooden boxes, that would set in between the inner hive and the packing case. In the side of these boxes near the top a slot was cut some 6 inches in length and $\frac{1}{2}$ inch wide. The boxes were found to leak when tried with water, but a hot iron and a very small quantity of beeswax soon soldered the joints on the inside and they were made water tight. These boxes were put next to the inner hive, the slot even with the top of the hive; a small piece of wood was inserted into the middle of the slot and projected about two inches; the cloth cover over the brood-frames raised enough to admit the small piece of wood; this makes a passage-way for the bees to the box,—and they readily find it. Then slide the cover of the small box 2 or 3 inches and pour in syrup, filling up to the slot; close the cover and the bees are fed without the least disturbance. At any time, more syrup may be given and the bees will never know how it came there.

The cheapness of this method and its practicability for those who have few, or many colonies, is admirable. One great point I claim over using a feeder inserted into the body of the hive, is, that with my method the bees are undisturbed, while with the others they are shifted about and more or less irritated; and the less you disturb the natural condition of bees in the spring, or any other time, in my opinion, the better it is.

Now as to the feed. I know that granulated sugar syrup is the next best thing to the natural honey for bee-food. And in my business I use it for spring feeding in the proportion of 7 lbs. of water to 10 lbs. of sugar. For fall feeding I should use 1 lb. less of water.

The syrup is boiled for a moment or two, then skimmed, and allowed to cool so that only the chill is off before feeding. I have wintered bees at a cost of one dollar per colony, solely on sugar syrup.

I will briefly state a few pointers: I do not believe in feeding often in the spring to stimulate breeding. If feed is required give all that is necessary at one time, and the breeding will proceed faster than if interrupted every few days. Neither do I believe in the pollen theory as the cause of diarrhoea, or the loss of bees. In some future article I wish to give my views on that question; but space forbids here, and more, it is not a timely topic. There is no use now, of telling how to pack bees for winter, etc.

Randolph, N. Y.

For the American Bee Journal.

Protection of Bees in Winter.

R. M. ARGO.

The best plan for the protection of bees in winter has not, as yet, been settled; and as the subject is still discussed quite extensively, I will give some plain facts on the natural method of wintering bees.

All recollect the severe winter of 1880-81, and the great mortality of bees which followed it. The theory then was that the extreme cold and long confinement killed the bees. I have for some time doubted this theory, and am now satisfied of its fallacy.

I generally have been successful in wintering bees for the past 20 years. The winter of 1868-69 will be remembered as one of great mortality among the bees, especially here in Kentucky. The disease was termed bee-cholera. Nearly every colony in this vicinity died; and all that saved my 13 was the feed I gave them before preparing them for winter. I believe it was not starvation that caused the death of the bees, but poor honey.

The past winter was the coldest ever known in this State; the thermometer, at times, being 33° below zero. My bees were confined longer than ever before, and still they came through stronger than I could have hoped for, and that without the loss of a single colony.

I had moved my apiary of 43 colonies, to a location which is high, well

drained, and much exposed. They were moved on a spring-wagon, and put on the ground in a semi-circular row facing the south. I intended fixing them up for winter and putting them in proper places, but I neglected doing so; not even putting in the honey-blocks, or closing such openings as were in the honey-boards. Of course after such an extremely cold winter, I expected that one-half of my colonies had perished.

I know of an apiary of 28 colonies which was moved in 1878, and left in a similar condition to mine; only 3 colonies were alive in the spring, but that was after a warm, damp winter had passed.

The winter before, my bees also were on as high and dry ground, and I lost only 1 colony by starvation; but they were not so much exposed, and had the entrance blocks in, but with no other protection.

Hereafter the only preparations for wintering I shall make will be these: 1. Leave the colonies on the summer stands, and see that each one has plenty of bees and sealed honey. 2. Protect the hives from dampness as far as possible. 3. Leave the entrances open about 2 to 4 inches, according to the strength of the colony. I would pay no attention to upward ventilation. Keeping the hive dry and the bees furnished with plenty of sealed honey, are the main ideas in wintering. Paint Lick, Ky.

For the American Bee Journal.

Bee-Keeping in Florida.

B. M. LINGLE.

I left my home in Indiana last October, to spend the cold season in the South. The winter here has been very pleasant indeed; but some of the old citizens say it was the coldest known for many years. There have been only two damaging frosts. Vegetables have been killed twice, and the gardeners are now shipping from the third planting. There were only a few days during the winter that bees did not work. About March 1, a lady gave me 2 colonies in rotten box hives. I began making hives to which to transfer them, and before I had completed the first hive one of the colonies swarmed. I hived the swarm, and soon transferred the colonies. They have been working nicely, but I have received no honey from them. Palmetto is beginning to bloom, and I think the bees will soon fill the sections. Here bees are kept in box hives; and when the apiarist wishes for some honey, he takes off the top of the hive and cuts out the honey. One of my neighbors had a swarm issue the other day, and it settled on a small tree. He put an empty hive under them, and then stepped back out of danger, and threw a club at them, but did not knock all of them off; so he took a fence rail and struck the tree, jarring off the balance. To my astonishment all of them went into the hive. Before leaving Indiana, I packed my 35 colonies with wheat chaff, on the summer stands;

and although the mercury was 30° below zero during the winter, I was informed that my bees were all right. Bees require no chaff-packing here, but need plenty of shade.

Palmetto, Fla., May 1, 1884.

For the American Bee Journal.

Randolph, N. Y., Convention.

Those interested in apiculture, met at Randolph, N. Y., on May 6, and organized the Western New York and Northern Pennsylvania Bee-Keepers' Association, by the adoption of a constitution and by-laws, and the election of the following officers for the ensuing year:

President—H. S. Elkins, Kennedy.
Vice-Presidents—O. H. Phillips, Conewango; S. S. Sleeper, Holland; H. D. Gates, Gerry.

Sec.—W. A. Shewman, Randolph.
Treasurer—V. Page, Kennedy.

These subjects were discussed: Regulating the price of honey; selling unripened honey; successful wintering; packing vs. other methods; division vs. natural swarming; age and prolificness of queens; clipping queens' wings; how to produce the most honey; how to prevent after-swarming; circus with fertile workers; how to winter for \$1.00 per colony; feeders, etc.

Those present represented 879 colonies in fall; spring count, 824; loss 55.

After a vote of thanks for the use of the Odd Fellows' hall, the Association adjourned to meet on Sept. 1, 2, at Jamestown, N. Y.

W. A. SHEWMAN, Sec.

For the American Bee Journal.

Bee-Keeping in Nebraska.

O. A. MULLON.

The working season for the bees has commenced in Nebraska. The spring has been backward; but since the middle of April bees have been at work on the maples and the cottonwood. Along the creek bottoms the abundant wild plum is in full bloom. It is interesting to mark the progress in bee-culture in a prairie State. The bee goes with the orchard, and the cultivation of flowers. For years the orchardists on the Missouri bluffs have been bee-keepers; it is only of late that apiaries have been located on the prairies. Fruit growing is extending west from the Missouri river, up into the Republican valley; Mr. Geo. M. Hawley, a mile and a half from Lincoln, had 175 colonies during the winter, in a large, dry cellar, and put them out about April 1,—later than is usual in Nebraska; the backward spring being the cause. His losses were not over 5 per cent, and that among the nuclei. The season now promises to be a good one.

Lincoln, Neb., May 1, 1884.

The Kentucky Bee-Keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed).

SELECTIONS FROM OUR LETTER BOX

Prospects for a Good Honey Crop.

As far as I can learn, bees have wintered well in this State, and are doing nicely at present. I have 8 colonies working in upper stories. I never saw bees work harder on linden and wild-plum bloom. The only trouble is that I have not enough strong colonies. I have extracted some honey, but do not like it. Buckeye is just commencing to bloom, and if I am not badly mistaken, I will have some honey soon. White clover never looked better; and I, for one, feel good over the prospects for a good honey crop in Iowa, for 1884.

W. M. MALONE.

Oakley, Iowa, May 7, 1884.

Bees Well Wintered.

I lost no colonies in winter; 8 were wintered in a shed, being packed in straw with a chaff cushion above the frames. I use the Simplicity-Langstroth, 9-framed hive. One colony wintered entirely on unsealed syrup-honey, which I had fed them late in the fall; and some combs were half full of pollen. I find this colony the strongest at present. Fruit bloom has just commenced, and promises well. The spring has been rather backward.

J. J. THIEROFF.

Defiance, O., May 7, 1884.

Bee-Business Overdone.

Judging from the price quotations of honey during the past 12 months about here, and in the country at large, the bee-business is being overdone. A little more reduction and all profit will be gone.

C. COVELL.

Buda, Ill., May 9, 1884.

Bees Storing and Breeding.

I put 107 colonies of bees into the cellar about Nov. 20, and placed them on their summer stands on March 26 and 27. The rats got into the cellar and destroyed one colony by eating nearly all the combs. I have lost 2 colonies since they were removed from the cellar. I do not think I would have lost any had it not been for the rats. All the colonies over which they passed in going to and

from the one they destroyed, had diarrhoea; caused, I think, by being frequently disturbed, for all others were free from it. My bees have never before been in as fine condition at this season of the year. In looking them over to-day, I find nearly all the colonies strong, and many of them with from 3 to 5 frames nearly full of sealed brood. Two of my neighbors reported to day that they had found sealed queen-cells. This is very uncommon in this latitude so early in the season. The bees have stored quite an amount of honey from fruit blossoms during the past 10 days.

REUBEN HAVENS.

Onarga, Ill., May 5, 1884.

Small Grain Looks Promising.

Willow is in full bloom, and the bees are busy working on it. My first swarm of Italians came out on May 10. Spring has been quite backward, but now prospects are better than was anticipated. Small grain is looking as well now as it has in many years past, at this season. Nearly all the farmers are planting corn.

EDMUND DE LAIR.

Oketo, Kans., May 12, 1884.

Small Loss in Wintering.

The spring has been cold and backward. Soft maple is just in bloom. Bees have wintered well in this section. I put 42 colonies into the cellar last fall, and all came through in good condition except one, which was queenless. Out of 300 colonies in this neighborhood, not more than 3 per cent. were lost in wintering.

C. S. HAWKINS.

Sank Rapids, Minn., May 12, 1884.

Anticipating a Lively Time.

While others have lost heavily in bees during the past winter and this spring, mine came through all right. I had them packed in single-walled hives on their summer stands, with 2 chaff division-boards, and leaves packed on the outside. I fed sugar syrup; nearly all the bees in this vicinity which were fed in this way came through all right. The principal cause of loss in bees here in Maine, is unwholesome stores, collected from elm and other kinds of bloom. It is yet cold, but we anticipate a lively time soon.

F. D. WELCOME.

Poland, Me., May 12, 1884.

Large Increase.

I had, in the spring of 1883, 17 colonies of bees, 15 of which proved very prolific, and on May 26, the first swarm issued. All were in box hives. I had prepared about 25 hives for the increase, and intended to transfer the bees into the Simplicity-Langstroth hives; but I got only 4 transferred before the first swarm issued. From this time on they continued to swarm so much, that I was unable to prepare hives fast enough. It was no unusual thing to witness 2 swarms issuing at once, and occasionally a third would get mixed up in spite of my efforts. In the fall I had 60 colonies. I sold 4,

lost 3, and built up 2 nuclei with tested Italian queens. I put 55 colonies into winter quarters, and all except 2, which were queenless, came through in good condition. I now have 55 colonies and one nucleus, from which I am obtaining eggs with which to Italianize. The surplus honey produced in my apiary last year, did not exceed 500 lbs. of comb, and 200 lbs. of extracted honey.

J. M. HAMBROUGH.
Versailles, Ill., May 14, 1884.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
Monday, 10 a. m., May 19, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for all honey is very slow; market dull and prices range from 6³/₄¢ for extracted. Different lots of choice comb honey in small sections have been offered and sold in our market lately at 12¹/₄¢ per lb. As I predicted some time ago, the preference for the production of comb honey seems to be prevalent; and, as we have the best prospects for an abundant harvest this year, we may prepare for low prices.
BEEWAX—Is in good demand; choice yellow brings 35¢ a lb. on arrival. CRAS, F. MUTH.

NEW YORK.

HONEY—The prospects are that but little honey will be carried over, and that will all be in 2-lb. sections. More one-pound sections should be produced for this market. We quote:
 Fancy white in 1-lb. sections, packed in clean crates, 16³/₄¢; 2-lb. 13¹/₄¢. Fair to good white, 11¹/₄¢; dark, 10¹/₄¢. Extracted, 8¹/₄¢.
BEEWAX—Scarce, 36³/₄¢.
 MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY—Demand light. 1-lb. sections comb honey, 18¹/₄¢; 2-lb. 16¹/₄¢. Extracted, 9¹/₄¢.
BEEWAX—35¢.
 BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—Extracted honey is a drug here. Very little of it is being used for manufacturing or baking purposes. Parties who last season used from 500 to 600 pounds, have for the past winter bought not to exceed 100 pounds in a like period of time. Many producers are anxious to realize on their last season's product, but it is impossible to find purchasers, even at the low price of 6 and 7 cents per pound. Comb honey stocks well reduced, but prices are low for anything short of fancy, quotable at 16¹/₄¢ per lb.
BEEWAX—Scarce at 30³/₄¢.
 R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Market is almost lifeless, there being no stocks of any consequence, and little or no demand. New honey is expected in about 3 weeks. White to extra white comb, 15¹/₄¢; dark to good, 10¹/₄¢; extracted, choice to extra white, 7³/₄¢; dark and candied, 5³/₄¢.
BEEWAX—Wholesale, 27³/₄¢@30¢.
 STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—I had orders to-day for 2,000 lbs. of choice comb honey in 2-lb. sections glassed on both sides, of which I had only 600 lbs. on hand. I can place several thousand pounds of 1 and 2-lb. sections readily at 15¹/₄¢, if in good order, and glassed on both sides. Extracted in fair demand at 7³/₄¢.
BEEWAX—None in this market.
 JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12¹/₄¢ per lb. and strained and extracted 6³/₄¢.
BEEWAX—Firm at 32³/₄¢ for choice.
 W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Market continues very fair, particularly for choice 1-lb. sections, which are in good demand at 15¹/₄¢; 2-lb. do not sell so readily, but in the absence of 1-lb. it moves at 17¹/₄¢. Second quality is very slow at 14¹/₄¢, and extracted not wanted at all in any shape.
BEEWAX—Very scarce; would bring 35 cts. on arrival for choice yellow.
 A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2-lb. sections, 18¹/₄¢; extracted, 7³/₄¢@8³/₄¢.
 GEO. W. MEADE & Co., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5. or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

ITALIAN QUEENS, HIVES, etc.

R. GRINSELL, Baden, Mo.
 21A11
 TESTED QUEENS, \$2; untested, \$1; 4 frame Nuclei, \$3.50 and \$4.50. Mississippi Wax Extractor, \$3. OSCAR F. BLEDSOE, Grenada, Miss. 21C12

Cincinnati, O., for a sample of

FOUNDATION that cannot sag or break down, with side-walls of Pure Wax from one-sixteenth to one-fourth of an inch high. **Cheaper than any other make.** 21A1t

NEW INVENTION.

Patented Oct. 17, 1882.

Bees forced to leave their surplus honey before removing it from the hive. Saves valuable time and labor; prevents robbing, and the liability of being stung. The Bees are first cut off from the brood hive, by closing the openings in a slat honey board; the conductor is then placed in position, which connects bees in surplus honey with brood hive. They soon find that they are imprisoned, and being anxious to escape, pass out through the Conductor into the brood hive. It also prevents their return.

Conductor and Langstroth hive complete.....\$6 00
Conductor and Honey Board, any size, and Sections to fill, which shows all the improvements..... 1 50
Conductor, by mail..... 50

Send for Circular giving full particulars.

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

| | |

Sixth Thousand Just Published!

New and Enlarged Edition

OF BEES and HONEY,

OR THE Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,
Editor of the *Weekly Bee Journal.*

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure.
T. F. BINGHAM,
Abronia, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN,
Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

VALUABLE ORIGINAL PATENTS.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always cool!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail orders and testimonials, send card. To sell again, send for dozen rates to

BOOKS!

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates, on larger quantities, given upon application.

Bees and Honey, or Management of an Apiary for Pleasure and Profit.—By Thomas G. Newman.—Sixth Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 220 pages, and is profusely illustrated. Price, bound in cloth, \$1.00; in paper covers, 75c., postpaid.

Dzierzon's Rational Bee-Keeping.—A Translation of the Masterpieces of that most celebrated German authority, by H. Dieck and S. Stutterd, and edited, with notes, by Charles N. Abbott, *Ex-editor of the "British Bee Journal."* Dr. Dzierzon is one of the greatest living authorities on Bee Culture. To him and the Baron of Berlepsch we are indebted for much that is now of scientific bee culture. Concerning this book, Prof. Cook says: "As the work of one of the great masters, the Langstroth of Germany, it can but find a warm welcome on this side of the Atlantic." Mr. A. I. Root says of it: "Old father Dzierzon... has probably made greater strides in scientific apiculture than any one man... For real scientific bee-keeping, there is no one else to be kept who's attention is at all inclined to scientific research, to purchase a copy. Cloth, \$2.

Queen-Rearing, by Henry Alley.—A full and detailed account of TWENTY-THREE years' experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price, \$1.00

Bee-Keeper's Guide, or, Cook's Manual of the Apiary.—This Manual is elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means can afford to do without. Cloth, \$1.25;

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Fuddings, Foam, Wines, etc.; and Honey as Medicine, with many Receipts. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 5c.; per dozen, 40c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. This is a chapter from "Bees and Honey." Price 10c.

Swarming, Dividing and Feeding Bees.—Hints to Bee-keepers, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how: 26 engravings. This is a chapter from "Bees and Honey." Price, 10c.

Bees to Winter, with instructions about Chaff-Packing, Cellars and Bee Houses, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price \$5 c. postpaid.

Fisher's Grain Tables for Farmers, etc.—142 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measurer, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. 40 cents.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Builders' Formulas, etc. of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gliders, Metal and Wood Workers of every kind.

The work contains 616 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

The Hive I Use.—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Foul Brood; its origin, development and cure. By Albert H. Kohnke. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. 15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Dzierzon Theory—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Apiary Register, for SYSTEMATIC WORK in the APIARY. The larger ones can be used for a few colonies, etc., or for an increase of numbers, and still keep the record all together in one book. Prices: For 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Deutsche Buecher, Ueber Bienenzucht.

Biene Kultur, oder erfolgreiche Behandlung der Bienen, von Thos. G. Newman. Dieses Pamphlet enthält Behauptungen über folgende Gegenstände—Derlichkeit des Bienenstandes—Honig pflanzen—Erziehung der Königin—Füttern—Schwärmen—Ableger—Verfehen—Italienisieren—Zusetzen von Königinnen—Ausziehen—Bienen behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschrieben ist. Preis 40 Cents.

Honig als Nahrung und Medizin—von Thomas G. Newman. Dieses enthält eine klare darstellung über Bienen und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angebend wie man Honigkuchen, Formkucheln, Puddings, Schaumkonfekt, Weine, u. s. w. zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Konsumenten bestimmt, und sollte vieltausendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Pferd und seine Krankheiten—Von B. J. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniß der verschiedenen Pferdekrankheiten, sammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Recepte. Preis 25 Cents.

Seasonable Hints.

The busy season in the apiary has now arrived, and we hope all are prepared for it. Very frequently the delay of a few days in getting hives, sections, comb foundation, etc., results in a partial failure of the honey harvest, or the loss of many swarms of bees. Therefore every one should endeavor to get such supplies before they are needed, and thus save annoyance and loss. We hope all our readers now have such things on hand. If not, no time should be lost in getting them. To buy the lower-priced articles simply because they are *cheap*, frequently is extravagant economy. Those that are sold for the lowest price, are often the most expensive when put to the test.

Another point is to provide pasturage for the bees, so that when the usual honey dearth comes, the bees may revel in nectar provided by the timely planting of good honey-producing plants.

Judicious forethought, displayed by liberally scattering good seed for honey plants, will be supplemented by Nature in the future, by extending that pasturage when most needed by the bees, and will also furnish the seed free of charge for doing so.

To those who expect to solicit public patronage of any kind, there is no economy in practicing a "masterly inactivity" by waiting for the public to discover unadvertised merits. If they have more bees than they wish to keep—or any meritorious supplies to sell to bee-keepers, let those papers that are devoted to that specialty announce it. All such should provide themselves with good stock or articles

to sell, and then place themselves prominently before the bee-keeping public as ready to receive its favors, and return an *honest equivalent* for orders lodged with them.

A word of caution is necessary here. We have received complaints of some who sent orders last year to supply dealers that have not yet been filled. Purchasers should be cautious about sending money to those who have not established a reputation, or can point to a good record.

Spurious California Honey.

The course of adulteration has made itself known in California, and in the following letter, Messrs. Stearns & Smith, honey dealers in San Francisco, propose the following remedy:

"Through the widely circulated AMERICAN BEE JOURNAL, we desire to call the attention of our Pacific Coast honey producers, and especially those of California, to the urgent and immediate necessity of a law or laws against the adulteration of honey, and the sale of the same. Our dairymen have met and discussed the matter of adulteration, and our State Legislature has enacted a law protecting them against the sale of "bull butter," or oleomargarine, and we hope our different Bee-Associations will take this matter up. California honey has a world-wide reputation for purity and excellence. There is for sale on the market a vile compound, under fancy labels named "honey," composed of about 40 per cent. of honey, 50 per cent. of glucose and 10 of water; it is a libel on our industrious bees; it works a great hardship to their owners; and, where it is shipped to other places, it gives our fine honey a bad name, and there lies the great damage to our honey producers. We hope they will talk this matter up and send men to the next State Legislature that will look to their interest and protect by law this great industry of California.

Mr. Orange Judd, who has for nearly a quarter of a Century edited the *American Agriculturist* in New York, has now moved to Chicago and become editor of the *Prairie Farmer*, and we hope he will make it a success. We welcome him to the West.

Some of the results of carelessness may be seen from the following, which occurred this week. We had a letter from a subscriber who complained of not getting any of his BEE JOURNALS for over a month; and then adds, send my paper to—post office. After spending much time to look the matter up, we found that he had moved from the former address, but did not notify us, expecting perhaps, that we "knew all about it," and would change the address. After several weeks the P. M. notified us to stop sending the BEE JOURNAL; that the person addressed had *moved away*. Then the name was taken from the "type-mail-list." Now we have to get it "set up" again, and inserted, send the numbers over again, and all the trouble and annoyance, on account of pure carelessness. This is only one of the many results of such heedlessness occurring all the while. We do wish all would do business in a common-sense way.

The *Indiana Farmer* has this to say about the use of bee-veils: "Many deary the use of veils in the bee-yard, but we believe that all beginners should use them until they acquire confidence in themselves. After one becomes conceited enough to think bees will never sting him, then let him throw aside the veils—at least for a time." There are times, during a good honey flow, that any one may do without any protection, but it is always best to have a smoker near by, ready for use; for when needed at all, it is very necessary.

We have received Prof. John Phin's book, entitled "A Dictionary of Practical Apiculture." It contains 80 illustrated pages, and is bound in cloth. Price 50 cents. This has long been a necessity, and will be found to be a very valuable assistant to writers on apiculture. We hope it will lead to the more correct use of apicultural words. For sale at this office.

CORRESPONDENCE

For the American Bee Journal.

Priority of Location.

JAMES HEDDON.

I am glad that I started the investigation of this subject. The more glad am I, because that it is one of great interest to the honey-producers of the near future. All that the earnest and honest are seeking in this discussion, is to get a clear, general understanding of justice in the matter.

On page 311, Mr. Pond says, that in my reply to his article upon this subject, I "nowhere touch his position." Has he changed his position, since seeing that the practical honey-producers of the country have grown wiser faster than he has, or he supposed they had? In order to discover that his "position" was to tear down my first claims upon this subject, read both articles. He set up a position, not of claims of priority, but actual ownership of nectar; that a poor man was "selfish," if he did not wish to have a rich one divide the honey-field with him; that professional amateurs had discovered most of the needs of the practical honey-producers, etc.

I thought I understood these positions; that they were weak, and I answered them. I think Mr. Pond has misunderstood me in referring to his being a lawyer. I had not the least idea of throwing a crumb at Mr. P.'s intellectual qualifications by mentioning his law-practice. The brightest ones, like the brightest apiarists, as a rule, make their business a specialty. What I meant was, that he who devoted all his mental or physical energies to the theory and practice of apiculture, and who must support himself and family from the profits of that business, would be most apt to have correct ideas upon the subject.

Mr. Pond, in using the term "right," forgets to prefix it with the word "moral," or "intellectual." We well know that all have and should have a legal "right" to locate where they please; hence the greater necessity for knowledge regarding this question, which is the very purpose of the present agitation.

It seems to me that the rest of Mr. Pond's arguments are like this last one, regarding "the butcher, the baker, and the candlestick maker." The fewer butchers and bakers we have in a town (below a certain number), the less the competition, and the worse for the buyers; because butchers and bakers (unlike honey-producers) are selfish, and want all they can get for bread and meat. They have no amateurs to tell them how wrong this selfishness is, in this communistic world where hardly any one looks much to his individual interest.

But in the light of our jealously watching the best interests of the consumer, it is, with us, very different from the "butcher and baker;" for

any invention, or aught else; take the honey extractor for instance, which enables us to produce honey more cheaply—gives it to the consumer correspondingly cheaper.

As we increase the number of well-gathered honey-fields, we lower the price of honey, redounding to the interest of the consumer. And in proportion, as we increase the number of apiarists in any given area or field, making the product cost each beekeeper more than it would did he enjoy the entire field alone, we are working against the interest of honey consumers, as well as the producers, in this divided field.

Mr. Doolittle does not mention the basic principle of my former article; let me repeat it: We believe from our experience, observation, and reading, that some number of colonies will overstock a field; *i. e.*, that there is a limit to the number placed in that field for profit. These can be owned and managed much more cheaply by one apiarist than by two; and one apiarist can manage them more profitably in one field than in two, provided that one is not overstocked.

I believe that the future price of honey will be regulated by the average cost of production; that he who produces at maximum cost, will fail; and he who produces at minimum cost, will succeed.

If we leave all legal "rights" to the field out of the question, then, for argument, throw out moral "rights." Can you not see that if all coming apiarists were properly educated upon this subject, there would be no division of fields, or need for this discussion?

Regarding personal experience, Mr. D. must take into consideration several facts which are not applicable to the future: 1. Bee-keeping is well-nigh a specialty with him; he has it "on the brain;" his neighboring farmers did not. About the time he had run in, they had run out. Bee-culture was changing from the old to the new system. He changed with it—they did not. In times and under conditions like that, he certainly had a right to go to keeping bees in that field; and his experience is only another evidence of the "survival of the fittest."

In regard to his chapter No. 2, where he has helped neighbors into business, he did just what I have done several times. His neighbor succeeded probably because he kept a comparatively small number of colonies in a field which was, no doubt, much more difficult to overstock than mine or the most of other fields. His honey-flow coming less continuously and more bountifully, makes it difficult to overstock.

I am beginning, this spring, with something over 200 colonies in each of two apiaries, and I do not believe that any second party can make apiculture profitable in either of these fields. If I am mistaken, I heartily wish I could be convinced of it; for then I would not sell a colony until I could start in each field with 400 colonies, spring count. Every additional colony that I keep, I can manage some cheaper than any one of the preceding number.

One would imply, by one of Mr. D.'s sentences, that if one did start in my field, I would be his enemy. By no means. Three or four have tried this, during the past 15 years. Because I had opposition, which might poison some minds, I took special pains to be courteous and friendly, and did all I could to assist them. Each made an ignominious failure, never producing one pound of honey that did not cost more than twice as much as it would bring.

Among intelligent and energetic apiarists, some are more successful than others, and perhaps would be so even in the same field; but there is not enough difference for any man to run out another of this class, who already has a good start in the business. There is no man whose energy and intelligence we need fear, who will be so weak as to attempt to do such an absurd thing. Capital has too much judgment and acquisitiveness behind it, to take so rash a step.

Messrs. Doolittle and Clarke concede that my ideas on this subject, with certain modifications, are correct. I have little faith in any pretention, in the line of apicultural missionary work. Bee-keepers like others should do business upon business principles. The intelligent apiarist does not expect, and will not accept of something for nothing. We do not want charity; we want honesty and justice. Give us the latter and we will never need the former.

Mr. Doolittle and myself seem to be "odd sheep" in the apicultural field. He is the only apiarist who depends upon honey alone for his support, who has a passion for "gushing." The latter, however, seems to be dying out in him. I am not sure but that I am almost, or quite, the only one whose financial interests are as great in supplies, as in the production of honey, and who is trying to brake the wheel of overdone apiculture. This may, perhaps, be accounted for upon the grounds that each thinks he is following truth, and enjoys her sweet fragrance more than dollars. Let us trust that this is so.

My friend and antagonist, W. F. Clarke, is a hard man to handle, even though he is wrong. His experience in discussion, literature and the world; his terse expression and vigorous, pointed thought, together with little experience as a modern apiarist, and never having a necessary concern in the interests of honey-producers, makes it very difficult to set him aright. Mr. Clarke should not claim better judgment in regard to the honey-yielding capacity of my own locality, than I have, after watching the results in it for 15 years. I ought not to be "oversensitive" in regard to matters in which my bread-and-butter interests are so evenly divided. I feel that I am not. I detest "monopoly," and I see no monopolizing spirit in trying to arrange matters so that honey-producers can sell their honey cheap (for they will have to), and yet be able to decently provide for their families.

Mr. Clarke, having such great faith in my field, congratulates me on the comforting fact that, when I find so

many bee-keepers in it, that none can succeed, we can "plant." Will it not be ample time to agitate the "planting" question, when at least one-half of the nectar now going to waste, in unoccupied fields, is gathered?

Have we not had evidence enough, that farming and apiculture are naturally opposed to each other's success? I can show ample evidence in this County.

I have already tried to show that comparison between selling goods and securing honey are great misfits; also between honey-producing and gardening. Increase gardens all you please, and the operations of one on the next acre, in no way makes the productions of the next one more expensive, as is the case with honey-production.

Mr. Clarke says, "it would be a long time before a village would have a second store, if the prior consent of merchant No. 1, must be had before starting it."

In this, Mr. Clarke has had a good chance to judge, and is, no doubt, correct. We also know that the propensity of benevolence is equally distributed throughout all the different legitimate callings of life. Are bee-keepers more interested in humanity? Or is it only the few who have some "ax to grind" (and expect that the dupes to these broad, philanthropic views, will turn the grind-stone), who advise us to abandon self-interest, for the interest of an outside class, who are assiduously working for their own individual interests.

Mr. Clarke wonders what I will think of him after reading his article. Well, I think he is among the "mistaken," and always will be, I presume, until he lays aside all other sources of income, except apiculture, and then in a few years will get at the facts. The inexperienced are on the one side, and the experienced on the other.

Dowagiac, Mich., May 15, 1884.

For the American Bee Journal.

Diarrhœa alias Dysentery.

J. F. LATHAM.

The editor of the BEE JOURNAL defines the malady "Bee-Diarrhœa." Perhaps his definition is as correct as any, when an allusion to the disease is made in a general sense; but, as the symptoms accompanying diarrhœa, and those accompanying dysentery, are developed by phases not strictly allied, characteristically, we will term the kind we wish to talk about dysentery or abnormal secretion; and assume a position that will admit of an analogical construction.

Any cause which produces an excessive stimulation of the animal functions, has a tendency to produce a deranged secretion of the fluids which are demanded by the animal economy to replace, by assimilation, the waste of organic tissue. In normal conditions the animal functions have a particular work, and each organ, by performing its allotted duties, is not overtasked by being compelled to aid a defective co-worker; no excessive heat

is generated in the removal and production of animal tissue.

Nature receives her revenues, and disburses them as her requirements demand, and the whole organic mechanism moves harmoniously. Introduce agents in any form, or of any character, that will cause disturbance in this harmonious process, and disorganized action will be the result. It matters not from what source the irritating elements are derived, the consequence of their working possesses a similarity, although they may not at all times effect the same results, being modified in a greater or less degree by the influence of surroundings or conditions in which their subjects are placed.

If this functional derangement continues for a certain time, it will terminate in general debility, weakness, defective action, etc. Digestion and assimilation are impaired and the chyle that should aid in renewing the wastes of the body, remains in the intestinal receptacles, and becomes virulent.

As bees in our Northern climate are compelled to remain in confinement a long time in winter, a portion of this effete matter is drawn into the circulation; and, as they will not void their feces in the hive, except from dire compulsion, it may be very correctly imagined what the consequence will be, when a colony is forced to combat such baneful conditions, without an opportunity to relieve its distended organs when necessity demands.

The causes tending to a development of the deranged condition alluded to in the foregoing, are so numerous and variable, and so connected in their relations, that the effect of their workings cannot be attributed to any one cause alone; but as the food eaten, the air breathed, and the means used for protection from cold, comprise the main requirements for the support of animal life, so do they contain elements which will tend to its destruction when improperly constituted, or defectively applied.

Nature has constituted the honey-bee to maintain life, and perform its allotted duties from the nectar and farina of the flowers; and, in the season of bloom, when she can sip the exuding sweets, and gather the chaste pollen in their pristine purity, and rear her young on their health-producing elements, her workings display vigor and activity. Then nature—instinct,—the indices of attributes omnipotent, require no manipulation.

But, as the devices of man have made the bee a domestic contributor to his desires, when the frosts of autumn forbid her aerial wanderings, and the rigors of winter confine her to the hive, his intelligent care is demanded for her protection and support. To fulfil the requirements of nature, honey in its original purity, or its substitute, is the only aliment needed by a colony of bees in winter; in fact, it is the only food they will partake of when inactive. As children of nature they live by her monitions, and in their acts comply with her promptings.

During their winter's sleep their physical requirements demand but little nitrogenous food. Comb-building is dispensed with, and no brood is reared, unless conditions prompt the renewal of a too rapid loss of numbers; then activity requires a nitrogenous diet, and pollen, an indispensable auxiliary in brood-rearing, is needed, and will be consumed by the old bees while nursing their young. The young bees reared under such conditions, and those reared late in the fall and do not leave their cells until winter has set in, must retain their feces until an opportunity for a "fly" is given them. If the weather is not favorable for such an opportunity, at a proper time, they must invariably succumb to the effects of virulent fecal accumulations.

This condition is prominently indicated by the bees crawling from their hives late in the fall, or in their flying out and perishing on the snow in early winter. This condition of brood-rearing after cold weather has set in, and its harmful effects on pollen-eating bees, seems to be one that will bear investigation by those who so very strenuously advocate "late fall breeding."

That there are other conditions, is evident; but, as activity prompted the consumption of pollen in this instance, it seems that to activity, should be accredited the prime cause of the trouble. Another cause exists in sour honey—nectar not sufficiently ripened to prevent acetic fermentation, and in the parasitic productions incident to such a stage of decomposition. This fermentation may take place before the honey is used as food, or it may occur in the debilitated stomach or intestinal canal of the consumer, when conditions will not permit sufficient capillary contraction to expel that proportion not needed in a healthy digestion or assimilation.

To unripened nectar, may be added other compounds accumulated as stores, which are too well known to the observing bee-keeper to need enumerating. All colonies of bees are not as neat in their house-keeping as health demands. The combs in some colonies are not kept as free from refuse matter as those in others; and, as the nectar when stored in foul combs must partake of their uncleanness, it cannot make such food as bees require in winter.

From these deductions, based on observation, and confirmed by the statements of others who have lost their bees under conditions attributable to the causes named, I have no hesitancy in stating that acetic fermentation is the first great cause of diarrhœa among bees during confinement in winter.

As a test, let any bee-keeper take a colony of bees that he wishes to kill, and feed them to distention on diluted honey in its first stages of fermentation, with or without pollen, keeping them the while in a cold atmosphere without "flying" at proper intervals; and if the process does not produce diarrhœa, let us know through the BEE JOURNAL.

Good air and protection from cold, are requirements that should receive a rigid attention from the bee-keeper, if located in our Northern climate; especially in the New England States, where one hour does not indicate what the next may bring forth.

Approximate localities differ. One apiarist may suffer loss of bees, and another a few miles distant may survive the winter in good condition; the colonies in both instances having received the same care, or as nearly so as is possible to give.

A warm, damp atmosphere will not kill a colony of bees in winter. It may stimulate activity, and induce brood-rearing; but if brood-rearing is not induced, the warmth generated by the cluster cannot be harmful where means are provided for a proper circulation of fresh air inside of the hive.

When in a semi-dormant state, the denizens of the hive require but little oxygen to support life, or to neutralize any harmful effects resulting from the accumulation of carbonic-acid gas in their surroundings. As this gas, when occupying space in quantities detrimental to animal life, moves earthward, it is easy to comprehend how readily the inside of a bee-hive may be freed from its effects, by proper downward ventilation, accompanied by an imperceptible "upward ventilation;" *i. e.*, an "upward ventilation" not strong enough to produce a rapid current of air through or around the cluster.

Again, where the life-supporting elements: oxygen, hydrogen, and carbon, are needed to maintain animal heat, dampness in some form is an actual necessity; for without these elements, the combustion required for the propulsion of the animal mechanism, will not be produced.

Cumberland, Me.

For the American Bee Journal.

Northern Ohio Convention.

The Northern Ohio Bee-Keepers' Association met in the City Council Chamber at Norwalk, O., April 24, at 10:30 a. m., with President Samuel Fish, of Milan, O., in the chair. The Secretary's report of the last meeting was read and approved. Seven new members were enrolled.

The election of officers was postponed until the afternoon, and the forenoon was spent in receiving reports from the members on "Wintering."

Pres. Fish: My Bees wintered successfully in a bee-house; set them out on April 14, after a confinement of about five months; they might have been profitably left in ten days longer. They came out strong in bees, but with very little brood; early brood-rearing having nearly ceased, but was rapidly resumed on being set out. Wintered 6 colonies on the summer stands, in chaff hives; lost one; I prefer indoor wintering.

H. R. Boardman winters bees successfully in a bee-house, essentially the same as Mr. Fish's, and in about the same manner, except setting them out nearly a month earlier. The old

bees having died the colonies are light but have an abundance of mature brood.

These two reports, so different in result, called forth a spirited discussion upon the policy of setting out bees early. The prevailing sentiment was not favorable to setting out early, unless set back again until the cold winds of March were over.

S. F. Newman winters bees in the cellar and on the summer-stands, in chaff hives. He prefers chaff hives and out-door wintering.

E. R. Gibbs wintered them successfully in chaff hives out-doors.

Mr. Darling: My wintering was not successful; they wintered out doors on summer-stands; I attribute my loss to lack of ventilation, from defect in the hive.

Mr. Bartow wintered them on summer-stands, with very poor results.

Dan White wintered them successfully on the summer-stands, in chaff hives, without loss.

Many other reports were received, all showing that bees wintered moderately well, but were much enfeebled by the cold and unfavorable spring.

Adjourned till 1:15 p. m.

The afternoon meeting was called to order at 1:30, by the President. The following officers were elected for the ensuing year:

President, S. F. Newman, Norwalk.
Vice President, Mrs. A. Bartow, N. Milan.

Secretaries, H. R. Boardman and E. Townsend.

Treasurer, E. R. Gibbs, Norwalk.
Treas. Gibbs reports a balance in the treasury of \$6.20.

Question—"Spring Management." Dan White described, with much enthusiasm, how he builds up in the spring even very light colonies, so that they will be strong enough to swarm in the swarming season, by using a division board in the hive to crowd the bees on as few combs as possible, and feeds, back of the division-board, either reserved stores or granulated sugar syrup.

Pres. S. F. Newman adopts about the same course as that practiced by Mr. White, except that he would not stimulate the lightest colonies by feed; but build them up from the stronger ones later in the season, by giving cards of brood.

Samuel Fish keeps his bees in late in the spring; discourages early brood-rearing, gives plenty of stores, uses the division-board sometimes, but does not attach as much importance to its use as many bee-keepers do.

Mr. Albright builds up light colonies in the spring by feeding sugar-syrup, which he pours into combs, and sets in the hive next to the bees; succeeds well in this way.

A warm discussion then arose upon the use of the division-board for building up colonies in the spring. Some advocated its use, and others would dispense with it as useless and unnecessary.

Mr. H. R. Boardman read a very interesting essay on Feeding Bees in the Spring, which will appear in the BEE JOURNAL soon. [Ed.]

Question—"Swarming, and the Production of Comb Honey"—which was very thoroughly discussed.

Mr. Fish adopts the plan practiced by James Heddon, of Michigan. Mr. White thinks shade plays an important part in preventing bees' swarming.

Pres. Newman gives the swarm some of the combs and brood from the colony from which it issued, and also the unfinished surplus of the colony is given to the swarm to finish.

Mr. Boardman has long ago given up trying to prevent swarming while producing comb honey.

Mrs. Allen Bartow made a few very sensible remarks on "Planting for Bee Forage." She also read the following report by her husband, Mr. Allen Bartow, of his observations in Southern Texas, during the last winter:

Bee-keeping in Texas is more profitable, as a whole, than it is in the North. Wintering is not a problem, as they do not perish with cold as many have done in Ohio during the last and many preceding winters. The Texan bee-keeper winters his bees out-of-doors without any protection other than their summer hives, thus saving the cost of building expensive bee-houses. 1. They have short winters and consequently the bees do not consume so much of their stores as ours do. 3. The long summers afford more time for gathering honey, and the great variety and abundance of flowers furnish an almost inexhaustible supply.

Besides the small flowers which clothe all the plains and valleys with beauty, there is a great variety of trees whose blossoms afford honey; a few are: Linden, live-oak, black-jack, box-elder, sumac and agaretta.

They do not have the advantage of fruit blossoms, except the wild fruits, as there are but few orchards. Apples do not do well in that climate, and probably never will, and the same may be said of cherries. Peaches do better but they do not afford much honey. The cotton plant, however, affords considerable honey and of good quality. Buckwheat is raised with tolerable success and is another resource; but last though not least, is the "honey-dew," which, I was told by Mr. Surber and others, giving such large quantities when it occurs that the amount gathered is often surprising to the bee-keeper who is unprepared. The Texans use hives of various kinds, from the box to the latest improved frame-hive.

At Camp Verde I ate honey of good quality. The product per colony is 90 lbs. comb, and often it is 100 lbs. Last season was a poor one owing to the long drouth, and no doubt was an exception to the average season, as Mr. Surber told me his yield was about the same, and he is an intelligent man and a good apiarist.

In Texas the bee-keeper's enemies are the bee-martin and the moth. The careless lose largely by the latter. I visited one apiary, the owner of which had lost fully one-half of his bees by the moth. This was evidently the result of neglect, as he had too much

other business, being a druggist. His hives were hard to handle, although they had movable frames, and they were also too much shaded. Bees require some shade in this climate, in the middle of the day in summer; but he had overdone the shade business, and as a consequence lost.

I believe bees handled there as we do in the North, would pay well. The climate is healthy and pleasant in winter and not overly warm in summer. The people are intelligent and courteous.

An interesting letter was also read by Mrs. Bartow, from Mr. A. B. Surber, a bee-keeper of Southern Texas, in reply to several questions asked him in regard to bee-keeping in that State.

The following was passed: "*Resolved*, That the thanks of this Association are due, and are hereby tendered to Mr. Samuel Fish, for the able manner in which he has presided over this Association during the past two years, and for the uniform kindness which he has at all times exercised toward its members." Mr. Fish thanked the members for their courtesy.

A vote of thanks was given to the City Council for the use of their room. Also to S. F. Newman, for his past services as Secretary of the Association.

Adjourned to meet at the call of the Secretary.

H. R. BOARDMAN, Sec.

S. F. NEWMAN, Pres.

For the American Bee Journal.

The "Keystone" Convention.

The Keystone Bee-keepers' Association met lately at Scranton, Pa.

After reading the minutes of previous meeting, the election of officers was held and J. Vandervort, of Laceyville, was elected President, D. J. Peck, of Harford, Vice President, A. A. Davis, of Clark's Green, Secretary, and C. E. Miller, of Justice, Treasurer.

After the transaction of business the subject, "Do Bees Injure Fruit or Crops?" was discussed; in which the majority of the members participated. The opinion expressed seemed to indicate that instead of being injurious they were a benefit in many respects.

One gentleman said that he had noticed that buckwheat always yielded a better crop if frequented by large numbers of bees, and so of other crops. An idea existed that some farmers Paris-green their buckwheat and other crops for the purpose of destroying the bees, and a remonstrance was expressed against such a deplorable measure. The President stated that the English government has gone to considerable expense to have the common bumble-bee introduced into Australia for the purpose of fertilizing red clover, and had met with but partial success. Others who had experimented in several ways claimed that bees, to all classes of fruit, were beneficial and should be encouraged. Adjourned.

C. E. MILLER, Sec.

For the American Bee Journal.

Northern Georgia.

L. K. DICKEY.

On page 139, in calling the attention of Northern bee-keepers to this country, I asked this question: "Why do not enterprising bee-keepers in the North, who are seeking a better field for their business, come to Northwest Georgia and help us develop out honey resources?"

On page 201 Mr. Leonidas Carson says: "The answer is plain. Enterprising men of all occupations in the North are loth to settle in the Southern States so long as lawlessness is excused and goes unpunished;" and then says he has reference to the trouble at Danville, Miss. I do not know whether he alludes to the riot at Danville, Va., or to the outrages in Copiah County, Miss. I can not see why the trouble at either or both of these places 500 or 600 miles distant should deter enterprising men of any section from coming to Northwest Georgia, unless there is evidence that our people sympathize with such lawlessness.

In my opinion there is no such evidence to be found outside the fertile imagination of Mr. Carson. I am a native of this State and county and an ardent Republican in politics, and now hold an honorable position to which I was elected chiefly by Democratic votes. No one can feel more keenly than myself, the injustice and wrongs perpetrated in some of the Southern States for political purposes.

Now let me say to Mr. Carson and others in the North, whose "eyes are turned southward," to the land he so beautifully describes, that our people are, in the main, plain, clever people, and are as law-abiding as those of any section of the union; and before becoming prejudiced against this section on account of those troubles which occurred in other States, and at great distances from us, to come, see, and investigate for yourselves. These unfortunate occurrences should no more deter you from coming here than the recent riot in Cincinnati, or the recent outrage on Mr. McDevitt in Ohio, should deter me from going to Grundy County, Ia.

For further information concerning our people let me refer you to an article published on page 171, BEE JOURNAL for 1881, written by Mr. Moon of Rome, Ga., who, I believe, was a Northern man.

This is a broken, hilly, mountainous country, with fertile valleys intervening. These hills are generally poor, though sufficiently fertile to grow fruit and vegetables, and moderate crops of grain. In the valleys it is reasonably productive, growing corn, wheat, oats, clover, fruit and vegetables. There is generally an abundance of running water. As a bee-country it is good, though our honey flow is not so profuse as it is in some sections of the North.

As I said in my letter, our honey resources are not developed. The largest yield that I have heard of is 160 lbs. extracted honey, per colony.

I think Mr. Good's advice on page 217 is timely and wise; though I think he has been in quite a poor country. I would much prefer a location reasonably near to Chattanooga which is a fast-growing city of about 20,000 inhabitants, and is of much importance as a manufacturing and railroad center.

High Point, Ga.

For the American Bee Journal.

What the Bees Think of it.

MRS. DR. E. MASON.

"Why so much uncertainty about wintering, ventilation, and spring dwindling?" I am thinking these much abused bees must often say, "what fools these mortals be. One stows us in a dark, damp, moldy and foul-aired cellar; restrains us of liberty, fresh air, and the bright sunshine, which is so essential to life and health, even in the coldest weather; another stows us in a room or dry cellar, but robs us of our liberty, prevents our flight also, until we crawl about the floor and die; another hills us up like cabbage and turnips, and almost all, more or less, shake us up, haul us away from our summer stands, fret and scare us until we are half crazy, every spring and fall. Then they talk of 'safe wintering' and 'spring dwindling.' Is it any wonder that, in our fright and anger at such treatment, we die, or, that our honey tastes strong and gives the cramps, and injures the sale of it? Give us gentle, loving hands to attend us, and our honey is sweet and healthful at all times. Good mortals, please let us rest from that kind of treatment. It is labor, fatigue, and loss to you, and disease, craze, and death to us. Please let us have thick, double-walled, chaff-lined hives, well painted to preserve the hive and keep the dampness out. Lay 2 or 3 bars or sticks, one-half inch thick, across the top-bars, that we may pass freely over and cluster on the top-bars. Lay over us a new cotton or burlap honey-cloth, covering every crevice; for ventilation, in the shape of crevices, hardens the combs and honey, and is death to us. Then lay a pillow smoothly over the honey-cloth, and shut the box cover closely, leaving no part of the honey-cloth or cushions caught between the cover and the hive to absorb dampness."

There is no other cushion-material equal to feathers; for they retain the heat—are always dry and light, and the space between the cushion and the top of the box-cover, is a hot-air chamber. Cotton batting, covered with unbleached muslin, is the next best cushion as a substitute for feathers. Raise the back of the hive 2 or 3 inches higher than the entrance, so as to carry off all water, dead bees, etc.

I have kept from 50 to 100 colonies of Italian bees for 10 years, and I have never had any trouble in wintering them; nor had sickness of any kind among them; nor "spring dwindling," which can be prevented by commencing in January, to place rye flour in sunny places about the hives, and on

the ends of the alighting-boards; also shallow pans with combs filled with slightly-salted water. A little judicious feeding stimulates and encourages the bees, and prevents their flying so far from home in the cold, spring air, to flour and sawmills, where sometimes whole colonies are killed by the flour and sawdust. Good wintering and spring care will prevent "spring dwindling." Keep the bees always on the same stands in winter and summer; put up good water-proof sheds fronting to the South or East, tightly boarded up on the back, eave troughs to carry off the rain at the back, and a wide board nailed across the front, to prevent the rain and snow from blowing in on the hives; and see that the earth or flooring under the hives is perfectly dry.

The advantage in keeping bees in one place is, that they are more gentle, and in swarming they rarely fly but a few feet from the shed, and settle on the first shrub or plant, and often on the corner of the same hive. As soon as they are hived, I lift them up and set them by the side of the hive from which they issued. If in rows near together, they are more friendly, and are not given to robbing.

As to disease among bees: I have not a doubt but that it is bred from dampness, mold, bad air, cold, and want of sunlight. One diseased colony might contaminate a neighborhood. Shut one family of children in dark, damp, and moldy rooms or basements, deprived of fresh air, sunlight, and exercise, and they may generate scarlet fever so deadly, as to deprive a healthful city of its inmates.

You do not want your houses filled with crevices, broken windows, and holes in the ceilings, in order to have "ventilation;" neither do your bees. They can fan in and out, with their wings, all the fresh air they want. Always have a sort of entrance hall or close portico in front of the hives. It shields the bees from cold blasts and sudden changes.

If the sun shines too warm on the fronts of the hives, and there is snow on the ground, stand up a shingle or board to shade the entrance, thus preventing their flying into the snow. Try this method of management. It has been a perfect success with my bees.

Vincennes, Ind.

For the American Bee Journal.

Clipping the Queen's Wing.

W. H. STEWART.

On page 612 of the BEE JOURNAL for 1883, I read the following:

On page 576 of the BEE JOURNAL for 1883, I find an article by Mr. W. H. Stewart, entitled, "Shall we Clip our Queens' Wings?" at the close of which he says: "If I were offering queens for sale as superior stock, I would compel the brood mothers to fly often, even if I had to toss them up to give them a start." I wish to ask him a question to illustrate the matter in a different light. Suppose

that he had a brood-mare from which he wished to rear colts noted for speed, would he consider it necessary or advisable, during foal, that she be driven at a high rate of speed, with a view of transmitting that quality to the offspring? W. N. HOWARD.
Derby, Vt.

I regret that he did not put the question differently. If by the word *foal*, he means the period during gestation, I would say that I think it would be very wrong to treat the mare as some bee-keepers are treating their queens, viz: placing them in a close, dark hive, and depriving them of their organs of locomotion. To treat the mare in like manner, would be to confine her in a close, dark stable, and cut her legs off.

I hold that it would be very necessary and advisable, to drive the brood mare every day at as high speed as sound judgment would dictate, with a view of keeping her organs of locomotion in a strong and healthy condition, for the purpose that she might be able to transmit that condition to her offspring.

I know not what Mr. Howard would have me understand by the term "a high rate of speed." Some horses are able to trot a mile in much less than 3 minutes, while it would overtax and injure others to travel half as fast.

In my article on, "Shall we Clip the Queens' Wings," I stated that "overwork or excessive strain, would injure any member of the bee or other animal." If any member of a horse or bee is overtaxed, then it becomes weak and diseased; and I stated that a "condition of weakness may be transmitted to the offspring."

I do not propose to write articles for the BEE JOURNAL on the subject of breeding fast horses; but I would like to have some fast bees. In one sense, the horse question has nothing to do with modern bee culture; but in the sense that I infer Mr. H. intended the question, it has very much to do with it.

In my article on page 54, I stated that "I hold that all animal life is governed by the same universal law, from which there is no divorce." When we have learned that temperate labor, in any class of animals, whether running, trotting, walking or flying, is healthful, and that its tendency is the development of vigor, then we have solved the question in regard to all other classes of animals.

We often hear of brood-mares working before the plow up to within 15 minutes of the birth of their colts, and yet both mares and colts remained in good health; yet if the mares had been worked or driven to excess, both would most likely have died.

I did not state that I would compel queens to fly until their strength was exhausted, or enough to do them a physical injury; but that "I would compel them to fly often."

We often see queens fly from the combs while being handled; they are gone for a short time, and then return to their hive all right, and appear as though they had enjoyed the fly first-rate; and, as work goes on in the brood department as regularly as before,

we conclude that the fly did them no injury. Birds seem to fly just as easily and safely, and seem to enjoy it just as well while they are producing eggs, as at other seasons of the year.

We have often opened the hive, after the queen and her young swarm had just left it, and we judged, from the abundance of fresh eggs found in the combs, that she has been busy depositing eggs up to the time when she started out with the swarm.

Again, when we have put the queen and the young swarm in a new hive on empty combs, the work of depositing eggs has been resumed in a few minutes, and, as the work goes briskly on, we know that the fly in swarming did her no harm. Some queens fly several times during the swarming season, and, when they leave for the woods, we find that they are able to fly long distances, and very swiftly, too.

None of us know how many times a queen with wing not clipped, leaves the hive during the warm season, for a healthful fly in the open sunshine; and we know not the pleasure and delight that they experience during those aerial excursions; nor yet do we know how important, and lasting impressions, both mental and physical, are being transmitted to the tiny egg-germs during the happy flight, because of the mental ecstasy of the mother.

Who can depict the power of mind over matter? The mind of man drives the "iron monsters across oceans and continents, and along the many rivers that thread the bosom of mother earth, and takes control of the lower forms of the animal kingdom." Who can tell what the mind of man may yet do with and for the honey bee?

I would answer Mr. Howard's question, by asking a few more questions, for the purpose of reminding him of truths with which he must already be somewhat familiar. Is he not aware that a scare, or other mental excitement of a disagreeable nature, often makes strange and woeful impressions, both mental and physical, upon the embryo, even in the human race? That certain mental conditions often make sad inroads upon our health, and at other times restore health after it is once broken? That the most successful physician is the one that has the happy faculty of approaching a sick person with a pleasing smile that awakens hope and confidence in the weak and nervous sufferer? That these manifestations are the expressions of one of nature's laws that embraces all animal life?

In his question, he "supposes that I have a brood-mare from which I wish to rear colts noted for speed, etc." Here I will "suppose" that the mare is able to travel at a "high rate of speed," and that her members of locomotion are well developed and hardened by practice; that her mental faculties have been well schooled on the race-course; that she, like many other sporting horses, is quiet and easily handled until she is led up to the well-known race-track, and hitched before a sporting sulky; that she sees and understands at that moment what is at hand, and at once becomes so ex-

cited and frantic for the match, that it requires a good horseman to control her. Every muscle becomes rigid, her ears lie back on her neck—her foaming and parted lips give you a clear view of her ivory that is violently grinding at the curbing steel between it; both front feet high in the air, and her nostrils wide distended. I will suppose that she is pregnant, and I will allow her to enter the match for a short distance, and often repeat the operation during gestation, being careful not to allow her to overdo at any time. I hold that it is not the "high rate of speed" that would be likely to injure her, or the colt; but compelling her to continue that speed until her strength was exhausted, would be dangerous to both.

Do you ask why I would thus treat the brood-mare? I answer that "it is a well known fact, that when any faculty of an animal becomes excited, that excitement prompts an extra flow of the best blood to a corresponding member. That blood makes an extra deposit of building-material with which it is laden, and the result is an extra development of that member. In thus exciting the faculties, and developing the members of the mother, a corresponding work is at the same time going on in the embryo.

In the production of colts, bees, or anything else that has life, the parents reproduce themselves, and neither the mental or physical condition of the offspring, at birth, can in any way exceed the combined conditions of the parents. All further development must be made by a process of growth of the offspring after its birth. Imprisonment comes not of the race in common; it is confined to favored individuals. Those individuals may, under favorable circumstances, transmit that individual growth or improved condition.

I hold that it is "advisable and necessary," that we excite the desirable qualities or faculties of the brood-mother, for the reason that, by so doing, we are all the while building up, through the mother, the desired capabilities in the offspring; and I also hold that, under proper treatment, the possibilities of improvement of the animal kingdom, are unbounded.

Who can deplet the coming speed,
Of coming bee, or coming steed?
With nerve to outstrip the iron horse,
And vie with the whirlwind round the course.

'Tis man that builds the iron steed,
His limited wisdom, means limited speed;
Infinite wisdom provides the nerves,
Adapted to the age it serves.

In balance nice, weigh nature's law,
Of growth and fitness 'gainst a straw;
Read on your standard when you're done,
What e're ends well, was well begun.

Orion, Wis.

Northwestern Ohio Convention.

The Northwestern Ohio Bee-Keepers' Association met at the residence of S. H. Bolton, in Hancock county, O., on May 9, 1884.

The meeting was called to order by the President, Jacob Ginsinger; and as the meeting was for the study of practical work in the apiary, the committee on programme announced the following as the order of business: 1.

Transferring bees. The first colony to be transferred by Mr. Frank Eaton; the second colony, by the President, and the third, by any one wishing to do it; 2. forming nuclei; 3. introducing queens.

All then adjourned to Mr. Bolton's apiary (containing 52 colonies) and, Mr. Eaton being absent, Mr. Ginsinger, with the necessary implements, transferred a colony from a box hive, in a short time. Mr. Eaton then came and did the same, making a neat job.

Adjourned until afternoon.

After dinner all took a view of Mr. Ginsinger's apiary, which consists of some 30 or 40 colonies, and is in fine condition. All then returned to Mr. Bolton's and the third colony was transferred in about 15 minutes.

The remainder of the programme was completed after which the convention proceeded to fix the time and place for holding the next meeting, and on motion, the time was fixed for July 25, 1884, at Ottawa, O.

On motion S. P. Weaver, Jacob Ginsinger and F. M. Blakeman were appointed a committee to arrange a programme for next meeting.

On motion the following resolution was adopted: *Resolved*, That any lady or gentleman may become a member of this Association, by furnishing the Secretary with his or her post-office address, and paying such sum as may be fixed upon by the Association.

On motion the fee for admission and annual dues was fixed at 25 cents.

J. H. Smith was elected Treasurer.

A vote of thanks was tendered Messrs. Bolton and Ginsinger, and their wives, for their kindness and hospitality manifested during the day.

Adjourned to meet at Ottawa, O., July 25. F. M. BLAKEMAN, Sec.

For the American Bee Journal.

Reversible Frames.

OSCAR F. BLEDSOE.

All valuable improvements in every department of civilization have arisen from suggestions to the minds of men who work and think at the same time. To work without thought leads to no progress; to think without work leads to vague and valueless theories; but to think and work, leads to progress.

After various suggestions, I hit upon a device by which all wood frames can be reversed at pleasure without manipulating a fixture or attachment; and now I am making all my new hives with reversible frames. About April 1, I hived a first swarm on reversible frames, which now has the brood-nest full of nice all-worker combs, and one set of section-boxes about ready to take off.

For starters on my frames, I use strips of worker comb fastened on with equal parts of rosin and wax melted. If the rosin is not put in, a heavy colony will pull off the starters. After a colony has nearly filled the frames with comb, I put starters on the bottom bar, reverse the frame, and soon have it solid with worker comb. If there is too much drone comb it should be cut out and replaced by

worker comb. If the frames are very nearly filled with comb, I reverse them without putting in any starters.

Now for the advantages of reversible frames, which are very many. You can get the frames entirely full of comb, if not reversed; but bees seldom attach comb to the bottom bar. You can force the bees to carry honey from the brood-chamber to the sections above. Instinct teaches them to remove the honey as far from the entrance and bottom of the hive as possible. By reversing the frames you put the honey at the bottom; and as brood occupies what is then the top of the frame, the bees are compelled to go above the frame into the sections with their honey.

With reversible frames no complaint will be made of the industrious Italians not working in boxes; the brood not being depleted of too much honey thus easily without extracting, and in such a way that the same cells will not again be filled; and the queen can be kept busy in the center of the hive and will not be tempted so strongly to go above or to the sides to deposit eggs; hence division-boards, at the sides, can be done away with.

All division-boards and fixtures in a hive which prevent a continuous communication between all parts of the hive are a disadvantage. There should be no stoppage possible to avoid, between the brood-nest, storage, and comb-building room, at the sides and above. Reversible frames help to realize this ideal by giving the queen full employment without confinement.

Grenada, Miss.

For the American Bee Journal.

Facts Regarding Sweet Clover.

DR. W. G. PHELPS.

In common with many bee-keepers, I have taken a lively interest in the propagation of that excellent honey-producing plant—sweet clover; and my experience may be of some value to the readers of the BEE JOURNAL.

In the spring of 1883, I had upon my place a patch of rye, sown the fall previous, with the intention of utilizing it for soiling purposes, or to turn under as a green manure. It flourished so well, however, that for various reasons I concluded to harvest it. This was about the last of May, and, according to general opinion, too late to sow thereon any of the many varieties of clover, and particularly the melilot; but sow it I did, even though the ground was dry, after which I harrowed it lightly.

The results, contrary to my expectations, was all that could be desired, proving conclusively that sweet clover seed will germinate freely, without being subjected to the action of frost, as commonly believed.

Furthermore, in less than 2 months from the time of sowing, after harvesting rye, the clover furnished a pasture for stock which they much preferred to any other. They would leave luxuriant red clover, to nibble at melilot.

In regard to sowing, the following extract by Mr. H. W. Garrett, of

Coyman's Hollow, N. Y., will be of interest:

"That sweet-clover seed needs the actions of frost upon it, I do not believe; for it will germinate much quicker than red clover. Having had a long experience with the two, I can speak from personal observations.

It is common to let red clover, cut for seed, remain on the lot a long time before threshing it, and there is no danger of the seed germinating; while sweet clover, if left on the ground and rained on, will frequently sprout when in close contact with the earth, or in thick bunches where the sun cannot penetrate and dry it out.

Sweet-clover seed being retained in its hull, holds moisture when sown, and will therefore quickly germinate. I would advise sowing it when all danger of frost is past. As a honey-plant for all seasons, wet and dry, it has no equal."

One of the objects of this article, is to make apparent the fact, not comprehended by many, that the present is the most propitious season for seeding "the waste places" with this desirable plant. If it be the "noxious weed" the unthinking have called it, give me more of it.

It stands on the patch referred to as sown last season, at least 4 inches higher than the red clover adjoining it, though the latter occupies much richer soil. Being eaten so readily by all kinds of stock in the green state, I believe it will make most delicious provender when cured as hay.

Last, but not least, I look to it as a most acceptable foraging ground for my bees, when other sources fail. With this fact in view, I have sown over 10 lbs. this season, in vacant places and on the highways; feeling that as "bread cast upon the waters, it shall return to me after many days."

Galena, Md.

For the American Bee Journal.

Packing, Feeding, Wintering, etc.

W. C. LESTER.

I use Root's chaff hive and Langstroth frames, and usually commence packing my bees on Nov. 1, or earlier if the weather becomes cool. I examine each colony to see how well they are supplied with stores, and if each has from 20 to 25 lbs. of honey, and $\frac{2}{3}$ sealed stores, I consider it in favorable condition for packing. Colonies that have not enough stores, I feed granulated sugar syrup, and prepare them the same as Mr. G. M. Doolittle explains on page 479, BEE JOURNAL for 1883.

I use cake-tins, 4x4x13 inches, for feeders; and one or more can be used in the same hive by placing them on top of each other. I take about half a handful of rye straw—cut it off the right length to fit inside of the feeder. I then pour the syrup into the feeder, and put straw in it on top of the syrup, this being a foothold for the bees while getting the syrup.

I place the feeder on the bottom-board of the hive, side of the combs; in this way the bees have free access

to the feeder, and empty it quicker than any other I have used.

I winter my bees on from 6 to 9 combs, or less if they cannot cover them, and use one or more chaff-division boards if needed, to occupy vacant space in the brood chamber. I prefer burlap or any other porous material, to enamelled cloth. I have used ticking successfully, before covering the frames. I use a block of wood or any small piece, or wood that forms a bridge over the top of the frames, after laying the burlap over it. I then fill the upper story with forest leaves. I have used chaff with $\frac{2}{3}$ cut straw, but I prefer forest leaves to any other packing I have used.

Having noticed considerable in the BEE JOURNAL in regard to the "pollen theory," I concluded to test it on a small scale, by taking 3 colonies of bees, one of blacks, one of hybrids, and one of Italians. I took all their stores from them, and, selecting such combs as had no pollen and entirely empty, I gave as many of them to the 3 colonies as they could occupy. I fed them nothing but granulated sugar syrup, and as much as they could store into the combs constantly, and then prepared them the same for winter as I did my other colonies.

On page 593, BEE JOURNAL for 1883, L. C. Johnson, M. D., speaks of the qualities of the different races of bees.

Taking all into consideration, as near as I can learn, the Italians possess as good qualities as any other race; but I do not think it advisable to cross the Italians with 3 or 4 different races. Nor do I think it advisable to mate them purely, except for breeding purposes, and then breed queens and drones from the very best queens.

I prefer a cross between the Italians and brown bees. My experience with them for the past 3 years, proves to me that they can store as much honey, either comb or extracted, as any other hybrids.

Washington Hollow, N. Y.

For the American Bee Journal.

Concerning Thermometers.

JOHN PHIN.

I reply as follows to Mr. R. E. Knapp's questions on page 172:

Ques. 1. "Does extreme heat or cold cause the mercury or spirit thermometers to incorrectly register degrees of temperature?" All thermometers when near the limit of their range, give irregular and uncertain indications. The limits for mercury are 35° below zero, and about 500° above zero. It is true that the indications are pretty nearly accurate at all ordinary temperatures; and perhaps the extremes of Mr. K.'s thermometer do not extend as far as the figures I have given.

A spirit thermometer has greater range below zero, but not so great above. Spirit thermometers are never used for temperatures higher than summer heat, but they afford the only convenient means of measuring temperature below the freezing point of mercury. Pure alcohol does not freeze at any natural temperature, but its indications become irregular.

Capt. Parry in his Arctic voyages observed differences of 18° between alcohol thermometers of the best makers; and similar facts were noted by Franklin and Kane. But the extremes to which these investigators exposed their thermometers, were greater than any that will be found in the climatic conditions to which we are exposed; and here, therefore, I may answer the 4th question. I say that except for temperature lower than 36° Fabr. below zero, the mercury thermometer will be found the most reliable.

Ques. 2. "Will a thermometer which registers incorrectly by the ice-test, run uniformly up and down the scale the same number of degrees that it varies?" This will depend upon circumstances. The error of the thermometer may be due to a change in the size of the bulb (due to a molecular change in the glass); and in this case the error will not remain the same; *i. e.*, we can not make a perfect correction by simply adding or subtracting a certain number of degrees; but if the thermometer tube were kept for a year or two after being filled it would then probably change as much as it ever would, and any error must be due to the displacement of the scale, or to bad original workmanship. If to a displacement of the scale, all we have to do is to add or subtract the known error as may be necessary. Bad workmanship can not be easily corrected; the only way would be to compare the thermometer with a standard instrument, and note the error at every 10°.

Ques. 3. "Will an old-tested thermometer, say 10 years old, mark the degrees as perfectly as a newly-tested one?" Thermometers which are exposed to great extremes of temperature may change somewhat even after the second year, but not to any great extent. Therefore, I should say, that a thermometer which had been tested when two years old, might be relied upon ever after in all ordinary work. This, however depends somewhat on the glass that is used, but it is true in most cases. For *extremely* accurate work thermometers should be tested every 3 or 6 months.

I may add that the variations of which I have been speaking are comparatively slight, and are nothing when compared with the ordinary errors of observation. In common thermometers the chief source of error lies in the bore of the tube. A thermometer may be perfectly accurate at the principal fixed points (32° and 212° above zero), and yet show great errors between them. The only really correct thermometer is the air-thermometer as used by Regnault; but this instrument can not be used by those who have not the conveniences of a large laboratory.

To sum up the whole matter: A good mercury thermometer which is over two years old, and which is correct at 32° and 212° above zero, (the freezing and the boiling points of water) may be depended upon for all the ordinary requirements of life, and it will not deteriorate by any ordinary usage or exposure.

**SELECTIONS FROM
OUR LETTER BOX**
Good Results.

I have 66 colonies which are doing well. Last year my bees produced 7,600 lbs. of honey, and over 100 lbs. of wax. MRS. C. M. KINGSLEY, Elvaston, Ill., May 15, 1884.

Are Bees Taxable in Illinois?

The assessor attempted to assess my bees, but I do not think it is lawful to assess farmer's bees. This is the first time it has ever been tried here. I believe it would be a great favor to bee-keepers generally, to have this determined. A. WICHERTS, Matteson, Ill., May 16, 1884.

[In this State it is by law made the duty of the assessor to "list" colonies of bees, as is shown by the published quarterly reports. That they are taxable in Illinois, we think does not admit of a doubt.—ED.]

Bees in Eastern Ohio.

Bees in this locality wintered moderately well so far as I have been able to ascertain. One apiarist put 15 young colonies into a vault last fall and this spring 8 of them were alive. Another apiarist lost 12 colonies out of 44. Last spring I began the season with 10 colonies in fair condition. I stimulated them by feeding them sugar-syrup until they could get their own living. It being a very poor season for honey, they did not gather very much surplus honey, and what they did gather I saved for feeding them this spring, if needed. Two colonies swarmed, one left and the other died late in the fall, thus leaving only 10 colonies. On March 24, I examined all of them and found 1 dead, and the rest in good condition; yet I gave each of them a comb of honey. They all contained brood at this time. The weather set in cold again, and I did not look at them until April 11, and I found 8 doing well, and for some cause the other was dead. I did not feed them very long. On May 11, a swarm issued and I put it into a hive with 8

nice combs. I looked at them May 15, and found new honey in 6 combs, and 2 with eggs in. R. Barnesville, O., May 16, 1884.

Women as Apiarists.

My bees wintered well. All came out strong and healthy. I have sold 50 colonies this spring. I cannot help thinking that bee-culture is a good occupation for women. I attend to my bees without the assistance of any one, except the supply dealers; for in these progressive times one can buy everything pertaining to the bee-business, all nicely prepared and ready for use. That alone is enough to tempt one into the business; and truly, I keep bees as much for pleasure as for profit, and have lots of spare time, too, for other work. I am sure if I were compelled to earn my own support, there are few pleasanter occupations in which an intelligent woman could engage.

MRS. DR. E. H. MASON, Vincennes, Ind., May 16, 1884.

Bees Storing Honey Rapidly.

Since I have kept bees I never saw them gather so much honey from fruit bloom as they have this year. Each colony has gained in weight from 10 to 15 lbs. All my colonies are now crowded with bees and brood. They are in the best possible condition for the clover bloom, which will be here soon. I expect some swarms in a short time. H. T. HARTMAN, Freeport, Ill., May 20, 1884.

Botanical.

Enclosed I send a plant which is very abundant here, and much used by bees. What is its botanical name? and its value as a honey plant? We have had a remarkably wet spring, and vegetation is unusually vigorous and dense with an endless variety and quantity of flowers. Notwithstanding much of the weather has been quite cool for the season and climate, bees are doing exceedingly well, and are very prolific in swarms.

W. P. HANCOCK, Salado, Tex., May 7, 1884.

[It is *Gaura filipes*. It belongs to the Evening Primrose family, most species of which yield nectar.—T. J. BURRILL.]

Bees along the Pacific Coast.

This spring has been the warmest and finest I have known in Oregon during my 32 years' residence. Bees have been doing better than ever before. I took out, for the first time since being a bee-keeper, comb honey made of the peach, pear, cherry, and plum bloom in the month of April. Some bees in smaller hives swarmed during April. We never had better prospects for a good honey crop; other crops also look well. I have quite a lot of fertilized young queens at my Washington Ter. apiary. I must here mention in connection with the rearing of young queens, that Oregon possesses what perhaps none of

the Eastern States do; and that is such a wonderful bee-man as a queen-bee surgeon, accoucheur, and midwife. This medical or surgical queen-bee genius, claims that he played the part of an accoucheur surgeon and midwife for one of his queen-bees, which after fertilization, would not lay the first egg. He did not apply browned butter like is done to young bees, but performed a surgical operation with the point of a very fine needle. He said the operation proved a success, and the mother and her egg lived and are doing well. Who of you Eastern queen-breeders can come up to that? Would it not be well for all the Eastern queen-breeders, as a whole, to engage this man's valuable services, as they are wasted here in Oregon, where apiculture is carried on in all kinds of boxes, and even in sugar and nail kegs. We have also a farmer who every year kills his old colonies of bees to obtain the honey. The old man thought that the old way of killing the bees was the best, and did not know he was killing his young queens in the old colonies. He has now learned his mistake—transferred his bees in movable-comb hives, and will no longer murder his young queens for honey in old combs. As the Pacific coast has never yet done anything for progressive apiculture with regard to introducing new varieties of bees, I have come to the conclusion to try introducing bees from China by the mail steamers via Japan. I believe the trip requires about 25 days, and I have found acquaintances who think it can be done through our former American Consul, who is now a resident of the city again, and is said to be a very obliging man. I shall let you know more about the prospects of the China bee in due time. GUST MURHARD, Portland, Oreg., May 10, 1884.

Dandelions and White Clover.

My 50 colonies of bees were never in as good condition before fruit bloom, as they are now. One colony is storing surplus honey. The roadsides are yellow with dandelions, and the white clover heads begin to appear. The apple trees will bloom this week if the weather is fair. Prospects for a good honey crop in this vicinity, was never better than now. GEO. E. HILTON, Fremont, Mich., May 19, 1884.

How my Bees Wintered.

Last fall I had 38 colonies and one nucleus. The 38 came through the winter in splendid condition. I always winter my bees on the summer stands, and they can eat pollen if they wish. F. J. SAWIN, Kirkwood, Ill., May 15, 1884.

Weather Unfavorable for Bees.

I hope the readers of the BEE JOURNAL are having a better spring for bees than we are having here in central New York. The last 2 weeks have been cold and wet; in fact, the whole spring has generally been cold, so that with the exception of a few strong colonies, bees are mostly weak. Many

of my colonies are not nearly so good as they were April 1, and this but echoes what I hear from all bee-keepers near me. High winds, rain, and frosts is the order of the day here.

G. M. DOOLITTLE.

Borodino, N. Y., May 17, 1884.

Still Room for more.

We have had a very late, wet and cold spring. Swarming is about two weeks later than it was last year. The prospect is good for an abundant honey crop. Apiaries are becoming very numerous in this part of the county. There are plenty of sage and other plants here, thus making it a good place for bees. Hundreds of acres of unoccupied land well adapted to bee-culture, can be found here.

JOHN L. SECOR.

Monterey, Cal., May 4, 1884.

Not One Colony Lost.

Last fall I had 17 colonies. I put 15 of them (12 strong and 3 weak) into my new bee-house, and the remaining two were left on the summer stands, and the latter, I think, will soon swarm. The three weak ones came out with more bees than when put in. I have had to feed them some, and I expect a good harvest. My bees consumed from 10 to 19 lbs. per colony, during the winter. B. E. FOSTER.

Utica, N. Y.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Introducing Fertilized Queens.

1. What is the best method of introducing a fertilized queen into a colony which has cast a swarm?

2. Ought a queen to be introduced into a colony as soon as the swarm is gone?

3. I know of parties who extract all the honey from the brood-chamber once a week, in the forepart of the honey harvest, and let the bees fill it up again with fall honey, for winter stores. Do you approve of such a course?

4. Is it not better to let the brood-combs alone? C. UPTON.

Fenwick, Mich., May 10, 1884.

ANSWERS.—1. Cut out all the queen cells, and put the new queen in a cage between the combs, and leave her there for 24 hours, then if no balling of the cage is going on, liberate her. Many of us have been successful by dabbling the new queen with honey, and smoking her in at the entrance.

2. I should never introduce a valuable queen to such a colony. They are less apt to be received in such an one. The idea that the colony should not remain queenless any time after the swarm leaves, without great loss, is only another of the mistakes of theorists.

3. I feel just as safe in wintering bees with fall honey, as with that from clover and basswood.

4. Yes; it is better to use 2 stories, and extract from the upper one almost exclusively; not because it injures the bees, or the chances of wintering them to extract honey out of the brood chamber, but because it is less trouble.

Questions About Queens.

1. When a first swarm issues, Mr. Heddon says that the queen is about a year old. How old is the queen which is left with the colony?

2. How old is the queen which goes with the swarm that issues from the first swarm? Is it the one which issued with the first swarm?

3. Does the oldest or youngest queen issue with the swarm.

4. Does one queen remain in the same colony until she is removed?

Please do not refer to back numbers. S. F. D.

ANSWERS.—1. The queen which is left with the colony is not yet out of the cell, nor does she usually emerge till about 8 days after the swarm issues.

2. Yes; it is the one that issued with the first swarm.

3. The oldest one.

4. No; they change every time a prime swarm is cast. About the 4th or 5th year of a queen's life, she loses her fertility, and is superseded by a young one reared by the bees to take her place. Sometimes we find both old and young queens in the hive together; the old one seemingly tolerated there out of respect for what worth she "has been." This may be used as a moral lesson.

Disabled Queen.

Did you ever know a good queen to become disabled all at once, and not have a cell of brood in the hive, and the bees still retain her?

WM. MALONE.

Oakley, Iowa, May 7, 1884.

ANSWER.—Yes; and I have never been able to learn the real cause. A bee is a small insect, and what are no doubt simple physiological facts when we understand them, are enigmas to the general honey-producer. Such men as Prof. Cook are the ones who know most about such matters.

The members and friends of the Northern Michigan Bee-Keepers' Society, will hold a basket picnic at the apiary of Miss F. A. Bellamy, one mile west of Ionia, on June 19. Teams will be in waiting to convey, free of expense, all who wish to attend. Purchase your tickets to Ionia, but leave the cars opposite the prison grounds. Miss B. requests that you bring your wife or husband, as the case may be, and also that you drop her a postal, notifying her of your intention to be present, in order that ample provision may be made to convey all from the trains. Come on the morning train and return in the afternoon. F. A. PALMER, Sec.

S. J. YOUNGMAN, Pres.

The Mahoning Valley Bee-Keepers' Association will hold its next meeting at Newton Falls, O., on June 6, 1884. It is desired that a display of apiarian supplies and samples of honey be made at that time. Mr. Hammon, of Bristolville, and Mr. C. R. Page, of Streetsborough, will read practical essays on topics pertaining to bee-keeping.

E. W. TURNER, Sec.

L. CARSON, Pres.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
Monday, 10 a. m., May 26, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for all honey is very slow; market dull and prices range from 6@8c for extracted. Different lots of choice comb honey in small sections have been offered and sold in our market lately at 12@14c per lb. As I predicted some time ago, the preference for the production of comb honey seems to be prevalent; and, as we have the best prospects for an abundant harvest this year, we may prepare for low prices.

BEESWAX—Is in good demand; choice yellow brings 35c a lb. on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—The prospects are that but little honey will be carried over, and that will all be in 2-lb. sections. More one-pounds should be produced for this market. We quote:

Fancy white in 1-lb. sections, packed in clean crates, 16@17c; 2-lb. 13@15c. Fair to good white, 11@14c; dark, 10@13c. Extracted, 8@9c.

BEESWAX—Scarce, 36@38c.

MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY.—Demand light. 1 lb. sections comb honey, 18@20c; 2 lb. 16@18c. Extracted, 9@11c.

BEESWAX—35c.

BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—Choice white comb honey in 1-lb. sections brings 18c; in 1½ to 2 lb. sections, quotable at 16c. Comb honey discolored and in undesirable shape is selling at 10@12c. Extracted honey is in light demand at 6@8c. Manufacturers of syrups and bakers say that the low price of sugar is the reason why they do not use as much honey as formerly. There is very little desirable comb honey on the market.

BEESWAX—Is scarce and fancy yellow brings 35c. Poor beeswax, but dark, and having more or less of dregs or refuse matter in it, quotable at 30@33c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—This market is almost wholly nominal, and will probably continue so for at least a fortnight, when new honey will be due. White to extra white comb, 15@18c; dark to good, 10@12c; extracted, choice to extra white, 7@8c; dark and candied, 5@—

BEESWAX—Wholesale, 27½@30c.

STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—No perceptible change in the demand for choice white comb 1 and 2-lb. sections, at 15@16c; but dark and irregular comb, or even choice comb in any but clean, neat and uniform packages, goes begging at 10@12c. Extracted, quiet and in good supply, nominal at 7@8c.

BEESWAX—Small lot sold to-day at 35c. None to speak of in the market.

JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@8c.

BEESWAX—Firm at 32@32½c. for choice.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1-lb. sections at 18c; 2 lbs. best white not quite so active at 17c; 1 lb. sections sell quickly on arrival, and often are sold to arrive. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.

BEESWAX—Scarce at 35c.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 18@20c; extracted, 7½@8½c.

GEO. W. MEADE & Co., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send *direct to this office*, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

| | |
|----------------------------------|--------|
| For 50 colonies (120 pages)..... | \$1 00 |
| " 100 colonies (220 pages)..... | 1 25 |
| " 200 colonies (420 pages)..... | 1 50 |

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75. Or, bound in cloth, with Weekly, \$3.00; with the Monthly, \$2.00.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

The first edition of the "Apiary Register" having been exhausted, we have just issued a new edition, elegantly bound in Russia leather, with a large worker bee and "Apiary Register" in gold on the side. It forms not only a Register of both Queens and Colonies, but has also an Account Book at the back, in which to keep a record of all the receipts and expenditures of the apiary, which will be found exceedingly valuable. We have also reduced the prices, as will be seen on another page.

Sample Copies of the AMERICAN BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Do not let your numbers of the BEE JOURNAL for 1884 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Convention Hand-Book.

This is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

It is extravagant economy to delay ordering hives, sections, foundation, etc., till the last moment, or till they are needed for use; for frequently a dealer finds it impossible to fill orders promptly when they are all held back till the last moment. Then, in the rush, many are disappointed. Therefore we would say to all, order early, and save yourselves much vexation and disappointment.

Advertisers' Opinion.

My advertisement in the BEE JOURNAL, has brought me over 400 responses. Dr. G. L. TINKER. New Philadelphia, O.

The queen business is *rushing*, and we think the BEE JOURNAL deserves much credit as an advertising medium. E. A. THOMAS & Co. Colerain, Mass., July 18, 1883.

Having advertised in the AMERICAN BEE JOURNAL quite extensively for the past two years, I would say (without solicitation) that it has sold more queens for me than any other three periodicals I have ever tried.

My bees are in fine condition this spring. I have lost but 4 out of 182 colonies. The outlook is fine for a good season. L. J. DIEHL. Butler, Ind., May 7, 1884.

We can supply photographs of Rev. L. L. Langstroth, the Baron of Berlepsch, or Dzierzon, at 25 cts. each.

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$3.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$3.00 and \$10.00 Extractors have no covers.

| | |
|--|--------|
| For 2 American frames, 13x13 inches..... | \$8 00 |
| For 2 Langstroth " 10x18 " | 8 00 |
| For 3 " " 10x18 " | 10 00 |
| For 4 " " 10x18 " | 14 00 |
| For 2 frames of any size, 13x20 " | 12 00 |
| For 3 " " 13x20 " | 12 00 |
| For 4 " " 13x20 " | 16 00 |

ALFRED H. NEWMAN,
923 West Madison Street, Chicago, Ill.

It may be arranged for any form of the Langstroth Frame; has been fairly tested, and is the **Best Hive** made for Comb Honey. Send for new Circular.

Sixth Thousand Just Published!

New and Enlarged Edition OF BEES and HONEY,

OR THE
Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.
Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure.
T. F. BINGHAM.
Abronja, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN.
Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

HEDDON'S COLUMN.

BEST GIVEN COMB FOUNDATION.

Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleaved from all impurities. Sizes of brood and surplus, $8\frac{1}{2} \times 16\frac{1}{2}$, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

One Hive complete for comb honey...\$3.00

(The above will contain two cases complete with sections).

The above Hive complete for extracted honey.....\$3.00

The above Hive complete for both in one..... 4.50

One Hive in the flat..... 2.00

Five or over, each..... 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: $4\frac{1}{2} \times 4\frac{1}{2} \times 6$, 7 and 8 to the foot, per 1,000, \$6.50; $5 \times 6 \times 7$, per 1,000, \$8.00. All shipped from here.

STUDENTS OF APICULTURE

Will receive terms for 1884 on application.

VOL. XX.—No. 23.

THE WEEKLY EDITION

OF

THE AMERICAN BEE JOURNAL

PUBLISHED BY

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

925 WEST MADISON ST., CHICAGO, ILL.
Weekly, \$2 a year; Monthly, \$1.

PREMIUM.—Any one sending one *new* subscription for the Weekly, or two for the Monthly, for one year, besides their own subscription for a year for the Weekly, will be entitled to a copy of "Bees and Honey," bound in paper.

☛ The receipt for money sent us will be given on the address label on every paper. If not given in two weeks after sending the money, write us a Postal card, for something must be wrong about it.

☛ Any person sending a club of six, is entitled to an extra copy (like the club), sent to any address desired. Sample copies furnished *free*.

☛ Papers are stopped at the expiration of the time paid for, unless requested to be continued.

FOREIGN POSTAGE, EXTRA:

To Europe—Weekly, 50 cents; Monthly, 12 cents.
To Australia—Weekly, \$1; Monthly, 24 cents.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Entered at the Chicago P. O. as Second Class Matter.

ADVERTISING RATES.

20 cents per line of space, each insertion.

For either the Weekly or Monthly Editions.

A line of this type will contain about 7 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance. Editorial Notices, 50 cents per line.

Advertisements may be inserted one, two or four times a month, if so ordered, at 20 cents per line, of space, for each insertion.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

CHAS. DADANT & SON,

5ABly HAMILTON, Hancock Co., ILL.

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON UNCAPPING KNIFE.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To sell again, send for dozen rates to

BINGHAM & HETHERINGTON, ABRONIA, MICH.

BOOKS!

Sent by mail, on receipt of price, by THOMAS G. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates, on larger quantities, given upon application.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Sixth Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 220 pages, and is profusely illustrated. Price, bound in cloth, \$1.00; in paper covers, 75c., postpaid.

Dzierzon's Rational Bee-Keeping.—A Translation of the Masterpiece of that most celebrated German authority, by H. Dieck and S. Stutter, and edited, with notes, by Charles N. Abbott, *Ex-editor of the "British Bee Journal."* Dr. Dzierzon is one of the greatest living authorities on Bee Culture. To him and the Baron of Berlepsch we owe the impetus for much that is known of scientific bee culture. Concerning this book, Prof. Cook says: "As the work of one of the great masters, the Langstroth of Germany, it can but find a warm welcome on this side of the Atlantic." Mr. A. I. Root says of it: "Old father Dzierzon... has probably made greater strides in scientific apiculture than any one man... For real science we look to Dzierzon, and every bee-keeper whose attention is at all inclined to scientific research, to purchase a copy. Cloth, \$2."

Queen-Rearing, by Henry Alley.—A full and detailed account of TWENTY-THREE years experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price, \$1.00

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.—This Manual is elegantly illustrated and fully up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Wafers, Puddings, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 50c. per dozen, 40c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. This is a chapter from "Bees and Honey." Price 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how: 26 engravings. This is a chapter from "Bees and Honey." Price, 10c.

Bees in Winter, with instructions about Chaff-Packing, Collars and Bee Houses, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Food Adulteration! What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables in cisterns, etc. Standard book throughout United States & Canada. Price 85 c. postpaid.

Fisher's Grain Tables for Farmers, etc.—192 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measurer, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. 40 cents.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gliders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, 50c.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Foul Brood—its origin, development and cure. By Albert R. Koubek. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. F. Dadant, giving in detail the methods and management adopted in their apiary. 15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Dzierzon Theory—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Apiary Register, for SYSTEMATIC WORK in the APIARY. The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book. Prices: For 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Deutsche Buecher, Ueber Bienenzucht.

Bienen Kultur, oder erfolgreiche Behandlung der Bienen, von Thos. G. Newman. Dieses Pamphlet enthält Belehrungen über folgende Gegenstände—Vertilichkeit des Bienenstandes—Honig pflanzen—Erziehung der Königin—Zütltern—Schwärmen—Ableger—Verfegen—Italienisiren—Zuseker von Königinnen—Ausziehen—Bienen behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschrieben ist. Preis 40 Cents.

Honig als Nahrung und Medizin—von Thomas G. Newman. Dieses enthält eine klare darstellung über Bienen und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angebend wie man Honigtuchen, Formkügeln, Puddings, Schaumconfect, Weine, u. s. w. zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Consumenten bestimmt, und sollte vieltaufendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Pferd und seine Krankheiten—Von B. J. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniß der verschiedenen Pferdefrankheiten, sammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Recepte. Preis 25 Cents.

National Experimental Stations.

By our exchanges we notice that there is a bill now before Congress providing for the establishment of National Experiment Stations in connection with the agricultural colleges of the different States. This bill appropriates \$15,000 to each State agricultural college, for the purpose of "conducting original researches or to verify reported experiments on the physiology of plants and animals, the diseases to which they are severally subject, and with the remedies for the same; the chemical composition of useful plants at their different stages of growth; the comparative advantages of rotative cropping as pursued under a varying series of crops; the capacity of new plants or trees for acclimation within the isothermal limits represented by the climate of the several stations and their vicinity; the analyses of soils and waters; the chemical composition of manures, natural or artificial, with experiments designed to test their comparative values for raising crops of different kinds; the composition and digestibility of the different kinds of food for cattle; the scientific and economic questions in the production of butter and cheese; and all other researches of experiments bearing directly on the agricultural industry of the United States."

The bill further provides that the management of the stations shall be in the hands of the trustees of the several colleges, one of whose professors shall be appointed superintendent, and such other assistance is provided for as may be needed. The State accepting the money from the

National Government shall agree to establish and conduct such station as is provided for. It is to be hoped the bill will become a law.

Prospects for Honey Crop in England

From the *London Journal of Horticulture* we learn the following concerning the prospects for a honey crop in England:

The cold dreary days and long nights of winter are over, and the warm breath of spring is felt. Bees begin to stir themselves, casting aside, with unmistakable vigor, the inactivity which has through a wise rule of Nature kept our bees in the warm shelter of the hive, when to venture forth would mean certain death to them. We have now, however, reached a season of great activity among bees, and usually the enthusiasm and energy visible about every healthy colony is communicated to its owner, and displays itself in the increased interest taken in the bee-corner of the garden.

The mortality of bees the past winter has been much below the average; for, except in cases of absolute starvation, very few colonies, so far as we can learn, have perished. There has been an immense show of bloom on fruit trees of all kinds, and whenever the leaden clouds which have so persistently excluded the sun's rays for a great portion of the month, allowed the warmth to be felt, it has been very cheering to bee-keepers to note how plentifully both honey and pollen could be gathered. Judging from a careful examination of our own colonies, and taking things altogether, we think the prospects of bee-culture are very promising for a really good season.

Foul Brood.—On pages 291 and 292 we gave space to a statement from each side of the controversy about Foul Brood between the Nebraska Convention and Mr. Flanagan, and having done so, we said we "could not consent to burden our columns with any arguments *pro* or *con*." President Von Dorn has sent us a response denying the statements of Mr. Flanagan, but we have concluded to let the matter rest where it is, so far as the BEE JOURNAL is concerned;

for if we re-open the controversy, there will be no good place to break it off. One statement from each side is all that can be reasonably expected of us. We would like to see an amicable adjustment of the whole matter.

Deep Cells in Foundation.

It had long been wished for, but so far had baffled the skill of man to make anything akin to the deep and perfect cells as made by the bees in their combs; but to-day Mr. E. B. Weed placed a sample of comb foundation on our desk, in which the cells are the deepest we ever saw. It is made with wood base, and the wax is pressed into the shape of cells on both sides by very powerful machinery—in the sample we have, the cells are over $\frac{1}{8}$ of an inch deep, by measure.

As this is something really new, we will here state the principal advantages claimed by Mr. Weed:

1. It cannot possibly sag, melt down or break down, no matter how many bees are clustered upon it, or what treatment it receives in shipment or extracting. Swarms can be placed on it with impunity. This advantage can hardly be over-estimated in swarming time.

2. The great height of side-wall insures acceptance by the bees, when ordinary foundation would not be noticed.

3. No wax is wasted in the base; no wire is used; there are no holes to punch in the frame and sew wire into; a much smaller quantity of wax can be used, ten feet to the pound, making a very good side-wall.

It has been demonstrated in every apiary that wood is the only substance to which bees will attach their combs without objection; but heretofore the inflexible nature of the material has proven an insurmountable difficulty in the way of its use for the base of the honey-comb. This difficulty is now overcome by the use of powerful machinery that moulds the wood to the proper shape, without splitting or breaking it. The wood is prepared so that moisture can have no effect on it.

Whether this is a success or not, Mr. Weed is entitled to much credit for his inventive development.

CORRESPONDENCE

For the American Bee Journal.

Loss of Bees in Bee-Cellars.

G. M. DOOLITTLE.

When I first began to keep bees, I always wintered them in the cellar, and for the first few years wintered them without the loss of a single colony; but when I came to increase them so that from 40 to 80 colonies were put into the same cellar, where at first I had only from 5 to 20 colonies, I began to lose, and after quite heavy losses, I gave up cellar wintering, and wintered my bees out-of-doors entirely.

The trouble seemed to be that with a large number of colonies in the same cellar, the temperature could not be kept down when there came a warm time of any length in the winter. During such a time the thermometer would often mark 50° to 60° in the cellar, which increase of temperature would cause the bees to leave the hives in large numbers, while their disquietude only caused the mercury to rise still higher, thus making matters still worse, resulting in heavy losses.

The first two or three winters after I had decided to winter out-of-doors, proved favorable for such wintering; but one spring, when I found that I had only 40 colonies left out of 130 which I had put into winter quarters, I again began to think of cellar wintering.

About this time Mr. James Heddon wrote an essay for the Northeastern Bee-Keepers' Convention, which I heard read, and in which he said that if we could keep the temperature around our bees the same as that found at 5 feet below the surface of the ground, they would pass the winter in safety, if there were sufficient stores in the hive, and a goodly cluster of bees. This may not be the exact wording of the essay, as I quote from memory; but the substance is nearly, if not quite, correct.

The idea impressed me favorably, and the next fall, when I moved to my present location, I dug a cellar in a side-hill on purpose to meet the very requirements Mr. Heddon advised. As this cellar has been described in the BEE JOURNAL, I will not give another description of it, except to say that its average depth is 7 feet below the surface of the earth; and that to keep the outside air from influencing the inside temperature, there are three doors at the entrance, which give two dead-air spaces of 2 feet each between the doors.

Into this cellar I put about one-half of my bees each year, and have used it thus for the past seven winters with uniformly good success till the past winter, which proved Mr. H.'s idea of a bee-cellar to be a good one. The temperature of this cellar would be 50° when the bees were first put in,

owing to the bees raising the temperature by the disturbance resulting from moving them in; but it gradually lowered till at the end of three weeks it was at 42°, where it remained the rest of the winter, no matter whether it was 27° below or 60° above zero outside.

The walls of the cellar would be quite damp during all the latter part of the winter, and the dead bees scattered on the cellar bottom would get moldy and emit a bad smell unless swept up often; but this did not seem to effect the live bees in any way, as all full colonies were generally sure to come out all right. By way of experiment, I put in some very small colonies or nuclei, but found that most of these would come out poor in the spring, as it seemed to be too cold for them.

When putting the bees into the cellar last fall, I began to think of the "high pressure" of temperature recommended by Ira Barber and some others, and thought, perhaps Mr. Heddon might be mistaken in his ideas, even though former winters had proved him correct. The next day, after putting the bees into the cellar, I went in to see them, and found them in a very quiet condition, with the mercury at 50° above zero. As several of the full colonies were lying on the outside of the hive, similar to the way Mr. Barber said his did, I again thought of the matter, and it seemed to me if I could keep the temperature at just 50°, they could be kept nice and quiet.

As 50° was given by L. C. Root and others as the right temperature for a cellar, and was midway between what I had formerly used, and Mr. Barber's 65° to 90°, I concluded to test the matter. So, as the mercury began to lower, three days afterward, I placed an oil-stove between the first and second doors of the bee-cellar. At first it took but a small blaze to keep the temperature as desired (50°); but as the cold outside increased, I had to increase the blaze. I soon ascertained that to keep the temperature at 50° in all parts of the cellar, it must be at 77° between the doors; and after discovering this, I only went inside of the cellar twice every month; once on the 1st, and the next on the 15th.

When I went in on Jan. 1, I found all as usual; bees all quiet, with a few colonies clustering on the outside of the hives, to some extent, with but very few dead bees on the cellar bottom. So far I had not looked at the bees at the top of the hive, and happening to think of the matter, I removed the covering from one of them, and to my surprise they were ready to fly out into the light the moment the quilt was raised; while winters before they would appear like so many dead bees, unless jarred or breathed upon. I returned to the house and told Mrs. D. that I feared I had begun a costly experiment; for in this case I was risking the whole lot of bees that was in the cellar, while all my experiments heretofore had been confined to a colony or two, and would not have been costly if the experiment had proved a failure.

In this case it was the "whole or none," and fearing it might be the "whole," I wrote to Mr. Barber asking him to tell me how he kept the temperature of his cellar so high, and what he knew of the matter. His reply showed that he knew very little of the matter at all; for he had no thermometer in his cellar except at the time the bees were put in, and again upon taking them out, when, of course, the temperature was greatly raised by the commotion of the bees, which is unavoidable at such times. He did not go into the cellar from the time the bees were put in until they were taken out, so he was entirely ignorant of what he advised others. The mercury might go down to 40° below zero and stay there the most of the winter, and he would not know it.

L. C. Root has a thermometer which passes down into the cellar through a tube so arranged that he can lower and raise it at pleasure, which gives him a knowledge of the temperature at all times. Mr. B. should do the same before he tells us of a temperature which is so misleading as is one obtained when the commotion of the bees is great enough to give a much higher temperature than really exists.

When I went into the cellar on Feb. 1, I found that the clusters on the outside of the hives had disappeared, and the dead bees on the cellar bottom were nearly an inch deep, with others on the wing adding to those already accumulated on the floor.

If I had, at this time, taken the stove out, I think I might have saved nearly all of the bees, though in a reduced condition; but I feared to do so, as it seemed to me that a lower temperature would be the ruin of them if they were not already ruined.

The middle of February showed that the mortality was still going on, while one or two colonies had all left the hives, except a dozen or two dead bees scattered among the combs. When I went in, on March 1, the full colonies were nearly all gone, while the bees were nearly 2 inches deep on the cellar bottom. The most of the nuclei were still alive, and now I resolved to take away the stove at all events. I also put out the remnant of one colony which had a choice queen, and left them out, after packing them with chaff. The mercury gradually sank after removing the stove, till on April 1 it stood at 45°, where it still stood on May 1.

Now for the result: I lost four-fifths of the full colonies and the one put out on March 1 being the best of any of them. I also lost one-fourth of the nuclei. Some few of them came through well, but the majority are weak, while there is not enough left of all the full colonies to make 2 decent ones at this season of the year.

In the above I have given the facts as I found them, so the reader may be warranted thereby to go cautiously on trying new experiments. It would have been more pleasant to have passed by this, but I feel it a duty to give my loss as well as prosperity, in the bee-business.

As to how the loss came about, probably each reader will have his

own opinion. Mine is that the high temperature caused the bees to become restless, thus wearing their life out, so that by Jan. 5, they began to die of old age. As an old bee always leaves the hive to die, if the temperature will admit, so my bees left their hives, one by one, till all went out on the cellar bottom. The half of my bees left on the summer stands have come through all right, with many of them strong, while I lost but 3 out of 38, two of which starved (bees in this vicinity used an undue amount of honey last winter), while the colony from the Texan Cyprian queen had the diarrhoea and died about the middle of March.

There are two points about the cellar wintering which I wish to notice: 1. Every time the mercury sank below 10° above zero, the vapor coming from the upper ventilation pipe would be condensed so as to appear for days at a time as does the smoke coming from a chimney having a wood fire below, thus showing that the ventilation was good, and also showing what a quantity of moisture the bees are continually throwing off. This also kept the cellar somewhat dryer than usual, though the walls were somewhat damp. 2. The temperature was so warm that the moth-larvæ, which took possession of the combs from which the bees first died, came to maturity, spun their cocoons, and passed to the miller state.

I ask, is there any conditions in nature, unaided by man, which will confine bees for several months at a time in so high a temperature that moths will mature? If not, is it well for man to try to do so?

Borodino, N. Y., May 10, 1884.

For the American Bee Journal.

Which is the True Policy?

R. J. KENDALL.

Mr. Pond's article on "Priority of Location," on page 149, was evidently written to combat and censure Mr. Heddon for his article on controlling an apicultural field, on page 86.

Mr. Pond says (in effect) that Mr. Heddon is selfish in advocating such a doctrine; that priority of location gives a man no "moral right" to a locality; that bee-keepers are more indebted to amateurs in bee-culture (fancy breeders) than to the professionals; and, in fact, that the proper and humane policy is to encourage every body who can, to keep bees. I think Mr. Pond is wrong in every one of his positions, if by bee-keeping is understood the making of money from the pursuit, as opposed to keeping bees for pleasure and fancy.

Mr. Pond seems to place some stress on the difference of policy between the bee-keepers of England and those of America. He says that in England every one is encouraged to keep bees, while here the policy seems to be the opposite. The circumstances of the two cases are very different to start with; but even if they were not, what is the result of this extensive encouragement in England?

I will state here that I am an Englishman by birth, and the son of an English farmer. I was brought up in the country, and know what English country-life is, although later on I lived in London. The English agricultural laborer, who is most encouraged in the way Mr. Pond speaks of, is generally very poor, and a person to whom every little is a real help. He is a person who has from time immemorial, kept bees in skeps, and then brimstoned them to get the honey, which is strained honey at that. Surely, it needs no argument to induce such a man to handle bees without killing them, and to teach him how to produce a better quality of honey. What little he can produce in no way injures the market, as it is easily used up, either entirely by his own family, or in his immediate locality.

The honey supply of England, too, is such that the cottager can put on his surplus arrangement, and it will, as a rule, hold all the surplus honey the bees can gather during the season, and needs little or no attention, so that he can continue his daily avocation without the care of his bees trenching upon it. Then the mere possession of bees will tend to keep this class from the "public house" (saloon). But the cottager's bee-keeping in no way interferes with the professional, or this liberality would, perhaps, not be so conspicuous.

The mass of kee-keepers in England may be said to be pleasure bee-keepers, in contradistinction to professional men or specialists. Here the tendency seems to be different—to make bee-keeping a business like any other, and men devote themselves to it exclusively, more than for mere pleasure. If this be the case, it must be viewed from a different standpoint entirely; and in my opinion that standpoint is the one taken by Mr. Heddon.

Still Mr. H. offers no opposition to the idea of a man keeping a few colonies for pleasure or slight profit, who can attend to them without trenching on his business proper; and I do not understand him to object to such, but to the man who is either going to make it a business (as to priority of location), or to the man who gets a lot of bees and goes on the principle that "bees work for nothing and board themselves."

Now, in the latter case, the careless bee-keeper is capable of, and very apt to injure his specialistic neighbor very materially, by breeding any strain of bees, getting foul brood in his apiary, and in many other ways which Mr. Pond understands as well as I. Such bee-keeping is undoubtedly wrong—wrong to the bees, and wrong to his neighbor. There is no charity, humanity or kindness in encouraging such bee-keeping.

Now as to priority of claim. This can only be discussed as a question of morals. The legality of the matter cannot be touched upon; for, of course, any body who likes to keep bees can do so, and keep them any how short of actual nuisance, and the law will not stop him. In nearly every

business there is more or less of what is termed (as a legal fiction) "good-will." This "good-will" is usually accorded the man who in any business gets the trade by priority of business; and it is very often sold for a considerable sum.

All over the West, and especially in Texas, where the grazing fields have been "free grass" heretofore, the shepherd or cattle raiser who first run his stock over a certain district, was universally accorded the right of priority by other "free grass" men.

Now as to bees. Suppose the case Mr. Pond puts that A. owns, say 10 acres of land, while B. owns 10,000 acres all around A. B. got his land first, and went into farming, stock-raising, etc. A., on the other hand, begins to keep bees, and makes a living out of the business. B., seeing this, says to himself, "A. is making a living by grazing my fields. I'll stop this." He then purchases or breeds large apiaries to graze his own honey-field. Legally he can do so; but at the same time he destroys A.'s living. Is he doing right? Is he doing unto A. as he would like A. to do unto him? Who is the "selfish" man, A. or B.? Bear in mind that A. never began to keep bees till he saw B. was not doing so, and in so beginning he made no hostile act against B.; and it is only when B. sees that A. is making money that he thinks of keeping bees.

Why, of course, B. in acting as described toward A., does A. a great moral wrong. If B. only keeps fewer colonies of bees, he injures A. to just that extent. Has he any moral right to do so? If B. wants really to do the right thing by A., he should go to him and offer to buy his bees, giving a recompense, so that in driving him out he tries to remedy the evil a little.

Take the case Mr. Heddon puts. Suppose Jones has a location, and is running 150 or 200 colonies, and is making a living. Brown sees it, and brings into the same neighborhood 70 or 80 colonies. It is true it is a very injudicious act of Brown, but suppose he does; what is the result? Why, he lowers the Jones average and takes so much money out of Jones' pocket. What is Jones to do? Silently and quietly submit to it, be content to be injured himself, and yet see Brown injuring himself (in not doing as well as he might) also? Why, the common-sense, the humane, the true and the right policy is for Jones to take just the course Mr. Heddon points out. Go to Brown, show him how he is injuring himself and his neighbor, and how it will benefit both for each to occupy separate fields; and so settle it in a common-sense, rational way.

If Brown says, "I have as much right here as you, and shall stay," then Jones is forced to act in self-defense, and he owes it as a duty to his family to do so. The self-defense is, to increase his own apiary till he lowers the average of Brown's to such an extent that Brown quits the bee-business and goes back to his old one, or moves away. Why, in such a case, in charging Jones with being "selfish," Mr. Pond is very wrong.

As to bee-keepers being more indebted to amateurs than to professionals, Mr. Pond by no means proves his case. The instances he gives may be his side, but it does not include the results of bee-keeping, which after all is the end. What he says has full weight, but the different phases of bee-keeping, as seen on this side the Atlantic, where are the professionals, and on the other side, where are the fancy breeders or amateurs, should be evidence enough.

The amateur keeps bees as a pleasure and study, and he is comparatively careless of the market results; but the specialist is the man who most practically asks and solves the question, "Will it pay?" and "Will it pay?" is the great question to bee-keepers.

George Stephenson is the father of railways, and James Watt discovered how to utilize steam; but railroad men—steam using companies—are the men who really confer the every day benefit on the people. The discoverer and the worker are united, and to put them in opposite camps and talk of one being of more benefit than the other, and so cause jealousy and semi-hostility, is not the wisest policy by any means.

The next point is, is it wise to encourage every one to keep bees? No, decidedly not. The "blighted hopes" list is long enough already; do not increase it, as it most assuredly will be increased, if this universal encouragement is given. I believe more men who started out to make a fortune, fail to make a living by keeping bees than in any other business.

The book, "Blessed Bees," reads very pretty with its blossoms, country life, and dollars at the end. I have paid for reading it I know. How many more have, I do not know. Still I am a bee-keeper, and propose to continue as such.

That keeping bees pays decently, and only decently well when properly kept, may doubtless be true. So does a law office, or being a professional politician; but it is not a question of what results may accrue at its prettiest, but what results are likely to accrue as men and things are, not as they should be. To say this is the fault of the men and things, is to beg the question; and even when begged, it resolves itself into such care and attention being given to bees that the man who does it becomes a specialist almost by necessity.

Why, even Mr. Root with his success, says bee-keeping is "hazardous." It is so. It is not a bonanza, but a living—a living to a man who makes it his business, and saves the surplus in honey and dollars of a good year to make up for the poor year.

I would write much more; in fact the more I write the more points and arguments I see on my side; but I recollect that you may think my screed is too lengthy already. I, however, do say that this is a very vital question to men who are putting money (or think of doing so) into the bee-business, and it needs threshing out thoroughly.

Austin, Texas.

Read at the Northern Ohio Convention.

Feeding Bees in Spring.

H. R. BOARDMAN.

Bees, like many other insects of the same family, consume very little food in their perfect state at any season of the year, and much less during the winter while in a dormant state, than during the activity of the honey season. We have been astonished at the statements of entomologists that this class of insects consume as much food during the few days of their larval development as in all the rest of their lifetime. This accounts for the rapidity with which their stores sometimes disappear when rearing broods extensively, and also throws some light upon that mysterious phase of life—the dormant slumber of winter, when animation is nearly suspended. We find them able to live for nearly half of the year, which would comprise nearly their whole life time, in winter quarters within the hive, without serious results. This is truly astonishing, but much less so in the light of the above facts; and these facts furnish us a very important factor in the consideration of our subject; for in order to supply the food in the most economical way, a knowledge of its disposition and uses within the hive is indispensable.

Brood-rearing that has been suspended during the winter, is resumed at the approach of warm weather, sometime in February or March on the summer stand, and in the beehouse or cellar, somewhat earlier. The food resources of the colony at this time was stored by the wise instincts of the bees of the previous season, not for their own use, for they do not live to use it, but for their posterity, and would prove sufficient for their necessities usually, were it not appropriated to increase the stores of avaricious man. Up to the time brood-rearing commences in the spring, the stores in the hive remain almost untouched; but as brood-rearing begins, the bees are gradually aroused from their winter sleep to increased activity, and the stores will be drawn upon as the season advances, in proportion to the amount of brood used. The first few warm days of spring, when the bees fly freely, make astonishing inroads upon their stores. This makes it very important that a critical examination be made to ascertain the condition of the stores, and all light colonies should be marked to be fed; and these light colonies should be made the objects of special care until honey is furnished by the flowers. I cannot attach too much importance to the vigilance necessary to succeed with these light colonies; for if we neglect them only a day or two when their stores are exhausted, not only does the work stop and much time is lost, but the brood is eaten and thrown out, and the work that has taken weeks to build up is destroyed. Even in the midst of the fruit bloom, when the weather was unfavorable, I have seen bees suffer for food, and in their extremity eat and destroy their young

larvæ to prevent starvation, and even perish outright, with the whole world a profusion of honey-bearing flowers.

There have been invented many kinds of feeders devised to supply food to bees; but undoubtedly the best feeder ever invented has not been patented, that made by the bees—the comb—and the best food, pure honey, stored and sealed by the bees. Probably no more economical way of supplying food to bees in need of stores can be found, than giving a comb of sealed stores. This can be placed in the hive just where it is needed, by exchanging it for an empty comb from the hive, and should be placed next to the cluster of bees; especially important is this if the colony is weak and the weather is cold. This they will use just so fast as they need it, and not so rapidly as to excite them to unnecessary activity. If no combs of sealed stores are to be had, the next best thing is empty combs for feeders, filled with sugar syrup, and fed in the same manner. Some prefer sugar syrup to natural stores of pure honey. I think this would be conceding too much. A division-board is sometimes used in the hive, dividing the stores thus supplied, from the colony, leaving an opening through which the bees can pass. But the best result, I think, can be obtained by crowding the stores close to the cluster of bees, and in considerable quantities at one time, when the capacity of the hive will admit of it. This plan being less trouble, and much less likely to induce robbing than feeding frequently in small quantities. Later in the season when the colonies have become too large to be fed in this way, an upper story can be put on with a cloth or board between to economize the heat, and the combs of feed put in the upper hive, leaving, of course, a small passage-way between the upper and lower hive. A colony supplied with an abundance of stores in this manner, will scarcely ever fail of surprising the bee-keeper with a large yield of honey at the end of the season.

Entrance feeders come next. These are so made that when placed at the entrance of the hive, they are only accessible from within, excluding outside bees. There are many other kinds of feeders too numerous to describe here, but I consider the entrance feeder the best of its kind. Having commenced feeding, whatever may be the plan, there is but one economical course to pursue: continue the supplies until natural stores are abundant. To the novice this may all seem very simple and easy; but it requires the utmost caution to feed during a scarcity of honey, especially with weak colonies in the yard, without inducing robbing; and when the disposition is once aroused, the effect on the apiary is very demoralizing, and it will prove a source of annoyance and perplexity to the bee-keeper. "An ounce of preventive is better than a pound of cure," is particularly applicable here. Feed at evening after the bees are done flying; be particular that no feed is dropped

about the yard, and see that no crack or peep-hole in any hive will admit a marauder. Keep watch with "Argus eyes," and nip in the bud the first attempt at pillaging, and when conducted with care, feeding is easy.

I have thus far spoken only of feeding to supply destitute colonies. Much has been said about stimulative feeding. This consists in feeding bees in order to form a substitute for the regular flow of honey from the field in the honey season, in order to arouse the bees to greater activity and increase the rearing of brood. I very much question the economy of this kind of feeding. If a colony of bees be fed a small quantity of warm syrup or honey, they immediately take wing in great numbers, and present the busy scene of a mid-summer day, although it may be so cold that no bees were flying before. Not only is the colony fed aroused to unusual activity, but the other colonies in the yard will sympathize in the excitement, and a disturbance will be caused more or less over the whole yard, which will increase at each successive feeding. If this kind of feeding is continued regularly each day, the effect upon the colony fed is similar to that produced by the natural yield of honey from the field. The brood-nest is extended, drones reared, and a general appearance of prosperity prevails. This condition, no doubt, would seem gratifying to the bee-keeper were it not that it must be continued by abundant feeding until natural supplies are furnished from the fields, and the weather will permit the bees to gather it in.

We may look forward hopefully to the apple bloom in expectation of relief, and be disappointed by dismal rains and continued cold; if so, we are confronted by the startling fact that our rapidly growing colonies are now looking to us for food until raspberry or white clover comes; and unless we supply it, the bees will surely economize at the expense of the valuable brood already in the hive—certainly a very poor economy for the bee-keeper.

We are almost startled on learning how short is the average life of bees during the activity of the honey-gathering season—very much shorter than in a season of rest. Thus showing us at what expense of vitality the full activity of life is enjoyed. This result is simulated in stimulative feeding. The simulation of the honey season that we are able to practice, is faulty in one important particular. We are unable to give the warm bright sunshine of June; but instead the sharp, chilling winds from the north prevail, and the workers which start out with bright prospects, pay dearly for their short-lived ambition. Most of us observed that those colonies having abundance of natural stores in the spring were built up quietly into strong colonies, crowded to overflowing with bees, and the first to cast new swarms. This is the natural way, and who can say it is not yet the best.

Flour feed in early spring, as a substitute for pollen, was a few years

ago almost universally advocated by the bee-keeping fraternity, and some favor it yet, although many who once practiced it have abandoned it, after giving it a test for years, satisfied that the good resulting from it would not compensate the evil. After considerable experience in this kind of feeding, I am satisfied that there are times when a judicious feeding of some kind of flour, as a substitute for pollen, would be beneficial. But I am not satisfied that an indiscriminate feeding of flour, whenever the bees will take it, always results beneficially. East Townsend, O.

For the American Bee Journal.

The Iowa Central Convention.

The Iowa Central Bee-Keepers' Association met at Winterset, Iowa, on April 18, 1884. The meeting was called to order by the President, A. J. Adkinson, who asked for a report of the successes and failures in wintering, which resulted as follows:

Out of 425 colonies put into cellars and clamps, 133 were lost; and from 148 colonies left on the summer stands, there was lost 101. Some had tried tacking wire screens over the fronts of the hives, which resulted in the death of the bees so treated.

Adjourned to meet at 1 p. m.

After calling the meeting to order, the President read a letter written by Mr. Thos. Chantry, who has again been very successful in "clamp" wintering.

The following questions were asked:

1. Which is the better plan of increase, swarming or dividing? The majority of those present seemed to favor the dividing plan.

2. How can the bees be made to build their combs straight? Mr. Bailey and others advised raising the backs of the hives 6 or 8 inches.

Adjourned to meet at Winterset, Iowa, June 20, 1884.

Reversible Frames.

M. M. BALDRIDGE.

My attention has once more been called to an article on "reversible frames," on page 167. The writer, this time, is one of those enthusiastic Michigan bee-keepers, and what he says reads about as follows:

"Reversible frames are not exactly what they have been *cracked up to be*. If I understand the matter, there are two desirable features claimed for reversible frames. First, by reversal the bees will fasten the combs to the bottom-bars, and if any honey is stored along the under side of the top-bars, the bees will remove this honey to the section boxes."

"Now, by using wired frames, the first desirable feature is rendered null and void; while, in regard to the second point, would it not be much more desirable to employ such a method of management that the honey will be stored in the sections in the first

place? If reversible frames were a very desirable thing, I think a reversible hive would be still more desirable. Had hives been made small enough so that ordinary queens could keep them full of brood, perhaps reversible frames would never have been thought of."

I see nothing in the foregoing to prove that "reversible frames" are not exactly what they have been "cracked up to be;" but, perhaps, I am blind. I do not see but that the writer admits, substantially, that by reversing the frames the bees will fasten the combs to the bottom-bars and make them as solid and perfect as they always do to the top-bars. If this be true, then in that respect, are not "reversible frames" exactly what they have been "cracked up to be?" The writer certainly does not deny the claim. He says, however, that the same result may be secured by using wired frames, and without reversing them. Now is that true? It may be true when the combs are built in the second story, but how is it when confined exclusively to the brood chamber?

It should be borne in mind that very few of our comb-honey specialists now use the two-story hive deep enough for two sets of frames. However, perhaps the wonderful "strain" of hybrid bees, so highly "cracked up" in Michigan, will do as he claims; but I have seldom seen it done in the brood-chamber in Illinois or elsewhere, by the *ordinary* "strains" of bees.

Our Michigan critic also admits, substantially, that when the combs in the lower story are supplied with both brood and honey, by reversing them the bees will remove the honey now at the bottom of the hive, owing to its *unnatural* position, to the sections above. If this be true, then in this respect, are not reversible frames "exactly" what they have been "cracked up to be?"

I infer from what our Michigan critic says, that he is, perhaps, acquainted with a system of management which forces the bees to deposit their honey in the sections "in the first place," and that the system does away with the necessity of reversing the frames, and possibly of scarifying the honey when sealed. This may all be true, but may not "reversible frames," at times, aid materially in securing such a result? And if they do not assist, will they do any harm?

If reversible frames are really desirable, then would not a reversible hive be more desirable? Possibly, but please tell us *why*. I can see no good reason for making the *hive* reversible.

For several years I have been convinced that the 10-frame standard Langstroth hive is too large for securing the best results in comb honey; and mainly because ordinary queens are unable to keep all the combs *full of brood*. For that reason some bee-keepers have made the hive smaller by using only eight standard frames; but by so doing they have diminished the capacity of the surplus-honey chamber. To avoid this, I prefer to reduce the depth of the 10-frame

hive to frames only 7 inches deep in the clear. I did this in 1876, and have used such hives more or less ever since.

On some accounts I prefer such hives to the 8-frame Langstroth, and yet I think it will pay me to use "reversible frames." So you see even the small hive, small enough so that ordinary queens could keep them "full of brood," did not stop me from thinking about reversible frames; nor am I yet convinced that such frames are not *exactly* what they have been "cracked up to be."

For the American Bee Journal.

Treatment of Foul Brood.

A. W. OSBURN.

After reading the able article by Dr. A. B. Mason, on page 231, I will relate a portion of my experience with "that dread disease" while in California, where it prevails to a much larger extent than in any country I was ever in. I agree with the Doctor that too little attention is paid to a subject which is of such great importance to every person who keeps bees, whether he has one colony or one thousand.

In treating a case of foul brood, of late years, I have tried but the one method—the starvation plan; and I have yet to see the case I could not cure by my method of operation.

When I discover I have a case, the same evening when it is too late for the bees to fly, I smoke the colony thoroughly and close the entrance for a few moments, so when I raise the cover no bees will rise and fly. I should have said, before opening the hive, I set it on a sheet in a clear, open space, so that when the cover is removed what bees rush to the top for fresh air, will not crawl off on the ground, and thus escape the fast to which I propose to subject them.

I have prepared an old hive with 4 or 5 old frames. I then proceed to shake and brush every bee into the box, invert the hive that formerly held the bees on the sheet, and thump all out and unite them with those in the old hive; and placing on the old hive a tight fitting cover in which are four 1½ inch holes, with wire cloth nailed on the under side. I nail this cover down that by no accident it may come off. I then put them in a cool place. In two of the holes in the cover I place sponges wet with a solution of salicylic acid, borax and salt. I make the solution as follows: Take a clear pint bottle, put in two heaping teaspoonfuls of salicylic acid, two of powdered borax, and two of the best salt you can get. Shake them well and let it stand till the acid is dissolved. With this solution saturate the sponges for the bees to drink from while they are confined; for bees, when shut up, will perish for the want of water much sooner than they will for the want of food. I keep them shut up just 48 hours; then give them a clean hive, a comb of honey, and a sheet of eggs and larvæ,

and they are fairly started to house-keeping again, cleansed, purified, and in every way all right; at least such has been my experience in all cases similarly treated, and those are not a few I assure you.

Now, as I said before, there never has been an exception to this; every colony treated as above directed have come out cured. I have tried all the other plans mentioned by the Doctor, but I never had the success with them that I have had with the Simon-pure starvation plan.

Now let us return to the hive and combs that have the disease. The combs and frames I burn, and while they are burning, I place the hive inverted upon the fire, which in a moment becomes a burning mass with the rest. I let it remain until it is well charred on the inside, and then boil it in ashes and water. I put it over the fire to melt the wax out of the cracks, that the water may have a fair chance to penetrate every crevice. I then consider it free from all traces of the disease; at least I have never had any bad results come from a hive treated in that way.

I wish to say to all those who have had no experience with foul brood, that if they find they have a case, not to get excited, but go about it as you would any other job which you are determined to do and to succeed in. Do not think because one colony has it that all you have in your apiary must and will have it. Experience has proven to me that such is not the case; for I have had as healthy colonies standing within 2 feet of as diseased a one as ever gathered a pound of honey.

While I would caution self-possession and determination in such cases, I would also advise that no time be lost before doctoring the sick colony; for how fast it will spread, depends upon a multitude of circumstances which would take up too much time to explain here; suffice it for all practical purposes that if as soon as a colony is found to be affected, it be resolutely dealt with, there is no danger but that you can keep the upper hand of it.

One year ago I was in the "hot bed" of foul brood (California); and with an apiary of 270 colonies I did not have over two cases, on an average, a year. But in that locality, where it was so common, I used a preventative. I prepared the drinking water for the bees as regularly as the morning came. To each quart of water I put two table spoonfuls of the solution used for wetting the sponges for diseased colonies when shut up; and any one who has never tried watering their bees, would be surprised to see how willingly they accept any act of kindness in that direction.

I take this ground for believing that the solution given to them in their drinking water, and the food prepared by the bees for the larvæ, is composed of water, honey and pollen; and if the water is impregnated with salicylic acid, and comes in contact with a spoon of foul brood that it will kill it. I can only assert this, but one thing I know; *i. e.*, I have had healthy and

strong bees in the midst of this scourge, while others have gone by the hundred colonies where they were not troubled by foul brood.

I am not one who believes that foul brood comes from any local cause, such as chilled brood, poor queen, or any thing of the sort. Where it has its origin, I do not know; but I am more fully prepared to accept Prof. Cook's solution of the problem than any other I have seen.

I would say to Dr. Mason and all other "old veterans," that I have not written this, thinking that they will learn anything new from it. It is simply my way of treating the disease in later years; and in which I have been very successful. If the novice can reach success through the same channel, I will be more than paid for my trouble.

For the American Bee Journal.

Right and Wrong Names.

JOHN PHIN.

Does Mr. Maltby really mean to tell us that an insect can be "perfect" in two States? Perhaps he does not mean the moth-larvæ, but the Editor of the BEE JOURNAL and Rev. Wm. F. Clarke. If so, allow me to congratulate them both; but, perhaps, I am again wrong. He may mean two States of the Union (printers sometimes makes mistakes and use lower case for capitals). I know that the moth is perfect in New Jersey. How is it in Illinois?

Again, are there really "drone" ants as Mr. Maltby asserts? If so, it is news to me. I have heard of male ants, but never of "drone" ants.

Is Mr. Maltby's vocabulary so limited that "drone eggs" and "worker eggs" are "the only ways in which the two sexes in the egg can be expressed" by him? How would "male eggs" and "female eggs" answer? or any other of half a dozen good ways that might be suggested? How would he understand "queen eggs"? Would this mean eggs laid in queen-cells or eggs laid by a queen? Did he ever hear of a white blackbird? Are all blackbirds necessarily black? Are all black birds blackbirds?

It is unfortunately true that a great many expressions "do not convey an idea of anything" to some minds. The ideas that we derive from words often depend as much upon our own previous knowledge, as upon the actual arrangement of the syllables, words and sentences.

Thus Mr. Maltby sees in the expression "ivory worker," only a person who works in ivory. A dairyman might see in it a worker made of ivory (and used for working butter). Another man of still broader views might see other meanings in the same sentence, and would, by the aid of the context, pick out the true one.

A former critic of the expression "egg workers," showed his ignorance of the elasticity of our language, by asserting that an "egg-worker" was a worker made of eggs, just as a tin

rooster was a rooster made of tin; but a tinsmith is not a smith made of tin, and an egg-worker is not necessarily a worker in eggs.

Patterson, N. J.

For the American Bee Journal.

Pollen not the Cause of Diarrhoea.

ROBERT CORBETT.

On page 233, Mr. Thomas H. Shepherd speaks of late swarms having the diarrhoea, and why they have it. I beg leave to differ from him, and to show that it has not been my experience in 50 years of bee-keeping.

I have always found that my late or young swarms are the cleanest, and in the best condition in the spring. No one must expect that a quart of bees will winter so well in the same temperature as four times that amount will, if each have the same space in the hive. While the full colony will come through all right with the tem-one-quart colony would require a temperature at 40° to 50° above zero, the perature of 55° to 60°. Everything else being all right such a small colony will come out in the spring cleaner than the full colony.

I agree with Mr. S. in regard to pollen, for I do not believe that it is the cause of diarrhoea, but that it is fall honey. Neither do I believe that fall honey is as good as summer honey on which to winter bees, if it has not been gathered from cane or cider mills. As a general thing fall honey is thicker and heavier than white clover honey. Mr. S. says that healthy colonies have their combs filled with summer honey, while the sick ones have theirs filled with boneset, aster and other kinds of fall honey. He seems to think that the weak must succumb to the strong, and take what they can get; and that I think is the principal cause of the disease.

He quotes this from Dr. Tinker: "When in the winter the temperature of the cluster and interior of the hive, falls below the point of health, the beginning of their ills is here." Truer words were never spoken. Then Mr. S. says, "Where he gets his proof I do not know." I can tell him that the doctor gets it right in the hive where the sick bees are. He also says, "I find, where diarrhoea does so much damage, there is an abundance of fall honey and a famine before it commences." How is this? Here we have no clover and but very little basswood, so the winter stores of the bees are, in a measure, all fall honey; and our bees are as free from diarrhoea here as anywhere else.

To obtain a good colony, take an August swarm which has had enough stores to winter on, and it will be cleaner and brighter in the spring, than an older colony in the same temperature. But in wintering light colonies the space which they occupy must be contracted, or there must be two holes four or five inches from the top of the hive, especially if the hive is a deep one, but no ventilation above.

While a full colony will bear some upward ventilation, the light one will

perish; and while the strong one is able to cast off its foulness below at the entrance, the light one is not. Therefore the two holes are required in the front of the hive above the entrance covered with wire cloth, then the light colony will be able to cleanse itself of its foulness. Whilst they can cast this foulness to the bottom of the hive they can cast it so far as to be carried away by the current of air which is passing from the entrance through the holes. Thus the light colony is preserved from any dampness; and if the atmosphere is all right the ventilation is also.

Tuscarawas Co. O., Convention.

The bee-keepers of Tuscarawas Co., O., met at Port Washington, O., on May 15, 1884, and duly organized by adopting a constitution and by-laws, and electing the following officers, viz.: A. A. Fradenburg, President; Geo. F. Williams, Secretary; and T. A. Swihart, Vice-President.

As the meeting was held at the time of year when farmers are planting corn, the attendance was not large. Several subjects relating to bee-keeping were discussed, and all present seemed to be much interested.

Adjourned to meet in New Philadelphia, O., on Oct. 23, 1884.

A. A. FRADENBURG, Pres.

For the American Bee Journal.

Shall we Rear Hybrids or Not?

J. E. POND, JR.

I am a stickler for purity of blood, and have, as yet, to learn that a superior race can be improved in its first generation by crossing with an inferior. I am well aware that our domestic breeds all sprang from one original, and that great improvements have been made by mixing blood; but to produce a distinct strain, like the Jersey cattle for instance, has taken a long period of time, and has been done only by using the greatest care in the blending of strains.

Now, if we apply this same principle to the honey-bee, we must know that a long period of time will inevitably elapse before a distinct strain can possibly be produced; and whatever we may rear that is less than a distinct strain, will be of no value whatever. I mean by a distinct strain in bees, such queens as will invariably produce such certain characteristics in their worker progeny, that we may know them with absolute certainty. Anything short of this is nothing but hybridizing, as it is called.

I have no fault to find with any one who prefers, for his own use, Italians mixed with blacks; that is his business. If he prefers hybrids, he certainly has the right to rear them; but I do find fault with any one who claims to have made by crossing the Italians with the blacks, a distinct strain, which is far superior to any-

thing now known, simply because I believe it is impossible so to do, and because it is putting hybrids into a prominent position under the garb of a new strain.

What is the claim made in regard to these "bees for business," as they are called? Simply that they will occupy sections more readily than the pure Italians. But will they? I have many times read the statement that they will do so, but my own experience teaches me the contrary; and I must conclude, judging by my own apiary, that he who cannot induce his pure Italians to readily work in sections, does not understand the "nater of the critter;" and that it is his fault rather than that of his bees.

I am well aware that the Italians are inclined to swarm out when the brood-chamber is filled, but not more so than other bees when they are properly managed. It is difficult to prevent swarming when working for surplus comb honey, still it can be done with the exercise of care, time and patience.

I have never known a colony of pure Italians to cast a first swarm before the brood frames were full; while the blacks and hybrids will often do so. This, I judge, to be a peculiarity of the Italians; and by taking advantage of it, I find they enter sections, and fill them too, as readily as any other race of bees.

I will give my method of management, and have, no doubt, that others upon trial of it, will meet with the same success that I do. I will say in the first place, that all attempts to prevent swarming must be made before the swarming impulse seizes the bees, else it will be almost impossible to prevent it, no matter to what race or strain the bees may belong; for that reason I begin early to prepare my bees for comb honey producing, and I am so successful, as a rule, that the sections are entered at once, after they are placed over the frames.

Every one knows that the instinct of the honey-bee teaches it to place its stores above the brood; so I take advantage of this principle, and cause the frames to be filled with brood completely to the top. It is not a difficult matter to do this, and requires but little time; but in any business, no matter what it is, we expect to expend time and run into difficulties, and, of course, must expect to do so in apiculture.

As soon as the frames are well filled with brood to the very top—if there is a flow of honey—I put on sections, with the result that the bees at once occupy them, and usually fill them before swarming. I use worker foundation in the sections, and if I allow a small amount of drone comb in the brood-chamber, and shave off the caps and drones' heads when capped, I find no trouble from the queen occupying the sections.

I admit that it requires some little care to be successful in the method I have outlined, but I would rather take ten times the care, and be at ten times the trouble, rather than to be bothered with a lot of hybrid "bees for business" in my apiary. But

we admit for a moment that the hybrids will work more readily in sections, do we then wish to go back to the dark ages of 30 years ago, since which time we have been laboring hard to get rid of these very hybrids, and overrun our apiaries and the country with them, and paying for them the price of pure Italians? If so, all right; but when I want hybrids, I shall not be seduced into buying "bees for business" at a high price, but shall get a colony of blacks and hybridize my own queens at a cheap rate.

Experts will not be injured by this sale of new strains, for they know just what they are; but beginners are the ones who are injured, for they suppose the strain which they buy will duplicate itself through several generations, till they learn the contrary by sad experience, and at the expense of ruining their apiaries.

Foxboro, Mass.

For the American Bee Journal.

Half-Pound Sections.

W. Z. HUTCHINSON.

MR. W. D. Wright is mistaken if he thinks that I am more solicitous for the welfare of the half-pound sections than I am for the welfare of *any* other apianian fixture. I wish *everything* to stand upon its own merits; and it was the fact that many bee-keepers were not willing that the half-pound sections *should* stand upon their own merits that inspired me to write as I did.

Half-pound sections *probably* will not come into general use, and they may be dropped altogether, but whether they are or not, again I say, why abuse them? Why look upon them as an enemy? Why *hate* them? Why rejoice in their downfall? I can see only one reason for this feeling; and that is, that if some bee-keepers succeed with them, their denouncers fear that *they* will be obliged to use them, or fall behind in the race.

Mr. Wright says that they are not noticed in the market reports. Perhaps the dealers can explain that. I have seen them upon the market and have seen them *sold* at a price that made it profitable to use them; but the dealer handling them did not quote them in his market report.

I doubt not that bee-keepers, quoted by Mr. W., as having used half-pound sections for three years, were practical men; but if they failed to secure as much honey as when larger sections were used, they yet have something to learn in regard to the "principles underlying the production of comb honey." Hear what Mr. Heddon says in a letter to me, concerning the half-pound sections:

"I have just read Mr. Wright's reply to your article, and wish to say, so far as my report and experience goes, I received no fewer pounds of surplus honey with the use of one-half pound sections than with the pound sections. They injured my business only because they complicated it by the addition of a size not not so much called for.

"They were detrimental in the apiary only for the same reason; that they complicated the work and fixtures. I think them too small for general trade, but for lunch-rooms, restaurants, and such places, they are in demand in small quantities at a price that pays us well for the extra cost of production; which I estimate at an advance of 20 to 25 per cent."

Mr. Wright thinks that my comparison of small packages of extracted honey, with half-pound sections, "not a parallel case at all." Is it not, so far as the consumers are concerned? And as I said before, so I say again: "If the public are unwilling to pay the cost why this feeling and prejudice against half-pound sections."

Rogersville, Mich.

For the American Bee Journal.

Objections to Dovetailed Sections.

JEROME TWICHELL.

Having had inquiries as to my reason for discouraging the use of dovetailed sections as reported in my address before the Western Bee-Keepers' Association, I will briefly explain it as follows:

The best section-box for all uses is the strongest, stiffest and lightest. Strength is required that they may hold together well; stiffness, that they may not give at the corners, and get out of shape; and lightness, that there may be no more wood than necessary sold for honey. My experience in having comb honey overhauled on its arrival, is that the best conditioned crates are always those containing the strongest and stiffest section-boxes, which have protected the combs against the jarring of the crates in handling.

I do not wish to be understood as deprecating the use of dovetailed sections, more than any other kind that has not good, stiff crates. As an additional means of stiffness and security to the combs, I would strongly urge the use of glass, firmly fastened on each side of the section; and fitting as closely as possible the inside of it.

It is better that the inside corners of the pieces forming the section be rabbetted so as to make a shoulder for the glass to fit in. This forms at once, a stiff, solid and tight box in which the honey will stand any ordinary handling, and carry safely by freight almost any distance. This is almost absolutely necessary for the shipping trade, and I have almost made up my mind to decline shipments of honey put up in any other way.

If some of my shippers could see the amount of work and worry, and mixed up messes that they have occasioned me, not to mention the loss to themselves, they would certainly institute a general reform in the manner of preparing and packing their honey.

Out of nearly 1,000 packages of honey prepared in the manner suggested above, and packed in crates of not over 25 lbs. each, with good hand-holes cut in the ends, there has not been 100 lbs. loss to the shippers. While on the contrary out of the same

quantity received in other shapes I venture to say that after having done all I possibly could to save it, there was still an average loss of not less than 10 per cent.

For the immediate home trade it does not make so much difference; but for shipping, it must be made secure against the rough handling in transit.

And while on this subject there is one other suggestion, I would make; *i. e.* with regard to color. No comb honey which is dark, no matter what the quality, flavor, or condition, will sell as well as the white; it will always hang as a drug in the market, and finally be forced off at a sacrifice or thrown in to make a bargain.

This honey though, if extracted, would sell very readily at 7 to 8 cents per lb., and the wax at 20 to 30 cents per lb., and really net more, and in a shorter time, than if shipped in the comb. But choice, white comb in good condition will always find a ready market at this place, and bring a fair price. Two-pound sections will be the favorite by about $\frac{1}{4}$ majority. One-pound sections will follow closely at about 1 cent advance over the price of the 2-pounds, and a few $\frac{1}{2}$ -pound sections may be sold at still 1 or 2 cents advance. The $\frac{1}{2}$ -pounds need not be glassed to carry safely. Larger sections than 2-pounds should never be sent to market.

Kansas City, Mo., May 27, 1884.

For the American Bee Journal.

Correct Nomenclature.

JOHN HEWITT.

Mr. R. J. Kendall, on page 108, has misquoted my article in the *British Bee Journal* for Jan. 15. By reference to it (page 31) you will see the "jarring" is to be done when the bees are not on the combs. I distinctly say jarring the hives or combs (with the bees in) will make them savage; and he cannot find the place where I say, "you have to tread on one to make it sting." If things are to be called by their right names, do let the principle extend to quotations.

On reading his article on page 40, I think I can safely form several conclusions; one of which is: he had better, by all means, get some *pure* and *true* Syrians, not Holy Land bees, then he would have no swearing, and handling bees would be a pleasure.

While on this subject, allow me to try to correct the Editor's foot-note to Mr. Frank Benton's article (page 39). I believe he will forgive my doing so considering his anxiety to have everything properly named: He says: "A glance at the map of Asia will show that Palestine is a portion of Syria, bounded on the north by Lebanon, and on the south by the Arabian Desert. Syria comprises this whole land, but extends north to Asia Minor."

It may do so now under the Turkish rule, just the same as England when spoken of, is understood to imply Scotland, Wales, and very often Ireland also; but an Englishman is never a Scotchman, nor, for that matter, a

Briton either. The proper use of this word being for the natives prior to the Saxon conquest, and at present includes the Cornish, Welsh and Scotch, but not the Saxon; though the word "Britisher" covers all who fall under our flag; and in addition to our islands, includes Cyprus, Canada, Hong Kong, India, Jamaica, etc., in fact people of all colors.

Neither do we in England call the inhabitants of the New World, indiscriminately, "Americans," though in this particular we are wrong; but reserve the appellation for those protected by the "stars and stripes" only; and if we wish to refer to others, they are spoken of as Canadians, Mexicans, Brazilians, etc.

Now Palestine, or Holy Land, never has been understood to extend north of the Lebanon mountains and if north of this barrier—in the land of the ancient kingdom of Syria—a distinct race of bees are found, why call them "Holy Lands?" or south of it, "Syrians?" The sooner everything is called by its proper name, the better for all progress; but do not let us have the same mess with these new races of bees that has been made with Italians.

Just to illustrate what I mean by this: These bees were at first thought to be a distinct species and were named *Apis Ligustica*, from the province of Liguria, in which they were common; and it was thought that all yellow-banded bees were of this species. As such bees were found north and south of the Alps, they were thought to be identical, and were known and sent out by the name, Ligurian bees. Then I suppose, because Liguria is in Italy, they were further dubbed "Italian" bees, whether they came from Switzerland or Italy; the Swiss is preferred by most apiarists.

If we go north or south, we find black bees; thus in Southern Italy the native bees are black; they are black also in Sicily and Malta. How is such a jumble to be unraveled? Are the Swiss or Italian Alps' bees to be called pure Italians, or the Southern, blacks?

But while we may not get out of this mess, we may avoid repeating it with the new races; so let us, by all events call them by the names Mr. Benton gives them. If there is any distinction he will be sure to notice it, and bee-keepers may rest satisfied on his judgment; for on your lines of reasoning, the Cyprian may just as well be called a "British," the same as the natives of Scotland; or Italians, "European," like you would call Canadians and Mexicans, "Americans." I think you will, on reflection, see that a better nomenclature is desirable.

In conclusion let me prophesy that in five years time, everybody will be keeping true Syrians, and smokers will be handed round as curiosities of bygone days of barbarism.

Sheffield, England.

[Our foot-note to Mr. Benton's article, on page 39, is, we believe, correct, notwithstanding this criticism. We did not say that a Scotchman was a "Briton," but we did say that he was "British." Is not Scotland one of the British Islands?

It is certainly wrong to say that the word "American" is applicable only to the people of the United States.

We intended to speak of Syria as it now exists, not what it was in ages past. Mr. Hewitt's objections are not valid. Let us "call things by their right names."—ED.]

SELECTIONS FROM OUR LETTER BOX

Bees in Texas.

Bees are doing very well at present. There are lots of bees kept in this part of the State, but only a few persons know how to manage them so as to obtain the best results. I have had some experience in bee-keeping in Missouri, and think some of trying it here.

CLARK S. FUGE.

Moody, Texas, May 16, 1884.

Oil Cloth Cover for Frames.

In reply to D. R. Rosebrough's remarks on this subject, on page 310, let me quote from the twelfth thousand of my Manual, page 135: "COVER FOR FRAMES.—In summer I prefer oil-cloth to cover the frames. This is used with the glazed or enameled side down, and should be just the size of the hive. This is durable, is not covered so quickly with propolis, and is easily cleaned. Some keep this on in winter, but I prefer a porous cover. From the cold days of fall to the warm days of spring, I replace the enameled-cloth covers with those made of the best factory cloth." As I do use and recommend such covers, of course I need not explain why I do not.

A. J. COOK.

Lansing, Mich.

Bees Gathering the Nectar.

I put 16 colonies into the cellar last fall. This spring I took out 3 strong colonies and 5 with queens, and enough bees to cover one-half of one side of a Langstroth frame. My bees gathered more honey during the last week than they did during any month last summer. We are having a cold spell of weather now.

HUGH WILLIAMS.

Racine, Wis., May 27, 1884.

A Good Report.

My bees have wintered very well. On Nov. 15 I put 82 colonies into the cellar, and put them out on March 20. All were alive, but 3 of them were queenless. I had 2 queens on hand yet, so I managed to save 2 of the 3 queenless ones; the other one I put with another colony. Only one colony showed signs of diarrhoea, I had my first swarm for the season on yesterday; and it is the earliest one I have had since keeping bees. It issued from a colony which has not been fed any this spring. I think that I will have 5 or 6 more if the warm spell of

weather continues much longer. Bees are working nicely on fruit bloom now, and they are storing honey rapidly. The outlook for an abundant honey harvest is good. White clover looks promising. At some future time I will give my plan of preparing bees for wintering, on which, I think, they will winter safely every time.

H. J. SMITH.

Burlington, Wis., May 19, 1884.

Light on the Subject.

I have read the book, "Bees and Honey," with interest. It has given me much light upon the subject of bee-culture and the habits of bees.

J. K. P. SOUTH.

Jett, Ky., May 26, 1884.

Bees Building up Fast.

Bees in this section are storing surplus honey slowly, owing to so much damp and cloudy weather. The present spring resembles very much that of 1878; and that year was noted for its large yield of honey. As it was then, there will be but very little honey extracted this year before June 1. In the mean time bees are building up strong, so that when the warm and sunny weather comes, there will be a tremendous large army of workers to go into the field to gather the harvest; and there is scarcely a doubt but what they will bring in the nectar by the tons.

J. E. PLEASANTS.

Santa Ana, Cal., May 19, 1884.

Almost Discouraged.

I put 15 colonies of bees that were Italianized last summer, into the cellar last November, and all died of diarrhoea, I think, as they kept coming out during the whole winter, and daubed the hives and every thing badly. The cellar was ventilated by a chimney and a kitchen adjoining. During the winter before last, I lost 20 colonies in Eclectic hives on the summer stands. I shall stock up once more, but I am almost discouraged. I have a new hive for wintering bees on the summer stands.

OLIVER K. PIERCE.

Ayer, Mass., May 26, 1884.

A Very Small Loss.

One year ago I started with 28 colonies, and increased them by natural swarming to 49. Last season I produced 1,000 pounds of comb honey in the 1-pound sections, and 500 pounds of extracted honey. In the fall I bought 10 colonies more. My loss so far has been one queen and one colony, the latter having starved. I use the Mitchell frame.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Trembling Bees.

I have, in my apiary, 2 colonies of Italian bees, and there is something wrong with them which I do not understand. There appears to be two kinds of bees in the hives; one kind, a fine looking Italian bee, and the other a smaller bee with a black head, and when alive the lower part of the body is of a dark purple hue. The alighting-boards are completely covered with bees, and all seem to be shaking, or of a trembling motion. The Italians have been killing them off in great numbers on the alighting-boards for the last two weeks. The colonies are very populous, having 8 Langstroth frames of brood in each of the hives. I send you a few of the bees, and would like you to inform me through the BEE JOURNAL what is the matter with them.

WM. K. LAWSON.
 Cold Spring, N. Y., May 21, 1884.

ANSWER.—I can only guess at the correct solution of the case. I do not think the "trembling" and fighting among your bees is from the same cause. I suspicion that the little black-headed bees are from another colony, and that is the reason they are being killed. The tremulous movement, I think, is a natural one, which bees often make. I believe your colonies will come out all right.

Carrying out Young Bees.

Last season I put a swarm of hybrid bees into a two-story Langstroth hive, and being anxious to have them strong early this season, I fed them during the latter part of March and the forepart of April, when they became very full of young bees; and as soon as they began to hatch, the bees commenced to carry them out, and have kept it up ever since. I took them out of the hive about 10 days ago, and could not see any thing

wrong. They were clean, and had plenty of room. What is the cause and the remedy, if any, for the above trouble?
 ULYSSES ADAMS.
 Missouri City, Mo.

ANSWER.—I have never known bees to carry out larvae or pupae except when moth-worms or something else had mutilated the cells and killed them; or when, during an excessive honey flow, they had to make room for more honey in the brood combs, or else lose it.

Transferring and Removing Bees.

Will Mr. Heddon please answer the following:

1. By your method, or the old way of transferring, can bees be moved a few rods (or ½ mile) without many of them going back to the old hive? That is by removing them in the evening of the day they were transferred.

2. Immediately after a natural swarm has been hived, or at the time of transferring a colony of bees, can their queen be taken from them, and a new one given them without danger of their killing the new one? Would either of the above times be suitable?

3. Upon removing a colony of bees from a bee-tree to a movable-frame hive, what hour of the day is the best in which to cut the tree down in order to save the most bees and brood combs?
 C. E. B.

ANSWERS.—1. To prevent their returning to the old location, moving them just as they are transferred, is a good plan; but you should also take the other precautions heretofore laid down in this department.

2. Yes, either time will do well; but in the case of the swarm, I would rather wait till the old queen had laid a few eggs.

3. The cooler the time the better (if in summer); and I would prefer to take a time when the largest number of workers were in the field. When they find the old home gone, they will come down to the hive.

The Iowa Central Bee-Keepers' Association will hold their next meeting on June 20, at Winterset, Iowa. A full attendance is expected.

J. E. PRYOR, Sec.
 A. J. ADKINSON, Pres.

The members and friends of the Northern Michigan Bee-Keepers' Society, will hold a basket picnic at the apiary of Miss F. A. Bellamy, one mile west of Ionia, on June 19. Teams will be in waiting to convey, free of expense, all who wish to attend. Purchase your tickets to Ionia, but leave the cars opposite the prison grounds. Miss B. requests that you bring your wife or husband, as the case may be, and also that you drop her a postal, notifying her of your intention to be present, in order that ample provision may be made to convey all from the trains. Come on the morning train and return in the afternoon.
 F. A. PALMER, Sec.
 S. J. YOUNGMAN, Pres.

The Mahoning Valley Bee-Keepers' Association will hold its next meeting at Newton Falls, O., on June 6, 1884. It is desired that a display of aparian supplies and samples of honey be made at that time. Mr. Hammon, of Bristolville, and Mr. C. R. Page, of Streetsborough, will read practical essays on topics pertaining to bee-keeping.

E. W. TURNER, Sec.
 L. CARSON, Pres.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
 Monday, 10 a. m., June 2, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for all honey is very slow; market dull and prices range from 6@9c for extracted. Different lots of choice comb honey in small sections have been offered and sold in our market lately at 12@14c per lb. As I predicted some time ago, the preference for the production of comb honey seems to be prevalent; and, as we have the best prospects for an abundant harvest this year, we may prepare for low prices.

BEEWAX—Is in good demand; choice yellow brings 35c a lb. on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—Present quotations are as follows: Fancy white in 2-lb. sections, glassed, 13@14c; fair to good in 2-lb. sections, glassed, 12@13c; dark grades in 2-lb. sections, glassed, 10@12c. No 1-lb. in this market.

BEEWAX—Scarce, and sells readily at 30@33c. McCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15c, and 2½-lbs. to 2½-lbs. from 10@12c. No 1-lb. in the market. Extracted, 8@10c.

BEEWAX—35c. BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—Choice white comb honey in 1 lb. sections brings 18c; in 1½ to 2 lb. sections, quotable at 16c. Comb honey discolored and in undesirable shape is selling at 10@12c. Extracted honey is in light demand at 6@8c. Manufacturers of syrups and bakers say that the low price of sugar is the reason why they do not use as much honey as formerly. There is very little desirable comb honey on the market.

BEEWAX—Is scarce and fancy yellow brings 35c. Good beeswax, but dark, and having more or less of refuse matter in it, quotable at 30@33c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—A little new extracted is on the market, but is not receiving much attention, buyers being rather timid. Several small lots of old extracted arrived within the week, mainly of quality, and the same are offering at low figures. Some very choice old extracted was sold at 7c, which is at present an extreme figure. The demand is very light, and the tone of the market weak. White to extra white comb, 15@18c; dark to good, 10@13c; extracted, choice to extra white, 6@7c; dark and candied, 4@5c.

BEEWAX—Wholesale, 27½@30c. STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—There seems to be no limit to the demand for choice white comb 1-lb. and 2-lb. sections, if in good condition, at 15c to 16c, and the supply is hardly equal to the wants of the trade. Dark and irregular combs can be bought at any price above extracted, and holders would be glad to get that. Extracted is in fair demand, 7c to 8½c, according to quality.

BEEWAX—Small lot sold to-day at 35c. None to speak of in the market.

JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@8c.

BEEWAX—Firm at 32@32½c. for choice. W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1 lb. sections at 18c; 2 lbs. best white not quite so active at 17c; 1 lb. sections sell quickly on arrival, and often are sold in advance. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.

BEEWAX—Scarce at 35c. A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 18@20c; extracted, 7½@8½c. GEO. W. MEADE & Co., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5. or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a continual statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an additional present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

"THE SON OF MONTE-CRISTO," being the sequel to "THE WIFE OF MONTE-CRISTO," and the end of the continuation of Dumas' masterwork, "The Count of Monte-Cristo," just published by T. B. Peterson & Brothers, Philadelphia, Pa., at 75 cents. Romantic in the highest degree, powerful in the widest sense of the term, and absorbingly interesting, it is a work absolutely without parallel at the present day. Every chapter has a strong and stirring feature of its own, while all the legions of intensely thrilling incidents are as original and surprising as they are strong.

Price Lists on our desk:

W. G. Russell, Millbrook, Ont.
 D. Kauffman, Needy, Oregon.
 E. B. Weed, Cincinnati, O.
 Derr & Kreider, Sterling, Ill.
 C. D. Duvall, Spencerville, Md.

BEST IN THE MARKET.—Send orders for the L. X. L. Extractor. The demand is heavy, but I ship them promptly. Price for the L. frame, including Knife, only \$8.00.
 23A1t W. C. R. KEMP, Orleans, Ind.

GIVEN FOUNDATION.—As I have purchased a Given press, I will make Foundation on the same, this season. Will take Beeswax in exchange for Foundation or work it up for two-fifths.
 23D4t A. WORTMAN, Seaford, White Co., Ind.

ONE-PIECE SECTIONS \$5 per thousand. Langstroth, Simplicity and Chaff Hives, Comb Foundation, Smokers, and a full line of Apiarian Supplies. DERR & KREIDER,
 23AB4t Sterling, Whiteside Co., Ill.

WHITEWOOD OR BASSWOOD SLICED SECTIONS, 4x4x4. A decided success. Can be used in Cases or Frames; \$2.00 per 1,000. Hives and Cases good and cheap. Address N. E. DOANE, Pipestone, Berrien Co., Mich. 16D4t

Bees, Bees! and Eggs, Eggs!

One to 200 Colonies of Italian Bees For Sale.

1 to 10, at \$6.50 each; 10 or more, at \$6.00 each. Tested Queens after June 1, \$2.00 each. Also Eggs for hatching, from choice stock of White and Brown Leghorns, at \$1.50 per set of 13 Eggs. Send Card for Price List and reference. Address to **W. M. LOSSING, HOKAH, Houston Co., MINN.**

DUNHAM COMB FOUNDATION MACHINE.

TESTIMONIALS.

MRS. FRANCES DUNHAM, De Pere, Wis. Hamilton, Ill., Dec. 10, 1883.
Dear Madam:—We have made about 38,000 lbs. of foundation on your mills this year, and the
foundation has given universal satisfaction; so much so, that several manufacturers have stopped
manufacturing to supply their customers with our foundation. We have also manufactured about
10,000 lbs. of this foundation on the Vandervort machine for surplus boxes, and it has been equally a
success, but for brood chamber foundation, yours is still unexcelled.
Yours,
CHAS. DADANT & SON.

MRS. FRANCES DUNHAM, De Pere, Wis. Beeton, Ont., Dec. 10, 1883.
Dear Madam:—I have made over 100,000 lbs. of foundation on one of your machines, and would
not now take double the price I paid for it.
Yours very truly,
D. A. JONES.

MRS. FRANCES DUNHAM: Genoa, Cayuga Co., N. Y., Dec. 12, 1883.
All prefer the foundation I manufacture on one of your mills, to that made on any other machine
I have no difficulty in rolling it from 10 to 12 feet to the pound for sections.
Yours respectfully,
J. G. WHITTEN.

MRS. FRANCES DUNHAM: Kenton, Ohio, Dec. 29, 1883.
After using one of your foundation mills for the past 3 years, we can't say too much in its favor
And for brood foundation, it stands head and shoulders above all.
Yours,
SMITH & SMITH.

MRS. FRANCES DUNHAM: Omaha, Neb., Jan. 18, 1884.
I made all brood on Dunham mill, and that I believed it by far the best for that purpose, and as
further proof, instance the testimony of E. Kretchmer, of Coburg, Iowa, and L. C. Root & Bro., of
Mohawk, N. Y. Messrs. Root & Bro. have only used brood foundation of me, and in a later communi-
cation say: "It (our foundation) gave the best results of any tried." I write this that you may have fair
play, which is to me always a jewel. You are at liberty to publish this. Yours truly, T. L. VON DORN.

HEDDON'S COLUMN.

BEST GIVEN COMB FOUNDATION.

Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8¼x16¼, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

- One Hive complete for comb honey. \$3.00
- (The above will contain two cases complete with sections).
- The above Hive complete for extracted honey. \$3.00
- The above Hive complete for both in one 4.50
- One Hive in the flat. 2.00
- Five or over, each 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4¼x4¼x6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

STUDENTS OF APICULTURE

Will receive terms for 1884 on application.

BEES and QUEENS.

If you contemplate the purchase of Bees in any shape, tested or untested Queens, it may pay you to send for my

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.

Address,

JAMES HEDDON,
DOWAGIAC, Cass County, MICH.

Sixth Thousand Just Published!

New and Enlarged Edition OF BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure. T. F. BINGHAM.

Abronia, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN.

Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ills.

A Liberal Discount to Dealers by the Dozen or Hundred.

Bingham Smoker

Borodino, N. Y., Aug. 15, 1882.

Cyprians Conquered—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. Respectfully,

G. M. DOOLITTLE.

Prices, by mail, post-paid.

- Doctor smoker (wide shield) 3½ inch. \$2 00
- Conqueror smoker (wide shield) 3 " 1 75
- Large smoker (wide shield) 2½ " 1 50
- Extra smoker (wide shield) 2 " 1 25
- Plain smoker 2 " 1 00
- Little Wonder smoker 1¾ " 65
- Bingham & Hetherington Honey Knife, 2 inch. 1 15

TO SELL AGAIN, apply for dozen or half-dozen rates. Address,

T. F. BINGHAM, P. M., or BINGHAM & HETHERINGTON,

ABRONIA, MICH.

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.

ALFRED H. NEWMAN,
923 West Madison Street,
CHICAGO, ILLINOIS.

A PRIZE.

Send six cents for postage, and receive free, a costly box of goods which will help you to more money right away than anything else in this world. All of either sex, succeed from first hour. The broad road to fortune opens before the workers, absolutely sure. At once address, TRUE & Co., Augusta, Maine. 4A1Y

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNSCAPPING KNIFE.

PATENTED, MAY 20, 1873.

The Original
BINGHAM
Bee Smoker

Patented, 1878.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always do!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Unscapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To sell again, send for dozen rates to

BINGHAM & HETHERINGTON,
6A2B1f ABRONIA, MICH.

BOOKS!

Sent by mail, on receipt of price, by
THOMAS G. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates on larger quantities, given upon application.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects:—Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quieting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, in cloth, \$1.00; in paper covers, 75 cents.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premium for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-Keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bienen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY ALLEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way to rear Queens, etc. Price, \$1.00.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either English or German.

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Nomenclatures in Bee-Keeping.

Mr. S. Corneil has sent us the following criticism on the use of the word "stock" for colony. He says:

On page 67 the Editor says, "A colony should never be called a stock." According to Horne Tooke, *stock* and *stuck* are two of the forms of the past participle of the Anglo-Saxon verb *stician*, to *stick*.

After mentioning several different senses in which *stock* is used, Dr. Trench asks: "What point in common can we find between them all? This: that they are all derived from, and were originally the past participle of the infinitive, to *stick*. * * * and they cohere in the idea of *fixedness*, which is common to every one. Thus the *stock* of a gun is that in which the barrel is fixed; the village *stocks* are those in which the feet are fastened."

Stock in trade, the *stock* of a farm, *stocks* or public funds, *stock* of a tree, family *stock*, etc., are all explained by Dr. Trench with reference to the idea of *fixedness*. In this sense *stock* is appropriately used as a term for a family of bees hived and *stuck* or *fixed* on a new stand. It seems to be even a better term than *colony*, because the latter implies dependence upon, or connection in some way with the parent body—a circumstance which does not exist when a swarm in the normal condition is hived and placed in a new location.

On turning to the writings of authors of books on bee-keeping, and the best educated contributors to the bee-papers, I find that they use the word *stock* in the same sense as the Editor of the BEE JOURNAL uses the term *colony*. So I think we may say that the usage of a majority of the leading writers is in favor of retaining the word *stock*; and if I have been successful in showing that it is properly so used, we must ask the Editor to "reconsider the question."

The words "rack," "case," and "crate," as applied to supers for storing comb honey, require to be defined.

At present there is a good deal of confusion in the use of these terms.

S. CORNEIL.

Lindsay, Ont., Feb. 21, 1884.

We have been unable to spare the time until now to reply to the above criticisms, as well as space to give the article an earlier insertion. As the subject is in no wise injured by the delay, we presume our valued correspondent will excuse it.

It is one of our principles to ever hold ourself ready and willing to reconsider any position we have taken on controversial subjects; but we must say that we require stronger arguments than those presented above to induce a change of opinion. We are quite slow in making up our mind, and do so only upon a review of the whole field *before* expressing our views, and hence we very seldom have to change. Our correspondent says that many prominent authors and correspondents for Bee-Papers have used the word "stock" for colony, and that it is, therefore, right to continue its use.

Many prominent writers for bee-papers and authors have blundered in the use of the adjective "apiarian" as a noun, instead of apiarist! They have also used the term "artificial comb" instead of comb foundation! and many other very foolish expressions. Shall we, therefore, adhere to such blunders when the fallacy of their use is exposed?

The only argument advanced by Mr. Corneil, is the idea of "fixedness" to be conveyed by the use of the word "stock," and he adds: "In this sense *stock* is appropriately used as a term for a family of bees hived and *stuck* or *fixed* on a new stand." If a "family of bees" are "stuck" or "fixed" on a stand, we fear they would not be very profitable to the apiarist. If anything is "stuck" or "fixed" on the stand, it must be the *hive* or *box* containing the bees—and not the "family of bees." That box or hive might be "fixed" there, by being waxed, glued or nailed—but the fam-

ily of bees would be free to rove over meadow or woodland in search of nectar. That idea of fixedness has "stuck" our correspondent in the mud, and "fixed" the word "colony" as the true word to be used to represent "a family of bees."

We hope we have "fixed" this matter firmly in the minds of our readers, and that they will hereafter use the word *colony* instead of *stock*, *stand*, *hive*, *gum*, etc.

We have received the Premium List of the Indiana State Fair, to be held at Indianapolis from Sept. 29 to Oct. 4. The premiums in the Bee and Honey Department amount to \$57 and a diploma—not as large as they should be, but better than they might have been. Here it is:

| | | |
|---|--------|--------|
| Comb Honey in the most marketable shape, not less than 20 lbs. | \$4.00 | \$2.00 |
| Extracted honey in the most marketable shape, not less than 20 lbs. | 4.00 | 2.00 |
| Display of honey—the product of one apiary of the present year. | 4.00 | 2.00 |
| Display of wax, not less than 10 lbs. | 2.00 | 1.00 |
| Display of apiarian supplies. | 4.00 | 2.00 |
| Apparatus for the manufacture of comb foundation, to include all necessary articles for its manufacture. | 4.00 | 2.00 |
| Comb foundation for use in the brood chamber. | 2.00 | 1.00 |
| Comb foundation for surplus honey. | 2.00 | 1.00 |
| Honey extractor. | 2.00 | 1.00 |
| Wax extractor. | 2.00 | 1.00 |
| Honey vinegar, not less than one gallon. | 2.00 | 1.00 |
| Section for surplus honey. | 2.00 | 1.00 |
| Display retail pkgs. for extracted honey. | 2.00 | 1.00 |
| Honey cake or cakes. | 2.00 | 1.00 |
| Collection of honey plants, properly labeled in order, with dates of bloom. | 10.00 | Dip. |

The Indiana Farmer says: "Now, within the next six weeks, are our brightest hopes to be realized or blasted for the year 1884. Who is ready? and, who not? We are pleased to notice many of our friends, profiting by their dearly bought lesson of last season, are fully prepared to reap the harvest when it comes; and, should the favorable weather of the past few days continue, we shall be amply paid for all our care and patience."

In the next to the last paragraph of W. H. Stewart's article, on page 345, "imprisonment comes not of the race in common, etc.," should read "improvement comes not, etc."

Large Bees—A Humorous Statement.

Mr. J. M. Shuck, of Des Moines, Iowa, has sent us the following humorous article concerning large bees, cut from a periodical.

Those who enjoy that kind of reading will laugh at the many humorous points made. Here is the article; take it for what it is worth, payable in smiling, either audibly or mentally, as may best suit the reader's pleasure:

It appears that some ingenious person has invented a method of producing bees of almost any desired size. If two cells, each one of which contains an embryo bee, are knocked into one, the two bees are consolidated, and the result is a new bee, double the usual size. Of course, if this can be done there is practically no limit to the size of possible bees. By knocking four cells into one a bee four times the usual size can be made, and if an entire hive of embryo bees is subjected to this consolidating process, we should have a bee about the size of a turkey—a size hitherto attained only by one species of bee, known as the Presidential bee, an insect inhabiting the bonnets of eminent statesmen, and never by any chance producing honey.

Before recklessly undertaking to enlarge our bees, we ought to ascertain what effect their increase of size will have upon their power and disposition to gather honey. The bumble-bee is much larger than the honey-bee, but he is certainly not a success. An insect so dull (that he fancies that "bumble" is spelled with an "h.") and so lazy that he makes less honey in a whole season than a honey-bee makes before breakfast on a spring morning), is by no means a model. It may be suggested that the bumble-bee's lack of success in producing honey is due not laziness, but to the inability of his wings to carry with ease the weight of his body; but no one who has been chased by an angry bumble-bee will entertain this suggestion. It may also be suggested that the trousers pockets of the bumble-bee are so small that he can carry very little honey in them; but there is no evidence that this is the case. We simply know that the bumble-bee is bigger than the honey-bee, and gathers less honey. So, too, the wasp and the hornet are bigger than the honey-bee, and they make only enough honey for their bare necessities. Evidently the rule of nature has hitherto been, that the larger the insect the less the honey.

Now, if the honey-bee, after being developed into a two or three-pound insect, is going to imitate the laziness of the bumble-bee, what shall we have gained? No one will care to have a score of big, lazy bees dawdling about his premises, upsetting furniture and children by flying against them, and tripping people up by concealing themselves in the grass. We shall have to go armed with big clubs to keep off the bees, and though some sport may be obtained by shooting

bees on the wing, there would be no sport whatever should the bees undertake to hunt the sportsman with stings capable of penetrating anything less than an inch of chilled steel armor.

Even if the mammoth bees should gather honey in quantities proportioned to their size, we should have no use for such a vast amount of honey. It is true that honey is used to a small extent in the arts, and that when one has a personal enemy addicted to buckwheat cakes, a horrible revenge can be obtained by sending him a bottle of pure Berkshire county honey to eat with them. Still, there is no such demand for honey as would justify an effort to largely increase its production.

Our bees are very well as they are. If a hive is kept on a shelf over the front door, and upset on a book agent, the bees will perform as much work as is necessary. To upset a hive of four-pound bees, in like circumstances, would be simply murder, and would in many cases involve the trouble of a trial and acquittal in a court of law. It might be well to keep large bees in Cincinnati for the encouragement of jurors, and of respectable citizens who call meetings at which people are incited to rioting; but in this region we are satisfied with our local bees, and will decline to have them enlarged.

Bees and Honey at Fairs.

Mr. H. B. Cony, of Augusta, Maine, Chairman of the Committee on Exhibits at the Maine Bee-Keepers' Association, gives the following address to the bee-keepers of Maine, in the *Home and Farm*, relative to making appropriate exhibits at the coming Fairs:

Bees and honey formed one of the attractions at the State Fair held at Lewiston last fall. For 1884 the State Society gives us the same amount in premiums, and promise us, should we desire it, a tent or separate building in which to exhibit, with room for those who come from a distance to lodge should they wish; each person to provide his own bedding, the society furnishing the necessary straw for filling the beds. Now, why not all of us bee-keepers attend and carry something with us to help out the display. In so doing we can be one of the attractions, and every evening we can have a bee-convention of practical bee-keepers, with stock and tools on hand to illustrate our latest ideas.

The Eastern State Fair, which is to be held at Bangor, gives us \$30 for bee-premiums, and promises us everything in their power to help us out, and seem disposed to consider this one feature of their next exhibition. I could have named a sum much larger than this, which they would have cheerfully given, had I been sure of a large display. I was more than pleased with the eagerness with which the managers of the Fair grasped at this feature, and the disposition which

they manifested to do us justice in every particular.

Now let us one and all, if possible, attend one or both of these Fairs, taking one or more articles to add to the display. It should be our aim to make honey a staple product. To this end let all endeavor to popularize the consumption of honey by the masses, as well as to raise the standard of production by applying correct principles and progressive art to the management of the apiary. These displays are the best educators of the people that have yet been devised.

I would ask as a favor that some one in every town or city would send me the names of all the persons keeping bees in their vicinity, with each one's post-office address, so I can address them in regard to the coming exhibition. I shall have a supply of premium lists as soon as published, to send to all who wish. Any information in regard to the manner of making the entries, or any other matters in regard to the different Fairs given on application.

☞ Picnics are now the order of the day. The bee-keepers of Hancock and Shelby counties, Indiana, held a picnic at the apiary of George Cole, near Fountaintown, Ind., last Saturday.

Convention Notices.

☞ The Iowa Central Bee-Keepers' Association will hold their next meeting on June 20, at Winterset, Iowa. A full attendance is expected.

J. E. PRYOR, Sec.

A. J. ADKINSON, Pres.

☞ The members and friends of the Northern Michigan Bee-Keepers' Society, will hold a basket picnic at the apiary of Miss F. A. Bellamy, one mile west of Ionia, on June 19. Teams will be in waiting to convey, free of expense, all who wish to attend. Purchase your tickets to Ionia, but leave the cars opposite the prison grounds. Miss B. requests that you bring your wife or husband, as the case may be, and also that you drop her a postal, notifying her of your intention to be present, in order that ample provision may be made to convey all from the trains. Come on the morning train and return in the afternoon.

F. A. PALMER, Sec.

S. J. YOUNGMAN, Pres.

☞ The joint session of the Bee-Keepers' Associations of Hendricks and adjoining counties will be held at North Salem, Ind., June 19, at the apiary of Davis Gully. All bee-keepers are cordially invited to attend. Ample provision will be made to haul all well-filled baskets to the grounds.

☞ The Kentucky Bee-Keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed).

N. P. ALLEN, Sec.

The Honey-Bee.

EMMA BASSETT HENNESSEY.

"Butter and honey shall he eat, that he may know to refuse the evil, and choose the good."—ISA vii, 17.

Where spicy shrub and clinging vine
Within the garden's bound,
Seemingly coax the sun to shine,
A gold-mine I have found.

And all about a busy camp
Arguments the yellow hoard,
And guards from every passing tramp
The treasure snugly stored.

But, see! no selfish law doth hold
Within the busy hive;
Benevolence pays out the gold
For which no brothers strive.

The greatest number's greatest good—
Such is the wise decree
That binds the noble sisterhood,
Of queen and honey-bee.

So quietly each busy life
Lived to its quiet end,
For individu' fame no strife—
As one the colors blend.

And yet, proud man—great architect,
Bring compass, square and rule,
And with your measurements, detect
The laws learn'd in this school.

With nicety of hand and eye,
Gauge me this matchless skill—
This indisp'nable unity
Of multitud' nous will.

These walls so delicate, yet strong;
So uniform and true:
These cells that predetermine long
What sort of life slips through.

And from your laboratories come,
Ye chemists grave and gray!
Translate for me the hive's soft hum—
Its secrets give away.

The mysteries of death and life
Perchance are waiting here,
The problems that occasion strife
Are surely now made clear.

Ah, well! since lab'ring brains evolve
No knowledge like the bee's,
Woman is tempted to resolve
Ne'er to curtail her ease.

Nor yield small homage to those schools
Which sap the springs of youth,
But bee-lines take, for life's best rules
To fountain-heads of truth.

—Manhattan, Kansas.

Those Six-Frame Hives.

G. M. DOOLITTLE.

I am asked by several to explain still farther about those six-frame hives I spoke of on page 69, as that article did not go far enough into the details so that all understood it.

In preparing the bees for winter where but 6 frames are used in the hive, these frames occupy but 9 inches of space, as $1\frac{1}{2}$ inches to each frame is the space I allow both in winter and summer. These 6 frames are either put close to one side of the hive next to the slotted division-board, and a movable division-board placed next to them, or they are left in the middle of the hive and a movable

division-board placed each side of them.

These movable division-boards are simply an inch board made to fit loosely the inside of the hive, except that they do not reach the bottom within $\frac{1}{2}$ of an inch or so. To the top of this board is nailed the top-bar of a frame, and then one of these boards, or "dummies" as some call them, will fit in the place of any frame in the hive. They are used solely for contracting the size of the hive.

After having the 6 frames fixed as above described, with these dummies, the cotton cloth is spread on the top (as I said on page 69), and down the sides over the slotted division-boards, just the same as would be done if the full 9 frames were used. Some hives have but 5 frames and a dummy, others 6, 7 or 8, as the case may be.

To make it plain, I should have said in my former article that this cotton cloth covering is in two pieces, each piece being long enough to cover the top of the brood-chamber and extend down one side over the slotted division-board; thus requiring two pieces 14 inches wide and 26 inches long, to each hive.

Thus it will be seen that there are two thicknesses of cloth over the bees, besides the chaff cushion. In the spring, when I wish to spread the brood, etc., all I have to do is to remove the cushion and lift up the strips of cotton cloth over the packing at the sides, when the frames are handy to manipulate. When I am through, the strips are spread back, and the cushion put on; and thus the bees are left snugly packed till they become so strong that they need combs put over in the 5-inch spaces at the sides, as I gave on page 69.

When the bees are wintered on 5 or 6 combs, they are so left till the combs are filled with brood and crowded with bees, when they are spread apart and an empty comb placed in the centre as needed, and so on till the "dummies" are all out, and the brood-chamber is filled with 9 frames of brood. This item of leaving the chaff packing all on during the changeable weather of spring is a great help in building up our bees in the spring.

I am next asked about those slotted division-boards. These are made of clear lumber $\frac{1}{4}$ inch thick, and are kept in place by a saw kerf $\frac{1}{4}$ inch wide and $\frac{1}{4}$ inch deep, being cut on the inside of the hive 5 inches from either end. This saw kerf is made before the hive is put together, which is easily done by passing the boards over a saw set a little wabbling, and by having the saw-table raised so that the saw cuts but $\frac{1}{4}$ inch deep. If you do not have access to a buzz-saw, it can be done by hand by sawing in two places, and then trimming it out with a $\frac{1}{4}$ -inch chisel.

When the hive is nailed together, these boards will slip down into the grooves cut for them. The slots should be placed in them so that one shall come at the top of the bottom tier of sections, just under the top-bar of the section, and the other at

the bottom of the top tier of sections, just above the bottom piece to the top sections. The board should also be narrow enough so there shall be a $\frac{1}{4}$ -inch passage way into the bottom of the bottom tier of sections, and the same at the top of the top tier of sections. In other words, make this board so that it shall take the place of two separators. I could give the exact size I use, but that would be of little use, as there are almost as many different sizes of sections as there are bee-keepers.

After you have once got these slotted boards right for the hive, you can slip one of them out to be used as a pattern. By adjusting the gauge on your saw-table so the wabbling saw will come just right, the slots are cut as fast as one can handle the boards. For a few as a trial, the slots can be cut with a carpenter's slitting-gauge.

If from any reason I wish to use this hive for extracted honey instead of comb honey, I remove these slotted boards, and then I have a 15-frame hive for this purpose, and in case of a large colony, it can be used as a two-story hive, which gives 30 frames, and which is generally ample room for any colony.

Again, I am asked the size of the sections which I use. I formerly used the section which is $6\frac{1}{4} \times 5\frac{1}{4} \times 2$, outside measure. Two of these were placed in a two-box case with a separator

Two-box Case.

nailed to one side, as shown in the illustration. These cases are now called "wide frames," I believe. I now use the same wide frames for sections; but instead of using the prize sections, I use three smaller sections in place of two, which gives a section $3\frac{1}{2} \times 6\frac{1}{4} \times 2$, outside measure, and weighing, when well filled, $1\frac{1}{2}$ pounds. In all of the Eastern markets these sections sell at the same figure as the one-pound sections.

By the above engraving it will be seen that the top-bars of these wide frames project as does the top-bar to our brood frames. In the 5-inch space is nailed a cleat to either side of the hive, in just the right position, so that the first wide frame put in hangs on these cleats, as a frame hangs on the rabbet to the hive. Two nails are driven into the top of all these wide frames, one at each end, so as to project $\frac{1}{4}$ inch, and the next wide frame rests on them, thus preventing the killing of any bees when the wide frames are set one on top of the other.

These nails are also so driven that the open side of the wide frame is always inclined toward the slotted division-board; and thus they allow of a frame of unsealed brood being put behind them, as I gave directions on page 69. When no brood is in this space, a board which I call a "follower," is placed next to the wide

frames of sections, which, by means of a wedge or key, is held firmly in place.

Thus it will be seen that 4 wide frames, or two tiers of sections with the follower and key, will just fill the 5-inch space at either end of the hive, behind the slotted division-board. I also now make a wide frame of the same dimensions as my brood frames, except that it is 2 inches wide. This frame holds 6 sections, $3\frac{1}{2} \times 5\frac{3}{8} \times 2$, outside measure, which sections weigh when well filled $1\frac{1}{2}$ pounds.

When sections are inverted in the brood-chamber proper, as they are where but 6 frames are used, I generally use this size, although the others can be so used, yet not so handily.

Now, if you still do not thoroughly understand how my hive and sections are arranged, send 5 cents to the office of the BEE JOURNAL for a description of my hive; which is so plain that any of you cannot fail to understand it, and make a hive just like mine, if you so desire. However, if you have many hives to your liking, I would advise you to adopt the plans of using sections which I have given, to one or two of your own hives, and then if you are pleased, work your whole apiary that way. If not pleased, the experiment will have cost you but little.

Having answered several questions, I now wish the privilege of asking one. I wish to ask Mr. Isham (see page 135) if his bees ever gnaw or eat his wood separators? and if so, how he prevents their doing it? After using wood separators on several hives the past season, I am prepared to endorse them, if I can keep the bees from eating them. They do not warp or twist to bother me, but nearly one-half of those used last season are spoiled for further use by having from $\frac{1}{8}$ to $\frac{3}{4}$ of an inch eaten off of them.

Bee-Keeping for Women.

MAHALA B. CHADDOCK.

Bee-keeping is too hard work for women. I say this as conscientiously as I would say that corsets are detrimental to health, or that tight shoes are injurious to the feet, and I say it with as little hope that it will do any good; for just as long as men admire small feet and slim waists, just so long will women go on lacing and cramping themselves; and as long as women in moderate circumstances are looking about for some way to earn a few dollars, there will be thousands of women bee-keepers.

If you must and will keep bees, I will help you all I can; and if any of you know of a better or easier way to do anything in the bee-yard, write it to me or to the BEE JOURNAL, and I will try it. I am daily in receipt of letters from beginners in bee-keeping, asking me how to kill moths, etc.

I quote from a letter I received today: "I have 3 colonies of bees, and

they are in boxes, we call them 'gums'; the bees are troubled with moths—a little worm. I suppose you know more about it than I can tell you. I am taking bee-papers, but they are all 'Greek' to me. I know what 'frames' are, and what they are for; but how are they 'wired' or 'tinned'? What does 'foundation' mean? Where is the honey-board, and what is it for? Are Italians better than the common bees? What is 'foundation' made of? etc."

Now here is a woman who stands just where I stood 14 years ago; and for just such ignorant people these letters of mine are written. People with hobbies, people of experience, and people who think they know how to care for bees are requested not to read them.

Vermont, Ill.

For the American Bee Journal.

Prevention of Bee-Diarrhœa.

A. A. FRADENBURG.

I have read with much interest the articles on bee-diarrhœa. I believe all heretofore written is theory only. We have had theory hot, and theory cold; theory dry and theory wet. We have had ventilation upward, and ventilation downward; ventilation crosswise, and ventilation from corner to corner. Indigestion, dyspepsia, inflammation of the bowels, etc., have been advanced as the prime causes of diarrhœa; but all have been theories and no proofs. Now I will give the proofs first and theory afterwards. My proofs are sustained by 59 living witnesses.

Last fall I prepared 25 colonies for wintering in chaff hives, and 20 in two-story single-walled hives with bees in the lower stories and chaff cushions in the upper stories, and all on the summer stands. These 45 colonies graded all the way from very light to very good, both as to stores and quantity of bees. A few colonies I had marked "too light for winter;" but having too many irons in the fire, I did not get around to help them until winter had set in. All of these 45 had such stores as they had gathered—honey and pollen.

I took a long hive that holds a Langstroth frame crosswise, and in it I put 7 nuclei colonies by giving each 3 Langstroth frames, and dividing them with a half-inch division-board. The centre comb was empty, and the two outside ones well filled with clear honey. Special care was taken that no comb should contain any "pollen." This hive had a lid 5 inches deep, which space was filled with chaff cushions. The cushions were made of "white cotton cloth;" then I put a rough box without a bottom, but with a hinged lid, over this hive with about 4 inch space all around the part filled with chaff on the sides only. I gave the nuclei a passage out through the chaff space. Then I prepared 7 more nuclei precisely like the first 7, only their combs were about 11 inches square, and they were almost totally

dry. They had no "pollen," and scarcely any honey, not to exceed 2 pounds in the whole 7, I think. One or two had 4 frames, the rest 3 each. I wish I could tell the weight and strength of each nucleus, but I cannot. They were all quite light, and I do not think the heaviest one would weigh 2 pounds. Some, I do not believe, would weigh 1 pound. I know that several of them would all hold to a Langstroth-frame comb and not be any double thickness.

I put the strongest ones at the end divisions of the hives. When I had these thus fixed it was already only a few days before real winter set in, and it was a cold winter too. I was often asked how my bees were standing it; and my reply was that I expected to find a large number dead. One day, when it did not seem quite so cold, I raised the lid off the rough box, then of the hive, and then one corner of the cushion—buzz z-z—down went the cushion, and down went the lids.

Towards the last of January we began to have some milder weather, but not warm enough to let the bees out. By Jan. 25 the situation began to be critical with the bees in all the regular hives; diarrhœa began to show badly in some, so that the bees were leaving the clusters and dying rapidly. I was becoming anxious for a warm spell, as I had in previous years lost over a hundred colonies by the dreaded disease; so I ought to know what it is.

But the long-wished-for day came just in time. Jan. 31 was bright, clear and warm, and the bees flew *en masse*. About 2 p. m. all of the 45 colonies had flown freely, and had nearly stopped, but the 14 nuclei, in the long boxes, scarcely showed any signs of life. Only one or two were flying any, so I raised the lids, took off the "white cushions" and turned up a corner of each cloth cover and left them so. In half an hour I looked out, and the first impression I got was that they were robbing; but upon getting nearer, I saw it was only a joyful play spell. An hour later and all was quiet.

I then went the rounds of the 45 colonies, every one had the spots of diarrhœa—diarrhœa pure and simple; it had the genuine color; aye, and the genuine smell. Some had it quite light, others very badly. Then I went to the 14 nuclei, got down close to them and looked carefully. I found two spots on one lot, and one only on the other. Then I could have waved my hat and shouted, "Eureka! Eureka! I have found it."

The true cause of diarrhœa: 45 colonies had pollen and the 45 had diarrhœa; 14 had no pollen and 14 had no diarrhœa. I fully believe that the 3 spots found on the nuclei were dropped by bees from other colonies, as they were flying over. The 14 were dry, bright and healthy; they are all alive to-day, and are building up as fast as could be expected.

But you ask: "how did those live which had no stores?" Why, I simply put lumps of pure candied extracted-honey right on the frames, over the cluster, about once in two weeks, that

was all. Of my 59 colonies some are weak, but none are dead.

Port Washington, O., May 12, 1884.

For the American Bee Journal.

Western Fair, London, Ont.

WM. H. WESTON.

The Western Fair, which is to be held in this city on Sept. 22 to 27 inclusive, has adopted the following price list. I might just remark in reference thereto, that this is the first year the Fair directors have formed a separate class for bees, honey, and apiarian supplies; and it being their first attempt, they have done handsomely, hoping thereby to draw a large number of exhibitors from both Canada and the United States; and at the same time to educate the public in this very important industry.

For the benefit of exhibitors from the United States, the directors are to make arrangements with the Custom authorities for the free passage of all goods for exhibition. The Western Fair is the most important one held in Canada, and always draws a large concourse of spectators. The following is the price list:

| | | | |
|--|---------|---------------|----------------|
| Queens and colonies cannot compete for more than one premium. | | | |
| | | <i>First.</i> | <i>Second.</i> |
| Display of Comb Honey in the most marketable shape, product of one apiary in 1884..... | \$10.00 | \$5.00 | |
| Display of Extracted Honey in the most marketable shape, product of one apiary in 1884..... | 10.00 | 5.00 | |
| Display of comb honey in the most marketable shape, by a lady, product of her own apiary in 1884..... | 10.00 | 5.00 | |
| Display of Extracted Honey in the most marketable shape, by a lady, product of her own apiary..... | 10.00 | 5.00 | |
| The first prize in the above section is offered by James Watson, Esq. | | | |
| Comb Honey, not less than 20 lbs., quality to govern..... | \$4.00 | \$2.00 | |
| Extracted honey, not less than 20 lbs., quality to govern..... | 4.00 | 2.00 | |
| Best Granulated Honey..... | 2.00 | 1.00 | |
| Crate of Comb Honey, not less than 20 lbs., in best shape for shipping and retailing..... | 4.00 | 2.00 | |
| Colony of Bees, not less than 10 must be the progeny of one queen, and exhibited in such shape as to be readily seen on two sides. Purity of race, docility, size of bees and numerical strength to be considered..... | 5.00 | 3.00 | |
| Display of Queens, to be put up in such shape as to be readily seen by visitors (blacks not to compete)..... | 3.00 | 2.00 | |
| Best marked Queen Bee, bred in Canada..... | 3.00 | 2.00 | |
| Greatest variety of Queens put up in same shape as for display of queens..... | | Diploma | |
| Best Bee Hive for all purposes in the apiary..... | 3.00 | *2.00 | |
| Best Bee Hive for Extracted Honey..... | | Diploma | |
| Best Bee Hive for Comb Honey..... | | Diploma | |
| Honey Extractor..... | 2.00 | 1.00 | |
| Wax Extractor..... | 2.00 | 1.00 | |

Road before the Southern Cal. Convention.

The Honey-Interest in California.

J. E. PLEASANTS.

You are all aware of the wonderful progress made in apiculture in the last quarter of a century. Of all the modern improvements I will only mention three of the greatest: The movable comb hive, the extractor, and the artificial comb; but these three have revolutionized bee-keeping, for with their use the quantity of honey is greatly increased. But, notwithstanding the great increase, the demand for honey to-day is greater than the supply, and so it will continue; for the more easily an article is produced, the cheaper it can be sold, and the cheaper it is sold the nearer it is brought within the reach of all.

As a nation, we should rejoice that America leads the van in all that relates to apiculture; and as the demand for honey increases, America is called upon to supply that demand. I am sure that California will, in the future as she has in the past, come to the front with her tons upon tons of unsurpassed and insurpassable honey. All of us will concede that the last 3 or 4 years have been unpropitious for the bee-business in this State; but with all the unfavorableness of the seasons, California has produced enough for home consumption and some to spare for our cousins over the seas, whose palates we love to tickle with our sweet product. The fear of glutting the market of the world with good honey is as absurd as to think of glutting it with wheat. Honey put up in a neat and marketable package will always bring remunerative prices. The honey interest is an industry which deserves encouragement from all. In a good year it brings into this district alone over half a million of as virgin dollars as those which the sturdy miner delves from the earth while the industrious bees extract it out of the blossoms which would otherwise go to waste on the desert air. Read over the list of premiums offered by the managers of the Fair of the Sixth Agricultural District, and see what you find there to encourage this great pursuit. Not one dollar.

This great industry has its enemies among the fruit growers. While admitting that bees are injurious to the raisin industry, I will defend them in most of the charges brought against them by their enemies, who oftentimes do not know the difference between a bee and a yellow-jacket. The damage done to fruit is always commenced by other insects or birds, but it is invariably laid at the door of the bee. Sometimes the fruit grower knows so little of the physiology of the bee that he accuses him of gnawing through an inch board to get to his fruit. So the cry is, "The bee must go." If not, they will be trapped and destroyed. Such work is both cruel and unlawful. I am opposed to keeping bees in the valleys between May and November, where there are orchards and vineyards. Generally the bees which are in the valleys are not owned by professional bee-keepers, but by men

who just keep a few for their own use. It is to the interest of professional bee-keepers to confine bees to the mountains exclusively, as the honey produced in the valleys is of inferior quality, and therefore injurious to the reputation of California honey. I am confident that the majority of the true bee-keepers will coincide with me.

As we all know, there are always two sides to a question; for, once upon a time a keeper of bees in the mountains, who for years had been quietly pursuing the even tenor of his way, had his tranquility interrupted by a tiller of the soil, who moved into the vicinity and planted his vines and melons. In the course of time the pioneer's bees fed upon the sour grapes and melons of his neighbor, and as it was not their natural food, they became diseased and perished. Whereupon their owner became enraged and called an anti-fruit-growers' meeting, the decision of which was that the husbandman must go.

Query: Will he go?

Somerset Co., Maine Convention.

The Somerset Bee-Keepers' Association held a convention at Athens, Me., on May 7, 1884, which was characterized with much interest to the bee-keeping fraternity in this and western Piscataquis county. There were about 25 members present.

The forenoon was occupied in discussing the methods of wintering bees, and relating the experiences of members of their successes the past winter. This subject was introduced by Isaac Hutchins, of Wellington, who read a paper on "Conclusions drawn from wintering bees on the summer stands the past winter." There was some diversity of ideas pertaining to wintering, by the members, but two methods were most fully endorsed: 1. In warm, dry cellars; 2. On the summer stands with some outside protection, as of chaff or sawdust, with holes made through the combs for bees to pass through from frame to frame. It was claimed that holes were preferable to sticks laid on top of frames, as bees would not pass over the frames if the temperature within was at all low.

In the afternoon an election of officers resulted in re-electing Wm. McLaughlin President; Wm. Lawrence, Secretary; Isaac Hutchins, Treasurer; W. H. Norton, S. J. Ward, G. H. Allen, H. J. Fogg and S. H. Whitehouse, Vice-Presidents, from as many different towns. Then followed an inquiry meeting on the management of bees from this time until our next meeting in August. Mr. Norton would prevent swarming and work for surplus honey until after the honey season, then divide the colonies and build them up for winter. If bees become too numerous, he would give them more room. He would induce bees to work in sections, by taking out a frame of sealed honey, uncap it, and then hang it in the centre of the frames when the bees are rearing brood, and the bees will remove

all that honey up into the sections in an incredibly short time, and thus continue to work there.

Dr. Brown would not use a smoker at all, but with some anise essence, syrup and chloroform sprinkled over them and at the entrances, he can do anything with them. He also gave a method of preventing moths by killing the millers before entering the hive.

Mrs. Wm. Lawrence would induce bees to work in the sections by cutting out a small piece of comb with drone brood, and fasten it in a section, and it is remarkable how quickly the bees will go up and work with a "vim" in the sections. She also would not use comb foundation in surplus sections at all, but use small pieces of empty comb, because bees will take to it better; and also where comb foundation is used there is always a tough, hard partition in the honey which is not palatable, and is not so nice as that made by the bees.

Mr. Hutchins gave many good suggestions. He is a live, progressive and veteran bee-keeper. His apiary consists of nearly 50 colonies in bee-houses packed with sawdust, both winter and summer, all finished and painted on the outside, placed in due form, which looks like a miniature village.

Others gave many suggestive facts and incidents in bee-management. At the close it was voted to hold the next meeting at W. H. Norton's, by his invitation, at North Madison, Me., on August 20, 1884. He proffers free entertainment to all. The time now is very favorable for examining bees, and for laying plans for the fall and winter's campaign. Let there be a grand rally.

For the American Bee Journal.

Queen Fecundated in a Cell.

GUYTON BROS.

On page 296 of *Gleanings*, we saw Mr. B. F. Lee's accounts of fecundating a queen in confinement. We thought of trying the plan. As an embryo queen in the larval state absorbs food at her posterior, we thought it might be possible that she could be fecundated while in that state; and, if so, the feasibility of so doing would be of paramount importance to all bee-keepers; and we tried it.

The *Modus Operandi*: We had four cells nearly ready for capping; one of them we inverted and squeezed into it the contents of a drone larva 5 or 6 days old. We did not do as Mr. Root advises: "scooping" out the drone food and giving it to the queen larva; for that was taken away with the larva. Into the other 3 cells we cut lids which opened downward, and likewise put the drone larva contents into each, then closed the lid and sealed it as well as we could. We did not do as Mr. Lee did—inoculating the queen larva with drone, but put the drone larva into the royal jelly just as close to the posterior of the

queen larva as possible, that it might be absorbed before spoiling.

The royal jelly run through upon the larva in one of the 3 cells thus prepared, and was taken away with the larva. The other 2 cells were capped nicely. As we did not know the exact age of the larva operated upon, they hatched out one day sooner than we expected and one was lost. The other one had two combs about as well filled with eggs as could be expected for one day.

Like Mr. Lee, it does seem doubtful to us; but she is there, and laying as busily as if she had met a hundred drones. We have some under the same process now, which will hatch out this week, and we intend watching them very closely. We think of clipping one or two of them as they emerge from the cell.

Waco, Tex.

For the American Bee Journal.

Bee-Moth.

A. C. CORSEY.

This formidable enemy of bees is not as well understood by many apiarists as it should be. The name is derived from the Latin *galaria cereana*—gallery wax so-called because the larva construct galleries in the comb.

Bee-Moth.

It is often seen about the hives during the day, but more frequently at night; and is often seen flitting about the candle or lamp. It is of a light grayish color, and is generally known by the name of miller.

It enters the hive at the same entrance as the bees, and deposits its eggs in some crack or crevice in the hive where the bees are unable to reach it. When the colony is weak, it will deposit its eggs in the combs, and the colony soon becomes a prey to its ravages. A strong colony will keep the combs free from these depredators.

The egg of the bee-moth, when hatched, produces a little worm which encloses itself in a case resembling white silk, which it spins around its body. It gradually increases in size, and feeds on the cells around it. As it increases, it enlarges its gallery by cutting the cell away before it. The gallery, as well as the insect, is impervious to the sting of the bee, but if one drops from its gallery, it is seized by the nape of the neck and forcibly ejected from the hive by the bees.

In the course of three weeks the larva or worm stops eating, and encloses itself in its silken case. It, however, soon deserts its case, and plumes its wings for flight. Many devices have been invented called

moth-traps, to prevent its entering the hive, but all have proved failures. There is but one effectual moth-trap, and that is a strong colony of bees. Moths never disturb a strong colony where the hive is properly made, so that the bees can pass all around their work.

Cucamonga, Cal.

For the American Bee Journal.

More About the Eastern Bees.

L. A. LOWMASTER.

On page 132 is an article from G. M. Doolittle, condemning the Syrian bees, classing them with those from Palestine, and calling them all "Holy Land bees." Syria is not the Holy Land, and never was; and I would like to know how the Syrian bees can be called Holy Land bees when they never came from the Holy Land.

The Syrian bees are the original and only pure race of bees in the world, and all races originated from them; if not, where did the other races of bees come from?

Before I notice a few of Mr. D.'s remarks, I will say that I have handled Syrian (not Holy Land) bees longer and more of them than Mr. D. has, and I know what I am talking about. I also have the dark and light-colored Italians and Cyprians, and I had one of the Palestine (Holy Land) queens, but I did not keep her long, for that race of bees is too cross, and not very good workers. I suppose that was the kind of bees that Mr. D. had instead of the Syrians.

Concerning the prolificness of the Syrians (Holy Lands as he calls them), Mr. D. says: "So I say, that when he (Frank Benton) says that he wants the hive overflowing with bees in the fall, there must be a mistake somewhere." That is just where Mr. D. is mistaken. I want lots of bees in the fall, then there is no danger of any loss in wintering. It is a well known fact that a strong colony of bees will winter far better than a small, good-for-nothing colony, and where is there an intelligent apiarist that will try to winter a small colony of bees?

Mr. D. says: "As soon as the honey harvest arrives the queen (Italians I suppose) ceases her prolificness, and thus we do not have a lot of 'hungry hands' to board when they are of no use to the apiarist." I am surprised to hear such remarks by one who claims to know all about bees. It is a well known fact that a queen will not "cease her prolificness as soon as the honey harvest arrives; but on the contrary, as soon as the bees are getting honey and pollen, she lays more rapidly; and when there is scarcely any honey to be gathered, she will lay more sparingly. From the strongest colony we always get the most honey; and to obtain this, we must have the hive overflowing with bees, and to secure them we must have a prolific queen. Please give the Syrians credit for their prolificness.

Mr. D. claims that the Syrians will keep on laying as long as there is any honey in the hive. Let us see what

race of bees lays the latest. Last fall, after the frosts, I put in a drone comb in the centre of one of my Syrian colonies, and fed them to get the queen to lay in the comb, but she would not. I also fed another Syrian colony to stimulate the queen to lay, so I could get a few eggs to rear some queens, but it was all in vain. I had one colony of Cyprians which had not killed their drones at this time, so I went to the hive that my Doolittle queen was in, and I found lots of brood and eggs. I then concluded to rear a few Italian queens and have them fertilized by Syrian drones. This is no opinion or idle talk, but facts.

Some say the Holy Land bees do not ripen their honey. If he means the Syrians, I emphatically deny all such absurd statements. They do ripen their honey well; and if any one denies it, I will send him some honey to prove it.

A strong prejudice exists against the Syrian bees by Italian queen-breeders; but in spite of all the opposition, they are fast moving toward the front. To prove it, I quote from *Gleanings*, page 241, May number of 1883. Mr. Good says: "Again the Holy Land bees have proven themselves to be the most hardy, as the Italians are all dead except a few weak colonies. I had about 80 colonies of Italians last fall. I have a brother who has a Holy Land apiary of 30 colonies only 40 rods from my own. He wintered his bees on the summer stands, and lost but one colony. The rest are nearly all in good condition, and very strong also." And farther on Mr. Good says: "In a letter from Mr. H. Alley, March 30, 1883, he says: "Have not the Holy Land (meaning the Syrian) bees wintered best with you? They have with me. The Italians are the poorest race we have to winter, and I am breeding Cyprians and Holy Land bees largely." At another place he says: "I tell you the new races will sweep the board sooner or later."

Dr. J. P. H. Brown, of Georgia, at the National Convention of 1881, reported that the tongues of the Cyprian bees, in a trial of six, aggregated 1-32 of an inch longer than his improved Italians, and they in turn aggregated 3-32 of an inch (1-10) longer than the imported Italians. Equally pronounced is the result of Prof. Cook's numerous microscopical measurements of the tongues of the Syrian bees, which he finds to equal those of the Cyprians, and .006 of an inch longer than those of the Italians. If the Syrians are capable of as great improvement as has taken place in the Italians up to this time, we may count upon a tongue more than $\frac{1}{3}$ of an inch in length, which will be sufficient to reach the nectar in the first bloom of red clover.

Last summer my Syrian bees worked the first bloom of red clover. If there is any one particular race of bees that may be claimed as the perfect one, it is the Syrians; but as no one race possesses all the good qualities of the "ideal bee," it is safe to say that the Syrians come nearer to that point than any other. They have less bad

qualities than any other race of bees, and they have more valuable qualities not possessed by any other. As they have powers of locomotion not possessed by any other race of bees I have ever seen, they seem to be able to carry immense loads, and fly wonderfully swift when so loaded.

I most emphatically affirm that in the Syrians we find larger numbers of the necessary qualities for the foundation of the "coming bees" than in any other race or strain in existence.

At the Eastern Iowa and Western Illinois Bee-Keepers' Association, Mr. T. G. Newman, in speaking of the bees of the future, or "ideal bee," said: "The queen must be prolific to be able to keep the hive full of bees in order to gather the honey harvest when it comes. The bees must be industrious to let nothing escape their vigorous search while gathering the sweet nectar. They must be docile to allow the apiarist to manipulate them with ease and pleasure; they must be strong and hardy to withstand the rapid changes in climate; and they must be of singular beauty to attract the admiration of the fancier of fine stock."

In the above we have the whole story of the Syrian bees "in a nutshell." In conclusion I will say that I have been speaking plainly upon this matter, because I have the best interest of apiculture at heart, and consider that when stricter attention is paid to rearing better queens, we shall have made a step in the right direction; and if there is any better bee in existence than the Syrian I would like to know it.

Belle Vernon, O.

For the American Bee Journal.

My Report on Wintering.

W. HARMER.

I have wintered my bees without loss; but I could not help it as they would live, contrary to some of the rules laid down by a few writers on safe wintering. I commenced last season with 6 colonies; sold one, and increased the remaining 5 colonies to 21. I sold 2 colonies in the fall, thus leaving 19 to winter. My receipts for bees and honey, last season, were \$97. I obtained from 20 to 25 cents per pound for honey here. I fed them about 50 pounds of granulated sugar syrup.

Allow me to say a word or two concerning their condition before going into winter quarters. 1. They had stopped breeding for weeks before being put away. 2. Some of them had to be fed at "the eleventh hour," when it was impossible for them to seal their honey. 3. After increasing over 300 per cent. in this northern latitude, you may imagine that they were none too populous. 4. (Last rule broken). I did not crowd the bees together with division-boards.

Now for the rules which I tried to follow: 1. On account of the great increase, there was very little pollen left in the hives. I think that was one reason why they stopped breeding

so early in the fall. 2. I cut a passage way through the combs. 3. They were kept at a temperature of from 40° to 50° above zero, except the last 2 or 3 days of their confinement, when it went up to 52°. 4. There was thorough ventilation in and out of the trench. 5. They were in a dry place. 6. They were in a quiet place—a trench in dry, sandy ground (under the house) covered with boards, and 2 or 3 inches of sand upon the boards.

I had a hole cut through a board at the end of the trench, so that I could see the thermometer. I had no other way of regulating the temperature but by ventilation. The hives could not be seen, and there was not a hand placed upon them for 164 days—the exact time of their confinement under ground, besides 10 days or 2 weeks in which they could not possibly fly, before they were put away for the winter; making in all 174 days of confinement.

I took them out on April 25, and found every colony alive. Not one bee (let alone a colony) was affected with diarrhoea. They were gathering pollen the next day, and about half of the queens had commenced laying; but there was not a piece 6 inches square of sealed brood and larvæ in all the hives put together.

Some of the bottom-boards were so dry, and so few dead bees upon them, that you would think they had only been shut up for a day or two in the busy time. The entrances were left wide open, and they went outside to die. I found very few moldy combs, although there were a great many unoccupied.

My experience in 1883 led me to winter in this way; for I had one colony buried for 165 days, and it came out clean, dry, and good-natured on May 1; while 10 colonies which I had packed outside on the summer stands, all died but one. Although the 10 had the advantages of outside cases packed with planer shavings; and also the chance of a cleansing flight. But they ran the chance of being smothered or frozen. Some starved (with honey by their side) while breeding on a lineday. They were attacked by diarrhoea, and then wanted a cleansing flight when it was too cold. So you can easily see how I lost them.

I think I have learned one important fact, and that is, that bees will live eight months when kept in a proper temperature and not allowed to breed out of season; or, perhaps I should say, in confinement. I believe some of mine are that old now, and I have no young bees hatched out yet. Every colony has a good laying queen, and promises to come through the spring all right.

My experience in wintering bees the last 3 or 4 years has led me to believe that Mr. Itteddon's "pollen theory" will come out ahead. Breeding in confinement, I believe, to be the cause of diarrhoea. I think it is generally understood that bees have to digest a great deal more pollen when breeding than when they are compelled to take only enough to sustain their own bodies.

My 19 colonies weighed 136 pounds less on May 25 than they did when put in for the winter. I found the difference in weight of each colony to vary from 3 to 10 pounds in 164 days. For spring dwindling, I am keeping the cold winds shut out of the hives, and the bees shut in, unless the thermometer shows that it is warm in the shade. I am buying 10 colonies more, and I think my time will be fully occupied between them and a garden of small fruits.

Manistee, Mich., May 3, 1884.

For the American Bee Journal.

Extermination of Foul Brood.

A. M. GANDER.

In consideration of the existence and spread of foul brood in Lenawee county, I would request every bee-keeper to examine his bees, or have them examined by an experienced bee-keeper, to make sure that the disease does not exist; or if it does, to take prompt action against its spreading over the country. All hives which contained diseased colonies should not be left where other bees can have access to them (by carrying away what honey there is left in them, and the germs of the disease with it), but they should be boiled thoroughly, or burning them would be better.

Bee-keepers cannot be too careful about the spreading of this disease. It may exist among their bees, and they not know it until their apiaries are nearly ruined. Every bee-keeper who cares to keep his bees, should give them a thorough examination and know certainly whether they are diseased or not. Some bee-keepers are too careless to pay the least attention to their bees, and do not know that there is anything the matter with them until their bees are dead.

There are but few of this class of bee-keepers who know what caused the death of their bees; and what is worse than all, they allow the hives to remain for other bees to carry away the foul-broody honey, and spread the disease in every direction. Such men as these will have to be looked after by others who are more interested; and where they will not give the matter the necessary attention, after being properly informed, they will have to be dealt with according to the law of the State. But how much better it would be if all would look to their own interests and eradicate the disease wherever it exists.

We have a foul brood commissioner in this county (Mr. D. G. Ediniston of Adrian), whose duty it is to examine bees whenever called upon by a written request according to law. It is the wish of every careful apiarist that this matter be attended to at once. Better have them attended to now than to lose your bees by this disease, which is sure to happen if left to pursue its own course. There is plenty of the disease throughout this county; and the above caution will apply to any county.

Adrian, Mich.

For the American Bee Journal.

Facts About Bees.

J. M. HICKS.

When a colony discovers that its queen is becoming or approaching barrenness, the bees will at once commence preparing queen-cells and rear another queen to take her place.

It usually requires about 30 days to rear a young queen from the egg, and have her brood sealed over for hatching; after which it requires 13 days for the young bees to emerge from the cells after they are sealed over, and 21 days from the time the egg is deposited, until it comes forth a mature bee.

A thousand young queens can be reared in one season from the eggs produced by a single queen, if properly managed for the purpose. It is a well-known fact that any and all eggs which produce worker-bees, are females, and are susceptible of being converted into a queen if rightly managed at the proper time.

All eggs laid by a virgin queen will produce drones only—they not being a perfect male; but drones which are reared from a fertile queen can be relied upon as being perfect male bees.

For the American Bee Journal.

Parodies, Fixed-Frames, etc.

A. WEBSTER.

The Weekly BEE JOURNAL for the year 1884 is so satisfactory that I wish to offer my congratulations for its excellent and interesting contents. I was especially interested in the article on page 9, entitled "Essentials of the Coming Steam Engine," and congratulate its author on the happy manner in which it was written. I also wish to thank him heartily for the high compliment he has paid to the literary excellence of my feeble effort to set forth the "Essentials of the Coming Bee-Hive," by making it a model for his discourse on his pet hobby. Such appreciation from such a source is exhilaratingly grateful to an humble bee-keeper who is more accustomed to constructing bee-hives than rhetorical sentences for publication, and goes far to efface from his mind the memory of the haunting thought of the waste basket, while the article awaited publication. "He builded better than he knew," is seldom said of any man's work in his life time; and the prompt and unequivocal approval of my literary work, that your esteemed correspondent has shown by parodying it, is dearer to my heart than hopes of posthumous fame.

I cannot forego the opportunity to add a few notes of experience with the new hives. I have had an unlooked-for demonstration of the advantages of fixed comb-frames. The high winds that prevailed so much last fall, lifted six standard Langstroth hives from their stands, in one of our apiaries, and laid them not very

carefully on their sides; some of the caps being blown to the distance of several rods. The poor bees were found in a sad plight; the combs being piled closely together; many bees were killed, and more wounded; and some of the queens lost. At the same time, in our home apiary, a large branch was torn from an apple tree, falling on two of the new hives. In removing it, one of the hives was accidentally over-turned and rolled over, coming to rest bottom upwards. The result was that not a frame was displaced or comb cracked, and the bees were but slightly disturbed.

The safety of these fixed, standing, movable-comb frames in case of accident, and in transporting hives, is only an incidental advantage—the purpose for which they were invented is far different and incomparably more important.

South Northfield, Vt.

For the American Bee Journal.

Let us deal with Facts.

A. W. OSBURN.

On page 328 is an article from the pen of D. K. Boutelle, on "The Production of Drones," which contains much food for thought. Mr. Boutelle's experience is precisely like my own.

Without wishing to contradict the statements of many of our old teachers; *i. e.*, that the queen controls the sex of the bee while laying the eggs; yet it is a fact that the nurse-bees can and do produce workers, drones and queens from the same eggs. That is, take a sheet of eggs from a prosperous colony and give it to a queenless colony to rear cells, and at the end of 10 or 12 days what do you find? In many cases you find queen-cells, worker brood capped over in the regular order, drone cells lengthened out, and perfect drones in them; only they are smaller because having been reared in worker cells.

The bees do not often do this, but they cut off the cells to the septum and build full sized drone-cells; place eggs or larvæ in them, and mature as finely-developed drones as were ever reared under other conditions. Now these are facts; and in the face of such facts, what are we to do with the old theories.

I leave the subject for abler pens than mine—for the earnest consideration of those who have a fancy for delving into the unforeseen and deep mysteries of this wonderful insect—the bee.

San Miguel, Cuba, W. I.

☞ We now club the *British Bee Journal* and our Monthly for \$2.50, or it and the Weekly for \$3.50.

☞ Letters for publication must be written on a separate piece of paper from items of business.

☞ We can supply photographs of Rev. L. L. Langstroth, the Baron of Berlepsch, or Dzierzon, at 25 cts. each.

SELECTIONS FROM OUR LETTER BOX

Considerateness of Bees.

We have had a cold, wet spring, but everything looks very well now. White clover is in full bloom, and the bees are utilizing it. I have had no swarms as yet, but some of my neighbors have had several. The more I study about bees and notice their habits, the more interesting they become to me. I caught two crippled ones on the ground and put them both upon a piece of wood, when one fed the other. One of them was an Italian and the other a hybrid. I was not aware that bees are so considerate of each other.

J. C. TANNER.

Huntington, W. Va., June 2, 1884.

Spreading the Brood Frames.

In the description of Mr. Doolittle's hive, on page 69, about the middle of the first column, he says: "The bees are stimulated by spreading the brood, and by other ways familiar to the apiarist, till the 9 frames are filled with brood." I would ask: 1. How does he get at the brood-chamber with the cotton cloth and packing in the shape as described in his article? In the second column he says that he put in "one tier of sections." I infer that they are put in sidewise to the division-board. 2. How many slots are in the division-board, to each section, and what size are they? 3. What sized sections does he use in those 5-inch spaces?

E. C. FARQUHAR.

Carlos City, Ind.

[Mr. Doolittle's answer to these questions will be found in his article on page 373.—ED.]

Jack Frost's Work.

From the Atlantic to the Pacific, reports have come of a cold, backward spring; and here, midway between these oceans, it is as discouraging. For three nights in succession we have had frost. Yesterday morning at 5 a. m. the thermometer indicated 6° below freezing. Corn, potatoes, hop-vines, etc., are very much injured.

JOHN MORRIS.

Mauston, Wis., May 30, 1884.

Snow on "Decoration Day."

On the morning of "Decoration Day," the hills between lakes Keuka and Canandaigwa, in western New York, were white with snow; and on the level of the lakes ice formed $\frac{1}{4}$ of an inch in thickness. The hills, with their newly-leaved trees covered with snow, were in strange contrast with the fruit trees in the valleys one week before, when they, too, were robed in whiteness; but they then were a more pleasing sight to the bee-keeper. Bees did well during fruit bloom, but our "freeze" was another of many hard baskets which bees have had here this spring; and now we shall have to

nurse them for a while, or until raspberry and clover bloom.

A. F. ROBSON.

Italy Hollow, N. Y., June 2, 1884.

Indications for Honey Harvest.

So far as I can ascertain, bees have wintered fairly well in this part of the State. My bees came through the winter without loss, on the summer stands. They gathered their first pollen on April 4, built up rapidly and stored considerable surplus honey from fruit bloom. I have delayed their swarming by removing queen-cells and forming nuclei. They are now in fine condition for the white clover, which is just beginning to bloom. Everything indicates a large honey harvest.

E. L. DRESSER.

Huron, Ohio, June 3, 1884.

Bees have received a Backset.

Bees in this vicinity have just received a backset, from which they will not recover soon. They were in fine condition, and were preparing for a general swarming. On May 26 a large swarm issued, and is now living at my expense, as a cold wave has been passing this way ever since. On the mornings of May 28 and 29 heavy frosts covered everything, and in some places ice formed $\frac{1}{2}$ inch thick. Drones are being slaughtered, and swarming is postponed for awhile at least.

IRA BARBER.

De Kalb Junction, N. Y., May 31, 1884.

Stimulating Bees in the Spring.

On page 69 of the BEE JOURNAL, Mr. G. M. Doolittle gives an explanation of his manipulations of hives in producing comb, which I consider the most rational handling of bees for the purpose I have yet heard. But when I study it for the purpose of imitation, I find considerable unexplained that I consider of importance. I would ask how he starts out with 9 brood frames when he puts his bees into winter quarters with but 6? True, in the spring, he says that he stimulates his bees "by spreading the brood, and by other ways familiar to the apiarist, till the 9 frames are filled with brood;" yet I find that his bees, in the winter, are covered with "a strip of common cloth spread over the frames, and down each side over the slotted division-boards. The 5-inch spaces are now filled with chaff, and a chaff or sawdust cushion placed over the frames." I now infer that the 6 frames occupy a space of 12x12x13 $\frac{1}{2}$ inches. Am I correct? or are there 9 frames now in that space? If but 6 frames are now in the hive, how does he get the other 3 into the brood-nest without removing the cloth or chaff until he is ready to remove 3 combs from the brood-nest, and put them behind the slotted division-board? Another thought: What width of sections does he use that it requires 5 inches of space to accommodate them? Also, how large are the sections he uses? Again I would ask: How is his division-board slotted, and the slots arranged "so as to

form openings at the right place for the bees to work to the best advantage, etc." Is the division-board fixed or movable? I consider just such matters of detail as of the most vital importance; and the want of such knowledge may upset the whole principle involved.

ABEL GRESH.

Weedville, Pa.

[A reply to the above queries will be found in Mr. Doolittle's article on page 373 of this number.—ED.]

Moving Bees on Horseback.

Last winter, wishing to remove 60 colonies of bees from my old apiary to a new one, and there being no wagon-road between them, I concluded to move them on horseback. The distance was over 12 miles. I took four pieces of board 2 feet long and 1 foot wide, nailed to them cleats 2 inches wide and 1 foot long across each end, and bored 1-inch holes through each cleat, and board at the end. I then put the edges of 2 boards together, and put strong rope through the holes, which made a kind of shelf. The lower one being level, I placed 2 of these on each horse, and a colony on each side of a horse, and one on top. They were in box-hives with the top-bars in each. I had good success in removing them, for only one comb broke down. The most of the bee-keepers in the East have boats, railroads, or a good spring wagon on which to transport their bees; but bee-keepers in California can move them on horseback.

Monterey, Cal. JOHN L. SECOR.

Bees Booming—Frost.

My bees are preparing to swarm. We had a severe frost on May 29 (22° above zero). The leaves of some forest trees were killed, and the fruit which was so promising is destroyed.

G. H. ADAMS.

North Nassau, N. Y., May 30, 1884.

Sweet Clover Honey.

I wintered 54 colonies on the summer stands without loss. Thirty-five of which were packed, and were much the strongest in bees and honey. For the first time for years we had fine weather during fruit bloom, and a fair amount of honey was stored. Bees have bred up stronger than usual. White clover has been a failure for the past two years; but we have a fair substitute in sweet clover, which is springing up along our river banks. This village is located near the confluence of the Susquehanna and Chening rivers, whose gravelly banks are white with blossoms, and each succeeding season increases the crop. An old forsaken cemetery near by has been seeded, and will soon yield something more fragrant than its usual crop of burdock. The largest part of my honey crop is now from sweet clover, which, if not so white as that gathered from white clover, is very rich and pleasant in taste.

D. F. PARK.

Athens, Pa., June 4, 1884.

An Editor's Experience with Bees.

I am amusing myself with 7 colonies of pure Italian bees, and find it a more interesting pastime than writing double-leaded political editorials. I am not an expert, but know how to get stung as well as any one. My father was a bee-keeper, and that gives me an advantage; but the bees do not seem to take this fact into account—do not respect my pedigree. "Honey dew" on maple trees has been abundant for a week—the product of turtle-shaped insects which adhere to the bark of the tree as thickly as three in a bed. White clover is coming on apace, and the prospect for an abundant yield of "sting-bug juice" never was better.

D. B. GIVLER.

Naperville, Ill., June 4, 1884.

Bee-Notes from Utah.

The Utah Convention, reported on page 324, was held in Salt Lake City instead of Tooele City. During April the weather was very bad for bees, and there were quite a number of losses during the month; but early in May I found my bees showing signs of swarming, in several of the colonies, and I lost one colony during April, which makes 2 in all. Most of my bees are working in upper stories, but I have not yet extracted any honey, although the apple, peach, plum and other fruit trees are in full bloom, and along the bed of the creek of Settlement Canyon, the willow is the great attraction to the bees. They have about finished with the cottonwood bloom. We have splendid pasturage for bees, so the prospects are very promising where bees are in a condition to take advantage of the harvest that awaits them.

JOHN DUNN.

Tooele City, Utah, May 24, 1884.

How to Separate Swarms.

In the Weekly BEE JOURNAL of 1881, on page 171, Messrs. Bray & Seacord gave a description of a swarm-separator as follows: "Make a box 3 feet long, wide and deep enough to hang the frames in, from the hive you use; place the frames in the box, the same spaces apart as they are in the movable comb hive; make one entrance for the bees on the side of the box, twice the length and of the same height as the entrance to the hive; make 3 or 4 division-boards to fit the box, then make a cover with cleats on both sides (no end cleats) to fit the box." Now, when two or more swarms unite, put them into swarm-separator in a cool place in the evening; and the next morning you will find them separated. Push the cover back even with the division-board, close the entrance and take the bees to hives. Having tried this plan, I wish to say that it works with entire satisfaction; and all bee-keepers who depend upon natural swarming should have a swarm-separator of the above description. I find the BEE JOURNAL good for a reference in times of need.

Monterey, Cal. JOHN L. SECOR.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Sundry Questions.

1. Do you think it possible to cut off drones' heads when examining a colony?

2. I have my bees (8 colonies) on an iron shed-roof. Is that as suitable a place as on the ground—ground room is very scarce with me?

3. I, last season, put an extra hive under the brood-chamber of one colony; they did not swarm; the queen did not go into the lower hive. I extracted 80 pounds from the bottom hive, and got 150 pounds from supers over the brood-chamber in 1½-pound sections. Can I reasonably expect like results, if I manage the same way with all my bees this season?

4. I desire very much to avoid increase by swarming; for they are almost sure to cluster on tall oaks out of my reach when they swarm naturally. How can it be done? I am having an unusual quantity of drones this season, and have no use for any that I know of.

5. Is it profitable to use old combs from ¼ to ½ filled with pollen? I have used several, and they appear to remain as when I put them in. It seems hardly profitable.

G. J. PEASE.

Ann Arbor, Mich., June 2, 1884.

ANSWERS.—1. Yes; and probably I shall do some of it right away. Of course I mean before they are hatched out of the cell.

2. I would prefer the ground, but you can succeed where you are, if you have the tact.

3. I do not think you gained any thing in upper surplus-storing, by placing an extra hive below.

4. It can be done in several ways, too lengthy in detail to describe in this department; but I should think cutting down the oaks, or moving the apiary to a suitable place, much more practical.

5. Yes; for the bees will clear out the old pollen, when the queen needs the room to breed in.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL,
Monday, 10 a. m., June 3, 1884.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for all honey is very low; market dull and prices range from 6½¢ for extracted. Different lots of choice comb honey in small sections have been offered and sold in our market lately at 12½¢ to 14¢ per lb. As I predicted some time ago, the preference for the production of comb honey seems to be prevalent; and, as we have the best prospects for an abundant harvest this year, we may prepare for low prices.

BEESWAX—Is in good demand; choice yellow brings 35¢ a lb. on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—Present quotations are as follows: Fancy white in 2-lb. sections, glassed, 13½¢; fair to good in 2-lb. sections, glassed, 11½¢ to 13¢; dark grades in 2-lb. sections, glassed, 10½¢ to 12¢. No 1-lb. in this market.

BEESWAX—Scarce, and sells readily at 36½¢ to 38¢. MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15¢, and 2½-lb. to 2¾-lb. from 10½¢ to 12¢. No 1-lb. in the market. Extracted, 8½¢ to 10¢.

BEESWAX—35¢.

BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—Choice white comb honey in 1 lb. sections brings 18¢; in 1½ to 2 lb. sections, quotable at 16¢. Comb honey discolored and in undesirable shape is selling at 10½¢ to 12¢. Extracted honey is in light demand at 6½¢. Manufacturers of syrups and bakery who the low price of sugar is the reason why they do not use as much honey as formerly. There is very little desirable comb honey on the market.

BEESWAX—Is scarce and fancy yellow brings 38¢. Good beewax, but dark, and having more or less of refuse matter in it, quotable at 30½¢ to 33¢.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—A little new extracted is on the market, but is not receiving much attention, buyers being rather timid. Several small lots of old extracted arrived within the week, mainly of quality, and the same are offering at low figures. Some very choice old extracted was sold at 7¢, which is at present an extreme figure. The demand is very light, and the tone of the market weak. White to extra white comb, 15½¢ to 18¢; dark to good, 10½¢ to 13¢; extracted, choice to extra white, 6½¢ to 7¢; dark and candied, 4½¢.

BEESWAX—Wholesale, 27½¢ to 30¢.

STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—There is now a little slackening in the movement of honey in anticipation of the new crop. Prices unchanged, 15½¢ to 16¢ being the range for choice comb, and a few choice ½-lb. sections bringing 10¢. I will be glad to receive shipments of new honey as soon as practicable, after it is thoroughly ripened. Remember the "early bird," etc. Extracted nominal at 7½¢ to 8½¢. I will be pleased to send a copy of "Suggestions on Packing and Shipping Honey," free to any one on application.

BEESWAX—None in this market.

JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12½¢ to 14¢ per lb., and strained and extracted 6½¢ to 6¢.

BEESWAX—Firm at 32½¢ to 32¢ for choice.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1 lb. sections at 18¢; 2 lbs. best white not quite so active at 17¢; 1 lb. sections sell quickly on arrival, and often are sold to arrive. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.

BEESWAX—Scarce at 35¢.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 18½¢ to 20¢; extracted, 7½¢ to 8½¢.

Geo. W. MEADE & Co., 213 Market St.

Cook's Manual in cloth and the Weekly BEE JOURNAL for one year will be sent for \$3. Manual and Monthly, \$2.00. We have no more of the old edition left, and, therefore, the club price of that edition at \$2.75 and \$1.75 is withdrawn.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a continual statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an additional present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

| | |
|----------------------------------|--------|
| For 50 colonies (120 pages)..... | \$1 00 |
| " 100 colonies (220 pages)..... | 1 25 |
| " 200 colonies (420 pages)..... | 1 50 |

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Convention Hand-Book.

It is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price still lower, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75. Or, bound in cloth, with Weekly, \$3.00; with the Monthly, \$2.00.

Do not let your numbers of the BEE JOURNAL for 1884 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Several hundreds of subscriptions run out this month. Last week we notified them by the blue pencil mark, and now we desire to impress them with the importance of *renewing at once*, to save themselves annoyance by the loss several numbers, and also save us the trouble of removing the names from our type mail-list, and then setting them up again a few days afterwards. Those who desire to have the BEE JOURNAL continued until they order it discontinued, should notify us of the fact, and we will mark it on the mail-list. Then no numbers would be lost or trouble made for any one.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

BOYS AND GIRLS!

YOUNG AMERICA, a large light page 32-column illustrated 50 cent Monthly, free one year to all that enclose this advertisement to us now with 15 cents. Sure to please all Boys and Girls. Address,

YOUNG AMERICA,

24A2t Lock box 675, Canal Dover, Ohio.

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$14.00 Extractor. 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and moving sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

| | |
|--|--------|
| For 2 American frames, 13x13 inches..... | \$8 00 |
| For 2 Langstroth " 10x18 " | 8 00 |
| For 3 " " 10x18 " | 10 00 |
| For 4 " " 10x18 " | 14 00 |
| For 2 frames of any size, 13x20 " | 12 00 |
| For 3 " " 13x20 " | 12 00 |
| For 4 " " 13x20 " | 16 00 |

DRESDEN, TEX., May 28, 1884.
Conquer the Cyps.—T. F. BINGHAM,
Abronia, Mich. Dear Sir:—Enclosed find
\$1.75, for which please send, per mail, one
"Conqueror Smoker" to Major H. A. High,
Waxahachie, Tex. He bought a Cyprian
Queen from me, and the Bees have worsted
the old gentleman. I told him that the Con-
queror Smoker would conquer the "Cyps,"
as I had tried one for two years, and "it
never failed." Respectfully,
B. F. CARROLL.

Borodino, N. Y., Aug. 15, 1882.
Cyprians Conquered.—All summer long
it has been "which and tother" with me and
the Cyprian colony of bees I have—but at
last I am "boss." Bingham's Conqueror
Smoker did it. If you want lots of smoke
just at the right time, get a Conqueror Smo-
ker of Bingham. Respectfully,
G. M. DOOLITTLE.

Prices, by mail, post-paid.

1884.

HEDDON'S COLUMN.

BEST GIVEN COMB FOUNDATION.

Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8¼x16¼, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

One Hive complete for comb honey.. \$3.00
(The above will contain two cases complete with sections).

The above Hive complete for extracted honey.....\$3.00
The above Hive complete for both in one 4.50
One Hive in the flat..... 2.00
Five or over, each 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4¼x4¼x6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

STUDENTS OF APICULTURE

Will receive terms for 1884 on application.

BEES and QUEENS.

If you contemplate the purchase of Bees in any shape, tested or untested Queens, it may pay you to send for my

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.
Address,

JAMES HEDDON.

Sixth Thousand Just Published!

New and Enlarged Edition OF BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure.
T. F. BINGHAM.
Aubonia, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN.

Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ills.

A Liberal Discount to Dealers by the Dozen or Hundred.

WE CALL

the attention of all wanting A No. 1 BEES, Italian, Cyprian or Hybrids, to the following, from one well-known to the readers of this Paper:

"I have never seen a case of foul brood; my bees are entirely healthy, and have always been so, and are O. K. in every respect."
GEO. B. PETERS, M. D.

We can furnish any number of Colonies of the above Bees, and will warrant safe delivery and satisfaction.

N. B.—No Bees will be sold by us, for any consideration, from any apiary that has ever had a case of foul brood in it. For prices and particulars, send to

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.

ALFRED H. NEWMAN,
923 West Madison Street,
CHICAGO, ILLINOIS.

A PRIZE.

Send six cents for postage, and receive free, a costly box of goods which will help you to more money right away than anything else in this world. All of either sex, succeed from first hour. The broad road to fortune opens before the workers, absolutely sure. At office address, TRUE & Co., Augusta, Maine. 4A1y

CHAS. DADANT & SON,

5AB1y HAMILTON, Hancock Co., ILL.

VALUABLE ORIGINAL PATENTS.

Prof. Cook, in his valuable Manual of the Apiculture, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies, but of those we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

BOOKS!

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates on larger quantities, given upon application.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects: Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quieting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, in cloth, \$1.00; in paper covers, 75 cents.

The Apiary Register, or THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premium for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-Keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees,—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bienen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY ALLEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way to rear Queens, etc. Price, \$1.00.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PRIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either English or German.

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Handling and Quieting Bees.

A Lanarkshire bee-keeper, in the *London Journal of Horticulture*, gives the following on handling and quieting bees, the remedies, when they are irritated, and the best treatment of stings :

When bees are accustomed to people and domesticated animals near the apiary, they seldom offer an attack unless through some provocation, which they are sure to resent. Incautious manipulation, turning the soil, and pulling weeds or vegetables; certain odors, such as musk and other scents; vinegar and smoke, and allowing bees to have access to honey-comb or robbing other hives, are a few of the many things that irritate them, all of which should be guarded against. One bee irritated and using its sting may set the whole apiary in a frantic and vicious state, which may last for weeks ere they be calmed down. It is possible that bees possess a sense that we are ignorant of. One thing is certain, when people of a nervous temperament manipulate bees there is something that excites them. We can avoid irritating bees in many ways, such as by leaving the apiary for a time when they are inclined to sting, or disturbing them as mentioned above; but there are times when all danger has to be faced, and caution with firmness is necessary, and veils, if stings are dreaded. When manipulating, I seldom use either a veil or smoke, carbolic acid being so much superior to the latter that it enables me to manipulate with safety, leaving the bees in a passive state after it. The hive also is the better able to resist foul brood, while moths do not harbor where it has been used, neither is the honey tainted nor the larvae affected by its use, as is the case when smoke is used. Carbolic acid is useful to prevent robbers attacking another colony. The robbing hive is well smeared at the entrance; this diverts the bees from making further inroads on its weaker neighbors. When commencing to manip-

ulate, if the bees are vicious or suspected to be so, I smear the alighting-board with some acid, then uncover the hive. I then smear the tops of the frames with the acid, and having a wing or feather also saturated so that I may dislodge the bees from any part by its use, placing it near the bees, causing them to retreat to or from any part I may choose. When this is done, the bees remain quiet, and do not crowd over the frames nor attempt to sting as they do when smoke is used.

There are many applications and nostrums recommended for stings, none of them being effectual as a cure, for the very simple reason that the poison has impregnated the system before the alkali can be applied and reach the acid to neutralize it. The best remedy I ever found was to apply heat by steam or water to the patient to cause a free perspiration, and to give a little sal volatile; but this latter ought to be prescribed by the medical man. Not a moment should be lost to bring on a free perspiration, and every means resorted to that will accomplish that end.

By the Lakeview, Mich., *Enterprise*, we notice that Mr. S. J. Youngman expects to receive 125 colonies of bees by rail from Louisiana to keep on shares until next September. The increase is to be limited to one swarm from each colony; Mr. Y. has all the increase and one-half of the honey for his share. The bees will be 5 days or more on the road.

We have received the Catalogue of High-Class Poultry and Fancy Dogs of Geo. H. Pugsley, Brantford, Ontario, Canada. It contains 68 nicely illustrated pages.

How to Grow fine Celery.—A new method, by Mrs. H. M. Crider, York, Pa. A 25-cent pamphlet, showing how to grow fine celery, according to a theory deduced from a study of the natural habits of the plant, and well attested by several years of experience. The importance of celery as an article of diet, and especially its value as a specific for nervous diseases, makes its successful culture of the first importance; and the method

herein given will enable any one to have it in perfection in his garden.

Statistical Report.

Pres. McCagg, of the Eastern Iowa and Western Illinois Bee-Keepers' Association, gives the following as all the reports received up to May 25, 1884. Some 15 or 20 members had not reported at that time :

The increase in the number of colonies is not over 5 per cent. in the past 2 years, and the increase in the consumption of honey has been at least 20 per cent. in the past 2 years; so you can see that honey must bring a good price. Weak colonies cannot be relied upon as honey-gatherers. This year's crop of honey, if large, should bring not less than 15 to 20 cents. Do not be deceived by large ideas and big yields at your neighbor's; we will not be able to supply the demand

Cure for Foul Brood.

T. W. Cowan, Esq., of London, England, lately visited the apiary of Mons. Ed. Bertrand, located at Allevays, in the Alps, Switzerland. Mons. Bertrand claims to have successfully cured "foul brood" there, and Mr. T. W. Cowan details the way in which it was done, in the following article from the *British Bee Journal*:

Allevays is situated at a height of 2112 feet, and is distant about six miles from Nyon, on the road to St. Cergues, on the Jura mountains. The scenery was very picturesque, and as we rose higher and higher, first one peak and then another of the Mont Blanc range came in view. On our arrival at Allevays, we were met by two English gentlemen who had been attracted thither by seeing the view of the apiary which appeared some time since in the *British Bee Journal*. This apiary, as will be seen by referring to the accompanying picture, is situated

vides the apiary, Layens hives being on the left, and Dadant hives on the right, so that by working the two systems together a comparison might be made; there being about 50 hives in the enclosure. In front of the apiary are small fir-trees destined to attract the swarms, and borders containing experimental plantations of honey-yielding plants, such as scrophularia, yellow and white melilot, borage, phacelia, alsike clover, and others.

This is a good neighborhood for the bees, for in the spring they find pollen on the willows, maples, nuts, and colt's-foot, and honey on the maples and wild cherry trees; later, on the cultivated esparcet, wild sage, and the flowers of the pastures. After the grass is mown, there are the lime-trees, raspberries, wild thyme, golden-rod, astrantia, and others. This apiary is one of the few which yield a regular and constant return; it shows that its owner is a thoroughly practical as well as scientific apiarist.

M. Bertrand is editor of the *Bulletin d'Apiculture pour la Suisse Romande*.

Mons. Bertrand's Apiary, in the Swiss Alps.

on the borders of the forest, and is enclosed in the American style. The hives are detached, each being on its own stand, the floor-boards close to the ground, similar to the hives used by me. They are well sheltered from the winds by the forest which extends on three sides. The hives are about 6 feet apart, in rows, the distance between each row being about 10 feet. In front of the hives, here and there, are planted shrubs which serve as guides to the bees to mark their homes. In the centre of the apiary is seen a shed, which is used for manipulation, and as a store and extracting room. It contains hives, frames, a cupboard for combs, and even in the ridge there is a bed which has been useful to its owner when he has been kept late at work with his bees.

From the windows there is a splendid panorama of Lake Lemman and the Alps. These windows are of peculiar construction, being made to reverse on pivots at the top and bottom, so that by merely turning them any bees that had gotten inside the shed and flown on the glass, could be turned out without any difficulty. A wide path di-

vided the apiary, Layens hives being on the left, and Dadant hives on the right, so that by working the two systems together a comparison might be made; there being about 50 hives in the enclosure. In front of the apiary are small fir-trees destined to attract the swarms, and borders containing experimental plantations of honey-yielding plants, such as scrophularia, yellow and white melilot, borage, phacelia, alsike clover, and others.

This is a good neighborhood for the bees, for in the spring they find pollen on the willows, maples, nuts, and colt's-foot, and honey on the maples and wild cherry trees; later, on the cultivated esparcet, wild sage, and the flowers of the pastures. After the grass is mown, there are the lime-trees, raspberries, wild thyme, golden-rod, astrantia, and others. This apiary is one of the few which yield a regular and constant return; it shows that its owner is a thoroughly practical as well as scientific apiarist.

M. Bertrand has a valuable and able assistant in the person of M. C. Auberson, who is a schoolmaster at St. Cergues, three-quarters of an hour's walk above Allevays, who, in addition to looking after his own bees, undertook to assist M. Bertrand at a time when they were stricken by foul brood, and when constant supervision was necessary to stamp out the disease, M. Bertrand's residence being at too great a distance from Allevays to give the bees necessary attention. As the subject of foul brood was one of par-

ticular interest to me, having some years ago had to battle with this disease myself, and knowing that it was only by perseverance and great care that I cured my bees of it, I was anxious to know how Mr. Bertrand had proceeded. When I cured my bees, fumigation with salicylic acid according to "Hilbert's" method was not known, and it was much more trouble than now. Experiments made on foul-broody colonies during the last two years, however, convinced me that fumigation, if properly done, was the simpler process. I was not satisfied with my way of fumigating, therefore I was curious to see how M. Bertrand proceeded. His method is so simple, that for the benefit of those whose bees have foul brood, I will give a description of it, and in doing so will give the French weights so that no mistake should be made. M. Bertrand told me that since the establishment of the apiary, he had had foul brood in some of his hives, these at first he burned, but being induced to try to cure them, he persevered and never allowed the disease to get to the worst stage, when a cure would be more difficult. The hives were constantly examined, and if the slightest trace of dead brood was detected, they were at once operated upon. Most of the colonies in the apiary were now perfectly healthy; there was one, however, that had only recently been cured—it is the one standing just behind the gentleman in the wide-awake hat in the engraving, and M. Bertrand and M. Auberson proceeded to operate upon this one in my presence. For fumigating, he has had constructed a lamp, which is cylindrical in form, 6½ inches in diameter, and with an elbow at the top, ending in an opening 5 inches by 1½ inches. The total height of lamp with elbow being 11 inches. Inside the cylinder is placed a spirit-lamp, and above this is a small tin dish about 3½ inches above the wick of the lamp. The hive is not removed from its stand, but is raised up at the back off its floor-board by means of blocks of wood, and wedges are inserted at the sides, so that all the space is closed except enough to admit the nozzle of the fumigator. One gramme of salicylic acid is placed in the dish, and the flame regulated so that the acid is gently evaporated.

Too much flame would cause it to boil over and waste, not enough would not even melt it, so the right amount can be found out by experiment. The nozzle of the fumigator in operation is now inserted in the opening at the bottom, and the corners of the quilt turned up so as to allow the vapor of the acid to circulate freely. A few minutes after the acid had all evaporated, the hive was examined and the bees did not seem to be in the least inconvenienced by the fumigation. M. Bertrand said that neither brood nor worker bees were hurt, but he was not sure whether or not the queens suffered sometimes as he had lost some. Hilbert says that each hive should be fumigated every six days, four fumigations being sufficient; but M. Bertrand has continued longer, so as to be certain of a cure.

The operations should be performed in the morning or in the evening when all the bees are at home. Besides the fumigations, the entrance, alighting-board, and the ground round the hive, and any portion not reached by the vapor, should be washed with a solution of salicylic acid. This is done with an ordinary syringe. The foul-broody colonies receive every other evening one-sixth of a litre of syrup containing 30 to 50 drops of Hilbert's solution No. 1 (8 grammes or cubic centimetres of pure alcohol to 1 gramme of salicylic acid).

A foul-broody hive should be fumigated previous to its being opened, and all diseased brood cut out and thrown away, as few frames left as the bees can conveniently occupy, and if possible the bees should be forced to build new combs. All the hives in the apiary should be fed at least once a week with a syrup containing acid, while the disease lasts. After this treatment M. Bertrand found that at about the end of six weeks all trace of the disease had disappeared, and the convalescent colonies gave a good harvest of honey. I was glad to see that in all his operations M. Bertrand took the same precautions I have always insisted upon, and to the neglect of which so many have failed to cure their colonies. After a hive had been examined, everything used, as well as the hands, were washed in water containing 50 drops of solution No. 1 in 50 grammes of tepid rain water. A special dress made of linen, which can be easily washed, is used in operating; and the great care taken is shown by the fact that M. Auberson, although constantly manipulating amongst the diseased colonies, had not introduced the disease into his own apiary. These operations are very simple, but not one of the precautions taken can be dispensed with. I prefer to scald hives that contained foul brood, and I have my hives constructed with a view to this; but M. Bertrand pointed out that it would be very inconvenient to do so with such large hives as the Layens, and I also prefer to give my bees salicylic acid in their food whenever they have any. It is now several years since I cured my bees of foul brood, but they have always been fed on syrup containing salicylic acid in the proportions set forth in the *British Bee-Keepers' Guide Book*, and, although situated in an infected area, I attribute the absence of disease in my apiary to the constant use of salicylic acid in the food.

Near-Sighted.—A Lanarkshire beekeeper writing on the question of the near-sightedness of queens, in the *London Journal of Horticulture* remarks as follows: "Some people are of the opinion that bees are not near-sighted—i. e., cannot discern an object near them. I cannot endorse that statement, as I have repeatedly observed when bees were feeding under a glass cover, they started when an object was made to pass over or close to them."

The Fertilization of Flowers.

Mr. James Reid, a nephew of Mr. Robt. Reid, Collector of Customs at London, Ont., who is now a prominent resident of Paisley, Scotland, has devoted much attention to botanical subjects, and lately delivered a very interesting lecture on "The Fertilization of Flowers," before the Botanical Section of the Philosophical Society, from which we make a few extracts:

We all know, said Mr. Reid, that most flowers have their stamens and pistil situated together in the same flower; but we likewise know that many species bear those organs on separate flowers, although both kinds of flowers are found growing together on the same plant, whilst still other plants bear their stamens and pistil not merely in separate flowers, but in flowers on perfectly distinct plants.

It is evident that, when these organs are each situated on separate flowers, fertilization can ensue only when pollen from the stamens of one flower is carried by some means or other to the stigma of another flower of the same species. In the most of cases this is effected by insects, in a few instances by birds, and in others by the wind. The Scotch fir affords a well-known example of wind-fertilization. Doubtless the enormous quantity of pollen shed by this species is meant to make up for the great waste incidental to its method of transmission. Meanwhile we will confine our attention to plants bearing hermaphrodite flowers.

It was long supposed—indeed, until quite recently, and, I may almost say, within the lifetime of the youngest members of our society, it was the almost universal belief amongst botanists—that all flowers of this kind were self-fertilizing; but it is now quite well known that very many flowers, although hermaphrodite in structure, are unisexual in function. Some of our most eminent botanists are of the opinion that cross-fertilization is the rule with many flowers which yet have the power of self-fertilization; and experiment has shown that when one flower is fertilized by pollen from another flower, the resulting seeds give rise to healthier and more vigorous plants than usually spring from seeds of self-fertilized flowers. However, we shall see as we proceed, that, with some hermaphrodite flowers, self-fertilization is physically impossible, and that in such cases the most beautiful arrangements exist for ensuring cross-fertilization.

In the remarks which I have to make, I will draw my illustrations from a few wild flowers which grow freely around Paisley, and I will, for two reasons, take up no more than three or four species—first, because it is impossible, within proper limits, to deal satisfactorily with many flowers; and next, because the nature of the principle which we are considering, can be as well illustrated by three or four as by a larger number. I will

also restrict myself to plants which I have for a number of years grown in my own garden, and thus have had opportunities of seeing confirmation of certain phenomena which have engaged the attention of botanists of acknowledged reputation. In many hermaphrodite flowers, the stamens come to maturity at one time and the pistil at another; and, of course, in such cases self-fertilization cannot take place.

Dichogamy is a technical term to indicate that the two sets of organs on the same flower are not developed simultaneously, but it does not tell us which of them ripens first. However, in flowers of this kind, the stamens generally arrive at maturity first; and, when this is the case, the flowers are said to be protandrous or proterandrous. But in many cases where both sets of organs are developed at the same time, insect agency is still essential to successful fertilization. We have a familiar instance of this in the common red clover (*Trifolium pratense*). Some naturalists affirm that the common red clover can be fertilized only through the agency of one of the common humble-bees; others are disposed to question the soundness of this opinion, although all appear to agree that insect agency is quite essential to its successful fertilization.

In the course of the late Darwin's numerous and valuable experiments, he found that 100 heads of red clover, when grown in the open air in the usual way, produced 2,700 seeds, but the same number of heads, when protected from bees, did not produce so much as a single seed. I remember reading in the newspapers, some 12 or 14 years ago, an account of the efforts of the Acclimatization Society, of New Zealand, to introduce red clover into that colony; but, although the seeds sent from this country yielded a fair crop of good plants, yet the plants thus grown totally failed to reproduce others "after their kind," and the failure was described to the absence of wild bees.

Like the red clover, the fertilization of the pansy is likewise due to the agency of insects, chiefly to the visits of one or more of the wild bees. As the pansy is believed to be one of the most highly specialized flowers not only in the British flora, but in the whole list of phanerogamous plants, it is very well worth the while of any one at all interested in the subject to take some pains to understand its structure and the contrivances which it exhibits to insure its reproduction from seed. The peduncle of the pansy, just below the flower, suddenly curves round to a position at right angles to its ascending axis, thus throwing the flower forward and downward. Look into the "eye" of the flower, and you will notice the round knob-like stigma, of a yellowish green color, situated almost right in the throat, so to speak, of the tube. This gobular organ you will likewise observe, is pressed closely down upon the front petal. Now, look beyond the stigma and in towards the very heart of the flower, and you will there

see something having a more or less orange tint. This orange color proceeds from the broad and membranous prolongations of the connectives. I may remind some of you that the connective is what might be called the mid-rib of the anther. It usually terminates at the tip of the anther, but it is sometimes produced beyond it, as it is in this case, and very strikingly so in *Paris quadrifolia*. An anther with prolonged connective is analogous to a leaf whose mid-rib is produced beyond the blade. The stamens of the pansy have very short filaments—much shorter than their anthers. The ovary is conical in form, and the anthers are arranged completely round it, their dehiscing sides inwards, facing the pistil. The prolongations of the connectives thus take up a position near the upper part of the ovary, their tips meeting at the apex of the cone, but in such a way as to inclose a hollow space, with the ovary in the centre. Each of the two lower or front stamens throws out from the base of the connective a long spur. These staminal spurs project into the spur of the lower petal, and penetrates its whole length. The honey-glands are situated in the somewhat thickened ends of the staminal spurs, whence it drops to the bottom of the spur of the corolla, where it remains until sought for by some insect whose trunk is long enough to reach it.

I will not weary you with these structural details further than to mention that the stigma, which seems to guard the entrance to the honey-chamber, is quite hollow, and has a remarkable round opening in front. Below this opening, and close in contact with the petal, is a recurved lip or valve. There is a bend at what appears to be a weak part of the style. Having examined the flower thus carefully, we are now in a position to watch the effect of a bee visiting the pansy in search of honey. The insect alights on the broad front petal, thrusts its trunk under the stigma and downwards to the bottom of the spur of the corolla, where it can either sip what has trickled into the tube or take the honey directly from the secreting glands of the staminal spurs. Now, observe what happens. If the anthers are mature, or have been so for a short time, the pollen will, partly at least, have dropped through the slits between the anthers into the spur of the corolla, where it will be caught by the thick brush of hairs which seem to be placed there for this special purpose. The proboscis of the bee, on its way to the honey, must pass completely through this brush of hairs, and is sure to get dusted over with pollen; but, in withdrawing itself from the tube, the insect comes against the recurved lip of the stigma, which is consequently drawn forward and pressed across the orifice, thus effectively preventing any of the pollen from entering the cavity. Should the bee visit the flower just at the time when the anthers have ripened, but before the pollen has been shed, then when it touches the stigma, the style bends at

the weak part, causing a movement of the ovary. This movement disturbs the encircling anthers; the hollow box opens, and the pollen, set free by the agitation, drops upon the bee, and is carried off by it to the next flower it alights upon. In following the bee to this other flower, we will see that in thrusting its proboscis beneath the stigma, it has to pass the open orifice, against which it must press with some degree of force. The pollen which it has brought from the first flower gets cleaned off its trunk, some of which is almost certain to enter the hollow chamber, thus securing cross-fertilization.

For the American Bee Journal.

Hail—Bloom without Nectar.

ALLEN PRINGLE.

On May 18th ult. a violent hail storm passed over this section, and all the bees that were out were killed. As the weather during the preceding week had been unfavorable, confining the bees to their hives the most of the time, they came out freely that fatal afternoon, the weather being fine. The hail storm came suddenly, without warning, and laid the busy workers low in the dust. They could be seen after the storm, scattered over the fields close to the earth, dead; with their pellets of pollen still adhering to them. Aside from considerations of loss, the sight was one to excite feelings of commiseration for the industrious little heroes, and Shakespeare's couplet was forcibly suggested:

"Blow, wind! come, wrack!
At least we'll die with harness on our back."

The colonies which before this were in fine condition, were all more or less depleted; and some of them with not bees enough left to care for the brood which was plentiful. This unfortunate state of things necessitated a general balancing of forces throughout the apiary, and some "doubling up." Had I not promptly attended to this, the field loss, great as it was, would in all probability have been supplemented by a still greater loss of brood—possibly ending in "foul brood."

Such untoward and unexpected exigencies as these are the ones which test the apiarist. He is thus put to his "wits' ends," and at such times, unless he has principles to fall back upon, he will find himself at sea.

But the hail storm was not all. During two or three days of the past week, it was freezing cold, with high cold winds, and ice forming at nights. And to complete the chapter of adverse circumstances, the fruit bloom has come, and is about over, but has yielded no honey. This, to me, is anomalous. So far, in all my experience, I have never observed an abund-

ant fruit bloom without nectar. I have had to feed my bees all through it, or they would undoubtedly have starved.

The absence of nectar in the bloom is, no doubt, due principally to the low temperature and the drying winds of last week. In utter perversity the weather this spring has been the worthy counterpart of that of last spring.

Ever since the bees were put out (about the middle of April), it has been a continual conflict with adverse (one would be pardoned for saying ill-naturedly, perverse) natural conditions. However, I suppose our only salvation from these meteorological ills (and *chills*) is to bring science and common-sense to bear, resolutely meet them, and parry them.

A part of my bees were wintered on their summer stands protected, and part of them in the cellar. I lost one of those which were outside, and one of those inside, after they were put out. All the others came through in excellent condition.

The one outside starved, though it had about 30 pounds of honey when I prepared it for winter. I account for the singular fact in this way: It was so well prepared, and so snug under the snow, and being one of the largest and best colonies, it kept up breeding all winter, until it had by March 1, consumed all its stores. Its *post-mortem* condition evidenced this.

Notwithstanding the very unfavorable spring, my bees are now in excellent condition, with the exception of 2 or 3 colonies. But they have no honey, nor are they gathering any to speak of. I am still feeding them, and will, no doubt, have to continue it until the white-clover bloom appears.

Many bees in this section died during the winter and spring; mostly, however, among the old-fashioned, non-scientific bee-keepers. One of this class, a neighbor (he does not take the BEE JOURNAL), said to Mrs. P. lately: "How is it that Mr. Pringle's bees live through the winter and spring and ours die?" The reply was that it was probably owing to the fact that the former knew how to care for his bees.

Now I do not suppose that the most careful and scientific apiarist can permanently escape winter and spring losses; but his average loss will be small compared with those of the careless and blundering bee-keeper. Bee-culture wants no sluggards or dullards. But the losses and disappointments consequent upon these traits, will have at least one good effect; viz., that of weeding out the careless and incompetent from our ranks. Not that the inevitable mistakes and losses of the earnest beginner determined to learn ought to be condemned—by no means; but the bee "dolt" who is too dull to comprehend scientific apiculture, or too negligent and careless to look after his industrious little exemplars, ought to be "weeded out;" and the Darwinia law of the "survival of the fittest" will assuredly do it.

Selby, Ont., June 2, 1884.

For the American Bee Journal.

Haldimand, Ontario, Convention.

The Haldimand, Ontario, bee-keepers met at Hagersville on Friday, May 30; 25 members being present.

The minutes of the previous meeting were read and adopted. The first subject discussed was "The Best Race of Bees."

The chairman, Mr. R. Buckley, advocated the Italians as the best race of bees.

Mr. Kindree had not much experience with any except brown bees and Italians; but he preferred the Italians, or a cross between them and the brown bees.

Mr. Smith preferred the Italians for handling, but thinks that hybrids are the best honey producers.

Mr. Abbott said he did not know anything about the Italians; he had good success with the German bees. He noticed that some of his colonies were becoming hybridized by meeting with Italian drones, and that they were powerful workers.

Mr. Williamson said that anybody who had any experience in keeping bees would never say that the brown bee is better than the Italian; but he thought the hybrids were better than either.

Mr. Armstrong had kept both brown and Italian bees for some years; but he did not want any brown bees, or hybrids either, after this. The Italians were better workers and easier to handle; they work earlier and later, and defend themselves from robbers and moths far better than the brown bees. He read extracts from Prof. Cook's and A. I. Root's bee-books in favor of the Italian bee.

The Secretary spoke in favor of the Holy Land bees, or a cross between them and the Italians. His Syrian bees were better workers, and quite as gentle as Italians. They winter better, and build up more rapidly in the spring. He believes "the coming bee" will be a cross between the Syrian and the Italian.

"PUTTING UP HONEY FOR MARKET."

Mr. Williamson did not produce more honey than he could sell in his home market; but he thought that the small sections sold more readily. Extracted honey put up in glass jars sold about as well as section honey.

Mr. Armstrong put most of his honey in glass jars, and only lost two in shipment. When he sold honey in large quantities, he put it up in half-barrels. Comb honey should be in one-pound or two-pound sections.

The Chairman said he thought the smaller the package the more readily it could be disposed of.

Mr. Smith had tried both tins and glass jars, and preferred the glass for home trade.

The Secretary thought it would not make much difference how it was put up, after the people had tried the honey. He had used both tins and glass, and preferred the tin, on account of its cheapness and safety in handling.

"THE BEST METHOD OF INCREASE."

Mr. Smith preferred natural swarming for the reason that the bees lost no time, but went to work at once.

Mr. Kindree also preferred natural swarming for the same reason. In reply to Mr. Hull, he explained how to divide them.

The Chairman preferred dividing, and said that all good bee-keepers practiced that method; but care must be taken not to divide too much. It takes less time, and there is less danger of losing swarms.

Mr. Armstrong said if a man did not know anything about bees, he should not try to divide them, but allow the bees to manage for themselves. For himself he preferred dividing, as it was easier; but a laying queen should always be given to the new colony.

The following was reported by the members present, as the number lost during the winter: Fall count, 443; spring count, 353; loss, 90 colonies.

INTRODUCING A QUEEN TO A COLONY HAVING A FERTILE WORKER.

Mr. Kindree had not much experience in this line, but he once succeeded by putting a weak colony with a queen, into the fertile-worker colony.

Mr. Armstrong advocated breaking up the colony altogether, and giving the frames to other colonies.

The Secretary stated that he had succeeded in getting rid of a fertile worker by removing the hive to another part of the yard, shaking the bees off the frames, and then putting the hive back on its old stand. He then introduced a queen without any trouble.

For the American Bee Journal.

Bees and Flowers.

CLARENCE M. WEED.

Every person at all acquainted with bees and bee-culture knows that without flowers bees could not exist; but it may be a new thought to some, at least of the younger readers of the BEE JOURNAL, that without bees flowers could not exist. It is proposed in a few short articles to give an idea of the mutual relations of bees and flowers, and of the views of eminent botanists in regard thereto. It will be seen that the subject is a much more interesting one than it would at first appear to be, and that for the beautiful tints and sweet fragrance of our most dearly loved flowers, we are indebted to the bee. Certainly it must be admitted that any bee-keeper who understands the philosophy of his calling, will make a more successful apiarist, as well as a broader and more cultured man.

Before discussing the subject properly, a knowledge of the structure of flowers is necessary. There are many flowers, which are not commonly called such, as those of the elm and ash, but these will be passed over and only those treated of which are of special interest to the bee-keeper. To illustrate flower structure, let us examine

an apple blossom: The first thing noticed is that there are five white, or pinkish-white flattened portions which form the most conspicuous part of the flower and clothe the tree in beauty. These are the petals. On the inside of the petals are a large number of small yellow stems surmounted by a cap of the same color; these are the stamens, and are a very essential part of the flower, because they contain the yellow powder called pollen. At the centre of the group of stamens is a greenish stem differing from the stamens in size and shape; this is the pistil, another essential part of the flower. The lower portions of the pistil is called the ovary, because it contains the ovules or young seeds. In order that these ovules may develop into seeds, a particle of the pollen from the stamens must fall upon top of the pistil and penetrate it by means of a microscopic "pollen tube." This is the process of fertilization. But if this is done by pollen from the same flower, the ovule will in most cases not develop at all, or if it does develop, it will be much less vigorous than if the pollen came from another flower of the same tree; or still better, of another tree. Here comes in the aid of the honey-bee; its function, as regards flowers, is to carry pollen from the stamens of one flower to fertilize the pistil of another.

In the apple, pear, peach, thorn, and many similar flowers, the process of fertilization is very simple. The bee lights upon the blossom, and in so doing some pollen is brushed upon its head and body, some of which will be rubbed on the pistil of the next flower visited in its eager search for the honey secreted at the base of the stamens.

Reversible Frames Once More.

M. M. BALDRIDGE.

It does seem that "the woods are full of them," for Michigan has been heard from again. I now refer to some exceedingly funny remarks on page 233 of the BEE JOURNAL, concerning "reversible frames."

The writer says: "When we have a frame all fixed so that it will reverse, when we say the word, of what advantage is it over a frame that does not reverse?" My reply is, please read carefully and critically what has been said in the BEE JOURNAL, and elsewhere, on that side of the subject, and then you will see for yourself. Now, please do not ask the advocates of "reversible frames" to fill column after column of the bee-periodicals with matter that would be a mere repetition of what has been said, and thereby nauseate the intelligent reader.

"When the combs are full of sealed brood, perhaps it might help the young bees to gnaw out, if we reverse the combs." This is evidently intended for one of those "funny" remarks, and I introduce it here simply to give everybody a chance to smile who feels like it.

"We have seen honey so thin that to reverse the combs would be sure to give the bees a job of house-cleaning." The writer now touches lightly upon a matter of some importance—but is he sure that he has made a statement of fact? or is it simply fancy? We have a "strain" of bees in Illinois (and they are not hybrids either) that has a knack of filling a comb with honey when it lies upon its face, and making it stay in, too! But suppose honey is so thin that it will run out when the comb is simply reversed, will that do any harm? And may it not after all be an advantage? That is, may it not hasten the "ripening" of the honey, if the bees are compelled to move it to some other part of the hive? By-the-by, what is the reason those wonderful hybrid bees in Michigan cannot be *strained* just a trifle more, so that they will not gather honey so thin that it will run out by simply reversing the combs?

"I can see no advantage" in reversible frames, but this may be owing to my "thick-headedness." The writer has possibly "hit the nail on the head" this time! But great men are often troubled with that complaint. Even the late T. B. Miner, the compiler of "The Bee-Keepers' Manual," a work that had quite an extensive sale 25 years ago, was sadly afflicted with "thick-headedness;" so much so, in fact, that he could not see that movable-frame hives had any advantage over those provided simply with *top-bars*!

The same is true to-day with many concerning the use of a honey-board when made properly. How few there are, comparatively, who fully appreciate the advantages of the style of honey-board so ably advocated by Mr. Heddon. So the writer will please console himself with the thought that other great men are often so "thick-headed" that they cannot always comprehend important discoveries.

For the American Bee Journal.

Priority of Location.

R. J. KENDALL.

Mr. Doolittle and Mr. Pond both attack this subject in the BEE JOURNAL for May 14. If I understand Mr. Heddon, he says just this: The man who begins to keep bees first in a locality, has priority of location—as a moral right. He then gives such bee-keepers a plan whereby they can maintain their right, if an intruder will not listen to reason.

That the first settler has a moral right of priority of location, seems to me undoubted. The legal right is another thing. Mr. Doolittle does not appear to dispute the moral right; but Mr. Pond attempts to turn the issue by saying one man has as much right to enter another man's locality as he has to set up a store beside him. Legal right, yes; moral right, no. The cases are not exactly alike—communities increase in population, localities do not in honey-flowers.

As a lawyer, I am not a little surprised at Mr. Pond's taking up the position he does; for law in its principle goes dead against him. The whole tenor of the writings of Blackstone, Coke, Justinian, and the American law writers, when treating of the principles of tenures and titles, go to affirm that the first occupant has a right to the selected locality. Discovery and first occupancy are the very foundation of title. The principle is so plainly recognized by the American law of pre-emption, and also by the free ranges over the public domain in the West by cattle and sheep men that I wonder all the more at his position.

So far as the point at issue in this matter of location is concerned, there is no difference between cattle and sheep and bees; or if there is, it is in favor of the bees—"they come home to roost."

Equity most certainly, if not actual law, would give the title to the first bee-keeper. Try it also by the rule of doing unto others as you would have others do to you, and see where this puts it.

Mr. Doolittle's contention appears to be thus: If Jones is a big property-owner near Kendall, who is a poor man keeping bees, that the big property-owner Jones can crowd Kendall out of the range by simply putting on his large range more colonies of bees than Kendall does on his.

Perhaps he can, and perhaps he cannot; and perhaps he will get so disgusted in doing it that he will eventually want to sell out to Kendall. Bear in mind these suppositions: Kendall is supposed to be an experienced bee-man, and up with the times; while Jones is not a bee-man at all, but seeing Kendall's success, wants to keep bees, and undertakes to crowd Kendall out. Kendall is supposed to have talked with Jones, represented to him that he (Kendall) has been in the business some time—it is his livelihood. To Jones it would be a mere adjunct, but both will be injured if Jones carries out his project.

Jones, however, says he does not care. The surrounding property is his, and the honey his also; he proposes to keep bees and collect it in self-defense. Kendall puts in more and more colonies. The average runs down in all the colonies, but knowing his business, Kendall keeps up the "racket" till he has his apiary as full as he can manage—there is a big lot of colonies, but the average is low, very low. Kendall knows just what he is doing; Jones does not. He has to buy hives, gets left more or less in doing so, and has to get bees. He gets stung, and mad, his swarms fly away, he loses or hurts his queens, gets the bees in "a deal of a temper" by his clumsy and awkward manipulations, and at their best, with scientific skilled treatment, they could only have secured Kendall's low average. But with Jones', ignorance, nervousness, and clumsiness, they have failed to get even that.

Do you not fancy, by the time he is through, Jones will be a pretty badly disgusted man, and feel like selling

out? Besides, while he is messing with the three, four or five hundred colonies with which he is going to beat Jones out, what will become of his farm or other business. It will take him all his time to handle his bees. Then again, how many years will it take him to build up his apiary; and how many years will he have to neglect his farm or other business. Is it likely he will neglect a better business for a poorer (to him) one? Scarcely; his only other way then would be to hire an experienced apiarist to manage his bees; and he would have to pay such a man a salary that would, I think, in addition to the cost of hives, bees, etc., amount to such a sum as would make Mr. Jones a pretty sick man on bees; and begin to think the game of driving out Kendall was not worth the candle burned to play it by.

No, no, Mr. Heddon has given us a valuable hint if we have to fight such a case—a hint that will enable an experienced bee-keeper with a small acreage, to win, over an experienced but envious landed-proprietor every time, I believe.

Mr. Doolittle's plan is to speak soft words to the big man; Mr. Heddon distinctly said the same. If the big man listens to the kindly words, all will be well in Mr. Heddon's case as well as in Mr. Doolittle's. But in case the big man says, "I don't care," and will not listen to reason—what then? (And this is the case Mr. Heddon supposes.) I presume Mr. Doolittle would move out or agree to work the big man's apiary on a salary; but Mr. Heddon would do neither, unless he was compelled to—an unlikely contingency—he would stop and fight it; and if there is any truth in the statement that "knowledge is power," the chances are, Mr. Heddon would come out ahead, and his big opponent would be the under dog in the fight.

Every reasonable man believes that quiet arbitrage is best; but the trouble is, every once in a while a big fellow comes along who will not listen to reason, but presumes on his size, and purposes to despoil you. In such a case you must do one of two things—give up or make a fight for it. If there is no chance of winning, and you cannot win, you have to suffer loss; but if you can see a chance to win, fight it; and I fancy it may be shown that your science, experience and knowledge will be more than a match for size and presumption. No, Mr. Doolittle's landed-proprietor would not be the "smarter" man, but the "smarting" one.

Austin, Texas.

The Iowa Central Bee-Keepers' Association will hold their next meeting on June 20, at Winterset, Iowa. A full attendance is expected.

Clipping Queens' Wings.

W. N. HOWARD.

In Mr. Stewart's reply to my question, on page 344, he rightly infers that I meant the period of gestation by the word *foal*; and as he has asked a few questions in return, I will give what I deem a sensible view of the matter.

I know of no bee-keepers (or any one else) who treat their queens as Mr. S. describes, in comparing them to the mare with her legs cut off. To be sure the interior of a hive, as a general thing, is dark; and this is no violation of any of the natural laws as regards a bee-hive; but to make the comparison parallel, as he puts it, would be to cut the queen's legs off as well as clipping her wing.

A queen with her wing clipped is not deprived of any of her organs of locomotion, neither is it any incumbrance to the fulfillment of any duties that nature requires of her after she has mated with the drone, with the exception of flying with the swarm; and the assistance of man provides for this deficiency in a much more satisfactory manner than to let nature take its course. If the clipping of queens' wings is injurious, why does it not so prove itself?

Mr. G. M. Doolittle has for the past 13 years made a practice of clipping the wing of each of his queens (if I am correct), and he rears his own queens; yet he makes the best report of comb honey (length of honey flow taken into consideration) of any bee-keeper in the known world; and he is each year improving his bees by careful breeding.

In a certain sense all animal life is governed by the same universal law in some of its details; but certain details which could be applied with success to one part of the animal kingdom, would be disastrous if applied to other parts.

True, queens do sometimes fly from the combs while being handled, but it is generally caused by their being disturbed; but do they produce better bees or larger yields of honey than the colonies by their side whose queen has a clipped wing?

The fact that a mare may be worked to within 15 minutes of the birth of the colt, does not prove that the colt would not have been just as strong and vigorous if the mare had been allowed to roam at her own "sweet will" in the pasture.

Perhaps Mr. S. will say that a queen with a clipped wing is prevented from going where she might wish to, and yet she is not prevented from doing all the duty that nature intended her to perform in all parts of the hive.

I am aware, as Mr. S. says, that a scare or other mental excitement of a disagreeable nature, often makes strange and woeful impressions, etc.; but can Mr. S. present any evidence that a queen has a mind, and is endowed with mental faculties? If so, could not she be taught to perform

more duties than her instinct now prompts her to do? Why not educate her to share her domicile with other queens, to assist in the egg-laying duties, to care for the brood, and if needed lend a helping hand at honey gathering? And what a boom it would be to the queen-breeder if he could educate queens to allow queen-cells to remain undisturbed in the same hive until hatched.

In Mr. S.'s description of allowing the mare to enter the match, he has given no conditions that were not prompted and brought about by nature, and he simply allows her to follow her instincts as far as his judgment tells him it is good for her. But is such a course of treatment as he describes practiced by breeders of horses noted for speed? In compelling the queen to fly, he forces her into an act that her instinct tells her is not needed; and if it does her no harm, it certainly is of no benefit.

Again he says: "In the production of colts, bees or anything else that has life, the parents reproduce themselves, and neither the mental nor physical condition of the offspring at birth can in any way exceed the combined condition of the parents." Here his doctrine is not sound, as will be seen by the evidence of Dr. J. S. McAllister, page 264; and also Mr. Geo. E. Boggs, page 150.

That bees can be improved and bred up to a high standard of excellence there is no doubt; for it is being done by some of our best breeders; but the methods they employ are not tossing their queen-mothers up and teaching them habits of idleness and neglect of home duties.

For the American Bee Journal.

The Honey Flora of Arkansas.

A. R. NISBET.

Clark county, Ark., is situated between the mountain and the swamp lands of Arkansas, and boasts of containing some soil as rich as can be found in the Southwest.

Red elm is the first to yield pollen, and it generally blooms about Feb. 1, and lasts one week. If the weather is propitious when it is in full bloom, the bees will gather pollen as well as at any time during the summer. Wild plum and peach bloom about March 5; and bees here generally get a good start in brood-rearing while the bloom continues. Cotton-wood and red-bud greets us in gorgeous robes of various hues about March 25, and bids us get our hives in readiness for the forth-coming swarms. They bloom for a week, and sometimes ten days, after which we have a scarcity of bloom until May.

Ratan is one of our best honey-producing plants. On May 5 is about its average time of beginning to bloom, and it lasts from 10 to 15 days. The honey gathered from it is of a beautiful rich color, and of excellent flavor. It compares favorably with that gathered from linden, but is not quite as bright. The holly opens a little later

than the ratan, but before the latter ceases to bloom; and together they make a honey-flow which is hard to excel.

We very often have a great deal of rain at that season of the year, and sometimes lose nearly all of the honey; but the fault is not in the bloom. At the close of this honey flow, I extract the honey from every comb in the apiary, which has honey enough to pay for the trouble. I do that to keep our nice honey separate from the chincapin honey, which begins to come in about that time.

The honey gathered from chincapin bloom is dark and very strong; and another extracting takes place when it is all gathered. This time I extract only from upper stories and outside combs of colonies in single-story hives.

We are now ready for the linden or basswood honey, and it is generally ready for us by June 10.

I will probably say something in the future about our summer and fall flowers. I would like to meet all the practical Arkansas bee-keepers at our State Fair next fall; also as many from other States as will come. Let us meet and organize that convention we talked of last fall.

Dobyville, Ark.

Read at the Somerset, Me., Convention.

Wintering Bees on Summer Stands.

ISAAC HUTCHINS.

Previous to the last two years I had wintered my bees without loss, and it was by uniting all small colonies in the autumn and contracting the hives by division-boards to the requirements of the colonies, cutting passage ways through the combs, and leaving no combs in the hives that contained less than 3 or 4 pounds of honey, and packing the hive in an outer case or house with chaff or dry sawdust, using a chaff cushion over the frames, and leaving the entrance open $\frac{3}{8}$ of an inch by 5 inches, and not allowing it to become clogged with dead bees or ice.

A year ago last fall, being pressed for time, I neglected to unite any small colonies, or to cut passage ways through the combs; but instead, I placed three sticks, $\frac{3}{4}$ of an inch square, across the frames, so as to give the bees a passage way over the combs. In some of the small colonies I contracted the hive by division-boards, and they came through nicely; but the most of them had the whole hive, and some of the combs contained but little honey, and such combs were, in most cases, in the middle of the hive; and some colonies ate all the honey out of these middle combs and one end of the hive, and died on the empty combs with plenty of honey at the other end of the hive. The entrance was open $\frac{3}{8}$ by 5 inches. Loss, 25 per cent.; cause, starvation.

Last autumn I packed my bees in the same way, only the combs containing the most honey at one end of the hive, and contracted the entrance to $\frac{3}{8}$ by 1 inch. I think 2 colonies died by suffocation from the entrance

becoming clogged, and the remainder by starvation, with plenty of honey in the other frames next to them. In some cases they had passed over and taken a little honey from the top of the comb, and then died with plenty of honey just below them. Loss, 25 per cent. From these experiments I draw the following conclusions:

1. That it is better to reduce the size of the hive in the fall, to the size of the colony.

2. That each comb should contain sufficient honey to last what bees cluster on it, until the first or middle of April.

3. That passage ways through the combs are more reliable in cold weather than any other way.

4. That much open-space above the combs is an injury, as bees will sometimes cluster there in cold weather and starve to death with plenty of honey just below them. I do not think they ever move downwards for food when it is too cold for the cluster to break.

5. That it is better to remove those frames that contain much pollen, in the fall, as it is not suitable food for bees in the winter season, and it occupies room that should be filled with honey; but such combs should be returned to the hive in the early spring, so that it might be used up in brood-rearing before they can get a supply from the flowers.

Wellington, Me.

For the American Bee Journal.

Will County, Ill., Convention.

The meeting of the Will County Bee-Keepers' Association was held on May 26, 1884, at Monee, Ill., and was called to order by the president, A. Wicherts. Secretary Nelson being absent, G. Kettering was elected to that office. After roll-call the President read a brief essay about bees and bee-keepers, which was very interesting. The committee reported a constitution and by-laws, which was unanimously adopted.

The following topics relating to bee-culture were then discussed: 1. "Indoor or out-door wintering." 2. "Is it wise to encourage everybody to keep bees?" 3. "Prevention of robbing." 4. "Transferring bees." 5. "The difference between the bright Italian and the leather-colored bee."

The first topic was then discussed, and a majority of the members concluded that they had better success in wintering their bees in a good, dry, ventilated cellar—especially weak colonies and nuclei. However, several preferred out-door wintering if the bees are well protected.

Mr. C. Schreier's opinion on the second topic was, that every man ought to keep bees to produce his own honey. The prevailing opinion was, though we should encourage all to keep bees, we should tell them not only the advantages, but also the disadvantages of bee-keeping.

Concerning the third topic, the President stated that he had a colony which was robbed. He first put a wet bag on the hive, so as to let the

water drop down in front of it, but it had no effect. He then followed the robbers to their own hive, opened it and disturbed some of their combs to make the honey run out of the cells; this gave them work at their own home, and the robbing ceased.

About the fourth topic, all thought it advisable to transfer bees from all box-hives into movable-frame hives.

The prevailing opinion concerning the fifth topic was, that the leather-colored bee is a cross between the Italian and a dark-colored German bee.

The question about deep or shallow frames was discussed at some length. Mr. C. Schreier is altogether in favor of the Langstroth frame, while Mr. A. Wicherts claim that a short, deep frame would be preferable because bees could have more honey above them, and they would winter better. Bees ought to have honey enough above them where they cluster. But as for handling during the honey season, he would prefer a shallow frame.

Mr. W. Cassens was elected Treasurer, and the sum of 25 cents from each member was collected.

The convention then took a short recess. After resuming business again, several new members joined the association. It was decided that the next regular meeting should be held on the first Monday in September, at 1 p. m., in Monee, Ill. After tendering a vote of thanks to Jos. Jordan, for the free use of his Hall, the convention adjourned.

GUSTAVUS KETTERING, Sec.

For the American Bee Journal.

Increasing Colonies by Division.

J. M. HICKS.

It has been many years since I first practiced increasing my colonies of bees by the above method of swarming, and thus saved a great deal of trouble as well as time in waiting for them to swarm at will; which I think is money to the bee-keeper who desires to prosper in the business of keeping bees for profit.

I am well aware that many object to the management of bees on any other than the old style, and say, "let the bees swarm naturally if you would succeed, as did our fathers;" but I desire different success from that of 50 years ago, when we so well recollect how father, mother, and sometimes grandpa as well as grandma frequently came over to show how to hive bees when they should swarm; and of all the whang-to-bang-bangs and jingling of cow-bells, played so as to get the bees to settle, frequently resulting in a total failure. Often the bees would return to the hive from which they came out, and sometimes going off to the woods, for there was plenty of woods here in the Hoosier State about that time, and were thus lost, or failed to cast a swarm at all.

It is a well-known fact, too well established to be misunderstood by any one except an old-time bee-keeper, that two-fifths of the colonies which are allowed to swarm in the old way,

are lost by going to the woods. While it is a well established fact to the more modern and scientific bee-keeper that a swarm produced by dividing a colony, at the right time, there will be no trouble about losing a swarm, or having them come out and leave the hive.

I think that it is much easier to swing the brood frames out and select such of the brood as is fit for putting into a new hive of the same shape and size (which they should all be); thus making up your new colonies in five to ten minutes. This should be so managed as to come as near to the time when the oldest of the brood would have swarmed had they been left to luck and chance.

But says one old fogey, "How are you going to do all this and not let the bees swarm in the old way?" Truly, this old question is a poser to us; but we must make ready one of our improved hives, just the same as all the bees are in, and we set it by the side of the hive of bees that we think is ready for dividing. We now swing the doors open and take out a frame from the middle of the new hive, then open the strong colony of bees, and swing the brood frames apart carefully, and we find the frame on which the queen is situated. Perhaps she is laying eggs at the rate of a hundred per hour; but we now lift the frame of brood, queen, and adhering bees on the same, and hang it in the new hive in place of the frame just taken out, and then hang the new frame in the old hive, and close up both hives carefully.

Put the new hive with the frame of brood, bees and queen, in the same place where the old hive stood, and move the old hive some distance off to a new location. Now, the work is done, the old colony which would have swarmed, returned to the new hive at the old location, thus strengthening them, and goes to work with a will, already having one sheet of brood, eggs, and the mother-queen as a start in house-keeping.

Battle Ground, Ind.

☞ Cook's Manual in cloth and the Weekly BEE JOURNAL for one year will be sent for \$3. Manual and Monthly, \$2.00. We have no more of the old edition left, and, therefore, the club price of that edition at \$2.75 and \$1.75 is withdrawn.

☞ Do not let your numbers of the BEE JOURNAL for 1884 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

☞ Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

SELECTIONS FROM OUR LETTER BOX

Honey-Dew.

There is a dearth of bloom here at present. The first few white clover blossoms just making their appearance. Yesterday I noticed that the bees were working rapidly, darting away with a jump from the entrance, and upon returning they entered at once—there was no loitering. I knew honey must be the field, and I went to find where it could be. I found the bees busily at work on the leaves and some of the twigs of the maples. I send a sample of leaves and twig. There is a sweet substance on the leaves. Is it honey dew? The bees were sucking around the little wart-like protrusions on the twig. What are they? Please answer in the BEE JOURNAL.
 W. B. DRESSER.
 Hillsdale, Mich., June 2, 1864.

[Yes; it is what is usually called "honey-dew"—which is reported to be quite plenty this season. It is the excretion deposited on the back of the leaves by small insects called aphidæ or vine-fretters. The fecundity of plant lice is almost incalculable. Reaumur supposes that in one year there may be 20 generations; and he has proved by experiments that one of these insects may be the parent of 5,904,900,000 descendants during its life.—ED.]

Honey from White Mustard.

I lost quite a number of colonies in wintering. The honey they gathered late last fall was not good, I think; for it was those which died that fed on late honey; and those which had early spring honey came through in good condition and are doing well now. They have been working on the white mustard bloom for the last two weeks, and some of it has bloom over 8 inches long. It grows about 3 feet high, flourishes best on cultivated land, and is a sure crop twice a year—once for a June, and the next for a

fall crop. I have also a fine lot of Rocky Mountain bee-plant for the bees to work on during July and August. It is a sure crop any where. If sown in the fall it yields fine honey, and keeps in bloom for a long time. My cure for bee stings is alcohol. I always keep a small quantity in the bee-yard and apply a little to the part stung when it prevents any swelling whatever; but I find what will cure bee-stings on one bee-keeper will have no effect on another.

JAS. JARDINE.

Ashland, Neb., June 9, 1884.

Good Work.

The season, although cold till within a few days, has been very promising with me. By slight feeding every night, brood-rearing has been fully kept up, and my colonies are now in No. 1 condition. During the week ending May 31, one colony of pure Italians gathered 72 pounds of honey from apple bloom; and the other colonies produced an average quantity. The prospect is fair now for a good yield from white clover; still we may have it spoiled by a drought. So far in June the weather has been very warm.

J. E. POND, JR.

Foxboro, Mass., June 7, 1884.

Damaging Floods in Texas.

We are having too much rain for bees or anything else. Such floods were not seen here since the days of Noah. Thirty-two inches of water fell in 16 days; and 20 inches of it fell in 48 hours. The farms are washed away, crops are badly damaged, and millions of dollars worth of property destroyed. Railroad bridges are all gone, and the mails are slow. Horse-mint is now blooming, and if we can have nice weather, we will get a fair honey crop this year. I have been looking for a report in the BEE JOURNAL of the Texas Bee-Keepers' Association, as it was selected as the bee-paper in which to publish the proceedings. Seventy-one full colonies and 100 3-frame nuclei is my report now.

B. F. CARROLL.

Dresden, Tex., June 4, 1884.

[The report you mention has not, as yet, been received.—ED.]

A Great Loss.

Owing to the extreme drouth of last fall in this section, a large number of colonies of bees starved to death during the past winter and this spring. What few colonies are left, unless they were fed early in the spring, are still weak. White clover was never better. Strong colonies are doing splendidly at present.

WM. ROBSON.

Rolla, Mo., June 9, 1884.

Good Results in Wintering.

My 101 colonies of bees were left on the summer stands, and were fixed up last winter simply by placing sticks across the holes of the tops of the close-fitting 12x12 frames, tucking quilts over the same, contracting the

entrances to the hives, and thus severely letting them alone until May 1. The result is: 95 colonies are in excellent, active condition; 6 died from being out of stores. I do not use the extractor, but work my bees for comb honey exclusively. I feed them no "slops," but winter them on the best ripe, sealed honey. I use no chaff or double-walled hives, and have always succeeded in wintering bees with but little mortality, and to my own entire satisfaction.

H. S. VAN ANGLIN.

Waverly, Mo., June 9, 1884.

Those Trembling Bees.

On page 364 of the BEE JOURNAL, a correspondent writes about trembling bees that are killing off small black bees. I have a colony that has been acting in a like manner for a fortnight. I opened the hive and could see these shiny blacks among the Italians on the combs. It appears to me that these little shiny ones originate in the colony which is infested by them. In the Dictionary of Practical Apiculture, recently issued, I find the following: "Robber bees that have lost their hair, and become black and shiny, were supposed by Huber to be a distinct kind of bee; and in several works they are mentioned by the name of black bees." I caught a black one, a few moments ago, and tried to make it sting, but it did not. I tried the same experiment before, and the bee made a very feeble attempt at stinging. I saw the same thing several years ago. The colony thus infested is quite populous, and apparently all right. The query is: Where do the trembling Italians and shiny blacks come from? If they are robbers, why do they not attack weak colonies? Why persist in attacking a strong one for weeks? And, what makes the Italians tremble?

MRS. L. HARRISON.

Peoria, Ill., June 10, 1884.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Fastening Foundation in Sections.

Will Mr. Heddon describe as explicitly as possible through "What and How," the manner of using the Parker foundation fastener?

MRS. E. L. SWARTWOOD.

Clearfield, Iowa, June 3, 1884.

ANSWER.—Yes; and I shall be glad to do so. In my estimation this fastener will never be equaled by any other that does not have the sliding-back movement, and any that does is a Parker fastener, is it not? When these machines are turned out from a manufactory, they are not fitted up. The receiver must adjust the screws (if they need it), and see that the bearing is equal on all sides and corners; that the section-rest is added

to or taken from, in accordance with the width of the section. You should have a little board, say 6 or 8 inches square, nailed in front of the fastener as a rest. The fastener is, of course, screwed fast to a solid table or bench. Tack rests on this little board near the fastener, to guide the section quickly to place, and keep it from moving to the right, left, or from you.

We have also made "ways" or guides for adjusting the side-wise position of the sheet of foundation. We also may have one to adjust its position regarding the amount of wax we mash down, provided that the pieces of foundation are all of one size. We do not value the "ways" for the foundation very highly, and seldom use them, as our eye and nerve adjusts it very quickly without any guides. See that the edge of the upper piece that does the mashing is coated with honey every few sections. Have the honey diluted about half-and-half with water. This honey can be applied with the fore-finger, or a little stick. After a while the fastener will not stick if lubricated every 20 or 30 sections. Set it so that the edge of the masher will over-reach the centre of the narrow piece of the section about 1-16 of an inch when pushed down and forward all it is capable of reaching. Then having the section and about $\frac{1}{8}$ of an inch margin of the foundation under the masher, lift up on the lever quickly and powerfully, and the foundation is fastened much firmer than can be done by melting it on to the wood. After all this talk about a 25-cent machine, I presume that it is still not clear to those who have never used one.

Establishing Apiaries.

1. I am establishing two new apiaries of 75 colonies each, and wish to ask Mr. Heddon whether the apiary grounds should be sown to lawn grass, white clover, or what?

2. How near to the apiary should the honey-house be, and on which side? or should it be in the centre?

3. How far apart each way should the hives be placed? and should the apiary be hexagonal in form?

4. Is sugar syrup equally as good as honey for brood-rearing?

F. M. CHENEY.

ANSWERS.—1. The color, green, is best fitted to the eyes. On some other accounts the lawn grass is best of any thing for an apiary carpet. Where there is no special danger to be apprehended from fire, I prefer the ground perfectly clean from all vegetation, and covered with 2 or 3 inches of sawdust, and kept so with a basket and hoe. Next to this I choose the lawn, and in that case I desire the sawdust about and under the stands of the hives, for it is very difficult here to keep down the grass too close to the hives to use the scythe or lawn mower.

2. This depends upon the amount of natural swarming expected. Where there is but little, I prefer the honey-house in the centre of the apiary; where there is much, I wish it at one

side. In this latter case, your bees cannot swarm "over on the opposite side of the house" entirely, or, for some time, unobserved. It also enables you to drive close to the house. If you are running for extracted honey, the central location has more advantages than if running for comb. I would decide according to the above conditions.

3. I prefer rows about 6 to 8 feet apart, and the hives placed about 8 to 10 feet apart in the rows, alternating with each other thus:

and all fronting the east. I should care nothing for the form or outline shape of the whole apiary, which would most economically be square and filled with hives. I prefer and use a high board fence all around the apiary, and two strands of barbed fence-wire just above this.

4. I think not, for the same reason that it is so much better winter food. It lacks the nitrogenous element which clogs the intestines of the old bees during cold and confinement, and which is so eminently adapted to the growth of animal tissue, as in case of brood-rearing, where the bees can gather plenty of pollen, with that it works nicely; but when pollen is scarce, I should prefer honey.

Apiaries near Highways.

1. How near to the road can an apiary be located without danger to the traveling public?

2. Does the law establish the distance bees should be kept from the highway?

3. If the bees should attack a team in passing, and cause them to run away, resulting in injury to themselves and driver, would the apiarist be liable?

4. How near to the road are your bees?

CHAS. SITTS.—18.

Brasie Corners, N. Y., June 3, 1884.

ANSWERS.—1. The actual distance depends upon two conditions: the disposition of the bees, and what fixtures may be between the road and the bees. I never had any trouble with a large apiary 3 rods away, with a tight board fence 6 feet high between.

2. I am not aware whether the law of any State does, or does not.

3. I feel quite sure that he would, if it was evident that the attack came about because the bees considered the team too close to their home and stores; for in that case the apiary is too close to land not owned and controlled by the apiarist.

4. The fence (8 feet high) of one of my apiaries is on the road line, but the bees therein, from breeding and management, are but little inclined to sting, though they are nearly all hybrids. The last time I was there, I led my horse twice through the apiary, close up to several of the hives, when the horse was warm, the day hot, and the bees were robbing; but he received no stings, though I knew we were taking the risk of a javelin. but

one would not have done much harm. My other apiary here is away from all other lands.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
Monday, 10 a. m., June 16, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for all honey is very slow; market dull and prices range from 6@9c for extracted. Different lots of choice comb honey in small sections have been offered and sold in our market lately at 12@14c per lb. As I predicted some time ago, the preference for the production of comb honey seems to be prevalent; and, as we have the best prospects for an abundant harvest this year, we may prepare for low prices.

BEESWAX—Is in good demand; choice yellow brings 35c a lb. on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—Present quotations are as follows: Fancy white in 2-lb. sections, glassed, 13@14c; fair to good in 2-lb. sections, glassed, 11@13c; dark grades in 2-lb. sections, glassed, 10@12c. No 1-lbs. in this market.

BEESWAX—Scarce, and sells readily at 36@38c. MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15c, and 2½-lbs. to 2½-lbs. from 10@12c. No 1-lbs. in the market. Extracted, 8@10c.

BEESWAX—35c.

BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—Choice white comb honey in 1½ lb. sections brings 18c; in 1¼ to 2½ lb. sections, quotable at 16c. Comb honey discolored and in undesirable shape is selling at 10@12c. Extracted honey is in light demand at 6@8c. Manufacturers of syrups and bakers say that the low price of sugar is the reason why they do not use as much honey as formerly. There is very little desirable comb honey on the market.

BEESWAX—In scarce and fancy yellow brings 35c. Good beeswax, but dark, and having more or less of refuse matter in it, quotable at 30@33c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—A little new extracted is on the market, but is not receiving much attention, buyers being rather timid. Several small lots of old extracted arrived within the week, mainly of quality, and the same are offering at low figures. Some very choice old extracted was sold at 7c, which is at present an extreme figure. The demand is very light, and the tone of the market weak. White to extra white comb, 15@18c; dark to good, 10@13c; extracted, choice to extra white, 6@7c; dark and candied, 4@5c.

BEESWAX—Wholesale, 27½@30c.

STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—The season has now practically closed, little or nothing being done in comb honey, and prices entirely nominal. Extracted quiet at 7@8c. One lot, about 5,000 lbs. new honey, received from the South this week, and partly sold at 7c. It is dark but of fairly good flavor.

BEESWAX—I have a little that I am holding at 35@40c, according to the quality.

JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@8c.

BEESWAX—Firm at 32@32½c. for choice.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1 lb. sections at 18c; 2 lbs. best white not quite so active at 17c; 1 lb. sections sell quickly on arrival, and often are sold to arrive. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.

BEESWAX—Scarce at 35c.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 18@20c; extracted, 7½@8c.

GEO. W. MEADE & CO., 213 Market St.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Convention Hand-Book.

It is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

What they Say of it:

From Prof. A. J. Cook, Lansing, Mich.—"I have greatly to thank you for getting up the exquisite little 'Convention Hand-Book.' Surely the old 'saying' is true—being a thing of beauty, it ought to be a joy forever."

From Mr. A. I. Root, Medina, O.—"Send me —dozen of the Convention Hand-Books. We have had quite a number of inquiries for something of that sort, and yours seems to be quite nicely gotten up, and just what is wanted."

From J. E. Pond, Jr., Foxboro, Mass.—"The Convention Hand-Book is just the thing. The digest of Parliamentary Rules it contains will prove of great value to every one. I trust it will receive the patronage it so well deserves."

From Mrs. L. Harrison, Peoria, Ill.—"The Bee-Keepers' Convention Hand-Book is a gem. It should be in the hands of every one who attends a bee-convention, and then there will be no need of embarrassment on account of ignorance of Parliamentary Rules. Accept my thanks for sample sent."

From G. M. Doolittle, Borodino, N. Y.—"I am in receipt of the new Convention Hand-Book, and must congratulate you on the happy thought of such a work, and the neat appearance of the book. It is a work you may well be proud of, both as to the matter it contains, and the splendid material used in its make-up. It will meet a long-felt want; and, were it so that I could attend conventions as in former years, ten times the price would not seem too much to pay for it, for by the instruction therein given, any man could be kept from many a blunder, much to his mortification. I hope in the near future to again be at liberty to go to conventions, when I shall prize the work very highly."

James Heddon, Dowagiac, Mich., writes:—"The Bee-Keepers' Convention Hand-Book is received. I saw it advertised, but conceived no approximate idea of its great value to bee-keepers attending conventions, until I perused it. Many times the price of my copy would be no temptation for me to do without it. It will make us all want to talk at once, I fear. You deserve the thanks of all, and I herewith tender mine for this helper."

EXCELSIOR WAX EXTRACTOR

The advantages of this Extractor are :

1. It is more easily operated, there being no necessity for removing the top to refill with water.
2. It melts quicker, because the wax is brought into a more direct contact with the steam.
3. It is more economical, because the steam has access to the center, thereby extracting all the wax from the refuse matter.
4. The filler for water acts also as an indicator as to the amount of water in the boiler, as when the steam escapes through the filler, more water will be required.

Keep a kettle of hot water ready to fill when required. We make two sizes, the smaller one having a larger capacity than the Swiss Wax Extractor.

Price, small size, \$4.00—large size, \$5.00.

BEST GIVEN
COMB FOUNDATION.

Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8¼x16¼, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

One Hive complete for comb honey...\$3.00

(The above will contain two cases complete with sections).

The above Hive complete for extracted honey.....\$3.00

The above Hive complete for both in one..... 4.50

One Hive in the flat..... 2.00

Five or over, each..... 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4¼x4¼x6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

STUDENTS OF APICULTURE

Will receive terms for 1884 on application.

Sixth Thousand Just Published!

New and Enlarged Edition
OF
BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure.
T. F. BINGHAM.
Abronja, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.
H. H. BROWN.
Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ills.

A Liberal Discount to Dealers by the Dozen or Hundred.

WE CALL

the attention of all wanting A No. 1 BEES, Italian, Cyprian or Hybrids, to the following, from one well-known to the readers of this Paper:

"I have never seen a case of foul brood; my bees are entirely healthy, and have always been so, and are O. K. in every respect."
GEORGE B. PETERS, M. D.

We can furnish any number of Colonies of the above Bees, and will warrant safe delivery and satisfaction.

N. B.—No Bees will be sold by us, for any consideration, from any apiary that has ever had a case of foul brood in it. For prices and particulars, send to

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.

VALUABLE ORIGINAL PATENTS.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

BOOKS!

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates on larger quantities, given upon application.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects: Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quieting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, in cloth, \$1.00; in paper covers, 75 cents.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premium for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey! by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-Keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees,—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bienen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY ALLEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way to rear Queens, etc. Price, \$1.00.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either English or German.

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 15c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XX.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Honey and Digestion.

"All foods," says an exchange, "if not already soluble (meltable) in water, have to be so altered within us that they become dissolved, and we call this solution, digestion. Starch, for example, which forms five-sixths of our daily bread, is utterly ineffectual to use while it remains as starch, because of its insolubility; but in the act of chewing, the saliva which we add to our bread begins to convert the starch into a sugar (very much like to the sugar of honey), and so renders it soluble in order that it may in due course be carried into our blood, and there do the work of giving us power or heat. Cane sugar, in like manner, although soluble, requires alteration, and this alteration is also brought about by contact with the saliva, and the result is a sugar, as in a previous case, nearly identical with the sugar of honey. Honey, on the contrary, or the sugar that we find in grapes, is *already* in the condition for absorption or assimilation, and really no kind of work has to be performed upon it before it is actually rendering us service as a force, or heat-producer." Honey is, therefore, given to mankind, in the most agreeable form, both for food and medicine. It produces healthy digestion, and holds defiantly that monster of torture, indigestion, at bay. Pure honey should be used freely in every family. Honey eaten upon wheat bread is very beneficial to health.

Children would rather eat bread and honey than bread and butter; one pound of honey will reach as far as two pounds of butter, and has, besides, the advantage that it is far

more healthy and pleasant to the taste, and always remains good, while butter soon becomes rancid and often produces cramp in the stomach, eructations, sourness, vomiting and diarrhoea.

Digestion (all-potent in its effects on the mind as well as the body) depends largely on the food. Poor food received into a poor stomach is the cause of many unhappy homes—while good, healthy food, received into a healthy stomach, becomes "an Angel of Peace" to many a household.

Docility of Cyprian and Syrian Bees.

A correspondent in the *London Journal of Horticulture*, when writing about controlling Cyprian and Syrian bees with smoke, remarks that they cannot even *smell* it or be jarred without making them irritable. If they are kept from smoke and handled gently, and the hives are opened only when the sun shines, he claims that they are perfectly docile and gentle; and that those who have found occasion to condemn them on account of their irritability, have been dosing them with smoke or handling them without care. As proof that his theory is correct, he says that "Mr. Benton in Cyprus had 500 colonies placed round his house, on the veranda, or anywhere where they could stand. One hive in particular was so placed that it had to be passed within 2 feet from the entrance scores of times each day by every visitor or inmate; and though Mr. Benton was working amongst them from early morning to late at night with no protection whatever, save a hat, shirt, pants, and slippers, no one was ever stung, and he very rarely. We have Mr. Blow's authority for saying that he saw Mr. Benton open hive after hive without veil or gloves, and none ventured to sting." Possibly this may account for the many conflicting opinions given by our American correspondents relative to the Cyprian and Syrian bees, and their irascibility.

Let some who have these bees in their purity, try it and report the result.

This writer approves of the crossing of Cyprian queens by Syrian drones, and then says that "it is only by crossing these foreign bees that we may hope to produce superior varieties. It has been done in every other branch of the animal and vegetable kingdoms, and why not with bees? for with all their virtues—which should make us more anxious to improve them—they are only wild bees we are cultivating at present. Cyprus gave us the cauliflower, and who would recognize the original in the immense varieties of broccoli and cauliflower, or would banish it from our gardens? And may not one or all of these bees produce a breed of bees as distinct and valuable to the present as the Magnum Bonum potato is to its first parents? Let us go about this matter in an intelligent manner, each adding his mite; and for the present those who want a good crop of honey and plenty of bees in the spring to fertilize their abundant fruit blossom, I would advise such to try the first cross of Syrians with pure black drones." With this idea in view, "crossing" is now being done largely in America in the hope of producing "the best bees in the world."

The Honey Season in Cuba.

Mr. A. W. Osburn, S. Miguel, Cuba, W. I., writes thus on June 14, 1884:

We are in the midst of our wet season. The wet season here differs from anything of the kind I have ever seen in any country. It is a succession of showers, then bright sunshine, and then more showers and more sunshine. And, of course, as this is a tropical climate, the rain is warm, and vegetation of all kinds grows wonderfully fast. The flowers thrive and bloom; thus furnishing plenty of feed for the bees; but the honey flow is not extravagant, the honey is not light in color, and its flavor is fair. After being here 9 months, I conclude that the main honey harvest is in the winter months, and then it is a harvest indeed, by far excelling anything I ever witnessed in any country.

Call Things by their Right Names.

Some time since Mr. D. K. Boutelle sent us the following criticism on this subject:

I was much interested in the Editor's remarks under the above caption in the BEE JOURNAL of Nov. 28, 1883. In his treatment of such expressions, as he "wintered" his "stands in the cellar," "they came out in bad shape," etc., he indicates clearly that, so far as possible, we ought to use terms or words in such a way as to correspond with their usual or dictionary definitions.

This, I think, is right, and that it is an important point to consider in establishing nomenclatures for apiculture. When we have anything so new that there is no convenient term to express it, then it will be time to coin a new name; but do not let us attempt to apply new definitions to old words. If it is done, it seems to me it would tend to confuse.

While we are about it, is it not better to adopt a vocabulary of bee-keeping terms, somewhat in harmony with a standard dictionary rather than in violation of it? With this idea in mind, I wish to offer a little friendly criticism on two of the terms put forward by the Editor.

He says: "A colony of bees is an organized body of bees," etc., "improperly called a swarm," etc. Webster defines colony thus: "A company or body of people transplanted from their mother country to a remote province or country, remaining subject to the mother country." This definition of the word colony is fully explained in Johnson's cyclopaedia. It says: "The settlements of the barbarians who destroyed the Roman Empire were not colonies, for the tribes were not connected with any parent State."

Now, in what one particular does a body of bees which emigrates from a parent hive, and becomes settled in another hive, correspond with these definitions of colony? Not one; unless it be that bees may be called a people. They are certainly under no allegiance to, or protection by, and have no connection with the parent hive or body. The term colony, seems to me, is about as inappropriate a name as could well be applied to them.

Again, he defines "swarm of bees" thus: "Bees issuing from the parent colony for the purpose of increase." 1. Does the purpose for which bees issue from a hive make a swarm of them; or would they be a swarm all the same if they swarmed out for some other reason than increase, as they sometimes do? 2. Webster defines swarm in this way: 1. "A large number of small animals or insects, especially when in motion. 2. Any great number or multitude. 3. A body of bees that emigrate from a hive at once; or a like body of bees united and settled permanently in a hive."

Here then, it seems, is a name that, so far as dictionary-meaning is concerned, is perfectly appropriate for a body of bees which inhabit a hive; and one, too, that has long been in

use. There may be reasons why some other term may be more convenient for bee-keepers. The word being used also as a verb may be thought to be liable to confuse; but does not the use of proper articles sufficiently indicate when it is used as a noun? To me, *swarm* seems far preferable to *colony*.

What, then, shall bee-keepers adopt as a convenient and appropriate name for a family of bees? I do not know. Let all bee-keepers suggest until we find the right or best one. If our language does not contain a word more appropriate than colony, then let us make one. As my suggestion, I would say, family; if there is no better. What are the objections to it? and who will offer a better?

I wish we had a truer name for the mother of a family of bees, than "queen." She is no queen in any true sense of that word. She is neither the wife of a king nor the ruler of a people. She is simply the mother-bee, and I wish that were her usual appellation.

Lake City, Minn.

Mr. Boutelle's desire for the word "mother" to supersede the word "queen," is quite reasonable. The mother bee is not a queen; but a difficulty is encountered at the very start, by the fact that two words are needed instead of one. The word "bee" is a necessary adjunct, making the name "mother bee" which is long and rather objectionable on that account. The word "queen" is more elegant as well as more ancient.

But on the use of the words "colony" and "swarm," we beg to differ from him. Personally we do not like the word "family" as a name for an organized body of bees. The "mixing up" which is so often occasioned by using these words interchangeably, is apparent in the necessity of saying the "old swarm," the "new swarm," the "parent swarm," or the "swarm that gave off a swarm," etc. In the foregoing, our correspondent realized the difficulty, and in the 9th line of the 5th paragraph, he used the words "parent hive." The hive is the box containing the bees—was the box the parent or mother of the bees? Such an idea is too absurd for even a passing thought.

We are hopeful that the new "Dictionary of Apiculture," by Prof. Phin, will greatly assist in the use of correct terms by apicultural writers.

We regret to announce that the Rev. L. L. Langstroth is still suffering from his old malady, at his home in Oxford, Ohio. The sympathy of thousands of bee-keepers all over the World are with him in his affliction.

The Season in England.

A correspondent of a London paper gives the following description of the season in England, with reference to the Bee and Honey interests:

So far this year the bees have had a hard struggle to exist. The year opened favorably on them with less mortality than ever I experienced. Large patches of brood were in every hive during January, and breeding was unremittingly carried on throughout the cold winds of that month. Many young bees were flying in February. Flowers and sunshine came with March, and good colonies collected much pollen from the crocuses, willows, tussilago, etc. Many colonies were then advancing rapidly, and were well forward, promising early swarms. April we welcomed, but it brought thunder, snow, and frost of unusual severity—bleak cold weather, with scarcely a ray of sunshine to gladden us. This lasted until May 23. Flowers had almost disappeared; those not destroyed looked sickly, and dead bees strewn on every path. Colonies that looked like swarming seven weeks ago, have made no progress, while many that by this time, with mild weather, would have been strong, are so reduced in bees that they will be unable to do more than keep themselves alive. Our locality is, however, not a sheltered one; there is a paucity of trees in the district, arising through proprietors of small estates cutting down every tree that can be turned into cash, and the ground they occupied made available for cultivation.

Putting Honey on the Market.

In one of our exchanges we notice the following on marketing honey:

Many bee-keepers err in putting their honey upon the market too early in the season and at too low a price. After reading a few encouraging reports in the bee-papers, they fear that there will be a glut in the honey market, and, in their efforts to secure the highest price by rushing their honey into the market before there is a demand for it, they often get the lowest price and help to spoil the market for others. Until the fruit season closes, the demand for honey is light, and bee-keepers should govern themselves accordingly. The honey should be well graded, put up in the most attractive packages possible, well taken care of, and placed on the market when there is a demand at a remunerative price, and not before.

This "advice is good and timely," and we hope will be heeded by the inexperienced, so as not to spoil the market for their more experienced neighbors. The markets are now bare of comb honey, and the demand will be good, and prices fair for the first marketed. Do not rush too much on the early market to spoil it.

For the American Bee Journal.

The Bees are Swarming.

ALICE WAVERLEY.

"Hurrah! hurrah!" came the father's voice.
From the onion-bed down by the peas.
"The bees! they are swarming! so hurry out quick;
Hurrish! don't you hear them—the bees?"

"Now, where's my old bucket, and where is my
stick,
And what makes ye all so slow?
If ye don't hurry out and rattle them quick,
They'll be off to the woods, I know."

There's a hurry and scamper for bonnets and hats,
A looking for kettles and tins.
Then out we'll all go, and stand in a row,
All ready to rattle them in.

Mother stands under the round apple tree.
The fire-shovel and poker are doing their best;
She must keep well out of the reach of those bees,
Or a swelled face, for days, to their skill would
attest.

Father stands under another old tree,
His face well hid in its sheltering leaves;
While he hammers away with bucket and stick—
He's doing his duty in settling the bees.

From the back of the vineyard there comes a faint
sound.
Like the tinkling notes of some far away bell,
"Tis only the echo of Maggie's tin pan—
She cannot get stung, I think, very well.

Kit has a milk-pan, wide over and roomy;
But it sends out a very good sound "for a' that."
And should the bees gather too near for good
manners,
This pan serves the place of a shield, or a hat.

Fannie goes flitting now here, and now there,
Down through the vineyard, then over the fence;
Through uncle Jim's garden she treads with great
care—
If they don't get away, she'll make fifty cents.

"Tum-dum, tum-dum!" goes the stick on the
bucket.
This "old oaken bucket" serves for hass in the play.
"Ting-a-ling-ling," goes Fannie's old pendulum
now.
*As with the wire poker she hammers away.

Well, well! after spending an hour, or so,
In climbing, and jumping and skipping around,
Going backward and forward, then in, and then
out—
They're now going to settle, I think, by the sound.

There! now they have lit on a tall apple tree.
And some one must hurry the ladder to get;
And the barrel and board, with the watering-can,
The smoker, the feathers, the hat with the net.

Outside of the fence stand our cousins and neigh-
bors.
For "distance lends charms" when the bees are
about.
And no one is anxious to get very near them,
For fear some stray skirminer might find them out.

"Now Fannie!" calls father from under the tree,
"You take up my grape-hoe and give them a shake.
When I call out *ready*, you just pull away,
And short work we'll out of them make.

"All ready!" a shake, and—"run, Daddy, run!"
For the bees fall on him, instead of the hive;
A moment's confusion, but no one was hurt,
And straight for the branch with the Queen do
they dive.

"Ah, sure, we must try some other new plan—
We never can shake them down, I see.
Some one must saw those branches off,
So I'll take the ladder, and climb the tree."

Down came the branches one by one,
Up go the bees as the branches fall.
"Now, if we don't try some other way,
We never can have these bees at all."

In the midst of our flurry, home comes John—
Runs up the tree—quick as a flash, you know;
Cuts off the branches, and carries them down,
Straight into the hive every bee will now go.

At last they're all in and the racket is over;
And the hive is put down in a row with the rest.
Like the hull after storm, our excitement has ended,
And each one thinks—"I was the one who did best."

—Macomb, Ills.

For the American Bee Journal.

Winter of 1883-1884.

JAMES HEDDON.

Last autumn I found that my home apiary contained 336 colonies of bees. Most of these colonies had been worked, during the preceding season, upon a plan adopting some new methods destined to bring them out at the close of the season with as little honey and bee-bread in their combs as possible. Though the season closed very much against such a result, still our hearts were gladdened to find on an average not half the usual amount of either.

The honey was stored above, and the pollen not at all. To these colonies we fed 11 pounds of granulated sugar made into syrup, which made on an average about 10 pounds to each colony, as about 70 colonies received none at all. The ones which were fed, received on an average of about 12 pounds each. We wintered them out-of-doors, both with and without protection, and about 30 colonies in the cellar. All except about 12 colonies of those out-of-doors were packed.

When all were prepared, I said to the assistants, "Now, for the first time in my life, I hope for a trying winter for bees." Well, in fact, we had such a winter. The confinement was not very long, but the cold weather was quite steady and severe. Judging from 15 years of experience and observation, I should have expected a loss of at least one-half of all my colonies had the usual amount of pollen and honey alone constituted their winter stores. Such, however, were not the condition of the colonies. Even those which were not fed or specially manipulated during the preceding honey season, had less bee-bread than usual; and those which were fed, I think I am safe in saying, had not one-fourth as much bee-bread as the others. I lost about 30 colonies by diarrhoea; but I think none in the cellar had it.

Taking the reports of all, I think statistics show that cellar wintering is the safest method. It is clear to me that when cold is the greater auxiliary to the cause of diarrhoea, bees in cellars come out best; but when confinement is its special aid, then out-door wintering is ahead.

We prepared 45 colonies without a cell of pollen, and about 25 of them without one drop of honey, while the other 20 had practically none or only a little in the out-corners of an occasional comb. These 45 colonies we fed liberally with the sugar syrup. During the examinations in early spring, the first cover I raised, my assistant exclaimed, "O! what little lean looking things!" We had previously been overhauling a few sick colonies, and many in comparatively good condition; but all whose hives contained mostly natural stores, had distended bodies. Did I say all the 45 wintered well? No, they did not. All were in perfect condition except one, which died—and that died with diarrhoea. As I raised the cover, I said to my foreman who superintended

the fall feeding under my directions, "Here is one of our non-pollen colonies dead; and died with diarrhoea as sure as you are born." I lifted a comb from near the centre of the cluster, and up came a little brood and a comb nearly half full of bee-bread. "Why! what is this?" said I. "O! this is my fault, Mr. Heddon," said the foreman. "I remember that in this one hive the queen bred very late in the fall, and this comb had a patch of sealed brood nearly as large as my hand, which I left to hatch out, determined to remove it in a few days, which I forgot to do."

The above are a few of the facts regarding last winter's experiments and the results, as witnessed by myself and my foreman, Mr. William Stolley.

We are so well convinced of the correctness of the pollen theory; *i. e.*, that floating pollen in the honey or bee-bread, or both, if consumed during confinement, is the direct cause of bee-diarrhoea, that we are laying our plans to henceforth prepare our bees for winter in accordance with that theory. As the reader will naturally suppose, after the discovery of certain facts, causing disease, and consequent methods of prevention, comes the best, cheapest and most practical methods of bringing about preventive conditions.

This we are and have been, for the past year, studying and also experimenting upon. That bee-culture of the future, which will not move off readily and practically with a business-like speed, will be forced to succumb to the survival of that which will. We do not propose to dig the bee-bread from the cells with tooth picks; we do not propose to remove it by removing the combs containing it; but we do propose to prevent its being stored in any considerable or dangerous quantity. Again, we do not propose to extract natural stores after the flow of honey has passed; but we do propose to prevent the existence of stored brood-chambers at the end of each year's honey flow.

That it can be done, we have experimented enough to become convinced. The next question in the wintering problem, will be: "Now that I can winter my bees with success, how can I do it with the least capital and labor?" We have ideas which we believe are correct regarding these points, which we shall write upon in the future.

The reason why I have delayed this report is, that I might be able to report the standing of these colonies which could not and did not hatch an egg till they gathered the pollen of 1884; while some other colonies began breeding in February. My foreman and students have examined them carefully, and report that if any difference can be detected between them and the other colonies which began to breed nearly two months earlier, is, that these conservative ones are now the strongest in bees and brood. This is just what I should expect.

I have for several years claimed, against the clamor of our ever-present corps of inexperienced apicultural

writers, that "spring dwindling" is "diarrhœa in disguise;" that no apiary would ever suffer from it if the colonies were well wintered. Our opposition accredited it to disagreeable spring weather, cold winds and shady dells. Here they made the same kind of a mistake that they have made regarding the true cause of diarrhœa. Their supposed prime cause are only helpers or secondary causes.

The present spring has been one of the most trying as far as bad weather being a cause of "dwindling"; but throughout all the regions where bees wintered well, no "dwindling" has occurred. I have looked upon this wintering-problem without prejudice, and I have little reason to entertain any. I am more fully persuaded that the "pollen theory" is the correct one. I will not take more space to describe the various plans of packing and ventilation used in this apiary during the past winter, as none of them, or the lack of them, prove to be a cause or a prevention of diarrhœa.

The other apiary was not mine till last March. Years ago sugar was found to be a much better winter food than honey. The reason why it was such, was not understood. Had it been clearly known, sugar, as a winter food, would not have been discarded; because, in some cases where it was fed, the bees died of diarrhœa by eating the bee-bread from the cells adjoining those containing the syrup.

Dowagiac, Mich., June 9, 1884.

Read at the Maine State Convention.

The Principles of Protection.

L. F. ABBOTT.

No one need get fidgety; it is not based on the political bearing of tariff protection, as the first thought might naturally suggest. I am a believer in protection, however, in every sense of the word, and especially where the rights of the farmer or the farmer's bees are concerned—the latter of which more directly concerns us at the present time. It is not my purpose to discuss each point exhaustively, but rather to introduce propositions which seem to me to be established as facts, and leave the discussion of the various points to wiser, if not older, heads.

Proposition 1:—The meaning of "protection." Not to be too critical, we will declare it to be, guarding against extremes of temperature both in winter and summer. Protection may be afforded in various ways at both seasons, but all forms may not be equally efficacious in accomplishing the desired end. We may use single-walled hives loosely constructed, for our bees, then leave them out-of-doors through the winter months, placing a few evergreen boughs or corn-stalks around the hives, and call it "protection;" and it would be, but I think not the best kind. We can also use such hives as I have named, and place the bees in a

good cellar, and call that "protection;" and this I have often done with good results; but neither of these ways, I am convinced, is the right kind of protection for bees.

Protection then, is something more than guarding against cold; it protects from cold, from humidity, from sudden changes induced by atmospheric influence, and also prevents the production and retention of deleterious gases and other influences incident to non-ventilation.

Proposition 2:—"Why is protection necessary?" Our bees are subject to unnatural conditions in the frame hive. To explain: Bees left to follow their own course seldom fill the hive with uniform straight combs. This change has been brought about by the skill of the apiarist. Bees in a natural state never had wired foundation, running from front to rear of the hive, in beautiful and exact sheets upon which these little insects could continue the work so deftly begun and left by the comb-foundation machine. A hive without bars or frames, occupied by bees, will, as a rule, be filled with combs of many forms, placed irregularly, some running at right angles with others, forming nooks, corners and galleries where the bees can find ample room to cluster in during the winter, and thus find protection from their mode of filling the hives with combs, which instinct leads them to adopt. On the other hand, the higher intelligence of man comes in and directs the work of the bees that now produce perfectly straight and true combs, subject to cold drafts of air from the entrance up through the narrowly spaced frames, and out by the loose joints of illy-constructed hives. Protection, then, is needed to restore the equilibrium destroyed by this abnormal condition to which our bees are subjected by the advances, of what is esteemed, apicultural science.

Proposition 3:—"Protection essential in both out-door and in-door wintering." It is certainly necessary to protect from cold and sudden changes of weather when bees are left out-of-doors, and I hold it is no less the part of wisdom to give nearly the same protection when wintered within doors. In either case, condensation of moisture within the hive will take place—out-of-doors to form frost within the hive, and in-doors to saturate the unpainted walls and frames of the hive and form in drops upon the combs, causing dampness and mold. The colder the hive, the more serious the trouble, in either case. Protection, as with the chaff hive, obviates both difficulties to a certain extent, both by preventing excessive condensation, and again by allowing the moisture to escape, and also by absorption. An example: A colony placed in the cellar, with enameled cloth on the frames with absorbents on top of that, in January were found with moldy combs, the enameled cloth on the side next the frames was covered with drops of water over its whole surface so it dripped when removed, and but little indication of absorption of moisture above the en-

ameled cloth. Another colony placed beside the former, with woolen cloth placed upon frames and bran-sacks above that, was found with the upper story of the hive and the inside of the cover, covered with drops of water, with the packing-material damp, while the quilt was dry and warm. The same state of things would exist in case of out-door wintering, with the exception that frost would collect unless more material was used to absorb the moisture. Protection, then, is needed to preserve an even temperature and a normal condition of dryness within the hive.

Proposition 4: "Bees, to winter safely out-of-doors, should be protected as with the chaff hive, or on the plan of Mr. Additon's shingle hive, or by packing in some manner, if in single-walled hives." If wintered in the cellar, full protection is well; but protection above the bees by some absorbing material, as chaff, finely-cut straw, or cloth, is fully as essential as in out-door wintering.

Proposition 5:—"Protection is the normal condition of bees in the natural state." Bees left to seek their own home, as a rule, seek a hollow tree. There they are in a single-walled hive, it is true, but not a thin-walled hive. But the conditions for disposing of the moisture arising from the bees is generally admirable. The hollow tree, made so by the decaying of its substance, is still subject to the same process of decay, while the bees are snugly ensconced within its dry and warm shelter. The first work of the swarm after domiciled in their new home, is to set up house-keeping by thoroughly clearing their apartment. This they commence to do at the top, but there is always a portion of the upper part of the cavity to which the combs are not attached, and this for the reason that the decayed wood is not easily removed, and still deemed by the bees insecure to fasten their combs to. This partially decayed portion above the combs affords fine absorbing material in winter, being as dry as powder in the fall when going into winter quarters, and in spring, wet with the condensed moisture absorbed during the cold weather. Such being the natural conditions, our artificial devices should be as adequate and as much better, as possible; hence protection is a necessity, to a certain extent, under all circumstances, in supplying natural conditions.

Proposition 6:—"Protection is needed in summer to guard against excessive heat." There is no doubt in my mind but that many times bees refrain from entering the surplus boxes, and cluster upon the outside of the hive, solely from the effects of the excessive heat within the upper portion of the hive. This I saw demonstrated last season, and have seen frequent cases before. An empty space above the section-case in the upper story of the hive, affords some relief; but I think some non-conducting material above the bees, immediately above the sections when they are on, or over the frames in spring and early summer, quite essential.

For the American Bee Journal.

Introducing Virgin Queens.

G. M. DOOLITTLE.

Formerly it was considered that virgin queens could not be introduced, to any advantage; and from this reason a queen-cell was always given to a queenless colony, unless a laying queen was at hand. In case no queen-cell was ready for use, brood was given to the queenless colony or nucleus, from which they would rear a queen. As it takes them from 12 to 16 days to rear a queen from this brood, a gain was made by having queen-cells constantly on hand, with which to supply the nuclei.

As a queen-cell was liable to be destroyed if given to a nucleus or colony as soon as the laying queen was removed, it was found best to wait 48 hours before giving such a cell; and as the cell would not always be ready to hatch as soon as given, the time elapsing before it would hatch, would, on an average, be about 2 days more; so that a gain of only about 8 to 10 days was all we would get by using the cells instead of the brood. Some tell us of inserting the queen-cells as soon as a laying queen is removed; but the fact that many of our best apiculturists entirely fail with that method, proves that such a procedure is very uncertain, to say the least.

After the young queen emerges from her cell, the average time before she commences to lay is about 10 days; so the colony must be without a laying queen 14 days when a cell is used in re-queening; or from 22 to 24 days where brood is used. As 24 days represent about so many 1,000 bees with a laying queen in the hive, it will be seen that the old way of giving brood is decidedly "too slow," and that of the cell-plan much too slow. For this reason it became a desirable object, especially to the queen-breeder to introduce a virgin queen as soon as a laying one is taken from the nucleus; thus making a gain of time to the breeder, and also keeping the nucleus constantly supplied with brood. With this desirable object in view, many plans were tried, and as a result it was soon heralded in the bee-publications, that if virgin queens could be given as soon as they were hatched from the cell, they would be accepted, as a rule, wherever put, if there was no queen in the hive; some asserting that they had no trouble in putting them in at the same time they took the laying queen out.

After trying the plan (all others being given up to within about two years ago, and after losing 19 out of every 20 queens so tried), I became discouraged, and went back to the cell-plan. Some of those I did get to laying, would be so crippled by the bees hugging them, that they would be of little use; and soon had to be killed on account of their legs being paralyzed so that they would fall off the combs, or otherwise being incapable of being a good queen.

About this time I had a lot of very nice cells reared by natural swarming, on which I "lotted" very much

for choice queens. The day before these cells were ready to be removed from the hive, a second swarm issued from a colony on the opposite side of the apiary. As I was about to secure the cluster and return it to the old hive, I happened to see the queen which was a very nice one; and being short of queens, I thought I would cut off a part of the cluster with the queen, and put them in a nucleus hive, thus securing a valuable queen, as I had reason to think there were two queens with the swarm. Having secured the queen and about a pint of bees in my swarming basket, I returned the rest of the swarm.

After they were all in the hive, I prepared the nucleus hive and placed the pint of bees in front of it. As they were entering, the young queen took wing, and fearing she might return to the old hive, I placed a sheet over it. Soon after, the bees were all in the nucleus hive; they commenced running all over it, thus showing that they were queenless. So I got a frame of unsealed brood and gave it to them to keep them from going back, supposing that the young queen had gotten back to the old hive before I covered them with the sheet. By keeping these bees I would have a good nucleus for my queen-cells, I thought, as I had more cells than nuclei to receive them. The next day as I went to get the nice lot of cells, you can imagine my surprise and chagrin when I found them all destroyed. After a little examination, I soon discovered the very same queen which had flown away from my little swarm of bees the day before.

After pocketing the loss of 25 as nice queen-cells as I ever saw, I began thinking how it was that after trying for years to introduce virgin queens, and failing, that this one should be received. The only solution I could make of it was, that these bees had been queenless so long that they expected their cells to hatch, and so they took this queen as one hatched from their own cells.

From this I went to experimenting till I ascertained that 9 out of every 10 virgin queens would be accepted if placed into a colony after the first queen-cells were sealed; while 9 out of 10 would be killed if given to the colony before the bees had sealed the cells. I also found, as a rule, that the first queen-cells would be sealed five days after the nucleus was made queenless; and from this knowledge I was enabled to introduce virgin queens with little risk of having them killed.

It will be noted that if I should give a colony a queen which had just emerged from the cell at this time, that I was one day behind the time gained by the cell-method; but if the queen given was 7 or 8 days old, she would be laying in 2 or 3 days now, which would give me a gain of a week, over the cells. Accordingly I made a queen nursery after the directions given in Alley's book, in which the cells were placed to hatch; and the young queens kept there until old enough to be used to the best advantage. When old enough, and

the nucleus was in the right condition, these queens were taken from the nursery, then daubed with honey and dropped on top of the frames of the hive. The next day the queen-cells would be destroyed, and in 2 or 3 days more the queen would be laying.

As I said before, this would work about nine times out of ten. This season I experimented farther, not being satisfied with losing one out of ten; and instead of waiting five days before giving the virgin queen to the colony, I placed her in a provisioned, wire-cloth queen-cage; and when she was 4 or 5 days old, I placed the cage over the cluster of a colony after it had been queenless but two days. She was then left for 3 days, when, upon opening the cage, she was allowed to run down among the bees.

In this way I have succeeded every time. I have opened the hive within ten minutes after releasing the queen, and found her on the queen-cells busily engaged in tearing them open. I now feel that I can introduce virgin queens successfully; and in the foregoing I have told the reader how I do it.

Borodino, N. Y.

For the American Bee Journal.

Building up Colonies in the Spring.

JAMES M'NEIL.

I desire to give the result of an experiment made in building up colonies in the spring. Mr. Doolittle says: "Beginning about May 1, shift the frames of brood and put the frames of honey or syrup in the centre of the brood-nest every week for the following six weeks." Mr. Heddon says: "Do not manipulate the frames at all. The bees will extend their brood-nest as fast as it is desirable." When such notable authorities in the apicultural world disagree, the novice must hold the weight of opinion in an even balance until he shall have experimented for himself. This I have done, and I throw the weight of my authority, whatever it may be, into the Doolittle scale. I selected 20 colonies, estimated very carefully the amount of brood in each, and then divided them into two equal lots; I ran one lot on the non-stimulating plan of Mr. Heddon, and the other lot on the brood-spreading-and-stimulating plan of Mr. Doolittle.

My observations were made at two different times, May 10 and June 2. Between these dates, 3 weeks and 1 day, the colonies run on the Heddon plan made an average gain of 1 1/4 frames of brood; those run on the Doolittle plan, 2 13-20 frames. Had the experiment covered the period of 6 weeks, the contrast would, of course, have been greater. I keep my bees in their winter packing till the middle of May, which allows them to spread brood, with less risk, before settled warm weather is assured.

Mr. Doolittle, in his directions, makes no account of fruit bloom. Perhaps he does not live in a fruit-growing region. In this section.

stimulative feeding is unnecessary from about May 8 till the 26. By implicitly following Mr. Doolittle's directions, I had my bees swarming during fruit bloom last year; and frames partly filled with honey, placed in the centre of the brood-nest, were completely filled from the abundant flow of cherry bloom.

This year, in the beginning of apple bloom, I put upper stories on the hives containing the strongest colonies; and they stored in them, on an average, from 20 to 25 pounds of honey. I have never seen a more abundant apple bloom; and for 4 days the weather was delightful, so that the bees could work from daylight till dark. The general June honey-flow began in good earnest to-day.

Hudson, N. Y., June 7, 1884.

For the American Bee Journal.

Wintering—Bee-Diarrhœa.

WARREN PIERCE.

As the above subjects are still being discussed, I wish to offer a theory, for the consideration of the bee-keeping fraternity, based, principally, upon the ventilation-theory to which I called attention in the BEE JOURNAL several years ago, but which is only just now becoming popular.

It is a well-known fact that carbonic-acid gas is extremely poisonous; but it is not as generally known that it is heavier than air, and may be poured from one vessel into another almost as readily as water, and evaporates very slowly. In the case of a colony of bees confined to a close hive, it is a case of slow poisoning, which, if not too long continued, is readily cured by a flight, and not so much by the voiding of feces as by the purifying effects of the air. But if no opportunity for flight occurs, and the gas is not permitted to escape, the poisoning continues until the result is fatal.

Diarrhœa is frequently attributed to late-gathered honey. I am aware that in some localities poisonous honey is gathered, but I think it a mistake to charge it with as much mischief, as many are doing, for want of a better reason for the disease.

In June 1881, I gave my views, through the BEE JOURNAL, on ventilation; and in that article I mentioned the case of two colonies in my bee-yard where one had nothing but the best white clover honey, and the other only late-gathered honey. The colony having the best honey died of a bad case of diarrhœa, while the other came out bright and clean. Both were on the summer stands. The one which lived had been carelessly left with the back-stop of the hive out, thus leaving an opening $\frac{3}{8}$ by 14 inches to the west.

Now, what are the evidences that carbonic-acid gas is the greatest enemy to successful wintering? That a colony of 30,000 or 40,000 bees must produce it in large quantities cannot be doubted; and if it does not pass away freely, it must act as a slow poison. We have the testimony of bee-keepers

who are successful by reason of giving large bottom-ventilation which allows the gas to pass off freely; the testimony of those depending upon top-ventilation which admits pure air to the cluster and assists in driving out impure air below: the claims of those who use deep hives on account of better wintering qualities, giving as they do, more room below the cluster for the dense gas to settle; the well-known superiority of the old box-hive, on account of its depth, frequently combined with unlimited bottom-ventilation; the bee-tree, the cavity of which usually has the form necessary to safety; and lastly, perhaps, by the fact that brief confinement in any weather will produce an effect similar in appearance to diarrhœa. I have no faith whatever in the "pollen theory;" none in the "moisture difficulty" which cannot be remedied by proper ventilation: and but very little in the "poor honey theory."

I believe that ample protection is necessary, if wintered on the summer stands, and would either have a two-story hive with the cluster in the upper one, or a large opening in the bottom-board, and a box without a cover for a stand. If bees are wintered in the cellar, the bottom-board of the hive should have a large opening, or be removed entirely, and wire cloth substituted.

The hives should be placed as far up from the cellar-bottom as possible, especially if the number of colonies is large, for the same reason that I would use a two-story hive. A recent number of the BEE JOURNAL gives the experience of one of its correspondents who found that the bees which were the nearest to the cellar-bottom, were the *most* diseased, and those which were nearest the top of the cellar, were the *least* diseased.

Garrettsville, O.

For the American Bee Journal.

Wintering Bees in Cellars.

IRA BARBER.

I notice on page 356, that Mr. Doolittle has met with heavy losses of bees, on a new plan of wintering. My sympathy is with the dead bees, and not for Mr. Doolittle; for, in my opinion, any man who originates a plan of wintering bees, and fails to make a success of it, should not try to make it appear that his plan was substantially the same as the one practiced by me for more than 20 years without a failure.

He used a cold cellar built in a side-hill, and depended on coal-oil to furnish heat; while the plan which I have practiced, requires a warm cellar under a dwelling-house, and one which never froze when bees were not in it.

Mr. D. asks that he found, by my reply to his letter, that I knew but little about the matter, as I used a thermometer only when the bees were put in and when they were taken out; and at such times the bees were agitated, and would raise the tempera-

ture. The tests of degrees of heat given were 12° above zero, outside, and 65° inside, 24 hours after the room was closed; and that of 60° outside and 90° inside were taken before a colony was carried out, and when the cellar was first opened. I should make tests oftener if I lived where the cellar is; but as my home is 20 miles from it, I did not propose to ride that distance, on extreme cold days, to test the degree of heat the bees were keeping up. He says that the mercury might fall to 40° below zero and stay there the most of the winter and I not know it. I am not located near enough to the north pole to have the mercury remain at 40° below zero nearly all winter: while the fact is, the mercury seldom, if ever goes so low in the coldest places in the open air; and that for only a few hours at a time.

Does Mr. Doolittle, or any intelligent bee-keeper, believe that a frost-proof cellar without bees would be in any danger of getting too cool for safety when filled with bees? The same week that I received Mr. D.'s letter, several other parties wrote to me asking the same questions that Mr. D. did; but this case is the first that I have heard of coal-oil being used to generate heat sufficiently to warm bees.

Mr. D. says that on Jan. 1 his bees were all right; but was surprised to find them active. What would he have done if he had seen my bees on March 24, when no part of the hives could be seen; for all that could be seen was piles of bees 5 feet high, or rather, walls of bees; for they were all from top to bottom and lengthwise of the rows of hives. All the damage done to them was the mixing up of Italians and hybrids, and they never saw a day, while in winter quarters, that the mercury was as low as 50° above zero.

Again, he says that the bees were 2 inches deep on the cellar-bottom on March 1. I fill the cellar full of hives, on my plan, and there is no cellar-bottom left to be covered with dead bees; and if any get tired of staying at home, they can step in to the next door neighbor and be received as a welcome guest.

He says that bees died of old age in winter quarters. What can be offered as proof of the assertion? In my experience in examining dead bees found in winter repositories, I have never seen any evidence of old age among the dead. The down or hair on their bodies was as bright and fresh as we find it on bees 3 or 4 weeks old; and the wings were in perfect shape, showing plainly that they had not been used to any extent. Bees in this locality often cease breeding quite early in August, and winter just as well as when breeding is kept up until Oct. 1.

Mr. D. asks if there is any conditions in nature, unaided by man, which will confine bees for several months in so high a temperature that moths will mature. My answer is: A warm cellar well filled with colonies of bees, will naturally furnish all the heat required to mature the moth

larvæ to the perfect miller, right on the outside of the hives; and the bees will come out in fine condition.

DeKalb Junction, N. Y., June 9, 1884.

For the American Bee Journal.

Docility of Syrian Bees.

R. J. KENDALL.

On page 362, Mr. Hewitt, of Sheffield, England, takes exception to my remarks on page 108, regarding a communication of his in the *British Bee Journal* of Jan. 15, relating to the docility of Syrian bees.

I am sorry if I misunderstood and misconstrued what he said; but the two articles are before the public, and I shall not discuss them further. Any one can see for himself how far I went wrong. I am glad, however, of Mr. H.'s letter, because it exactly agrees with my ideas; for in sum and substance it really amounts to saying that Syrians are no more docile than Italians, when you get down to bed-rock.

In Mr. H.'s complaint as to the wrong use of the word "Briton," I think he is also striking at me, not at the Editor, as he (the "Ed.") seems to think. I designated Mr. H. as a "Briton;" the Editor merely used the word "British." The difference between the two may be the difference between tweedle-dum and tweedle-dee. It is not very important, but Mr. H. thinks it enough to lecture one of us on, and at the same time to show that we, on this side of the Atlantic, are ignorant (?) of national derivatives. I have frequently noticed in the *British Bee Journal* this tendency to exhibit a depth of pedantic knowledge of no practical use.

But now in regard to these words, "Briton" and "British." In their original and earlier sense the words were used, doubtless, to designate the semi-barbarous race of people who inhabited "the tight little Isle" prior to the Saxon conquest; but in their later and common acceptation, it is equally sure that they are used to designate the natives of Great Britain—and this latter acceptation is equally as valid as the former. Mr. H. must remember that it is not Americans who gave the name of "Briton" to Englishmen, but Englishmen themselves.

I want to ask Mr. H. a question or two: Between you, me, and the Wicker, will you tell me how many times after, or at, a Good Friday excursion to Conisbro Castle, a Whit Monday trip to Roche Abbey, a picnic in Norfolk Park, a run-over to see "t Leger" on Doncaster Town Moor; or a political meeting in the old Pot Market, or the Albert Hall, have you expanded your lungs by affirming with great vehemence that "Britons never, never, NEVER shall be slaves," "Britons' Strike Home," and like patriotic songs about "Britons?" When you sang those songs, who were the "Britons" referred to—the dead-and-gone, before-the-Saxon-conquest braves, or yourself and countrymen now living?

If you will take your Nuttall's Dictionary, I think you will find that it says, a "Briton" is a native of Great Britain," as, of course, he is; and any English school-boy will give such an answer every time. The English papers claim to be, and are included in "The British Press." Are they not eternally telling us about "British Interests in India," and other parts of the world? Do we not read, every little while, of the "British Troops" doing this and that? Have we not read, or heard of "The British Soldier" and "The British Tar?" and even today there are lots of schools in England called "British Schools." Why, their second national song is called, "Rule Britannia;" and next to "God Save the Queen," this song is the dearest to the hearts of Englishmen.

I would recall to Mr. Hewitt's remembrance that well-known song, "The Englishman"—note the title, "The Englishman." The first line of one verse begins:

"The Briton may travel from the pole to the zone, etc."

and the verse ends:

"'Tis a glorious charter, deny it who can,
That breathes in the words, I'm an Englishman."

What becomes of Mr. Hewitt's assertion that the word "Briton" cannot properly be applied to an Englishman? Again, it is news to me to hear that either the natives of "Cyprus, Canada, Hong Kong, India, Jamaica, etc.—in fact people of all colors—are Britishers." The direct contrary is true; they are *not* Britishers. There may be people living there who are Britishers, but they were born in the British Isles or of British parents if they are. If Mr. Hewitt's bee-ology is no better than his ethnology, I am afraid we cannot depend upon it.

Austin, Texas.

For the American Bee Journal.

Prevention of Bee-Diarrhœa.

J. E. FOND, JR.

On page 374 Mr. Fradenburg says: "I have read with much interest the articles on bee-diarrhœa. But all have been theories and no proofs." "Now," he says, "I will give the proofs first and the theories afterwards;" and then states further: "My proofs are sustained by 59 living witnesses." But what do his proofs prove after all? Certainly not that pollen is the cause of bee-diarrhœa, but simply that in the cases he mentions, no diarrhœa was found when sugar syrup was used for winter stores.

Per contra, I will give some proofs; true, I have but 9 living witnesses, but they will certainly give one-sixth as much proof as Mr. F.'s 59. Last fall, when preparing 9 colonies for winter, I allowed all the pollen left over to remain in the hives; the result was, that not one of these colonies showed a sign of diarrhœa, and I never saw bees in better condition, or recruit up faster than these 9 colonies did, this spring. One of them, in fact, gave me 72 pounds of surplus honey from apple bloom, gathered in five days.

This proves nothing in itself, but it certainly is as strong proof as that given by Mr. F. If, however, it does prove anything, it goes far toward proving that pollen is not the cause of bee-diarrhœa; for if it is, my 9 colonies would have been affected with that disease.

The fact is, we must all of us look further yet, for the cause; when found, there will be a general rejoicing all through the land.

I am satisfied that I have found the solution of the wintering problem, and in a future article, will give my ideas. For the present I hope that every bee-keeper will do his part toward ascertaining the cause of bee-diarrhœa, and he who first discovers it, will receive the heartfelt thanks of his grateful brethren.

Foxboro, Mass.

For the American Bee Journal.

Profitable Use of Comb Foundation.

W. H. STEWART.

Although I have kept bees nearly every season for the last 40 years, and have all the while striven to learn all that I could of their nature, wants and habits; yet, after becoming somewhat acquainted with the many good lessons on modern bee culture, as given in the bee-papers by Mr. G. M. Doolittle, I feel that he is capable of teaching me very much which I have not yet learned. And, notwithstanding his superior judgment and keen powers of observation, I must say that I am quite sure that the doctrine (or a portion of it) taught in his article on pages 671 and 672 of the *BEE JOURNAL* for 1883, is unsound.

Though Mr. D. seems to express the wish that the article above mentioned should be allowed to pass without criticism, when he says, "If any think that it is not the right way to work, they can pass this article by, the same as if it had not been written;" yet I propose to review the article in part.

The first mistake which I notice in Mr. D.'s remarks is, "Many cannot afford to buy it (foundation)." I hold that no person can afford to keep bees at the present stage of the art without buying or making all the best improved appliances which have been discovered, and put them into profitable use. We might as well conclude that some persons who keep horses could not "afford to buy" oats or corn for feed. I cannot conceive of any reason why a bee-keeper could not "afford to buy" foundation, unless it is because he is poor; and if poverty be offered as an excuse, I would reply that no poor bee-keeper can afford to put up with a small yield of honey, when he could in any proper way get a larger yield, and at a less cost than the market value of the honey.

One of the most happy facts connected with bee-keeping is, that those having but limited means and only a small patch of ground, may engage in the pursuit on a small scale, and by proper management, obtain good re-

turns in proportion to the outlay. Yet another fact, and not so "happy" a one is, that those who engage in the business, and neglect the bees in their wants, are very sure to lose all the time and money which they invest.

Mr. D. states that in order to secure straight combs in the brood frames, he has "found a guide of some kind an absolute necessity." And, although he recommends the plain strip of wax "on the under side of the top-bar of the frame . . . as being the best," yet he admits that his choice of a guide is a practical failure; for he states in the very next sentence that he has "found that no guide can always be depended upon, as the bees are sometimes very obstinate, and will leave the guide so as to build crooked combs, if they do not go directly across the frames."

Mr. D. starts out in his article by stating a truth; viz: "To have all our combs built true, in the frames, so that each comb is as true as a board, is *certainly worth working for*;" (the italics are mine) and now, as he admits that his kind of a comb-guide is sometimes a failure, he has virtually admitted that it will pay to try some other; and he cannot claim that he has thoroughly tested good sheets of foundation; for he says, "I have never used 10 pounds of foundation in brood frames since I have kept bees." It seems rather strange that Mr. D. should assume to set himself in judgment against an article so highly recommended and so universally used as is comb foundation; and then with the same dash of his pen, write that he had never used 10 pounds of it; which is virtually admitting that his opinion in regard to the matter, is of no practical value whatever.

Prof. A. J. Cook, in his "Bee-Keepers' Guide," page 208, in speaking of the usefulness of comb foundation, says: "The most promising use of foundation, to which there can be no objection, is in the brood-chamber. It is astonishing to see how rapidly the bees will extend the cells, and how readily the queen will stock them with eggs if of the right size, 5 cells to the inch. . . . The advantage of foundation is, first, to insure worker comb, and thus worker-brood; and second, to furnish wax so that the bees may be free to gather honey." Mr. D. thinks we "cannot afford to" do this.

"Prof. Cook also says: "We proved in our apiary the past two seasons, that by the use of foundation, and a little care in pruning out the drone-comb, we could limit, or even exclude drones from our hives." Mr. D. says that all colonies having straight worker combs will be "profitable." I have owned several foundation mills, and have made several different kinds myself; and have used much of different kinds of foundation for several years. I have tried the experiment thoroughly with 100 colonies, which Mr. D. recommends in his closing remarks, and from actual and thorough experiment, I do know that it would pay me to purchase foundation at \$2 per pound rather than to do without it.

Again, Mr. D. says that he hives his swarms on 9 frames (Gallup frames of course, as he uses that kind), and in 2 days he opens the hive and finds that the bees have made a start in 5 frames. Why! Mr. D., a good, new colony of bees and only "a start" in 5 frames in two days? If you will come to see me work, this season, I will show you that such swarms as I put on 10 frames, each nearly full of foundation, will, in 2 days, have all of them $\frac{2}{3}$ finished, and 5 of them complete.

Again, let me suppose that the weather is such that you cannot go through those new colonies until the fifth or sixth day, and then if you find that the colony had turned out to be one of that "obstinate" kind which cuts down the guides and builds the combs across the frames,—how much would you lose in the operation? Do you not think that in that case it would have been good economy to have put the swarm on frames well provided with foundation?

A wise and careful bee-keeper would not be apt to so manage as to lose from 2 to 6 days' work of a new colony in the time of a good honey flow; and that is just the time that swarms are cast. I have often put swarms on 10 frames as nearly full of foundation as the bees could work them to advantage, and in examining them 6 days afterward, I found every frame full of comb, every comb complete, and but a few cells that did not contain either brood, eggs, or honey. Let me say, also, that in all which I have used foundation, I have never known a colony of bees to build combs in a different direction than that in which the foundation was put in for them. It is true that if the sheets of foundation are so placed in the hive that the distance between them is too great, then the bees will be very likely to build thin sheets of comb between them. It is also true that some kinds of foundation, if put in nearly large enough to fill the frame, will, many times, sag and warp while the bees are working them out. Mr. D. says: "It pays the apiarist to look at each colony hived on empty frames, while they are building combs, as often as once in three days. If any combs are found going wrong, they can be bent back in line very easily." I would like to have Mr. D. tell us whether a comb a little out of a true plane built on comb foundation, is not as "easily" straightened as is one built after one of his favorite comb-guides?

I have had several thousand combs built on foundation, and I do not now remember that I ever found one, when finished, so badly warped as to spoil it; and I have never examined a colony for the purpose of straightening the combs; I pay no attention to that work until I have the combs out for some other purpose.

Mr. D. says that until he is better satisfied that comb foundation pays, than he has been from past experiments, he expects to build all his combs in the future, after the plan which he has given. I would like to ask Mr. D. how he expects to become

better satisfied that comb foundation pays while he refuses or neglects to give it a full and fair trial?

Mr. D. states that he would like to have all the "advocates of foundation" try an experiment, as given in his closing remarks, and see which of the two colonies comes out ahead. I would like to have Mr. D. try 2 or 3 swarms hived on a full set of Gallup frames, half of those frames furnished with 2 sheets each of foundation, and each sheet $2\frac{3}{4}$ inches wide and 3 inches deep. This would leave a little open space between the sheets in the centre, and also between their outer edges and the end-bars (these sheets, 6 square feet to the pound, will give good results). Furnish the other half of the frames with his simple wax-guides, and hang those furnished with foundation in one end of the hive, and the empty frames in the other; then open the hive every day until all the combs are complete, and see which progresses the fastest from first to last, and also where the most eggs are deposited from first to last.

Try another swarm on like furnished frames, hanging those with and those without foundation alternately through the hive, and then examine them daily as above. Notice in the latter also, whether he does not succeed as well in securing straight combs, and in the right direction, in his empty frames as he would if he had hung them between full combs. And finally, will Mr. D. tell us how large young-swarms he gets down there in Borodino? I would laugh to see him crowd a good colony of bees up to the capacity of 5 Gallup frames after being hive 2 days here in Wisconsin.

Orion, Wis.

For the American Bee Journal.

Overstocking a Locality.

W. F. KANZLER.

1. All persons have the right to keep bees on their own premises.
2. If a man has an aversion to bees and bee-stings, he will not keep bees.
3. Any man who likes bees and their handling, will keep as many colonies as he can profitably care for.
4. No man knows overstocking by his own experience—concerning the number of colonies: for if he keeps a certain number of colonies, he, at the same time and place cannot keep a lesser or higher number. For instance: If he keeps 20 colonies, he cannot keep 5, 100, 200 or 300 colonies at the same time in his yard; neither can he know what these 5, 100, 200 or 300 would yield in the same season; but he knows only the yield of his 20 colonies.
5. Therefore, if we cannot prove overstocking, by our own experience, we can only speak of it by guessing at it—it is nothing but guess-work, or an imaginary evil.
6. In a good season my bees will produce as good an average as my neighbor's; *i. e.* provided we both have the same skill, hives and strains of bees, regardless of the number of colonies.

7. In a poor season, when bees do not gather enough honey for winter, I must feed my colonies, and my neighbor must do the same thing or kill his bees; and my yard is overstocked if I have only one colony.

8. Therefore, my neighbor cannot lower my average in honey, but the season can.

9. The expression, "bees can graze a field," is wrong; for bees have no teeth like a sheep or cow, and cannot eat the whole plant at once, but they will only sip the sweets out of the blossoms and other parts of the plants; while those plants grazed off by animals, require several days, and perhaps weeks, to give another nourishment. Therefore, we can overstock a clover field with sheep or cows, but not with bees.

Fulda, Ind.

is a strong colony, and that they would attend to the moths. I informed her that the honey-board was formerly used directly over the brood-nest; that it is an article made of wood; and that it is now superseded by a piece of Indian-head muslin the size of the hive, and laid on next to the bees. I told her that the very first thing for her to do is to get movable-frame hives and put her bees into them, so that she could see what they were doing at all times.

MAHALA B. CHADDOCK.

The BEE JOURNAL does its advertising wonderfully well. It brought to me responses from Canada to the Gulf of Mexico, and from the Alleghanies to the Rocky Mountains.

WM. M. ROGERS.
Shelbyville, Ky., June 12, 1884.

Swarm Separators.

In making a swarm separator, as described by Mr. Secor, on page 380, do the division-boards extend to the bottom-board, and as near to the top-board as the frames: viz: $\frac{3}{8}$ of an inch? If not, how will bees separate if the separator fills the hive flush on all sides? I wintered my bees in a cellar, and they all were strong quite early this spring. Fruit bloom is abundant. I took 75 pounds of honey from 3 colonies—25 pounds each—last week. As yet, I have had no swarms, and I do not want any before June 20. There are about 120 colonies within a radius of a mile here. Will we soon be overstocked? T. F. KINSEL.
Shiloh, O., June 16, 1884.

[Will Mr. Secor please reply to the above? There is not much danger of overstocking the radius of a mile with 120 colonies.—ED.]

Heavy Bloom.

We are having a fine honey flow, and have had a heavy bloom of locust and tulip. Now we have white clover in abundance. On yesterday morning the leaves of the grape vines, chestnut and oak trees was fairly glistening with honey-dew.

W. E. STATHERS, M. D.
Middlebourne, W. Va., June 11, 1884.

What do we Know?

I have been studying bee-lore for 15 years. I have formed theories, planned hives, frames and sections, and have built for my own use a good circular saw. I have made my own hives, etc., etc., and yet I find that I am absolutely an old-fashioned know-nothing. I have read Mr. Root's and Prof. Cook's bee-books, and the BEE JOURNAL; and I find that all of these authorities are at sword's points, and that all the correspondents of the bee-papers are as opposite in their opinions and practices as it is possible to be. I have looked in vain for some one person whom I could follow with a certainty of success, and as

freely as I would a teacher of any of the common branches of human knowledge. I have learned one thing of which I am certain; i. e., that bees will sting; though I do not think I have learned that as thoroughly as some others have. I wish that some one would brimstone all these quarrelsome writers, editors, novices, etc., etc., and let the "fittest survive" to teach the "young idea how to shoot." Stop quarreling, write sense, and the common sort at that, and the moment any writer cracks up any hive, which is not as simple as a hollow tree, charge him 5 dollars a line for inserting his valuable foolishness.

S. RUFUS MASON.
Purple Cave, Neb., June 10, 1884.

Unripe Extracted Honey.

The BEE JOURNAL for 1883 says: "The sale of extracted honey is dull on account of too much unripe honey on the market." In the first place, who puts this unripe honey on the market? It must be beginners or some who are trying to spoil the sale of extracted honey, or trying to see how much honey can be produced by one colony of bees. When the combs are sealed $\frac{3}{8}$ of the way down, they are ready for the extractor, and no sooner. My bees came through the spring in fine condition. I have had 6 swarms, and my hives are full of honey and bees. I have the Syrians, and I believe that in 5 years' time they will stand at the head of all races of bees. I hived a swarm 8 days ago, and they have their 8-frame Langstroth hive full of combs and brood: and there is no comb foundation in the hive either. Colonies which have not swarmed, have their combs sealed fully $\frac{1}{3}$ of the way down. The temperature at which I keep my cellar for wintering bees, is 36° to 45°.

FAYETTE LEE.
Cokato, Minn., June 7, 1884.

Queen Rearing.

I bred, last year, from fine young queens reared last year, young queens which almost all proved fidgety little queens, and very shy. Their workers died to a great extent, during the winter, and the colonies fizzled out this spring. I have reared, this season, of the same queens, the finest queens I ever saw, and the most prolific ones, and I have come to the conclusion that it is as poor policy to rear young queens of queens reared the same season. I wish, through the medium of the BEE JOURNAL, to hear the opinions of the bee-keepers who are not queen-breeders, as to their experience and opinion in this matter. If my opinion is correct, queen-breeding from a young queen reared the same season, would be as bad a policy as in-and-in breeding, and perhaps worse, and to ascertain this fact would be of importance to apiculture. GUST. MURHARD.
Portland, Oreg.

The Southwestern Iowa Bee-keepers' Association, will meet in Corning, June 28, 1884.

W. J. OLIVER, Sec.

SELECTIONS FROM OUR LETTER BOX

Bees are Busy.

The colonies which were wintered in a dry and well ventilated cellar, in this locality, came out strong in bees in the spring. I have 100 colonies, and had the first swarm of this season on May 27. There is plenty of white clover, and the bees are busy.

DAVID ROWE.
Lime Ridge, Wis., June 16, 1884.

Increased Experience.

I wintered 110 colonies on the summer stands without loss. In the spring I found 2 of which were weak, and I doubled them up. I lost one by robbing. Bees are doing well, and have stored some very nice section honey. Financially, I am ahead on last season's crop, and also have added some experience.

JAS. MCCONNELL.
Clay Village, Ky., June 12, 1884.

Use of Comb Foundation.

When I wrote to the woman spoken of in my last article, I told her not to be ashamed of her ignorance, but to live up to all the light she had, and more would come to her. I told her that comb foundation is made of bees-wax; that a few enthusiasts thought they could make it of paraffine, but it all melted down in a heap, and they did not try it again; also, that it is made on a little machine something like a clothes wringer; and that it is good to use in bee-hives for the following reasons: 1. It saves wax, as bees are said to consume from 16 to 20 pounds of honey in making a pound of comb. If the comb foundation is furnished them ready for use, it saves them a lot of honey and a great deal of time. 2. It enables one to have all worker-comb in the hive. 3. It compels the bees to build straight combs. I told her that I thought the Italians are the best race of bees out; and that the only moth-trap in the world,

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Transferring Bees.

1. How can I transfer bees from the box-hive to movable frames?
2. When is the best time, with a view to increasing the number of colonies? J. F. McMILLAN.
 Strawn, Ill., June 5, 1884.

ANSWERS.—1. By the method given on page 367 of the BEE JOURNAL for 1883; a repetition of which would be too long for this department.

2. For either purpose I should prefer the time just before or just at the commencement of swarming.

Prevention of Swarming.

I stored 19 colonies in the cellar last December, and took them out on March 10. One late swarm starved, but the rest were strong in numbers, and had used but little honey. Some colonies show signs of swarming. I do not want more than one swarm from each colony. Where will the queen-cells be most likely to be built? I shall have to find and destroy them to prevent after-swarms.

G. C. BILL.

Plainfield, Ill., June 9, 1884.

ANSWER.—I do not like your plan of prevention of increase. See page 126 of the BEE JOURNAL for 1883. You will be obliged to carefully scan every portion of all the combs in the hive.

Reversing the Frames.

Speaking of reversible frames, the question is often asked, "How about the cells, which have an upward inclination, and when reversed, will pitch downward, will the bees change this, or is it not necessary for brood-rearing?" C. G. BEITEL.
 Easton, Pa.

ANSWER.—I do not consider any change in the pitch of the cell necessary. On page 392 Mr. Baldrige speaks of this. Here we have had eggs, larvæ and pupæ in a perfect state of development, in combs laying flat on their sides. It seems that Mr.

Baldrige has had the same experience regarding vertical cells. We find that bees invariably (without guides) build their cells horizontally, and never vertically. We also find that when we give them foundation with vertical rows, no injury or drawback is realized. The Dadant foundation is made in that way, I believe. Many think that we must follow the "wisdom of nature;" but if we do that, we will find the greatest portion of such wisdom in the brain of man, and by crossing lower instincts in accordance with reason, is the great and useful work of science.

Chickens and Bees.

One of my neighbors had a brood of chickens that were in the habit of frequenting the shed in which he kept his bees. The bees stung all the dark-colored ones to death and did not molest the light-colored ones. Why this preference? I am well pleased with my success. My bees have wintered on the summer stands.
 Pioneer, O. JOHN DYE.

ANSWER.—Several times, through the BEE JOURNAL, I have spoken of the advantage of wearing light clothes among the bees. We wear black bee-veils because we cannot see clearly through any other color. Woolly, fuzzy and dark materials are objected to by bees. A man with a plug hat on rarely gets stung, unless by a bee that in trying to "shoot the hat," aims too low, and hits the face by mistake, while a companion at a suitable distance is perfectly safe.

Very Small Bees.

Enclosed please find 4 bees. Will Mr. Heddon please state their name and occupation? They are small, and I find them at the entrances of my hives. The other bees do not try to sting them, but will catch and fly away with them, but they soon return, flying clear into the hive. In a few minutes they appear on the alighting-board. They are very quick, and jump at almost every loaded bee that comes, until it is taken out for another ride. I find some of them at almost all of my 30 hives, but more at some of the Syrians.
 Oregonia, O. W. C. STEDDOM.

ANSWER.—This case is entirely outside of any of my experience or observation. The sample bees appear to be of the yellow-banded variety, and quite handsome little fellows, but very, very small. It must be a case of peculiar abnormality, but is more of an enigma than I can solve.

Use of Honey from Diseased Bees.

If bees die of diarrhea in the winter and leave the combs full of honey, will this honey injure a swarm if given to it? C. W. BRUNER.
 Bascom, Ind., May 31, 1884.

ANSWER.—I have no fears in giving such combs to swarms. Whatever the combs did contain when the old colony went into winter quarters to

die, or whatever they may contain after their demise, the swarm will replace with food of the season in which they are hived. This is a rule, with very few exceptions; but not where the hive is constructed upon correct principles, and the swarm contains a vigorous queen.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL. }
 Monday, 10 a. m., June 24, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for all honey is very slow; market dull and prices range from 6@9c for extracted. Different lots of choice comb honey in small sections have been offered and sold in our market lately at 12@14c per lb. As I predicted some time ago, the preference for the production of comb honey seems to be prevalent; and, as we have the best prospects for an abundant harvest this year, we may prepare for low prices.
 BEESWAX—Is in good demand; choice yellow brings 35c a lb. on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—Present quotations are as follows: Fancy white in 2-lb. sections, glassed, 13@14c; fair to good in 2-lb. sections, glassed, 11@13c; dark grades in 2-lb. sections, glassed, 10@12c. No 1-lbs. in this market.
 BEESWAX—Scarce, and sells readily at 36@38c. MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15c, and 2½-lbs. to 2½-lbs. from 10@12c. No 1-lbs. in the market. Extracted, 8@10c.
 BEESWAX—35c. BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—Choice white comb honey in 1 lb. sections brings 18c; in ½ to 2 lb. sections, quotable at 15c. Comb honey discolored and in undesirable shape is selling at 10@12c. Extracted honey is in light demand at 6@8c. Manufacturers of syrups and bakers say that the low price of sugar is the reason why they do not use as much honey as formerly. There is very little desirable comb honey on the market.
 BEESWAX—Is scarce and fancy yellow brings 35c. Good beeswax, but dark, and having more or less of refuse matter in it, quotable at 30@33c.
 R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Offerings are mostly of ordinary quality, especially so of comb. The demand is very light. Sales of candied extracted are quoted at 5c. White to extra white comb, 15@18c; dark to good, 10@13c; extracted, choice to extra white, 6@7c; dark and candied, 4@5c.
 BEESWAX—Wholesale, 27@30c. STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—Nothing doing now in comb honey, except in a very small way, and will not likely be until the new crop comes in. I quote choice white nominal, at 14½@15½c. Dark and irregular, no sale at all. Extracted in fair request at 7@8½c. Some new Southern honey (extracted) arriving.
 BEESWAX—Nominal, at 30@35c. JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@6½c.
 BEESWAX—Firm at 32@32½c for choice. W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1 lb. sections at 18c; 2 lbs. best white not quite so active at 17c; 1 lb. sections sell quickly on arrival, and often are sold to arrive. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.
 BEESWAX—Scarce at 35c. A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 18@20c; extracted, 7½@8c.
 GEO. W. MEADE & Co., 213 Market St.

We can supply photographs of Rev. L. L. Langstroth, the Baron of Berlepsch, or Dzierzon, at 25 cts. each.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Convention Hand-Book.

It is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount. post-paid.

What they Say of it:

From Prof. A. J. Cook, Lansing, Mich.—"I have greatly to thank you for getting up the exquisite little Convention Hand-Book. Surely the old 'saying' is true—being a thing of beauty, it ought to be a joy forever."

From Mr. A. I. Root, Medina, O.—"Send me a dozen of the Convention Hand-Books. We have had quite a number of inquiries for something of that sort, and yours seems to be quite nicely gotten up, and just what is wanted."

From J. E. Pond, Jr., Foxboro, Mass.—"The Convention Hand-Book is just the thing. The digest of Parliamentary Rules it contains will prove of great value to every one. I trust it will receive the patronage it so well deserves."

From Mrs. L. Harrison, Peoria, Ill.—"The Bee-Keepers' Convention Hand-Book is a gem. It should be in the hands of every one who attends a bee-convention, and then there will be no need of embarrassment on account of ignorance of Parliamentary Rules. Accept my thanks for sample sent."

From G. M. Doolittle, Borodino, N. Y.—"I am in receipt of the new Convention Hand-Book, and must congratulate you on the happy thought of such a work, and the neat appearance of the book. It is a work you may well be proud of, both as to the matter it contains, and the splendid material used in its make-up. It will meet a long-felt want; and were it so that I could attend conventions as in former years, ten times the price would not seem too much to pay for it, for by the instruction therein given, any man could be kept from many a blunder, much to his mortification. I hope in the near future to again be at liberty to go to conventions, when I shall prize the work very highly."

James Heddon, Dowagiac, Mich., writes:—"The Bee-Keepers' Convention Hand-Book is received. I saw it advertised, but conceived no approximate idea of its great value to bee-keepers attending conventions, until I perused it. Many times the price of my copy would be no temptation for me to do without it. It will make us all want to talk at once, I fear. You deserve the thanks of all, and I herewith tender mine for this helper."

The first edition of the "Apiary Register" having been exhausted, we have just issued a new edition, elegantly bound in Russia leather, with a large worker bee and "Apiary Register" in gold on the side. It forms not only a Register of both Queens and Colonies, but has also an Account Book at the back, in which to keep a record of all the receipts and expenditures of the apiary, which will be found exceedingly valuable. We have also reduced the prices, as will be seen on another page.

Several hundreds of subscriptions expire with this number, which completes the first half of the year. We desire to impress all with the importance of *renewing at once*, to save themselves annoyance by the loss of several numbers, and also save us the trouble of removing the names from our type mail-list, and then setting them up again a few days afterwards. Those who desire to have the BEE JOURNAL continued until they order it discontinued, should notify us of the fact, and we will so mark it on the mail-list; then no numbers would be lost or trouble made for any one.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75. Or, bound in cloth, with Weekly, \$3.00; with the Monthly, \$2.00.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

THE COUNTESS OF MONTE-CRISTO; being the companion to Alexander Dumas' Celebrated Novel of "The Count of Monte-Cristo," and fully equal to that world renowned novel, is in press, and will be published immediately by T. B. Peterson & Brothers, Philadelphia. It is a work of extraordinary power, fascination and interest, while it is great in plot, incidents and characters.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

**EXCELSIOR
WAX EXTRACTOR**

The advantages of this Extractor are:

1. It is more easily operated, there being no necessity for removing the top to refill with water.
 2. It melts quicker, because the wax is brought into a more direct contact with the steam.
 3. It is more economical, because the steam has access to the center, thereby extracting all the wax from the refuse matter.
 4. The filler for water acts also as an indicator as to the amount of water in the boiler, as when the steam escapes through the filler, more water will be required.
- Keep a kettle of hot water ready to fill when required. We make two sizes, the smaller one having a larger capacity than the Swiss Wax Extractor.

Price, small size, \$4.00—large size, \$5.00.

ALFRED H. NEWMAN,
923 West Madison St., CHICAGO, ILL.

Sixth Thousand Just Published!

New and Enlarged Edition OF BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure. T. F. BINGHAM.
 Abromia, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN.

Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ills.

A Liberal Discount to Dealers by the Dozen or Hundred.

WE CALL

the attention of all wanting A No. 1 BEES, Italian, Cyprian or Hybrids, to the following, from one well-known to the readers of this Paper:

"I have never seen a case of foul brood; my bees are entirely healthy, and have always been so, and are O. K. in every respect."
 GEO. B. PETERS, M. D.

We can furnish any number of Colonies of the above Bees, and will warrant safe delivery and satisfaction.

N. B.—No Bees will be sold by us, for any consideration, from any apiary that has ever had a case of foul brood in it. For prices and particulars, send to

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.

925 WEST MADISON ST., CHICAGO, ILL.
Weekly, \$2 a year; Monthly, \$1.

PREMIUM.—Any one sending one new subscription for the Weekly, or two for the Monthly, for one year, besides their own subscription for a year for the Weekly, will be entitled to a copy of "Bees and Honey," bound in paper.

The receipt for money sent us will be given on the address label on every paper. If not given in two weeks after sending the money, write us a Postal card, for something must be wrong about it.

Any person sending a club of six, is entitled to an extra copy (like the club), sent to any address desired. Sample copies furnished free.

Papers are stopped at the expiration of the time paid for, unless requested to be continued.

FOREIGN POSTAGE, EXTRA:

To Europe—Weekly, 50 cents; Monthly, 12 cents.
To Australia—Weekly, \$1; Monthly, 24 cents.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Entered at the Chicago P. O. as Second Class Matter.

ADVERTISING RATES.

20 cents per line of space, each insertion.

For either the Weekly or Monthly Editions.

A line of this type will contain about 7 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance. Editorial Notices, 50 cents per line. Advertisements may be inserted one, two or four times a month, if so ordered, at 20 cents per line, of space, for each insertion.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE.

PATENTED, MAY 20, 1870.

The Original
**BINGHAM
Bee Smoker**

Patented, 1878.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

BOOKS!

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates on larger quantities, given upon application.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects:—Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quieting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, in cloth, \$1.00; in paper covers, 75 cents.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premium for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bienen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by I. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY ALLEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way to rear Queens, etc. Price, \$1.00.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 85 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either English or German.

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XX.

CHICAGO, ILL., JULY 2, 1884.

No. 27.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Markets for Honey in Asia.

In the London *Telegraph* of recent date, we find an article on the uses of honey, in India, and setting forth the inducements as well as the difficulties in the way of finding an excellent market there for our surplus honey. As we feel sure that our readers will be much interested in this article, we will copy the following portions of it:

Bee-keepers will be interested to know that, according to the results of recent inquiries made by the government of India, a large market for their produce appears to be open in our Eastern Empire. This at any rate is certain, that honey is everywhere in demand throughout the peninsula for domestic, medicinal and sacrificial purposes, and that at present no attempt has been made by indigenous industry to meet it.

The Oriental, wherever you find him, is a great consumer of sweets; and, just as the British workman spends his spare half-pence in liquid refreshment, so the Eastern, seeking to recruit himself after a bout of work, looks out for the nearest lollipop stall.

Nor should it be forgotten that in religious offerings also, candies play an important part. There is nothing the deities like better than lollipops—so, at least, the priests tell such votaries as cannot afford more costly offerings—and the shrines are, therefore, liberally supplied with sweet confectionery.

Now, honey is an important ingredient of many of those things for which Orientals, both human and divine, have such a sweet tooth; and at present the amount in the market is nowhere commensurate with requirements.

Medicinally, as a gargle, and a cordial especially, the bees' treasures are in equal demand in all the Presidencies, but are not always obtainable when wanted. Yet India has been specially favored by nature in the matter of bees, for the indigenous va-

rieties of those insects are very numerous.

The Hindoo, however, classifies them much as children classify bears—there are, they say, big bees, middle sized bees, and little bees; and the first two kinds are of no use for domestication, as they have stings. The third, they say, might be of use for hiving, but unfortunately it is very small. Some describe this stingless insect as "a quarter the size of the house fly," others "about as large as a mosquito," while one says "it should perhaps be called a gnat rather than a bee."

This delightful innocence of entomology is not more refreshing than the Oriental's idea of the sting of the bee being a fatal objection to its utility under cultivation. But we should not forget that he wears very scanty clothing, and that few of us, even the most expert, would care to be honey-taking with no more personal protection than a waist-cloth round the loins, and a dab of yellow paint on the forehead. It would require something more than even the sang-froid of a professional bee-keeper to venture among the angry bees in such Garden of Eden apparel, and a good deal more than good manners in the insect to forbear attacking such an extent of undefended surface.

There remains the fact that India possesses several breeds of bees which have no stings. We should like to hear some disciple of Darwin explain this development of the inoffensive bee. It would be simple enough if the people of India were all hide-bound like their rhinoceroses, or went about iron-clad, for stings would then, no doubt, be given up by the insects as being of no use; but considering, as we have already said, that their costume is so carefully adapted to the climate, and that the provocations to attack are so copious and extensive, the natural fact justifies some surprise. We could have understood the India bees having tips to their tails like scorpions, or being all sting; but when it comes to their deliberately doing away with "the business end" of their bodies, we are compelled to credit the bees with a measure of good taste and magnanimity that entomologists have not hitherto done justice to. These harmless honey-makers, however, produce but poor stuff, and little of it, though in fairness to them it should be said the native has not tested their capabilities with any remarkable degree of judgment or intelligence. Our own apiarists, for instance, will agree with us

that to tie a string round the waist of a queen bee, and then tether it down inside a hollow tree, is at best a crude and primitive way of attracting the hive of bees—especially so in a country where the ant, "edax rerum," is omnivorous and omnipresent, and where lizards and large spiders, the particular enemies of bees, swarm in hollow trees.

What the result might be under more scientific treatment remains, of course, a matter of conjecture; but meanwhile it may be accepted as established that the majority of the inoffensive species give only an inferior quality of honey, and that the quantity as compared with that of the insects which are less pleasant to handle, is inconsiderable. It would seem, therefore, that if the experiment of apiculture in India is ever to be made in earnest, it must be made with the bees that have stings, and here the possibilities of yield appear to be almost without limit. At any rate, the quantities said to be produced by wild bees of some of the larger and more ferocious kinds are so large as to be almost incredible.

What, for instance, would our English bee-owners say to a colony that could produce in a year, without any attention, 200 pounds of honey, and half as much wax? or to a wild rock-bee that stores up, without assistance or any incentive beyond its own instinct for industry, an average of 40 pounds in a season? They would probably think such insects as these to be well worth cultivation, and no one could disagree with them if they did.

To be put against this amazing productiveness is, however, the fact that these bees, especially the large cliff-bee, are exceptionally fierce. They are tigers of their kind. Man himself is not safe for them, and beasts perish under their stings without a chance. Combined with the dreadful potency of the venom is a liability to provocation to which only a parallel can be found among beasts of prey when on guard over their young. For these bees will attack a passer-by if he even makes any unusual noise.

A gun fired off in their vicinity sets the whole to buzzing, and the bees—though hornets would almost seem to be a better name for them—if they catch sight of any moving object, whether man or beast, while thus irritated, throw themselves upon it with a malignity that is always terrifying, and an effect that is often fatal. Animals have, as a rule, no hope of escape, for in their panic they at-

tempt to escape by headlong flight, a useless endeavor when pursued by insects so swift of wing. But human beings, either by lying down and feigning to be inanimate, or else by rushing into the nearest water and defending the head till sundown, make their escape, though not always, as the memorial cross on the banks of the Nerbudea, at the Marble Rock, testifies only too well.

From the above, then, it is evident that India possesses an abundance of bees, and offers also a prodigious market for honey, but that hitherto, owing to local causes, the industry has never been systematically developed. Whether it can be, except in purely European hands, is very doubtful, for the native in India has little taste for new enterprises. At present the honey-takers belong only to the lowest castes of the people, chiefly the poor jungle tribes who literally pick a substance under the trees and off the rocks of the wildest parts of the interior of the country; and to enter deliberately upon a system of bee-rearing would seem to the conservative Oriental like descending to a lower sphere of work to take the bread from the mouths of inferiors.

As it is he only recognizes their existence with a lofty indifference, and to compete with them in the bazaars in the vend of honey would present itself to him as an intolerable social degradation. So that to induce the Hindoo to turn to apiculture, it would be first of all necessary to persuade him to revolutionize both his apparel and his ideas of caste occupations. But in the hills, where the thrifty mountaineers have no compunction as to the kind of work they will do so long as it helps them to make both ends meet, the experiment could be made under far more favorable circumstances; while the numerous mission stations—where the profession of Christianity levels all distinctions of caste, and requires a more liberal distribution of clothing over the body—would seem to afford excellent nuclei for bee-cultivation. In the meantime, however, an exceptional market would seem to be fairly open to the European producer. Not only has every one in the country a sweet tooth, but offerings, if made in honey, are specially acceptable to the divinities.

Sweet Clover as a Honey Plant.

Mr. J. W. Walker gives his opinion of *melilotus alba* as follows in the Highland, N. C., *Enterprise*:

While I am led to infer that the abundant and varied flora of this "land of the sky," is perhaps amply sufficient to supply the honey bees, yet it is suggested to me that you may have some sections where the material for bees to work upon may be somewhat lacking, and if such should be the case, there is nothing easier than to supply the deficiency by having the *melilotus alba*, which, as a honey plant, stands second to none. It is beautiful when it dons its inflorescent paraphernalia, and fills the

surrounding space with a most pleasant and multiflorous aroma, attracting the honey gatherers from every direction. The bee never made its dreamy flight around the classic Hybla or Hymettus more persistently than they do in countless myriads about this plant, which for quantity, quality, and flavor of honey, stands unrivaled. It is not only good for bees, but furnishes good grazing, and makes excellent hay, if cut when from one to two feet high, as it is then tender. It frequently grows to the height of 12 feet, even on poor places. It is thought that its fragrant odor, green or cured, is one reason why all kinds of farm stock are so fond of it. This plant possesses only a tap root, which penetrates deeply into the soil, thereby causing it not to be affected by our driest summers. It should be replanted about once in three years, and to start it in a new place sow in April or August. Early in the fall it may be seen putting in its appearance for the winter, attaining several inches in height by January, and is the only green plant to act as food for stock during our very often rigorous winters. So to sum up, this plant has advantages more varied than perhaps any other plant known to this country, as it is unequaled for honey, furnishes good grazing for cattle, horses, sheep and swine, makes good hay, and fills the air with a most delightful, pleasant and fragrant aroma.

Honey Cakes.

Mrs. L. Harrison, in *Gleanings* for June 15, writes as follows on the subject of using honey for making cakes and in cooking and preserving fruit:

I have just been eating some of Lydia R. Smith's cakes; that is, made after her recipe, and her papa is a judge of what is "good." These cakes have set me to thinking, and it would be well if it has the same effect on other bee-keepers. "How silly I've been to spend time selling honey to buy sugar when honey is better, and the purest sweet known!"

I lately read in a paper an account of how many bushels of corn are daily manufactured into grape sugar, to be used, it said, "for the adulteration of sugar, honey, etc." That is one reason why sugar is sold so cheaply; for every pound of sugar has more or less glucose. If I buy glucose, I would prefer to purchase it pure, not mixed with sugar.

I am glad children write, for they are wide-awake, and will set us to thinking, and I hope they will tell us every way they know, how honey is used. If that little girl away off in Washington Territory had not written her recipe, I should have had the cakes made of sugar. If am not mistaken it was a little girl who asked her papa, when she saw him boring a hole with a gimlet, to put in a screw, why the screws were not made with points like gimlets, and so the idea was born, of making screws with points, so that they did not need gimlets to bore holes first.

I have eaten gooseberries preserved in honey, and peaches canned with a teacup of extracted honey to a two-quart can of fruit, and they were excellent. Who will help to introduce honey? Take it to grange suppers, church festivals, old settlers' gatherings, picnics, etc. Use it in making layer cakes, and tell the people the cakes are made of honey, and many cakes of other kinds, of honey.

Will not some little girl work this motto and hang it in the hall of a neighboring grange—"My son, eat thou honey, because it is good?"

Mr. Root gives the following as his comments on the above: "I am very glad indeed to see the tendency to use honey in place of sugar, for cooking. Friend Newman publishes a very nice little book, entitled *Honey as Food and Medicine*, which every bee-keeper ought to have, if he has not got it already."

Expose Hives to the Morning Sun.

A correspondent has sent us the following from the *North American Quarterly Review* for December, 1882, with a request for its publication in the BEE JOURNAL:

"A story is told that in a village in Germany where the number of colonies kept was regulated by law, a bad season had nevertheless proved that the place was overstocked, from the great weakness of all the colonies in the neighborhood. There was but one exception, that of an old man who was generally set down as being no wiser than his neighbors; and this, perhaps, all the more because he was very observant of the habits of his little friends, as well as careful in harvesting as much honey as he could. But how came his colonies to prosper when all the rest were falling off? His cottage was no nearer the pasture. He certainly must have bewitched his neighbors' hives, or made 'no canny' bargain for his own. Many were the whisperings, and great the suspicions that no good would come of the gaffer's honey thus mysteriously obtained. The old man bore all these surmises patiently; the honey harvest came round, and when he had stored away just double the quantity that any of the rest had saved, he called his friends and neighbors together, took them into his garden and said: 'If you had been more charitable in your opinions, I would have told you my secret before. This is the only witchcraft I have used,' and he pointed to the inclination of his hives—one degree more to the east than was generally adopted.

The conjuration was soon cleared up; the sun came upon his hives an hour or two sooner by this movement, and his bees were up and stirring, and had secured a large share of the morning's honey before his neighbors bees had roused themselves for the day."

For the American Bee Journal

A Woodchuck Manœuvre.

WM. F. CLARKE.

I have had several tussels with Mr. Heddon, and always, until now, he has taken a good square "hold," but in his article on "Priority of Location," on page 340, so far as I am personally concerned, he fails to grip, and only dodges the points I made. Perhaps this is not altogether surprising, in view of the fact that he attempts to floor both Mr. Doolittle and myself at once, and I suppose that either of us is conceited enough to think it will take all his time for him to do it one by one.

Mr. Heddon deals me out a large ladle of taffy, which, being as fond of as most weak mortals are, I have swallowed with a great relish; the result being that I feel very much like the historic "Jack Horner" when he got through with his Christmas pie. This is perhaps why I am not quite willing to let Mr. Heddon have the last word on the present occasion.

He says: "Mr. Clarke should not claim better judgment in regard to the honey-yielding capacity of my own locality, than I have after watching the results in it for 15 years." I did not "claim better judgment;" I merely said, "I have an impression." This is greatly strengthened by Mr. Heddon's statement that he is stocking his field, the present spring, with nearly double the bees he has been in the habit of keeping, which is either an admission that he has underrated it in the past, or that it has improved by spontaneous growth or artificial seeding and planting.

After trying, in my article, to stiffen Mr. Heddon's backbone, it is gratifying to find him expressing the belief that now he has such "a good start in the business," that he is not likely to be troubled by the rivalry of a competitor with enough more of energy and intelligence to run him out!

But I took up my pen mainly to point out what I have called in the caption of this article, "A Woodchuck Manœuvre," on Mr. Heddon's part. I do not mean any disrespect by this comparison, which, it seems to me, is a very striking one. How often do we see this little creature poising in a calm and dignified manner beside its hole apparently regardless of the fact that it is pursued. But no sooner does the pursuer come to close quarters, than Mr. Woodchuck dives into his hole, where he knows he is perfectly secure. Mr. Heddon's honey-producing business is to him what its hole is to the woodchuck.

He takes the ground that no one can form a correct opinion on the question at issue, unless he derives his income wholly from apiculture. Even then it seems to be difficult, for Mr. Doolittle is mistaken as well as

myself. It is my misfortune, or my fault, that I do not "have a necessary concern in the interests of honey-producers." My case is, apparently, a very hopeless one. Mr. Heddon is not only of the opinion that I am mistaken now, but "always will be, I presume, until he lays aside all other sources of income, except apiculture. Then, in a few years he will get at the facts."

"Lor'-a-massey!" what chance is there for me? I am ruled out of the race altogether. Life is too short for me to change my business, adopt another, and prosecute it for "a few years" in order to qualify myself to form and express an opinion which will not at once be branded as necessarily "mistaken."

Let us turn the cake over. Mr. Heddon and I differ far more widely on a subject which bears about the same relation to my livelihood that apiculture does to his. Now if I were to take the ground that he is, and always will be mistaken on the subject of religion, because he does not lay aside all other sources of income except preaching, what would he think of my line of argument? I fancy he would have a vision of a reverend woodchuck diving into his hole.

Speedside, Ont.

Bee-Keepers' Magazine.

Cuba Flora and Honey Production.

A. J. KING.

The Island of Cuba is about 650 miles in length, extending nearly east and west, with an average breadth of about 50 miles.

A range of mountains traverses the whole length, nearly in the centre. At the eastern end they attain an elevation of 8,000 feet above the sea, but gradually diminish in height till at the western terminus, they are scarcely 1,000 feet high. From the base of the mountains, the country opens into extensive meadows and beautiful plains, which extend on either side of the central range, down to the ocean, where, in some places, the land is swampy.

Owing to the small breadth of the island, and the nature of the soil, there are no large rivers, yet the undulating surface being continually renewed by so great a variety of vegetation, gives rise to the most beautiful landscapes imaginable.

Cuba is not destitute of mineral wealth, but the copper mines of the Siera del Cobre Mountains, are the main source of wealth in this direction. Coal, marble, chalcidony and coppers are mined to a limited extent. There is also a thick firm slate, of a dark blue color, almost equal to marble, which is used extensively for pavements and for floors in some of their finest edifices.

Some of the finest mineral springs in the world are to be found on the island, and are patronized by patients from all countries.

In some parts the limestone constituting the secondary and tertiary formations is exceedingly porous, and

caverns, some of great extent, are common.

We visited what is known as the "Caves of Balmore," near Matanzas, in the western portion of the island. These caves extend for about three miles, much of the distance under the Bay of Matanzas, and are filled with objects of marvelous beauty; numerous rooms of from 200 to 300 feet square and 25 to 75 feet high exist, the walls and ceilings of which are completely frescoed with stalactites of the most beautiful forms, and the floors are covered with stalagmites so grouped as to greatly resemble thrones, beautiful gardens and fine scenery in endless variety, the reflection and refraction of the light from our torches caused the whole to appear like a vast sea of the most beautiful diamonds, and one could easily imagine himself in Fairyland.

The climate of Cuba, though somewhat hot and dry, is more equable than is generally supposed; the average temperature, near the coast, being 78°, while in the interior it is only 73°. Even the hottest months, July and August, give an average temperature of only 83°, and the coldest, December and January, give only 69°. In summer the thermometer rarely exceeds 82°, and in winter it is seldom noticed as low as 50°. The direct rays of the sun are hot, but in the shade it is almost always refreshing, and that feeling of sultriness and stagnation, so common in the North in hot weather, is almost unknown in Cuba, and there is seldom a night, even in summer, when one is uncomfortable under cover. Snow has never yet fallen on the highest mountains, but frost forming thin ice occasionally happens. Hail storms and hurricanes are much less frequent than in the other antilles, and earthquakes are seldom experienced, except in the eastern end of the island. Most of the rains occur from July to September, when it frequently comes down in torrents, but before and after these months only an occasional shower is experienced.

We have spoken of the vegetable productions in previous letters, and so will at present only give a list of some of the more common trees and plants depended on for honey.

The palm tree, at least four varieties, stands at the head of the list, as it affords quantities of delicious honey every month in the year.

The Campana—four varieties—furnishes large quantities of honey from December to March. In appearance it is almost identical with the "morning glory."

Almerygo, or Indian tree, has red and brown flowers, in size and shape the same as the large blue asters of the United States, blooms from October to April, and is a fine honey-producer.

Romorico blooms at the same time, having flowers much the same.

Cedro, a large tree, blooms all through January, and has bright yellow flowers smaller than the *Romorico*.

Mahogany is a large tree, and flowers at the same time as the *Cedro*, and has large, round blue flowers which are very sweet.

Coopa grows only in the immediate neighborhood of the ocean, and blooms every month in the year; its flowers closely resembles the pear.

Harsmendapersa (large tree) blooms twice in the year, in the months of June and December; flowers like the *Coopa*, and is a very excellent honey tree, both as to quantity and quality.

Mulla is a weed like shrub, has small yellow flowers, which yield nectar only in wet weather.

Acacasta (large tree) white flowers; blooms during May; the flowers are about the same as our small white asters. It is only a medium producer of honey.

Oranges and lemons bloom profusely in May, and afford only a moderate yield of honey. The bloom closely resembles the pear.

Attah is a tree with a small yellow flower, blooms during May. The flowers appearing in tresses greatly resembling bouquets. It is regarded as a very fine producer of delicious honey.

Pendahara is a small branching tree, with small yellow, round flowers, blooming from October to February.

Peng Yong is a tree with dark blue flowers, blooming in April. Honey very white, and of fine flavor.

Astronomia has blue flowers; resembles a bean in appearance, and blooms in December. The honey is very sweet, but not so agreeable in flavor as most of the others in this list.

The banana affords but little honey, and not of good quality, it being known as a "dead sweet." It affords nectar only immediately after a rain. The flowers are few, small and white.

For the American Bee Journal

Trembling Bees.

O. O. POPPLETON.

I have noticed several allusions to trembling bees in late numbers of the BEE JOURNAL, and I see that none of the bee-doctors seem to understand what is the trouble. Mrs. Harrison has also noticed them, and is puzzled.

I am sorry to say that I am able to give some information in this case; and but for the fact of the condition of my eyes at present, preventing my doing any amount of pen work, I would give a full description of the disease, with such facts regarding it as my observations have taught. I will endeavor to do so some time during the season.

It is a very bad disease, which is to a certain extent contagious. It has been in my apiary every season for the past 4 or 5 years; it having gradually grown less each year since its first appearance until this season, when it is again bad. It has already caused the loss of several colonies this season, and may cause more.

I have had some correspondence with Prof. Cook in reference to the origin or cause of the disease, but have not succeeded in discovering the cause. I am intending to make more thorough investigations than any we

have yet made. I judge, from experiments so far made, that sick bees will carry the disease from one hive to another; but that brood, honey, etc., can be safely given from a diseased colony to a well one without danger of contagion, provided no bees are transferred.

The disease is very irregular in its coming and going. It will sometimes disappear suddenly from a badly-infected colony, and I have never been able to find out what caused its sudden disappearance.

I cannot at this time attempt to describe the disease, its peculiarities, etc., as it should be done, but will do so as soon as possible, together with the results of whatever experiments I may make this summer. I only call attention now to what may be a very serious matter to others, as it has been and is to me, with the hope that some one will determine its nature, and find a remedy.

Williamstown, Iowa, June 18, 1884.

Bee-Keepers' Guide.

Do Bee-Keepers' Conventions Pay?

G. M. DOOLITTLE.

Well, that depends upon the spirit in which they are conducted. If they are simply for the purpose of getting a crowd of bee-keepers together, the majority of whom are obliged to listen to the dissatisfaction of a few who wish to discuss our bee-literature, or meet for the express purpose of puffing their wares, then such conventions are not beneficial. If, on the contrary, one convenes wholly for the purpose of discussing subjects connected with the practical part of bee-keeping, each one freely imparting knowledge on any subject to which he can add his mite, so that all are willing to give an equivalent for the knowledge gained, then I say bee-conventions will pay.

Had I been to our last Northeastern Bee-Keepers' Convention when they were discussing "bee-literature" to the benefit of none, but much to the disgust of many, thereby making enemies and scattering discord throughout the country, I should have tried to have instituted a discussion regarding some practical question pertaining to bee-culture in place of it.

If I disapprove of the course of my lawyer, I shall not employ him, and so with others until such a lawyer is obliged to quit his profession for lack of patronage. Of what account is it to him for me and others to be always talking against him and still always employing him in every suit. "Actions speak louder than words." Most of those who condemn the BEE JOURNAL, *Gleanings*, etc., keep right on taking these papers, and by their actions say they cannot get along without them. Hence, all this waste of time and temper is only a good advertisement for the papers they would feign have the world believe they are trying to kill.

There are three points to be kept in mind in attending conventions, if we would make them pay. The first is,

we should forget all the cares and duties which have pressed upon us during the year, and go to the convention like a boy let loose from school, to recuperate our health and life, by a free and social intercourse outside of convention hours. By such intercourse we often learn more of value than we do during the hour the convention is in session.

"But," says one, "I can go over to A's and chat with him on bees, and save the expense of attending the convention in a distant city."

This is so, but you cannot see B., C. and D. there, besides a host of others with whose names you are familiar, many of whom you could not see except at a cost several times that of going to a convention.

I fear we do not prize these social privileges high enough. There are things which pay besides money getting, and the social part of life is one of them.

To best illustrate this, I will give a little anecdote. A miserly man in this vicinity hired a man who was in the habit of attending all the fairs and places of social enjoyment; and after his going to such places several times, when the employer thought it would be better for his interest to have the laborer stay and work, the employer addressed him thus: "My friend, let me say to you, you are squandering your time in attending these fairs and picnics. If you would stay away from them and work, you would save one dollar a day, which, if laid up, would so accumulate that in old age you would have quite a snug sum saved that will now be wasted." The laborer listened patiently till the lecturer was finished, when he straightened up and said: "Mr. H. I expect I am going through this world now for the last time, and as this is so, I must get my pay as I go along. I never expect to come this way again, so of what use would that snug sum be to me after I have passed away. I propose to get some good of life, as my pay, instead of spending my life for naught save money."

Our second object is to get all the information we can, so that we can put it in practice during the season, and, if of value, impart this value at some future convention or to a bee-keeping neighbor. To best do this, I place myself in the position of a reporter, and jot down on a book the leading thoughts of each speaker, so that, when I arrived at home, I can go over this report, digesting it. What I think of value, I write out in my reference book, under the month during which it is applicable. This reference book has also in it all the good things I read in the BEE JOURNAL, each one put down under the proper month, so that under June we find what A. said at the convention, regarding the best method of swarming, and what is said on certain pages about putting on sections, etc. Thus we have all the good things stored up from the convention and otherwise, applicable to the month of June before us in such a shape that we can give them a practical test and tell at the next convention of that which

proves of value, and throw away the rest.

Thirdly, we want to examine all the implements, hives, etc., to see if any of them, or parts of the same will help us in securing our product in better shape, or give us more than we already secure with our fixtures.

To illustrate: One little thing I learned at a convention several years ago has paid me for all I ever spent attending conventions. It was this: Formerly my shipping cases had always bothered me, leaking so that when I piled them up on top of the other, the top one would leak a few drops, more or less, on to the case of the next one. When they were shipped, the dust would settle and stick to these places, thus spoiling the beauty of the nicest case. I tried halving the joints of the cases together, and numerous other ways, but leak they would, till I learned at a convention that a sheet of good manilla paper folded around a board so as to make a tray which would just slip into the bottom of the cases would catch and contain all the drip. By putting little strips across the bottom of the cases $\frac{1}{4}$ of an inch square, the sections were held above the drip, and thus all was kept clean and nice for the retailer.

I might give other things I have learned and other ways of making a convention pay, but it would make this article too long.

Borodino, N. Y.

For the American Bee Journal.

Deep or Shallow Frames.

WILLIAM HALLEY.

A good deal has been said about a standard hive. You will get people to think alike on this or any other when they look alike; but if it can be shown by actual test that one is any better than the other, it may have an influence with some. With this end in view I propose to give an old man's experience, hoping that others may test it fully.

I suppose that, perhaps, I made the first Langstroth hives in Winnebago county; at least I knew of none at that time. In the spring of 1865, I made a dozen hives according to Mr. Langstroth's directions; before I filled any of them, however, Richard Griffiths brought some filled with bees from Freeport. I bought Italian queens from Mr. Langstroth 15 years ago; these were the first queens that I know of being sent to these parts, and Mr. Langstroth was the only person, as far as I know, that sold queens at that time.

But to return to the hive; I thought after a time, that the frame was too shallow ($9\frac{1}{8}$ inches) for successful wintering. I think now the trouble was more the fault of being a beginner—a wish for too rapid increase, accompanied with bad seasons, and not knowing as well as I ought, how to take care of them. In late years I find no difference between wintering bees in them and in the deeper hives.

At any rate, I altered most of my hives over so as to take a 11-inch

frame. I thought they would swarm less and throw larger swarms. I found that the frames were difficult to handle; being apt to break down in hot weather. I did not gain much in regard to swarming, and they are very heavy to carry into and out of the cellar; but last spring I had 5 colonies in the shallow hives, and 10 in the deep ones, all in good condition. I put on a nest of 8 sections, partly filled with comb. When white clover bloomed none of them had much honey; unexpectedly I noticed, after a time, that all those in the shallow hives were working freely in the boxes, and had stored, I think, an average of 25 pounds each, before the bees commenced in the deep hives; the difference was so marked that I resolved to keep an account of them separately. The result is, that from the 5 shallow hives I got 400 pounds of honey and 4 swarms; they did not swarm so soon as those in the deep hives, and I think the hives contained more bees and gave stronger swarms.

From the 10 deep frames I got 8 swarms and 300 pounds of honey—this is at the average rate of 80 and 30 each. It will be seen that the deep hives had more room to fill up below, and several colonies in them did not get up to full working force as soon as they ought, but there was none that stored less than 15 pounds in the sections. I hope to be able to test this matter more fully another year. If I can get 25 pounds of white honey in sections, it will be worth more to me than the entire contents of a well-filled hive in the fall, as I do not extract, and I have to use brimstone to keep down the surplus colonies.

I will say that there are now about 800 Langstroth hives in use within my acquaintance in some of the northern towns of this county. I do not know of but one bee-keeper who uses any other. This does not look much as though the Langstroth hive was being abandoned.

Roekton, Ill.

Prairie Farmer.

Why Bees Swarm—Hiving.

MRS. L. HARRISON.

This question is often discussed at bee-keepers' conventions and elsewhere. The *why* always appears to me to be, that the Creator ordained that they should, for the multiplying of their species. When a hive is teeming with population, and honey is coming in freely, preparations are made for swarming. Scientists tell us that when drones are flying in the open air, bees construct queen-cells; but I have opened many a hive, from which an Italian colony had just issued, in search of cells, and could find none. I am not able to say whether the common bees issue without building queen-cells or not.

It is impossible to determine the exact time when a swarm will issue: the bees may have capped their queen-cells, and may have their haversacks packed for their journey, and a sudden rain cause them to suspend oper-

ations for the present, and destroy the queen-cells. A sudden check in the honey flow may cause them to do the same thing. Hives may be so full of bees that the outside is nearly covered with them, and their owner watch them for days, a week, or even a month, and they not even issue at all. No bee-master, worthy of the name, in these days of advanced bee-culture, allows his bees to manœuvre thus.

There is nothing that delights the ear of a bee-keeper more than to hear the slogan, "the bees are swarming." They pour out of the hive in steady columns, not one looking behind, but pushing straight ahead, rising, circling around until the air seems alive with them. They sing a peculiar tune, while swarming, which is never heard at any other time. When they are all organized in the open air,

"Round the fine twig, like cluster'd grapes they close,

In thickening wreaths, and court a short repose."

It is best to hive swarms as soon as clustered, for they immediately send out scouts in search of a home, and if these remain until they return, no amount of persuasion will induce them to tarry. The peculiar hissing sound they make while swarming, agitates other colonies, and they may issue and unite with the first, until there is a monster meeting, resulting in vexation and loss to owners. Hives and conveniences for speedy colonizing should be in readiness, and as soon as the bees are fairly clustered, remove them to the home they are to occupy. Sometimes it answers best to place the hive where it is to remain, and have a smooth board or a sheet, whichever is preferred, in front, and carry the bees to it; this can be done nicely when the limb or twig upon which they have clustered is removed from the tree. If placed in front of the hive, and slightly jarred, the bees will enter, uttering a joyful note that a home is found, and calling to their companions to come on.

When a swarm is large, and rich in honey and wax, bees frequently fall in large bunches on the ground; in such cases bring the hive to them, but as soon as they are all in, put it on the permanent stand before the scouts return.

A lady who is engaged in bee-culture, writes me she fears being unable to hive her swarms. She says: "I have supplied myself with all necessary dress, and with hiving-box, hook and poles, also with a hiving-bag, with a hoop in the end, and if necessary can climb a tree." Some apiaries are supplied with large baskets, lined with muslin, and have a burlap cover or flap, which can be turned over when full of bees. When many swarms are issuing, the bees can be left covered up for a short time, without detriment. Fountain pumps are a convenience in wetting absconding swarms, and in preventing swarms from uniting. Newly hived swarms should not be left in the sun; neither should hives be used that have been exposed to its rays. Bees are excited and hot while swarming, and if not

put into a cool hive, in a shaded place, will desert. It is not necessary to wash a hive with apple leaves or mint, as our grandmothers did, but a bucketful of fresh cold water may be dashed into a hive, washing out the dust, and making it fresh and cool. Bees always desert a hive for good cause; it may have a disagreeable odor.
Peoria, Ill.

For the American Bee Journal.

Michigan Hybrids.

W. H. SHIRLEY.

My experience so far with the Michigan hybrids is, that they have no control over the weather, so far as I can see, and in consequence have to gather thin honey sometimes, or none at all. Such was the case here in 1882 (part of the season), and to put a frame filled with honey in any position except the one in the hive, would cause the honey to run out. I can well see why Illinois doubts our word, with her strain of bees, for a description of the same see pages 391 and 392.

In regard to reversible frames I stand reversed, because by their use I now can see that a larger majority of our frames are more perfectly filled with comb. The brown German bee and the Michigan hybrids with us never needed their combs turned upside down to force them up into the surplus arrangements.

I have read the back numbers of the BEE JOURNAL; also, such part of the "elsewhere" as I could find, and yet fail to see any great bonanza in reversible frames, except the one point mentioned—viz: perfect combs, and that is a valuable point.

Glenwood, Mich., June 23, 1884.

For the American Bee Journal.

Priority of Location.

J. E. POND, JR.

When I wrote my last article on this subject, I intended to stop right there, and not allow myself to be drawn further into the discussion; not that I had nothing more to say, but that I thought enough space had been devoted to a matter that was more of a personal than apicultural nature. When, however, I am attacked as a lawyer, I feel it a duty to make a defence.

Mr. R. J. Kendall, on page 392, admits that *legally* I am right, and then says: "As a lawyer I am not a little surprised at Mr. Pond's taking up the position he does, for the *law* in its principle goes dead against him." Let us try and analyze this somewhat strange idiosyncrasy of Mr. K. He states two propositions; first, I am legally right; second, he is surprised that I take the position I do, for notwithstanding the fact that I am legally right, legal principles do not sustain me. Well, I am willing to leave this branch of the subject right there; but Mr. K. goes a step further, and opens up the question of tenures and titles; what point he expects to

make by this I fail most decidedly to see; neither do I know of any legal principle whatever, whether relating to tenures and titles, estates in fee or entail, that will give Jones' bees tenure of my estate in fee, even if Jones has stocked an apiary before I get ready so to do. The principles of law, as I understand them, require 20 years of adverse, uninterrupted and exclusive use, to get tenure of my estate in fee. Jones, by squatting on my land for 20 years, may get a legal title to it, but he certainly cannot get such a title through such agents as his bees. When Mr. K. comes to think the matter over a little, he will see that he has made a slight mistake in his application of legal principles; he forgets that bees are partly in *fera natura*, and that while they are considered property while in sight of their owner, or when occupying his hives, the instant a swarm leaves Jones' apiary and settles on my land without Jones' knowledge, the bees become mine by right of possession, if I choose to hive them. What then becomes of tenures and titles?

Foxboro, Mass., June 20, 1884.

For the American Bee Journal.

Manufactured Comb Honey.

J. W. MARGRAVE.

A few days ago I chanced to meet a member of a large grocery firm of St. Joseph, Mo., who very positively affirmed that they had often bought manufactured comb honey of Jerome Twitchell, of Kansas City, that it was sold to them for manufactured honey; that he had met persons who had been to the factory and had seen the machinery, and *knew* all about it.

It was in vain that I told him that was all a mistake, that glucose had often been mixed with extracted honey and sold for pure honey; but that comb honey could not be made by machinery, that that abominable lie was the result of a silly canard written a few years ago, and had to be revamped and peddled around every year or so, and that he was the last man to so peddle it.

I think it due to Mr. Twitchell to say that I think him incapable of any complicity with fraud in such a deal, if it were at all possible.

I told my informant that Mr. Twitchell had more sense than to ruin his business in any such way. If Mr. T. wishes the name of the firm, I can give it, as also the name of witnesses to the conversation who were present; it being in a grocery store where I had gone to try to sell some nice basswood comb honey. Such things are very embarrassing.

At a meeting of our County Agricultural Society last fall, I was asked to speak on bee-culture; at the close of my remarks I was catechised by one old man in regard to feeding bees on glucose and letting them fill up their combs in that way. He said a Mr. H. of Linn County, Iowa, fed his bees on it, two days in the week, and let them work the rest of the time on the flowers, etc., and said he had

spoiled the honey made in that county, etc., etc.

Now, Mr. Editor, what can be done to stop all this despicable foolishness, that is corrupting the public mind in regard to the adulteration of honey? It is very damaging to our legitimate business, and we as bee-keepers must do something to vindicate ourselves. What shall it be?

Hiawatha, Kansas.

[The practice of feeding bees with glucose, even though it were of harmless intent, was one of the greatest of curses to the bee-keepers of America. It opened the way for all these foolish stories about manufactured comb honey, etc.

We are glad that these peddlers of Wiley's lies have located it somewhere at last. Now Mr. Twitchell will be able to clear it up, we think.

Mr. H., of Linn County, Iowa, we hope will be able to show that these are but foolish stories of gossippers, without the shadow of proof except, perhaps, the foolish practice of feeding bees glucose to keep them from starving in the spring. Both gentlemen are invited to "speak out" in the BEE JOURNAL.—ED.]

Marshall County, Iowa, Convention.

The Marshall County, Iowa, Bee-Keepers' Association met at Marshalltown on April 5.

The meeting was one of much interest all through, and was well attended. The following officers were elected for the coming year, viz: Joseph Swift, President, State Centre; G. W. Keeler, Vice-President, Marshalltown; J. W. Sanders, Secretary, Le Grand; and G. W. Calhoun, Treasurer, Marshalltown.

The Secretary made the following report on the subject of a better display of the apiary at our county fair:

I had a conference with the officers of the fair, and was promised a department for the apiary, and a donation of \$25 in premiums and fixtures for this important industry. By request of said officers, I prepared a premium list for the fair, including almost all the arts and novelties of apiculture, the object being to promote and encourage this industry in a practical and scientific way; and not for the money we may obtain on premiums. In this way we can learn much from each other, and at the same time encourage the sale of our honey.

On motion of Mr. Nichols, it was decided that the society increase the premiums of said list by donations, and \$8 were subscribed and paid in for that purpose. The executive committee were appointed to have charge of this donation, and still solicit aid by subscription for this purpose, it being the desire of the society that \$50 more be raised for this purpose, which would aid the fair appropriation very much.

After an extensive and instructive discussion on "Spring Management," concerning "Summer Care of Bees," Mr. J. Moore said he had not given his bees the attention they needed in the past, owing to his farm work, but intends to give more care in the future. Had tried dividing, but did not like it, for he got 3 or 4 weak colonies instead of 2 good ones.

"How many swarms would you allow to the colony?" "Only one, and if second swarms issue would double up. I unite them by the use of smoke."

"How do you manage two swarms settled together?" "I take two hives and a sheet; shake the bees on the sheet and start them to both hives, and capture one of the queens so as to prevent both going into the same hive, then add the captured queen to the one that proves queenless."

Mr. L. Cooper sprinkles with water to separate the swarms.

Mr. W. P. Cover sets out as soon as it will do in the spring, feeds rye flour and gets them to swarming as soon as possible. He was questioned:

"How do you prevent swarming too much?" "I kill the old queen that issues with the first swarm, and return the swarm to the hive they came from, and when it swarms again with a young queen, I live this swarm. I some times add a new swarm to a weak colony. I had 23 swarms in one day, last summer. When two or more settle together, I separate them as has been stated, by the use of a sheet and two or more hives to drive them into. I use 5-pound boxes for surplus honey. I never keep light colonies, for my object is honey and not increase in number."

On "Profits of Bee-Keeping," Mr. G. W. Keeler being called for, said he had kept bees for five years. The first two years they did not pay expenses. The third year they made about \$3 per colony, spring count. The fourth year, 1882, he began with 23 colonies, and obtained in comb and extracted honey 4,738 pounds, which is 206 pounds per colony, spring count. He sold \$700 worth of honey, and had all they could use besides. The expenses were \$100. The fifth year, 1883, he began with 37 colonies, took 3,730 pounds of comb and extracted honey; 100 pounds per colony. He had sold \$400 worth, and had a quantity on hand yet. Expenses were \$100 for hives and surplus arrangements.

Mr. L. Cooper stated he makes his swarms or new colonies after the honey season. His average per colony, spring count, in 1882, was 200 pounds of extracted and 20 pounds of comb honey. He uses a large hive, and has taken from a single colony at one time 2 gallons of extracted honey. He extracts from the body of the hive. In 1882, from the same number of colonies of equal strength run for comb and extracted honey, he obtained ten times as much of extracted as comb honey, and last year six times as much. He obtained in 1883, 100 pounds per colony, spring count. It was not a very good honey year. One trouble in extracting is wet weather.

He was questioned thus: "How do you prevent swarming?" "I allow no drone comb, cut out the queen-cells, and keep a good supply of worker comb for the use of the queen. I do not keep so many bees but that I can attend to them in connection with other work. I have Italian bees. I do not use smoke, and I am not troubled with their stinging when working with them, for they have got used to it."

The subject for discussion at the next meeting is, "Late Summer and Fall Care." The executive committee appointed G. W. Putnam, of Holland, and J. W. Sanders, of LeGrand, to read essays. The society then adjourned to meet Saturday, July 5, 1884, at 10:30 a. m., at the Court House in Marshalltown, Iowa.

JOSEPH SWIFT, Pres.

J. W. SANDERS, Sec.

For the American Bee Journal.

Apis-Americana.

DR. G. L. TINKER.

In working my bees for comb honey without separators, several interesting facts have been developed. The first is, that there is a greater difference in the comb building capacities of the various strains of bees than was supposed.

One caps over the combs very smoothly and white, and builds all of their combs as true and regular as if laid off with a straight-edge. The comb built is also exceedingly delicate, the amount of wax in it being at a minimum, and the nectar stored is as clear as water; the whole being "fit for the gods" truly.

Another strain builds heavy combs (that is containing much wax), although straight, and caps them over roughly, and also only moderately white. The same also stored at the beginning of white clover bloom quite a quantity of wine-colored honey so strong as to be unfit for the market.

Another strain builds delicate combs, but the capping looks as if water soaked. They also build in between the combs many bits of wax or cross-bars, which is a bad trait in any strain.

A strain of German bees, crossed with Italian drones, cap their combs very white but roughly, and are prone to build all of their combs crooked, so that with them it would be impossible to get nice straight combs without separators. They are also inferior in many respects to the Italians, do not make so much honey, and in the height of white clover bloom have collected a lot of dirty-colored nectar, and stored in sections. Yet they are located near by.

What bee-keepers want is a strain of bees that will build clean, straight combs without separators, cap them over white and smooth, and at the same time use as little wax as possible in their construction. (True, such comb honey does not ship so well, but those who consume it will appreciate it, and want more.) They must be prolific and good workers, breed up

rapidly in the spring, and swarm early to get the most out of them.

As I look at it, this is the ideal of what "the coming bee" must be. By a lucky hit I have just such a strain in which every one of the above points would be hard to excel. The strain was produced as follows: The beginning was a pure Syrian queen obtained from Mr. D. A. Jones, and mated on the islands of the Georgian bay. I have her still, although she is now about three years old. She has not yet led a swarm this season, but is soon expected to, as she has led a swarm every year without regard apparently to the flow of nectar, but never early. She is very prolific, and the workers are very gentle to handle, even more gentle than the Italians. Last season there was a second swarm when I opened the hive and began to cut out the queen-cells. There were 25 or more of them, and they were laid on the tops of adjacent hives. I had a number of tumblers to put over them, but not enough, and soon the young queens were flying and running in all directions. After some time I had killed them all but one of the finest and largest. This queen, I think (but of course do not know), mated with an Albino drone. Her bees were very beautiful and gentle, so I bred a number of queens, and introduced to colonies not up to my idea, and these queens were mated with Italian drones. They were at first, on emerging from the cells, almost white, but soon had the general appearance of Italian queens. The bees from each of these queens build comb like the bees of their mother, and cap it over very white. They build no cross-bars of wax, and as truer combs were ever obtained by the use of separators, and the sections used on two of the colonies are nearly 6 inches square. The brood combs, likewise of the new colonies, are built as straight and regular as it is possible to be, and were spaced $1\frac{1}{2}$ inch.

In clipping the fine queen above referred to, in April, I found her to be the largest and strongest queen I ever handled, and I clip all queens held between the thumb and forefinger of the left hand. In breeding up, the past spring, she had 11 Gallup frames filled almost solid with brood on May 1. I then gave her no more, and she led my first swarm on May 24. She could easily have filled 18 Gallup frames with brood by the first of June. Her bees will produce more than twice the amount of comb honey of any Italian colony I have.

Her daughters were in hives made to hold only 9 frames, so I could not give them more combs, and they did not have a fair chance, but far exceed the Italians in the number of bees and the quality and the amount of their work. What these queens require is a hive holding not less than 10 Langstroth or 12 Gallup frames in breeding up. But I have never had an Italian queen that could fill that many frames full of brood by the first of June. All my full colonies were fed in April and May, and several Italian colonies were pushed to

the utmost, but in every case have turned out second best to the colonies of the new strain which were fed less, and of which less was expected.

What caused me to supersede the other daughters and grand-daughters of the old Syrian queen that I have reared at different times, was because the workers capped their honey so that it appeared water-soaked, and also because some of them had mated with black drones and were ugly. How it comes that the bees of my favorite queen and her daughters build such nice white combs while the others have not, I will leave to others to explain, but of one thing I am assured, the "coming bee" has no German blood in her veins.

New Philadelphia, O., June 25, 1884.

SELECTIONS FROM OUR LETTER BOX

Excellent Honey Crop.

The season was slow here, that is, the early part of it, but is now most excellent for clover surplus. Swarming commenced unusually late, but once having commenced, it is exceedingly rampant, though not equal to last year. We are bound to get an average crop of surplus from clover this season, because we have got it now, and still it comes. Our bees shake their heads at "loose" honey "laying around." They prefer the nectar in its virgin bloom.

G. W. DEMAREE.

Christiansburg, Ky., June 23, 1884.

Bees Working on Clover.

I started this season with 120 colonies, and they have the boxes mostly filled, but not capped sufficiently to be removed. As the brood-chambers are also full, I find it impossible, in the absence of tiering-up material, to keep them from swarming. Ten swarms yesterday, and more to-day, makes a tired bee-keeper "hump himself."

L. HUBBARD.

Waldron, Mich., June 25, 1884.

Honey Report.

My report for 1883 is as follows: I ran 27 colonies for honey last season, which gave me 2,250 pounds of honey, mostly extracted, making an average of 83 pounds and a fraction to the colony. In 1882 my report from 17 colonies was 1,400 and some odd pounds, making an average of 84 pounds and a fraction to the colony.

Up to this date, this season, I have extracted about three barrels, and the flow still continues. I have on hand about 500 pounds of last year's crop unsold, which is all granulated, and almost as nice as granulated sugar: the balance I sold at 12½ cents per pound. I have a Root chaff hive from which I extracted 7 gallons of honey at one time, this season, and it will be ready to extract from again in 4 or 5 days. The 7 gallons at 11 pounds to

the gallon, would be 77 pounds. Nearly all the honey we have extracted up to this date, this season, is poplar, and so thick that it was difficult to extract. I think this the finest honey produced. I like the flavor of it better than white clover, although it is not so light in color.

JOHN FARIS.

Town House, Va., June 23, 1884.

Foundation with Deep Cells.

In the latter part of May I put several samples of the deep-celled foundation, mentioned on page 355, in the second story of one of my hives, and the bees built it up nicely. As far as I can see now, they will make very good combs with it.

Cincinnati, O. WM. STUEBING.

What Ails my Bees?

My bees have swarmed but once this season. I have 7 colonies in good condition, in Langstroth hives; at least we call them that: the brood-chamber is 12x16, and 10 inches deep, with 6 frames inside and 3½ inch honey-board on top, and 3 honey boxes over that.

G. W. HENSON.

Dulaney, Ky., June 17, 1884.

[One swarm from each colony should satisfy you, unless you wish increase instead of honey. The hive is an antiquated mongrel, but management is of more importance than the particular kind of hive. You should use one or two-pound sections instead of the 3 large boxes, however. They are completely out of date now.—ED.]

No Swarms.

Generally, the bees have wintered with only small losses, but they consumed a larger quantity of honey than is usual while in confinement. The spring has been so late, cold and rainy that in most cases the bees have had to be fed until this week; and, so far, there have been no swarms cast that I have heard of yet, and in my opinion, there will not be any for 10 days more. White and Alsike clover commenced blooming one week ago, but yielded no honey until yesterday, and now the bees are working hard. As this is the off year for basswood bloom, there will not be more than a half yield from that; and unless the weather will be favorable for the clover, the yield of honey from it will not be more than half of a crop.

E. J. SMITH.

Addison, Vt., June 16, 1884.

Fastening Foundation in Frames.

I am a beginner in the bee-business, and I am having some strange developments and experience. The first of last December I bought 9 colonies in Langstroth hives, moved them 30 rods to my new bee-house all right, and packed them for winter. On March 12, 4 colonies were dead, on March 18 another one died, and by May 1, 7 colonies had died. The 2 saved are now strong and are doing well. My third swarm hung on the outside of the hive

for 55 hours before they would all enter at once. I shall never move bees again in cold weather. To fasten foundation in the frames, I slit the top-bar in the centre to within one inch of one end; that keeps them together till they are notched and ready for the foundation; then with a back-saw separate the two halves, start a nail in one-half of the frames 4 inches from each end, and lay the foundation on the other half; smooth and straighten it, bring the other half to its place and drive the nails through, then the top-bar is ready for the frame. In this way I can put on ten times as much foundation in the same time, and in better shape than in any other way.

C. W. STANLEY.

Dunlap, Iowa, June 18, 1884.

Not a Honey Plant.

My bees are working on white clover. Enclosed find leaves and bloom of a plant, the seed of which was among some sweet clover seed I sowed a year ago. This plant looks like tansy when first coming up; it has from 10 to 17 stalks from one root, and grows from 18 to 24 inches high. What is it? If it is a honey plant I will let it go to seed; if not, I want to destroy it before it seeds my field.

D. S. KALLEY.

Ferndale, Ind., June 19, 1884.

[The plant is *Archangelica hirsuta*, entirely worthless for honey.—T. J. BURRELL.]

Bee-Keeping in Texas.

I have before given my experience in apiculture up to Feb. 1, 1883. I began with 31 colonies; increased to 50. However, owing to inexperience and a poor honey season, I had but 45 to go into winter quarters (if I may use such an expression in my extreme Southern home). For on the last day of December my bees were at work on a late crop of sorghum, and the wild flowers of the country. It was well for me (to use a familiar term) that it was an "off year" in honey. It gave me time to study, to read, and to put in practice the working of the apiary. I have studied all the works I could procure, and the BEE JOURNAL, which comes weekly freighted with words of cheer and practical advice. At no time through the winter was there more than 3 days at a time that my bees were not on the fly. On Feb. 2 my bees brought in their first fruits of 1884; they came loaded with pollen. I then began the work of 1884 feeling very much of an apiarist. Out of the 45 I found one dead and 4 queenless, and the majority of the remaining 40 were weak. I fed none, though I see now that it was false economy. From Feb. 1 we had an unusual cold spring. My bees have been up on a "continual boom" of 4 months. By following Doolittle's advice upon spring management, I got my colonies as near the same strength as possible. On April 1, I had my first swarm. I have increased them to 70. On May 1 the 70 colonies took to the horse-mint. I did my first extracting on May 26, then in every 8 days each

frame would be full, and the bees were starting in the 2-inch cap. I use the Langstroth hive, but not the standard frame. I run for extracted honey. I changed the frame to run crosswise. I am pleased with the change. I had but few sections, one and two-pound. They have been filled, and so even, without separators, that, out of 200, there is not more than 10 that could not be crated. I have, up to date, extracted some 1,200 pounds, and took 400 pounds of comb honey. I expect another run on the Brazil or red wood. I feel encouraged, and know that I will be instructed for 1885.

JNO. A. EMISON,
Mission Valley, Tex., June 17, 1884.

Carbolic Acid for Quieting Bees.

I notice in the Weekly BEE JOURNAL an article on handling or quieting bees, where carbolic acid is used, by an Englishman, and claimed to be superior to smoke. I would ask him if he has had any experience in the use of the acid? Does he use it of absolute strength, or does he dilute it? If so, what per cent. of water does he use? Bees are on a regular "boom" here. My hives are all full of surplus. E. R. W. McCRARY,
Lindale, Texas, June 23, 1884.

[Will our English correspondent please reply to these queries.—Ed.]

Poor Prospect in Southern California

The season of 1884 opened with a fair prospect for a good yield of honey, but for the last month we have not had 5 clear days, and it is very discouraging to the bee-keeper in this part of California. Bees have swarmed very well; and swarming is about over. I started in the spring with 67 colonies; increased to 130 by natural swarming. I expect about 30 more. Mr. Enas complains of bad weather in Napa, and says it looks discouraging. JOHN L. SECOR,
Monterey, Cal., June 14, 1884.

White Clover Yielding Finely.

White clover is yielding finely. I have never known the bees to be busier than at the present. W. Z. HUTCHINSON,
Rogersville, Mich., June 14, 1884.

MARRIED.—At New Boston, Ill., May 15, 1884, at 7:30 p. m., by the Rev. H. K. Metcalf, Miss Mary Scudder, adopted daughter of L. H. Scudder, to Mr. Will M. Kellogg, of Oneida, Ill.

We congratulate our young friend for his wisdom in entering *this kind* of partnership. Being a bee-man ought to insure a sweet disposition, and this in turn will cause the *honeymoon* to shine on through life. We hope the festal board of our friend may, in time, be swarmed with beautiful workers, and not a *drone* among them.—*Magazine*.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Cleansing Wax.

1. Which is the best way to cleanse old, dark-colored combs?
2. Is it of any use to cut holes through the combs, when putting bees into winter quarters?

E. W. MERRILL.

Barker Creek, June 16, 1884.

ANSWERS.—1. Old dark combs, if otherwise good, need not to be discarded or melted, and they need no cleansing.

2. The "use" of this practice has never struck me with force enough to make me think that it pays for the trouble to bees and bee-keeper.

Removing Starch from Foundation.

Please tell, through the BEE JOURNAL, how to remove the starch or alkali used upon the rolls from foundation sheets. I find some difficulty in drying the sheets when packed. Bees are booming, and hard to prevent from swarming. L. HUBBARD,
Waldron, Mich.

ANSWER.—I know of no better way than rinsing in water. Pile the sheets up edgewise on sloping shelves, and they will soon drain and dry. The white precipitate removing from the use of lye, is perfectly innocent and harmless. I presume the same is true of starch. We know whereof we speak by careful experiment among the bees.

Increase.

I have purchased a superior colony, and I wish to increase the stock as fast as I can. I do not care for honey this year, what is my best method of procedure? I cannot see any queen-cells yet. They are storing fast from oceans of white clover. GAYLORD, Mich. J. H. SCOTT.

ANSWER.—There is no method of increase a description of which would be suitable for this department, or which I would advise a beginner to practice. If your colony would rather gather honey than swarm, give them plenty of surplus room. Sell the honey and buy increase, is my advice.

The Use of Salt in the Apiary.

Will it do any injury to throw salt in front of the hives, to kill the weeds? I was told it would kill the young brood. What is the best way to keep the weeds out of the apiary? A. SUBSCRIBER.

ANSWER.—No, the salt will not effect the young brood if thrown down in front of the hives. I would cut the weeds 3 or 4 times during the season, or lay a board down in front of the hive, or both, and use the salt for some more useful purpose.

Plan for an Apiary.

For the last two years I have been very successful in the culture of bees and grapes. I want to enclose a piece of ground with a tight board fence 6 feet high all around, except the portion near my house, as Mr. Heddon directed on page 396; and on the same page is his plan for locating the hives. The plan, I think, is a good one.

1. Can two hives be set together one facing the east, the other the south; with the end of one to the side of the other in the shape of a T, a few inches apart so that one shade or cover will protect them both, two and two, 10 feet apart each way? Will that be too thick—my ground is limited?

2. After placing the hives as above mentioned, then plant a grape vine, 3 or 4 feet south of each hive, setting a good locust or mulberry post, 3 feet deep and 7 feet high, with two cross-bars in the shape of a letter X of good wood, and wire interwoven for vines to run upon, making a shade for each set of hives, 6 or 7 feet square overhead?

One of these to 10 feet square will leave 3 or 4 feet all around, by keeping them trimmed while growing. Would such be in the way of the bees, while at work? J. M. PRATT,
Todd's Point, Ky.

ANSWERS.—1. I do not see how you can make one shade board do justice to 2 hives. Again, when manipulating one, the other is in the way.

2. Regarding the grape vines, I prefer a "readily movable" shade, such as the wide board before described; and that I can take out of the way entirely, just when I desire. There are times of the year when we want everything tending to shade, out of the apiary; and when "room is limited," I should certainly prefer the shade-board to a vineyard. The vines would not, if properly trimmed and trained, interfere with the egress and ingress of the workers.

Errata.

On page 405, in the second paragraph of "My Winter Report," read: "and excess of pollen not at all. Read, 11 barrels of granulated sugar. Let me here add, that the 45 pollenless colonies that could not breed till later in the season, are very preceptibly ahead of those that did; after "untested," remove "to breed from." I suppose it was my mistake. I do not consider any fit to breed from except those tested for qualities, and most thoroughly too.

The Lucas County Agricultural Society offers the following premiums at its 17th annual exhibition, Sept. 10, 11 and 12, 1884: Best colony of Italians, \$10, \$8; best colony of Cyprians, \$10, \$8; best colony of hybrids, \$8, \$6; best honey, comb, \$5, \$3; best honey, extracted, \$3, \$2; best bee-hive, \$3. The Bee-Keepers' Association will meet on the second Saturday in July, at the Court House at 1 p. m. sharp. All are requested to attend.

Chariton, Iowa. A. REUSCH, Sec.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
 Monday, 10 a. m., June 30, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour :

CINCINNATI.

HONEY—The demand for all honey is very slow; market dull and prices range from 6@8c for extracted. Different lots of choice comb honey in small sections have been offered and sold in our market lately at 12@14c per lb. As I predicted some time ago, the preference for the production of comb honey seems to be prevalent; and, as we have the best prospects for an abundant harvest this year, we may prepare for low prices.

BEESWAX—Is in good demand; choice yellow brings 35c a lb. on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—Present sales of comb honey are slow, and will be until the new crop arrives. We quote : Fancy white 2-lb. sections, glazed, 13@13c; fair to good in 2-lb. sections, glazed, 11@13c; dark grades in 2-lb. sections, glazed, 10@12c. No 1-lbs. in this market. Extracted, white, 8@9c; dark and buckwheat, 7@8c.

BEESWAX—Prime yellow, 34@35c.
 MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15c, and 2½-lbs. to 2½-lbs. from 10@12c. No 1-lbs. in the market. Extracted, 8@10c.

BEESWAX—35c.
 BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—The new crop of comb honey is coming on the market, and nearly all of the arrivals to note are in good order, and the quality of the honey is of the best, being white, and flavored with clover and Linden; frames are unusually well-filled. The crop of comb honey of 1883 is nearly all cleaned up. We have not had any old comb honey to offer for several days. Extracted honey is in very light demand, and prices irregular; the stocks of it are large.

BEESWAX—Not plentiful, but the demand is also light at 30@37c for fair to prime.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There are moderate receipts but little or no demand. Values are not well defined. White to extra white comb, 15@18c; dark to good, 10@13c; extracted, choice to extra white, 5@7c; dark and candied, 5@6c.

BEESWAX—Wholesale, 27½@30c.
 STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—Some little activity has developed in the honey market since my last report, and several thousand pounds have gone out in the past few days, both comb and extracted. But it happens to be only a bunching of orders, and has had no material effect on prices, which rule at 14½@15½c for comb, and 7@8½c for extracted.

BEESWAX—Nominal, at 30@35c.
 If any one has failed to receive a copy of my little Pamphlet on "Preparing, Packing and Shipping Honey," I will be pleased to mail one free.

JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@6½c.

BEESWAX—Firm at 32@32½c for choice.
 W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1-lb. sections at 18c; 2-lb. best white not quite so active at 17c; 1-lb. sections sell quickly on arrival, and often are sold to arrive. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.

BEESWAX—Scarce at 35c.
 A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2-lb. sections, 10@17c; extracted, 7½@8c.
 GEO. W. MEADE & CO., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

We now club the *British Bee Journal* and our Monthly for \$2.50, or it and the Weekly for \$3.50.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows :

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can not be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter on your label notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

We have received the Circular and Price List of Bagnall Bros. & Co. for 1884-85, in Turua, New Zealand. It contains 24 pages and is nicely printed with a cover, and illustrated with lots of American engravings of bee-keepers' supplies. The BEE JOURNAL congratulates New Zealand upon such a creditable enterprise.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Convention Hand-Book.

It is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

What they Say of it:

From Prof. A. J. Cook, Lansing, Mich.—"I have greatly to thank you for getting up the exquisite little Convention Hand-Book. Surely the old 'saying' is true—being a thing of beauty, it ought to be a joy forever."

From Mr. A. I. Root, Medina, O.—"Send me—dozen of the Convention Hand-Books. We have had quite a number of inquiries for something of that sort, and yours seems to be quite nicely gotten up, and just what is wanted."

From Mr. J. E. Pond, Foxboro, Mass.—"The Convention Hand-Book is just the thing. The digest of Parliamentary Rules it contains will prove of great value to every one. I trust it will receive the patronage it so well deserves."

From G. M. Doolittle, Borodino, N. Y.—"I am in receipt of the new Convention Hand-Book, and must congratulate you on the happy thought of such a work, and the neat appearance of the book. It is a work you may well be proud of, both as to the matter it contains, and the splendid material used in its make-up. It will meet a long-felt want; and, were it so that I could attend conventions as in former years, ten times the price would not seem too much to pay for it, for by the instruction therein given, any man could be kept from many a blunder, much to his mortification. I hope in the near future to again be at liberty to go to conventions, when I shall prize the work very highly."

From Mrs. L. Harrison, Peoria, Ill.—"The Bee-Keepers' Convention Hand-Book is a gem. It should be in the hands of every one who attends a bee-convention, and then there will be no need of embarrassment on account of ignorance of Parliamentary Rules. Accept my thanks for sample sent."

From Mr. Jas. Heddon, Dowagiac, Mich.—"The Bee-Keepers' Convention Hand-Book is received. I saw it advertised, but conceived no approximate idea of its great value to bee-keepers attending conventions, until I perused it. Many times the price of my copy would be no temptation for me to do without it. It will make us all want to talk at once, I fear. You deserve the thanks of all, and I herewith tender mine for this helper."

From Mr. G. W. Demaree, Christiansburg, Ky.—"The Convention Hand-Book is the most exquisitely gotten up, and the nicest book in my collection of apicultural works. It contains much valuable information, and especially as many of the presiding officers of our conventions are selected to fill those important positions because of their practical skill as apiarists rather than for their fitness as presiding officers, this little work will fill a long-felt want. Please accept my thanks for your untiring labor to promote the apicultural interest of the country."

From Dr. G. L. Tinker, New Philadelphia, Ohio.—"I prize the Convention Hand-Book very much, and it will be a valuable aid to bee-keepers attending conventions. The questions for discussion are concise, and cover the field of the most interesting and unsettled points in bee-culture. The book will help to systemize convention work, and enable the members to do business properly."

From Mr. W. Z. Hutchinson, Rogersville, Mich.—"If every bee-keeper would read the Convention Hand-Book, and profit by its perusal, our Conventions would be more orderly and have more beneficial."

From Mr. George Hilton, Fremont, Mich.—"I think the Convention Hand-Book is destined to fill a long-felt want, and should be in the hands of every intelligent bee-keeper."

Honey as Food and Medicine.

A pamphlet of 16 pages giving Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On order of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

A Canadian wishes us to state in the BEE JOURNAL, whether we take Canadian money for subscription or books. We do; and for fractions of a dollar, Canadian postage stamps may be sent.

Syrian & Italian Queens
BY RETURN MAIL.

Tested, \$2.50 each. Untested, Single Queen \$1.00, Six for \$5.50. Twelve for \$10.00. Cook's Manual (cloth) with order for Queens, only 90 cents. Safe arrival guaranteed.

G. H. KNICKERBOCKER,
PINE PLAINS, N. Y.

Bingham Corner.

MARENGO, ILL., June 18, 1884.

The Doctor Subdues All.—Mr. T. F. BINGHAM, Dear Sir: I've used the "Doctor" till its all daubed up with bee-glue, and although at first sight I thought I did not like anything so large, I could not now be induced except by the direst poverty, to do with anything smaller. As a matter of "economy" I much prefer the "Doctor" to any of the cheaper smokers, of which I have worn out several. The "Doctor" has entirely cured me, so that I am now a Bingham man, as my wife always has been. If the somewhat vague remark in your letter means that nothing was charged for the Smoker sent, except the reading of your letter, I shall be very glad of another "Doctor" for the money sent, so that my wife won't take mine from me. Bees just booming on white clover.

Yours Truly, C. C. MILLER.

WOODARD'S LANDING, Wash. Ter.

The Best Smoker.—To BINGHAM & HETHERINGTON, Abromia, Mich., Dear Sirs:—Find enclosed money for 3 Conqueror Smokers, which please send per mail—one to each, Dr. Balch, J. M. Louderback, and H. A. Towner. The Conqueror is the best Smoker I ever used. Respectfully,
May 17, 1884. H. HASTINGS.

DRESDEN, TEX., May 28, 1884.

Conquer the "Cyps."—T. F. BINGHAM, Abromia, Mich., Dear Sir:—Enclosed find \$1.75, for which please send, per mail, one "Conqueror Smoker" to Major H. A. High, Waxahachie, Tex. He bought a Cyprian Queen from me, and the Bees have worsted the old gentleman. I told him that the Conqueror Smoker would conquer the "Cyps," as I had tried one for two years, and "it never failed." Respectfully,
B. F. CARROLL.

BORODINO, N. Y., Aug. 15, 1882.

Cyprians Conquered.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. Respectfully,
G. M. DOOLITTLE.

Prices, by mail, post-paid.

DUNHAM COMB FOUNDATION MACHINE.

TESTIMONIALS.

MRS. FRANCES DUNHAM, De Pere, Wis.
Dear Madam:—We have made about 38,000 lbs. of foundation on your mills this year, and the foundation has given universal satisfaction; so much so, that several manufacturers have stopped manufacturing to supply their customers with our foundation. We have also manufactured about 10,000 lbs. of thin foundation on the Vandervort machine for surplus boxes, and it has been equally a success, but for brood chamber foundation, yours is still unexcelled.
Yours,
CHAS. DADANT & SON.
Hamilton, Ill., Dec. 10, 1883.

MRS. FRANCES DUNHAM, De Pere, Wis.
Dear Madam:—I have made over 100,000 lbs. of foundation on one of your machines, and would not now take double the price I paid for it.
Yours very truly,
D. A. JONES.
Keeton, Ont., Dec. 10, 1883.

MRS. FRANCES DUNHAM:
All prefer the foundation I manufacture on one of your mills, to that made on any other machine I have no difficulty in rolling it from 10 to 12 feet to the pound for sections.
Yours respectfully,
J. G. WHITTEN.
Genoa, Cayuga Co., N. Y., Dec. 12, 1883.

MRS. FRANCES DUNHAM:
After using one of your foundation mills for the past 3 years, we can't say too much in its favor and for brood foundation, it stands head and shoulders above all.
Yours,
SMITH & SMITH.
Keeton, Ohio, Dec. 29, 1883.

MRS. FRANCES DUNHAM:
I made all brood on Dunham mill, and that I believed it by far the best for that purpose, and as further proof, instance the testimony of E. Kretschmer, of Coburg, Iowa, and L. C. Root & Bro., of Mohawk, N. Y. Messrs. Root & Bro. have only used brood foundation of me, and in a later communication say: "It (our foundation) gave the best results of any tried." I write this that you may have fair play, which is to me always a jewel. You are at liberty to publish this. Yours truly, **T. L. VON DORN.**

COLUMN.

BEST GIVEN
COMB FOUNDATION.
Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8¼x16¼, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

- One Hive complete for comb honey...\$3.00
(The above will contain two cases complete with sections).
The above Hive complete for extracted honey.....\$3.00
The above Hive complete for both in one..... 4.50
One Hive in the flat..... 2.00
Five or over, each..... 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dove-tail Sections as follows: 4¼x4¼x6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

QUEENS!

Our New Strain,

Also IMPORTED ITALIANS!

Take your choice. Prices:

- Tested, to breed from.....\$ 3 00
Untested, to breed from..... 1 25
Untested, after July 1st..... 1 00
Untested, (per doz.) after July 1st..... 11 00

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.
Address,

JAMES HEDDON,
DOWAGIAC, Cass County, MICH.

Sixth Thousand Just Published!
New and Enlarged Edition
OF
BEES and HONEY,

OR THE
Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure.
T. F. BINGHAM.
Aronia, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN.

Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ills.

A Liberal Discount to Dealers by the Dozen or Hundred.

WE CALL

the attention of all wanting A No. 1 BEES, Italian, Cyprian or Hybrids, to the following, from one well-known to the readers of this Paper:

"I have never seen a case of foul brood; my bees are entirely healthy, and have always been so, and are O. K. in every respect."
GEO. B. PETERS, M. D.

We can furnish any number of Colonies of the above Bees, and will warrant safe delivery and satisfaction.

N. B.—No Bees will be sold by us, for any consideration, from any apiary that has ever had a case of foul brood in it. For prices and particulars, send to

FLANAGAN & ILLINSKI,

Lock box 995, Belleville, St. Clair Co., Ills.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.

ALFRED H. NEWMAN,
923 West Madison Street,
CHICAGO, ILLINOIS.

"STUFF FOR STINGS."

The sting of a bee at times proves serious. "Stuff for Stings" is warranted to cure or money refunded. Try it. Don't wait till you are stung, but send 25 cts. in stamps at once.
MONMOUTH APIARY, FREEHOLD, N. J.

OLDEST BEE PAPER IN AMERICA

THE WEEKLY BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED TO THE INTERESTS OF HONEY PRODUCERS.

ESTABLISHED IN 1861

Chicago, Ill., July 9, 1884.

VOL. XX.—No. 28.

THE WEEKLY EDITION

PUBLISHED BY
THOMAS G. NEWMAN,
 EDITOR AND PROPRIETOR.
 925 WEST MADISON ST., CHICAGO, ILL.
 Weekly, \$2 a year; Monthly, \$1.

PREMIUM.—Any one sending one *new* subscription for the Weekly, or two for the Monthly, for one year, besides their own subscription for a year for the Weekly, will be entitled to a copy of "Bees and Honey," bound in paper.

☞ The receipt for money sent us will be given on the address label on every paper. If not given in two weeks after sending the money, write us a Postal card, for something must be wrong about it.

☞ Any person sending a club of six, is entitled to an extra copy (like the club), sent to any address desired. Sample copies furnished free.

☞ Papers are stopped at the expiration of the time paid for, unless requested to be continued.

FOREIGN POSTAGE, EXTRA:

To Europe—Weekly, 50 cents; Monthly, 12 cents.
 To Australia—Weekly, \$1; Monthly, 24 cents.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Entered at the Chicago P. O. as Second Class Matter.

ADVERTISING RATES.

20 cents per line of space, each insertion.

For either the Weekly or Monthly Editions.

A line of this type will contain about 7 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance. Editorial Notices, 50 cents per line.

Advertisements may be inserted one, two or four times a month, if so ordered, at 20 cents per line, of space, for each insertion

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE.

PATENTED, MAY 20, 1873.

The Original
**BINGHAM
Bee Smoker**

Patented, 1878.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To sell again, send for dozen rates to

BINGHAM & HETHERINGTON,

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates on larger quantities, given upon application.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects: Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quieting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, in cloth, \$1.00; in paper covers, 75 cents.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered in help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premium for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bienen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY ALLEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way to rear Queens, etc. Price, \$1.00.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either English or German.

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XX.

CHICAGO, ILL., JULY 9, 1884.

No. 28

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Another Falsehood Exposed.

It will be remembered that Mr. Margrave, on page 424, referred to the statement of a St. Joseph grocer, that he had bought manufactured comb honey of Mr. Twichell, of Kansas City. We invited Mr. T. to reply, and here is what he has sent to us about it:

DEAR EDITOR.—I was somewhat surprised as well as amused in glancing over the BEE JOURNAL, to find, on page 424, an article by Mr. Margrave headed "Manufactured Comb Honey," in which he stated that a St. Joseph grocer told him positively that I had been selling manufactured comb honey, and that I had sold it *as manufactured honey*. Well, I hardly deem it necessary to make a long argument in self-defense on so absurd a charge, because I think that most bee-keepers, like myself and Mr. Margrave, consider the successful imitation of comb honey (except perhaps at a great expense) to be almost an impossibility. I must thank the St. Joe groceryman, however, for this much, that he gave me credit for selling the article for what it was, and not for pure honey, which is but just, for I assure my friends that if I am ever tempted to sell manufactured or adulterated honey of any kind, I will certainly sell it for what it is, and not misrepresent it. But I deny in the most emphatic terms, having ever sold to a St. Joseph merchant, or any one else, any manufactured or adulterated honey, and I am much indebted to Mr. Margrave for his kindly words in my defense. I would be pleased to have the name of the St. Joe groceryman, but do not care for the names of any of the witnesses, as Mr. M.'s word is sufficient.

I guess a good many readers of the BEE JOURNAL have seen my affidavit as to the purity and genuineness of the honey I sell, but I herewith enclose a copy which can be inserted if necessary.

There are a great many persons

who can hardly realize the perfection to which bee-culture has risen, and the almost absolute control the apiarist has over the little workers; and when they see a beautiful white, smooth, well-filled section of comb honey, they with the general and wide-spread distrust of everything and every body, hastily pronounce it a fraud. I hear this nearly every day, and I almost lose my temper at times, and want to tell them what I think of people who are so suspicious of every thing. As a rule they need watching themselves. I explain to them as well as I can how comb foundation is made and used, and how that, in a great measure, gives rise to the impression of manufactured honey.

I know no way to overcome this impression except to live it down, and let each of us try to establish a reputation for honesty and pure goods, that when we are assailed in the presence of any who knows us, we can feel sure of a generous defense.

I spare no pains and lose no opportunity of setting people's minds aright on this matter, and also to explain why extracted honey is not necessarily adulterated, because it is so much cheaper than honey in the comb. I enclose a little circular I had printed giving the latter explanation, and I would suggest to Mr. Newman that he get up a plain but brief explanation of how comb foundation is used, and how impossible it is to manufacture and fill the combs in competition with the bees, etc., etc., and place a reasonable price per 1,000 on them to his subscribers, that each may order a few for distribution and publication in as many newspapers as will give it space. This in connection with an honest reputation among honey-producers and dealers will go far toward correcting the evil, and in time, I trust, wipe it out altogether.

JEROME TWICHELL.

Kansas City, Mo., July 3, 1884.

The above puts the matter to rest so far as Mr. Twichell is concerned; but it will be only a few days until the scandal-mongers will endeavor to hitch it upon some other person or reassert it as truth, as though it had never been refuted.

Not long ago a person in this city asserted that machinery to make paraffine combs and fill them with glucose were in use at the office of the BEE JOURNAL. The person to whom

this "news" was told, was Mr. J. L. Harris, of Wheeler, Ind. As he knew there was not a particle of truth in the assertion—nor anything upon which to found such an idea—he told the scandal-monger he would give him \$1,000 if he would show him the machinery, and offered to go to the JOURNAL office with him. Of course this non-plused the "informer" somewhat, but he had no time or inclination to verify his statements. In fact it would spoil a good "story" to be convinced of the contrary.

Concerning the assertions relative to Mr. H. of Linn County, Iowa, Chas. Dadant & Son writes us on July 3, as follows:

We would say on behalf of Mr. H., that he has bought large quantities of honey from us last winter, and that we think if he fed his bees glucose and sold glucosed honey, he certainly would have little desire to buy honey at honey prices.

If it is desired, we will get up another Leaflet on the subject proposed by Mr. Twichell. We will think it over, and others can do so, and if it is demanded, it will be forthcoming.

Mr. Twichell's affidavit is, "That every pound of honey, in any shape, sold by me, is absolutely pure and free from adulteration." Even that, however, is not enough to still the tongue of the slanderer.

Our little grand-child, Maud Newman Cook, died at our residence in Chicago, on July 1, of marasmus. She was a great sufferer, but had a sweet disposition, and bore her agonies heroically. She was buried on Wednesday last in Oak Hill Cemetery, Cedar Rapids, Iowa.

The *Seed Time and Harvest* for July says that "The attractive appearance of the 'Bee-Keepers' Convention Hand-Book' is a sufficient recommendation to any bee-keeper desiring to secure a nice pocket companion."

Seasonable Hints.

Mr. F. L. Dougherty gives the following in the *Indiana Farmer* concerning the present honey crop, and seasonable work in the apiary:

Delude yourselves as you may with the idea that it is simply a matter of dollars and cents, or so many pounds of honey. There is something in the humming of the bees, returning well laden, that will stir the heart of the most matter-of-fact apiarist.

As we suggested a short time since, a few weeks more would decide the success or failure of the honey crop for 1884. Metaphorically we toss up our hat. The dark cloud has disappeared, the little silver lining has turned into one grand luminous cloud. With us the honey flow is bounteous.

Colonies that have cast a swarm should be examined at intervals that you may know that they have not become queenless. The young queen may have got lost on her bridal trip, and the bees with no brood in the hive from which to rear another will soon become depopulated, dwindle down and fall an easy prey to the moth, which infests all colonies at this season of the year. A safe precaution is to give a frame of eggs and brood to colonies that have cast a swarm, 12 or 14 days after the swarm came out of the parent colony.

Natural Swarming.

The following was translated from the French *Ami du Clerge* for the *Haldimand Advocate*:

Admire how obedient our little creatures are to the command of the Creator, "Increase and multiply, and fill the earth." Some of the signs indicating the near approach of a swarm. We are in the full month of June, the sun, according to the beautiful expression of the Holy Scriptures, "hath rejoiced, as a giant, to run the way," vegetation is displaying its choicest colors, flowers are distilling an abundant and ever-renewed honey. Thus broods have matured, families have multiplied, population has increased in most exuberant proportions. Already some drones have made their appearance. Behold some of them flying out in the afternoon to enjoy the aerial outing; that odor of wax you breathe with so much pleasure towards the evening; that vapor which in the early morn bathes the front of your hives; that humming which you hear, dull at first, but day after day more distinct and more pronounced, indicate that the colony is contemplating some extreme measure.

Let everything needed be then under your hand, the hives, the section frames, the water to sprinkle the swarm with, when it ascends in the air, and after it is brought down together, the cloth to preserve it from the ardor of the sun, the smoker and the veil, if needed to protect yourself against the anger of the bees; in a

word, have ready at hand all things that may be required for the swarm.

Here are some signs indicating the very near exit of swarms. Do the crowd of bees which were outside the hive enter it again, while those of the other hives remain out? Is the flight of the workers less frequent than usual? Then the swarm is preparing to leave. Or yet, do you notice in front of the hive, towards noon, in considerable group of bees which seemingly increase? Do the bees which return from pasturage, their legs loaded with pellets of pollen, join the crowd, or do they stop astonished on the alighting-board of the hive? Do the bees from the inside rush out to the platform as if to give signal, and do they return immediately? All these signs foretell an imminent departure. (Be ready!) if no obstacle is presented by rain, wind, a great drought; if, on the contrary, the weather is warm and brewing a gentle storm, if the sun shines at intervals, the swarm is also about to leave.

EGRESS OF THE SWARM.—This is one of nature's most exciting spectacles. The order of departure has been communicated to the whole colony. Hear that humming, which increases more and more, and which a bee-keeper knows well how to distinguish from any other sound! It is a swarm which rushes out into the air. The opening of the hive is not large enough, the bees rush forth like an impetuous torrent; it is a general rout; it is surprising how so many bees can come out of a hive in such a haste. The air becomes obscured by them; it is a cloud which moves on, gyrating, interlacing itself in constantly recurring circles. No sooner has the swarm entirely left the hive than it remains for a short time as if suspended in the air, and soon it seeks in the vicinity of the hive a convenient spot to alight on, sheltered from the wind or the burning rays of the sun. Look at it without anxiety, and throw not on it either water or dust, unless it tarries too long to alight, seeming as if it would soar higher in the air and escape. The bees fear water, and come down as soon as it touches them.

Perplexing Beginners.

The following from an exchange shows how some beginners in bee-culture are humbugged by clap-trap live vendors:

A few days ago I called at a place not over 100 miles from Indianapolis, where I was shown a colony of bees in an old box. The owner had obtained a good hive, as he supposed, to give the swarm, when it left the old home. This was a box about twice the depth of a one-story Langstroth hive, larger every way, and filled with close-fitting frames about 3 inches wide. The maker of this hive left directions that when the owner wanted to make new swarms, he should simply take out the frame having the "king bee" on, and put it in a new hive and set it off by itself. As I am not in the "bee fixin'" busi-

ness, I advised the bee-keeper to go and examine some standard hive, and remarked that if I were to step in his shoes as a beginner in bee-culture, I would consider \$10 for some standard hive a good bargain, and after all he would very likely have to pay no more for it than the cost of his worthless box.

Fastening Starters in Sections, etc.

Rachel Brown, in the *Home Farm*, remarks as follows:

I have been putting starters into sections to-day, and tried the method given by S. M. Locke in his *American Apiculturist*, which is: "Take two parts rosin and one part beeswax, and melt them together. To use, take the section in one hand and the foundation in the other. Touch one edge of the strip of foundation into the heated mixture, after which touch it upon the under side of the top of the section to which it will adhere." This is a great improvement over rubbing foundation upon the section, bending it up and waxing with a brush, as we have been in the habit of doing. By this method one minute is sufficient to put in twelve.

I will give you M. H. Berry's remedy for ants about bee-hives: Put gum camphor on the enameled cloth around the edge of the bottom-board, or any place where they are troublesome; they will keep away as long as the scent of the camphor remains.

Create a Local Honey Market.

Now is the time to create Honey Markets in every village, town and city. Wide-awake honey producers should get the Leaflets "Why eat Honey," (only 50 cents per 100) or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully all over the territory they can supply with honey, and the result will be a demand that will readily take all of their crops at remunerative prices. The prices for "Honey as Food and Medicine" are as follows:

Single copy 5 cts.; per doz., 40 cts.; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Letters for publication must be written on a separate piece of paper from items of business.

For the American Bee Journal.

Hiving Swarms of Bees.

W. Z. HUTCHINSON.

My apiary is located in an apple orchard in which there are no limbs that cannot be reached by means of a ladder. My hiving implements are two clothes baskets lined with cotton cloth, and furnished with burlap covers sewed fast at one side. I might remark, parenthetically, that a long basket, like a clothes basket, is better than a round basket for taking down swarms, as the bees often form long clusters lengthwise of the branches. I also have a step-ladder, a pair of heavy pruning shears (with these, small branches can be severed more easily and with less jar than with a knife or saw), a fine-tooth saw for cutting large limbs (I do not often use the saw, as I am opposed to cutting large limbs from the trees). I also use a quart dipper, a fountain pump, two large tin pails, and if the apiary was not located near a small stream, I should add to the above a barrel for holding water.

When a swarm begins to issue, I carry a hive to the stand that I wish the swarm to occupy, and prepare the hive for occupancy. When the bees begin to cluster, I make an examination to see if they are clustering in a favorable location for shaking them into a basket. If they have selected a spot where two or more limbs cross, or small branches are interlaced, I take the shears and clip away some of the branches, and thus secure the cluster in a convenient location for dislodgement.

If the bees are slow in clustering, at a time when more swarms are momentarily expected, I sometimes hasten matters by sprinkling the flying bees, by using the spraying attachment of the pump. When the bees are fairly clustered, I first detach a small portion of them that perhaps are adhering to some small twig, and carry them, still adhering to the twig, and place them at the entrance of the hive, without dislodging them from the twig. These bees at once commence running in and setting up that joyful hum announcing that they have found a home; and when the rest of the swarm is brought and shaken down in front of the hive, this humming at the entrance calls in the swarm at once; while, if the swarm is shaken down without this precaution, a large portion of the bees often take wing, perhaps the queen among the number, before the entrance to the hive is discovered, and the fact announced by joyful humming.

Many of the bees that take wing go back and cluster where they originally clustered, and if the queen takes wing she may go with them. If there is no small cluster that can be readily de-

tached, I then dip off a quart of bees from the lower part of the cluster and pour them down at the entrance of the hive. After some of the bees are running in at the entrance of the hive, I hold a basket close under the cluster and shake the bees into it with a quick shake, throw the burlap cover over the basket to prevent any of the bees from leaving, carry the basket to the hive, strike one end of the basket sharply upon the ground 2 or 3 times, which will shake all the bees to one end, and dislodge them from the cover; throw back the cover and shake the bees out upon the ground in front of the hive.

I do not shake them against the front of the hive, as the entrance would at once become clogged; but perhaps 18 inches or 2 feet from the hive. I do not sit right down by the hive and drive the bees in with a smoker, and keep a constant watch that the entrance is not stopped up, but I do go occasionally and see how things are progressing; and, if there is a great mass of bees clustered over the entrance, I poke them away and thus clean the way for another installment of bees to enter.

There is a great difference in swarms as regards the agility with which they will enter the hive. Occasionally there is a laggard that never gets inside the hive until the coolness of night, or till the bee-keeper with a smoker drives it in. If the bees cluster upon a small branch that I am willing to sacrifice, I cut it off and put it with the bees in front of the hive.

The fountain pump is a favorite implement with me. With it and plenty of water it is next to an impossibility for a swarm to abscond. I have had 3 or 4 swarms try to leave, but I compelled them to stay, and in one instance there were no trees near, and they clustered upon so small a shrub that I was obliged to hold it up until they had finished clustering, as it was too small to support their weight.

In controlling a swarm in the air, the spraying attachment should not be used, as the water cannot be thrown far enough; but by using the nozzle attachment, and giving a swinging or sweeping movement to the arm as the stream is thrown, the water is so scattered that it falls in a shower. The pump is also useful in preventing swarms from uniting. Only yesterday I had two swarms issue at the same time from hives only about 20 feet apart; and yet I kept them from uniting, and induced them to cluster in trees several rods apart. I did this by keeping a constant spray of water between the swarms as they came out and circled in the air; and sometimes I almost despaired of accomplishing the object, but I persevered and succeeded.

Among the colonies purchased during last year and this season, were some having queens with clipped wings, and I had more trouble with swarms from their colonies than from those with queens having unclipped wings. If the swarm is not seen the moment it issues, the queen sometimes

gets out of the hive and crawls and hops some little distance away, and while looking for her, one is liable to step on her. The bees circle about for a long time, and if another swarm issues they are almost certain to join it. When they do finally decide to return, they sometimes make a mistake and enter the wrong hive or hives; and when they do find the right hive they sometimes cluster all over the outside of it instead of going in. When the queen is released, as the bees are going in, she sometimes comes out again, after having entered the hive, thinking, perhaps, that she has not swarmed; when, of course, the bees follow her. Placing the caged queen at the entrance of the hive aids the bees in finding the hive. Rogersville, Mich.

Collecting Honey Plants.

CLARENCE M. WEED.

Honey plants are every year becoming of more importance to apiarists; as new portions of the country become settled, and the marshes of older portions are brought into cultivation, the conditions surrounding honey production are much changed. Hence an acquaintance with honey-producing plants is also becoming more important, that all such may be preserved where they are now growing in waste and out-of-the-way places, and planted where they are not growing. In view of this, as equally of many other facts, a few directions for collecting and preserving such plants may be of service. As most of the Fair managers now offer premiums for such collections, young people interested in bees and bee-keeping would derive both pleasure and profit from making and exhibiting them.

Whenever possible, collect when the plants are dry; if they are wet, more labor is required and poorer specimens obtained. Where the plants are to be carried some distance, some sort of a tin box is useful in preventing wilting. As a guide to the most important honey-producing plants and time of flowering of each, nothing is better than the list in Prof. Cook's Manual. In all cases where practicable, the fruit as well as the root, or a portion thereof, should be preserved.

DRYING.—For drying, old newspapers will suffice, but thick felt carpet-paper cut into sheets, called driers, 12 by 18 inches, are much preferable. Enough for the purpose can be obtained at any stationers or carpet dealers for a few cents. For holding the plants while drying, a sheet of thin paper, (a newspaper is good), twice the size of the driers is folded once. These are called specimen sheets, and into them the plants are placed as soon as possible after being gathered. Between each specimen sheet 2 or 3 driers are placed, and over the whole a heavy weight transmits pressure through a board slightly larger than the driers. For

a weight nothing is better than a stone weighing from 20 to 40 pounds. For very tender plants less weight should be used than for hardier ones.

Twenty-four hours after the plants are put into the press, they should be looked at, and wherever a leaf or flower is out of place, it should be placed naturally; as the plants are in a sort of wilting condition, this is easily done. At this time, also, the driers should be removed and others substituted, placing those taken out in where they will dry. This operation is repeated every day for one or two weeks, when the plants will usually be dry. This is told by placing the plant against the cheek, if it feels cold it is not yet dry.

Where very fine specimens are desired with the natural colors preserved, heated driers should be used and replaced two or three times a day. By this method I have produced specimens which rival in beauty of form and color the fresh unplucked flowers of fields and woods.

After the plants are dry they may be kept in the specimen sheets an indefinite length of time, or until they are to be mounted. For mounting either for exhibition or for private purposes, I use heavy book paper cut $11\frac{1}{4} \times 16\frac{1}{2}$ inches, this is the size used by botanists for herbariums. They cost about 2 cents per sheet. There are two methods of attaching specimens to the sheet, either by gluing small strips of paper over different portions of the plant, or by gluing it bodily to the sheet. For exhibition the latter method is much to be preferred. Any strong, light-colored mucilage will suffice. I have used with good results a solution of gum-arabic.

As dried plants are liable to insect attacks, they must be poisoned. This process is very simple; apply a saturated solution of corrosive sublimate in alcohol by means of a camel's-hair brush to all parts of the plant.

Tree-Trunk Method of Wintering Bees on the Summer Stands.

WM. F. CLARKE.

This is a somewhat pompous and lengthy title for an article, I must admit, and a modest blush mantles my cheek as I read it. But there is no use in giving a small name to a big idea, which I firmly believe the one I have struck to be. For several years it has been impressed upon my mind that I should some day make

A GREAT DISCOVERY IN BEE-KEEPING

Mr. Heddon sarcastically twitted me on this point in one of his articles in the BEE JOURNAL, but it must have been a species of mind-reading on his part, for I never told any body my dream of becoming a discoverer. But I did not deny "the soft impeachment" on Mr. Heddon's part, because I inwardly felt that it would yet become true. I find it very difficult to write with that calm dignity and equanimity which befitted a literary man. In fact, my hand quivers

with a tremulous excitement, so that, as the Editor can plainly see, I do not write with my usual steady chirography. I feel somewhat as Galileo did when the true theory of the universe dawned upon him, and my fellow bee-keepers must bear with me if I "blow off steam" a little at the start. To quote Puck's motto, "What fools we mortals be!" Or to make a more original remark, "Why did nobody think of this before!" It seems to me so simple and self-evident, that I am afraid somebody will yet get it before the apicultural world before I do! Life is too short, and I am too impetuous to wait two or three seasons and experiment. I must take the whole bee-keeping fraternity into my confidence, and ask each one to test the method I am about to develop, with one colony. This is a small request, and I think my brothers and sisters in apiculture will not refuse compliance with it.

PREVALENT MODES OF WINTERING BEES.

I have tried every known plan of wintering except the clamp and coal-oil-stove methods. After the disastrous experiences of Messrs. Hutchinson and Doolittle, I do not feel disposed to waste time in trying these, particularly as I feel sure I have found "a more excellent way." For myself, I must own I am not satisfied with any of the modes of wintering now in vogue. Every season the question comes up, which of them all I shall venture to adopt the coming winter. All are more or less haunted by risk and uncertainty. All result in loss, at least now and then, sometimes in very severe and crippling loss. I have felt until now, and the majority of experienced bee-keepers have felt with me, that the true mode of wintering bees has been an undiscovered secret.

A QUESTION.

In my young days, I helped clear many acres of timber land, and never felled a tree, nor heard of one being felled, that gave evidence of a colony of bees having been winter-killed in it. I would ask bee-keepers all over this broad continent if they ever saw or heard of a colony of bees being winter-killed that had its home in a hollow tree? The fact that bees winter well in hollow-tree trunks was the vein that revealed to me what I believe will prove a gold-mine to bee-keepers. "There's millions in it" of live bees, yet to be saved from perishing through the ignorance and stupidity of that very wise being called "man."

NATURE'S METHODS.

Without raising that vexed question in theology, whether nature's laws are the *dicta* of an all-regulating mind, which would bring Mr. Heddon and others after me with a sharp stick, I will simply lay down the position that the closer we can adhere to nature in our artificial arrangements, the more likely we shall be to come out right. Well, have we observed this principle in the construction and location of bee-hives? Not much.

When did a colony of bees ever voluntarily make its home in a dark, damp cellar, or a gloomy, close-pent bee-house? Or in a box or other receptacle close to the cold, damp ground? Who invented the plan of setting hives close to the surface of the earth? Where is the practical benefit of so doing? Almost the only argument in its favor I know of is, that bees, laden with honey, are apt to miss the hive and fall to the ground. But I believe more bees are gobbled up by toads in consequence of the hive's near proximity to the ground than are ever lost by having them higher up. Undeniably nature's method is to give the bee a home suspended in mid-air, away up from the damp, heavy vapors that always settle down to the earth's surface. It is man who forces this insect to live among reptiles, toads and worms, when it was made to be the companion of birds and squirrels in the tree-tops. I have arrived at the conclusion that most of our troubles in regard to wintering arise out of the absurd attempt to make a denizen of the air become a dweller on the ground.

BEE-LIFE IN A TREE-TOP.

What are the characteristics of the bee's natural home? Elevation above the damp, foul gases that by the law of gravitation sink to the surface of the earth. In winter, an abundant supply of *still air*; a long shaft of hollowness, so to speak; a crevice or opening usually some way up that shaft, and not far from the bee-nest; no upward ventilation; provision for dead bees falling away down low enough not to pollute the home of the living with their dead carcasses; and the natural gradual change of air which takes place in a long atmospheric column. We violate nearly, if not quite all these conditions in our prevailing modes of wintering bees. Is a cellar or bee-house a good place for a human being to live in? The respiratory organs of the bee are probably as sensitive as those of a human being. Tough specimens of men and women have made out to live in wretched underground bastilles for months and years, but if people in general were doomed to inhabit such places, there would probably be as much mortality among them as there is often among bees in cellars, bee-houses and earth-clamps. In the tree-top, air is filtered to the bees through a long air-shaft, the outer crevice, and by means of ventilating processes which these insects understand how and when to apply; but our customary methods give them unfiltered and foul air, often in very small proportions, and in manner that prevents their employing their own instincts in the way of artificial ventilation. More or less old bees usually die in the course of the winter. Their dead bodies lie on the bottom-board not far from their living companions. It is as though we had a corpse or two in the first story of our houses, got the diarrhoea from the bad smell, and then attributed it to the family eating oatmeal or buckwheat cakes! How delicate is the sense of smell in bees!

Can we suppose that a lot of dead bees can remain close to the frames on which the colony is clustered, and not poison them with foul odor? Finally, our methods go on the principles of securing a uniform temperature, which does not obtain in nature, but is one of man's so-called *improvements*. There is no evidence that bees are not the better for having a change now and then, if gradually brought about, by means under their own control.

HIBERNATION OF BEES.

It is generally admitted that bees hibernate; that is, go off into a state of torpor or semi-torpor, when they winter under purely natural conditions. There are differences of opinion among scientific men and practical bee-keepers as to the nature and extent of this process in the case of bees. I cannot now discuss this point at any length, but will simply say that hibernation is to a considerable extent, if not wholly, prevented by our customary methods of wintering. Among hibernating animals and insects, there is a difference of habit. The bear goes into winter quarters fat, sleeps during the cold weather, and wakes lean in the spring. His excess of adipose matter has kept him alive without eating. The squirrel and other creatures that lay in a stock of food, have several spells of torpidity during the winter, out of which they awake at the touch of warm weather, to eat. Bees are like squirrels rather than bears. They do not become fat in the fall, and sleep themselves lean, but have short terms of torpidity, out of which they awake in mild weather and take a feed. Then as the mercury goes down, they yield to drowsiness again. A little reflection will show that the tree-top conditions are favorable to the hibernation of the bee, but cellars, beehouses clamps, and chaff-packed hives are not. They go on the principle of one uniform temperature as nearly as possible all winter. If that temperature is too warm, the bees do not go to sleep at all, but become restless, eat lots of honey, foul the hive, many old bees die, and get up what Mrs. Partington called "an antagion," and so forth. If the temperature is too low, they get cold victuals—icy honey, frozen pollen, etc., and why should not such food give a bee the colic and diarrhoea as well as human beings? Mark this, that the bee to winter naturally, must be able to take *hibernating spells*; not one, long sleep, nor one long wake, either of which will be injurious if not fatal.

MY PLAN OF WINTERING.

There is very much more to be said in the way of general discussion of points connected with the central idea, but I must simply state it, and close for the present. In brief, then, I go for the hollow tree-trunk plan of wintering; not literally, for that of course is out of the question, but the nearest approximation to it that can be got. If I had a flat-roofed building, which I have not, I would set my ex-

perimental hive on that, and have a long hollow tube connected with the hive by a hopper, and extending to within a foot or two of the ground. That I should consider a fair way of testing the theory, I have set forth; and if any bee-keeper has the chance of trying it thus, it would be well to do so. But "I have faith to believe" the thing will work without going so high up into the air, and have just completed a hive-stand embodying the principle set forth in this article. It consists of a box about table high; just the height at which you can handle bees without hurting your back. The bottom of the box is one wide board $1\frac{1}{2}$ inches thick, 20x26 inches; the dimensions calculated for a Langstroth hive. The box is tight with the exception of four auger holes covered with wire gauze, which are made within 6 inches of the top. The extra size of the box is meant to afford an opportunity to cover the hive with a rough shelf in winter, and if desired, pack with chaff. I also gives a wide alighting board in front, and some shelving on the sides, and at the rear, which will be found handy during the working season. The hive to be used is without a bottom-board, but a sliding bottom-board, put in and taken out from the rear, is to be used during the honey harvest. When that is over, and all danger of comb extension is past, it is to be removed. Immediately below it is a hopper fitting tightly to the stand just beneath the hive, its flaring sides terminating in a square tube 4 inches wide each way inside, which reaches to within a few inches of the bottom of the box. The usual entrance to the hive is to be left open. Through it and through the auger holes on the four sides of the box, abundance of air will find its way into the hive. Its dead bees will choke the entrance, as they will fall to the bottom of the box. A little door in the box enables the bee-keeper to see the dead bees, dry excrement, etc., that may have dropped from above, and thus the state of the colony can be judged at a glance to the extent that these signs reveal it.

It will perhaps be asked, why not have a skeleton stand with merely the hopper and tube reaching to within a few inches of the ground? I answer, because it would not so nearly fulfill the conditions of tree-trunk wintering. My box gives me a reservoir of still air obtained 2 feet or more from the ground, and, being tight, cuts off dampness and excludes foul gases. It should be added, that the bottom-board of the box is spiked to pieces of cedar pole slightly flattened on the lower side, giving the least possible contact of the box with its round sills. My idea is now roughly out-lined, and the practical use of it will doubtless be improved upon by others whose inventive genius in that line is greater than mine.

For the American Bee Journal.

Reversible Frames.

J. E. POND, JR.

Are reversible frames of any real practical value, or at least sufficiently so to pay for the trouble in fitting them up so that they can be made of use? When they were first mentioned, the idea struck me as being one of value, and theoretically it is, but it proves with me to be one of those theories that after all are of no real practical value, and for the simple reason that I find I can accomplish the same results without them, in a far more simple and easy manner than I can by going to the trouble and expense of fitting up for their use.

Again, the points of superiority claimed for them are really more a matter of fancy than of real utility. Perhaps in a poor season, or at a time when honey is coming in slowly, frames may be found to be filled more completely by reversing than by allowing them to remain in their usual position; but it is to be hoped that at such times, the prudent and economical apiarist will be enabled by regular feeding in small quantities, to cause his frames to be well filled out, and while doing this, stimulate his colonies sufficiently to keep the cells filled with brood; and thus, as the old saying is, "kill two birds with one stone."

One of the chief points of superiority claimed by the advocates of reversible frames is, that by the process of reversing, the cells are filled with brood close up to the top-bars, and the bees will then more readily enter into the sections. I am aware, and have been for years, that bees deposit their stores above the brood, and have made good use of the extractor to cause them to go into sections, when I got ready to place them on the colony. I have found also that extracting stimulated brood rearing precisely as does feeding, and that when I extract the honey stored in the upper parts of the frames, the queen will deposit her eggs in the cells from which the honey is extracted, and the bees will at once occupy the sections and begin storing therein.

When a flow of honey is coming in from the fields, there is no trouble at all in getting frames well filled out, and sections well filled out also, if care is taken to provide the proper facilities. Those who claim that the instinct of the bee is all-wise, and allow it to work its sweet will, must fall far behind in the race, with him who uses his reason in directing (not forcing) that instinct to work for his own advantage. If the extractor could be used for no other purpose than simply giving the queen room to deposit her eggs in the location desired by the owner, it would well pay for itself in a very small apiary; and with myself, after a fair trial, I find it will do so much more easily, simply and cheaply than can be done by any arrangement I have yet seen or heard of in the way of reversing or reversible frames.

I speak only for myself; others may view the matter differently; but my

candid opinion is, that reversible frames, like many other new things, will soon be laid away as cumbersome, troublesome, and not sufficiently valuable to pay for the time needed to operate them.

The idea of reversible frames may prove a profitable speculation to the supply dealer for a short time, but no one else, in my opinion, will ever realize any profit from them. Let those who may choose, test them if they like, but as for me I want no more of them.

Comb Honey-Rack Again.

JOHN HODGSON, JR.

I send you another engraving of my honey-rack with description and improvements, as the former cut and

FIG. 1.—Rack with side closed.

description given on page 96 of the BEE JOURNAL for 1883 did not give a correct idea of the rack. This second mention of it is due to many who have been making a multitude of inquiries about this rack, and other honey-racks.

Figure 1 represents a closed rack with a honey-board with slats (which can be made any width to suit the

FIG. 2.—Rack with side opened.

width of sections used), and with a full set of sections in place. The portable side A is held in its place by the V-shaped beveled wedges B B. The section-board C in Fig. 2 is intended to take the place of a row of sections, when it is necessary to have the bees work in only a part of a set; and when there is a shortening up in the honey flow, then one or more of these boards can be used.

Figure 2 shows a rack with the wedges B B removed, the portable side A loose, and the section space open to remove from or fill with sections as the case may be. The wedges B B are of great advantage in case of the sections swelling or shrinking, as the side A can be let out or drawn up

3-16 of an inch by loosening or tightening the wedges.

The row of sections on the top, in Fig. 2, are full and removed, and the section-board C is being put in their place. This cut and the description given above will enable any one, by careful examination, to understand this rack.

Read at Arcadia Farmers' Convention.

Bee-Keeping for Profit.

E. A. MORGAN.

There are very many works treating upon this subject, which are more or less a help to the beginner; but what I have learned is by experience, and in many instances it has been dearly bought. To succeed in this business, a person must first understand the natural laws governing the honey-bee. He can then tell at a glance what should be done to promote their best interests. For as Josh Billings says, "A bee is sudden in his impressions, and hasty in his conclusions." It is therefore very necessary to do what you do, just at the right time, to secure the best results.

Many farmers in this vicinity have tried bee-keeping from time to time, and are satisfied that it is very profitable, and while all was favorable they made it pay well, but sooner or later something turned up which they did not understand, and all were lost.

In bee-keeping, as in all other pursuits, it is all important to make a good beginning; and to do this, it is as important to get good stock as it is with your cattle, horses, or hogs. Having obtained this, next in import-

combs, which, being shallow and open at the top, admits of the bees going directly into the surplus boxes from the main hive; and being directly above their brood, they receive the heat of the cluster, which is very essential, especially in cool weather, to aid them in manipulating wax. This hive can be made to accommodate any sized colony by the use of a close-fitting movable division-board. This hive is not too large nor too small, and will receive surplus receptacles for 50 pounds of honey, and can be tiered up to any height desired. It is not, however, the best out-door wintering hive, on account of its shallowness. Bees in this hive require some sort of winter protection; but when we figure its advantage as a summer hive, above the cumbersome and costly out-door wintering hive, we can well afford to pay the difference of winter preparation required for this hive.

Just a word about boxing for surplus honey. Many beginners and inexperienced bee-keepers constantly encounter difficulties in first getting their bees to go up into the boxes; and after the first set of boxes have been filled, much valuable time is often lost in finishing and capping the sections, and getting the bees to begin anew in other boxes; and not unfrequently a strong colony will send out a new swarm in preference to making a beginning in new boxes, which, of course, is very ruinous to their owner. In short, the profit of the apiary, where it is run for surplus, is governed largely or wholly by the amount of box or section honey stored, and this depends entirely upon the readiness with which bees can be made to work in boxes. Since the time in which bees store surplus honey is divided into short seasons during the summer, known as honey flows, it is all important that the bee-keeper bas his colonies in condition to "improve every shining hour" to the best advantage, as these honey flows are sometimes "few and far between. My plan of boxing is to use foundation starters in all sections, and put on but one crate at a time, as it is not difficult to induce bees to work in one crate, where it would be impossible to start them in three or four. When one crate is about half filled, put on another, and so on until the frames are covered, making it a rule to take off the first crate of honey before the last empty box is put on, so that but one filled crate is taken off and one empty crate put on at any one time, thus avoiding the necessity of much sudden change, and removing the difficulty of starting bees in a full new set of boxes. This process of rotation, if carefully adhered to, will sometimes save hundreds of pounds of honey to an ordinary bee-keeper, in one season. One more suggestion on this point. Arrange your crates so that the sections will run parallel with the brood-frames, thus giving the bees a free passage into the boxes, and not merely a small square hole, as is the case when they are placed at right angles, which is often the cause of much delay and

ance is a thoroughly practical hive. And in bee-keeping for profit, it is necessary that the main feature of the hive should be simplicity, which would at once exclude doors, drawers, and traps of all kinds. The combs should be movable, so that the operator can, in a moment's time, remove any or all of them to another hive if necessary, which is often the case in spring when clogged up with dead bees or dirt. All hives and frames should be alike, and the frames interchangeable, which is very necessary in feeding, in strengthening weak colonies from strong ones, in extracting, in queen-rearing, and in many other things. For this climate I would recommend the Langstroth hive, holding 10 frames or brood

tardiness in getting bees to work in boxes.

Had my paper been on the "Honey-Bee," I could doubtless have made it more interesting than on keeping bees for profit; but will say this much for the bee or race of bees to be kept for profit: that after having tried several races, I am decidedly in favor of the Italians, for the following reasons: 1. They possess longer tongues, and can, consequently, gather from flowers which are useless to the black bee. 2. They are more active, and with the same opportunities, will gather much more honey. 3. They work earlier and later, not only of the day, but of the season. 4. They are far better to protect their hives against robber bees. Bees which attempt to rob Italians of their stores, soon find that they have "dared to beard the lion in his den." 5. They are proof against moth millers. 6. The queens are far more prolific, and breed up faster in the spring. 7. The Italian bee is more hardy, longer lived, and stronger of wing than other breeds. 8. And lastly, they are more amiable. A stock of pure Italians may be handled without the least danger of stings.

And now I will close by speaking of their advantage to the farmer, other than by supplying his table with honey, and filling his pocket with money. All bees feed exclusively upon saccharine juices or nectar of flowers, called honey, and the food of their young in the larval state, is the pollen of flowers, called bee-bread.

The honey-bee was not only created to gather the nectar from each opening flower, and store it in shape for food and medicine for mankind, but at the same time there was a double purpose intended. They were made to perform a very important part in the economy of nature—that of the fertilization of flowers, which depends upon the contact of the pollen with the stigma; and, as if to secure this object more perfectly, in their search for honey and pollen, they pass from flower to flower of the same kind, and are never known to visit two varieties of flowers on the same trip, as many have supposed. It is indeed wonderful how so small an insect can be made to do so great a work, and governed by natural laws, they become most populous at the season of the year when most needed in this work. It is estimated that not more than one-half of the blossoms on our fruit trees would bear fruit, were it not for this agency. The bee, eager for the nectar secreted in the flower, plunges into the blossom, covering himself with its pollen dust, and thence to the next, scattering it there, and so on.

When we realize that in a strong working colony there are 50,000 of these workers, and that each one makes hundreds of trips each day, we can readily see how much may be accomplished in one day's time. And it is indeed possible that the nectar there secreted was for the sole object of attracting the insects thither, that they might accomplish this work.

Farmers are becoming more acquainted with these facts, and it is

very noticeable that in sections where many bees are kept, the fruit crop is more abundant, and the clover yields far more seed. Only a short time since I saw an article on the transportation of bees to Australia, where the clover has never been known to bear seed. Some one suggested that bees might be made to distribute the pollen.

The experiment was tried, and it is reported that in the vicinity where the bees were stationed, the clover, the present season, has borne seed, thus proving conclusively that their work alone wrought the change.

For the American Bee Journal.

Reply to W. F. Clarke.

JAMES HEDDON.

I shall have to ask my old friend, Mr. Clarke, to excuse me for not taking a firmer "hold" of him in the "Priority of Location" controversy. If he will not again blame me for "taffing" him, I will say that it is very difficult for me, or any other apicultural writer, to keep a "good square hold" of him when we cross the swords of sharp sarcasm; and as far as the philosophy of the subject at issue was concerned, truly I did not discover much to get "hold" of.

As sharp and pointed as Mr. Clarke takes hold of me, he is not faultless in his logic, nor correct in his assertions. Because I am, the present season, increasing the stock of my field, is not "an admission that I have underrated it in the past," or that the field is in any way improved. I am doing this to put to test the results and standard of overstocking in this locality. Regarding the elegant and classical caption of Mr. Clarke's article, I have only to say that Mr. Clarke has mis-applied it. I need no "burrow." I will try to prove my claims. I feel that time and experience will assist me.

I do not say that no one can form a correct conclusion regarding any point in apiculture who is only an apicultural dabbler, but I do say this, that being only a dabbler is the mantle that practical producers throw over the heads of those who almost always get the impractical theory side of such subjects.

I think Mr. Clarke is mistaken, and I imagine that more than nine-tenths of the honey-producers of this country think that he is mistaken. He can convince me that he will not "always be in error on this subject," when either he or I see our mistake.

Mr. Clarke's comparison in his last paragraph is entirely unfair. Why could he not compare my position in the science of apiculture with a similar position of some one in another science? Why could he not have said, if Mr. Heddon says that editing a daily newspaper is not labor; is only just child's play; that dull, prosy items take as well as sharp and spicy ones, he is mistaken, and nothing will set him right, but to depend upon holding such a position for the bread and butter of his family. "In the

realm of the unknown (and that intellectual giant, Herbert Spencer, says, 'possibly the unknowable'), ALL have an equal right to guess."

No doubt the "Priority of Location" subject has gone its normal length. Mr. Pond is reduced to one stale law-point. Mr. Kendall appreciates anew the old law of logic, viz: Never back up a strong point with a weaker one, for an opponent will cunningly attack the weaker one, entirely ignoring the one he cannot answer.

Marketing Extracted Honey.

WM. MUTH-RASMUSSEN.

A paper published in Los Angeles, *News and Recreation*, contains an article complaining of the unjust and exorbitant fare exacted from honey-producers. Not only the weight of the cases, but also that of the cans, including the weight of what honey adheres to the inside of the can after it is emptied, is deducted from the gross weight. The same cans are frequently returned to the bee-keeper, who has to pay for them over again, besides cleaning them and paying the return freight charges. While I have suffered from this extortion myself, and admit that there is just cause for complaint, I cannot help feeling that the bee-keepers themselves are in a great measure to blame for this state of affairs. Finding that new cans, made to order in the tin-shops, were too expensive, they adopted second-hand coal-oil cans, which, after being properly cleaned, might do well enough for manufacturers and other large consumers of honey, but were unsuitable for the retail trade. Aside from the more or less founded objection to the previous use of these cans, very few customers will buy such a quantity of honey at one time. This same objection, being once fixed in the public mind, will be slow to disappear, even if entirely new cans should be used for the purpose, particularly if the new cans retain the same size and shape as the old coal-oil cans. The consequence is, that a new trade has sprung up, whose business it is to place the honey before the public in smaller and more attractive packages, without which there would hardly be any sale for honey at all.

Producers of comb honey have long ago taken the matter into their own hands, and thereby remedied the evil of too much tare. None of them would now think of placing whole caps of honey, built irregularly through the frames, on the market. The popular one and two-pound sections are sold with the honey; the sections are so light that nobody objects to paying for them, while the producer gets his money back and really loses nothing by buying the sections. If all producers of extracted honey would insist on being allowed the actual cost of the cans, including purchase price, freight charges and

cost of cleaning and repairing them (without talking about selling the cans by weight at the same price as the honey), and would agree not to sell any honey unless this demand was complied with, they *might* accomplish their object, although I well know that it is very difficult, if not impossible, to get a large body of men, competing with, and more or less jealous of each other, to sign such an agreement; and without concerted action it would be useless to try this remedy.

But there is, in my opinion, a better way of doing it. Producers of preserved fruit, meats, fish and other canned goods, as well as of wine, tobacco and many other articles which enter into the daily consumption of the public, do not place their wares on the market in bulk. True, some of the articles are re-handled by packing firms, but many of them are put up in retail packages by the producers themselves. Why cannot the bee-men do the same? They have a large amount of leisure time during the winter which might be well employed in making cans. They are all used to handling the soldering iron, and, with a little practice, can do such work as well as a professional tinner. Material in the flat can be procured at one-half the cost of ready-made cans, and, considering the small bulk, at much less freight. For sealing-wax, made of equal parts of rosin and beeswax, with which to close the cans, they have one-half the material at home and do not need to buy it.

I will give a little of my own experience when I first settled in this part of the State. I put most of my honey up in new ten-pound, screw-top cans, charging 25 cents extra for each can, as the actual cost of the cans laid down here. I never heard any complaint of this extra charge, as I advertised that customers might bring their own vessels, and thus avoid paying for the can. But after awhile the honey would granulate, and some would object to the trouble of melting it, or the difficulty of getting the liquid, but thick honey out of the can in cold weather, while others who preferred the candied honey, disliked cutting the can and thereby spoiling it for future use. To obviate this trouble I adopted the "Jones' honey cans," made like ordinary fruit cans, having a large cover which can be secured with sealing wax. As before, I charge the cost of the cans, get fair wages for my time and work in putting them up, and obtain a living price for my honey. As the cans, after being emptied, are useful for preserving fruit, and for many other purposes, nobody objects to paying for them. The handsome labels, with which the cans are adorned, no doubt help the sales considerably, and my name and address on the label are a guarantee that the contents are as represented, and not adulterated. Some may put up honey in irregular sizes of second-hand, picked-up cans, and a certain class of customers will buy them, thinking that—the contents being the same—it does not matter about the style of the can, if they can get it a little cheaper. But the ma-

majority will insist upon having my honey, because the irregular style and size of the package assure them that they get what they pay for.

The sizes, which I have found most suitable for the retail trade, are 2½ and 5-pound cans, the difference in favor of either being almost imperceptible. I have shipped such cans in cases holding a dozen of the former, or one-half dozen of the latter, by team, rail and pack-animals, without any loss by breakage or leakage; and, as the honey always granulates here in the fall, there would be no danger, even if the sealing-wax should get broken. For home storage, or when short of small cans, I use 60-pound cans, but never sell any unless ordered or called for at the apiary. If the bee-keepers as a class would follow my example, I am sure they would have the same experience to the mutual satisfaction of themselves and the public at large. Let them once agree to use a few standard sizes of small packages, and, when found suitable for their market, forever after strictly adhere to them, and I have no doubt that they will wonder at and regret that they did not try it long ago, and thereby establish a good reputation, a lively demand and a fair price for the honey. Independence, Cal.

Norfolk, Ont., Convention.

The 14th regular meeting of the above association was held in Simcoe, Ont., on June 7. The 1st Vice-President, Mr. Moses A. Kitchen, in the chair. The minutes of the last meeting were read and adopted.

Questions were answered as follows:

1. Which is the better for bees, during the time of breeding, honey or pollen? After a full discussion, it was decided that both are absolutely necessary.

2. What is the cause of so many bees leaving their hive in the spring? There are various causes; but the principle one is a need of supplies.

3. When a colony finds itself queenless, and then rears a queen of its own, is it advisable to leave this queen with the colony? No; for when the bees find that they are without a queen, they are sure to set about rearing one from a larva already 8 or 9 days old, and which has previously received no special nourishment; and the result is sure to be an imperfectly-developed queen.

The next question that came before the association, was one concerning adulterated honey. Some one had said that a bee-keeper had placed adulterated honey on the market. A sample of the article being produced, was examined by experts, and pronounced to be undiluted, but of an inferior quality; having been gathered late in the season, and not properly ripened.

After discussing other matters, the meeting adjourned to meet at 2 p. m. on Saturday, Sept. 6, at the residence of Mr. Moses A. Kitchen, on the gravel road between Bloomsburg and Waterford. All are cordially invited to attend. ELIAS CLOUSE, Sec.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

How to Clean Barrels for Honey.

I have some barrels to clean, and I have been trying to clean them with hot water, but I cannot get the smell out of them. Would whisky barrels need to be free from smell so as not to injure honey? Can wine barrels or other barrels be cleaned through the bung-hole so as not to sour or taste the honey? The spring has been very poor for bees in this part of the land. We had a very heavy frost and killed all the fruit bloom. Bees wintered well here last winter. GEO. KEMP. Navan, Ont.

ANSWER.—Yes; hot water persistently used will cleanse your barrels fit for honey.

Why do the Bees do so?

On the 19th we had a swarm from one of our hives, and on the 26th we cut out all the queen-cells but one; to-day the bees acted, for quite awhile, as if they were going to swarm, flying in and out of the hive, making quite a noise. Please tell me the cause of this commotion. A NOVICE. Jerseyville, Ill., June 30, 1884.

ANSWER.—I think that you must have left a second cell, or else the bees concluded that they must have one, and thought of swarming with the queen that hatched.

Swarming Fever.

Bees are now working lively on white clover, of which we have an abundance. Where allowed to swarm they are making good use of it. One of my neighbors had one colony that swarmed and returned five times, having been hived 2 or 3 times. The owner is a beginner in bee-keeping, and did not understand how to manage them to save such trouble. I was there the other morning, and they were hanging out in abundance. I told him if the queen could be found the colony could be divided so as to make it the same as if it had done its own swarming. So we went at it and found a mystery that I would like to have solved. We found plenty of queen-cells in different stages of development, but could find no queen, and the age of the brood showed that there had been no laying queen for 4 or 5 days, for there was no eggs nor fresh hatched larvæ. It had swarmed the day before, and I believe every day preceding for 5 days. So we divided it by making a division of the bees, giving each part some queen-cells, supposing the queen was lost. But to our surprise, the next day, the part that contained the greater part of the bees swarmed again; it being the part that was set away, and the part that we supposed contained the

queen, if there was any, as we brushed the most of the bees into that part and gave it two combs with 2 or 3 queen-cells. There was no indication that any young queen had hatched out. Now, what I wish to know is, will a queen cease laying during a swarming fever? He had another that had been out and returned. This we divided also, but did not find the queen, but found eggs and brood in all stages. So we divided it on the common rule, by putting in a comb of brood in the new hive on the old stand, brushing the bees into the new hive and setting the old hive in another place. This one is doing all right.

J. W. SANDERS.

Le Grand, Iowa, June 25, 1884.

ANSWER.—Yes; we have known such cases, where just as soon as the efforts at swarming began, the queen ceased to lay, and was undoubtedly the condition of affairs in the case you mention.

Maltine.

Have American bee-keepers made any trial of maltine (or extract of malt) to feed the bees, with honey, as a remedy for the so-called diarrhoea? If not, I would recommend it. I think it is worthy of a trial, and would prove of service if "the pollen theory" be correct.

A NEW ZEALAND BEE-KEEPER.
Pukekohe, N. Z., May 26, 1884.

ANSWER.—I know of no one who has ever tried maltine, nor can I understand how it can assist us in preventing diarrhoea among our bees, whether "the pollen theory" be correct or not. The latter theory is based upon the idea that nitrogenous food should be avoided in winter, and I should suppose that maltine would rank higher than honey as such food, and thus tend to increase rather than decrease the tendency towards the disease.

Tiering up Sections.

I have a very strong colony of bees. I have 8 frames in the brood-nest, and two tiers of sections; 42 sections in both. They are clustering in front of the hive, very much. I thought they were about to swarm, so I looked for queen-cells, and there was not one started. The top tier of sections are almost finished, but not quite ready to take of. The under tier is ready to cap. Should I give them another tier or not, as white clover is drying out on account of the drouth? If I should give them another tier, and the flow of honey is getting poor, will they finish the upper tiers or not? I have no experience, or I would not ask such a question, but it is of importance to me, as I want to get all the salable honey I can.

S. M. HICKEN.

Dell City, Del.

ANSWER.—This question hits a vital point, and is one that may well be asked by the inexperienced. You seem to have about the right idea of it. If you had, as we have, a bass-wood crop just opening, you should

put on a third case, because you could not afford to lose a case of honey to get another finished a little sooner; but the lying out of your bees, indicates one of two conditions, viz: that either your hive communications are faulty, and your bees exposed to the direct rays of the sun, or else that the flow is drying up. Supposing the latter to be the case, just leave the cases as they are until finished, or another flow begins. Take them off as soon as finished.

Candied Honey in Kegs.

How is honey handled after it is candied, to put up in pails and cans? My idea is to cut it out of the kegs and put in a double boiler and liquefy it, then run it in the jars, pails, etc. Is that right? I am going to try and build up a trade on extracted honey, and as we have a city of over 15,000, I think I ought to sell large quantities of it.

R. B. HOLBROOK.

Winona, Minn.

ANSWER.—The better plan is to draw it into the cans just before candying takes place. It too late for that. I would place the candied honey in a warm room to soften just enough to settle down compact into the pails or cans.

Wax Production.

Most of us now use comb foundation to save bees the labor of wax building. But in the market wax seems to be more valuable than honey. Would it not be possible to invert the process, and by supplying the bees with honey and rye flour for pollen, and denying them comb foundation to induce them to concentrate their energies exclusively to the production of wax?

W. H. BARLOW.

Charlottesville, Va.

ANSWER.—As I understand it, the use of comb foundation not only as a perfect guide to straight combs, but in full sheets as a guide to all worker cells, and a material of economy, paid all through the season of 1883. It is no dearer in price this season. My idea is that it pays me well now. I am, the present season, using nearly one thousand dollars worth. I am of the opinion that I am gaining by so doing. I know that honey may run down so low that this material can hardly be afforded in full sheets; but it has not, as yet. I do not believe that we can ever produce wax at a profit at any price it is likely to go to.

Honey Candying, etc.

I find the bees in this county in fine condition, and gathering plenty of honey. I transferred one colony, and they filled 3 frames and put about 10 pounds in the boxes in 5 days. I found in two places where bees are putting candied honey in their new combs; it seems that it candies as they gather it. What do they get it from? I sold some of my first honey in one-pound sections for 20 cents each, this year. We had a heavy honey dew this year. What credit

should a queen have for cells taken from her hive, on the Apiary Register? I have one colony that I have reared 8 from. I take the frames out that have the cells on them.

H. C. AUSTIN.

Austin's Springs, Tenn., June 27.

ANSWER.—I am unable to say, not knowing much about your Southern plants. We all know that honey from some sources candies almost as soon as stored. It is further true, that in this respect, honey from the same plants varies in different seasons.

Regarding the credit you should give the colony you take cells and combs from, your own judgment as to the force you deprive them of should be best.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Bee-Keeping in New York.

I had 12 colonies of bees last fall, and wintered 10. I have had eight swarms which are in 7 hives, and doing well. They are gathering honey from white clover and Alsike. The yield from Alsike seems to be abundant. Farmers are sowing Alsike quite extensively now, which is fine for bee-pasturage. The spring was wet and cold until in May, since that time it has been growing warmer until now it is dry and the air sultry. Although my bees have plenty of shade, I have covered the hives with boards to protect them from the heat. The thermometer indicated 92° in the shade at 2 p. m. to-day.

WM. A. BRUNDAGE.

Lodi, N. Y., July 2, 1884.

Eccentricities in Queen Breeding.

I have had beautiful golden Italian queens mate with a black drone in a tent, and the first workers would be of golden color, but in the course of a month the workers would be all black; a month later they would be all mixed in color. A black queen mated with an Italian drone, in confinement gave similar results; the first bees would be black, later ones yellow, and still later, mixed. Further experience has shown that if an Italian queen mates with a black drone, the yellow is predominant, and vice versa. Have any readers of the BEE JOURNAL noticed similar facts?

Milford, Ill.

HUGO VOLLAND.

Good Honey Yield.

We are having a fine honey flow, and have had a very heavy fruit bloom this spring. Our winter here was very cold and severe, and the spring was late, so that many colonies of bees was transformed into the "stingless variety." However, the excessive swarming that is now going on, will more than repair the loss. There are many bees kept in this part of the State, but only a few persons appear to know how to manage them, so as to obtain the best results. Since keeping bees and practicing "beeology," in this locality, many have taken the "bee-fever" and embarked in the enterprise with good results, and if the "fever" does not become too contagious (so as to overstock the country), we may expect good returns; for this year we have a prospect of a large increase in bees and a good crop of honey. A. W. FISK.

Bushnell, Ill., June 30, 1884.

Apiarist or Apiator?

I notice that Keys calls a bee-keeper an "apiator." Do you think that will do as well as apiarist?

J. M. SHUCK.

Des Moines, Iowa, June 25, 1884.

[No; we very much prefer to follow Webster's Dictionary, and use the word "apiarist."—Ed.]

That Deep-Celled Foundation.

A few days ago I sent for a sample of the Weed foundation. I wanted to try it on a small scale before buying much. I thought that more was claimed for it than ought to be claimed for any foundation, that it cannot sag nor break down, and when the bees so readily accept of it, it must be an improvement on the old kind. The piece that I obtained, I put into an old comb just as I would a queen-cell; when next I saw it, a day or two afterwards, the bees had it drawn out and filled with honey. I think it is a pity this was not found out long ago. I have 20 colonies of bees; lost one last winter. They were on the summer stands packed with straw and chaff; they are doing very well.

M. HIGGINS.

Windsor, Ont., June 20, 1884.

Bees Doing Nicely.

Basswood will be in blossom in a few days, then I hope to see them "boom," as white clover is nearly gone, unless we have more rain very soon.

ARAD C. BALCH.

Kalamazoo, Mich., June 30, 1884.

Large Honey Flow.

My bees are doing well—storing 10 pounds per colony each day. I have only had 2 swarms yet; they were from the Italian colonies. The Cyprians stick to their home as long as they have room. There was a heavy loss of bees last winter, but they are increasing rapidly now.

D. R. ROSEBROUGH.

Casey, Ill., June 23, 1884.

Prospects for Honey in California.

Summer has now actually come, and California has now emerged from the "clouds;" and in the place of heavy fogs and drizzling rain, we have bright sunshine and clear blue skies. All seem to welcome this delightful weather with a thankful heart, but no one more than "the little busy bees," whose joyous and contented hum may now be heard from early morn until the setting of the sun. The faces of the bee-keepers have now a contented smile, in spite of their effort to look grave and pre-occupied. In this section, the black sage is almost out of bloom. The wild alfalfa is at its best. White sage is just coming in, while sumac and wild buckwheat are yet to come. The rains in California have been, this year, unusually late, and as a matter of course the bees have not had good weather for work; but, notwithstanding the lateness of the season, the prospect is good for a fair crop. As a general thing, bees are in most excellent condition.

J. E. PLEASANTS.

Santa Ana, Cal., June 25, 1884.

But few Swarms.

Bees are very slow about swarming, this season. I have only had 4 swarms, up to this date, out of 49 colonies. The season has been very wet. White clover is now abundant.

SAMUEL C. WARE.

Towanda, Ill., June 27, 1884.

Transferring Bees.

I have 15 colonies of bees that I wish to transfer from box hives to movable frames. Mr. Heddon, on page 412 of the BEE JOURNAL for 1884, refers me to page 367 of the BEE JOURNAL for 1883. Will you please publish the part about transferring bees, and oblige a subscriber.

J. F. McMILLAN.

Healy, Ill., June 29, 1884.

[As there have been several calls for that article to be re-published, we here give the new plan as described by Mr. Heddon.—Ed.]

About swarming time I take one of my Langstroth hives containing 8 Given pressed wired frames of foundation, and with smoker in hand, I approach the hive to be transferred. First, I drive the old queen and a majority of the bees into my living box. I then remove the old hive a few feet backward, reversing the entrance, placing the new one in its place, and run in the forced swarm. In two days I find 8 new straight combs with every cell worker, and containing a good start of brood. Twenty-one days after the transfer, I drive the old hive clean of all its bees, uniting them with the former drive, and put on the boxes, if they are not already on. If there is any nectar in the flowers, the colony will show you comb honey. About the queens: I usually kill the forced queen as the bees run in.

I run them together as I would one colony in two parts. Now to the old

beelless hive; of course there is no brood left, unless a little drone brood, and we have before us some combs for wax, for more foundation, and some first-class kindling wood.

If you have no method by which you can use a full hive of frames, of full sheets of foundation, running a full swarm into them at once, by all means procure it without delay.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL,
Monday, 10 a. m., July 7, 1884.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for all honey is very slow; market dull and prices range from 6⁰⁰/₁₀₀ for extracted. Different lots of choice comb honey in small sections have been offered and sold in our market lately at 12⁰⁰/₁₀₀ per lb. As I predicted some time ago, the preference for the production of comb honey seems to be prevalent; and, as we have the best prospects for an abundant harvest this year, we may prepare for low prices.

BEE SWAX—Is in good demand; choice yellow brings 35c a lb. on arrival. CHAS. F. MUTT.

NEW YORK.

HONEY—Present sales of comb honey are slow, and will be until the new crop arrives. We quote: Fancy white 2-lb. sections, glassed, 13⁰⁰/₁₀₀; fair to good to 2-lb. sections, glassed, 11⁰⁰/₁₀₀; dark grades in 2-lb. sections, glassed, 10⁰⁰/₁₀₀. No 1-lbs. in this market. Extracted, white, 8⁰⁰/₁₀₀; dark and buckwheat, 7⁰⁰/₁₀₀.

BEE SWAX—Prime yellow, 34⁰⁰/₁₀₀.

MCCALL & HILDBRETH, 34 Hudson St.

BOSTON.

HONEY—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15c, and 2¹/₂-lbs. at 23⁰⁰/₁₀₀. From 10⁰⁰/₁₀₀. No 1-lbs. in the market. Extracted, 8⁰⁰/₁₀₀.

BEE SWAX—35c.

BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—The new crop of comb honey is coming on the market, and nearly all of the arrivals to note are in good order, and the quality of the honey is of the best, being white, and flavor that of clover and linden frames are unusually well-filled. The crop of comb honey of 1883 is nearly all cleaned up. We have not had any old comb honey to offer for several days. Extracted honey is in very light demand, and prices irregular; the stocks of it are large.

BEE SWAX—Not plentiful, but the demand is also light at 30⁰⁰/₁₀₀ for fair to prime.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Only small lots of new crop have thus far arrived. There is no urgent inquiry at present, and considerable difference exists between the views of buyers and sellers as to values. Small lots of new white comb have been sold at 15⁰⁰/₁₀₀. White to extra white comb, 15⁰⁰/₁₀₀; dark to good, 10⁰⁰/₁₀₀; extracted, choice to extra white, 5⁰⁰/₁₀₀; dark and candied, 4⁰⁰/₁₀₀.

BEE SWAX—Wholesale, 27⁰⁰/₁₀₀.

STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—No change to note in prices. As predicted in last report, the temporary activity was only accidental, and last week has been dull. Some little new honey is now arriving, but it falls as yet to tempt buyers to any extent. I look, however, for a very large demand a little later, and would suggest shipment by Aug. 1, of all that is ready in quantities to justify. I have still a few more "Suggestions on Packing and Shipping Honey," to mail free on application. I will also furnish shipping stencils free to any one desiring to ship to me.

BEE SWAX—Nominal, at 30⁰⁰/₁₀₀.

JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12⁰⁰/₁₀₀ per lb., and strained and extracted 6⁰⁰/₁₀₀.

BEE SWAX—Firm at 32⁰⁰/₁₀₀ for choice.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1 lb. sections at 18c; 2 lbs. best white not quite so active at 17c; 1 lb. sections sell quickly on arrival, and often are sold to arrive. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.

BEE SWAX—Scarce at 35c.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2 lb. sections, 16⁰⁰/₁₀₀; extracted, 7⁰⁰/₁₀₀.

GEO. W. MEADE & Co., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

We now club the *British Bee Journal* and our Monthly for \$2.50, or it and the Weekly for \$3.50.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an additional present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75. Or, bound in cloth, with Weekly, \$3.00; with the Monthly, \$2.40.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Do not let your numbers of the BEE JOURNAL for 1884 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference

Advertisers' Opinion.

My advertisement in the BEE JOURNAL, has brought me over 400 responses. Dr. G. L. TINKER. New Philadelphia, O.

The queen business is rushing, and we think the BEE JOURNAL deserves much credit as an advertising medium. E. A. THOMAS & Co. Colerain, Mass.

Having advertised in the AMERICAN BEE JOURNAL quite extensively for the past two years, I would say (without solicitation) that it has sold more queens for me than any other three periodicals I have ever tried.

My bees are in fine condition this spring. I have lost but 4 out of 182 colonies. The outlook is fine for a good season. L. J. DIEHL. Butler, Ind.

The BEE JOURNAL does its advertising wonderfully well. It brought to me responses from Canada to the Gulf of Mexico, and from the Alleghanies to the Rocky Mountains. WM. M. ROGERS. Shelbyville, Ky.

A Canadian wishes us to state in the BEE JOURNAL, whether we take Canadian money for subscription or books. We do; and for fractions of a dollar, Canadian postage stamps may be sent.

Cook's Manual in cloth and the Weekly BEE JOURNAL for one year will be sent for \$3. Manual and Monthly, \$2.00. We have no more of the old edition left, and, therefore, the club price of that edition at \$2.75 and \$1.75 is withdrawn.

DR. FOOTE'S HAND BOOK OF HEALTH,

HINTS AND READY RECIPES,

is the title of a very valuable book that gives a great amount of information, of the utmost importance to everybody, concerning their daily habits of Eating, Drinking, Dressing, Sleeping, Bathing, Working, etc.

It Costs only TWENTY-FIVE CENTS, and contains 28 pages, and is sent by mail, post-paid, on receipt of price. This is just the Book that every family should have.

IT TELLS ABOUT

It will Save Doctor Bills!

Price only 25 Cents. Sent by Mail, post-paid, by

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

Convention Hand-Book.

It is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

What they Say of it:

From Prof. A. J. Cook, Lansing, Mich.—"I have greatly to thank you for getting up the exquisite little Convention Hand-Book. Surely the old 'saying' is true—being a thing of beauty, it ought to be a joy forever."

From Mr. A. I. Root, Medina, O.—"Send me—dozen of the Convention Hand-Books. We have had quite a number of inquiries for something of that sort, and yours seems to be quite nicely gotten up, and just what is wanted."

From Mr. J. E. Pond, Foxboro, Mass.—"The Convention Hand-Book is just the thing. The digest of Parliamentary Rules it contains will prove of great value to every one. I trust it will receive the patronage it so well deserves."

From G. M. Doolittle, Borodino, N. Y.—"I am in receipt of the new Convention Hand-Book, and must congratulate you on the happy thought of such a work, and the neat appearance of the book. It is a work you may well be proud of, both as to the matter it contains, and the splendid material used in its make-up. It will meet a long-felt want; and, were it so that I could attend conventions as in former years, ten times the price would not seem too much to pay for it, for by the instruction therein given, any man could be kept from many a blunder, much to his mortification. I hope in the near future to again be at liberty to go to conventions, when I shall prize the work very highly."

From Mrs. L. Harrison, Peoria, Ill.—"The Bee-Keepers' Convention Hand-Book is a gem. It should be in the hands of every one who attends a bee-convention, and then there will be no need of embarrassment on account of ignorance of Parliamentary Rules. Accept my thanks for sample sent."

From Mr. Jas. Heddon, Dowagiac, Mich.—"The Bee-Keepers' Convention Hand-Book is received. I saw it advertised, but conceived no approximate idea of its great value to bee-keepers attending conventions, until I perused it. Many times the price of my copy would be no temptation for me to do without it. It will make us all want to talk at once, I fear. You deserve the thanks of all, and I herewith tender mine for this helper."

From Mr. G. W. Demaree, Christiansburg, Ky.—"The Convention Hand-Book is the most exquisitely gotten up, and the nicest book in my collection of apicultural works. It contains much valuable information, and especially as many of the presiding officers of our conventions are selected to fill those important positions because of their practical skill as apiarists rather than for their fitness as presiding officers, this little work will fill a long-felt want. Please accept my thanks for your untiring labor to promote the apicultural interest of the country."

From Dr. G. L. Tinker, New Philadelphia, Ohio.—"I prize the Convention Hand-Book very much, and it will be a valuable aid to bee-keepers attending conventions. The questions for discussion are concise, and cover the field of the most interesting and unsettled points in bee-culture. The book will help to systemize convention work, and enable the members to do business properly."

From Mr. W. Z. Hutchinson, Rogersville, Mich.—"If every bee-keeper would read the Convention Hand-Book, and profit by its perusal, our Conventions would be more orderly and have more beneficial."

From Mr. George Hilton, Fremont, Mich.—"I think the Convention Hand-Book is destined to fill a long-felt want, and should be in the hands of every intelligent bee-keeper."

QUEENS!

We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.50 a year.

Bingham Corner.

MARENGO, ILL., June 18, 1884.

The Doctor Subdues All.—Mr. T. F. BINGHAM, Dear Sir:—I've used the "Doctor" till its all daubed up with bee-gue, and although at first sight I thought I did not like anything so large, I could not now be induced except by the direst poverty, to do with any thing smaller. As a matter of "economy" I much prefer the "Doctor" to any of the cheaper smokers, of which I have worn out several. The "Doctor" has entirely cured me, so that I am now a Bingham man, as my wife always has been. If the somewhat vague remark in your letter means that nothing was charged for the Smoker sent, except the reading of your letter, I shall be very glad of another "Doctor" for the money sent, so that my wife won't take mine from me. Bees just booming on white clover.
Yours Truly, C. C. MILLER.

WOODBARD'S LANDING, Wash. Ter.

The Best Smoker.—To BINGHAM & HETHERINGTON, Abronia, Mich., Dear Sirs:—Find enclosed money for 3 Conqueror Smokers, which please send per mail—one to each, Dr. Balch, J. M. Loderback, and H. A. Towner. The Conqueror is the best Smoker I ever used. Respectfully,
May 17, 1884. H. HASTINGS.

DRESDEN, TEX., May 28, 1884.

Conquer the "Cyps."—T. F. BINGHAM, Abronia, Mich., Dear Sir:—Enclosed find \$1.75, for which please send, per mail, one "Conqueror Smoker" to Major H. A. High, Waxahachie, Tex. He bought a Cyprian Queen from me, and the Bees have worsted the old gentleman. I told him that the Conqueror Smoker would conquer the "Cyps," as I had tried one for two years, and "it never failed." Respectfully,
B. F. CARROLL.

BORODINO, N. Y., Aug. 15, 1882.

Cyprians Conquered.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. Respectfully,
G. M. DOOLITTLE.

Prices, by mail, post-paid.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure.
T. F. BINGHAM.

Abronia, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN.

Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ills.

A Liberal Discount to Dealers by the Dozen or Hundred.

WE CALL

the attention of all wanting A No. 1 BEES, Italian, Cyprian or Hybrids, to the following, from one well-known to the readers of this Paper:

"I have never seen a case of foul brood; my bees are entirely healthy, and have always been so, and are O. K. in every respect."
Geo. B. PETERS, M. D.

We can furnish any number of Colonies of the above Bees, and will warrant safe delivery and satisfaction.

N. B.—No Bees will be sold by us, for any consideration, from any apiary that has ever had a case of foul brood in it. For prices and particulars, send to

FLANAGAN & ILLINSKI,

Lock box 995, Belleville, St. Clair Co., Ills.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.

ALFRED H. NEWMAN,
923 West Madison Street,
CHICAGO, - ILLINOIS.

A PRIZE. Send six cents for postage, and receive free, a costly box of goods which will help you to more money right away than anything else in this world. All of either sex, succeed from first hour. The broad road to fortune opens before the workers, absolutely sure. At once address, TRUE & Co., Augusta, Maine. 4A1y

65 ENGRAVINGS

THE HORSE,
BY B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents.—Sent on receipt of price, by

THOMAS G. NEWMAN,

OLDEST BEE PAPER IN AMERICA

THE WEEKLY BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED TO THE INTERESTS OF HONEY PRODUCERS.

ESTABLISHED IN 1861.

Chicago, Ill., July 16, 1884.

VOL. XX.—No. 29.

THE WEEKLY EDITION OF

PUBLISHED BY

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

925 WEST MADISON ST., CHICAGO, ILL.
Weekly, \$2 a year; Monthly, \$1.

PREMIUM.—Any one sending one *new* subscription for the Weekly, or two for the Monthly, for one year, besides their own subscription for a year for the Weekly, will be entitled to a copy of "Bees and Honey," bound in paper.

☞ The receipt for money sent us will be given on the address label on every paper. If not given in two weeks after sending the money, write us a Postal card, for something must be wrong about it.

☞ Any person sending a club of six, is entitled to an extra copy (like the club), sent to any address desired. Sample copies furnished *free*.

☞ Papers are stopped at the expiration of the time paid for, unless requested to be continued.

FOREIGN POSTAGE, EXTRA:

To Europe—Weekly, 50 cents; Monthly, 12 cents.
To Australia—Weekly, \$1; Monthly, 24 cents.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Entered at the Chicago P. O. as Second Class Matter.

ADVERTISING RATES.

20 cents per line of space, each insertion,
For either the Weekly or Monthly Editions.

A line of this type will contain about 7 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance. Editorial Notices, 50 cents per line.

Advertisements may be inserted one, two or four times a month, if so ordered, at 20 cents per line, space, for each insertion

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE.

PATENTED, MAY 20, 1878.

The Original
BINGHAM
Bee Smoker

Patented, 1878.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go! Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To sell again, send for dozen rates to

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects: Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quitting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, in cloth, \$1.00; in paper covers, 75 cents.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the **English or German** edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 25 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bielen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY ALLEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way to rear Queens, etc. Price, \$1.00.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either **English or German.**

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XX.

CHICAGO, ILL., JULY 16, 1884.

No. 29.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Comb Honey Without Separators.

We must say that we have never been favorable to the plan of dispensing with the use of separators, when getting comb honey ready for the metropolitan markets. We have seen so many ill-effects of the non-use of separators, that we have about concluded that it was detrimental to the best interests of honey producers to favor the plan.

We have just now received the following letter and the box of honey therein mentioned :

DEAR EDITOR:—I send you to-day, by express, 2 of my two-pound section boxes with honey produced without separators, by my new strain of bees. I got 54 sections like the ones sent, every one of which could be glassed like the ones sent. So much for comb honey without separators. The quality of the honey, also, is the finest I have ever obtained. None of my Italians ever produced honey so fine and clear.

DR. G. L. TINKER.

New Philadelphia, O., July 7, 1884.

The honey is elegant in appearance, superb in quality, and though the sections are only one and three-sixteenths of an inch thick inside the glass, the honey is as straight as a board, and the glass (though it almost touches the honey all over) seems to be equi-distant from the capping of every cell. The glass is held to the section by two elastic bands.

The Doctor should feel highly gratified at the production of such elegant specimens of comb honey.

If this can be done, without separators, in large quantities, it is all that can be desired, and its accomplishment will be hailed with delight by thousands who have hitherto considered separators a necessity.

It is true that neither one flower nor one bird will make summer—we need the full chorus of myriads of birds of every hue, the universal bloom of nature's loveliest gorgeousness, the genial and refreshing showers, and the light and heat of the glorious "orb of day" to complete the indispensable features of summer. It is just the same with this important matter of the use of separators—we need the test applied to large products, in order to demonstrate the possibility of the successful production of comb honey without separators, so that we may be assured that it will alike answer all the requirements of the producer, the wholesaler, the retailer, and the consumer.

Let us hope that the present experiments, and the many individual successes which have been reported, may prove to be the first-fruits of the great harvest of such experiences which shall fully and unequivocally demonstrate the successful production of comb honey without separators. If not, then we cannot afford to dispense with their use.

Mr. J. Stewart, Rock City, Stephenson County, Ill., Secretary of the "Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association" makes the following request :

At our last meeting in Rockton, the Association passed a resolution ordering me to correspond with all bee-keepers' associations in the State, in order to endeavor to have a law passed by the State Legislature for the prevention and destruction of foul brood. As I do not know the names of the associations in the State, or the addresses of the secretaries, I would request the secretaries to furnish me with their addresses and the names of their associations, as required, so that we may act in concert.

This is "convention year," and there is to be an International Convention of bee-keepers at South Kensington, London, England, on Aug. 7.

Cyprians, Syrians, etc.

Mr. L. C. Root, author of "New Bee-Keeping," in the July *American Agriculturist*, gives his views of some of the new varieties of bees which have been introduced into the United States with considerable expenditure of time and money.

The Cyprians have some marked characteristics. They have been quite thoroughly tested, but do not grow in favor with the majority. They are far too irritable to be agreeable to handle. Some consider them superior honey gatherers. I have given them quite a thorough trial, and the only point I could find in their favor, was a tendency to breed late in the fall, which is desirable as affording a good force of young bees when going into winter quarters. I have not tested the Syrians. Mr. Benton pronounces them among the very best. The Carniolans are said to possess some very desirable qualities, and a cross between them and the Italians has a good reputation. Much has been said of the Holy Land or Palestine bees, but my own experience does not corroborate all that is claimed for them.

Mr. Julius Hoffman received an importation of Caucasian bees in 1880. He has experimented quite extensively with them, and is of the opinion they are superior in many respects. In fact, I have never heard more desirable points claimed for any one variety than Mr. Hoffman claims for these. He is one of our most practical bee-keepers, and his conclusions should be received with confidence. Much credit is due those who have been so persevering in securing to us these new varieties. The ultimate results must be of great good, as the future crossing of these strains will, no doubt, give us one with a combination of very superior traits.

The article on page 420, entitled "Expose your Hives to the Morning Sun," should have been credited to the *British Quarterly Review* for December, 1842. It was intended to show rather a fine specimen of magazine bee-writing of 42 years ago, but the date there given, by an oversight, made it quite a recent matter.

Letters for publication must be written on a separate piece of paper from items of business.

Migratory Bee-Keeping.

Since the disastrous failure of migratory bee-keeping, as tried by Mr. Perrine in 1876, by conveying them on steam barges on the Mississippi River, to follow the bloom, we have heard but little about it.

That such things do pay when properly managed, is demonstrated every year in Scotland, where bees are taken to the highlands where a perfect "sea" of bloom is provided by the heather; and in Egypt, the bees are taken up the Nile to gather the sweet nectar from the bloom, in its successive development. Messrs. Dadant & Son often move their bees to the "bottom lands" of the Mississippi River with complete success, and a remunerative yield of honey.

Mr. Baldrige, in connection with Mr. Flanagan, has inaugurated a similar experiment, and from an exchange we quote the following:

Last November they took to the neighborhood of New Orleans some 300 colonies of bees for wintering. The plan was to keep them there to work in early spring, say to about the second week of June, then ship them north to Kane Co., Ill., to feed upon white clover and other superior honey-producing plants, until the first of August; then move them down to St. Clair county to gather honey from heart's-ease, Spanish-needle, etc., until cold weather closes honey-gathering. It is expected to secure three distinct honey seasons, and if desired, three periods of natural increase. Besides the advantage of an early honey crop, it is calculated that in the mild climate of Louisiana there will be little if any loss in wintering.

The first part of this programme has been carried out, and the 300 colonies, filling two cars, have arrived in St. Charles, their summer home. Mr. Baldrige informs us that the bees wintered without loss, but that the extreme wet weather along the lower Mississippi greatly interfered with plant bloom, and that the honey crop was exceedingly light—indeed less than for many years, so he does not consider the profit settled for the first third of the season. The test for the second third will now be entered upon in Kane county.

The freight on bees in quantity, from New Orleans to Chicago, is about one dollar per hive, to which expense must be added the time and services of the attendants. To take them back, stopping at St. Clair county, will add something to the cost of freight and handling. Apiarists will watch the progress of this new bee-enterprise with interest.

The Kentucky Bee-Keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed). N. P. ALLEN, Sec.

Another Bee-Paper Gone.

The *New England Apiarian* has ceased to exist. The June number contains the following announcement:

My expectations have not been realized, and I find that I have lost considerable money during the past year, with a prospect of losing a great deal more this year. I think none of my subscribers or patrons desire me to run this at a loss, and certainly I do not feel like continuing to publish it unless it receives proper patronage. I propose to discontinue its publication, and want to be honorable and just with every subscriber. Those who have paid in advance I will arrange with some other bee-paper or magazine to send them copies for the time they have paid.

Making Honey-Vinegar.

Mr. W. T. Maddox, of Alexandria, La., write us as follows:

In the pamphlet on "Honey as Food and Medicine," I find this receipt for making honey vinegar:

"Take 30 gallons of rain-water; heat it, and put it into a barrel; add two quarts of whisky, 3 pounds of honey, 5 cents worth of citric acid, and a little mother of vinegar. Fasten up the barrel and put it into the cellar, and in a short time it will contain vinegar unsurpassed for purity and excellence of taste."

I wish to ask the following questions concerning it:

1. Is it necessary to heat the water? If so, why?
2. Is it absolutely necessary that rain water alone should be used? Will not clear bayou or river water do as well?
3. Having no cellars here, will not a house do to keep it in? Is it a cool or a warm place it needs to be kept in, after making?
4. Will it make a No. 1, strong vinegar, like the old-time apple or cider-vinegar, to warrant one in making it on a large scale? What is its color?
5. How long after making, before it will be ready for use? Should the bung be driven tightly, or the hole left open?
6. If, by adhering strictly to the recipe, it is made in warm weather, is there any chance of a failure?
7. What is the best method of making "mother of vinegar" by the quantity?

I have always been under the impression that it was necessary to put the barrel in a warm place (in the sun even), to make it work freely and quickly, and that it should be left open. A reply to the above questions will oblige.

As Mr. T. F. Bingham has had considerable experience in making honey vinegar, we requested him to answer the foregoing questions, and he has sent us the following:

Two pounds of honey to two gallons of water is not far from my plan,

and it would change (color, time of making and quality of vinegar) vastly. I am doubtful whether such vinegar would pass in our family. I think, however, that the merchants make vinegar about as above described. But I have never bought vinegar at the stores since we began to make it for our own use. There is no money to be made in producing such vinegar as we make. It is simply good to use, and we always have it in the house.

T. F. BINGHAM.

Any one who has had experience in making honey vinegar is invited to answer the other queries.

Beeswax.

In an Exchange we find the following, concerning the care of cappings, and obtaining beeswax from them:

The "cappings" which accumulate in the extraction of honey, and all odds and ends of comb, should be carefully saved, but in warm weather it is well to render them into wax as soon as possible; otherwise they are liable to become infested with the bee moth's larvæ. What is called a Wax Extractor is a very convenient utensil for rendering wax. It is simply a "basket" of perforated zinc, inside a "steamer" which is set over a kettle of boiling water. The refuse comb is placed in the basket, and the steam rises and melts the wax, which is caught by a false bottom in the steamer, and runs out through a spout in the side. When there is not much wax to render, the cappings of combs can be put into a tin sieve, the sieve covered, and then set over a pan of boiling water. The steam will melt the wax, which will run down and rest upon the water in the pan. The pan and its contents can be set aside until cold, when the wax will be found formed into a cake. Another method is to put the combs into a cloth sack, and the latter into a wash-boiler—the sack being held at the bottom of the boiler by means of a stick, the upper end of which presses against another stick, lying across the top of the boiler, and tied to its handles. When the wax is melted, the boiler is set aside until the wax is cool enough to be removed. Wax can be cleaned from utensils by using a cloth saturated with kerosene oil.

Comb, in frames, can be kept over the summer free from the depositions of the larvæ of the bee-moth if they are suspended in the light and air, and are 3 or 4 inches apart. Moths love darkness and uncleanness, and deposit their eggs in cracks and crevices about hives, where bees cannot gain access to them. Do not permit refuse comb to lie around the apiary or bee-house. I have put frames of comb containing their larvæ into a hive of Italian bees, and in half an hour could see the bees bringing them out. There is no need of any other moth-trap, for they are always baited and set.—*Exchange*.

CORRESPONDENCE

For the American Bee Journal.

"What do we Know."

G. M. DOOLITTLE.

On page 411, under the above caption, Mr. S. R. Mason says: "All the correspondents of the bee-papers are as opposite in their opinions and practices as it is possible to be. I have looked in vain for some one person whom I could follow with a certainty of success, and as freely as I would a teacher of any of the common branches of human knowledge * * Stop quarreling, write sense, and the common sort at that."

As there seems to be an opinion similar to the above prevailing with most of the beginners in bee-keeping, and also with many who have kept bees as long or longer than Mr. Mason, perhaps a little explanation of the matter may help us, as readers of the AMERICAN BEE JOURNAL, to understand each other better, or at least help us to understand why nothing pertaining to bee-lore can be followed like a rule in arithmetic. Twice 2 makes 4 every time, because it cannot be otherwise, no matter by whom it is multiplied, nor at what season of the year the computation is made, or in what locality; hence we have the rule of multiplication as being always the same. The same of addition, subtraction, etc., but if we come to apply any rule similar to the above, to the bees, we find it wont work, for the reason that every season brings its changes. For instance, last season, in our basswood honey-harvest, I found I could introduce a queen by letting her run in at the entrance, and smoking the bees 2 or 3 minutes after I had let her run in; and as I did not lose a single queen out of 30, I set it down as a rule that queens could be thus introduced safely every time.

Now, thought I, here is our common-sense rule that will apply to bees like the rule of multiplication applies to the multiplication table; but when I came to use the same rule after the honey harvest was over, I found my rule was "no good," as 3 out of 4 queens put in in that way would be lost.

Again, I wrote to a friend at the time I was having success, how to introduce queens, in reply to such a question from him; and when he tested it in a different locality, he lost every one so tried. The result was, he wished Doolittle were "brimstoned," or something else, as Mr. Mason wishes of "all the writers, editors, novices, etc."

Now, why was it that my friend did not succeed as I did. Simply because all things were not in the same condition in his locality that they were in mine. Again, when there came a change in the condition of my apiary, I so failed, and I doubt if those excursions ever came to my apiary

again. Thus we see that no rule regarding bee-culture can be formed which will do to follow throughout the country, as can the rules in arithmetic; and the only thing we can do is to try the plans of others cautiously till we know it is suited to our wants, using charity all the time. There is a great difference in individuals: some experiment carefully, proving everything critically step by step as they go, arriving at almost a definite conclusion with the first experiment; while others experiment in such a careless slipshod manner that their experiments at the end of several years are of little value. Notwithstanding all these drawbacks, any careful reader of the BEE JOURNAL will find much of value after he has sifted the chaff from the wheat. One hundred dollars per year would not hire me to dispense with bee-papers, for it is to them that I owe nearly all the knowledge I possess relative to bee-keeping.

Now, having the above before us, I wish to reply in a few words to W. H. Stewart's article found on page 409. He says that I make a mistake in saying "many cannot afford to buy foundation;" and further on he says: "We might as well conclude that some persons who keep horses could not afford to buy oats or corn to feed. I cannot conceive of any reason why a bee-keeper could not afford to buy foundation unless it is because he is poor."

Well, the reason Mr. Stewart's conception is so limited, is that he judges all locations like his own. Does he suppose that the horsemen of the large, fertile plains of Texas find it expedient to pay high prices for oats with which to feed their horses, when the luxuriant grass is going to waste from the want of more horses to graze it? No; such cannot afford to buy oats, for the grass affords them all that is needed.

Again, in saying that swarms are cast in a time of good honey flows, Mr. S. only shows his ignorance of other localities; for here the greater part of our swarming is done when the bees are only living from "hand to mouth." In 1876 I had 339 swarms from 68 colonies, yet that was the poorest year for honey, during the last 12 years. That all those swarms would fill a hive with comb and brood (where such swarms were not returned) in from 10 days to 2 weeks, while colonies not having swarmed would not even work foundation, was the reason I said that I could not afford to buy foundation; for the natural comb was cheaper than foundation at 10 cents per pound.

If Mr. Stewart can afford to pay \$2 per pound for foundation in his locality, I still say as I did before, he can pass the article by, the same as if it had never been written, as it was not intended for those who are sure that foundation is profitable.

Mr. S. thinks that 10 pounds of foundation was not sufficient for me to use to know of its worth. I could inform him that I tried to use much more, but as it sagged and warped so, I tore it from the frames, as it was

not worthy of the name of comb, hence I did not use it.

As my article in a late number of the BEE JOURNAL answers the rest of Mr. S.'s objections to my article written in 1883, I will not dwell further upon it, except to notice what he quotes from Prof. Cook's Manual, where he says: "The advantage of foundation is first, to insure worker comb; and second, to furnish wax so that the bees may be free to gather honey."

Now I wish to say that the second proposition is what troubles me; for in all my use of foundation, both in the brood-chamber and in the section boxes, $\frac{3}{4}$ of the foundation used is never utilized by the bees except as a base on which to add their wax which they secrete, as in this locality our flow of honey is so copious that wax is secreted by the bees in such quantities that they have no need to use that furnished them in the foundation.

I have always been considered a heretic on this foundation question, and when I wrote Mr. A. I. Root, years ago, relative to foundation killing our honey markets if we persisted in using such as was then made in our section of the country, he refused it a place in *Gleanings*, saying that the thousands of pounds of beautiful comb honey built on foundation, now sold in our markets, proved that I was wrong, and that foundation would be a "joy forever." But now I am not alone, for in the last *American Apiculturist*, almost the largest bee-keeper in the world (P. H. Elwood), says: "The question of adulteration is important; but why not throw a bright light toward those bee-keepers who adulterate by using fish-bone foundation in sections. It is a well-established fact that bees do not always thin the base of foundation. When consumers of comb honey, who have never heard of such a thing as foundation, speak of the large amount of wax in the honey, and say the honey has the flavor of soap suds, it is time that producers awake to the evil that threatens to seriously curtail the demand and consumption of comb honey. In comparison, I regard the packing of comb honey and glucose in glass jars, when properly labelled, a subject of little importance. If the consumer does not like the flavor of the liquid surrounding the comb, as well as the comb honey, he can buy only the latter in boxes; but who shall estimate the loss when bee-keepers themselves shall adulterate what has heretofore been thought to be pure beyond the power of the adulterator." Again, a honey dealer from the State of Indiana writes me, wishing to secure all the honey that he handles, in natural comb, and says: "I fear that this foundation in sections will, and is doing honey-producers harm. It may not be noticed much yet, but if the bee-keepers continue adulterating their own comb honey, the demand surely will keep dropping off until it will be dead. Choice comb honey, if really nice, will all melt away in the mouth while being eaten; but I never

saw any built on foundation that had not a tough piece of wax in the centre. In one lot in this market there was a regular 'fish-bone,' and one would as soon think of eating paste-board as that stuff."

Dear readers, you who are so strongly in favor of foundation in sections, have you tested the honey you are thus putting upon the market, to see if it would compare with that in natural comb? If it will not, is it doing justice to our fraternity to place such on our markets? It will be remembered that by a careful test I made several years ago, I proved that the base of the foundation of a certain maker was even thinner than natural comb; but this was only a sample lot sent to me for trial. When I came to order quite a quantity, the next season, I found that it was nearly twice as thick as that I had the previous year. When I expostulated, the reply was that no man could live at the price paid for making foundation, if made as thin as the sample sent.

I sincerely hope that we shall all be careful that we do nothing to injure the market of our comb honey. I have not written anything for the sake of being an "off-ox;" but because I see reasons why we should all study carefully what we do relative to apiculture, and know that we are right in every particular, lest we be guilty of doing injury to our brother. Borodino, N. Y.

Convention at North Salem, Ind.

The joint meeting of the Hendricks and Boone county bee-keepers was held at the apiary of Gully & Davis, one mile east of North Salem, Ind. The weather promised all that could be desired, and early in the day the friends commenced coming in, all intent on making the meeting a pleasant one. The time was well taken up in social chat, and looking over the tastily arranged bee-yard, the greatest attraction being the rows of brick hives, which Messrs. Gully & Davis are thoroughly testing.

The meeting was called to order at 11 a. m., Mr. A. Furnas being made President, with F. L. Dougherty Secretary. Messrs. Davis and Catterson, of Hendricks, with Messrs. Frey and Nolton of Boone, were appointed as a committee to select the place of the next meeting.

Mr. C. F. Muth, of Cincinnati, was asked to address the meeting, which he did at some length. He was both surprised and pleased to see so large a gathering of bee-keepers. There is much to be learned at meetings of this kind, and he knew that every one there would be benefitted by what they would hear and see, for some one would have a new idea to advance or a new mode of accomplishing some desired object. He said the question of marketing our honey crop was one of particular importance, and something to which each one of us should give particular attention. Honey should be placed on the market only in the nicest possible shape. The

consumption of honey was increasing at a rapid rate, and it behooved each and every one of us to still increase the sales. Extracted honey is being more extensively prepared each season. Full markets bring low prices, and so our aim should be at all times to increase the demand.

In answer to a question by Mr. Furnas as to the relative cost of the production of comb and extracted honey, Mr. Muth said, counting from the field to the market, he thought the cost of comb honey was double that of extracted honey, while the price was only about one quarter more.

Mr. Dougherty knew by experience and by the reports from those who had made the effort, that each and every one could increase home markets ten-fold. The adulteration of our syrups is now so great that the people have become entirely disgusted in the effort to find a good article, such as they like, and now is our time to introduce to them about the only pure sweet obtainable—extracted honey.

Mr. Furnas, though not a honey-producer, said that they had about the same thing to contend with, in the production of sorghum molasses. The people are becoming educated up to this fact, and rely to a very great extent on the reputation of the producer. He agreed with Mr. Muth that each producer should label the packages and strive to make his goods reliable, so that his brand would be a guarantee of a pure and wholesome article.

Dr. Orear moved to a new location last fall, where extracted honey was hardly known, and but very little used, but his efforts to create a market had been very successful; in fact, far beyond his most sanguine hopes or expectations.

After some discussion, the meeting then adjourned to do justice to the bounteous supply of eatables furnished by the ladies.

The hour of adjournment was too soon over, but the imperative call of the President soon brought the meeting to order. The committee to whom was assigned the selection of a place, recommended that the next meeting be held at the apiary of Mr. A. Cox, $1\frac{1}{4}$ miles east of Fayette, in Boone county, on Aug. 21, which was adopted.

Mr. Wheitell was decidedly in favor of these meetings; had been a bee-keeper for many years, but could gain more good, solid knowledge in one meeting of this kind than in one year's hard work in the apiary.

Mrs. C. Robbins, President of the State Society, was called on and made a few pleasant remarks. Was highly gratified to see the number of ladies present; thought it argued well for the bee-keeping interest among the ladies. She believed this a grand opening for women, who from necessity or desire wanted a business of their own, and hoped some day to see as many lady bee-keepers as men. She called attention to the advantages of making a good display at our coming State Fair, and urged the impor-

ance of each and every one taking a part, though small. What we need, said she, is a united effort.

Natural and unnatural conditions of bees in winter quarters, shading bees during the hot months, controlling the swarming impulse, rearing of good queens, etc., were some of the subjects further discussed, until interrupted by a sudden shower, which caused an adjournment for the day.—*Indiana Farmer.*

For the American Bee Journal.

The Real Cause of Bee-Diarrhœa.

A. A. FRADENBURG.

In my article on page 374, I said that I would give the proofs first and the theory afterwards, of the cause of bee-diarrhœa. I wish now to advance some theories.

On page 409, I notice that J. E. Pond, Jr. disputes my proofs. Being a lawyer it would naturally be supposed that he would know what proofs are, but it seems that he does not; for when I produced 45 witnesses that testified that where there was pollen there was diarrhœa, and 14 that declared that where there was no pollen there was no diarrhœa, I think that the large body of jurymen who read that testimony will agree that the proof was sufficient.

In the fore part of his article Mr. P. says: "But what does his proofs prove after all? Certainly not that pollen is the cause of bee-diarrhœa, but simply that in the case he mentions, no diarrhœa was found when sugar syrup was used for winter stores." Now, if Mr. P. will re-read my article, he will not find "sugar syrup" mentioned or referred to, either directly or indirectly. He will also see that I have proved that *very light* colonies of bees can be wintered just as well as large ones, and on the summer stands too.

Much stress has been laid on the necessity of having "sealed stores" for winter supplies; but I think that I have proved that sealed stores are not so very essential after all, and that pure, candied extracted honey is as cheap, safe and convenient food for bees, as can be had where they are in need of feed between early fall and spring.

I hold that all the foregoing proofs are of great importance to the bee-keeping fraternity, whether they have anything to do with bee-diarrhœa or not, but certainly some of them do.

Mr. P.'s 9 witnesses prove nothing at all, for it is a well-known fact that we may have pollen without diarrhœa; but I will challenge Mr. P., or any bee-keeper, to produce a case of diarrhœa, such as is known as the prevalent diarrhœa, without the presence of pollen or its substitute. I do not say that bees cannot be killed by unwholesome winter stores, such as sour honey, cider vinegar or sulphuric acid, etc., but I believe that good stores, with reasonably good protection and no pollen, will bring them through all right nearly every time, on the summer stands. I am glad that Mr. P.

has criticised my article, for I think such friendly criticisms help to bring out the fine, and often very valuable points that would otherwise pass unnoticed.

Mr. P. closes by saying: "He (the bee-keeper) who first discovers the cause of bee-diarrhœa will receive the heartfelt thanks of his grateful brethren." Now I claim to be that one; for I gave to the world the first proofs, *i. e.*, that pollen is the cause; and Mr. James Heddon is the second to claim those thanks; but I think I am just head-and-neck ahead of him, yet I heartily congratulate him, and I think his article, on page 405, fully confirms my proofs.

My theory is, that bees often have large quantities of pollen in their combs, and yet come through the winter well, and with but little if any signs of diarrhœa; but the reason is, that in such cases they do not eat of the pollen. I have seen whole combs of pollen, in winter and early spring, that had been uncapped and the honey taken out, but the pollen untouched; then at other times they seem to eat of the pollen as fast as they come to it, and then they have diarrhœa in proportion. To find out under just what circumstances or conditions pollen can be left in the hives during winter, and not have the bees eat of it, is the next important question, and that far I have not yet advanced; but the "pollen theory," I believe, sooner or later, every bee-keeper will yet have to admit.

Port Washington, O.

Prairie Farmer.

Honey-Dew and White Clover Honey

MRS. L. HARRISON.

"The best laid plans of mice and men gang aft aglæ." At the commencement of the white clover bloom I put some nice white comb in frames, into the super of a hive, in order to secure some extra fine extracted honey. When the combs were filled and nearly all sealed, I extracted them and found the product to be very thick, dark honey of a peculiar flavor. I inferred it was from the black locust, but reports from different sources by persons who have investigated the matter, indicate it to be the product of honey-dew, gathered from the unusually luxuriant growth of maples, and some other trees. There is an aphid found on the leaves of these trees. This dark honey will be mixed more or less with white clover, and damaged to some extent.

The bees are holding high carnival to-day, and it is mete they should, for the linden bloom is at its height. They have not a minute to lose, and dart in and out of their hives with astonishing rapidity. As I write by the open window the perfume from thousands of linden flowers is wafted in. The delicious nectar secreted in the corollas of the linden bloom is a very different article than the product of plant lice, and yet many persons think bees make honey, and that it is

all alike, and should sell for the same price.

Bees are very rich in wax, and good natured too, while forage is so abundant. I came along on the sidewalk to-day, and a run-away swarm had clustered on a small willow tree close to the fence; a lady was anxious to secure them, and I shook them off into a box for her. The bees rattled down all over me like shelled corn, but did not try to sting, and the limb where they clustered was covered with wax.

There are a number of run-away swarms heard from in this locality, and they will continue plenty as long as people are so slow to learn that bees should be hived as soon as clustered. A neighboring Irishman had a very large first swarm lately, and he said he "would have them until evening, and when it was cool he would hive them." His bees did not wait until evening, but emigrated to a home of their own finding.

Bees will often desert a hive the next day after swarming, if it is very hot and the sun shines directly upon it. We had a swarm lately that was hived and placed in the shade in the afternoon; the next morning the sun shone upon it and the bees came out and clustered, although they had built considerable comb.

In watching a swarm issue, we noticed a ball of bees as large as an apple on the alighting board of an adjoining colony. We poked off the bees and secured the queen, and placed her in a cage in a new hive, setting it where the one from which the swarm issued formerly stood, and in a few minutes the bees returned and entered the hive. It would have been a safer way to throw the ball of bees into water, as they sometimes sting a queen when they are being pulled off. When thrown into water, the ball quickly falls to pieces, and the queen can be picked out without being injured.

The best place to store honey is in a dry, hot, well-ventilated room. If kept in a cellar it gets watery and oozes from the cells. Do not allow colonies to swarm 3 or 4 times, as there would be little or no income excepting from the first. If the queen cells are cut out and the second swarm returned, then there will be 2 large colonies, and surplus may be expected. If bees are the object sought in lieu of money, then build up these after-swarms by giving them frames of chipping brood, and honey from strong colonies. If left to themselves, they generally perish during the following winter.

It is well to save the queen-cells in the very best colonies. When the cells are ripe, or, in other words, the young are ready to emerge, the colony can be divided. Bees gnaw off the ends of the cells, not clear through, but partially, about the time the queen is expected, and a frame containing such a cell and covered with bees may be removed to a hive where she will soon hatch, and the bees remain with her. Queens reared under the swarming impulse are claimed to be the best. These young queens are

a bonanza, when fecundated and laying, for introducing into a queenless colony, or where an impotent queen is discovered.

Peoria, Ill., July 1, 1884.

Ontario Bee-Keepers' Association.

A meeting of the Ontario Bee-Keepers' Association was held at Toronto, July 3. The following were in attendance: S. Corneil, President; J. Hall, Dr. Thom, Jacob Spence, D. A. Jones, B. Chalmers, C. Mitchell, Messrs. Patterson, Walker, Losee, Baxter, Pellet, Webster, and others.

The President explained that the objects of the meeting were: First, to obtain necessary legislation to protect the bee-industry against the dangers of foul brood. A letter addressed to Dr. Thom was read by the President, showing the dangers to the interests of the Association generally, growing out of the attempt of incompetent persons to conduct apiaries.

Reference was made to the interview between members of the Ontario Government and a deputation from the Association in reference to the desired legislation, in which the Government requested that the Association supply statistics showing the extent of the bee-keeping industry, and the grounds of its claims to Government aid. During the discussion a number of opinions were advanced in favor of the union of the Association with the Ontario Fruit Growers' Association, but no formal action was taken in this connection.

Considerable time was occupied in the discussion of the best methods of collecting the required statistics. Finally, Messrs. S. Corneil, D. A. Jones and Dr. Thom were appointed to wait upon Hon. A. M. Ross to request that the Bureau of Agriculture and Statistics take charge of the matter, and procure the information in connection with one of the season's crop reports.

The Association, at the request of the management of the Industrial Fair, made the following nominations for judges for the honey and apiary departments at the approaching Toronto Exhibition: Dr. Thom, S. T. Pettit, D. Chalmers, C. K. Tench and P. C. Dempsey.

Mr. D. A. Jones was heard by the Association with reference to the proposed Foul Brood Act. He thought experts should be appointed, whose duty it would be, when so requested, to examine supposed diseased honey. He thought it would be a good idea to have diagrams and full descriptions of the various stages of the disease prepared. He believed the only danger of spreading foul brood was in the bees carrying it from hive to hive.

Dr. Thom called attention to the necessity for the proper inspection of imported bees, and Mr. Jones claimed this matter as urgently requiring attention as the inspection of imported cattle. Mr. Jones, in reply to a question, also expressed the opinion that the present season would prove a favorable one for bee-keepers.

Direct Introduction of Queens.

S. SIMMINS.

Having in common with many others, experienced much annoyance, anxiety, and loss of time, by introducing queens with the cage, I have adopted a system of immediate introduction, which proves to be not only more expeditious and economical, but invariably certain in its results.

Having often united bees without disagreement, by alternating the combs of the respective hives, I came to the conclusion that a queen on a comb parading unconcernedly among her own bees, would be taken no more notice of than the others; and this I have, by unvarying success, proved to be the case, and the amount of vexation, time, and labor, saved to myself, has already been considerable.

INTRODUCING QUEENS FROM NUCLEI.

Where one has spare queens in nuclei, and all the frames are of one size, a queen can be introduced to the desired colony simply by inserting the frame of comb on which she is, surrounded by her own bees.

Carry the comb from one hive to another in an ordinary comb box; remove the queen that is to be superseded (if one), and as soon as the stranger, with her attendants on their comb, is placed in the hive, the union is certain, and there is no need to examine them again until their turn comes in the ordinary course of manipulations.

It will be observed that, instead of the bees being first permitted to find out their loss, the exchange is completed before they are aware of the fact; and the colony is not without a laying queen even for five minutes—a great consideration, especially when building up at the commencement of the season.

A queen received from a distance in a nucleus hive with frames of the right size, can be united, together with her bees, in the same way; but it is advisable that the nucleus be first placed near the full colony, and the bees allowed to fly. By evening they will have recovered from the excitement of the journey, when the union may take place.

QUEENS RECEIVED IN BOXES OR ON ODD FRAMES.

In the former case a queen should be shaken with her attendants into a comb-box on to a comb containing unsealed honey (if a comb containing unsealed honey is not at hand, a little syrup can be substituted by pouring it into the cells on either side of a comb before it is given to the strangers, previous to their introduction); close up securely, and leave them for a few minutes, while the colony to be operated upon is being deprived of its queen, when the combs should be parted at about the centre of the hive or cluster of bees. The sides of the combs nearest this vacant space, and the adhering bees may then be sprayed with sweetened water (not scented), when the occupants of the comb box

on their comb may be immediately inserted, as in the first instance, and all will be well.

A queen can also be inserted alone, on a comb of unsealed honey (or syrup). In this case she should be without food for a short time previous to being placed on the comb, when she will at once proceed to feed at the open cells, and while doing so, can be inserted (together with the comb) as before. Wherever a queen may be placed, whether being alone or with a few attendants, she should be kept warm; the slightest chill being injurious to her constitution.

Where on odd frames, a queen can be brushed off the comb with a good number of bees into the comb box, with a feather, and then united in the same way.

INTRODUCING TO HIVES WITH FIXED COMBS.

Drive the bees until the queen is seen to ascend, when she must be captured. Now discontinue the driving, and spray the combs, and the bees left among the combs with thin syrup; turn the hive the right way up on to a news sheet, raising one side about 2 inches from the sheet with a stone or piece of wood. The bees that were induced to leave the hive may now be returned, by shaking them out on the sheet close to the hive, and while they are rushing in, place the stranger queen and her attendants among them, and all will go in and unite peaceably.

CONDITIONS NECESSARY.

Brushing the queen from a comb with a feather, is much to be preferred to handling her, and if the operation is quickly performed with a light touch, she is not rendered restless and nervous, as is the case when liberated from the hand.

When introducing a queen on the comb from her own hive, no syrup whatever is necessary, and none should be used; but where she is first placed on to another comb, the conditions are different. She has been disturbed by being turned from one box or hive into another, and in some cases a long journey has preceded the change; therefore it is best to use a little, as advised, just to give the bees something to do for a time, in case any such queen should show a momentary nervousness, which, however, will soon pass off, and no hostility is shown towards her.

On no account, in any instance, should a queen be daubed with syrup, or disturbed more than is absolutely necessary, as so much depends upon her appearing among her new subjects in an unconcerned manner. This is just the secret of the success of this system. The queen is placed where she feels at home—on a comb, surrounded by a number of her own bees. On the other hand, bees are delighted to receive a comb of honey, especially if it also contains brood, as is mostly the case where the queen is transferred on her original comb.

It is a mistake to suppose that bees cannot be united unless they have the same scent. Wherever there is a case

of fighting in uniting bees, it has been brought about by the new-comers not making themselves at home in their fresh quarters, and this attitude of uncertainty and strangeness is sure to bring down upon them the vengeance of the original inmates of the hive. This state of things is brought about through the operator being ignorant of the peculiarities of bees, and, therefore, not proceeding with his work upon the right principles of management. In his hands the result would have been the same had both lots of bees been sprayed with scented syrup.

By following the rules I have here laid down, the merest novice may always succeed in uniting alien bees or queens to any desired colony, and no scent need be used in any case.

Where the bee-keeper has no spare combs, one should be taken from the colony that is to receive the queen, but every bee must be removed before it is given to the queen and her attendants in the comb box.

The author very rarely uses syrup in any case, and never where the queen is inserted on her original comb, but where it is advised, the novice cannot do better than follow the instructions given, when he can be assured of a satisfactory result.

IMPORTED QUEENS.

I would never advise that a good laying queen be deposed to make room for one just received from a long distance. The latter will not produce an egg for the first day or two, and very few, for a time, when she does begin, and will often be two or three weeks before she recovers her natural fecundity. Some never lay at all, while others, for a time, produce as many drones as workers, and soon die, or are superseded by the bees, if the bee-keeper does not trouble to do it himself. Long confinement and exposure are the causes of this tardy development and failure of production; although, of course, there is the probability that by an oversight a queen may not have been mated before being sent out. In that case she would either not lay at all or produce drones only.

Bearing these facts in mind, the careful bee keeper will give imported queens to nuclei, and either gradually work them up to a full colony, by occasionally giving frames of brood, or, after a few weeks, unite them to the desired colonies. Thus, the condemned and often prolific queens are not displaced until the new comers have had a chance of proving their fertility.

Many a new hand buys an imported queen expecting great things from her, but very often, even if given to a good colony, she disappoints him. The cause of so many failures and bad reports is to be accounted for by the fact that out of the large number of queens imported, only a very small percentage are really first-rate after being confined and exposed to the wear and tear of the journey, besides, in some instances, not being accompanied with sufficient bees to provide against the variations of temperature,

and thus being subjected to a possible chill.

Out of several dozens of imported queens introduced into my own apiary during the past few years, I have found few to equal, and not one to excel those that being raised at home are enabled to commence their duties (after being mated) without the least check whatever.

The time will come when every bee-keeper, having in view the improvement of his stock, will not buy his imported or other queens forwarded as they now are with only a small number of bees, especially as is the case where they are sent through the post. Though I admit that at times, and during the warmest months, a queen may come through without being materially injured, the practice of sending only a few attendants, is one that must be strongly condemned by all intelligent bee-keepers.

Once exposed to a low temperature, the fertilizing fluid received at the time of copulation becomes abortive, and the queen, henceforth, is a drone-breeder. In cases of slight exposure only, a large admixture of drones is often produced, and the queen, appears to lose her own vitality as well, and soon dies if not superseded by the bees or their master.

The novice may be assured that where an imported queen has been introduced to a good colony, and does not excel those of the old kind, it does not prove the inferiority of the Ligurians in general, but rather that the constitution of the said queen has been impaired by some accident, such as previously stated, or he may, himself, have allowed her to become chilled, though only slightly, while inserting her.

Where a good queen is given to a weak lot of bees, in the expectation that she will build them up to a rousing colony, grievous disappointment will be the result. But on the other hand, had the small colony received the addition of a comb of brood and bees occasionally, the owner would have had his hopes realized.

UNITING BEES.

As I have never used scented syrup when uniting bees, I will only say that my success has proved that the various articles advised for the purpose are simply useless. In every case where a union has been effected, when adding peppermint, etc., to the syrup, without hesitation I assert that the same result would have been attained without the scent, and, in the hands of an expert, without syrup in any form. If the bees are pre-disposed to fight, through the operator not understanding their peculiarities, or the exact condition of those in hand, it matters not, even should he smother them in syrup, scented or otherwise, fighting will result.

The following directions will show how bees can be induced to amalgamate under all conditions, and without being sprinkled with syrup of any kind:

If the colonies to be united are not already adjoining, bring them a few feet daily nearer to each other, keep-

ing the entrances towards the original directions. In the mean time take away all combs that the bees cannot cover, and when the hives are brought together, remove the queen that is not wanted, and then insert the combs with the adhering bees of one hive alternately with those of the other. What few are left about the sides of the denuded hive, can be brushed out, or shaken on top of the frames, when the hive may be closed up, and the union is effectual; the remaining queen also being undisturbed and allowed to reign supreme.

Where both colonies are in odd-sized frames, bring them together as before, remove one queen, and then shake off from their combs the whole of the bees of both lots on to a wide board slanting up to the entrance of the hive they are to remain in. Give plenty of room at the entrance, and all will unite in one happy family. Should there be any brood left in the rejected frames, it should be given to other hives containing the same size, or it may be cut out and fitted to those of the size given to the united bees, and placed about the centre, where it will soon be fixed up.

It will be of no use to toss the strangers on top of the frames, thinking they will draw down among the occupants of the hive. In that case instant fighting would be the result, and this will continue until the intruders are exterminated.

The only effectual plan is to shake or brush off from their combs, the whole of the bees on to a board as before, and then, after removing all but the selected queen, mix the newcomers up indiscriminately with the rushing "fanning" crowd, and all will draw in peaceably together.

The same method applies in the same case to straw hives, except that the bees will first have to be driven out of the fixed combs, and then returned together with the strangers.

Where both lots to be united have no combs, being either swarms, or driven bees, nothing is easier than to mix up both lots on a sheet, or board slanting to the front of the hive, when they will all draw under cover together.

In every instance there is one thing that must not be neglected, and that is, only one queen must be retained, whether selected or otherwise.

FERTILE WORKERS.

The presence of fertile workers is readily perceived. The eggs are dropped about in the most indiscriminate manner; often three or four in one cell, while others have none. Only one, however, of these are allowed to hatch in each cell—producing nothing but a drone, and when capped over, if on worker comb, it is considerably higher than the surrounding cells, whereas had the brood been worker larvæ, the capping would have been but slightly raised.

What is very remarkable, when these eggs are laid in drone comb, the insect produced is as large, and perfectly formed as those from a queen properly mated.

These laying workers are a pest to bee-keepers, and have often been

quite a trouble to get rid of, as they cannot be distinguished from the other workers, and seldom could a queen be introduced to a hive containing them.

The means generally adopted for their extermination, though not always effectual, besides entailing much labor, is to remove the hive to some distance from the old site, when by staking from the combs the whole of the bees, the main body fly back to the original location, while the laying workers, supposed not to have flown, are thought to be unable to return.

My method of direct introduction always answers most effectually in disposing of the nuisance. No matter how bad the case may be, even if they have queen-cells (so called, but containing only drone larvæ), the fertile workers subside immediately on the insertion of a queen on her own comb of brood with adhering bees.

Brighton, England.

For the American Bee Journal.

The Use of Carbolic Acid.

MAHALA B. CHADDOCK.

I have tried carbolic acid and it does not quiet my bees. I have a colony of bees which is very hard to manage, and I read what the Englishman said about carbolic acid, so I thought here is a good chance to try it. I put about a table-spoonful of it on a rag, and raising one corner of the muslin, laid it under, shut the cloth down and left them about two minutes. I used the acid full strength; but I diluted some of it, washed my hands and arms up to the elbows, and then carefully raised the muslin a little at a time, pushed the rag along, and the bees kept coming out all the time and stung me terribly. I had on a bee-veil, so that I did not care for stings, but they stung my arms so that they swelled up badly before I was done working with them—just 10 minutes. As soon as I saw that the acid was "no good," I used the smoker; but they had their "backs up" and kept on stinging. My fingers were swollen so that I could hardly hold the frames, and they were so numb that the last dozen or so of stings did not hurt much. I had always managed my bees with smoke, but I had to keep one hand working the smoker all the time, and I thought if I used the acid, I could have both hands to work with. The Englishman said that the acid would keep out ants, but I have tried it and it did not do it. I put it on the bottom-boards of the hives, where the ants are troublesome, and they walk around the spot and go right into the hives.

Vermont, Ill., July 6, 1884.

The Northwestern Illinois and Southwestern Wisconsin Bee-keepers' Association will hold its next meeting on the third Tuesday in August, at Leroy Highbarger's, near Adaline, Ogle County, Ill.

J. STEWART, Sec.

Rock City, Illinois.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Bees not Storing in Sections.

My bees will not work in the sections. I have glass on one side and tin on the other; the bees come up between the tin and the bottom, and cluster thick in the boxes, but will not work. Will you please tell me what is the trouble? I use the Langstroth hive. I have a division-board that separates the honey-boxes from the brood. The division-board comes down within $\frac{1}{2}$ of an inch of the bottom of the hive where the bees run under and up in the boxes, on each end of the hive.

Clifton, Ill. GEO. W. COMPTON.

ANSWER.—Although you do not plainly say so, I guess that you are working on the side-storing plan. I think this is not nearly as good as the top-storing system. I also object to glass in connection with cases of sections. The practical apiarist does not care for it. Even the farmers about here would laugh at you if you insinuated that they needed any glass to look through to know the condition of their surplus cases. I think you do not give your bees sufficient communication with the sections. The bottoms and ends are not enough, though I must confess I cannot see why they refuse all work, after they once enter that unnatural out-of-the-way place.

Preventing After-Swarms.

On page 412, I asked the question about taking queen-cells from the comb to prevent swarming. I was referred to page 126 of 1883. I did not take the BEE JOURNAL in 1883. I have 6 new swarms. I have taken the queen-cells out of each hive; it is but little trouble with straight combs, but if there is a better way I would be pleased to know what it is.

Plainfield, Ill. G. C. BILL.

ANSWER.—The method of clipping all of the queen-cells, or all but one, to prevent after-swarms, always has been, and always will be, an impractical one. The reasons are simple; but it would require an article to give them all as I would wish to.

I will proceed to give you a plain, simple method that I have used successfully for the prevention of after-swarms. Let us suppose that colony No. 14 swarms June 14. With a non-erasive crayon we mark upon the hive O, June 14, and on the hive in which we put the swarm, S, June 14. Thus, we distinguish the old colony from the swarm, at a glance, as we make these marks in large figures. When we have the swarm (always on full sheets of wired foundation), we place it close on the north side (our hives front the east) of the old colony, with the entrance turned northward, away from

the old colony, about 45°. As soon as the swarm is well at work, having their location well marked (say two days), we turn the hive around parallel with the old colony. Now both hives face east, setting side by side, and close together. Sometimes, however, being governed according to the size of the swarm, as compared to the number of bees left in the parent colony, we place the newly-lived swarm on the old stand, putting the old colony through the process above described. In fact, we do this most of the time. Now, you will remember, that while each colony recognizes its individual house, they are, at the same time, as regards all other colonies in the yard, practically in one location, or on one stand.

Now, the dates on the back ends of the hives plainly indicate that second swarming will take place in about 8 days. In about 6 or 7 days (according to season or weather) after this date on the hives, we remove the old colony to a new location.

As we do this at such a time in the day as most bees are in the field, this depopulates the old colony, giving the force to the new, leaving too few bees for the young misses to divide, and as they at once recognize this fact, they fight it out on the line of the "survival of the fittest." It may be proper, just here, to say a few words regarding how we manipulate the surplus departments of these two hives, as it may have something to do with the object in view. Let us suppose that, at the time of swarming, the old colony was working in three 28 one-pound section cases. Suppose the upper one to be $\frac{3}{4}$ completed, the middle one about $\frac{1}{2}$, the lower one just started. We will put two (which two only the minor circumstances in the case can decide) on the hive when first swarmed, leaving one, and, sometimes, we get another to put with it, on the old hive. Perhaps this surplus room on the old colony also has a tendency to prevent swarming.

Getting Bees to Work in Sections.

Will Mr. Heddon please answer the following questions:

1. My bees will not work in the sections. What can I do to induce them to work in the sections?

2. How long will a colony of bees live without a queen?

3. Will you please describe fertile worker-brood? SARAH W. VEECH.
Terre Haute, Ill., July 4, 1884.

ANSWERS.—1. Before I could tell what to do to get your bees to work in the sections, I should have to know the reason why they are not already so at work. The conditions necessary are these: The colony must be of normal strength, or stronger; plenty of nectar in the flowers; free communication to the surplus receptacles, and the brood-chamber not too large. Foundation in the sections is also an inducement.

2. Bees will live several months without a queen; their vitality being much greater when queenless, either because they do not work as energeti-

cally, or that brood-rearing is very wearing; quite likely both.

3. You can tell fertile worker-brood by the elongated cells, or elevated cappings; by the less quantity of brood, its irregularity in distribution, and there being more than one egg in a cell, while other cells are empty.

Separating Bees from Surplus Honey.

For the benefit of several inexperienced bee-culturists, will Mr. Heddon please answer through "What and How" in the Weekly BEE JOURNAL the following questions: What is the most approved method of separating bees from surplus honey, and removing the combs from the hive? Is smoke available? Must the bees be brushed off? What is the best plan? Does any book explain this *modus operandi*? C. H. COGSWELL.

Viriden, Ill., July 2, 1884.

ANSWER.—The old favorite method of getting the bees out of the old style of surplus receptacles was to put them in a dark room with one small opening to the light, and then the bees would desert the boxes and return to the hives. We used to practice this when we used the "honey-box" with openings at the bottoms only. The objections to the plan are, that sometimes a box will contain a queen, and then the bees will not leave, but as many from the other boxes as can get in and about the box will do so. If a little brood should happen to be in one of the surplus combs, the same result was sometimes experienced. With the cases which we now use, containing sections with open tops and bottoms, we smoke over 9-10 of the bees down, and then remove the case and shake out nearly all the remaining ones, and then put the case in a wire-screen house. We never get a queen off, and have no brood in the small sections. The few remaining bees at once desert the cases and go to the wire, when the whole of two sides of the screen house is opened, and the bees put out at once, and the doors immediately closed. In old times we used to number our boxes and hives, so that when a queen was found we would know where she belonged. I think all the books on apiculture speak of this subject.

Weak Colonies.

Which is the best time to double up weak colonies, *i. e.*, break them up and put the bees in with other colonies that are weak?

Freeport, Ill. J. GOCHENOUR.

ANSWER.—This is a practice that I very seldom use. If I did unite colonies, I should do it either for wintering (when they were very weak) or for the surplus harvest, when they were too small to build comb to advantage; were I running for extracted honey, I should not unite colonies at all. Weak colonies give me as much extracted honey in proportion to the number of workers as strong ones; often more. They often come through the winter in the best condition.

Quantity Small, Quality Good.

The clover bloom here is about over, and although there was an abundant bloom, and plenty of honey while it lasted, the amount of honey gathered from it is very small. On account of the hard winter and cold, wet spring, bees were in poor condition to work in sections when clover bloom came; and as it lasted only 4 weeks, it took the bees all this time to build up; and as swarming commenced as soon as numbers increased, very little time was given to surplus storing. Bees that were packed in chaff all winter and cared for during the spring, have gathered a good harvest of honey. However, the honey crop in this locality is not as large as it was last year, but it is of very good quality.

J. G. NORTON.

Macomb, Ill., July 5, 1884.

Increase by Division.

I commenced in the spring with 6 colonies, and now have 24—all by natural swarming. I hope to make bee-business profitable by increasing by division. I believed that method of increase impossible until I had read the book, "Bees and Honey;" and now I see that it can be done with perfect success. Here, I am the laughing stock of the whole community, as I stand almost alone in bee-culture. I am trying to get people to take bee-papers and buy books on the subject and read them. They say that all movable-frame hives are humbugs. Worrell's complete hive would be a show here. My intention is to make bee-keeping a specialty.

S. H. BURGESS.

Chesser, Ala., June 21, 1884.

Death of a Bee-Keeper by Lightning

William Howlett, of Beaver Lick, Boone County, Ky., was instantly killed by lightning May 19. He was at work on his farm, and took shelter under some trees during a shower, when the fatal bolt laid him low, where he was found late on the following night. Mr. Howlett owned, at the time of his death, about 125 colonies of bees. He was a member

of the North American Bee-Keepers' Society at the sessions of that body at Cincinnati and Lexington, Ky. He was a quiet, pleasant man, and leaves aged parents and a sister of whom he was the chief support. The present year proves to be almost equal in honey production to 1883. Swarms hived three weeks ago have already filled both stories of 20-frame Langstroth hives. In some instances newly-hived swarms have cast a swarm in 10 days. By the use of the nice honey-labels, and "Honey as Food and Medicine." I have built up a home market which will probably take all my crop of honey. My bee-yard presents a scene of beauty, activity and raiming sweets.

L. JOHNSON.

Walton, Ky., July 4, 1884.

Good.

I have already taken 5,000 lbs. of honey from 46 colonies, spring count, and perhaps there are 2,000 lbs. more in the hives now. J. S. TADLOCK.

Luling, Texas, July 3, 1884.

Blackberry Jelly made with Honey.

This has been a good year so far. No time to snooze. If you want a delicious thing, get nice, ripe blackberries, get the pulp or juice free of the seeds, then take the best comb honey and do up the juice as a jelly (women know how to do it), then eat it on bread, pancakes, or biscuit. Try it.

J. E. BREED.

Embarrass, Wis., July 4, 1884.

Carbolic Acid.

Some one asks in the BEE JOURNAL about using carbolic acid. I am using it when I remove the sections, and I find it superior to smoke in every respect. I mix half water, take a goose quill saturated with it, and put it carefully down between the sections, and the bees will go down into the body of the hive and sing a natural tune that every bee-keeper understands to mean submission. The sections can be removed without difficulty. I do not use a veil or gloves when I use carbolic acid, and the bees are not cross afterwards. A. T. ALDRICH.

Wilcox, Pa.

Shaking Bees.

I notice in one or two of the late numbers of the BEE JOURNAL, several articles referring to shaking bees. I have had them in my apiary for 2 or 3 years, but only in one colony. I believe that they are hatched in the same hive with others, but the bees are killing them all the time. These trembling bees are quite annoying to the other bees. They seem to be a peculiar bee. At one time I thought that they were the indication of the purity of the Italians; but now I am beginning to think otherwise. My colonies began swarming on May 14, and some of them cast 3 swarms. Our honey crop will not be anything extra, this year. All the honey we will have was gathered from locust bloom, and it was the largest yield I have ever seen from that source. I

would like to know whether Holy Land bees swarm and settle like the Italians. I am nearly 69 years of age, and have been a bee-keeper all my life; and I have yet to find the man who can beat me in finding bee-trees. I took a colony out of a bee-tree in the woods, recently, and it is doing well.

COL. R. WALTON.

Industry, Pa., July 7, 1884.

Bark-Louse Honey Injurious.

We have had a good yield of honey. The bark-louse honey is an injury.

A. J. COOK.

Lansing, Mich., July 10, 1884.

Good Prospects for Fall Honey.

Bees wintered quite well in this locality, but the spring was rather hard on them. June 1 found them but little better than on May 1, and many colonies had entirely perished. The bees have swarmed but very little, only about 15 or 20 swarms from 70 or 80 colonies. Bees have gathered some honey; but white clover bloom, in this section, though good, was shortened up by dry weather. Bees have just begun to work on basswood, and I cannot yet tell what the result will be. The prospects for fall honey are quite good now.

R. BACON.

Verona, N. Y., July 10, 1884.

Fastening Starters in Sections.

I have just been reading, on page 436, how to put starters in sections. There is no need of using any rosin in the beeswax. The sections should be grooved, and the edge of the foundation dipped into the melted wax until it almost melts; and then put into the groove as quickly as possible. If they are put in right they will never fall down with any kind of rough handling. With the Parker foundation fastener there is always some trouble about the foundation falling out of the sections. When it is put into the groove, it will break before it will fall out.

R. S. BECKTELL.

Three Oaks, Mich.

But Little Basswood Honey.

This has been a tolerably good season for honey, so far. I have 720 lbs. of honey, mostly from white clover and honey-dew. The honey-dew is dark and strong, and spoils the white clover honey. Linden is a failure this time, only about half the trees are blooming, and most of the bloom has fallen off from those that have bloomed.

WM. MALONE.

Oakley, Iowa., July 5, 1884.

Unusual Honey Flow.

We are having an unusual honey flow here. At present the hives and sections are all full to overflowing. The extractor is running almost constantly. There is a poor show for basswood, but a good prospect for sweet clover and goldenrod.

N. E. DODGE.

Fredonia, N. Y., July 5, 1884.

Honey Harvest—Wintering, etc.

The clover harvest was a poor one here. Whitewood or tulip yielded well for a few days. Basswood is half gone, and there is hardly any thing gathered from it. I am testing reversible frames, and will report as soon as time makes me capable of giving something of value. I have 6,000 in use. Mr. Hutchinson's article on "Hiving Swarms," graphically describes our ideas and exact experience for years past in this interesting and important branch of our pursuit. I think Mr. Clarke is all wrong regarding this new theory of wintering. Time and experience will show. Bees in trees about here have suffered with diarrhoea more than those in Langstroth hives assisted by the ingenuity of man. JAMES HEDDON.

Dowagiac, Mich., July 9, 1884.

Marketing my Honey Crop.

I have extracted about 8,000 pounds of honey from 160 colonies of bees, and will extract from 1,000 to 2,000 pounds more. I distributed a lot of the pamphlets on "Honey as Food and Medicine," last year, and it paid me well. E. DRANE.

Eminence, Ky., July 5, 1884.

"Colony" or "Nation"?

There is probably no branch of science in which the writers lay themselves more open to criticism than those who attempt to criticize the bee-nomenclatures of others. I suggest the word "nation" of bees, for what is now improperly called a "colony" of bees. It is not dependent upon, or in any way tributary to the colony from whence it originated; but is an independent nation or republic of itself. The word "nation" can be used wherever the word "colony" can, and is much more expressive.

Watson, Mo. R. V. MUR.

[Nation refers more especially to people, and is, we think, entirely out of place when speaking of bees.—ED.]

Few Swarms and but Little Honey.

With an abundant display of white clover bloom from June 10 to the present time, bees in this locality have stored very little surplus honey, and as white clover is our main source from which we expect it, the present prospect looks discouraging to bee-men. Swarming has been going on since the middle of June, in a limited way. I have not had over 15 from 125 colonies that are in good condition so far as quantity of bees and honey in the hive is concerned. Although the past winter was so exceedingly cold and of long duration, yet the loss of colonies was not great; but we have never had as serious loss of colonies after mild weather began, or "spring dwindling" as it is termed, as we have experienced during the past one. The greatest loss was from robbing. On May 1 fully $\frac{1}{3}$ of the colonies were dead that were in good condition on Dec. 1, so far as I can learn in this vicinity. Although

my hives are populous and well-filled with brood and honey, I have not a box of surplus honey ready to come off yet, and most of them contain but very little, while the other bees have done nothing in boxes. L. JAMES.

Atlanta, Ill., July 8, 1884.

Poor Honey Crop.

Bees have done poorly thus far this season. The weather has been too cold and wet. My honey yield will be about 5,000 lbs. less than it was this time last year. Last season I had from 80 to 100 colonies, and the honey yield was 20,000 lbs.; now I have from 93 to 95, and have but 4,700 lbs. of honey up to this date. The bees are in good condition. P. LOUCKS.

Selma, Cal., June 28, 1884.

Wild Bergamont.

I send to Prof. Cook a flower a man gave me, saying that it was horse-mint. What is it? Please answer through the BEE JOURNAL. J. L. WILSON.

Mortonsville, Ky.

[It is wild bergamont (*monarda fistulosa*). It is closely related to the horse-mint, as it belongs to the same genus. The horse-mint is *M. punctata*. This wild bergamont is common all through the country, from New England to Kentucky, and southward. This is the plant which I speak of in the "Manual" as being punctured by the wild bees (Carpenter bees); and when thus punctured the bees utilize the honey. The flower tubes are very long.—A. J. COOK.]

Storing Honey Rapidly.

My bees are doing well, but were late in commencing. They seem to be storing up honey from white clover at a rapid rate. I have had but few swarms, and none of them absconded, though many of my neighbor's swarms have "gone to the woods," after staying in the new hive for 3 days.

L. E. BROWN.

Eminence, Ky., July 7, 1884.

Remarkable Season.

Our honey harvest closed about two weeks ago, and I have to report about $\frac{1}{2}$ to $\frac{1}{3}$ of a crop of very excellent clover honey. The season has been a remarkable one. The first 16 days of the white clover bloom were excessively wet, and some days cool, during which, a few intervals of warm sunshine, bees gathered sufficient honey to stimulate them; then followed 9 or 10 days of as fine honey weather as I ever saw, and the bees stored a considerable quantity of very fine honey. We then had cold, drying north and northeast winds for more than a week, when honey gathering ceased, and comb-building was abandoned entirely. We had a few more days when the atmosphere was moist and warm, but clover was almost gone; and yesterday morning a dry, northwest wind cooled off all

aspirations for a continuation of any further surplus gleanings from white clover. My bees, both hybrids and Italians, have worked on red clover the whole season. E. DRANE.

Eminence, Ky., July 7, 1884.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL,
Monday, 10 a. m., July 14, 1884.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The honey harvest is now virtually over, in this part of the country, and the yield is below the average of former years. The average, per colony, in Ohio and Indiana is, perhaps, 30 to 40 lbs.; in Kentucky it may come up to 100 to 110 lbs. per colony. I can only speak from observations obtained so far, and my figures may not be entirely reliable. Sugar being cheaper than it has been, perhaps, for the last 20 years, we cannot expect honey to be high; but there was a short crop, and it would be my advice to bee-keepers not to be in too much of a hurry to dispose of their product. The demand for extracted honey is fair, and to all appearances, gradually improving. It brings 6@9c per pound on arrival. There is a small demand for comb honey, but we had small offers only, and a good deal could be sold. It brings 14c per pound on arrival.

BEESWAX—Offerings plentiful at 30@32c on arrival. C. F. MUTH, Freeman & Central Ave.

NEW YORK.

HONEY—Present sales of comb honey are slow, and will be until the new crop arrives. We quote: Fancy white 2-lb. sections, glassed, 13@14c; fair to good in 2-lb. sections, glassed, 11@13c; dark grades in 2-lb. sections, glassed, 10@12c. No 1-lbs. in this market. Extracted, white, 8@9c.; dark and buckwheat, 7@8c.

BEESWAX—Prime yellow, 34@35c.

MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15c, and 24-lbs. to 24½-lbs. from 10@12c. No 1-lbs. in the market. Extracted, 8@10c.

BEESWAX—35c. BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—This week we have had liberal receipts of comb honey, and the prices are irregular. As a rule, the honey is of first quality, and put up in good shape; a gradual improvement is noted in this respect. Prices range from 14@16c for the best; occasional buyers will pay more than that, but it is in a retail way. The extracted honey is still sluggish, at nominal prices—6@8c per pound.

BEESWAX—Fair receipts; prices, 30@37c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Receipts are on the increase. Buyers manifest no anxiety to operate. Prices are largely nominal. There is every indication that low figures will be necessary to effect a free movement this season. White to extra white comb, 15@20c; dark to good, 10@13c; extracted, choice to extra white, 5@7c; dark and candied, 4@5c.

BEESWAX—Wholesale, 27½@30c.

STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—No change to note in prices. As predicted in last report, the temporary activity was only accidental, and last week has been dull. Some little new honey is now arriving, but it falls us yet to tempt buyers to do more than that, but it is for a very large demand a little later, and would suggest shipment by Aug. 1, of all that is ready in quantities to justify. I have still a few more "Suggestions on Packing and Shipping Honey," to mail free on application. I will also furnish shipping stencils free to any one desiring to ship to me.

BEESWAX—Wholesale, at 30@32c.

JEROME TWICHELL, 514 Walnut Street

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@6½c.

BEESWAX—Firm at 32@32½c for choice.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1-lb. sections at 18c; 2-lbs. best white not quite so active at 17c; 1-lb. sections sell quickly on arrival, and often are sold to arrive. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.

BEESWAX—Scarce at 35c.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2-lb. sections, 17@18c; extracted, 7½c.

GEO. W. MEADE & CO., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5. or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

We now club the *British Bee Journal* and our Monthly for \$2.50, or it and the Weekly for \$3.50.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00).—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75. Or, bound in cloth, with Weekly, \$3.00; with the Monthly, \$2.00.

Do not let your numbers of the BEE JOURNAL for 1884 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Create a Local Honey Market.

Now is the time to create Honey Markets in every village, town and city. Wide-awake honey producers should get the Leaflets "Why eat Honey," (only 50 cents per 100) or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully all over the territory they can supply with honey, and the result will be a *demand* that will readily take all of their crops at remunerative prices. The prices for "Honey as Food and Medicine" are as follows:

Single copy 5 cts.; per doz., 40 cts.; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Young Men!—Read This.

THE VOLTAIC BELT CO., of Marshall, Mich., offer to send their celebrated ELECTRO-VOLTAIC BELT and other ELECTRIC APPLIANCES on trial for thirty days, to men (young or old) afflicted with nervous debility, loss of vitality and manhood, and all kindred troubles. Also for rheumatism, neuralgia, paralysis, and many other diseases. Complete restoration to health, vigor and manhood guaranteed. No risk is incurred, as thirty days trial is allowed. Write them at once for illustrated pamphlet free. 6D1y

THE MONTE-CRISTO SERIES.—Foremost among the best and most absorbing novels of the season are, "The Wife of Monte-Cristo," "The Son of Monte-Cristo," and "The Countess of Monte-Cristo," just published by T. B. Peterson & Brothers, Philadelphia, but already pronounced successes. These fine romances, fully worthy of Dumas' pen, appropriately conclude that celebrated novel, "The Count of Monte-Cristo." All the characters figuring in Dumas' masterpiece, the Count himself, his Wife Haydee, his Son Esperance, Mercedes, the sweetheart of Edmond Dantes, and all the rest, are introduced. These books literally overflow with exciting episodes.

Bingham Corner.

MARENGO, ILL., June 18, 1884.
The Doctor Subdues All.—Mr. T. F. BINGHAM, Dear Sir:—I've used the "Doctor" till its all daubed up with bee-gum, and although at first sight I thought I did not like anything so large, I could not now be induced except by the direst poverty, to do with anything smaller. As a matter of "economy" I much prefer the "Doctor" to any of the cheaper smokers, of which I have worn out several. The "Doctor" has entirely cured me, so that I am now a Bingham man, as my wife always has been. If the somewhat vague remark in your letter means that nothing was charged for the Smoker sent, except the reading of your letter, I shall be very glad of another "Doctor" for the money sent, so that my wife won't take mine from me. Bees just booming on white clover.
 Yours Truly, C. C. MILLER.

WOODARD'S LANDING, Wash. Ter.
The Best Smoker.—To BINGHAM & HETHERINGTON, Abronja, Mich., Dear Sirs:—Find enclosed money for 3 Conqueror Smokers, which please send per mail—one to each, Dr. Balch, J. M. Louderback, and H. A. Towner. The Conqueror is the best Smoker I ever used. Respectfully,
 May 17, 1884. H. HASTINGS.

DRESDEN, TEX., May 28, 1884.
Conquer the "Cyps."—T. F. BINGHAM, Abronja, Mich., Dear Sir:—Enclosed find \$1.75, for which please send, per mail, one "Conqueror Smoker" to Major H. A. High, Waxahachie, Tex. He bought a Cyprian Queen from me, and the Bees have worsted the old gentleman. I told him that the Conqueror Smoker would conquer the "Cyps," as I had tried one for two years, and "it never failed." Respectfully,
 B. F. CARROLL.

BORODINO, N. Y., Aug. 15, 1882.
Cyprians Conquered.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. Respectfully,
 G. M. DOOLITTLE.

Prices, by mail, post-paid.

 Rogersville, Genesee Co., Mich.,
 can furnish pure Italian Queens, reared under the swarming impulse, in his own apiary, at \$1.00 each. Make money orders payable at Flint, Mich. 29Atf

EXCELSIOR HONEY EXTRACTORS

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the can leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

| | |
|--|--------|
| For 2 American frames, 13x13 inches. | \$8.00 |
| For 2 Langstroth " 10x18 " | 8.00 |
| For 3 " " 10x18 " | 10.00 |
| For 4 " " 10x18 " | 14.00 |
| For 2 frames of any size, 13x20 " | 12.00 |
| For 3 " " 13x20 " | 12.00 |
| For 4 " " 13x20 " | 16.00 |

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.

ALFRED H. NEWMAN,
923 West Madison Street,
CHICAGO, ILLINOIS.

A PRIZE. Send six cents for postage, and receive free, a costly box of goods which will help you to more money right away than anything else in this world. All of either sex, succeed from first hour. The broad road to fortune opens before the workers, absolutely sure. At office address, TRUE & Co., Augusta, Maine. 4A1Y

CHAS. DADANT & SON,

23AB1f Hamilton, Hancock Co., Ills.

VALUABLE ORIGINAL PATENTS.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To sell again, send for dozen rates to

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects: Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quieting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, bound in cloth, \$1.00; 2 copies for \$1.80; 3 copies for \$2.55; 5 for \$4.00; 10 for \$7.50. Paper covers, 75 cents; 2 copies for \$1.40; 3 copies for \$2.00; 5 for \$3.00; 10 for \$5.00.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premium for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and cure of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bienen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY ALLEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way to rear Queens, etc. Price, \$1.00.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either English or German.

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XX.

CHICAGO, ILL., JULY 23, 1884.

No. 30.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Work Up the Local Markets.

Do not fail to try to work up the local markets for honey. This not only helps to increase consumption, but also adds to the profits of the honey producer—by obtaining a larger price at retail than by selling it at bulk to middle-men in large commercial centres. By saying this we are in no way underrating the valuable services of wholesale merchants in cities, for there is always enough comes to such places to stock that market, and by selling more at retail, it will keep from overstocking such markets, and thereby depreciating the salable value of the product.

We can do the producers no better service, therefore, than to advise them to work up the markets in their own immediate neighborhoods. To do this, get some "Leaflets," or "Honey as Food and Medicine," with the producer's name and address printed on them, and scatter them over the territory that can be supplied. Try this plan, and see how it will astonish you by its results.

We have received a very nice sample of one-pound dovetailed section for honey from Julius Tomlinson, Allegan, Mich., and placed in the Museum.

We have just issued a new edition of Doolittle's "Hive I Use," to which is now added a detailed statement of his system of management for producing comb honey in the largest quantity and best quality, and how to put it up in the most desirable manner for the market. It contains 16 pages, and the price is 5 cents.

Missouri's Honey and Bee Show.

We have received the Premium List of the Inter-State Exposition at St. Joseph, Mo., to be held Sept. 1-6, 1884. We notice that Mr. E. T. Abbott is the Superintendent of the Bee and Honey department. With the following liberal list of premiums, there ought to be a very large bee and honey show:

| | 1st Pr. | 2d Pr. |
|--|---------|--------|
| Best colony of Italian bees..... | \$10 | \$5 |
| Best colony of Carniolan bees..... | 10 | 5 |
| Best colony of Syrian bees..... | 10 | 5 |
| Best colony of native bees..... | 5 | 3 |
| Best display of imported bees..... | 10 | 5 |
| Best display of queens reared by exhibitor, and with progeny..... | 10 | 5 |
| Best display of the habits and economy of a colony of bees..... | 10 | 5 |
| Best display of honey in comb, not less than 75 lbs..... | 10 | 5 |
| Best display of extracted honey not less than 50 lbs..... | 10 | 5 |
| Best display of honey in various and fancy forms..... | 10 | 5 |
| Best display of beeswax..... | 2 | 1 |
| Best display of honey-producing plants, including stalks, flowers and seeds, all labelled with name..... | 5 | 3 |
| Finest bouquet of honey plants..... | 2 | 1 |
| Best comb-foundation machine, to be operated on the ground..... | 10 | 5 |
| Best honey extractor..... | 3 | 2 |
| Best wax extractor..... | 2 | 1 |
| Best bee smoker..... | Diploma | |
| Best section box for comb honey..... | Diploma | |
| Best comb foundation..... | Diploma | |
| Best bee veil..... | Diploma | |
| Best honey knife..... | Diploma | |
| Best keg for extracted honey..... | Diploma | |
| Best bee feeder..... | Diploma | |
| Best queen cage..... | Diploma | |
| Best drone trap..... | Diploma | |
| Best display of apicultural literature..... | 5 | 3 |
| Best hive for manipulation, procuring comb and extracted honey and winter protection..... | 10 | 5 |

Mr. William P. J. Gerow, of Patterson, N. Y., died on April 21, 1884, aged 23 years. He was a successful and progressive bee-keeper, and will be missed in that locality.

German Bee-Keepers will be pleased to know that we have just issued a new and enlarged edition of our pamphlet "on Bee-Culture, in German." It is revised and brought down to the present time, in all the developments of our rapidly-advancing pursuit. The Price being only 40 cents, it is within the reach of every German bee-keeper, and should be in the hands of all.

Letters for publication must be written on a separate piece of paper from items of business.

The Clover Harvest, etc.

The Indiana *Farmer* of last week contains the following concerning the clover honey harvest, and the care of bees and honey at this season of the year, as well as how to protect honey from the ravaged of the moth:

The white honey harvest for this season is over. Though the flow was good while it lasted, the crop secured will be small, compared with that of last year. Bees suffered badly during the month of May, leaving them in poor condition at the commencement of the harvest. Brood combs, but poorly filled with brood, gave too much space below, in which to store honey, producing ill results especially where comb honey was the object, leaving many sections in the hives only partially filled. Should the fall flow of honey prove good, many of these may be finished, but not in the most desirable shape.

In most localities there is a dearth of honey-producing flora, from now until about the middle of August, when the fall bloom may bring a good yield. As the white clover yield ceases, bees are easily excited to robbery, and care should be taken to protect weak colonies or nuclei by reducing the size of the entrance, making it adequate to the force defending it. All work done in apiary should be carefully done, and all judicious care taken to prevent robbing. Prevention may be easily accomplished, but should they once get a start, it is sometimes very difficult to stop them.

Comb honey that has been removed from the hives, should be examined every few days. If the comb shows signs of worms, the honey must be fumigated with sulphur. Care must be taken not to give them too much, or it will discolor the comb, giving it a greenish cast. The amount used will depend, of course, on the size of the room or the box used. It requires but very little of the fumes of sulphur to destroy life, either animal or vegetable. Sulphur will not destroy the eggs, so it may be necessary to give them a second dose after all the eggs have had time to hatch. By watching closely, you will be able to discover the worms before they have done any material damage. They are very small at first, but you will detect their presence by seeing a small, thread-like streak of a mealy looking substance, on the capping or round the edge of the combs.

Natural Swarming

Translated from the French *Ami du Clerge* for the *Haldimand Advocate*.

In the majority of cases, the swarm will alight on the branch of a tree, on a hedge, or fence, where it will cluster, assuming the shape of a cluster of grapes. If no trees are in the vicinity of the hive, plant therein two or three branches. The hive that is to receive the swarm should be very clean. If it is an old one, it is wise to burn under it some straw to destroy the little insects that have nestled in it. The interior of the hive might also be rubbed with some odoriferous plant or flowers, such as the thyme, the rose, or with a cloth moistened with salt water. But, should the hive be clean, these precautions are not necessary. As soon as the bees have clustered, busy yourself to secure them, for fear they may escape.

SECURING THE SWARM.—There are situations in which that operation is very easily performed, others when it meets certain difficulties; let us speak of the principal ones. As soon as the swarm has alighted, put on your veil and make yourself ready to secure it. If it is fixed to a low and flexible branch, with one hand hold the opening of the hive under the swarm, with the other shake smartly the branch to cause the bees to fall into the hive. Immediately after, upset gently the hive and place it on the platform to facilitate the means of ingress. Disturbed by this operation, some of the bees will fly out again and return to the branch. They seem as if they would all escape. In that case smoke the bees remaining on the branch, and also those on the alighting-board which tarry to return. You may also replace the smoking by putting, where the bees are, some herbs of a strong odor disagreeable to the bees. In a quarter of an hour, all the bees have returned to the hive, and then you put it in its place without any anxiety concerning the few bees that may fly around the hive. They will work that very day. If you were to wait until the evening, they would for a few days flutter around the place where the hive was first placed.

If the swarm fixes itself to the trunk of a tree, with one hand hold the hive near them, and with the other, with the help of a brush or a feather-broom, softly and swiftly sweep all the bees into the hive. The capital point in all these operations is to secure the queen.

If the hive is difficult to handle, place it on the platform, but raised at the front a few inches with sticks or blocks: then with a shallow box or net secure the bees with the brush or soft broom and upset them gently at the opening of the hive into which they will immediately enter. If your hive is the Langstroth, take off the cover and put the bees into it, place in some section frames and some brood from other hives, and if possible, put the cover on and the operation is completed. Of course there are circumstances which may cause you to alter

the way of securing the bees. A skillful bee-keeper will easily overcome such difficulties.

To estimate properly the value of a swarm, first weigh the empty hive and note it on a conspicuous part of the hive or on a register in which are inscribed numbers corresponding to those of your hives. In the evening or the next morning, weigh the hive with the bees; if its weight is four pounds over the weight of the empty hive, your swarm is sufficiently strong, especially if it is one of the early ones. Toward the end of swarming time and in countries where flowers are scarce, the weight of the swarm should be from five to six pounds. Under that weight, the swarm should be increased by division. As the bees leave the hive, to swarm, they fill themselves with honey sufficient for at least three days sustenance; they are therefore heavier than at ordinary times. Two pounds of bees filled with honey contain about 9,500; at other times in the same weight of bees, there should be nearly 11,000.

Is it possible to know wherefrom came the swarm, in case of dispute between two bee-keepers, each claiming it as his own?

Yes, this is the means to find it out. Take from a swarm where it has alighted, some fifty bees into a glass in which you shall have put two or three pinches of flour. Go thence a distance of three hundred yards and let the bees go. As a certain number will then return to their old hive, watch and it will be easy to recognize them by their bodies sprinkled with flour. This will clearly prove who is the owner of the swarm.

To what cause must be attributed the returning of the swarms or their dispersing in all directions?

Sometimes rain or a great wind will force the swarm to return, or oftener, the fall of the queen to the ground, where she loses her way, or wanders away from the swarm. Then the swarm returns, but not before it has searched everywhere with great anxiety for the queen.

One looking at such a swarm can easily guess that something is missing. In such a case, search carefully in front of the hive, and you will find the queen crawling among the grass where she fell, or struggling to free herself from some snare in which she may be held a prisoner.

What is to be done in case two or more colonies swarm at the same time and cluster together?

Be very careful not to separate them, since all profit of the bee-keepers consist in strong colonies. However, as in everything, excess is bad; should four or five swarms unite, you may divide them into two or three colonies and pick out the queens separately to give one of them to each colony.

A Canadian wishes us to state in the *BEE JOURNAL*, whether we take Canadian money for subscription or books. We do; and for fractions of a dollar, Canadian postage stamps may be sent.

Adulteration a Curse.

The following taken from the *North-western Grocer*, shows more forcibly the general feeling among traders concerning adulterations than anything which has been written for some time upon the subject:

Few men are so destitute of conscientiousness as not to feel, in their inmost soul, a sense of shame and wrong-doing when they adulterate goods of any kind; but especially when they offer to their fellows as food and drink what they have corrupted, defiled, debased, contaminated, vitiated. They may say, when pushed to the wall, "the food and drink we offer is pleasant to the eye, grateful to the taste, wholesome and nourishing to the stomach, and we do the recipient no injury." But at the same time he is conscious that when he adulterated his goods he did it, not for his neighbor's good, but for gain—to add to his own profits. He diluted and debased what he sold to gratify himself and not his neighbor, and in so doing he violated the golden rule: "Whatsoever ye would that men should do to you, do ye even so to them." Every common-sense man and woman in the land despises the person who deceives and defrauds them. This is so obviously the case that we pause neither to prove, argue or illustrate the assertion. If we have a reader who questions the proposition, he has lost one of the choicest jewels of human nature, and that is self-respect. When men or women lose their self-respect, reformation and improvement are works not easily accomplished. So long as we respect our humanity there is hope for us; but when we tamely submit to allow men to palm off on us, roasted barley, peas, corn, sweet potatoes, acorns or even chicory for Old Government Java or even Rio coffee, without a spirited protest, then are we beginning to trifle with our self-respect; and the villains who, in their dungeons and dens of infamy, thus practice on the credulity and ignorance of weak humanity deserve a higher and deeper reprobation than the counterfeit of greenbacks, or the adulterator of our national gold and silver coins.

The summer meeting of the Lorain County Bee-keepers' Association will be held in the Court House at Elyria, Ohio, on Wednesday, August 6, 1884. O. J. TERRELL, Sec. North Ridgeville, O.

The Kentucky Bee-keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed). N. P. ALLEN, Sec.

The Northwestern Illinois and Southwestern Wisconsin Bee-keepers' Association will hold its next meeting on the third Tuesday in August, at Leroy Highbarger's, near Adaline, Ogle County, Ill. J. STEWART, Sec. Rock City, Illinois.

CORRESPONDENCE

For the American Bee Journal.

Shall we Breed Hybrids?

JAMES HEDDON.

I have no barren statements to offer. I conceive that the mind of the bee-keeper of to-day would relish something in accord with his present knowledge of bee-culture. An assertion of what I am doing, and have done, still falls upon the ear of the most credulous as merely an assertion. I wish, if possible, to convince the reason of every reader. My preference for hybrids, or crosses between the best strains of German and Italian bees, is based upon certain facts, many of which are well known to the reader of less experience.

Did you never think it strange that the product of two races of bees should, as a rule, possess certain traits in a more radical degree than either parent race? Apropos to the above, do you not distinctly remember that the decisions of bee-keepers have been largely in the majority—that hybrids, crosses between Italian and German bees, were excellent honey gatherers? equaled by few and excelled by none; but oh! so universally cross.

Just why it should be a rule that this product possessed more belligerency than either parent, attracted my attention some years ago. I first built up a theory to account for the enigma, to which by fitting every day facts, I proved to my own satisfaction to be correct.

My first proposition is, that we have but two distinct races of bees—the dark, and the yellow; and second, that the yellow race of bees possess much the most belligerent disposition.

A thousand voices will now ask, "Why has the black bee been called the crosser?" I will try to explain. If you receive 3 or 4 stings during the manipulation of 10 colonies of dark or German bees, and only one sting in handling the same number of yellow colonies, would you not arrive at the conclusions so unanimously declared by bee-keepers of the past? Still, a mistake has been made. In opening a hive you are very rarely stung by bees that do not take wing. A well known and marked characteristic of that branch of the yellow race, known as the Italians, is, that compared with the dark or German bees, they are very tenacious of their foot-hold on the combs and in the hive. I think I am safe in saying that during the manipulation of a colony, from 8 to 10 times as many bees take wing when handling the German bees as would when handling Italians.

Now, as the proportionate number of stings received is not one-half as much against the German bees as their greater proportion are in condition to sting, here is an argument of two

to one in favor of the good-nature of the Germans; but here are more arguments based on what your experience has already taught you. There are ways to test the disposition of bees when on the wing—ways which we all use of necessity. Apply smoke equally to the races under equally unfavorable conditions, and while the Germans mind its admonitions and give up at once, the Italians seem to "lay back their ears" preparing for battle, as soon as the fog clears away.

Another way: When it is too cool for bees to fly, if you approach a hive carefully (I mean in the winter), and cautiously pull back the cloth cover, black bees, as a rule, will show no resentment, while Italians will tip up their posteriors and thrust out their stings. By the worst of treatment arouse a colony of Italians till they take wing quite freely, and you have nothing worse to fear from blacks.

It seems that the offspring of these two races, as a rule, inherited about equally from the dispositions of the parents, while those crosses coming from the little blacker, German strain, and the bright, yellow Italians were most sure to partake of the light-footed, take-wing tendency. Does this not account for the fact that the hybrids were, as a rule, worse to handle than either parent race in its purity? Does it not also account for the ferociousness of the Cyprians? They possess to the full extent the innate meanness of the yellow race and light-footedness of the blacks.

Now, if you will rid your apiary of all German bees, except the larger brown variety, and of all the yellow bees except the leather-colored Italians, you will find cross hybrids largely in the minority. You will find that most of your hybrid colonies are as good-natured as any bees you ever saw, and standing well up to, or above the reputation given them by the bee-keepers of the past—as being par excellence as surplus honey producers.

You must not forget that this most valuable strain is not a fixed race; that it is liable to sport from one "side of the house" to the other; *i. e.*, strongly show the tendencies, sometimes of one parent and sometimes of the other. They will rarely fall below the aggregate worth of either parent. This sporting tendency gives a most excellent opportunity to breed for qualities. Were I keeping either race in its purity, I should always breed for qualities, rearing my queens from my best colonies, which produce the largest quantity of surplus honey, and good behavior as one of the main points of valuation. No matter whether you have purchased a queen, and are breeding for Germans or Italians in their purity, or their crosses in their excellency, if you do not direct their breeding, rearing your queens from your best colonies, you will fall behind those who do, and you will always need to purchase queens from them.

For the benefit of many who are now breeding from hybrids, let me say that it is my advice to breed from the greatest honey-gatherers, and always such bees as stick to the combs

in the good old-fashioned Italian style. I want no Cyprians or Syrians to knock at my apiarian gate, unless they are possessed of the fast-footed tendency. I cannot admit such a queen, even though she came mantled in a ten-dollar greenback.

My opinion is, that very many who suppose that they have "good-natured Cyprians," have only Italian bees. If we find such radical differences in disposition of different colonies of the new races, as is reported from those who think that they have the pure Cyprians and Syrians, then surely there is little fixedness to be found in these new races. Next to the crossed strain of bees above described, I prefer the leather-colored Italians in their Simon-purity. Early and late brood-rearing are now being proven to be injurious qualities. My students will tell you that our 45 colonies that could not breed at all till they gathered the pollen of 1884, notwithstanding they ceased breeding early last autumn, are now the strongest colonies we have in our yard; and every one has been the pink of health for a year past.

Would that I were as sure of an 1884 fall honey-crop as that the introduction of the Cyprians and Syrians into this country has been a serious draw-back to our business. I have tried to appeal to known facts and reasons, asking you to take therefrom nothing for granted. How well I have succeeded, I leave the reader to judge.

The Honey Crop in Texas.

B. F. CARROLL.

This part of the State of Texas has been truly blessed with another grand honey flow. About June 1, as soon as the terrible floods subsided, our bees began to work on the mint. At that time I had 50 full colonies set apart for honey gathering, and the balance, all weak colonies, were broke up into two and three-frame nuclei. I put supers on a few hives, and as I had 40 acres in wheat and oats, 23 acres in corn, and 20 acres in cotton and millet, I had my hands full. I hired a man to run the farm, and I would run the bees; but he quit me about the time I was badly needed in the apiary, and I got fearfully behind.

I offered \$2 per day for a hand to work at the extractor, but none could I get. I finished my grain crop and let the cotton go, and began running the extractor. By this time all the hives were full, and the honey well sealed over. In two weeks I was up with the bees, but lost over 4,000 pounds of honey. I took a little over 6,000 pounds of extracted honey, and a few pounds of comb honey. I will get about 1,000 pounds more, making an average of about 140 pounds per colony. My big colony swarmed, and the old queen went to the woods. A second swarm gathered 100 pounds; the old colony 277 pounds, making 377 pounds; and if I could have saved the

first swarm, I could have taken from them over 200 pounds. The honey flow is not yet over, and it may yet average nearly 200 pounds per colony.

The honey taken is very fine, weighing 12½ pounds per gallon. I use spruce and cypress wood kegs, holding 5 and 8 gallons, and find them to be better than tin vessels, and much cheaper. My bees are pure Cyprians, and some colonies did not like the feather brush, so on these I used the tops of the camomile weed, and found it did not make them so hostile. After working four years with the Cyprian bees, I can truthfully say for them that they are the best bee yet for our hot, windy prairie country, and I think they will do well anywhere in the South. Heddon's "pollen theory" is certainly correct. I will soon give my experience on this subject.

Dresden, Texas.

For the American Bee Journal.

A Plea for Pollen.

DR. G. L. TINKER.

The recent report of the costly experiments made during the past winter by Mr. Heddon in support of the pollen theory, as anticipated, brings to light no facts not already reported by Prof. Cook, who several years since made many careful experiments in wintering bees on sugar syrup, and which proved clearly enough that cane-sugar is a better winter food for bees than the natural stores; but those who hold that thereby the theory is also proved, are taking much for granted.

There are too many questions involved to be settled by a single line of experiment. The theory is not only *not* proved, but it is far from being advisable to reduce it to practice, although our friend is so very confident that it is all right. I am pleased that he is so; but trust that he will not think Mr. Corneil, myself and others, obstinate in our opposition, because we believe the theory inadequate to cover the facts which he alleges.

The experiments required to be made to prove anything at all, must exclude honey entirely; and the stores be confined to sugar syrup and bee bread in a hive properly prepared for winter; but after these have been made, there will still remain the great question of the primary cause.

Now, Mr. Heddon talks to us very familiarly about the causes "auxiliary to the cause;" and it has become interesting to learn how he knows which is primary and which secondary. Of course we know that there is no *first* cause, scientifically speaking, and hence we are to consider only those causes or conditions which may be controlled or modified by the hand of man.

First of all it will be noted that Mr. Heddon places much stress upon the unity of the cause of bee-diarrhea. This he is obliged to do if he would substantiate the theory. It must not only be a cause, but the one great cause. It will hardly do to admit so

many auxiliary causes, lest some one living in the South might suggest that, notwithstanding all the pollen, bees winter tip-top down there. As cold is the principal factor here in the North, not experienced by our Southern friends, it strikes one that cold as "the greater auxiliary to the cause," is assuming too much, and liable to turn out as with one of our own politicians, who, before the ballots were counted, always claimed everything with confidence.

My investigations of the cause of bee-diarrhea prove what Prof. Cook, Mr. Doolittle, and a host of other able observers have found, viz: that "restlessness," "excitement," or "undue activity" of the bees in winter quarters are the first symptoms of the disorder. On the contrary, those colonies which remain quietly clustered upon the combs and have enough to eat, usually winter all right; but if they become restless there will soon be a demand for nitrogenous food to supply the waste of tissue. If, now, they cannot void themselves in confinement as held (which, however, is not yet clearly proven), then the indigestible particles of the bee-bread consumed, together with the excretion of the worn-out or effete tissues (which, as one of the adjunct causes of bee-diarrhea, completely dwarfs that of pollen), may accumulate, after a time, in quantities producing serious harm. It would, however, be a great mistake to suppose that the accumulations are the cause of the restlessness, since it is certain that bees do eat pollen all through a long winter confinement, and yet winter well. This fact is now well established, as pollen husks are always to be found in the intestines of bees in winter confinement; but no trouble comes from slight accumulations. It is only when, as in such a winter as that of 1880-81, bees are obliged to consume inordinate and almost unprecedented quantities of both honey and pollen to keep life in them, that these harmful accumulations arise.

If restlessness, then, causes the bees to eat too freely of pollenized food, it ranks as a prior cause; and the most that could be held is, that the latter may be an auxiliary cause, while restlessness, as the effect of cold, humidity and confinement, one or all, must stand as the primary cause or causes amenable to the hand of man. I am, therefore, unable to see the propriety of excluding the bee-bread from the bees in winter, but think that we should provide against the primary causes; and I shall hold that the latter policy may be more economically executed than the former, and that it is practicable, effectual in results, and consistent in theory.

To prevent the consumption of too much pollen by the bees, under adverse conditions, it would be necessary to exclude nearly all of it from them, which measure will certainly require more "fussing" than most men will care to give their bees. It will not be enough to limit the amount to one-half or one fourth of the ordinary quantity stored; for the colonies

dying of diarrhoea, do not eat all their bee-bread, but leave large amounts of it.

Again, Mr. Heddon has given one case which died of diarrhoea, as he states, caused by eating from only one comb; and yet, when he examined it, it was "nearly half full of bee-bread." As this comb undoubtedly contained some honey, and also a patch of brood "as large as a man's hand," in the fall, how much bee-bread, think you kind reader, does it take to kill a colony of bees? According to this showing, a few dozen cells of it is ample to kill any colony, other things being favorable. It is plain, therefore, that it will be impracticable to exclude it in such amounts as to insure safe wintering; unless, indeed, we come down to the use of "tooth-picks."

There are bee-keepers living farther north than Mr. Heddon, and who winter, year after year, a great many more colonies, and with almost no loss at all. Wintering is no trick for them; bee-bread in the hives in winter gives them no concern, and they seldom have a case of bee-diarrhoea. That their methods are not practicable and efficient, there is no doubt; and that all other bee-keepers may be equally successful, there is also no doubt. Could Mr. H., therefore, give us a practical method of excluding all pollen from the hives in the fall, it would offer us no advantages in wintering not already possessed, even if his method of wintering would always prove safe, which is not now, has not been in the past, and will not be in the future.

On page 171 of the BEE JOURNAL, for 1881, is a report by Mr. Wilber which is especially commended to Mr. Heddon's consideration. The report, like all others that I have read on the use of sugar syrup, is, on the whole, favorable against the use of natural stores. In this case, however, one of the sugar-fed colonies wintered in the cellar, died of "dysentery," and two of those wintered on the summer stands, died; but they "were the only ones that died without the dysentery."

In view of such a report as this, of what was clearly a carefully made test, who will say that, if we had had such a winter as that of 1880-81, Mr. Heddon would not have lost one-half of his 45 sugar-fed colonies; and that, too, not from diarrhoea, but from another trouble not less to be dreaded, viz: *restlessness* under the smarting effects of bitter and prolonged cold in a damp, devitalizing atmosphere? It is plain that, if bees get restless from any cause, and they have not access to bee-bread or other nitrogenous food to supply waste of tissue, their vitality will be speedily exhausted.

I shall repeat, therefore, what was stated a year since: that I believe that the pollen which bees consume in winter, is essential to their well-being, and never detrimental, except when the force of circumstances compels them to eat not only more pollen, but more honey than the vital powers can endure.

This being true, should we not give bees better winter protection, better

ventilation, and more of that "highly oxygenized food"—sugar syrup—which is found to be so much better than honey to aid the bees to withstand our inclement winters? We may take from them the combs containing excess of bee-bread, and return them as soon as they have need in the spring, and especially if it takes up needful room for other stores; but to undertake to prevent the storing of pollen, or to remove it after it is stored, as contemplated by Mr. Heddon, will be just so much loss, at the rate of \$1 per pound (which is the value placed upon it by an eminent authority), while the compensating advantages of the prevention or removal do not yet appear.

We often have bad spring weather, when the bees cannot gather the needful supplies of pollen to enable them to breed up in time to take advantage of the yield of white clover. We can well imagine Mr. H. with his pollenless bees, under these circumstances, and what would be the result of it. For my part, I have never seen too much bee-bread in my hives, and never expect to. When the combs are well filled with it in the spring, it is soon gone, often long before fruit bloom, which I consider chiefly valuable to our bees, only because of the very large amount of pollen collected from it.

The past spring I had one colony which had been built up from nuclei last fall, which, it seems, had little pollen but plenty of honey and sugar-syrup. After a time, I wondered why they did not breed up faster, and I suspected that the queen was worthless; but upon examination, I found that they had not a particle of bee-bread, and had not been able to collect enough pollen before fruit bloom to fill one comb with brood. The result was, no surplus from this colony.

In conclusion I cannot refrain from commending to Mr. Heddon the very valuable advice given by Rev. Wm. F. Clarke, in the closing paragraphs of an article on page 364 of the BEE JOURNAL for 1884.

New Philadelphia, O.

For the American Bee Journal.

Central Illinois Convention.

A bee-keepers' association was formed at Jacksonville, Ill., on July 12, 1884, by the adoption of a suitable constitution and by-laws, and the election of the following officers: Capt. Henry W. Hitt, Merritt, Ill., President; Jno. W. Bowen, Jacksonville, Ill., Vice-President; Wm. Camm, Murrayville, Secretary; G. F. Middleton, Jacksonville, Ill., Treasurer.

Some discussion arose as to the name of the new society, but it was finally decided to call it the "Central Illinois Bee-Keepers' Association;" though some members thought that there was a society at Bloomington styled the Central Illinois; yet it could be changed if such proved to be the case.

It was intended to include the bee-keepers of Scott and Morgan counties

only, but J. M. Hambaugh, of Brown county, desired that others be allowed the privilege of joining; so it was decided to accept all without reference to the county in which they lived.

An interesting discussion arose as to prices of honey and prospects for honey crop. It seemed to be the opinion of all that the flattering prospect for a large honey crop, this year, would not be realized. Nearly all reported that white clover was still plentiful, but few bees working on it; and that the bees were cross and inclined to rob. Adjourned to meet on July 26, 1884. Wm. Camm, Sec.

H. W. HITT, Pres.

For the American Bee Journal.

The Report of the Honey Crop.

W. H. STEWART.

While we question the correctness of some reports, we are forced to admit that sometimes one, or may be 6 colonies out of 50 or 100 do produce wonderful yields.

On page 115 of the BEE JOURNAL for 1883, Mr. Doolittle states that he obtained 566 pounds from a single colony that did not swarm, and was not divided; but we notice that this colony was one of many in the same apiary; and, although he states that it had no help from any other colony, yet we understand that the empty combs which he gave them, aided them very much.

On page 434 of the BEE JOURNAL for 1883, Mr. Flory reports over 600 pounds from one colony; but does not state whether it was "spring count," or whether divided—making 2 colonies instead of one. If this were the case, then it would appear quite reasonable that 1 or 2 colonies should produce 300 pounds each, when kept in the same locality with many other colonies.

Again, Mr. F. does not state whether he supplied those bees with empty combs or not. It has been proven by experiment that as much honey is consumed in the production of a comb (in the natural way) as the comb will hold when finished. If this be true, then the 20 combs (Gallup combs that hold about 6 pounds each) which Mr. Doolittle gave to his colony would be equivalent to giving them 120 pounds of honey; and not only so, but the bees which were thus enabled to gather honey to fill those combs, would otherwise have been compelled to stay in the hive to build their own combs, thus very much reducing the honey-gathering force of the colony.

I am of the opinion that many bee-keepers make great mistakes in reporting that certain colonies accomplish so much more than the average. They may be correct in regard to the amount of honey taken from a colony, but in jumping at the conclusion that the colony had gathered that much from the field, is where the mistake comes in.

On page 560 of the BEE JOURNAL for 1883, Mr. J. E. Pond has truly

stated as follows: "I presume that every intelligent bee-keeper who gives his own time to the care of his apiary, has noticed that in a dozen colonies, all apparently alike and in good condition, 1 or 2 will give exceedingly good results, comparatively, while the balance will hardly come up to the mediocrity in the amount of surplus obtained from them.

At first I concluded that it must be owing to the superior strain of bees, and endeavored to remedy it by making such changes as would—theoretically, at least—equalize the matter; but when, the next season, I found the best colony of the previous year showing a decidedly poor state of affairs, I concluded that something besides poor stock was the cause of the trouble."

In another portion of his article, Mr. P. expresses the opinion that the reason that different colonies give such different results is, that all, or most of the bees belonging to the same colony, work in the same direction from their home, and in the same pasture; and that, as honey is found in much smaller quantities in some localities than in others, hence the difference.

Mr. P. gives the above opinion very modestly, and does not claim to have given the "whole truth, and nothing but the truth," but has given it, "hoping" to "create enough interest in the matter to start an amicable discussion in regard to it;" and at the close of his remarks on the subject, says: "Who will give the subject some attention, and the readers of the BEE JOURNAL their views upon it?"

Mr. P. has done well in calling for an investigation of this matter, and I hope that our most able and experienced bee-keepers will at all times give, in the BEE JOURNAL, such facts as may come under their observation. To give my views and experience in full, on this subject, would make this article too long.

Orion, Wis.

For the American Bee Journal.

Mr. Heddon's Report.

WM. F. CLARKE.

I have read the above article which appeared on page 405, with much interest, and with a sincere desire to divest my mind of prejudice. It carries, throughout, the air of a knock-down argument in favor of the pollen theory, but I submit that the proof is far from being conclusive. There is evidence, which we had long ago, that under certain conditions bees will winter well without either honey or pollen; but it is by no means demonstrated that, if there be pollen in a hive, bees will be silly enough to eat it in such quantities as to cause diarrhoea. In fact, the reverse is shown by the facts which Mr. Heddon narrates.

Only 45 colonies out of 336 were "prepared without a cell of pollen." There were, therefore, 291 colonies that had more or less pollen stored.

Seventy were not fed sugar, and these, we are told, had "less bee-bread than usual," while those that were fed, "had not one-fourth as much bee-bread as usual." Mr. Heddon gives us no information as to the consumption of bee-bread, either in the 70 unfed colonies, or those which were fed; he merely informs us that he "lost about 30 colonies by diarrhoea," but does not state any facts as to the consumption of bee-bread by the colonies he lost.

The history of the 45 colonies is not so conclusive, when you come to think it out as it might seem to be on the first blush. That 44 of them wintered well, only proves what we knew before, as I have already stated, viz: that under favorable circumstances in other respects, bees will winter well in the absence of either honey or pollen. The report on the 45th hive is open to criticism on at least two points: First, it does not appear that this colony had any more bee-bread than many of the 291 which wintered well; and secondly, though this colony had, by mistake, pollen left in it, the "pizen" does not seem to have been eaten by the bees. When the foreman examined that hive, in the fall, one comb had a patch of brood nearly as large as his hand; and when Mr. Heddon opened the hive in the spring, one comb had "a little brood," while the comb was "nearly half full of bee-bread." So, then, the bee-bread, which the foreman saw in the fall, appears to have been left untouched, for there was about the same quantity at the two examinations. Is bee-bread so fatal that its mere presence in hives will cause diarrhoea?

My comment on Mr. Heddon's report would be, that his bees were prepared for wintering with great care, and that the season happened to be of a character that most of the colonies were able to hibernate, and so, did well. There is nothing in the whole narrative to conflict with the position I have taken in regard to wintering. I would like to know what amount of stores those bees consumed. If a small quantity, then the hibernating conditions were nearly perfect; and if a considerable quantity, then the bees were only able to hibernate partially—still, hibernation was so far practical as to bring them through the ordeal in good condition.

Too much consumption of food, whether honey, sugar or pollen, interferes with normal hibernation. Establish the hibernating conditions, and they will eat the minimum of food.

Mr. Heddon does not tell us how well any of his colonies wintered, except the 44 which were prepared without a cell of pollen. Did others that had some pollen winter equally well with the 44 that had none? If so, what becomes of the no-pollen theory? The fact is, that whatever may be true in regard to the pollen question, Mr. Heddon's report squares exactly with my discovery, that *successful wintering depends on hibernation*. That is the key to the mystery, and I earnestly hope that every bee-keeper in the country will accede to my modest

request, and prepare at least one colony for the winter of 1884-5, so that it can hibernate as it would do in a hollow-tree trunk.

I am sorry that Mr. Heddon indulges in such a contemptuous fling at "our ever-present corps of inexperienced apicultural writers." Of course, by these he means all who do not obtain their livelihood exclusively by bee-keeping. At the head of this "corps" stands the Rev. L. L. Langstroth, who gave us the movable-frame, and, at the tail, there is your humble servant, who has lately evolved the hibernation-theory, out of which, after due experiment, will come to the true method of wintering bees; and in the success of which we shall remember the "bacteria" and "pollen" vagaries of a certain experienced apicultural writer, as an illustration of the fact that "it takes great men to put forth great nonsense."

Warren Pierce's article in the same number as is Mr. Heddon's report, is a splendid contribution to the mass of proof that will soon be forthcoming to show that the problem of wintering is solved by *hibernation*.

Speedside, Ont.

For the American Bee Journal.

Facts in Regard to Wintering.

J. E. POND, JR.

I do not intend, at this time to enter into a discussion of the "pollen theory," but, instead, to give a few facts from my own experience. Discussions on mooted questions will always prove valuable, and whether the "pollen theory" is correct or not, a full and complete investigation in regard to it will aid all of us greatly, in solving the winter problem, for the reason that it must bring out facts which otherwise would not have been generally known.

I do not know that the facts which I shall recite will add anything of value to the discussion on wintering; but having wintered my bees on the summer stands for years without the loss of a single full colony, possibly these facts may prove of some interest.

Last fall I prepared 2 colonies for winter by selecting and giving to them such frames as contained the largest amount of pollen of any that I could find. I should judge that at least $\frac{1}{4}$ of the cells in each frame contained more or less pollen. These 2 colonies were of fair size, and covered 6 Simplicity-Langstroth frames. They were both put in single-walled Simplicity hives, with division-boards on each side of the frames: a "Hull's device" over the frames, covered with a thin woolen blanket, and the upper story filled with forest leaves; the cover having inch holes in each end for ventilators. An entrance $\frac{3}{8}$ of an inch wide by 6 inches long was also given them.

My other colonies were prepared for winter in much the same manner; the only real difference being that I took no particular pains in regard to pollen, and giving them such frames as I had containing sufficient stores. In pre-

paring the frames for winter, I always begin as early as Sept. 1, and so arrange them that at least the upper third part of each frame is filled with capped stores; thus giving food enough in a situation where it can be reached at all times, no matter how severely cold the winter may prove.

The result of my experiments was, I did not lose a single colony; that none of them showed any signs of bee-diarrhoea; but that the 2 wintered on what ordinarily would be called an excessive amount of pollen, came through in the best condition of any. Brood-rearing having begun early, one of those colonies gathered 72 pounds of honey from apple bloom.

I have no theories to advance; I simply state the facts. I am of the opinion, however, that bees prepared for winter, as an experience of years teaches me, is the correct method for my own location, will meet with a minimum of loss. I will say that if pollen is the cause of bee-diarrhoea, the 2 colonies mentioned above, ought to have been terrible sufferers from its effects.

Foxboro, Mass.

Texas State Convention.

The Bee-Keepers' Association met at McKinney, Texas, April 12, 1884, at 10 a. m. Judge W. H. Andrews, President, declared the sixth annual session called to order. He said it was now swarming time, and that the bee-keepers had now clustered and were ready to be hived. That the Association was, year after year, drawing some new member from a distance. This year we have the Cyprian from as far south as Navarro—Mr. Carroll, of that county, now being for the first time present with us—and that he hoped to see the good work go on.

Business now being in order, a motion was made by Dr. Marshall, was carried that a committee on questions be appointed, and that all members desiring to put questions to the Association, present them to the committee; the committee to select the most important for discussion, and report them to the Association. T. C. Goodner, J. S. Kerr, and M. H. Davis were appointed on the committee.

A motion by Dr. Marshall to appoint a committee on foul brood, was carried. Dr. Marshall and Judge Goodner were appointed.

Moved and carried that the Association recommend the AMERICAN BEE JOURNAL, and that it be the organ of the bee-keepers in Texas.

Report of committee on questions was next made.

1. "Should the queen's wing be clipped?" Answer by committee, "Yes."

Dr. Marshall opposed the clipping; thought it would end in a race of bees without wings. Mr. Carroll took the same ground, saying in addition, that it injured the beauty of the queen. Mr. Davis favored clipping as a means of preventing swarms from absconding. Mr. Graham opposed clipping,

and did not think nature should be crossed. Judge Andrews said that the conclusion of the National Bee-Keepers' Association was against clipping. He thought there was no doubt that the bees like a queen with perfect wings the best, and that a mutilated queen was not acceptable to the bees. But did not think the clipping would ever tell injuriously on the progeny of the queen—the loss from clipping was greater than from the absconding swarms—as the queens not being able to fly, would crawl off in the grass.

On taking the sense of the Association on the decision of the committee, two members sustained it, the others against it.

2. "Does it pay the better to run an apiary for extracted or comb honey?" Answer by committee, "Extracted honey."

Report of committee unanimously adopted.

Adjourned till 1 p. m.

EVENING SESSION.

3. "What is best to plant for honey pasture?" Answer, "Horse-mint."

Dr. Marshall thought black locust a good forage. He thought lime might succeed well here; also recommended the protection of honey-locust for the benefit of bees. J. S. Kerr said he had made some experiments with sweet clover. He thought it a good honey forage, and not dangerous to farms. Scott McKinney had observed that china or scratchberry afforded a good flow of honey, and also motherwort. Mr. Carroll had tried the blue thistle of Virginia, and considered it about as good as anything. Also pepper-wood is very excellent. Judge Andrews said sweet clover did yield honey, but not of such a quantity as to attract bees if they had anything else to go to. The Simpson honey-plant was the best honey-producer for the black land. He believed the Canada thistle would grow here, and in its native country was considered a most excellent honey plant. That honey locust and black locust should both be encouraged and protected in their growth. Raspberry, he said, made the best honey. Ratan is a tip-top honey producer; also, red-bud yields a good supply of honey.

The special committee on foul brood next reported the following resolutions:

Whereas, Foul brood has appeared in our State, and is now found in Dallas and in the surrounding country, and is now spreading into other counties; and

Whereas, It is spreading with wonderful rapidity, and threatens to be one of the most fearful evils with which we have to contend; and

Whereas, It threatens, if not checked, eventually to destroy the whole industry of bee-keeping in the State, therefore,

Resolved, 1. That we urge all the friends of bee-culture to use every effort in their power to prevent its spread.

2. That we urge every bee-keeper, at its first appearance, to burn the hive in which it appears, with all its

contents, believing that fire is the only sufficient remedy; and

3. That a committee be appointed to prepare a draft of a Bill in reference to foul brood, to be presented to the next Legislature, and that the members of this Convention present a copy of this Bill to the member of the Legislature from his county, and urge him to use his influence to secure its passage.

Dr. Marshall held that foul brood was the greatest evil that bee-men had to contend with. It was imported into the neighborhood of Dallas by Mr. Collin. It had spread as far south of that city as Lancaster, eight miles east, and as far west as Arlington. He had never found a remedy for it. It is never discovered until after the larva is capped over, then by the sinking of the cap. He advocated legislation that would compel its destruction as the only means of getting rid of it. A swarm of bees may run away and settle in a hollow tree in the woods, and die from foul brood, and the bees for several miles each way may carry off the honey they leave, and thus scatter the disease in all directions. Judge Andrews had seen foul brood eight years ago in Mr. Collins' apiary at Dallas; since that time there has been no alarm, but now it is spreading rapidly, and he recommends that on first appearance the hives be destroyed solidly and effectually.

As to its appearance, there will be found a small hole in the centre of the cap. There is a very foul odor peculiar only to foul brood, and can be smelt outside the hive.

Scott McKinney gave an account of what was thought to be foul brood in Mr. Binckley's apiary at Sherman, but did not know whether it proved to be foul brood or not. Mr. West, who, it was thought, had foul brood in his apiary in Tarrant county, now gave his views. He did not know whether he had foul brood or not. About the first of February he noticed cells with caps open in the centre, thought it was chill brood. He then then found there were 12 colonies affected with it, and sent these off several miles. Thought his entire apiary was affected with it. Had checked it to a great extent. His colonies had sent out swarms. Had seen bees hatching in the hive beside it. Did not think it affected the drone or queen-cells. He burns the combs and boils the hives as a remedy. Mr. Horn advocated the boiling process with red pepper added to the water.

After prolonged discussion the resolutions were adopted. The Association then proceeded with a further discussion of the questions handed to the committee.

4. "Will it pay to rear young queens to introduce into new colonies?" Answer, "Yes." Sustained by the Association.

5. "Can more than one race of bees be kept successfully in the same apiary?" Judge Andrews held that more than one race would mix, and recommended that only one race be kept in the same apiary.

6. "Are artificial better than natural swarms?" Answer by the committee, "For increase, yes." "For honey, no." Report of committee adopted unanimously.

7. "Can a bee-keeper make a success of a one-story hive without an extractor?" "Yes," by committee. Judge Andrews thought that for the use of an extractor anything but a one-story hive would be best. Mr. Carroll thought that when there was a good flow of honey two, three and four stories were best. Mr. Cooper held that a two-story hive was best, as it gave the honey time to ripen. Judge Andrews did not believe it necessary that honey should be allowed to remain in the comb to ripen, but should be thrown out as soon as possible and ripen in open-mouthed vessels. Mr. West was opposed to two-story hives. Mr. Carroll held that to throw honey out before it had ripened, was a good way to make vinegar or metheglin; and that honey evaporated in barrels did not have the same flavor as that ripened in the comb. Dr. Marshall thought it would require an expert to throw out the honey and then ripen it; and he thought a two-story hive the best, as the brood would be disturbed in one-story hives by extracting. Judge Andrews' plan is to store honey first in open stone jars and cover with thin cloth—the temperature for ripening the honey is from 80° to 90°. Mr. Horn said he had ripened honey in 10-gallon kegs. Answer of committee sustained.

8. "Are drones from an Italian queen that has mated with a black drone, pure Italians?" By committee, "Yes." Mr. Carroll thought they would be pure. Judge Andrews thought not. Also, Dr. Marshall thought not, and that the progeny of the queen, both male and female, were affected by the mating. Dr. Howard thought the offspring a mongrel of no certain degree. Report of committee not sustained.

9. "How can one or more weak colonies be combined in the beginning of the season so as to make a strong one?" Mr. Carroll recommended placing the hives one upon the other, or make the new colony by taking frames alternately from the old ones and place them in the new hive. Dr. Howard recommended placing one hive on the other, and give both a thorough smoking, and lean a board against the front of the hive to aid the bees in marking their new locality. Mr. Wilson's plan was to put in one colony with half the frames, then a division-board; at night take out the board and smoke the bees thoroughly. Judge Andrews did not approve of removals, but if necessary, would move the hive the whole distance at once, and keep the bees in for two nights and one day.

10. "Does the amalgamation of bees produce good results?" Answer of committee, "No." Mr. Carroll thought it might possibly do so, but said we could not know it. Referred to Mr. Heddon as authority, but thinks pure stock the best. Judge Andrews held that nothing could possibly be gained

by mixing the races. Much is claimed as a superiority in bees, which is not an advantage in any way; thought the Italian the best, but would rather have a black bee than a mixed race. Those who have a large stock of bees always say (that is in the papers) that all other bees are of no account. He has found all bees to yield about the same amount of honey. Report of committee was sustained.

Adjourned till 8:30 a. m.

April 25. The Association met at 9 a. m., Dr. Marshall presiding. A motion was carried to fix the next place and time of meeting. McKinney was unanimously chosen, for the first Thursday in May, 1885, to continue two days. The election of officers for the ensuing year resulted as follows: Dr. W. K. Marshall, President; B. F. Carroll, Vice-President; Dr. Howard, Secretary; W. B. Graham, Treasurer.

Judge Andrews, delegate from the State Bee-Keepers' Association of Texas, for 1883, to the North American Bee-Keepers' Association at Toronto, Canada, made his report: He thought that his attendance of the Association was of much value, but his visit to Mr. Jones' apiary was worth much more. Mr. Jones has 2,500 or 3,000 colonies, distributed over a territory nine miles in diameter, keeping 150 to 176 colonies in each yard. He breeds his queens and drones at home, and sends them over to Islands in the Georgian Bay, and by this means keeps them unquestionably pure, impregnation being made sure. His profits arise largely from the sale of queens, but he also sells large quantities of fine honey at 20 cents per pound. The Judge spoke well of Canadian honey, and exhibited a sample which he had brought home with him. He said there was a great quantity of fine extracted honey on exhibition at the Convention. The most prominent questions discussed in the Convention were left without taking a vote. On spreading the brood, the weight of opinion was against it, many contending that it was one course of foul brood. It requires an expert to accomplish it successfully. The weight of opinion was in favor of the Langstroth hive. Mr. Langstroth is entitled to be called the Huber of America. He thought Mr. Jones the prince among bee-men. He spends vast sums of money in experimenting. According to Mr. Jones' experiment, there was no great difference in the products of the different kinds of bees, as he observed in Mr. Jones' apiary. In Convention he met distinguished bee-men. There were but three representatives from the Southern States. Mr. J. P. H. Brown, of Georgia, Mr. W. S. Hart, of Florida, and himself. He thought more honey was produced in the North than in the South, because they have more honey-producing plants. It was unanimously agreed that extracted honey was the most profitable, and the disparity between comb and extracted honey was fast disappearing. As to different varieties of bees, he formed a diversity of opinions. There was no decision of the Convention as to which were best.

A motion prevailed to appoint a delegate to the next National Convention to meet at Rochester, N. Y. Judge Andrews was selected as delegate. A motion was carried to so amend the Constitution as hereafter to collect \$1 as an initiation fee. Also another motion carried, that voluntary contributions of \$1 from each member be asked for, in order to defray all expenses of the Association. A resolution passed instructing the secretary to notify all the members not present, of the one-dollar contribution, and request them to send in theirs.

Association adjourned till 1 p. m.

EVENING SESSION.

The Association met pursuant to adjournment, Mr. Carroll presiding.

11. Question from the committee. "Is the moth a destructive enemy to the bee in any way?" Answer, "Not to the bees, but to the comb." Judge Andrews held that the moth never hurt a colony of bees, but destroyed unprotected comb. That a strong colony is never hurt by moths, and advised that combs be hung up and smoked like bacon. Dr. Howard said he put his combs where light and air could reach them, and they were never injured by moths; but if they were put in a dark, damp, and warm places moth would destroy them. Judge Goodner had found, by experience, that it would not do to hang combs in a dark smoke-house. Mr. Kerr hung his to joists over-head, and found it a safe plan. The report of the committee was adopted.

12. "What is the best method of increasing colonies." Answer, "By artificial swarming." Sustained by the Association.

13. "What is the best plan of keeping the bees from swarming?" No answer by the committee. Mr. Carroll said swarming could be prevented to some extent by using the extractor freely. Dr. Howard said swarming could be prevented by keeping the bees too weak, but did not like the manner in which the question was put. Judge Andrews said he would be obliged to any one who would give him any information as to how to limit swarming without injuring the bees. He had been for years trying to solve the problem. No conclusion arrived at.

14. "Is the swarm always led by the queen?" Committee answered "No." Mr. Carroll thought the queen always led. Judge Andrews thought all the bees went out by instinct and one bee never leads another. Bees will come back to hunt the queen sometimes but not always. Mr. Horn remarked that he could see no practical bearing in the question; he had seen the queen come out first, in the middle, and the last. Answer of the committee sustained.

15. "Does the queen control the colony in anything?" Answer by the committee, "yes." Judge Andrews held that she did, only so far as the work of the one depends on the other. Both are moved by instinct. Dr. Howard did not think the queen "bosses" the bees or tells them what

to do. Instinct prompts them all and tells them how to do. Mr. Davis did not know what was meant by instinct, as he never had heard that bees had reason. Mr. Horn thought all acted from instinct. Dr. Marshall said it was difficult to define the difference between reason and instinct. Bees pay respect to the queen only after impregnation. They feed her and give her other attentions. He said the queen controlled the colony to a certain extent. The queen is the first to become excited before swarming. The report of the committee was adopted.

16. "Is a division-board desirable, and are the advantages sufficient to justify the expense?" Answer, "No". Judge Andrews and Dr. Marshall favored the use of division-boards. Mr. Carroll said that an empty comb was sufficient. Answer of committee reversed.

Judge Andrews asked, "Should the old queen be removed before the new queen is selected?" Mr. Carroll said that, in a good honey season, the old queen should remain until the other was turned loose. Mr. Kerr had lost queens while in the cage in the hive.

Adjourned to meet on the first Thursday in May, 1885.

W. B. HOWARD, Sec.

For the American Bee Journal.

"Reversible Frames."

H. DAVIES.

On page 439 of the BEE JOURNAL of July 9, I read Mr. Pond's article on "Reversible Frames;" and a few minutes afterwards I began to read the *Kansas Bee-Paper* for July, when, on page 105, I saw the following article on the same subject. Imagine my surprise to find it signed "P" (which, I believe, is Mr. Pond's signature for his editorial articles in that paper). I am now puzzled to know what Mr. Pond's real ideas are on reversible frames. Here is the article:

"The question of reversible frames is one of no little importance; that is to say, the results said to be produced by reversing, are exceedingly advantageous. The experience of all bee-keepers is, that the lower part of frames are never as well filled out as the upper; reversing is said to overcome this entirely. We, however, look for far greater results therefrom. Our experience is, that when we get the brood placed to the top-bars of the frames, the bees will at once begin work in the sections. In order to accomplish this in days past, we have been obliged to make use of the extractor, which causes considerable hard labor at a time when we are busy otherwise. Now, it seems we can accomplish this result simply and easily, all we need to do, is to reverse the frames, at the time we put on the sections. The bees will rear brood close up to the top-bars, and at once proceed to fill the sections. If any trouble is feared from the queen going into the section also, it can be easily remedied by using the perforated-zinc honey-board between the frames and

sections. We experimented somewhat last season in this matter, and with good results. We are again experimenting this present season on this point, and so far it has proved a success. Many plans of making reversible frames have been given to the public; but the simplest one we know of is to make frames with a projection only at one end of bottom-bar. These frames can then be used in any hive, by simply putting a strip of tin or sheet iron across the bottom of the hive for the projection of the bottom-bar to rest on. Then, when desired, the frame can be turned over without trouble, or change of the hive. P."

I cannot make the two articles agree at all. "Can Mr. Pond?"
Austin, Texas.

SELECTIONS FROM OUR LETTER BOX

Large Crop of Honey.

We have had a heavy run on clover, which has just closed, and we have on hand more honey than the whole of last year's crop. All of the white honey is of the very best quality. The prospect is yet fair for some basswood and button-willow honey before the fall honey begins to come.

J. O. SHEARMAN.

New Richmond, Mich., July 10, 1884.

Honey from Cotton.

The honey-flow from mint is over, and bees are working some on the cotton. The weather is dry and very hot—104° F. in the shade. I expect we will get a good flow from cotton, as the plant is very late blooming, and the main bloom will be during the last of July and the first of August.

B. F. CARROLL.

Dresden, Tex., July 12, 1884.

Bees Gathering Honey Rapidly.

The work of the apiary, in this part of the country, is up to boiling heat. I put 18 colonies into winter quarters, and by neglect, one starved. After spring opened I lost two more. A number of bee-keepers in this neighborhood wintered their bees all right, and then lost them in the spring. I have 21 strong colonies, and I do not think that I ever saw bees gather honey as fast as they have done this spring. I use foundation, and in 9 days after being hived, the bees will be ready for boxes. I use a modification of the Langstroth hive, called the Fisk hive. I have been using the brood-frames, but I am now introducing a crate into the hives, and I think it is going to be an improvement. I have a splendid location for an apiary. It is two miles from timber and running water, and is bounded by pastures over-flowing with white clover bloom, which, through the bees, lavishes their copious streams of wealth upon my scanty store.

WM. STALEY.

Adair, Ill., July 3, 1884.

No Honey, and Prospects Blighted.

I am sorry that I am compelled to say that we have got no honey, as yet, from our bees in this city. It seems that our prospects are blighted in regard to the rich harvest which, to all appearances in the spring, we were promised; but this season we have been over-run with caterpillars and moths of all kinds; in fact, there is not a blossom that is not alive with insects of some kind, and in some places the caterpillars have eaten every green thing. The first crop of lucern has been cut without coming into bloom; so the bees are just getting as much honey as will feed them and their young. I went through my apiary, July 5, but I could find only 2 frames that I could extract from, and those were not sealed over. I think that if a change does not take place soon, the bees will have to be fed their winter supplies. I have fed to my bees about 400 pounds of honey this spring and summer, but I could not get 40 pounds back. I have now 25 colonies, and they are all in good condition. No blame can be attached to the condition of the bees. T. W. Lee told me, the other day, that he had fed over 500 pounds of honey to his bees, and did extract 5 pounds during May; but it was only to keep the "baby from crying," as he had fed so much that he was left without any honey for his own family. I had about 60 pounds with which I have been able to keep peace in the house, so far; but I rather fear that there will be a cry soon, if a new supply is not forthcoming. In 1882, our honey months were July and August; in 1883, June and July; and, perhaps, to make a change, it may be August and September for 1884. I will be pleased to notify you of such a change.

JOHN DUNN.

Tooele City, July 8, 1884.

Honey Crop.

The swarming season is about over, and the bees have done but little so far. I have had only 25 swarms from 135 colonies, and have only about 1,200 pounds of finished comb honey ready to come off. Bees are in fine condition, and we have a fair prospect for a fall crop.

J. V. CALDWELL.

Cambridge, Ill., July 16, 1884.

One-Fourth of a Crop.

Clover harvest is over here, and the bees are robbing. The season has been peculiar; plenty of bloom, but cold nights and wet days, so we have not more than one-fourth of a crop.

B. H. STANDISH, 156.

Evansville, Wis., July 15, 1884.

On a Still "Hunt."

I desire to state, since the matter has come up, that a Mr. F. H. Hunt, of Iowa (Linn county I think) has been selling stuff unfit to eat as honey, in Iowa, and tried the same in Nebraska last winter. A caution over my signature was promptly published, and that was the last I heard of him. The matter is in the hands of a

chemist. For particulars I would refer to letters from Mr. O. O. Poppleton and a Mr. McElroy, of Iowa, now in possession of Mr. M. L. Trester, Secretary of the Nebraska State Bee-Keepers' Association.

T. L. VON DORN,

Pres. Neb. S. B. K. Ass'n.

Omaha, Neb., July 11, 1884.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

How to Make Honey-Boards.

1. Will Mr. Heddon tell me in which number of the BEE JOURNAL he gave a description of his honey-board (sink honey-board), and how to make it? I have mislaid it, and I am unable to "come up with it."

2. If you were working, or intended to work for extracted honey, would you use frames for the upper story the same depth as the brood frames, or shallow frames half that depth?

3. When preparing bees for wintering on the summer stands, do you leave the slat honey-board on, or remove it and cover the frames with a quilt?

E. E. EWING.

Highlands, N. C.

ANSWER.—1. I have never given any description of how to make my honey-board, because it would take up a great deal of space, and then one might not get it correct without a sample to work from. I can do so in the near future, however.

2. After carefully weighing, in my own mind, the advantages of both systems, I have made up my mind that I would use the whole story above. I would make the super the same width as the hive, $\frac{1}{2}$ inch shallower, use sink honey-board between it and the hive, and use the same number and style of frames as in the hive. I have fixed one whole apiary of 200 colonies that way, and have made 500 supers (or $2\frac{1}{2}$ per colony, spring count). By the use of two supers to the colony, you can leave the honey to be well ripened before extracting, and yet never lose any honey by so doing, even during the most excessive honey-flow.

3. I sometimes turn over the honey-board (thus doubling the bee-space above the frames), and lay a cloth over it, and put the packing over the cloth. For ten years I have used a basswood stick thus  bent and held bowing, by its  ends being within the sides of the hive. The hives are $11\frac{1}{2}$ inches in the clear, and the stick is $3-16 \times \frac{7}{8} \times 12$ inches long. I soak them and press them into hives to dry. They should be cut straight grained. I am not sure that these bows are any better than the inverted honey-boards. I cannot say that I know either device is of much value. I do not think as much of it as I once did. I am revolutionizing my whole wintering methods.

Honey Gathering Qualities, etc.

It will soon be time for bee-men to begin to brag on big yields, increase, etc. I am satisfied with present success, though convinced that, with experience and suitable apparatuses to manage 30 to 50 colonies, I can do better. I have 30 colonies of bees, and only 2 are working industriously. One is 3 years old, and cast one swarm about June 15; the other is a second swarm from a 3-year-old colony. Now, if these 2 colonies can find honey to gather, why do the other 28 colonies take it so easy? They work some, and all except this second swarm have sections over the brood-chamber, and plenty in which to store all they could gather, though ever so energetic. I remove all of the sections as soon as capped, and new ones, with starters of natural combs, put on; and if there should be a few uncapped sections at the outside of the honey-rack (I use the Langstroth hive), I return them in the new rack to be filled and finished. I never tier them up, but remove and re-crate them for surplus, using two-pound nailed sections. Some of my colonies, of apparent equal strength, will store double the surplus honey of one setting close by its side. I do not understand why. Reasoning from cause to effect, there is a why, and bee-men whom we (beginners) look to as "the wise men of the East," ought to give us a satisfactory explanation. Mrs. Harrison says: "No good bee-keeper of the present day allows his bees to hang out and not work." I have seen a good many such cases this summer, and generally in box hives, though not always. What is to be done to such or with such bees to get them to work? They will not swarm nor work in boxes, but some store honey outside of the hive under the bottom-board, or against some building near which the hive is. Would you consider 50 pounds per colony, spring count, a reasonably good average? For profit, would you run bees for comb or extracted honey, or both? If both, when do you begin to extract? Would you extract surplus or section honey, or both? If extracting were done after basswood, and the bees did not fill up the combs again, what would you winter them on?

T. F. KINSEL.

Shiloh, O., July 14, 1884.

ANSWER.—Your questions are all pertinent to success in our business; and I will answer them in the best way I can. The great difference in the working of these two colonies, compared with the rest, proves too much to be accounted for by traits of the bees. It seems likely that they have found, by accident, some reservoir of nectar or honey, that the other colonies have not found. We know there is an appreciable difference in the honey-storing powers in different strains and colonies of bees—one great enough that one colony of apparently the same strength, condition, and opportunities, will store twice as much surplus as another; and this difference is based upon mental and physical characteristics

which it is worth while to breed from. But when we see such a radical difference as nothing on the one hand, and lively storing on the other, we can hardly account for it entirely upon characteristics. When Mrs. Harrison says, "No good bee-keeper of the present day allows his bees to hang out and not work," she undoubtedly means when there is work to be done. No matter how good the bee-keeper or his bees are, when there comes a sudden cessation of honey flow, strong colonies will lay outside the hive in festoons, when the weather is excessively warm. This is, no doubt, best.

They will, however, build no comb outside the hives. When bees do this outside work, you may rest assured that they have not sufficient inside room in proper communication with the brood department. Whether 50 pounds per colony, spring count, is a reasonably good average or not, depends upon whether it is comb or extracted honey, how much capital and labor is expended, how good the season, etc. Whether it is satisfactory to the producer or not, only each individual producer is the proper one to judge. Whether I would run colonies of bees for comb or extracted honey, would depend entirely whether my apiary was at home or abroad; whether situated in a climate especially adapted to comb building or not; whether I wished to keep strictly pure Italian bees or not; or whether my market was general or local. In Northern Michigan, especially in an apiary away from home (an out apiary), I would produce extracted honey. In any locality where the honey is mostly dark, I would produce extracted honey. In a location where I was forced to ship my production great distances, I should for that reason favor the production of extracted honey. I should never produce but one kind in one apiary, unless the local trade consumed my crop, then I would not if I had more than one apiary. I should begin to extract as soon as the stored honey is thoroughly ripened—say when it is from $\frac{1}{2}$ to $\frac{2}{3}$ capped over; much depending on the condition of the atmosphere and stage of development of the blossoms from which it is gathered. I should never extract from sections, but from full-sized Langstroth frame, from a super above the same size of the brood-chamber, always using the two-story system. In a small apiary where you have plenty of time, and are running for comb honey entirely, you can often advantageously extract some honey from the side brood-combs, near the close of an excessive flow, with which to supply a small local trade. I am always glad to have my bees come out in the fall without sufficient stores to winter on; but not if caused by a dearth, but by such management as has placed the honey in the surplus receptacles, and upon the market; which condition of things allows me to feed sugar syrup without first having to go through the trying ordeal of extracting their honey after all gathering is past, when bees are inclined to rob and be cross.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, {
Monday, 10 a. m., July 21, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The honey harvest is now virtually over, in this part of the country, and the yield is below the average of former years. The average, per colony, in Ohio and Indiana is, perhaps, 30 to 40 lbs.; in Kentucky it may come up to 100@110 lbs. per colony. I can only speak from observations obtained so far, and my figures may not be entirely reliable. Sugar being cheaper than it has been, perhaps, for the last 20 years, we cannot expect honey to be high; but there was a short crop, and it would be my advice to bee-keepers not to be in too much of a hurry to dispose of their product. The demand for extracted honey is fair, and to all appearances, gradually improving. It brings 3@9c. per pound on arrival. There is a small demand for comb honey, but we had small offers only, and a good deal could be sold. It brings 14c. per pound on arrival.

BEESWAX—Offers plentiful at 30@32c. on arrival. C. F. MUTH, Freeman & Central Ave.

NEW YORK.

HONEY—Present sales of comb honey are slow and will be until the new crop arrives. We quote: Fancy white 2-lb. sections, glassed, 13@14c.; fair to good in 2-lb. sections, glassed, 11@12c.; dark and in 2-lb. sections, glassed, 10@12c. No 1-lbs. in this market. Extracted, white, 8@9c.; dark and buckwheat, 7@8c.

BEESWAX—Prime yellow, 34@35c.

MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15c. and 2½-lbs. to 2½-lbs. from 10@12c. No 1-lbs. in the market. Extracted, 8@10c.

BEESWAX—35c.

BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY—This week we have had liberal receipts of comb honey, and the prices are irregular. As a rule, the honey is of first quality, and put up in good shape; a gradual improvement is noted in this respect. Prices range from 14@15c. for the best, occasionally a case sells for more than that, but it is in a retail way. The extracted honey is still sluggish, at nominal prices—6@8c. per pound.

BEESWAX—Fair receipts; prices, 30@37c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—The market is quiet and weak. There is considerable white extracted on market, thin and watery, and showing a tendency to candy. Such stock cannot be placed much over our inside quotation. Sales of thin and water white have been made at 5½c. In a retail way choice extracted of heavy body is offering at 6½c. White to extra white comb, 14@17c. Dark to good, 10@13c. Extracted, choice to extra white, 5@6½c. Dark and candied, 4c.

BEESWAX—Wholesale, 27@30c.

STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY—No change to note in prices. As predicted in last report, the temporary activity was only accidental, and last week has been dull. Some little new honey is now arriving, but it falls as yet to tempt buyers to any extent. I look, however, for a very large demand a little later, and would suggest shipment by Aug. 1, of all that is ready in quantities to justify. I have still a few more "Suggestions on Packing and Shipping Honey," to mail free on application. I will also furnish shipping stencils free to any one desiring to ship to me.

BEESWAX—Nominal, at 30@35c.

JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY—Steady; demand and supply both small. Comb, 12@14c. per lb., and strained and extracted @26½c.

BEESWAX—Firm at 32@32½c. for choice.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—The honey market is fairly active on best white 1-lb. sections at 18c.; 2-lb. best white not quite so active at 17c.; 1-lb. sections sell quickly on arrival, and often are sold to arrive. Second qualities continue very dull—are hardly salable at any price. Extracted is not wanted.

BEESWAX—Scarce at 35c.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—We quote comb honey in 2-lb. sections 17@18c.; extracted, 7c.

GEO. W. MEADE & CO., 213 Market St.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

We now club the *British Bee Journal* and our Monthly for \$2.50, or it and the Weekly for \$3.50.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an additional present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75. Or, bound in cloth, with Weekly, \$3.00; with the Monthly, \$2.00.

Do not let your numbers of the BEE JOURNAL for 1884 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Create a Local Honey Market.

Now is the time to create Honey Markets in every village, town and city. Wide-awake honey producers should get the Leaflets "Why eat Honey," (only 50 cents per 100) or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully all over the territory they can supply with honey, and the result will be a demand that will readily take all of their crops at remunerative prices. The prices for "Honey as Food and Medicine" are as follows:

Single copy 5 cts.; per doz., 40 cts.; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Convention Hand-Book.

It is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programine of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Bingham Corner.

MARENGO, ILL., June 18, 1884.
The Doctor Subdues All.—Mr. T. F. BINGHAM, Dear Sir:—I've used the "Doctor" till its all daubed up with bee-glue, and although at first sight I thought I did not like anything so large, I could not now be induced except by the direst poverty, to do with any thing smaller. As a matter of "economy" I much prefer the "Doctor" to any of the cheaper smokers, of which I have worn out several. The "Doctor" has entirely cured me, so that I am now a Bingham man, as my wife always has been. If the somewhat vague remark in your letter means that nothing was charged for the Smoker sent, except the reading of your letter, I shall be very glad of another "Doctor" for the money sent, so that my wife won't take mine from me. Bees just booming on white clover.
 Yours Truly, C. C. MILLER.

WOODARD'S LANDING, Wash. Ter.
The Best Smoker.—To BINGHAM & HETHERINGTON, Abronja, Mich., Dear Sirs:—Find enclosed money for 3 Conqueror Smokers, which please send per mail—one to each, Dr. Buleh, J. M. Londerback, and H. A. Townner. The Conqueror is the best Smoker I ever used. Respectfully,
 May 17, 1884. H. HASTINGS.

DRESDEN, TEX., May 28, 1884.
Conquer the "Cyps."—T. F. BINGHAM, Abronja, Mich., Dear Sir:—Enclosed find \$1.75, for which please send, per mail, one "Conqueror Smoker" to Major H. A. High, Waxahachie, Tex. He bought a Cyprian Queen from me, and the Bees have worsted the old gentleman. I told him that the Conqueror Smoker would conquer the "Cyps," as I had tried one for two years, and "it never failed." Respectfully,
 B. F. CARROLL.

BORODINO, N. Y., Aug. 15, 1882.
Cyprians Conquered.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. Respectfully,
 G. M. DOOLITTLE.

Prices, by mail, post-paid.

It makes the finest extra thin Foundation for comb honey. For Sale by
ALFRED H. NEWMAN,
923 West Madison Street. CHICAGO, ILL.

WE CALL

the attention of all wanting A No. 1 BEES, Italian, Cyprian or Hybrids, to the following, from one well-known to the readers of this Paper:

"I have never seen a case of foul brood; my bees are entirely healthy, and have always been so, and are O. K. in every respect."
GEO. B. PETERS, M. D.

We can furnish any number of Colonies of the above Bees, and will warrant safe delivery and satisfaction.
N. B.—No Bees will be sold by us, for any consideration, from any apiary that has ever had a case of foul brood in it. For prices and particulars, send to

FLANAGAN & ILLINSKI,
Lock box 995, Belleville, St. Clair Co., Ills.
18A13T 6B3T

IF YOU WANT A VEHICLE,

SEND A POSTAL CARD TO THE
COLUMBUS BUGGY CO.

COLUMBUS, OHIO.

When Catalogue and name of nearest dealer, where our SUPERIOR Vehicles can be seen, will be sent.

We have the LARGEST FACTORY in the world for manufacturing first-class and SUPERIOR

Buggies, Phaetons, Light Carriages, Surrey Wagons,

AND OUR POPULAR

American Village Carts,

the latter most perfect and free from horse motion.

✶ We make our own wheels from the best timber (sawed by our own mills) that can be obtained from the hills of Southern Ohio—famous for the second-growth bickory.

Any of our readers who will inclose 18 cent stamps, in a letter to the **COLUMBUS BUGGY CO.,** Columbus, Ohio, will receive in return a beautiful engraving in colors representing an "Austrian Scene," and their manner of traveling in that country with ostriches as a motor. 24A18T

HEDDON'S
COLUMN.

BEST GIVEN
COMB FOUNDATION.

Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8¼x16¼, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

- One Hive complete for comb honey.. \$3.00
- (The above will contain two cases complete with sections).
- The above Hive complete for extracted honey.....\$3.00
- The above Hive complete for both in one..... 4.50
- One Hive in the flat..... 2.00
- Five or over, each..... 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4¼x4¼x6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

QUEENS!

Our New Strain,

Also IMPORTED ITALIANS!

Take your choice. Prices:

- Tested, to breed from.....\$ 3 00
- Untested..... 1 25
- Untested, after July 1st..... 1 00
- Untested, (per doz.) after July 1st..... 11 00

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.

Address,

JAMES HEDDON,
DOWAGIAC, Cass County, MICH.

Sixth Thousand Just Published!
New and Enlarged Edition
OF
BEES and HONEY,

OR THE
Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey-Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure.
T. F. BINGHAM.
Abronia, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN.

Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ills.

A Liberal Discount to Dealers, by the Dozen or Hundred.

BEE-KEEPERS, before ordering your
APIARIAN SUPPLIES,

Send for our large Illustrated Catalogue, sent free to any address.

10A24 E. KRETCHMER, Coburg, Iowa.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

Given's Foundation Press.

PUBLIC SENTIMENT affirms that the PRESS is SUPERIOR for making Comb Foundation either in Wired Frames or for SECTIONS, and insures straight and perfect combs, when drawn out by the bees. Send for Circular and samples.

D. S. GIVEN & CO.,

1A Bff HOOPESTON, ILL.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.

ALFRED H. NEWMAN,
923 West Madison Street,
CHICAGO, ILLINOIS.

A PRIZE. Send six cents for postage, and receive free, a costly box of goods which will help you to more money right away than anything else in this world. All of either sex, succeed from first hour. The broad road to fortune opens before the workers, absolutely sure. At once address, TRUX & Co., Augusta, Maine. 4A1Y

CHAS. DADANT & SON,

5AB1y HAMILTON, Hancock Co., ILL.

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE.

PATENTED, MAY 20, 1879.

The Original
BINGHAM
Bee Smoker

Patented, 1878.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 will not be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To sell again, send for dozen rates to

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects: Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quiet-ing and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, bound in cloth, \$1.00; 2 copies for \$1.80; 3 copies for \$2.55; 5 for \$4.00; 10 for \$7.50. Paper covers, 75 cents; 2 copies for \$1.40; 3 copies for \$2.00; 5 for \$3.00; 10 for \$5.00.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premium for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey! by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-Keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees,—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bleuen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping.—A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY ALLEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way to rear Queens, etc. Price, \$1.00.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Price 5c.

Poul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either English or German.

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Hibbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XX.

CHICAGO, ILL., JULY 30, 1884.

No. 31.

ESTABLISHED 1862
PUBLISHED BY
**THE AMERICAN
BEE JOURNAL**
PUBLISHED EVERY WEDNESDAY, BY
THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

"Honor to Whom Honor is Due."

We have received the following from W. Z. Hutchinson, being upon the above subject:

After Mr. Heddon has battled as he has for the "pollen theory," borne up bravely under the slurs and sarcasm which has been hurled at him, met all arguments that have been brought forward, and, best of all, after having conducted extensive experiments to prove the theory; and now, just as success appears to be poised upon her bright wings above his head, for Mr. Fradenburg to step forward with claims of priority, appears to me to be unjust, and I cannot resist the temptation of commenting on the subject.

When Mr. John Longmate, last March, coolly gave in the BEE JOURNAL an illustrated article embracing principles already illustrated and described by Messrs. Heddon and Alley, and never mentioned their names, I said to myself, "there is cheek;" but this claim of Mr. Fradenburg, of being "head-and-neck ahead" of Mr. Heddon regarding the "pollen theory," caps the climax. Has Mr. F. so soon forgotten that Mr. Heddon reported, about a year and a half ago, how he (Heddon) produced diarrhoea at will, by feeding stores well mixed with flour for pollen? Mr. Heddon has made and reported at least three as conclusive experiments as the one reported by Mr. F. on page 374; and why Mr. F. should consider his the first experiment is beyond my comprehension, unless it is the first one that he believed to be proof.

It is, perhaps, natural that each should look upon his own experiments as the most conclusive. Many regarded Mr. Heddon's experiments as proof—some did not. Mr. Pond did not, and he views Mr. F.'s experiments in the same light. Mr. F.'s experiment resulted in exactly what Messrs. A. B. Mason, Kohnke, Oatman, Heddon, myself, and many others would willingly have staked our reputation upon, that it would;

but because Mr. Pond put him (Fradenburg) in mind of it, it is simply preposterous that he should claim the honor of priority. Dr. Tinker would not allow that.

I do not wish to be misunderstood. Others may have thought of the "pollen theory" before Mr. Heddon did, but what have they done?

The "pollen theory." Theory to whom? Theory to those who have no proof but somebody's word. Knowledge to whom? To those who have tested it over and over again, year after year. To the mass of beekeepers it is yet a theory, and will so remain until the common voice says, "scientific fact."
Rogersville, Mich.

In reference to Mr. Longmate's illustrated article, we must in justice state that both the illustration and article were in our drawer awaiting room for an insertion in the BEE JOURNAL for several months before they appeared.

Mr. Fradenburg's assertion that he was the discoverer of the pollen theory is, of course, not proven—merely asserted. Upon looking for the proof, we find on page 374, that he only claims to have started his experiments "last fall," while Mr. Heddon had then been writing upon that theory for two years.

Inasmuch as we have placed Mr. Fradenburg upon record, by publishing his claim to be the author of "the pollen theory," we now kindly call upon him for the proof, which, of course, he must have (or thinks that he has) or he would never have dared to make his bold assertion. Until he has sufficient time to present his reasons for putting forth the claim, let all suspend judgment.

We cannot refrain here from giving a caution to all writers for the BEE JOURNAL, to be sure to make no assertions which they cannot substantiate, in the most satisfactory manner—no matter what may be the subject under consideration. To do otherwise often engenders strife and confusion, as well as leading to ill-feeling and contempt.

Local Convention Directory.

1884. Time and place of Meeting.
- Aug. 6.—Lorain Co., O., at Elyria, O.
O. J. Terrell, Sec., North Ridgeville, O.
- Aug. 2.—Gibson Co., Tenn., at Trenton, Tenn.
T. J. Happell, Sec.
- Aug. 13.—Northeastern Ky., at Covington, Ky.
G. W. Cree, Sec.
- Aug. 19.—N.W. Ill. & S.W. Wis. at L. Highbarger's,
J. Stewart, Sec., Rock City, Ill.
- Oct. 11, 12.—Northern Mich., at Alma, Mich.
F. A. Palmer, Sec., McBride, Mich.
- Oct. 15, 16.—Northwestern, at Chicago, Ill.
W. Z. Hutchinson, Sec.
- Nov. 25.—Western Mich., at Fremont, Mich.
Geo. E. Hilton, Sec.
- Dec. 3.—Southeastern Mich., at Adrian, Mich.
A. M. Gander, Sec.
- Dec. 10, 11.—Michigan State, at Lansing.
H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

We have received a copy of a pamphlet entitled "The Poulterers' Guide, for treating diseases of poultry, giving cause, symptoms, and remedies for their cure; also, how to caponize fowls, and feed and rear chickens hatched in an incubator." It is a handsome book, and well worth the price (25 cents), for it is full of information valuable to every breeder of poultry. It is written by Mr. C. J. Ward, the editor of the *Poultry Journal*, of Chicago. We can supply it at the publisher's price.

A Bee-Keepers' Association has been formed for Hamilton County, Texas; Constitution and By-Laws have been adopted, and officers elected. Mr. W. M. Sparkman is president, Mr. C. S. Doubleday is secretary.

We have received the Premium List of the Tri-State Fair, which will be held at Toledo, O., Sept. 8 to 13, 1884. Dr. A. B. Mason, of Wagon Works, O., is the superintendent of the Apiary Department. The premiums are substantially the same as last year, and amount to \$219. The Doctor will send a copy of the Premium List to any one who desires to have it.

Honey Dew.

In a recent issue of *Gleanings in Bee-Culture*, a correspondent has an article on Honey Dew, and asks Prof. Cook for an explanation, as follows:

"I noticed an article in *Gleanings* for June 15, from E. R. Root, about honey-dew. I had a little experience in that line this season, which may be of interest to your readers. About the 8th or 9th of this month, I went to the pasture after the cows, when, near the woods, I heard a tremendous roaring of bees, and, thinking a swarm was passing over, I looked in every direction, but could see no bees. As I got nearer the woods, the sound seemed to increase in volume. Just in the edge of the woods, I saw a young hickory tree in blossom, and thinking the bees might be working on that, I went up to the tree, when I found the leaves completely covered with what is known as honey-dew. The trees were fairly alive with bumble-bees, honey-bees, yellow-jackets, wasps, hornets, and flies; the leaves were so covered with the honey-dew, that they had the appearance of being varnished.

"Looking up to the top of the tree, I saw myriads of small insects, which I took to be aphides or plant-lice; but on looking closer, I discovered that they were small, striped bugs, which seemed to be gathering honey-dew, with the rest. After looking around and finding the honey-dew on oak, maple, elm and beech trees, I went on over to friend Phelps', taking some of the leaves with me. I found him at home, and together we went back to the woods, to see if we could discover the source of the honey-dew. After looking at the trees for some time, we about came to the conclusion that it was a natural secretion of honey in the leaves of the trees. While we were talking and watching the bees, we noticed a bee running along the branches, stopping from time to time to gather something. Upon pulling down the limbs and looking closely, we discovered that they were literally covered with the scaly aphid, or bark-louse. Upon close inspection, we discovered a small drop of clear fluid exuding from the backs of the lice. This was what the bees were gathering on the branches, and it was falling all the while in a fine spray, it being visible on our coats when we came out into the sunshine. Now, this scaly aphid assumes the color of the bark of whatever kind of tree they are working on, and being quite small it requires close inspection to see them. I think we would not have seen them but for the bees working on the branches. Now, may not this, in a measure, account for some of those mysterious falls of honey-dew that we hear of? The flow of honey from this source lasted about two or three weeks, or until the bees began to work on white clover, and perhaps a little longer, as I find, in taking off honey, the boxes are spotted more or less with the honey-dew, while some are filled entirely with it. As to quality, all that I have

to say is, that if any person can eat it, he is capable of eating anything. It looks nasty, it tastes nasty, and it is nasty; and what to do with it, I do not know, for it is not fit for a hog to eat.

"Now, as I am rather ignorant of the subject of entomology, will Prof. Cook, or some one else who is posted, inform us of the different stages of the bark-louse, and about the time that they remain in each stage, and whether they often produce this so-called honey-dew? This is a new thing to me, having never in my life noticed it before, and I would like to know how many different kinds of insects and worms are capable of producing honey-dew."

Prof. Cook has prepared an article on this subject, as follows:

From very numerous inquiries as to name, habit and remedies regarding this louse, I have for some weeks intended writing you; but an overwhelming amount of work has prevented, until your letter drives me to it. Pres. E. Orton writes me that this insect is killing the soft maples, and wishes a remedy. Mr. O. J. Terrell, from North Ridgeville, says they are affording much nectar which attracts the bees and seems excellent, and wishes to know if it is probably wholesome. The editor of the *Coldwater Republican* asks if there is any way to save the maples. These are samples of a score of inquiries coming thick from Ohio, Illinois, Indiana and Michigan.

DESCRIPTION.

The maple tree scale or bark-louse (*Pulvinaria innumerabilis*, Rath.) consists, at this season, of a brown scale about five-eighths of an inch long, which is oblong, and slightly notched behind. On the back of the scale are transverse depressions, marking segments. The blunt posterior of the insect is raised by a large, dense mass of fibrous, cotton-like material, in which will be found about 800 small, white eggs. These eggs falling on to a dark surface, look to the unaided eye like flour; but with a lens they are found to be oblong, and would be pronounced by all as eggs, at once. This cotton-like egg-receptacle is often so thick as to raise the brown scale nearly a fourth of an inch. These scales are found on the under side of the limbs of the trees, and are often so thick as to overlap each other. Often there are hundreds on a single main branch of the tree. I find them on basswood, soft and hard maple, and grape-vines, though much the more abundant on the maples.

Another feature at this mature stage of the insect, is the secretion of a large amount of nectar. This falls on the leaves below, so as to fairly gum them over, as though they were varnished. The nectar is much prized by the bees, which swarm upon the leaves. If such nectar is pleasant to the taste, as Mr. Terrell avers, I should have no fear of the bees collecting it.

From the middle to the last of June, the eggs begin to hatch, though hatching is not completed for some weeks

after it begins, so we may expect young lice to hatch out from late in June till August.

The young lice are yellow, half as broad as long, tapering slightly toward the posterior. The seven abdominal segments appear very distinctly. The legs and antenna are seen from the other side. As in the young of all such bark-lice, the beak sucking-tube, is long and thread-like, and is bent under the body till the young louse is ready to settle down to earnest work as a sapper. Two hair-like appendages, or setæ, terminate the body, which soon disappear.

The young, newly-born louse, wanders two or three days, then inserts its beak into the leaves where it first locates. It prefers the middle under-side of the leaf. In autumn, the much-enlarged louse withdraws from the leaves and attaches to the under side of the twigs and branches; while on the leaves, they sometimes, though rarely, withdraw their beak, and change their position. In winter, the young lice remain dormant; but with the warmth of spring, as the sap begins to circulate, the lice begin to suck and grow. The increase of size, as the eggs begin to develop, is very rapid. Now the drops of nectar begin to fall, so that leaves and side-walks underneath, become sweet and sticky. In the last *Ohio Farmer*, Mr. Singleton states that leaves of the maple do secrete honey-dew. It is on the leaves, and there are no aphides or plant-lice. Mr. Singleton's honey-dew is, without doubt, this same nectar from bark-lice. Had Mr. S. looked on the under-side of the branches, instead of on the leaves, he would have found, not aphides, to be sure, but bark-lice.

If these spring lice are examined closely with a low magnifying power, a marginal row of hairs will be seen.

MALES.

Some few of the scales, in late July, will be noticed to be dimmer, lighter in color, and somewhat more convex, above. In these, the setæ do not disappear, but may be seen projecting from the posterior end of the scale. In August, the mature males appear. These have the scales, have two wings, and are very active. Although the females are to continue to grow till the next June, coition now takes place. The males are seen for two or three weeks, though each individual probably does not live as many days. It is quite probable that, as in case of production of drone-bees or aphides, the males of these scale-lice are not absolutely necessary to reproduction. We know they are not in some species.

REMEDIES.

By use of a long-handled broom, dipped in strong lye or soap-suds, the thickly gathered lice could be readily removed, on the lower side of the branches, at any time in the spring. This would kill the lice, and prevent egg-laying, or destroy the eggs already laid. The earlier this is done in the spring, the better. The position of the lice, on the under-side of the branches, makes this more practicable, if not the only practicable rem-

edy at this season. On a few trees, or on small trees, this is no serious task. If this is neglected, or is thought to be too great a task, the trees may be syringed in early July, just when the young lice are most susceptible, with the following: One quart soft soap, ten quarts water, and one quart kerosene oil; stir all together. This can be thrown on with a fountain pump. As the lice are mostly on the lower side of the leaves, it should be thrown from below, upward. This also applies to other species of bark-lice, which are very common this season. The basswood, the tulip (see my Manual, p. 249), the elm, the hickory, the blue-ash, etc., are all suffering from bark-lice, much like the above, except that the cottony substance is wanting. It is a comforting truth, that all these species are often destroyed by their enemies before they entirely kill our trees, though they often do great harm.

Bee-Keeping in Cuba.

Mr. A. J. King has written the following very interesting letter to his paper, the *Bee-Keepers' Magazine*:

The average Cuban bee-hive consists of a box 10 to 12 inches square, and 5 feet long, nearly always open at both ends; often instead of boxes, hollow palm logs about the same capacity and length are employed. These hives always occupy a horizontal position, sometimes on the ground, but oftener on a rude frame-work about 3 feet high, driving down crotched stakes about 4 feet apart, and as long as is deemed necessary to accommodate the number of hives owned by the bee-keeper.

Long poles, usually of bamboo, are stretched from crotch to crotch, the whole length of the apiary; these poles supporting the ends of the hives.

The bees usually build their combs continuously from one end to the other of these hives, and often project them some distance beyond the ends of the hive, making combs 6 and 7 feet long, and only from 10 to 4 inches wide. We transferred some of the log hives, in Puerto Principe in the dense forest, which were placed on the ground, and the bees had extended their combs several feet beyond the ends of the hive into the thicket. They were connected with fine brush and vines, and so firmly attached that after smoking the bees back into the hive, we had to sever all these attachments with a sword, when we cut off the combs even with the end of the hive, and placed them in a basket, which made a feast for a dozen men who had come on horse-back six miles to witness the operation. This honey was pure Campana, freshly made, and was the most delicious we have ever tasted. We transferred quite a number of these hives into movable frames in different parts of the Island, and it was amusing to witness the different expressions depicted on the faces of our

Cuban friends, at seeing the bees handled as though they were harmless flies. Extreme doubt mingled with fear, deepened into astonishment, ending in surprise, admiration and joy.

On one occasion, after handling some Italians in a manner greatly exceeding their expectations, they declared that their "creoles" (native bees) could not be thus handled with impunity. So we selected a fine, populous colony, occupying one of the long board hives described above. We carried the hive under the shade of an orange tree, about 20 feet from the apiary, laid two small sticks on the ground, and stood the hive on end on these sticks. We then took an empty hive of the same dimensions and placed on top of this, one containing the bees, the top of the empty hive extended over 10 feet high, and was held in place by the branches of the orange tree. The combs in the lower hive extending from end to end, it was a matter of only a few minutes to drum and smoke all the bees from the full into the empty hive, then putting a movable-frame hive on the old stand, and spreading a cloth in front, we dumped all those bees in a heap in front of the hive; and soon all entered and clustered on some sheets of wired foundation previously placed in the hive. We then removed the combs from the drummed hive, placed the brood in frames and gave them to their original owners in the new hive, and in a couple of days removed it to the Casanova apiary—one and a half miles distant, where it has since multiplied to 5 colonies.

From what we have said it might be inferred that the Cubans are far behind our own countrymen in the management of bees; but leaving out of the question our progressive bee-keepers, and confining ourselves to those who still use the log gums and box hives with stationary combs, and tried by this rule, the Cubans are far in advance. They have less superstition, and manifest more intelligence in their work; they never kill their bees to get their stores, but smoke them from one end of their long hives clear into the centre, then cut out the combs until the brood is reached, then from the other end, perform the same operation, thus saving the brood and securing the honey instead of killing the "goose that laid the golden egg."

The honey press is made as follows: A solid log, about 2 feet in diameter, and 12 feet long, is hollowed out for about 8 feet from one end into a complete trough or shell, holding often 2 or 3 barrels. The remaining 4 feet is cut down squarely for about 6 inches, forming a cavity holding about two bushels of comb honey. A wooden follower closely fitting into this cavity is placed on top of the combs, and a long lever fastened into the end of the trough, is brought down onto the follower, and the honey is all pressed out and runs into the trough, leaving the wax in the cavity, from whence it is collected for market.

In the region about Puerto Principe large numbers of these old honey

campes are to be seen, where, previous to the war, from one to three thousand hives were worked in single apiaries, and where those marvelous quantities of honey and wax came from.

The native bees in Cuba are the common black, imported from Spain more than a century ago. They work vigorously all the time, and under favorable circumstances, produce marvelously, forming a standing contradiction to that old lying whim, that bees will work in warm climates, only enough to supply their own demands.

There is another bee, indigenous to Cuba, which produces a very nice honey, but whose habits are entirely different from any bee our readers have ever seen. Of these we propose to speak hereafter.

Bees & Honey at the London Health Exhibition.

A correspondent in the London *Horticultural Journal* remarks as follows on the Bee and Honey Exhibits, Honey Biscuits, the use of the Magic Lantern as an aid to apicultural lectures, etc.:

A few words will here be in season respecting the exhibits in connection with bees and bee-keeping at the Health Exhibition. All those interested in honey and bees should not neglect to pay a visit to this department. The second turning to the right after entering the Exhibition at the main entrances in Exhibition Road brought us into the midst of a very good collection of appliances and products in the shape of honey, wax, etc. The first thing to attract attention is a capital model of a swarm of bees. It is so good that at a little distance it is like a real cluster suspended from a branch. There is a fair display of honey, both in the comb and in bottles. The extracted honey is nicely put up, and we must hope that the public will learn to appreciate pure English honey, and to cease to countenance the importation of adulterated foreign stuff.

Messrs. Huntley & Palmer, the famous Reading firm, have lately brought out some exceedingly nice biscuits, called "Honey Drops." Visitors must not fail to taste them, and they will certainly appreciate this new biscuit. Immense quantities of honey are now purchased by this firm for the manufacture of this pleasant food, and this will help to provide a market for English produce. Honey is largely employed in other manufactures, and we should have liked to have seen more exhibits showing the utility of honey in foods and medicines, and so show it is conducive to health. Among the many interesting exhibits is one which, although in its present state most instructive, might be much enlarged and improved.

We refer to Mr. Abbott's case of various natural objects explanatory of the science of bee-keeping. The

various queens, workers, and drones are preserved and thrown together with the varieties of comb, queen-cells, etc. The depredators of the hive are shown in the shape of the wax moth and its grubs, and the damage done by these loathsome maggots is shown by a piece of comb tunnelled by the moth grubs and covered with their spider-like web. Much of the natural economy of the bee-hive can be gathered by a careful inspection of this case. With this class of instructive exhibits must be connected the magic lantern slides shown by Mr. A. Watkins, of Wilcroft, Hereford. These are most instructive, and some of them as amusing as they are interesting. The queen, worker, and drone are capital photographic slides, and vivid recollections of various cottage apiaries come to the mind when looking at the amusing picture of "All Dead but One." By the use of such slides, a lecture on bee-keeping is made doubly interesting, and such illustrations enlarged on the sheet are highly appreciated.

We have ourselves, when lecturing on bee-keeping, used such slides, copied from the appearances under the microscope, but these photographic slides are a great improvement on pen-and-ink sketches. We must not neglect to give the due meed of praise to those who, at much expenditure of time and trouble, have placed such good collections of bee-furniture on the stages. Messrs. Neighbour, Abbott, Overton, Baldwin, and others have such good exhibits, that the various schools of bee-keepers must find sufficient to appease any amount of longing for what is good and substantial. Smokers, feeders, extractors, hives, supers, and a host of other necessities and luxuries are all there represented.

How the "Queen" was Captured.

We allude to the Queen of England, and not the queen bee. The following from the *New York Sun* is sent to us by a correspondent, who desires to have it in the *BEE JOURNAL*. As it gives some facts about the way in which American honey was introduced into England, it will, no doubt, be read with interest. Some of the items mentioned, we know are true; but some of the assertions we have not so much confidence in. While all of the items *may* represent very nearly the facts in the case, as we do not know, we cannot fully indorse them, but give the article for what it is worth:

"While California is the greatest bee-ranching or honey region in the world, owing to the excellence of its climate, and the endless variety of of its honey-yielding flowers, the quality of its honey does not excel, even if it equals, that of the honey produced in New York State," said a large wholesale dealer.

"One of the most extensive bee-culturists in this or any other country," he continued, "is Capt. Hetherington, whose apiaries along the Cherry Valley Creek, in Schoharie county, annually turn out over 100,000 pounds of the choicest honey. It takes nine men and two steam saw mills five weeks to prepare the lumber for the boxes in which the honey is made by his bees. Nearly 150,000 panes of glass, about six inches square, are used in these boxes. Capt. Hetherington has at work, this season, nearly 2,500 colonies of bees. These are not all on his own premises, but are scattered among the orchards and fields of farmers along the creek, to whom he pays a rent for the privilege of his bees working in the clover, buckwheat, or whatever blossoms are in season on the farm. The care of these bees does not fall upon the owner of the land. Capt. Hetherington keeps men and teams constantly employed looking out for them. He has received as much as \$26,000 for one season's crop.

"Another large York State bee-keeper is C. B. Isham, of Peoria. Up to 1879 there was no market in England for American honey. The English dealers would not handle it, and the periodicals devoted to the bee-keepers in that country, cried it down in every possible way. The reason for this was that they knew the superiority of American honey, both in flavor and appearance, over the British article, and were aware that if it was once introduced in London, it would be a great blow to the trade in the home supply. There was a smart Yankee named Hoge working for a grocery in this city, and he assured his employers that, if they would give him the commission, he would manage to place American honey on the English market. A large lot of Isham's honey, which the firm was then handling, was packed, just as it came from the hives, and Hoge was sent to London with it. He found he needed all his Yankee ingenuity and acuteness, for he met with universal opposition among the dealers. He labored with them for weeks to no purpose. In conversation one day with the proprietor of the hotel at which he stopped, the latter told Hoge that if he could manage to have his honey introduced upon the table of Queen Victoria, it would solve the problem at once, for if she was pleased with it, she would communicate to Hoge through the Lord Steward. This communication once made public, would make American honey the fashion in England.

"A former Lord Steward was a friend of the hotel keeper, and was at that time engaged largely in the manufacture and sale of pickles. This man the landlord introduced to Hoge. They dined together. Hoge gave the pickle man an immense order for his goods, to be sent to the American grocer. More wine followed, and before the ex-Lord Steward went away, he promised to use his influence to have the American's honey introduced on the royal table. He succeeded in inducing the then Lord Steward, Sir

John Cowell, to accept a box of honey for the Queen, and to serve it on her table. The Queen was so delighted with the honey that she directed the Lord Steward to present her thanks to the donor, to order a supply of ten cases at once, and to keep American honey constantly on the royal table.

"Hoge lost no time in making this communication public. The consequence was, that the opinion of American honey changed at once, and Hoge came back to New York secretly laughing at the Britishers, but rejoicing over an order for 500,000 pounds of American honey for the English markets, which he carried in his pocket. The demand for it has increased ever since, and the trade that was started in New York State honey is now largely shared in by the California product.

The Use of Comb Foundation.

A correspondent of the *Farmers' Gazette*, Dublin, upon the question of comb foundation for storing honey and for brood says:

The Germans, for the past twenty years, have used impressed sheets of wax as a foundation for comb. The bees thin out the so-called foundation to the natural thickness, and use up the shavings to form the walls or cells in which the queen deposits eggs and the workers store pollen and honey. The bees thin it so accurately that epicureans cannot tell comb honey with such foundation from that wholly made by the bees. The most promising use of comb foundation is in the brood chamber. It is astonishing how rapidly the bees will extend the cells and the queen fill them with eggs, exactly five cells to the lineal inch, or twenty five to the square inch, when used for worker brood solely. The real advantage is to ensure worker brood, and to furnish wax, that the bees may be free to gather honey and store it, instead of elaborating wax.

If we wish to test the actual value of foundation, we select two strong colonies of bees; we supply one with comb foundation and withhold it from the other; we find this last sends fewer bees to the field, as the majority are engaged in the art of wax selection. The other colony, furnished with the so-called foundation, gains much more rapidly in honey, with less food consumed. Foundation is becoming so popular and is made of better substance than formerly, whole sheets can now be used; and when we bear in mind that it takes twenty pounds of honey to produce one pound of wax, it will be seen that the bee-keeper who uses comb foundation largely, has an immense advantage over one who does not. This foundation was originally imported from America, but now it is made in Ireland.

Advertisements intended for the *BEE JOURNAL* must reach this office by Saturday of the previous week.

CORRESPONDENCE

For the American Bee Journal.

Hiving Swarms of Bees.

G. M. DOOLITTLE.

After reading W. Z. Hutchinson's article under the above heading, in a late number of the BEE JOURNAL, I cannot help but think that he and others do not understand how to treat swarms issuing with queens having clipped wings. The ease with which natural swarming is conducted where all the queens have their wings clipped, is one of the greatest reasons I have for clipping queens' wings.

Because the queen has her wing clipped, it does not follow of necessity that the swarm must be hived on the returning-plan, nor that the queen should be lost in the grass or stepped upon as Mr. H. says; for, in an experience covering a period of 14 years with every queen's wing clipped in my apiary, I have yet to step on, or lose the first queen from any cause arising from her having a clipped wing. In fact, I am so well pleased with the plan of natural swarming, with queen's wings clipped, that I am led to give my plan of treating such swarms, so that the reader may compare it with Mr. H.'s, and thus decide which to adopt. If I shall so explain it that any of the cares and burdens of my fellow apiarists are lightened, I shall feel well repaid for my effort in the explanation.

Before proceeding, I wish to say that Mr. H. has given us the best article on hiving bees where the queens are allowed to go with the swarm, that I have ever seen in print; for he gives us a view of some of the hard work, climbing of ladders, despoiling of an orchard by sawing off limbs, etc., which always attends that plan; and had he told us of swarms settling on the large trunks of trees, and in other places where scraping and smoking the bees off was the dernier resort, the picture would have been complete.

For the past five years I have hived very few swarms by the returning-plan, but when I do the plan is thus: When a swarm is seen issuing, I (or Mrs. D.) step to the rear of the hive and then look on the grass to one side of it to see if there are many bees there, thereby indicating the presence of the queen; and if not, step up on that side and glance over the ground in front of the hive. If the swarm has nearly done issuing, the queen is readily found by a little cluster of bees being about her. If just commenced to swarm, look at, or near the entrance where she will be seen running as soon as she comes out. Have on hand a round wire-cloth cage, 1½ inches in diameter by 8 inches long, made by rolling a piece of wire cloth around a stick, and sowing the sides together, when a stopper is to be fitted in each end.

As soon as the queen is seen, place the cage in such a way that she will crawl into it, and if a few bees go in with her, all the better. Now move the old hive back, and place in its place the one which the swarm is to occupy, when the cage with the queen is to be laid near the entrance. Place the old hive where you wish it to stand, or move it up beside the new hive at right angles, *a la Heddon*, as you prefer. Have on hand two sheets, one of which is to be placed on each of the hives on either side nearest the one now awaiting the swarm, so that they can be spread over them should the swarm attempt to enter these hives upon returning, which they rarely will do if the queen, with a few bees, is left at the entrance of the new hive. Leave the queen caged until nearly all the bees have entered the hive (or become clustered on the outside, as they sometimes will do), and are quiet, when you will let the queen go in. By thus keeping the queen caged, you will avoid the difficulty of her running out, and the bees with her, as spoken of by Mr. H.

If they are clustered on the outside of the hive, let them become quiet after the queen is out of the cage, when you will detach a few and start them to running into the hive; then detach more bees, and so on until all have run in.

If several swarms come out together, more sheets are needed, so that if more than the right proportion of bees draw toward one of the new hives placed on the old stands, a sheet can be thrown over until they go as you wish them to. But, as I said at the outset, this plan of hiving does not necessarily follow having the queen's wing clipped, although many prefer it. The simplest plan, and the one I use most, is to go to the woods and cut a light, tough pole, which will reach to the top of my tallest tree, providing that it is not more than 20 to 25 feet high. If swarms attempt to cluster higher than this, I always use the returning-plan above given. Have the large end of this pole sharpened so it can be pressed into the ground when necessary. Near the upper end of it fasten a few dry mullein tops, or a roll of black rags, as large around as your arm, and a foot long, when your pole is ready.

When a swarm issues, proceed to get the queen as before, and when caught, secure the cage to the black bunch at the top by means of a bent wire. Raise the pole in the air, and keep it where the bees are the thickest, when they will often alight on the pole; and if not, they will soon select a spot to alight upon the same as they would if the queen was flying with them, for her presence is known to them just the same as if she had her wing whole and was among them.

As soon as they begin to alight, place the pole in such a position that the queen and black bunch comes in the place they are clustering, and leave it thus while you are preparing a hive for them. When they are partially clustered, raise the pole, or push it up and out, so that the queen and bunch of rags, with the bees on

them, is a foot or so from the limb, when all the bees will cluster with the queen; after which you can carry them wherever you please, the same as Mr. H. does his branch after he has cut it off.

You should also hive them as he tells you, by first detaching a small part of the cluster, and after they start up the call of a "home is found," detach more, and lastly let the queen go in.

No matter in how bad a place they cluster, the operation of getting the swarm on the pole is always simple, and there is no need of being in a hurry, for they cannot go to the woods if left hanging on the pole in the hot sun all day; for should they attempt it, they would soon come back to their queen, as I have often had them do.

Now we will suppose that the second, third or fourth swarm issues before you get ready to hive the first (a thing which very often happens), you have not got to work as did Mr. H. with his fountain pump "till you are almost in despair" to keep them apart, but simply let them cluster on the pole, and you are at liberty to prepare the second, third, or fourth hive, as the case may be, leaving a queen in front of each hive except the first, as that has the queen on the pole. When all are clustered, take the pole and carry it to one of the hives having a queen in front of it, when you will proceed to hive them as at first, till you have got the right proportion of bees for one hive, then go to the next, leaving enough for a colony there, and so on until all are hived as you wish them.

All is done with a perfect ease and certainty, which no other plan can give. I often leave the bees hanging on this pole two or three hours, or till I get other pressing business done, when I hive them at my leisure; the only caution being necessary is to see that the pole is so fixed that it cannot break from the great weight of bees, and that the queens not with the cluster have a few bees with them to feed them, or are otherwise fed.

Again, if I wish to hive two or more swarms in one hive, as I frequently do in the latter part of the honey season, I do not have to hunt out the queens, for one is kept with the swarm, and the others I let go back into their old hive.

One more item, and I leave the subject. Many seem to think there is danger of losing the queen when her wing is clipped, if a swarm issues when the apiarist is not at home; but such is not the case, for some of the returning swarm is sure to find and cluster about the queen if she does not get back. When I return, after an absence, I go over the yard, between each row of hives, looking on the ground, and if a swarm has issued, and the queen failed to return, I find a little knot of bees on the ground from the size of a butternut to that of a goose egg, in which will be the queen. Now comes the perplexing part to many, which is, to find where a swarm found hanging on a limb, or where such a queen came

from. In case of the queen, I leave her where she is until nearly sunset, so there are but few flying bees in the air, then she is taken from the bees, when they will go back to their hive, setting up a joyful hum, after which I let the queen go with them.

In case of a clustered swarm, I give all but a half pint or so of bees, which are kept in a cage till nearly sunset, when they are let out, and tell me, as did the others, just the hive the swarm came from.

In the above I have given a few of my reasons for preferring queens with clipped wings, and I am willing to leave the matter with the readers, to choose which they prefer after having a fair hearing of both sides of the question.

For the American Bee Journal.

Reversible Frames Again.

A. H. DUTTON.

It is now an admitted fact by many apiarists, among their number being some of the largest and most successful honey-producers on the American Continent, that under certain circumstances brood-frames, capable of reversion, possess advantages which do not belong to the ordinary style of suspended frames. Such being the case, the question would naturally arise, with those who are unaccustomed to their use, "What are the most feasible methods of making the various patterns of suspended frame reversible? and what are the conditions under which they can be employed to advantage?"

Without attempting to answer the last inquiry, which has already been done very fully by various writers in the different bee-periodicals, I shall meet the first question in detailing a system for reversing frames which for simplicity, thorough practicability, ease of application to any style of frame, and inexperience, is ahead of anything I know of in this line.

Presuming that the frame which you wish to make reversible, is the Langstroth, cut off the corner projections and straighten the end-bars by inserting inside the frame in close contact thereto, strips of wood, tack them securely in position (the bars at the ends of the frame are now about $\frac{1}{2}$ inch in thickness); next drive two stout wire nails, each about $\frac{7}{8}$ of an inch in length, parallel with each other, into the outside of the end-bars of the frame; do not drive them clear in, but allow them to project $\frac{3}{8}$ of an inch, and insert the nails across each end of the frame exactly in the centre (see diagram). This completes the arrangement of the frame.

We shall now observe a slight change in the hive itself. The metallic edges on which the projecting corners of the ordinary suspended frames rest, is removed from their position on the rabbeted edges of the inside end-walls of the brood-chamber, and transferred to the middle of the walls, so that when the nail projections of the prepared frame rests

upon them, the top of the frame will occupy the same level in the brood-chamber as it does when the usual style of frame is employed. The metal strips should stand out from the walls $\frac{1}{8}$ of an inch.

To secure this result effectively and easily, cut two strips of card-board about 3-32 of an inch in thickness and $\frac{3}{8}$ of an inch wide, and the whole length of the inside end-wall of the hive, and tack these lightly in position $\frac{1}{8}$ of an inch below the centre of each end of the brood-chamber. Now tack the metal strips, which should be $\frac{1}{2}$ of an inch in width, and the same length as the card-board strips, securely over the latter, leaving $\frac{1}{8}$ of an inch projection above. (See diagram.) This finishes the reversing fixtures.

It will now be found, on trial, that the frame will securely rest by the nail projections on the metal rabbets, whether top or bottom be uppermost; and that the reversing of the same consumes no more time than it takes to turn the frame over in the hands after it is removed from the hive. It is free from sharp points and edges at the corners (which, in my opinion, are objectionable in any style of frame), and when in the hive its lateral motion if anything is more perfect than the usual style of suspended frame; and now I think I have said as much as can be mentioned in favor of any pattern of reversible frame.

Brussels, Ont.

From the Los Angeles News.

Production of Surplus Honey.

DR. E. GALLUP.

I wish to describe my method of managing bees for surplus honey; and in this climate we must commence to put them in condition by the middle or the last of February. The first thing is to select the colonies which are desired to breed from, and then build them up strong by fitting the brood-chamber with frames well filled with hatching or sealed brood, from other colonies; and when the weather is not favorable for gathering food, I feed them a little every evening, so as to keep the queen at her work. Then I examine every colony, and any that does not equal my expectations, I ascertain the cause, and if the fault is in the queen, she is killed just as soon as I can succeed in getting natural queen-cells; for I prefer the natural to the artificial queen-cells whenever they can

be had, and especially early in the season.

Now, just as fast as I get young laying queens, I build the bees up, until the time the honey harvest commences; either by placing empty combs as fast as needed, in the centre of the brood-nest for the queen to fill, or by giving brood from other colonies to strengthen up; and as soon as the brood-chamber is well filled with brood, providing the honey harvest is on hand, I put on the supers; otherwise I sometimes take a frame of brood to strengthen a weaker colony. I never think of putting on the supers until the brood-chamber is completely filled with brood.

Every young queen that begins to lay in March, produces, by the above plan, an excellent colony for storing surplus, as there is scarcely any disposition to swarm. If the colony is as it should be, many of those young queens will require two supers, as one will not give sufficient room for the amount of bees she will rear. All the old queens that are saved in the apiary, must be built up strong, by spreading the combs judiciously, and inserting an empty comb in the centre of the brood-nest for the queen to fill with eggs; for, remember, that almost double the amount of eggs can be secured by so doing, than if they are left to manage their own affairs.

In a good season every colony can be brought up to the standard, and the swarming all done by the middle of April. I prefer the natural swarms if they come early, and when artificial swarms are made, I give the division natural and nearly mature queen-cell. If I want any increase, I allow all colonies that swarm early, to swarm two or three times; because every young queen that I can get to breeding early in March, can be brought up to the standard in time for honey gathering.

If I do not want increase, I get as many young queens in the place of old ones as I possibly can. In a poor season every colony cannot be built up in time for surplus; because I take brood from some colonies to build up others for surplus. Those which I take brood from, I only calculate to make into profitable colonies for wintering.

Now, understand that if honey is wanted, we must have bees, and any colony that is strong in bees will store honey, even if there are not over a five-days' honey-flow in the season. How is it that Mr. Doolittle manages to get a crop of surplus honey every season in a comparatively poor locality? Simply by managing his bees on a plan similar to the above.

I want all the supers taken off by Feb. 1, so as to confine the animal heat in the brood-nest; and supers should be put on only as fast as the bees are in condition to occupy them. Now, providing the weather is favorable, we can put in one or two frames of foundation at a time in each hive, and have the queens fill them with eggs. A frame of foundation filled with eggs by a good Italian queen, is a sight worth looking at; and I have always had the best satisfaction in

having them filled in the breeding-season, early before the honey-flow commences.

You will probably say that the above plan makes work; but for what are we keeping bees if not for profit? and if we expect to have profit, we must work for it. The man who keeps bees and does not work with them, and yet expects profit, will always be disappointed. How is it that Mr. Miller, of Bell Canyon, always has a crop of surplus honey every season? Last season he had eight tons, while some of his neighbors had nothing? He worked with his bees. His bees never starve to death by the wholesale as some of his neighbors' bees do. In all my life-long experience in bee-keeping, I have always found that bees are self-supporting in the poorest season, if properly managed; and I have had experience in bee-keeping in Canada, Vermont, Wisconsin, Northern Iowa, and now three years in California. In some seasons and localities I have had to stimulate my bees by feeding them in the summer, but have never had to feed them in the fall or winter. I always save the poor honey which is unfit for market, and feed it to the bees.

For the American Bee Journal.

Overstocking a Locality.

J. E. POND, JR.

The question of overstocking has been more or less of a bug-bear, with a few, since I first began to keep bees, nearly 20 years ago. Every little while some poor fellow, fearful, I suppose, that all the honey yielded by the flora of the country, would be gathered by others, and none left for him, would raise the cry of overstocking, and over-production.

What are the facts which the last 20 years have shown? First, bee-keeping, as a business, has grown enormously; hundreds now pursue it successfully where only one was engaged in it when the BEE JOURNAL first started into life; and not only has this large increase been made in the accession of members to our ranks, but by means of better and more advanced methods, hundreds of pounds of honey are now produced as a consequence of these improved methods, while under the old regime, hardly a pound of surplus was obtained.

Now, if these results have followed during 20 years, and I defy any one to prove the contrary, what need is there to fear overstocking in the future? "But," the reply comes, "we do not mean overstocking in the whole country, but certain small areas that we call our feeding-ground whose radius is equal to the flight-range of our bees." Well, what danger is there of overstocking even that territory? A single acre of white clover will furnish, in a good season, at least 100 pounds of surplus each to 25 or 30 colonies. Spin this out to a diameter of 8 or 10 miles from a given location, and it is easy to be seen that it will take more bees than by any

possibility will ever be kept in a locality, to overstock it.

But who can determine this question of overstocking? and how can they determine it? In a poor season, when the flowers yield no nectar (and we do have such seasons), a very few colonies might starve, not because the locality is overstocked, but because there is no honey to be gathered. Has any one ever considered for a moment the state of things that must necessarily exist, in order to overstock a locality? Simply this: It is well known that the flowers are constantly secreting nectar during the time they are in bloom, and this nectar, in order to be utilized as honey, must be gathered at once, or it will evaporate. If a certain flower secreted a certain amount of honey, which, when gathered, exhausted its supply, then there might be some strength in the argument in favor of overstocking, but such is not the case; for the nectar thus secreted must either be gathered at once, or it evaporates and is lost, and in either case a fresh supply is at once secreted to supply its place. In about five minutes after the nectar has been gathered from a white clover or other blossom, more is secreted, and sufficient to load up any bee, even if it is as large as "*apis dorsata*."

Now, to overstock a locality, every honey-yielding flower within that locality must be visited by a honey-bee oftener than once every five minutes during the duration of its bloom. I, myself, do not know the number of colonies of bees required to accomplish this work, but it is easy to see that it will require an immensely larger number of colonies than it is at all presumable will ever be kept in any locality, either by one or many persons.

When I first began keeping bees, I had some fears in regard to the matter; but as I have seen the business increase, and the honey yield increase ten times more largely in proportion, than the increase of bee-keepers, and that, too, without glutting the market, or causing any falling in prices, I have concluded that the danger is fancied, and not real; and more particularly do I so conclude when I find that hundreds of colonies are kept at a profit in our large cities, where it would naturally be supposed that no honey at all could be gathered, unless yielded by stones and bricks. Some localities undoubtedly give larger yields than others, but that is a matter of chance or design in the growth of honey-yielding plants and trees, and does not in anywise form a factor in the problem under consideration.

Foxboro, Mass.

For the American Bee Journal.

A Visit to G. W. Demaree's Apiary.

W. T. STEWART.

On July 5, I made a visit to Mr. G. W. Demaree's apiary, where I remained two days and nights. As the readers of bee-papers are "well aware" he is an enthusiastic writer, and if you will pay him a visit, as I

have done, you will at once see that he is enthusiastic in the whole business of bee-culture, especially the rearing of fine queens. Mr. D. is a lawyer and farmer, and has plenty of this world's goods, and no children to leave it to; so he has almost given up law and farming, and concentrated his whole time and talent upon bee-culture.

His apiary consists of about 180 colonies and nuclei; very tastefully arranged. He prides himself very much upon his improved Italian bees, and well he may, for his Italians are indeed beautiful. He and the Cyprians have had so many "ups-and-downs" and disputes as to who should "boss" the apiary, that he has discarded the breeding of them, and breeds only Italians.

He uses the Jones' perforated zinc or drone excluder, and says that it is a perfect success, and I agree with him in this. He took me out to his sweet clover field, which is so thick and tall that it is nearly impossible to go through it, and the bees were making it fairly hum. He uses a half-story (that is a story half the depth of the Langstroth) for extracting purposes. The combs are shallow and straight, and the bees fill and seal them very quickly. When full he lifts the whole set off and puts them into his extracting-room, in which there is a bee-escape, and in a short time the bees leave it and go home, when it is ready for the extractor; thus he saves the labor and time of brushing bees from the combs in the hot sun. The plan is a good one, and in the future I shall use it largely in my own apiary.

He has horse-power and also foot-power machinery for hive making.

In passing through his queen-rearing department, I stopped to read on the slates, which hung on each hive, but they were embellished with hieroglyphics only, such as none could read, but he understood them.

I expected to see many things at Mr. D.'s apiary that were new to me, he being a sort of natural genius, and in this I was not disappointed. Many a little idea I caught and stored up in my memory for future use. Mr. D. is an incessant talker, and talks about bees from the beginning to the end. He despises meanness in any form among bee-keepers, and lives up to the old adage, that "Honesty is the best policy."

Mr. D. is president of the Kentucky State Bee-Keepers' Society, and we may naturally expect that he will spare no pains in getting up a good programme for the fall meetings. We hope that he and Dr. Allen, the secretary, will arrange to have a bee and honey show at the beginning of the Exposition at Louisville, and also at our regular fall meeting at Eminence, Ky. Right here let me say to Kentucky bee-keepers: Let us each donate any amount that is necessary, to raise money enough to offer large premiums on the best display of honey, bees, etc., such as is customary to give premiums on; and then let us get up a rousing show. All try to get the premium by an energetic effort

As many of us know that swarms have, very frequently, deserted the hives after being hived, this season, and bee-men have different theories as to the cause of it.

After experimenting a good deal, I believe I have found the cause to be the absence of pollen in the new combs for use in rearing brood. Just at the swarming season there were no flowers in bloom that yielded pollen, and on examining many new combs, after the bees had deserted them, I found them full of eggs and entirely destitute of pollen. I then hung old combs containing pollen, in each hive, and not one swarm deserted after so doing.

I proved to my satisfaction that the reason bees or swarms desert their hives is because they have not or cannot get pollen at the time.

If I knew of a good place to which to move 75 colonies of bees, in order to secure a fall crop of honey, I should be pleased to try the experiment, as I am now ready to do so, and then report whether it pays to practice migratory bee-keeping.

Eminence, Ky., July 8, 1884.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Comb Honey, or Extracted?

1. Which is preferable, producing extracted honey at 12½ cents per pound, or comb honey at 20 cents per pound? markets and all else being equal.

2. After extracting, at the close of the season, do you let the bees clean the empty combs before storing them away? If so, how do you manage it so as not to induce robbing?

3. Would we not, as a rule, get as straight combs in your cases of 4¼x-4¼x1½ sections with ½ inch starters, as if the full-sized were used?

M. F. TALMAN.

Rossville, Kans., July 19, 1884.

ANSWERS.—1. Much depends upon the individual and the location. In regard to what respects, see another answer in this, or perhaps the next issue. As a general thing, I think I should prefer producing extracted honey at the prices you quote.

2. No; I do not. A good extractor will throw them clean enough for all practical purposes.

3. I think you would, but you would get drone comb, and lots of brood in it, if you used full sheets of worker foundation below, unless you also used a queen-excluding honey-board. A letter, just this moment opened, from a bee-keeper of experience and close observation, contains the following paragraph: "I have used a good many sections with V-shaped foundation starters, all of which are built perfectly straight and even, and mostly drone comb. There was no drone comb below, and still the queen

did not go above to occupy drone comb in the sections. I account for it by the use of a good honey-board."

Small Black Ants in the Apiary.

Will the small black ant injure or annoy my bees in any way? Can you tell me what to do to prevent their climbing on the bench? L. HOYTE.

Tuscarora, N. Y.

ANSWER.—You need not be at all alarmed by the presence of ants about your hives. The bees will not let them come inside. They are working around crevices and in dead-air spaces where they enjoy the heat from the colony which assists in developing their young, etc. As our hives are so constructed that all surfaces are either next to the bees or out-door air, we never find them any more concealed about the hives. Sometimes they bother us slightly by attacking our surplus honey after its removal. There are various methods of preventing their annoyance in this respect. We usually crate our honey at once, in ant-proof crates. Where this is not done, some pile it on tables and benches whose legs are in dishes of water. Some poison them with insect powder, etc.; but I would not advise it, as the poison might get into the honey. We have built a new honey-house with stone foundation, and it is ant-proof except at the doors and windows, and we have no trouble from ants whatever. Keep things clean.

Bees Uncapping Honey.

1. What is the cause of bees uncapping the honey after capping it over once?

2. Which is the best way of getting the bees out of the boxes that are filled with honey? J. HURST.

ANSWER.—1. A sudden cessation of the flow of nectar, and at a time when the brood-combs are not crowded with honey, especially in large hives. The bees seem to fear being caught in winter quarters with their honey in an unavailable position.

2. Answered on page 458, present volume.

Transferring Bees.

1. Will Mr. Heddon kindly explain the "driving" process, as practiced by himself, in transferring bees from box to movable-frame hives?

2. What is a "hiving-box"?

BEGINNER.

ANSWERS.—1. To drive a swarm of bees from a colony, if in a box-hive, we turn the hive bottom upwards, (after smoking the bees,) and place an empty box on top of the hive (or what was the bottom), and by drumming on the box-hive, the bees, and nearly always the queen too, will desert the combs, going up into the box. The drumming must be radical, after striking the hive, so as to jar its whole contents. This forced swarm can be hived the same as any swarm, only it must be placed upon the old stand, the old box-hive being removed

to the new stand, as a forced swarm will not so readily mark and accept a new location; most of the bees returning to verify Father Langstroth's axiom:

"A bee removed against its will, is of the same opinion still."

2. In these days of improved hives, we do not go after a swarm with the hive, but place the hive on its future stand, and go after the swarm with a box or basket arranged and kept for that purpose, and it is designated "hiving-box" or "hiving-basket."

SELECTIONS FROM OUR LETTER BOX

When to Sow Sweet Clover.

When is the best time to sow sweet clover? If sowed in the fall, will it bloom next year? I have 16 colonies, and have no pasture for them.

Venice, Ill.

H. C. SMITH.

[Sow any time. If sown early in the fall, it will soon come up, and bloom in the following July. Fall sowing is best, because it saves one year's time.—ED.]

Basswood a Complete Failure.

The harvest is past, and bees have gathered only about ¼ of a crop. White clover has been quite plentiful, and we have had all kinds of weather, but it did not seem to affect the secretion of honey. Basswood was a complete failure. I moved 60 colonies to a belt of basswood trees, and I can bring back all the honey in one keg. Let bee-keepers in different parts of the country report, so that we may be guided in selling the small amount of honey which we did get.

JAMES NIPE, 137.

Spring Prairie, Wis., July 24, 1884.

Satisfied.

I have received that beautiful book entitled "Bees and Honey," and have read it carefully and with pleasure. I would not take five times the price of it, to be without the information I have gained from it. The Weekly BEE JOURNAL comes regularly, and is highly appreciated.

Z. WELLS.

Sheridan, Ark., July 16, 1884.

Introducing Virgin Queens.

I have discovered a very valuable method of getting a colony of bees to accept a virgin queen, which is as follows: Take a hollow tube with an opening large enough to receive the upper end of the queen-cell. Cut open the upper end and put it into the tube about one-half the length of the queen-cell. Then cap the lower end with a thin skin of wax, put the queen into the tube, and close it up with a sponge saturated with honey for the queen to feed upon, and put the whole thing between the frames where the queen is to be introduced.

Any colony of bees will accept a virgin queen as soon as they begin building queen-cells, which will be in about 24 hours. In most cases, I have succeeded immediately after their old queen was removed from them. I think that it is the best plan I have ever tried, and would be pleased to know what others think of it. So far, bees have done but little work. I have about 1,000 pounds of honey, and 25 swarms from 80 colonies. To-day is the first good honey day that we have had since basswood began to bloom, and I judge they will gather 10 pounds per colony within 24 hours. If this weather holds out for 4 or 5 days, we will have a crop of honey from that source; and if we get a shower of rain, clover will yield honey for 2 weeks or more.

A. WICHERTS.

Mattison, Ill., July 19, 1884.

Wolf-berry.

The bees which were wintered in dry, well-ventilated cellars, in this locality, came through in good condition. The spring was cold and wet. I had my first swarm on May 28. Bees have done well on raspberry, clover, and a plant of which I enclose a specimen. It grows in thick clusters about 3 feet high. What is its name? Linden has been in bloom 5 days, and the bees are busy.

JOS. GILBERT.

Mankato, Minn., July 11, 1884.

[The plant is *Symphoricarpus occidentalis* or wolf-berry—a good honey plant.—T. J. BURRILL, Champaign, Ill.]

Wiring Foundation Unnecessary.

I have been experimenting with comb foundation, this season, and find that wiring it is entirely unnecessary. I fasten the foundation in frames, and place them in the top stories of hives which contain strong colonies, and let the bees draw it out, say half-brood thickness. If they store some honey, all the better, which will set up the young bees in house-keeping. Then place the frames in a new hive to put the bees on. There will be no warping or sagging, and I think it is much easier and cheaper than using wire. I hope Mr. Heddon will give this plan a trial, and report through the BEE JOURNAL.

PETER BRICKEY.

Lawrenceburg, Ky., July 19, 1884.

Quick Work.

On Saturday, May 31, at 12:30 p. m., I hived a swarm of bees on empty combs. On Monday, June 2, at 8:30 a. m., they had gained 30 pounds, all from apple bloom.

H. E. MITCHELL.

Greece, N. Y., July 13, 1884.

Honey Dearth Now.

Bees are not doing very well in Eastern Ohio. The weather has been too dry; we have had but little rain since the first of April. Bees have nothing to gather honey from.

JACOB OSWALT.

Maximo, O., July 18, 1884.

Bees with Diseased Feet.

I send you some bees that have diseased feet. It is something new to me. The bees are taking them out of the hives and carrying them off at a rate which will weaken them very much in a short time. I wish to know the name of the disease and the remedy, if there be any.

W. W. TRUSSEL.

Colby, Mich., July 15, 1884.

ANSWER.—The bees are weighted with the pollen masses of the *Asclepias* or milk-weed. This is illustrated in my Manual. I think the losses from this cause are not great, while I am sure that milk-weed is an excellent honey-plant. The bark-lice on maples and other trees can be washed off, in cities, where they have high-pressure water-works, by turning on the hose. The grovied females in May, and the young lice in June, may easily be overcome in this way.

A. J. COOK.

Lansing, Mich., July 19, 1884.

How to get rid of Ants.

Two years ago I struck upon the plan that is often used for rats and mice. I mean poisoning. Thoroughly poison a small quantity of meat or honey with arsenic or strychnine, and put it in wire-cloth cages, or in some way manage to keep it from every thing else, and place it in places frequented by the ants; and they will quickly vanish, at least mine have.

Saugatuck, Mich. W. B. HOUSE.

Fastening Starters in Sections.

If the top piece of the section is rubbed with wax, and the foundation put in moderately warm, the starter will be perfectly fastened, and with very little pressure. We use a Clark fastener, and have no further trouble with falling starters, since pursuing the above method. Bees have done well on white clover, in our vicinity, but we fear that basswood will be a failure. The weather has been cool and cloudy during the past week, thus checking the honey secretion; but clover still looks well, and, with favorable weather, may continue to yield honey for some time.

LIBBIE LONG.

Williamsville, N. Y., July 18, 1884.

Bees Not Busy.

Bees are doing but little work now. White clover was almost a failure. Our main hope now is on heart's-ease.

J. W. MARGRAVE.

Hiawatha, Kans., July 21, 1884.

Basswood Abundant, No Honey.

With us the honey season has closed, and we have to report only $\frac{1}{2}$ of a crop. No swarming this year. I have 80 colonies which I fed heavily during April and May, and all were exceedingly strong. They made a good start on locust, and filled their hives fit for winter, when the white clover came on in abundance; but it rained continually, and north winds prevailed during June. We hoped to

have a good flow of honey from basswood bloom, as the bloom was unusually abundant; but it came and went, never a bee looking at it. North winds have blown cold during the whole month of July, so far, and the mercury settles down to 38° and 40° above zero every night. Although my colonies have been extra strong all the season, only 5 swarms have issued, and now the colonies are idle and listless, killing drones, etc. None but experienced bee-men have a drop of surplus honey. E. A. MORGAN.

Columbus, Wis., July 21, 1884.

Honey-Dew Honey.

Bees are not doing well at present. My big crop of white clover honey proved to be honey-dew honey. Everything looks favorable for a big honey crop this fall, if it is not too cold; but what the result will be, I cannot foretell. Many of my customers say that they like the honey-dew honey better than any other that they can get.

D. R. ROSEBROUGH.

Casey, Ill., July 18, 1884.

Uncapping Knife.

Do all who have occasion to use the honey uncapping knife know how much nicer and easier it works, if kept immersed in hot water as much of the time as possible while in use, or even dipped occasionally? Let those who have never tried the plan do so, and if not pleased I will be surprised. "TYPO."

[Yes; that is the most approved method, and has been so stated many times in the BEE JOURNAL during the past few years.—ED.]

Bees Gathering Honey-Dew.

Bees have been gathering large quantities of honey-dew of late, but it is poor stuff. On the whole, bees have done fairly well so far.

W. H. STOUT.

Pine Grove, Pa., July 21, 1884.

Accidentally Disabled.

In the spring of 1883 I commenced with 22 colonies of bees, from which I received about 1,200 pounds of honey, and increased them to 41 by natural swarming. I sold 3 colonies, and wintered the balance without loss. Of these I lost one after placing them on the summer stands. The result of the season up to July 1, was only a little over 600 pounds of comb honey, with enough left, perhaps, to supply a family of nine members. Why my bees have done so poorly, I cannot tell. They were nearly all in fine condition when white clover began to bloom, and the bloom was quite profuse. From my 40 colonies I have had but 4 swarms, thus increasing my number to 44, 33 of which I sold about July 1. I think that bee-keeping is a pleasant occupation, and though my profits have been small, I have taken considerable delight in the business. But from the fact of having been almost totally disabled in my back, by a horse which, in 1880, fell with me

with my foot hanging in the stirrup, and dragging me on the frozen ground at a fearful rate of speed until I was crippled, perhaps for life, I have thought it best to retire from the bee-business, at least for the present, and keeping only a few colonies for family use. With best wishes for the continued advancement of this ever increasing industry, I now withdraw from the active duties of the business.

F. M. REEDS.

Hindsboro, Ill., July 18, 1884.

Hybrids Better than Italians.

I have 28 colonies of bees in two-story chaff-hives. On June 10, from 2 hybrid colonies I extracted 56 lbs. of honey, and from 8 Italian colonies, 196 lbs. I think the hybrids cannot equal the Italians in honey-gathering. I sold 100 lbs. of the honey at 12½ cents per lb., which was shipped, and the balance in my home market at 15 cents per pound.

CHAS. HAAS.

Lower Salem, Ohio.

No Basswood Honey.

Bees have done well here until June 20, when there was a sudden cessation of the honey-flow. Some farmer's colonies swarmed as many as 4 times. There are a great many bees in Atchison County, Mo., and Southern Iowa. Rocky Mountain bee-plant grows in large quantities on the bluffs of the Missouri river, and bees do well when it is in bloom. We have hundreds of acres of goldenrod and other fall flowers. I am now Italianizing my colonies for the purpose of rearing queens. I have 34 colonies. Basswood was a total failure this year.

CHAS. HARROLD.

Hamburg, Iowa, July 21, 1884.

Neither Increase nor Surplus.

On page 452, migratory bee-keeping, as practiced by Messrs. Flanagan and Baldrige, is described. I received 90 colonies of bees from Mr. Flanagan, of New Orleans, La., on June 18, 1884. They were entirely destitute of stores, and depleted in numbers; and having arrived in the midst of the white clover bloom, they soon filled their hives with nice honey, but have yielded no increase or surplus, as we are having a severe drouth—there having been no rain for 4 weeks. Basswood has yielded no nectar this season, and the outlook is discouraging at present. Large numbers of bees are working on over-ripe red-raspberry fruit, and searching everywhere for nectar. They are killing drones and carrying all drone-brood out of the hives.

S. J. YOUNGMAN.
Cato, Mich., July 20, 1884.

"Tree-Trunk Method of Wintering."

According to my declaration as an expert bee-hunter, Mr. W. F. Clarke's article has brought to my mind some of my past experience in tree-trunk wintering of bees. Last fall I knew of 6 bee-trees, 3 in Ohio and 3 in Pennsylvania, in which all of the bees died during the past winter. Had they lived, I intended transferring

them into hives. I know of another tree which contained bees every year for 15 or 20 years, and the bees died during every winter for that length of time, when another swarm would occupy it as soon as the next swarming-season arrived. As the tree had been watched for the above length of time, Mr. C., in my humble opinion, and judging from what my experience has taught me, must find some other theory than "tree-trunk wintering," before he can claim the championship of making a grand discovery. With the best of feeling for Mr. C. and his new theory, I should have told the bee-keeping fraternity that the tree of which I spoke on page 459, contained about 1 wash-tub and 3 patent buckets full of honey, besides many combs.

COL. R. WALTON.

Industry, Pa., July 17, 1884.

Good Enough.

I have increased my colonies of bees 150 per cent., and taken from them an average of 70 pounds of white clover honey.

A. B. MASON.

Wagon Works, O., July 21, 1884.

Still Hunting.

The honey harvest, in this section, is about ended for this year. We have had an abundance of bloom, but the weather has been anything but what bee-men would desire. The nights have been very cold. I have colonies that swarmed about the middle of June, and have not yet finished their first set of sections. Basswood commenced to bloom on July 3, and I think it is all gone now. White clover will last sometime yet, but I never knew bees to gather much from that after July 20. We have seen some few offerings of comb honey in the market, but none finished well, so we do not think that there will be more than half a crop of comb honey, judging mostly from our own. We have waited patiently for Mr. H., of Centre Point, to explain something about the "glucose business." We know he has used large quantities of the article some way; so much so that he cannot sell honey in this market. We do know it has hurt the sale of extracted honey in Cedar Rapids. As we produce mostly extracted honey, and deal in it exclusively, we know what we are talking about. We want to hear from Mr. H. through the BEE JOURNAL.

T. B. QUINLAN.
Cedar Rapids, Iowa, July 18, 1884.

Hiving Bees, etc.

I hive swarms of bees somewhat differently than Messrs. Hutchinson and Heddon. My plan is as follows: Take a common peach basket, separate the partially separated staves, that the bees may have ready ingress; also bore the bottom of it full of ¼-inch holes, attach a 6-inch strap to the centre of the bottom of the basket, with a snap of an old suspender, or of a tie-rein of a horse, at the end.—Stick on the inside of each stave, and ¾ of its length, very narrow strips of old comb (lengthwise), and some on the bottom (inside); now have light

poles, say two or three different lengths, with a loop on the snap at the end of the strap attached to the end of the pole. When the bees have mostly collected on the bush or limb of the tree, attach the basket to the pole, jar the bees on the limb, hold the basket up so its bottom will touch the exact spot from which the bees were jarred, and the bees will go into it, then carry them to the bee-yard. They are simply collected in a basket instead of on a bush or limb. Put the basket on the frames of the hive, cover all with table or other cloth, shake the basket, and give two or three minutes time for them to run down into the hive. I would not take \$20 for my basket if I could not get another. Mr. Heddon also tells us how to draw the bees from the sections. This is my method: Simply place a partition-board between the case of sections and the brood-chamber, first blowing in a little smoke to awaken and scare the bees; then cover the case, except a ¼-inch slot or opening for egress to the outside of the hive. It is best to have it in front. It works like a charm, and as soon as robbers are troublesome, I bore holes in the board at or near the front end of the cap of the hive, and place in the holes for egress, small wire-gauze conical tubes, not unlike Mr. Alley's to his drone or queen catcher.

St. Paul, Minn. MOUCH AMIEL.

Honey in Mountain Regions.

I agree with Mr. Pleasants, in his article on page 375, and think the time is not far distant when our valley apiarists will have to be moved back into the mountains, beyond the range of fruit-men; and besides the honey-production is better, and the honey is of a better quality, much clearer than that gathered in the valleys. Not nearly so much honey is gathered along the coast. We also have sections in this county which are overstocked with bees. Within an area of six square miles there are over 1,500 colonies kept; and from observation I have never known any of them to get any where near the amount of honey, per colony, compared to those with smaller apiaries and larger ranges of bee-pasturage. Where bees are left with plenty of honey in the fall, thus leaving but little cold air space, and having a good queen, they come out in the spring strong and vigorous, as such an amount of honey encourages brood-rearing earlier and stronger. They seem to know that they have the "backing" when they have so much honey, the same as a man who has plenty of capital in his business. I have found that to stimulate bees in February or March, in this mild climate, is a great advantage. Last season I experimented in rearing late queens, but found it unprofitable. I have had them fertilized in November, but have had five failures to one success. Drones are generally scarce then, and the winds drive the queens before it, causing much loss, and the result is drone layers, etc., and they do not live as long. M. H. MENDELSON.
San Buenaventura, Cal.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

All money orders from foreign countries, should be made payable at Chicago, as the "Madison Street Station" is not an International office.

In reply to many correspondents let us say that we take any kind of postage stamps at their face value—including the 3 cent ones. Silver should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

We now club the *British Bee Journal* and our Monthly for \$2.50, or it and the Weekly for \$3.50.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

GETTING UP CLUBS.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send direct to this office, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

Dzierzon's new work entitled "Rational Bee-Keeping," we now club with the BEE JOURNAL as follows: The Weekly for one year and the book, bound in cloth, for \$3, or in paper covers for \$2.75. The Monthly BEE JOURNAL and the book, \$1 less than the above prices. It is an imported book, printed in the English language, and the price of the book is \$1.50 bound in paper covers, or \$2.00 when bound in cloth.

For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or the Monthly BEE JOURNAL and the book for \$1.75. Or, bound in cloth, with Weekly, \$3.00; with the Monthly, \$2.00.

Do not let your numbers of the BEE JOURNAL for 1884 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Cook's Manual in cloth and the Weekly BEE JOURNAL for one year will be sent for \$3. Manual and Monthly, \$2.00. We have no more of the old edition left, and, therefore, the club price of that edition at \$2.75 and \$1.75 is withdrawn.

Create a Local Honey Market.

Now is the time to create Honey Markets in every village, town and city. Wide-awake honey producers should get the Leaflets "Why eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully all over the territory they can supply with honey, and the result will be a demand that will readily take all of their crops at remunerative prices. The prices for "Honey as Food and Medicine" are as follows:

Single copy 5 cts.; per doz., 40 cts.; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Convention Hand-Book.

It is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-Keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Letters for publication must be written on a separate piece of paper from items of business.

Bingham Corner.

MARENGO, ILL., June 18, 1884.

The Doctor Subdues All.—Mr. T. F. BINGHAM, Dear Sir:—I've used the "Doctor" till its all daubed up with bee-glue, and although at first sight I thought I did not like anything so large, I could not now be induced except by the direst poverty, to do with any thing smaller. As a matter of "economy" I much prefer the "Doctor" to any of the cheaper smokers, of which I have worn out several. The "Doctor" has entirely cured me, so that I am now a Bingham man, as my wife always has been. If the somewhat vague remark in your letter means that nothing was charged for the Smoker sent, except the reading of your letter, I shall be very glad of another "Doctor" for the money sent, so that my wife won't take mine from me. Bees just booming on white clover.

Yours Truly, C. C. MILLER.

WOODARD'S LANDING, Wash. Ter.

The Best Smoker.—To BINGHAM & HETHERINGTON, Abronia, Mich., Dear Sirs:—Find enclosed money for 3 Conqueror Smokers, which please send per mail—one to each, Dr. Balch, J. M. Louderback, and H. A. Towncr. The Conqueror is the best Smoker I ever used. Respectfully,
May 17, 1884. H. HASTINGS.

DRESDEN, TEX., May 28, 1884.

Conquer the "Cyps."—T. F. BINGHAM, Abronia, Mich., Dear Sir:—Enclosed find \$1.75, for which please send, per mail, one "Conqueror Smoker" to Major H. A. High, Waxahachie, Tex. He bought a Cyprian Queen from me, and the Bees have worsted the old gentleman. I told him that the Conqueror Smoker would conquer the "Cyps," as I had tried one for two years, and "it never failed." Respectfully,
B. F. CARROLL.

BORODINO, N. Y., Aug. 15, 1882.

Cyprians Conquered.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. Respectfully,
G. M. DOOLITTLE.

Prices, by mail, post-paid.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL, }
Monday, 10 a. m., July 28, 1884. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY.—The demand for extracted is fair, and to all appearances, gradually improving. It brings 6@9c per pound on arrival. There is a small demand for comb honey, but we had small offers only, and a good deal could be sold. It brings 14c per pound on arrival.

BEESSWAX.—Offering plentiful at 30@32c on arrival. C. F. MUTZ, Freema & Central Ave.

NEW YORK.

HONEY.—Sales of comb honey continue slow. As yet there are no arrivals of this season's crop. We have received several small shipments of new extracted honey, which sold readily. For prices on this year's crop, we quote: Fancy white, 1-lb., 16@18c; fancy white, 2-lb., 15@16c; fair to good, 1 and 2-lb., 12@14c; fancy buckwheat, 1-lb., 12@13c; 2-lb., 11@12c. Extracted, white clover, in kegs or small barrels, 8 1/2@9c; dark grades, 7@7 1/2c.

BEESSWAX.—Prime yellow, 30@32c.
MCCAUL & HILDBETH, 34 Hudson St.

BOSTON.

HONEY.—The sale of honey is almost over, and we are obliged to sell 2-lb. combs for 15c, and 2 1/2-lb. to 2 3/4-lb. from 10@12c. No 1-lb. in the market. Extracted, 8@10c.

BEESSWAX.—35c.
BLAKE & RICHLEY, 57 Chatham Street.

CHICAGO.

HONEY.—This week we have had liberal receipts of comb honey, and the prices are irregular. As a rule, the honey is of first quality, and put up in good shape; a gradual improvement is noted in this respect. Prices range from 14@16c for the best; occasionally a case sells for more than that, but it is to a retail way. The extracted honey is still sluggish, at nominal prices—6@8c per pound.

BEESSWAX.—Fair receipts; prices, 30@37c.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—Offers do not receive any noteworthy attention; there are no urgent orders in the market, and little or no disposition to purchase on speculative account. Honey producers make a mistake to ship their honey for sale to parties not in that particular line of business. Outsiders having lots of honey to sell, run about to find a buyer, and not knowing the market, or the value of honey, offer a little under the market, and when these outside lots get out of the way, our market will have some to do. White to extra white comb 14@17c. Dark to good 10@13c. Extracted, choice to extra white 5@6 1/2c. Dark and candied 4c.

BEESSWAX.—Wholesale, 27 1/2@30c.
STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY.—There is beginning to be some demand for new honey now at somewhat better prices. Choice 2 and 1-lb. sections bringing 17@18c; choice old honey 10 less. I am having more inquiry for 1/2-lb. sections than I anticipated, and I could use a few hundred pounds at pretty good figures. Who has any? Extracted, dull and unchanged, 7@8c.

BEESSWAX.—30@35c.
JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY.—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@6 1/2c.

BEESSWAX.—Firm at 32@32 1/2c for choice.
W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY.—There are some arrivals of new honey which is very nice, unusually so. Our market does not seem to be quite ready for it, the demand not having begun, and no sales made worth mentioning. It is our aim to get 15c for best 1-pound sections, and 16c for 2-pounds. Extracted, as usual, is dull.

BEESSWAX.—30c.
A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY.—We quote comb honey in 2-lb. sections 17@18c; extracted, 7 1/2c.
GEO. W. MEADE & Co., 213 Market St.

The meeting of the Bee-Keepers' Association of Northeastern Kentucky, will be held in the city of Covington, Walker's Hall, on Aug. 13, 1884. G. W. CREE, Sec.

The Kentucky Bee-Keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed). N. P. ALLEN, Sec.

QUEENS!

BY RETURN MAIL,
FROM OUR NEW STRAINS OF
ITALIAN AND ALBINO BEES.

We are happy to announce to the bee-keeping public that we are now prepared to send you QUEENS on short notice, at the following low rates:

| | |
|-------------------------------|---------|
| Untested, each | \$ 1.00 |
| " per 1/2 dozen | 5.50 |
| " per dozen | 10.00 |
| Warranted, each | 1.10 |
| " per 1/2 dozen | 6.00 |
| " per dozen | 11.00 |
| Tested, each | 2.00 |
| Select Tested, each | 2.50 |

Send for our descriptive Price-List and see what our customers say of our goods.

Address, W. W. CARY & SON,
COLERAIN, MASS.

(The oldest breeders of Italian Bees in America.)
28Atf

For Rent. My Apiary of 100 colonies of Bees, including a house honey-house, etc. Also, Bees and Honey for Sale. For terms, address
H. S. BECKTELL, Three Oaks, Mich.
30A3t

Syrian-Albino Queens!

My new Strain AHEAD of all. They build beautiful, straight Combs, without Separators, and are UNEXCELLED as workers. Reared by Alley's method.

| | |
|--|--------|
| Select-Tested, to breed from | \$3.00 |
| Untested | \$1.50 |

By an error of the type, in last week's Journal, the latter figures were \$1.00.—ED.

Address, DR. G. L. TINKER,
New Philadelphia, Ohio.

DR. FOOTE'S HAND BOOK OF HEALTH,

HINTS AND READY RECIPES,

is the title of a very valuable book that gives a great amount of information, of the Utmost importance to Everybody, concerning their daily habits of Eating, Drinking, Dressing, Sleeping, Bathing, Working, etc.

It Costs only TWENTY-FIVE CENTS, and contains 28 pages, and is sent by mail, post-paid, on receipt of price. This is just the Book that every family should have.

IT TELLS ABOUT

| | |
|--------------------------|------------------------|
| What to Eat, | Parasites of the Skin, |
| How to Eat it, | Bathing—Best way, |
| Things to Do, | Lungs & Lung Diseases, |
| Things to Avoid, | How to Avoid them, |
| Perils of Summer, | Clothing—what to Wear, |
| How to Breathe, | How much to Wear, |
| Overheating Houses, | Contagious Diseases, |
| Ventilatoos, | How to Avoid them, |
| Influence of Plants, | Exercise, |
| Occupation for Invalids, | Care of Teeth, |
| Superfluous Hair, | After-Dinner Naps, |
| Restoring the Drowned, | Headache, cause & |
| Preventing Near-Sight- | Malarial Affections, |
| edness, | Group—to Prevent. |

IT TELLS HOW TO CURE

Black Eyes, Boils, Burns, Chlbrulias, Cold Feet, Corns, Coughs, Cholera, Diarrhea, Diphtheria, Dysentery, Dandruff, Dyspepsia, Ear Ache, Felons, Fetid Feet, Freckles, Headache, Hiccough, Hives, Hoarseness, Itching, Inflamed Breasts, Ivy Poisoning, Moles, Pimples, Piles, Rheumatism, Ringworm, Snoring, Stammering, Sore Eyes, Sore Mouth, Sore Nipples, Sore Throat, Sun-stroke, Stings and Insect Bites, Sweating Feet, Toothache, Ulcers, Warts, Whooping Cough, Worms in Children.

HEDDON'S COLUMN.

BEST GIVEN COMB FOUNDATION. Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8¼x16¼, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

- One Hive complete for comb honey..\$3.00
- (The above will contain two cases complete with sections).
- The above Hive complete for extracted honey.....\$3.00
- The above Hive complete for both in one.....4.50
- One Hive in the flat.....2.00
- Five or over, each.....1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4¼x4¼x6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

QUEENS!

Our New Strain,

Also IMPORTED ITALIANS!

Take your choice. Prices:

- Tested, to breed from.....\$ 3 00
- Untested.....1 25
- Untested, after July 1st.....1 00
- Untested, (per doz.) after July 1st.....11 00

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.

DOWAGIAC, Cass County, MICH.

Sixth Thousand Just Published!

New and Enlarged Edition

OF

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 220 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey-Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

FRIEND NEWMAN:—I acknowledge with pleasure the receipt, this morning, of a very beautiful book, entitled, "Bees and Honey, or, Management of an apiary for Pleasure and Profit; sixth edition, enlarged." The book opens with a kind, familiar face, and the whole subject matter is concise, easy and comprehensive. I read it with much pleasure. T. F. BINGHAM.
Abronja, Mich., May 1, 1884.

I have received a copy of the revised edition of "Bees and Honey," and after examining the same, find it to be a very handy and useful book of reference on the subject of bees and honey, and believe it should be found in the library of all interested in the study of bees.

H. H. BROWN.

Light Street, Pa., May 8, 1884.

PRICE—Bound in cloth, \$1.00; in paper covers, 75 cents, postpaid.

THOMAS G. NEWMAN,
925 West Madison Street, Chicago, Ills.

☞ A Liberal Discount to Dealers, by the Dozen or Hundred.

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

50 TONS OF COMB HONEY WANTED.

Believing it to be advantageous to both seller and buyer to deal with the same parties year after year, we have for several years bought the entire honey crop of many bee-keepers. In view of our increasing trade, we wish to add to our list of producers the names of a few more reliable men whose honey crop is from one to ten or more tons yearly. Through the actions of certain bee-keepers, the trade now demands mostly one-pound sections. We pay spot cash at railroad station for what we buy. Those desirous of becoming acquainted with such dealers, will state how much honey they have of each size section. How much of each quality. How soon the whole or part of it can be in shipping order. Name lowest cash price, and say how much more is in your locality. If answer is favorable, we will call on you. York State, Michigan, or Vermont preferred. Address,
E. I. SAGE & SON, Wethersfield, Conn.

A NEW BEE VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces.

Price, by Mail or Express, \$1.00.
ALFRED H. NEWMAN,
923 West Madison Street,
CHICAGO, ILLINOIS.

A PRIZE.

Send six cents for postage, and receive free, a costly box of goods which will help you to more money right away than anything else in the world. All of either sex, succeed from first hour. The broad road to fortune opens before the workers, absolutely sure. At once address, TRUE & CO., Augusta, Maine. 4A1Y

CHAS. DADANT & SON,

5AB1y HAMILTON, Hancock Co., ILL.

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE.

PATENTED, MAY 20, 1878.

The Original
BINGHAM
Bee Smoker

Patented, 1878.

Prof. Cook, in his valuable *Manual of the Apiary*, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top up or down, they always go!

Bee-keepers will save money and vexation by using genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such grounds as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To sell again, send for dozen rates to

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "tully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects: Ancient History of Bees and Honey—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quieting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, bound in cloth, \$1.00; 2 copies for \$1.80; 3 copies for \$2.55; 5 for \$4.00; 10 for \$7.50. Paper covers, 75 cents; 2 copies for \$1.40; 3 copies for \$2.00; 5 for \$3.00; 10 for \$5.00.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premiums for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-Keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey." 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bienen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

A B C of Bee-Culture, by A. I. ROOT.—Embraces everything pertaining to the care of the Honey-Bee, and is valuable to the more advanced bee-keeper, as well as the beginner. Cloth, \$1.25; paper, \$1.

Blessed Bees, by JOHN ALLEN.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Price, 75c.

The Hive and Honey-Bee, by REV. L. L. LANGSTROTH.—This is the work of a master, and will always remain a standard. Price, \$2.00.

Dzierzon's Rational Bee-Keeping. A translation of the master-piece of that most celebrated German authority. Price, bound in cloth, \$2.00; in paper covers, \$1.50.

Queen-Rearing, by HENRY AILEY.—A full and detailed account of 23 years experience in rearing Queen Bees. The cheapest, easiest and best way of rearing. Price, \$1.

Bee-Keepers' Text Book, by A. J. KING.—A new edition, revised and enlarged. Price, \$1.00, bound in cloth.

Extracted Honey; Harvesting, Handling and Marketing.—By CHAS. DADANT & SON.—Details their management. Price, 15c.

Practical Hints to Bee-Keepers, by CHAS. F. MUTH.—Gives his views on the management of bees. Price, 10c.

Dzierzon Theory.—The fundamental principles of Dzierzon's system of apiculture as set forth by Berlepsch. It was translated by the late Samuel Wagner. Price, 15c.

Dictionary of Practical Apiculture, by PROF. JOHN PHIN.—This gives the correct meaning of nearly 500 apicultural terms. Price, bound in cloth, 50c.

The Hive I Use, by G. M. DOOLITTLE.—Details his management of bees. Price 5c.

Foul Brood, by A. R. KOHNKE.—Its origin and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic.—Contains over 1,000,000 industrial facts, calculations, processes, trade secrets, legal items, business forms, etc. Price, \$2.50.

Kendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has many good recipes, etc. Price, 50c., in either English or German.

Food Adulteration.—What we eat and should not eat. This book should be in every family. Price, 50c.

Scribner's Lumber and Log Book.—Gives measurement of all kinds of lumber, logs and planks; wages, rent, etc. Price, 35c.

Fisher's Grain Tables.—For casting up the price of grain, produce and hay; wood measurer, ready reckoner, tables for plowing, etc. Price, 40c.

Hand-Book of Health, by Dr. Foote. Rules for eating, drinking, sleeping, bathing, working, dressing, etc. Price, 25c.

Emerson Binders, made especially for the BEE JOURNAL, and lettered in gold on the back. 75c. for the Weekly; or for the Monthly, 50c. They cannot be sent by mail to Canada.

Constitution and By-Laws, for local Associations, \$2 per 100. The name of the Association printed in the blanks 50c. extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, 10c. each, or \$8 per 100.

Poulterer's Guide, for treating diseases of Poultry, etc., by C. J. WARD. Price 25c.

The Honey Crop.

The honey crop of the present year is not up to the standard either in quantity or quality. In some localities the so-called "honey-dew" has been so abundant as even to kill the leaves of the trees where it was deposited, and, of course, the bees gathered it in large quantities, and deposited it in the hives, but it is unworthy of the name of honey, not being of the nature of that article at all. A communication by Prof. Cook, in last week's BEE JOURNAL, describes very minutely the insects that deposit it; and also gives the remedies for preserving the trees from injury.

But now comes a worse trouble, and it is of a two-fold nature—we refer to the uses to which this so-called "honey-dew" secretion is put, when gathered by the bees. To sell it for honey will be as damaging to the sale of pure honey as to put glucose upon the market and sell it for honey, and it should not be done under any circumstances. A one-pound section well-filled with this stuff was placed on our desk a few days ago, with the question, "What is it?" It neither has the *smell* nor *taste* of honey, and is the poorest kind of a substitute for it. To all, then, the BEE JOURNAL would say: "Do not undertake to sell it for honey; no matter what the amount may be which the bees have deposited in their surplus honey sections."

The other point of the "caution" which we would give, is this: If the fall crop of honey should be a poor one, the bees may have nothing upon which to subsist during the coming winter, except this secretion of the

aphidæ, misnamed honey-dew, and the result of such a state of affairs may be very detrimental—spreading disease and death all around.

Should there be a bountiful honey crop this fall, it will be indeed "a God-send" to the poor bees—saving the lives of millions. Let us hope that it may be so, especially as the basswood has failed in many places, and the early harvest has been, generally, but a very slight one.

In case the fall-harvest is also a failure, there should be a close inspection of the contents of the hives, a general cleaning-out of the aphidæ secretion by the use of the extractor, and a systematic feeding of the bees with sugar-syrup, or good honey, for winter stores.

We give this word of warning thus early, so that no one may have an excuse for neglecting the matter until it is too late and thus entail a severe loss of bees during the next winter.

☞ We have received from Mr. C. B. SCHMIDT, Commissioner of Immigration, Topeka, Kansas, a copy of a little pamphlet published by him, which presents in very ingenious and striking form the facts about Kansas as an agricultural and stock-growing State. The statements made are illustrated by colored diagrams; comparisons are instituted between Kansas and other States, and different years of Kansas history are compared with each other to show the progress made.

☞ We have received the Premium List of the Upper Mississippi Inter-State Fair, to be held from Aug. 29 to Sept. 5, at Dubuque, Iowa; but it does not contain any premiums for bees and honey.

☞ The next meeting of the Bee-Keepers' Association of Boone and Hendricks counties will be held at H. Coxe's apiary, 1¼ miles east of Fayette, Boone County, Ind., on Saturday, Aug. 16, 1884. O. KNOWLTON.

Local Convention Directory.

1884. *Time and place of Meeting.*
- Aug. 6.—Lorain Co., O., at Elyria, O.
O. J. Terrell, Sec., North Ridgeville, O.
- Aug. 2.—Gibson Co., Tenn., at Trenton, Tenn.
T. J. Happell, Sec.
- Aug. 13.—Northeastern Ky., at Covington, Ky.

Grading, Crating & Shipping Honey.

In the *American Agriculturist* for August, we find the following very good hints on marketing honey:

The first grade should consist of only perfect, white combs, and it is the writer's opinion that, in many instances, there should be only this one grade of comb-honey. Some bee-keepers make a second grade of unfinished sections, but if the apiary is rightly managed, there will be but few of these at the close of the season, and it is better to extract the honey from them, and keep the combs until another season. Honey that is too dark for the first grade, should not, as a general thing, be stored in sections, as it is usually more profitable to extract it. Before crating, sections should be scraped clean of propolis. A small crate is preferable; it is more easily handled, and less liable to be "dumped," while it sometimes enables the retailer to sell a whole crate of honey at once. Sections should be placed only one tier high in shipping-crates; because if any combs of the upper tier become injured, the honey drips down and soils those of the lower tier. Some bee-keepers make a shallow "dish" of heavy manilla paper, and place it in the bottom of the crate, then if combs are injured, the "dish" catches the honey, and prevents the soiling of other crates. All honey-crates should have glass on at least one of the sides.

Reviewing the Situation.

Mrs. L. Harrison gives the following in the *Prairie Farmer* of last week:

Clover and linden bloom in this locality are now nearly over, and we are looking after the delinquents. The young queens, reared from cells taken from the best colonies, are laying, and if not built up into full colonies for the late harvest, will be introduced whenever a delinquent tax-payer is found. Sometimes a young queen is lost on her "bridal tour", and the bees have no eggs to rear another. In such hives, laying workers are found, and it is exceedingly difficult to introduce a queen there, as these aspiring mothers cannot be distinguished from the workers, and will destroy every queen that is put into their hive—there may be several of them. I have known them to let a virgin queen live, and destroy her when she returned from her flight. I have sometimes exchanged their frames for frames of brood, with another colony, and when the young bees emerged, they were not satisfied with laying workers, and protected the queen given them. The presence of these workers may be known by the brood in worker comb being all drone and in irregular order. The eggs of an unfecundated queen produce drones only, and the sooner she is supplanted the better.

During the interim between the early and the late flow, is a good time to utilize the odds and ends of unmarketable honey. At this season there has been in many localities a large amount of dark honey, the product of plant-lice. This can be fed during a scarcity, and the bees will rear young for the autumn harvest. It should be fed slowly so as to keep them breeding, and not enough for them to store it away. I feed weak colonies in the caps of their hives (so no bee can gain access to rob from the outside) the cappings from honey that is to be extracted, and all leakage and odds and ends of every sort, during wet days, when the bees cannot be in the fields.

The Marketing of Honey.

The *Indiana Farmer* gives the following timely hints on the above subject:

One might infer by the haste with which some of our friends rush into the market with their honey that it was a perishable article, or that it was a matter of life or death that their honey should be disposed of at once. Many again have an idea that by getting in a little ahead of their neighbor they will secure better prices and quicker sales. While the facts in the case are directly the reverse. But very little honey is consumed until the cool weather comes. Customers will buy a taste of new honey and there they stop, and are satisfied until the berry, fruit and vegetable crops are out of the way.

Then we may expect a good sale for our honey.

For the most satisfactory results in disposing of our honey crop, the home market should first be taken into consideration, especially when the crop to be disposed of is not very large. Honey, like all other commodities, loses in the price to the producer, the farther from home it goes to find a consumer. Large crops, of course, must seek large markets. At present we are considering only those who have a few hundred pounds to dispose of. There is scarcely a family in the land but can be induced to purchase a few pounds of honey, if offered to them in the right manner.

Our people are large consumers of sweets. The adulteration of syrups has been carried to such an extent that they have become disgusted and nauseated with them, and are in search of something to fill the want, and now is the time for bee-keepers to take action and offer to the people the products of our apiaries. Pure honey is about the only pure sweet now obtainable. As to just what shape in which the honey shall be offered depends entirely on the kind of trade you wish to supply. To home-consumers, extracted honey in fruit jars, tin buckets or cans holding from three to thirty pounds, seem to give best satisfaction, but for fancy grocers' trade, the one-half pound, one and two-pound glass jars suit the best. Each package, let it be what it may, should bear the producer's name. People of to-day rely much more on brands and producers' names than many suppose, or than was formerly the case, when adulteration was so little practiced.

Comb honey is marketable only in sections, the one-pounds finding preference in our larger markets. These should be packed in neat shipping-cases, holding about 20 pounds each, as such find quicker sales and are less liable to be damaged in handling.

Melting out Beeswax.

A lady correspondent in the *Pacific Rural Press* gives her experience in melting out beeswax, as follows:

I will not say who of our family can make the most muss while melting out wax, but even the worst one can not make much muss in my way of melting; but by the boiling-out process there is too much chance for it. I have tried both ways, and know of what I say. I take the pieces of comb and press them together in as small a compass as possible, without too much trouble; then put it into the large dripper that fills the oven, or into two small ones if preferred. Make a good fire and put the pans in the oven; in a very short time it will be all melted. Then have a dish ready, also a hoop covered with house-lining, and pour the melted comb into the dish through the cloth. Then fill up the pan, set it back into the oven, and take the impromptu strainer, from which all the wax will have dropped by this time, and empty the refuse

into the stove to make fire for melting out more wax. The wax, in that way, is pure and clean, and much whiter than when boiled, because the water takes out the dirt and coloring-matter in the comb and mixes it with the wax; and in this way I can do it much faster and with much less wood, which is quite an item in some places. Try it and see if it is not the best way.

Honey and Beeswax Market.

OFFICE OF THE AMERICAN BEE JOURNAL,
Monday, 10 a. m., Aug. 4, 1884.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY.—The demand for extracted is fair, and to all appearances, gradually improving. It brings 6@9c per pound on arrival. There is a small demand for comb honey, but we had small offers only, and a good deal could be sold. It brings 14c per pound on arrival.
BEESWAX—Offers plentiful at 30@32c on arrival. C. F. MUTH, Freeman & Central Ave.

NEW YORK.

HONEY.—Sales of comb honey continue slow. As yet there are no arrivals of this season's crop. We have received several small shipments of new extracted honey, which sold readily. For prices on this year's crop, we quote: Fancy white, 1-lb., 16@18c; fancy white, 2-lb., 15@16c; fair to good, 1 and 2-lb., 12@14c; fancy buckwheat, 1-lb., 12@13c; 2-lb., 11@12c. Extracted, white clover, in kegs or small barrels, 85@90c; dark grades, 7@7½c.
BEESWAX—Prime yellow, 30@32c.
MCCAUL & HILDRETH, 34 Hudson St.

BOSTON.

HONEY.—New honey is coming in, and selling at 16@18c, for best white 1 and 2-pound sections. New extracted, 8@9c. Honey in unglazed sections sells the most readily. Old comb honey all gone.
BEESWAX—35c.
BLAKE & RIPLEY, 57 Chatham Street.

CHICAGO.

HONEY.—This week we have had liberal receipts of comb honey, and the prices are irregular. As a rule, the honey is of first quality, and put up in good shape; a gradual improvement is noted in this respect. Prices range from 14@16c for the best; occasionally a case sells for more than that, but it is in a retail way. The extracted honey is still sluggish, at nominal prices—6@8c per pound.
BEESWAX—Fair receipts; prices, 30@37c.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—Receipts are increasing. There is no improvement to note in the inquiry. Buyers are few and bids low. There is not a single transfer of a wholesale character to report. Strictly choice extracted was offered at 5¼c. Comb from the San Joaquin, and of choice quality for that section, sold for 12c. Stocks are distributed in so many hands that sellers are placed to much greater disadvantage than if offerings were more concentrated. White to extra white comb, 12@15c; dark to good, 10@12c; extracted, choice to extra white, 5@6c; dark and candied, 4c.
BEESWAX—Wholesale, 25c.
STEARNS & SMITH, 423 Front Street.

KANSAS CITY.

HONEY.—Choice new 2-lb. sections are now bringing 17@18c, and 1-lb., 18@19c, ½-lb., 19@20c. Extracted in fair demand at 7@8c; extra choice would bring 9c in barrels. No other packages wanted in this market.
BEESWAX—Nominal, 30@35c.
JEROME TWICHELL, 514 Walnut Street.

ST. LOUIS.

HONEY.—Steady; demand and supply both small. Comb, 12@14c per lb., and strained and extracted 6@6½c.
BEESWAX—Firm at 32@32½c. for choice.
W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY.—There are some arrivals of new-honey which is very nice, unusually so. Our market does not seem to be quite ready for it, the demand not having begun, and no sales made worth mentioning. It is our aim to get 18c for best 1-pound sections, and 16c for 2-pounds. Extracted, as usual, is dull.
BEESWAX—30c.
A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY.—We quote comb honey in 2 lb. sections, 15@16c; extracted, 7@7½c.
GEO. W. MEADE & CO., 213 Market St.

CORRESPONDENCE

For the American Bee Journal

The Pollen Theory Again.

JAMES HEDDON.

It seems that some of our honey-producers are agreeing with me regarding the above theory. It also seems that some of them, who believe that there is much honor in priority of discovery, propose to take unto themselves priority regarding the "pollen theory." Some of our Professors take less kindly to the above theory than do practical honey-producers.

One producer has lately claimed priority because I have been more modest than himself and others in asserting that I "knew, and had the whole problem in a nut-shell." I have believed the theory. I said so at an early date to draw out this friendly discussion and get at facts. I thought that I might be wrong, and so I felt my way carefully, and I am still doing so with an increasing show of evidence pointing to the truth of the theory.

For this care and conservatism, Mr. Fradenburg proposes to relieve me of any honor which might, and as he believes, will grow out of my discoveries.

Dr. Tinker seems to be edging over toward the theory, getting upon one plank at a time, but using great energy to push me off from each plank as he gets on. He appears to desire my wintering theories, in part, but not my company in their enjoyment.

I will, for the sake of self-defense, reply to the Doctor in part and parcel, and trust that this reply will also do for my literary friends whose attacks appear in the same issue. Not only "Prof. Cook," but others (myself among them) have made several experiments with sugar syrup vs. honey as winter stores. I made one experiment with 16 colonies during the winter of 1871 and 1872, I think it was, but perhaps it was 1872 and 1873; another about 3 years later, another 2 years ago, and again the one of the report in question.

Like the Professor and others, I found and declared effects in favor of the cane sugar. I found that the judgment of man knew better than their own instincts what was best for bees. I find that if a choice between sugar syrup and poor honey is left to their instincts to decide upon, that they will be "silly" enough to choose the worst food. I find that they are sometimes nearly as "silly," and need the intelligence of man to protect them in regard to a choice between honey and bee-bread as a winter diet.

Now, in regard to "causes," I do call cold no less than one of the great "auxiliary causes," and in this all will agree. I do not give it the place

of "primary cause," because I find that bee-diarrhoea rages in mild climates and in cellars where the temperature never is lower than 40° Fahr. above zero. I also find that bees do winter successfully where a severe cold is brought against them. The same line of facts forces the reasoner to shut out "confinement" as a primary cause; it too, being only an auxiliary cause. Now, it would be very "interesting" to me to know why I have made any error in the classification of cold and confinement as auxiliary, and not primary causes.

The Doctor tells us that our Southern friends look upon our cold as the primary cause of the disease. Well, they have it, and suffer from the disease in Missouri. There they do not look upon cold as the cause, or yet Doolittle's "confinement." Perhaps a few of the less literary Southern friends who have not suffered in their immediate vicinity, may ascribe the lower temperature of our Northern climate as the cause; but such are only making the same mistake that some of our people do, in thinking that the heat of the South is the primary cause of yellow fever.

The Doctor tells us that some of our able observers have proven that "restlessness," "excitement," and "undue activity" are symptoms of the disease. Yes, they are symptoms, and effects only, in nearly all cases; but sometimes may act as auxiliary causes, in a lesser degree. I supposed that not only the "abler" but the less "able" apiarist had found that out. The Doctor further tells us that those colonies which remain quietly clustered upon the combs, usually have no disease. That is true; but I put it this way: those colonies which do not get over-loaded with feces, remain quiet and have no disease. Agitation and excitement, I think, do sometimes act as an auxiliary cause, but not a primary cause. And why? because I have witnessed and cited the readers many instances when an intense agitation and excitement failed to produce any signs of the disease. Take the case of Mr. Milliner, of Big Rapids, when he put his bees into the cellar in the rattle-jam, closed entrance method, which I have heretofore given; also my own experience with the bees brought from the country in mid-winter. Now, Doctor, do not say that pollen is not a primary cause, because bees do not have diarrhoea in summer; because they get the disease only by an aggregated loading of the intestines, which cannot take place when they fly and void daily. They will have it, and in less time than in winter, if confined.

A man lost his life. He was killed by a lion. No such death could have occurred had it not been for the mother of this lion. However, the old lioness is not called the primary cause of the death. "Yellow Jack" cannot exist after a frost, but heat is not its cause, only a necessary condition to the development of that primary cause, microcoxi. I hope that I am now clearly understood, and shall never have to go over this ground again.

The Doctor hints that restlessness causes the demand for nitrogenous food, and the residue from this food, and worn-out tissue, constitute the excrement which we find in cases of bee-diarrhoea. Now, I believe that there is plenty to cause the disease, resulting from the pollen alone. I further believe that there is not enough resulting from effete tissue to do any harm whatever. I will call your attention to the fact that Prof. Cook, or his assistant, found the solid matter of diarrhoea excreta, examined by them, almost wholly pollen, and distinguished it so plainly with the microscope, that they could determine the flowers from which some of it was gathered.

Now I come to an assertion which I am not prepared to accept or reject. I have had no evidence either way. I have never met a gentleman who claimed to have had any.—It is this: That bees can and do eat pollen all winter long, and yet winter well. Some way or other, I do not remember of ever reading any thing corroborating this assertion, the source and style of which, settled itself upon my mind as any evidence. If "pollen husks" (whatever they may be) are found in the intestines of bees that have wintered well, I should next want to get to an agreement of what condition is meant by "well." Bees may be wintered safely, *i. e.*, so as to save the individuality of the colony, and not to be wintered as "well" as I wish and as I wintered the 45 colonies referred to in my report.

The Doctor says that "no trouble comes from slight accumulations;" this I agree to. He further says: "It is only when, as in such a winter as that of 1880-81, that bees are obliged to consume inordinate and almost unprecedented quantities of both honey and pollen to keep life in them, that these harmful accumulations arise." Right here is one more of the Doctor's fatal errors.

I told you that I put colonies with plenty of as good, sweet honey and pollen as one could wish, and in a cellar whose temperature never was below 42°, nor above 45° or 47° (as I recollect it); and that they began dying with diarrhoea in its worst form in less than three weeks after confinement; and that before two-thirds of the confinement (at other times successful) was passed, nearly every one of that whole apiary was dead. You also know that in Kentucky, some 16 years ago, without any such conditions regarding cold or confinement as those present in the North during the winter of "1880-81," the beekeepers were all panic-stricken with the fatality caused by the disease in question. Now the Doctor tells us that "if restlessness then causes the bees to eat too freely of pollenized food, it ranks as a prior cause; and the most that could be held is, that the latter may be an auxiliary cause, while restlessness, as the effect of cold, humidity and confinement, one or all, must stand as the primary cause or causes amenable to the hand of man. I am, therefore, unable to

see the propriety of excluding the bee-bread from the bees in winter, but think that we should provide against the primary causes; and I shall hold that the latter policy may be more economically executed than the former, and that it is practicable, effectual in results, and consistent in theory." Right here we differ again, and in more ways than one. Whatever may be the most practical method of avoiding the disastrous results, I believe that bee-keepers will bear me out in asserting that to pollen is properly attached the term "primary cause." The disease is intestinal inflammation. The inflammation was produced by the irritation of pollen residue coming in actual contact with the diseased parts.

But we also differ regarding the most efficient method of prevention, according to our present light in the matter. It is preposterous to make the claim that any repository, system or ventilation, out-door packing, absorbant, or anything of the kind, can be relied upon as a prevention of the disease. The sad experience of hundreds of bee-keepers not only proves to them, but likewise to every thoughtful bee-keeper, that there is no certainty of success through any of the conditions mentioned by the Doctor.

Whenever we know just what is the cause of this premature consumption of pollen, it may or may not turn out that we can remove that auxiliary cause more easily than the primary cause—pollen; but at present I have this advantage: If we agree that consumption of pollen produces the inflammation, we do not agree to any cause of said consumption.

For two years past we have been experimenting in regard to the prevention of bees storing their combs with pollen in the fall, and we now think it clear that cheap, off-hand practical methods can readily be adopted to avoid such storing. I do not doubt, and have so stated to my students, that we may so arrange auxiliary conditions that a moderate amount of bee-bread may remain in the hive without danger of any winter consumption; for we know that nature sometimes so arranges it.

I have for some time been of the opinion that the more honey the combs contain, and what is better, the more heavily they are filled with sugar syrup, the least apt the bees will be to consume any bee-bread.

Now, allow me to digress long enough to say that, in this locality bees gather at least $\frac{1}{3}$ more pollen than they ever consume. They place large quantities of it in brood-comb during the autumn. When new pollen comes in the following spring, the bees cut and carry out great quantities of that old bee-bread, much preferring the new, and needing the room it occupies, for brood, etc.

The Doctor's and Mr. Clarke's catch-quipple regarding the comb-full of bee-bread, savors of being hard pressed for argument. Did you ever see a comb full of brood? and would it all have to be capped, or ready to cap to warrant that name? Did you

ever see a comb full of eggs? I have heard men say they had. I did not suppose they meant that the cells were even full, only the comb was fully occupied. The comb of pollen in question contained very many cells of bee-bread not full, but occupied with it. In the spring it also contained many cells occupied with it—nearly as many as in the fall; but the pollen eaten down in many of them. Does it not seem strange that out of 45 sugar-fed colonies this one, and this one only, should show any signs of diarrhoea? I do not think such would usually be the case, but the late brood threw the cluster upon this comb.

Mr. Clarke makes the point that a majority of my bees having natural stores, came through also. I told you in my report two facts which answer that: First, owing to certain manipulation, we reduced the bee-bread more than one-half, we think; secondly, we further told you that the workers of every undiseased colony, which we examined, except the 45 in question, had distended bodies; while those of the 44 gave no appearance of such distention. Mr. Clarke's question was answered before he asked it, it seems to me.

The Doctor tells us that away up North, bee-keepers winter their bees with almost no loss at all; that wintering is no trick for them; that bee-bread in their hives in winter gives them no concern; and that they seldom have a case of bee-diarrhoea. How does this statement of the Doctor's accord with his cold, confinement, restlessness, consistent theory? The cold and confinement is far greater there than here, and in Southern Indiana and Kentucky. Fall weeds for pollen are not one-tenth part as profuse as here and farther South. The Doctor says that if I can give any practical method of reducing or excluding bee-bread from the hives in winter, it will offer us no advantages not already possessed. I fail to see where he gives us any evidence of the truthfulness of that statement. I expect to prove it false in the future.

Dr. Mason, of Wagon Works, O., says that he has proved it false for several winters. Many others say the same thing. I have re-read Mr. Wilber's communication on page 171 of the BEE JOURNAL for 1881, and studied it carefully, and see nothing inconsistent with my theory and practice. The Doctor does not offer us any reason why sugar syrup is any better than honey as a winter food. I have done so. I have told you that consistent with my pollen theory, sugar excels honey, because of its freedom from floating pollen nitrogenous substance, and its superior heat-producing qualities. Then the Doctor wonders who will say that had we had such a winter as in 1881, I would not have lost half of the 45 sugar-fed colonies. Well, I will say so, and I think that $\frac{3}{4}$ or more of the readers will say so.

We know that bee-diarrhoea is our only fear. We laugh at all winters, not going hand in hand with bee-diarrhoea, that we have never lost a

colony that did not have the disease, or died of starvation. Restlessness is no primary cause here. In the Doctor's thirteenth paragraph let us chronicle that he believes that some pollen is essential to the welfare of bees in winter.

Mr. A. I. Root says that his experience and aggregated reports teach him that bees are safer without pollen in the hive during confinement. I agree that bee-bread is very valuable for certain purposes when needed; even worth more than \$1 per pound; but it is like fire, a splendid servant, but an infernal master.

The Doctor's remarks about bees suffering in the spring for want of pollen, only shows that he is attacking what he does not understand. There is no danger from that, as we will explain in the future, as we have already gone too far now.

Regarding Mr. Clarke's new theory of wintering, I have to say that none of his essential claims have ever been presented to my practice as truth. I think he will soon have such a buzzing about his hibernation theory, that he will have no time to apply any of his literary vigor to the pollen question.

Dowagiac, Mich., July 24, 1884.

For the American Bee Journal.

How to Make Honey-Vinegar.

DR. L. C. WHITING.

All substances which contain sweets, or any substance capable of being converted into alcohol, can be made into vinegar. The old and slow method of producing acid-fermentation has been abandoned by the professional vinegar-maker, for a quicker process. On visiting a vinegar factory you will see a number of very tall, slim tubs; the bottom of which is made tight with a good head. A foot or so above this is a false bottom bored full of small holes, and the sides of the tub above this is bored full of holes which slant downward and inward, so that any drip will run in instead of out. The inside of the cask is filled with coarse shavings of beechwood, and the top is open. These chips are saturated with the best cider vinegar that can be had, and left to stand a few days to become well soaked and soured.

Old, hard cider, or sweetened water that has fermented, will become good vinegar by dripping slowly through these chips once or twice. Even sweetened water without fermentation will become vinegar; but if much is used at one time, the chips lose their acidity, and you have to sour them as at first, before you can do good work.

Whisky and water makes the best vinegar we have, and you can make from six to ten barrels per day, by passing it through this tub of chips. The room must be kept warm.

This process is not necessary in making honey-vinegar, except on a large scale, which would not be profitable on account of the price of honey; and it shows the importance of sour-

ing the cask, and having plenty of fresh air in contact.

Drawing from one cask to another in such a way as to expose it to the air, facilitates the change in proportion to the exposure. The strength of the vinegar depends upon the amount of sweet or alcohol you can work into it. If too sweet, it will not sour. The mother in vinegar is not only useless, but a detriment. One gallon of good vinegar will do more good than half a barrel of mother. Honey-vinegar, when fully ripened by age, loses all taste of the honey.

Large Yields of Honey.

W. H. STEWART.

In a recent article I referred to extraordinary reports of honey yields; and I will now state that I do not think that Mr. Pond has hit upon the true reason why a few colonies in an apiary give much more than an average yield of surplus honey.

It is very true that there may be circumstances that will, for a time, call most of the bees of the same colony off in the same direction. This is manifest in hunting bees. When we get one bee to carry home a load of honey, she will, on her return, be accompanied by others belonging to the same colony; and if the bait be allowed to remain at the same spot, the number of bees working on it will multiply at a rapid rate, and it is quite probable that in a short time nearly all, or perhaps the entire working force of the colony would work on the same spot.

Again, a colony of robbers having subdued a neighboring colony, would soon be out in full force to carry home the booty. There may be other circumstances that would induce an entire colony to work in the same direction from home, but where there is no inducement, there are not many bees to be found. I have kept bees in several different States, and have often watched them as they started out and returned home; and when the flow of honey has been nearly equal in all directions, I have noticed that the bees of the same colony work in all directions about the same.

Where I am now located, there are swamp lands south and west of me; and in early spring all the bees work in those directions. Later, when they work on white clover, they go east, north and west, as there is no clover within working distance of my bees on the south. What basswood they find is northwest, and nearly all go together in that direction during basswood bloom. About a week after basswood bloom is past, there opens a species of horse-mint or burgamont, which grows on the sandy plains south of me, on the other side of the Wisconsin river; and when the weather is such that it yields honey, nearly all of the bees seem to work in that direction. As they start out, they rise quite high in the air, and as I stand on the high river bank, or if

I am on an island in the river, I can hear the very heavy buzz of the bees going and returning over the river. This proves that all colonies work in the same direction when the honey yield is in one direction; but if the clover, basswood, buckwheat, mint, and other honey-yielding plants which in order, were equally distributed in all directions, then I am well satisfied that bees of the same colony would work about alike in all directions during each successive bloom.

We often notice that when bees start out in the morning, they fly around in the air, all the while enlarging their circle of flight, and it is probable that in so doing, they catch the sweet aroma of distant bloom as it is borne along on the wind, and that they search the location of that aroma until they are at the bloom from which it came. This being the case, the bees of the same colony would be apt to work in different directions, as the wind changed, provided that the blooming plants were found in different directions.

I think my experience during the season of 1883, will give some important light on the question under consideration. I may, perhaps, be considered a little wild when I state that I am well satisfied that those colonies which give such very large yields, are the most unprofitable colonies that we have; and when we find one producing much more than an average yield, we had better look well to their movements, and put a stop to their mischief as soon as possible.

In the spring of 1883, I managed to equalize my colonies as nearly as possible, and at the beginning of white clover bloom, they were about equally strong in numbers; all had plenty of combs, and all seemed to promise similar results; but when I began to extract the honey, I found that some produced double or three times as much surplus as others; and as this had been the order of things in by-gone years, it excited in me no particular suspicion until late in October.

I had been managing my bees through the summer, on Geo. Grimm's plan, *i. e.*, by saving through the season two or three full combs of early white honey to give the bees for winter stores. About the last week in September, I examined all the colonies, and gave each a good supply of heavy combs of well-cured and capped honey, and thought that I had all in good condition for the coming winter.

You can imagine my surprise, when on Oct. 20, I had occasion to examine a colony. I found those combs which I had given them a month before, were perfectly empty; and that the other combs in the hive were poor, and I had to feed them again. I then examined all the other colonies, and found it the rule: that those which had given the least surplus through the summer, were robbed of the winter stores that I had given them in September; and those which had given larger yields had all of their large frames of honey just as I had hung them in the hive in September; and not only so, but they had a large

amount of fresh honey in their other combs, and were just capping it over.

It will be remembered that early frost had cut off the honey flow in this vicinity before I fed my bees in September, and thus those colonies which had increased their stores, could not have gathered the honey from the field; but it is clear to me that they had been borrowing of their more honest neighbors, until the one had double the stores that they needed, while the others were poor.

Be it understood that during all this time, there had been no visible signs of robbing in the apiary (I watch closely during the spring and fall months for robbers); but the mischief had been done so adroitly and noiselessly that I suspected that nothing was wrong.

It is my opinion that this work is commenced in the spring; and when a colony gains access to a neighboring hive, the two colonies soon become so well acquainted that the robbers are allowed to pass in and out at pleasure, and that they thus obtain those large yields; while those that produce the small yields have been busy in the field, and have gathered for us far more honey than have those which gave the large yields.

Comments on Many Subjects.

DWIGHT FURNESS.

There is hardly a number of the BEE JOURNAL, so far, but what has contained valuable and practical articles which I have indexed in my reference book, for future use. The article on "Direct Introduction of Queens," by S. Simmins, on page 456 is, I believe, "sound doctrine," and well worth the price of the BEE JOURNAL for the year. I first got the idea from the writings of Messrs. Doolittle and Heddon, and have used it to a limited extent, but always successfully.

My experience in introducing queens, during the past two seasons, has led me to believe in the theory, that in ninety-nine cases in a hundred, where a queen is not accepted, she is herself the cause of the failure. In support of this theory, I have used Mr. H. L. Jeffrey's method of introducing, with uniformly good results.

I have a few nuclei colonies which take 4 frames $\frac{1}{2}$ -Langstroth size, and when short of queens or cells, I frequently change a queen from one colony to another, every 3 or 4 days, always taking a frame of comb and bees, with her. In this way one queen can be made to keep a good many nuclei strong and full of brood. I once got rid of a fertile worker in this way.

I can heartily endorse W. Z. Hutchinson's article on "Hiving Swarms of Bees;" but do not like his clothes-basket arrangement. I use a common box made of light wood, fastened to the end of a long pole, and seldom need to climb ladders or cut off branches. A neighboring bee-keeper, whose apiary is surrounded by a lot of

tall and slender oak trees, gave me his method of capturing swarms, which I have used a good deal. It is as follows: Fasten a common dry-goods box to the end of a long pole, and as soon as a swarm issues, go to the more convenient hive (an extracting super is best), take out a frame and shake the bees from it into the box. These bees at once set up a loud humming, and if the box is now held up in the midst of the flying swarm, they accept the call to cluster, enter the box without delay, and can be hived immediately; or if another swarm issues, set them aside and cover them with a sheet.

My apiary is situated in a grove of fruit and evergreen trees on a hillside, with some tall forest trees just below it, and swarms generally fly pretty high. If they start to cluster in an inconvenient place, I drive them away with the fountain pump, until they choose a place that suits me also. As soon as the cluster is partly formed, shake it into the box, by means of a long-hooked pole, and when nearly all have entered, carry them to the hive prepared for them. Have a piece of burlap tacked to a couple of laths, *a la* Hasty, down in front of the hive to shake them on; lower the box carefully and lightly, jar off a few bees close to the entrance, and when they have "sounded the call," shake down the rest of them in a long, broad stream. If properly done, they will not fly up again; but if they do, the box will catch them. Heddon's plan of preventing after-swarms, works like a charm with me, and is very easily executed.

I am convinced that it pays me to use full sheets of wired foundation, and have yet to hear of a bee-keeper going back to anything else, after a thorough trial of the wired frames. I once bought some colonies which were hived on full sheets of foundation without the wires, and the cells near the top-bar were stretched so much that they were used for drone brood. Drones bred in them were weak and dwarfed, and were dragged from the hives by the hundreds as soon as hatched. Another bee-keeper here has noticed the same thing.

I have also used Doolittle's plan of hiving on starters, with a division-board in the middle of the hive, with good results; although some colonies will persist in building drone-comb whether they have much worker-comb or not. With a large apiary it requires too much manipulation to be practical.

During a good honey flow, I prefer to hive swarms on 4 or 5 frames of foundation, and put on the boxes at once. (Put on partly filled boxes for a day or two to prevent the queen from using them.) Add more frames of foundation as fast as the queen needs them. This year, when put in a hive full of empty combs or frames of wired foundation, the bees nearly filled 3 or 4 of the combs with honey before the queen had time to lay in them, and thus crowded out another swarm within 10 or 15 days. Plenty of surplus was soon given

them, and they did good work in the sections at the same time.

Some of my colonies are confined to 7 frames in winter and summer, and I get fully as good results from them as from the 8-frame colonies. Seven frames solid with brood are all that an average queen can manage, and will produce enough bees.

Upon visiting an apiarist in this county, I found him by the kitchen stove fastening foundation-starters in flat, top-bar frames, and this is the way he did it: The frame was placed on a lap-board, top-bar down, the foundation put in place, and a piece of board, notched out at the ends so as to come exactly to the centre of the top-bar, was laid on the foundation. Then taking a putty knife, he held it for a moment in the steam of a tea-kettle's nose, and then with a quick, strong stroke, pressed the projecting edge of the foundation to the top-bar. Quicker and better work I have never seen done, and now I use the steam-heated knife for my wired frames also.

I should judge from an editorial in the *Kansas Bee-Keeper*, that Mr. Pond has already "reversed" his opinion in regard to reversible frames, as given on page 439 of the *BEE JOURNAL*. His next reversing will be, no doubt, in regard to "Italians vs. bees for business."

Furnessville, Ind., July 19, 1884.

For the American Bee Journal.

Bee-Diarrhœa.

C. W. DAYTON.

If we cause a colony to cluster the right distance (which is governed by the outside temperature) below the covering of the brood-chamber, moisture will accumulate over the cluster, in drops which will do no harm until they attain sufficient size to drop or run into or near the cluster.

This done, the first bee with which the drops of moisture come in contact, will take up a load with the intention of carrying it out of the hive at the first opportunity. The more moisture, the more loaded bees to become chilly and go back into the cluster to await a higher temperature; and as day after day wears away, with no chance to get out, all the bees become loaded with cold water which can cause indigestion, thus resulting in an overloading of the intestines with undigested food and water, and inflammation of the bowels may ensue.

I have seen healthy bees in mid-winter walk out to the edges of the combs, sip water, and go back distended, and in 15 days only the distended ones began to die of diarrhœa.

By re-adjusting the packing over the colonies when first affected, to avoid moisture, I find that the noisy ones will mostly go to the cellar-bottom in 25 days, and the remainder of the colony will come out healthy after 100 days more of confinement. I have regulated the temperature and covered the brood-chambers of normal colonies with a material which produced

diarrhœa in 10 days, the removal of which was prevention, and its re-adjustment brought additional disease.

When the moisture accumulated at the side, or in the corners of the hive, I have seen no signs of disease until a disturbance, shift of the cluster, or a rise in temperature set the bees to taking up the moisture. So long as the inside of the hive remained dry, I have been unable to produce diarrhœa by shifting the cluster, changing temperature, reasonable but frequent disturbances, or brood-rearing.

In wintering 60 colonies, a large share of whose hives were dripping wet inside, in February, there was but one whose combs showed mold in the spring, and that was the only one where the bottom-board was left on the hive, and the entrance contracted. I have frequently noticed signs of diarrhœa at such times as is described on page 639 of the *BEE JOURNAL* for 1883; yet never unless the temperature had been such as to cause the condensation of moisture inside the hive, and followed by a day somewhat warmer, but not enough to allow the bees a flight.

Bradford, Iowa.

Breeding and Selling Queens.

E. P. CHURCHILL.

Since the new races of bees (aside from Italians) have spread over the country, and since queens are bought and sold by thousands of bee-keepers, how are we to know when we get what we pay for? I bought 2 early, untested queens through a reliable breeder, here in Maine, who had a number from the South at the same time, and from parties who advertise largely, and are considered honest, and who claim to have all pure stock.

One of these queens proved to be a hybrid, and about as soon as she commenced laying she died; perhaps from old age, for all the others (about a dozen) proved to be the same. Is it not strange that such a number should all prove impure? Now for the result of the other queen which was bought from another party. I have tried reversible frames, and like them; but reversible bees I do not like. When I smoke them, do they not reverse? Take up a frame as carefully as you can, and you may deliberately get stung on the hand or face. These bees are well marked, 3 banded, and look, at first, like pure Italians. Suppose that I should breed queens from this queen, and scatter them over the country, would it not tend to spoil the kind disposition of the pure Italians? No person can sit close to this colony without noticing that they are reversible (and yet they use the same end every time).

Again, I have a select-tested queen from a breeder here, whose bees have not yet stung any one; and I have brushed bees from combs, and extracted the honey, and that too without a particle of smoke. These bees and queen are what I consider perfect.

I bought a queen from an Ohio queen-breeder, last season, which pleases me very much in all respects. A horse can feed close to the hive, or a person may stand by the hive all day, and when we handle the frames, the bees are there, and not in your face.

I believe that the matter of queens demands the greatest care; *i. e.*, if we wish to know what we are getting. If I buy a hybrid, I want to be told so, or at least I want that impression. I believe as Mr. Root says, that "the one who sells the best is the one who will win." It is a great disappointment, after waiting to test a queen in a full colony, to find that the bees are no improvement over those from the superseded queen, and that we must try again.

I am more in favor of pure Italians, since I see their kind disposition; and I almost think that it is best to buy tested queens, if I can get them where other bloods have not been mixed with them. I would be pleased to hear from others on this subject.

In regard to reversible frames, I have reversed all which were not full at the bottom, but which are now, and such a full set of brood I never saw; so much so that the bees have hardly any honey-cells, and must take the supers.

North Auburn, Maine.

For the American Bee Journal.

Priority of Location.

R. J. KENDALL.

Mr. Pond is a curious man—and his arguments on the above question are curious too. He either cannot or will not see; and which one it is, I am at a loss to understand. The history of this discussion is brief: Mr. Heddon wrote an article in which he showed how a practical apiarist *could* control a honey-field; how it could be done, and how an intruder could be driven out. Mr. Pond wrote an article in which he argued against the rightfulness of it (not against its possibility), and said Mr. Heddon was "selfish," etc.; in fact, his article was directed at Mr. Heddon and his motives. With Mr. Pond it was not right to do as Mr. Heddon proposed. He did not argue against his power or his legal right. Mr. Heddon replied, and so disposed of the morality, the rightfulness of the question, that Mr. Pond immediately shifted his ground and argued that a man had a *legal right* to come into another man's location.

I saw the injustice Mr. Pond was doing Mr. Heddon, and chipped into the discussion, saying that we were arguing first the moral right of the first locator to keep out intruders if he could; and secondly, his power to do so, and I said that no one doubted that an intruder had a legal right (and in that sense Mr. Pond was "legally right," and in that sense only) to enter another man's location, but he had no moral right, and that even looking upon this as a question of law, that the principles of law were

against Mr. Pond, and I gave illustrations. Mr. Pond, in his reply, tries to ridicule me as he did Mr. Heddon, and asks with an air of exultation, if he is legally right, how can the principle of law be against him? I can tell Mr. Pond very easily the how, but before doing so, I would point out how in his manner of asking that question he changes the sense, and makes it bear an entirely different look to the position and point we are discussing. His "legal right" he puts in the sense of being according to the principles of law, whereas he is only "legally right" in the sense that I doubt whether any court would issue an injunction to keep the intruder out; but I apprehend that the court would soon be convinced (as Mr. Pond himself was, and showed that he was, by changing his position) that the intruder, by intruding, did the settler an injury, and consequently did a moral wrong, so far as bees went, and that being so, an equity decision might be rendered, as a precedent, for as yet such a question has not been passed on by any court that I ever heard of. Legal principles are based on equity, they are equity.

The equity of the matter Mr. Pond has accepted by his silently accepting and not answering the equity argument. He only now contends for the legality, inasmuch as that the settler cannot legally sue out an injunction and prevent an intruder putting bees in his locality. Cannot Mr. Pond see the difference, the wide difference? and that he is "legally right" in the sense of present special enactments, yet that the *principles* of law go dead against him? One of the principles of equity is, I think, that "where there is a wrong there is a remedy." In the case we are discussing, the remedy would be an injunction preventing the intruder coming into the settler's field.

Mr. Pond then goes on to discuss the foundations of titles and tenures. He says, and says as a lawyer, "The principles of law, as I understand them, require 20 years of adverse, uninterrupted and exclusive use to get tenure of my estate in fee." Now we all know that while that is true in certain cases, it is not true in all cases, and that it is false in millions of cases. I can get an absolute title in a few minutes, a title as absolute as Mr. Pond's 20 years, and Mr. Pond knows, or should know this; but there are other ways of getting title as I told Mr. Pond, and discovery and first settlement are two of the very strongest titles. This idea was carried out by every one of the discoverers of past days, and recognized by other nations, and is to-day. The idea is recognized by pre-emption, and it is recognized by the cattle and sheep men, and by miners in the West by first entry, and priority of location. Nobody is foolish enough, no one has contended that a man can get a title to *land* by letting his bees graze the flowers on it for 20 years. This is one of the ways Mr. Pond tries to put his opponent into a position he never put up. I do not forget anything about

bees being in *fera natura*, and never raised that question to permit Mr. Pond to force any such position as he again tries to do, on me.

Mr. Pond says he had determined to quit the discussion, because it had become "more of a personal than apicultural nature." It was Mr. Pond who made it personal by ridiculing and speaking disparagingly of Mr. Heddon. "Consistency thou art a jewel" indeed.

I do not know that this discussion will do much good, except that as we have the morality, the rightfulness, the equity of the "priority of location" theory in bee-keeping recognized, it may be a step towards getting an equity decision, and so enforcing by direct enactment a right recognized but not protected by law. If this is not obtained, let every bee-keeper whose honey is his livelihood, practice Mr. Heddon's teachings, as set out on page 86 of the AMERICAN BEE JOURNAL.

Austin, Texas.

[This discussion is altogether too personal to be beneficial, and here let it stop, for the present. Discussions, to be profitable, should be impersonal—confined to measures and not men.—ED.]

Read at the Maine Convention.

Profitable Bee-Keeping in Maine.

J. B. MASON.

The question of most importance, because the one which affects us most pecuniarily is, "Can we keep bees at a profit in Maine? I answer, yes, I think we can. From a wide range of observation in our own State, and from reports received from other States, I find that bee-culture, systematically and understandingly carried on, pays well. Some may say that the Western States possess advantages which we do not. I have traveled some there, and as far as my observation goes, the honey-flora of Maine compares favorably with those States, and nowhere is better honey produced than here. And better still, we realize better prices here than in the West. I have lately conversed with a man who had formerly lived in Illinois, but subsequently moved to Maine, and last season, with the help of a man and a girl, cared for 140 colonies, increased them to two hundred, and produced three tons of honey which he sold for twenty-five cents per lb. at wholesale, thus giving him, for honey, \$1400, and the increases were valued at \$360, making a total income of \$1760. While one such individual case does not prove the assumption that bee-keeping is profitable in Maine, it is one case pointing in that direction, and by gathering facts from such sources is the voice of the State expressed.

Mechanics Falls, Me.

Letters for publication must be written on a separate piece of paper from items of business.

For the American Bee Journal.

Proofs vs. Evidence.

J. E. POND, JR.

It would seem that not only my ideas as a bee-keeper are criticised, but also my knowledge as a lawyer. If I did not know more law than my critics show evidence of knowing, I should at once quit the profession.

A few weeks ago I was accused of mis-applying legal principles; last week a friend insists that I do not understand the principles of evidence. Now, a lawyer who neither understands law nor evidence, must be a pretty poor tool. But does our criticising friend understand fully what he is writing about? He claims to have 45 proofs in favor of the pollen theory against 9 of mine. I did not suppose that either of us had proved anything. He offered a certain amount of evidence, but evidence is not proof.

We prove facts by means of evidence, but the evidence must be weighed carefully in order to judge of its value. Now, in regard to proving the pollen theory to be correct or not, my 9 witnesses that had no diarrhoea, with pollen in the hives, prove conclusively that pollen did not cause the disease in them. I may not be able to judge of proofs, but I do know that evidence may or may not prove a thing, depending upon its value.

Foxboro, Mass.

For the American Bee Journal.

Obtaining Statistical Information.

M. BRAY.

The subject of obtaining statistics in regard to apiculture, may be somewhat worn, but I do not like to see it dropped altogether, and so I propose to outline a little; if it shall lead to any plans which are practical, my object will have been obtained.

I would suggest the forming of an association for the express purpose of obtaining the desired information; and we must make it an object for bee-keepers to report. The time and place to form an association will be at the North American Bee-Keepers' Convention at Rochester, N. Y. Let the members of that association organize for obtaining the desired information, and then invite members of district, State and county associations, and all bee-keepers who are interested, to send in their names with dues (which shall be determined by the association), and take a membership; thus we will have a sprinkling of bee-keepers in all parts of North America as a foundation to build upon.

I do not wish to be considered as writing a code of by-laws, but will name some of the work of the association when organized. The officers shall be, President, Vice-President, Secretary and Treasurer. The Secretary shall receive all dues; and also all reports, transfer them to the Society's books, and receipt for the same. The following will do for a

receipt, and can be printed on a postal card: "Dear Sir:—Your report is received and transferred to the Society's books." The bee-keeper will then know that his or her report has been received, and that he or she is on record as a honey-producer. This is not all. When the reports are all in they shall be listed by districts or States, and a list of names that have reported, sent to each member so reporting from such district or State, with address and amount produced affixed to each individual name so reporting. All bee-keepers who have a supply business shall have a short notice of their business appended to their report. Dealers in honey and beeswax shall have the right to take a membership, and have a notice of business and address appended to their names.

Thus we would get what would be an equivalent to a formal introduction to each bee-keeper who reports from the State in which he resides, which would be one form of sociability, and have the satisfaction of knowing what those around us are doing.

I would allow any one to obtain lists of names in districts or States, other than that in which they reside, by sending to the Society a stipulated amount, and naming the State or district which they wish the names from; or any one may have their name and address listed in any district or State, other than their own, with notice of business appended, by paying dues for that district or State.

Members will be considered under obligations to report once a year, and besides their own report, to send such other information as may be of value, and also to lend their influence against fraud and adulteration.

As a prospectus, I would suggest that an invitation be given through the various bee-publications, for all parties interested to send their names with addresses to some one that will be kind enough to receive and care for them up to the time of meeting of the North American Bee-Keepers' Association, all such being considered as charter members.

I would suggest that Dr. C. C. Miller, of Marengo, Ill., is "the right man, and in the right place" to receive and present the names.

This may look visionary to some, but I have talked with several bee-keepers on the subject—some that do not take publications on apiculture—and without exception they have expressed a willingness to assist in it. I think dues can be made small enough to make it an object for any bee-keeper to take a membership. In case we could only get a small list of names, the whole United States might be listed together. If we can get 1,000 names, I would pay \$1 for a list—and I have no ax to grind either.

New Almaden, Cal., July 22, 1884.

The Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will hold its next meeting on the third Tuesday in August, at Leroy Highbarger's, near Adaline, Ogle County, Ill.

J. STEWART, Sec.

SELECTIONS FROM OUR LETTER BOX**Disagreeable Weather for Bees.**

Bees have done very poorly, so far, in this locality. We have had rain, hail, sleet and snow for the last eight months, with, perhaps, one day of clear weather each week. My bees have been fed since May 1. In fact, it has been so cold that ventilation on the bottom-board has been closed during the season. With the entrance $\frac{1}{2}$ closed, I have managed to keep my bees from freezing during July. Mt. Shasta is covered deeper with snow this season than for years, and as I am located within 10 miles of its base, I feel the cool nights quite forcibly.

BYRON BRYAN.

Edgewood, Cal., July 20, 1884.

California Honey at the World's Fair.

To the Bee-Keepers who wish to make an Exhibit at the World's Fair:—The District Bee-Keepers' Association of Southern California intend to send an exhibit to the World's Fair to be held at New Orleans, from December 1, 1884, to June 7, 1885. The collection will be taken from the display made at the District Fair held in Los Angeles this fall. I have made arrangements with the Chief of Installation to make an exhibit of the honey-industry of California, and I would ask all bee-keepers who would like to help in making a display of our industry to send to my address at El Monte, by freight or express, whatever they have that would help out the exhibit. I will see that the material is taken proper care of, and at the proper time sent to New Orleans. All comb honey should be sent in crates, and extracted honey in tin cans, accompanied by suitable glass bottles or jars in which to exhibit it. I hope that all will take an interest in the matter, so that we may make a display that will be a credit to the apiarists of the Pacific coast.

W. W. BLISS.

Duarte, Cal.

Honey Harvest Over.

The honey harvest for this year is past. The season has been only tolerably good. I think that less than half as much honey was gathered this year as was gathered last year. The secretion of nectar was very good from June 8 to 23; but owing to the very poor season prior to June, the bees did not fill the hives with brood, and did not have the necessary amount of laborers to secure the nectar during its flow. Some colonies were few in numbers, and only became populous as the honey in the flowers evaporated. Those colonies will need attention and feed, unless a favorable fall helps them through. The swarms were few in this section, owing to the lateness of the honey harvest and its sudden cessation.

S. HATHAWAY.

Muncie, Ind., July 28, 1884.

No White Honey.

Central New York has no white honey to speak of. We got a fair yield from apple bloom, and a little from clover. Raspberries produced quite a nice flow, but not enough to store in the boxes. Only $\frac{1}{4}$ of the basswood bloomed, and nearly $\frac{1}{2}$ of that was killed by the May frost, which froze ice as thick as a window-pane. The wind blew from the west very hard all the time basswood was in bloom, and with cool nights the bees did not whiten the combs a particle with wax. The two places, Groton and Lansing, produced over 20,000 pounds of white honey last year—this year not 100 pounds. There have been but very few natural swarms. The outlook is splendid for buckwheat, which is just coming into bloom. If it fails as it did last year, we will have to feed our bees from this time on. W. L. COGSHALL.
West Groton, N. Y., July 28, 1884.

Bee-Keeping in the Mountains.

We have had a splended honey flow for two months past. We are now 18 miles from the sea, at an altitude of about 2,000 feet above the sea level, and in the mountains between the Sanantone and the Nasemeento rivers, thus having the advantage of the valley bloom as well as that of the mountains. The higher up the mountains, each variety of flowers bloom. A most delightful climate to live in, and many varieties of fruit do well in this mountainous region. Apple, pear, peach, apricot, nectarine, cherry, figs, Japanese persimmon, olive, almond, and English walnut do well here; and we still have some Government land yet for the actual settler. I have recently purchased 3 Italian queen-bees from Georgia, which are the finest, and produce the best workers of any queens I ever bought; and in that long distance, almost from the Atlantic to the Pacific, they came through with a loss of but 7 of the workers. JOS. SAYLER.
Pleito, Cal., July 22, 1884.

The Use of Foundation in Sections.

It is a well known fact, that several manufacturers of comb foundation make it so thin that it cannot be detected if used in the production of comb honey. Now what objections can there be to the using of such foundation in sections? Because it is adulterating honey? Is it adulterating honey, or the cells in which honey is stored? and is that adulteration? No; if we use pure beeswax, it is not adulteration. If we should take two barrels of pure sugar, both alike, and mix them, would that be adulterating sugar? When we use pure beeswax in the manufacture of comb foundation, it cannot be adulteration, as all honey-comb is made of wax. Were paraffine used for foundation, it would then be adulteration.

This extra-thin foundation cannot be called "fish-bone," as it is as thin as natural comb; and if any bee-keepers are so careless as to use thick foundation in their sections, they

should be paid only about half-price for their honey. Some say that thin foundation is too expensive; but it is really cheaper at \$1 per lb. than the thick foundation, at 50 cents per lb.

Mr. Doolittle says on page 453, that choice comb honey, if really nice, will all melt away in the mouth while being eaten. That is a fact; but that the wax will melt away, I cannot believe. I have tested honey with and without foundation, and cannot see or taste the slightest difference. By filling a section one-third full of foundation, and letting the bees build the remainder of natural comb, we will have an excellent opportunity of testing the two theories. Let us all test it. H. W. SIMON.

Youngstown, O., July 24, 1884.

But Little Honey.

The yield of white clover and basswood honey, in this section, is very light, and unless the fall honey harvest is better, we will have very little honey this season. D. D. UPDYKE.
Bible Grove, Mo., July 18, 1884.

Gloomy Prospects.

We are in the back-ground with our bees and honey this season. It is with gloomy prospects for honey that I enter my bee-yards to work. Basswood is nearly gone, and there is no honey stored yet—no, not a pound to sell from this section, unless we have a good flow from buckwheat. We are overstocked with bees in this vicinity, and the frost killed the basswood buds. It has been very cold and lowery, so that the bees could not work. I hope that there will be honey gathered in other sections of the country. D. H. COGSHALL, JR.
West Groton, N. Y., July 25, 1884.

Bees have done Swarming.

Bees generally have done swarming. I have had only 35 natural swarms from 128 colonies, spring count. I kept swarming back as much as possible with the extractor. The flow from clover is abundant, but short on account of dry weather. The basswood bloom is good, but bees are unable to secure the honey on account of cold, raw winds during its continuance. Sweet clover is coming into bloom, and bees are storing quite freely. The weather is good at this date. On the whole, it has been a very fair season. Most of the colonies run for comb honey have filled one case of sections, and a portion of the second set. All the hives used for extracted honey are two-story; from the upper story I extracted once, and a portion the second time; all will be ready for the extractor next week. It will be a busy week with me, if the weather is such that I can open the hives, brush the bees, and handle the combs. My 163 colonies are all supplied with laying queens, with a fair prospect for goldenrod, and no extracting from the lower stories. I think I shall be able to put my bees into winter quarters in good condition on natural stores; although I constantly keep putting in

my honey-house a barrel of the best granulated sugar, and my feeding-can filled with good syrup made from the same; yet I believe that natural stores are as good as any, if not better, and I shall not give myself the trouble and expense to remove good, natural stores—either pollen or honey—to substitute something else. Heddon's and others' theory to the contrary notwithstanding.

Fredonia, N. Y. U. E. DODGE.

Milk-Weed and Honey-Dew.

Enclosed find part of a plant with its flowers. Bees work on it lively all day, and seem to get a good deal of honey. Owing to the deep red color of the flower, I do not think the honey can be anything extra. Please give name of this plant, and if it is a good honey-producing plant. We are bothered a great deal this year with honey-dew, bees will not work on anything else, and the honey seems unfit for use, being dark and having a very bad taste. All that we can do with it will be to feed to weak colonies next spring. The honey crop with us, so far, is rather light. White clover did not yield much. We will have to depend upon fall honey. Spanish-needle looks promising.

High Hill, Mo. E. NEBEL.

[It is milk-weed (*Asclepias*), rich in nectar, and well-known to bee-keepers. Sometimes the bees get the pollen masses from this weed, so abundantly adhering to their legs as to cause much trouble. The honey-dew honey will, we fear, be very injurious to the bees, if we do not have an abundant fall honey crop.—ED.]

Good Work.

My number of colonies increased from 47 to 82, during the month of June. I had only 2 second swarms. All of my new colonies filled the brood-chamber with comb before they went into the sections. Basswood bloom lasted only 9 days, and the bees filled 30 crates with honey; but they did not cap $\frac{1}{4}$ of it, on account of the cessation of the honey flow. I extracted 1,100 pounds of honey, and the brood-chamber is yet full. One hive weighed 122 pounds before extracting the honey which it contained, and all of my honey is No. 1 in every respect. I do not rear queens for sale; but I do rear bees, and produce honey too, when there is any in the flowers. FAYETTE LEE.

Cokato, Minn., July 30, 1884.

The bee-keepers of Decatur and surrounding counties are cordially invited to meet on Saturday, August 16, 1 o'clock p. m., at the residence of R. R. Cobb, one mile east of Greensburg, Ind., for the purpose of organizing a bee-keepers' society.

HENRY CARTER.

The Kentucky Bee-Keepers' Convention meets in Louisville, Ky., during the opening of the Exposition (day not fixed). N. P. ALLEN, Sec.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

What ails the Bees?

One of my colonies of bees seems to be in a critical state, and I do not understand the cause. Two of the combs containing brood are being torn to pieces and the brood thrown out. The larvæ appears lifeless. It may be foul brood. Please state in the next issue of the *Weekly BEE JOURNAL*, the cause and the remedy. Goshen, Ind. V. KEIPP.

ANSWER.—As usual, the description of the condition of your colony is not minute enough to warrant me in saying just what might be the trouble. So far as you describe the conditions, I should not call the trouble foul brood at all, but it seems more like the work of the moth-worm. Can you not see any of these worms, their paths or cocoons?

Queer Little Bees.

I have a full colony of bees like the sample sent you. What do you think of them? I caught them wild last season. I now have them in the "hive of all hives," the Langstroth. These bees have not attempted to swarm, but have worked with a will all summer. The queen is very prolific, so that the hive is overflowing with bees; and that too with a capacity for 72 pounds of box-honey. I have up to this date taken 305 pounds of honey in one-pound boxes, and every day they are storing large quantities of very white honey, while other bees in this neighborhood are storing dark honey. At the end of the season (which is not yet) I will report the largest yield of comb honey ever obtained from one colony of bees in one season. I might say the drones from this colony are nearly black, and of good size. The queen is large and the workers small.

CHARLES WHITE.

Tarry Town, N. Y.

ANSWER.—The sample of your bees was received, but the feed being too soft, the bees and it were all rolled together in one mass. I have washed and examined them as closely as possible, and will say that they are the queerest looking little things I ever saw. If I had seen one at work on the flowers here, I should have called them "sweat bees," or something closely related to them. Considering your statement, and the looks of the samples sent, I am quite surprised.

Late Breeding.

1. I have read somewhere that we should have our bees breed late in order to have them winter well, and also to prevent "spring dwindling." How shall I accomplish this? Is it done by feeding?

2. I have my hives in a straight row about 18 inches apart. Would

you advise me to drive stakes and nail planks to them, say a foot or more away from the hives, and then fill up the space with shavings or coarse sawdust? Of course I would give the hives ventilation at the entrance, as recommended for boxing up a single hive. I would rather take care of my bees this way, if it will answer the purpose as well, because I cannot spare them room in the cellar, and this is the easiest way I can do, provided it would be as well.

3. Would sawdust cushions answer as well as chaff cushions or forest leaves, to put above the frames?

M.

ANSWERS.—1. Bees can be kept breeding at any time of the year, when not too cold, by slowly feeding them. I have, on various occasions, experimented with feeding them in autumn, to produce young bees and strong colonies for wintering; and in the spring to stimulate breeding up strong colonies for the surplus harvest; but I have abandoned both practices. It is very unfrequent that spring stimulating produces good results in this locality. As for wintering, I consider young bees not as good as old ones.

2. While I prefer the cellar to out-door packing, the plan you speak of will be a great help in out-door wintering.

3. No; I should much prefer the chaff, or forest leaves for cushions. Sawdust for upper packing has not given good results.

Bee-Stings, Cross Bees, etc.

1. My bees are a great deal crosser than ever before. I fed them rye flour, salt water, and sugar in the spring, to stimulate them. Is that the cause? or does having more of them together in one yard cause them to be crosser?

2. Will much stinging affect the wrists and muscles of the arms? Mine are affected with something more than common.

3. Are the bees in the East smaller than those in the West? The reason I ask this is, I have one of Alley's drone and queen traps, and not one bee in ten can pass through the perforated zinc, although Mr. A. says there are thousands of them in use.

The honey flow here is over, and the crop is $\frac{1}{3}$ less than that of last year.

D. S. KALLEY.

Ferndale, Ind., July 22, 1884.

ANSWERS.—1. Feeding rye flour, salt and sugar would not make your bees cross, unless the sugar was carelessly given, and got them to robbing. Robbing bees are always cross; and robbed bees likewise. Where hives are set close together, I have fancied it had a tendency to make the bees cross.

2. I think it will. I think bee-poison constantly discharged in the blood for years, will produce symptoms of neuralgia or rheumatism.

3. I do not think there is any difference in the size of bees in the East or West. I do think there is considerable difference in the size of bees of different colonies located wherever

they may be. I have little doubt but that old combs produce smaller workers than new combs, and the same is true of queens. Many report that queens pass through Jones' metal; so Mr. Root made a smaller passage through his new metal honey-boards. We have used quite a number of both, and in our apiary the Jones' metal excludes all queens under the most radical tests; while the new Root metal has such contracted passages that our workers get through them with great difficulty.

Waxing Honey-Barrels.

Will Mr. Heddon please answer the following questions through the *Weekly BEE JOURNAL*:

1. How do you wax barrels on the inside, so that they will hold honey?

2. What is the cause of honey-dew?

J. T. GRAVES.

Centre Point, Ky., July 22, 1884.

ANSWERS.—1. Melt about a gallon of wax, and when quite hot, pour it into the bung-hole of the barrel. Have the barrel warm also, for the cooler the wax or barrel, or both, the thicker coat of wax will be left, and a very thin coat is the best, considering the cost. When you pour in the hot wax, see that the barrel has a vent, or you may get burned. Shake the wax all about the inner surface, by turning the barrel over, and changing ends with it rapidly. After you think the wax had touched all parts, pour out most of the wax which you poured in. The waxing costs as much as the barrel, and there is no need of waxing good, worthy cooperage.

2. All the honey-dew I have ever seen was caused by the aphide, which are fully described in the *BEE JOURNAL*.

Convention Notices.

The second annual picnic of the Eastern Iowa and Western Illinois Bee-Keepers' Association will be held at Black Hawk's Watch Tower, four miles south of Rock Island, Ill., on Thursday, Aug. 14, 1884. Trains will run from Rock Island, near post-office, every 30 minutes. Fare from Rock Island and return, 17 cents. Ample supply of tables and seats, on the grounds. First-class restaurant in the pavilion. Ice water free. Headquarters of the bee-keepers will be in the pavilion. Meeting of the members at 11 o'clock, to review the past and block out the future. Dinner at 12 m. After dinner, five minute addresses by members and visiting friends. The C., R. I. & P. railroad will return those attending the picnic who have paid full fare one way, at one-third rates. Apply to Secretary, on the grounds, for return certificates.

WM. GOOS, Sec.

I. V. McCAGG, Pres.

The meeting of the Bee-Keepers' Association of Northeastern Kentucky, will be held in the city of Covington, Walker's Hall, on Aug. 13, 1884.

G. W. CREE, Sec.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

In reply to many correspondents let us say that we take any kind of postage stamps as money, but coins should never be sent by mail, as it endangers the loss of the letter either by thieves, or else breaks through the envelope and is lost in that way.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Apiary Register—New Edition.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it. The prices will hereafter be as follows:

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 25
 " 200 colonies (420 pages)..... 1 50

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Do not let your numbers of the BEE JOURNAL for 1884 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Create a Local Honey Market.

Now is the time to create Honey Markets in every village, town and city. Wide-awake honey producers should get the Leaflets "Why eat Honey" (only 50 cents per 100), or else the pamphlets on "Honey as Food and Medicine," and scatter them plentifully all over the territory they can supply with honey, and the result will be a demand that will readily take all of their crops at remunerative prices. The prices for "Honey as Food and Medicine" are as follows:

Single copy 5 cts.; per doz., 40 cts.; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Convention Hand-Book.

It is a nice Pocket Companion for bee-keepers. It is beautifully printed on toned paper, and bound in cloth—price 50 cents.

It contains a copy of a model "Constitution and By-Laws" for the formation of Societies for Bee-keepers—a simplified manual of Parliamentary Law and Rules of Order for the guidance of officers as well as members, a blank form for making statistical reports—a Programme of questions for discussion at such meetings—model Premium Lists for Fairs which may be contracted or enlarged, and then recommended to the managers of adjacent County or District Fairs—32 blank leaves for jotting down interesting facts, etc.

We have aimed to make it suitable for any locality, and a book that will commend itself to every bee-keeper in the English-speaking world.

We have had some bound in Russia leather, with colored edges—price 60 cents.

We will supply them by the dozen at 25 per cent. discount, post-paid.

"THE MAN FROM TEXAS"—A Western romance by Henry Oldham, just published by T. B. Peterson & Brothers, of Philadelphia, Pa., has the rare merit of taking a firm hold upon the reader from the start. It is a novel that for excitement and absorbing interest, will certainly take a front rank among all the romances of the present day, being literally packed with stirring adventures and hair-breadth escapes from beginning to end. Price, 75 cents. For sale by booksellers and news-agents everywhere.

Bingham Corner.

MARENGO, ILL., June 18, 1884.

The Doctor Subdues All.—Mr. T. F. BINGHAM, Dear Sir:—I've used the "Doctor" till its all daubed up with bee-glue, and although at first sight I thought I did not like anything so large, I could not now be induced except by the direst poverty, to do with any thing smaller. As a matter of "economy" I much prefer the "Doctor" to any of the cheaper smokers, of which I have worn out several. The "Doctor" has entirely cured me, so that I am now a Bingham man, as my wife always has been. If the somewhat vague remark in your letter means that nothing was charged for the Smoker sent, except the reading of your letter, I shall be very glad of another "Doctor" for the money sent, so that my wife won't take mine from me. Bees just booming on white clover.
 Yours Truly, C. C. MILLER.

WOODARD'S LANDING, Wash. Ter.

The Best Smoker.—To BINGHAM & HETHERINGTON, Abronia, Mich., Dear Sirs:—Enclosed money for 3 Conqueror Smokers, which please send per mail—one to each, Dr. Balch, J. M. Louderback, and H. A. Towner. The Conqueror is the best Smoker I ever used. Respectfully,
 May 17, 1884. H. HASTINGS.

DRESDEN, TEX., May 28, 1884.

Conquer the "Cyps."—T. F. BINGHAM, Abronia, Mich., Dear Sir:—Enclosed find \$1.75, for which please send, per mail, one "Conqueror Smoker" to Major H. A. High, Waxahachie, Tex. He bought a Cyprian Queen from me, and the Bees have worsted the old gentleman. I told him that the Conqueror Smoker would conquer the "Cyps," as I had tried one for two years, and "it never failed." Respectfully,
 B. F. CARROLL.

BORODINO, N. Y., Aug. 15, 1882.

Cyprians Conquered.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's Conqueror Smoker, did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. Respectfully,
 G. M. DOOLITTLE.

Prices, by mail, post-paid.

| | | |
|-------------------------------------|-------------------|--------|

DUNHAM COMB FOUNDATION MACHINE.

TESTIMONIALS.

MRS. FRANCES DUNHAM, De Pere, Wis.
Dear Madam—We have made about 38,000 lbs. of foundation on your mills this year, and the foundation has given universal satisfaction; so much so, that several manufacturers have stopped manufacturing to supply their customers with our foundation. We have also manufactured about 10,000 lbs. of thin foundation on the Vandervort machine for surplus boxes, and it has been equally a success, but for brood chamber foundation, yours is still unexcelled.
Yours,
CHAS. DADANT & SON.

MRS. FRANCES DUNHAM, De Pere, Wis.
Dear Madam—I have made over 100,000 lbs. of foundation on one of your machines, and would not now take double the price I paid for it.
Yours very truly,
D. A. JONES.

MRS. FRANCES DUNHAM:
All prefer the foundation I manufacture on one of your mills, to that made on any other machine I have no difficulty in rolling it from 10 to 12 feet to the pound for sections.
Yours respectfully,
J. G. WHITTEN.

MRS. FRANCES DUNHAM:
After using one of your foundation mills for the past 3 years, we can't say too much in its favor. And for brood foundation, it stands head and shoulders above all.
Yours,
SMITH & SMITH.

MRS. FRANCES DUNHAM:
I made all brood on Dunham mill, and that I believed it by far the best for that purpose, and as further proof, instance the testimony of E. Kretzmer, of Coburg, Iowa, and L. C. Root & Bro., of Mobawk, N. Y. Messrs. Root & Bro. have only used brood foundation of me, and in a later communication say: "It (our foundation) gave the best results of any tried." I write this that you may have fair play, which is to me always a jewel. You are at liberty to publish this. Yours truly, **T. L. VON DORN.**

Send for description and Price List to

HEDDON'S COLUMN.

BEST GIVEN COMB FOUNDATION.

Wholesale and Retail.

I now have on hand a freshly-made lot of GIVEN COMB FOUNDATION, made from strictly pure domestic wax, thoroughly cleansed from all impurities. Sizes of brood and surplus, 8¼x16¼, or Langstroth size. I have also Dadant's best Brood Foundation of same size; also Dadant's 11x11 for American frames. Send for prices, and state amount wanted. I offer a liberal DISCOUNT to DEALERS.

HEDDON'S LANGSTROTH HIVE.

I believe my Hive is growing in popularity, to a much greater degree, than is the business of bee-keeping. I am now prepared to furnish these hives made up, and in the flat, at very reasonable prices.

- One Hive complete for comb honey. \$3.00
- (The above will contain two cases complete with sections).
- The above Hive complete for extracted honey. \$3.00
- The above Hive complete for both in one 4.50
- One Hive in the flat. 2.00
- Five or over, each 1.50

No one should ever order these Hives in the flat, without ordering one made up complete to work by. Parties are advertising Hives as Heddon Hives, that in no wise embrace my principles. Judge only by those purchased from me.

SECTIONS.

I am now ready to furnish white all-Dovetail Sections as follows: 4¼x4¼x6, 7 and 8 to the foot, per 1,000, \$6.50; 5x6x2, per 1,000, \$8.00. All shipped from here.

QUEENS!

Our New Strain,

Also IMPORTED ITALIANS!

Take your choice. Prices:

- Tested, to breed from. \$ 3 00
- Untested. 1 25
- Untested, after July 1st. 1 00
- Tested, (per doz.) after July 1st. 11 00

CIRCULAR for 1884

And be SURE to state whether or not you have my Circular for 1883.

Address,

JAMES HEDDON,
DOWAGIAC, Cass County, MICH.

A NEW BEE-VEIL.

There are five cross bars united by a rivet through their center at the top. These bars are buttoned on to studs on the neck-band. The bars are of best light spring steel; the neck-band of best hard spring brass; the cover is of handsome light material. It is very easily put together, no trouble to put on or take off, and folds compactly in a paper box 6x7 inches by one inch deep. There would be no discomfort in wearing it either day or night, and the protection against Mosquitoes, Flies, Bees, Gnats, etc., is perfect. The weight of the entire Veil being only five ounces. Price, by Mail or Express, \$1.00.

ALFRED H. NEWMAN,
923 Weal Madison Street. Chicago, Ill.

A PRIZE.

Send six cents for postage, and receive free, a costly box of goods which will help you to more money right away than anything else in this world. All of either sex, succeed from first hour. The broad road to fortune opens before the workers, absolutely sure. At once address, TRUE & Co., Augusta, Maine. 4A1Y

This offer only holds good until Sept. 1. Circular of Bees and Queens free.
32A1f **CHAS. DUVALL,** Spencerville, Mont. Co., Md.

50 TONS OF COMB HONEY WANTED.

Believing it to be advantageous to both seller and buyer to deal with the same parties year after year, we have for several years bought the entire honey crop of many bee-keepers. In view of our increasing trade, we wish to add to our list of producers, the names of a few more reliable men whose honey crop is from one to ten or more tons yearly. Through the actions of certain bee-keepers, the trade now demands mostly one-pound sections. We pay spot cash at railroad station for what we buy. Those desirous of becoming acquainted with such dealers, will state how much honey they have of each size section. How much of each quality. How soon the whole or part of it can be in shipping order. Name lowest cash price, and say how much more is in your locality. If answer is favorable, we will call on you. York State, Michigan, or Vermont preferred. Address,

F. I. SAGE & SON, Wethersfield, Conn. 31A4f

Dadant's Foundation Factory, wholesale and retail. See Advertisement in another column.

CHAS. DADANT & SON,

5AB17 HAMILTON, Hancock Co., ILL.

VALUABLE ORIGINAL PATENTS.

BINGHAM & HETHERINGTON
UNCAPPING KNIFE.

PATENTED, MAY 20, 1878.

The Original
BINGHAM
Bee Smoker

Patented, 1878.

Prof. Cook, in his valuable Manual of the Apiary, states that "Mr. Bingham was the first to improve the old Quinby smoker by establishing a direct draft." Five years of persistent effort has demonstrated that no one but Bingham has been able to improve a Bingham smoker. Hundreds of Bingham smokers have been in use five years, and are yet in working order. They burn lots of blocks and chips and stuff, and make lots of smoke and comfort, and have no dampers or match-box attachments, as they never go out or fail to blow smoke up or down or sideways, much or little, swift or slow, just as you please, any or all the time; top or down, they always go!

Bee-keepers will save money and vexation by buying genuine Bingham smokers and Bingham & Hetherington Uncapping-Knives first. We neither make nor handle any other supplies; but of these we are the original inventors, and only legal makers, and have had over 45,000 in use from one to five years, and receiving but one letter of complaint.

With European and American orders already received for over 3,000, there is evidence that 1884 with us is not likely to be an idle one. Also that such goods as we make have met the advanced wants of the most advanced bee-keepers in Europe and America.

For mail rates and testimonials, send card. To sell again, send for dozen rates to

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by THOMAS G. NEWMAN.—It is "fully up with the times," in all the various improvements and inventions in this rapidly-developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey-bee, and at the same time produce the most honey in its best and most attractive condition. It embraces the following subjects:—Locating an Apiary—Transferring—Feeding—Swarming—Dividing—Extracting—Queen Rearing—Introducing Queens—Italianizing—Bee Pasturage a Necessity—Quieting and Handling Bees—The Management of Bees and Honey at Fairs—Marketing Honey, etc. 220 profusely-illustrated pages. Price, bound in cloth, \$1.00; 2 copies for \$1.80; 3 copies for \$2.55; 5 for \$4.00; 10 for \$7.50. Paper covers, 75 cents; 2 copies for \$1.40; 3 copies for \$2.00; 5 for \$3.00; 10 for \$5.00.

The Apiary Register, by THOMAS G. NEWMAN.—A Record and Account Book for the Apiary, devoting 2 pages to each colony, ruled and printed, and is so arranged that a mere glance will give its complete history. Strongly bound in full leather. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25; for 200 colonies, \$1.50.

Honey as Food and Medicine, by THOMAS G. NEWMAN.—It gives the various uses of Honey as Food; recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc. Also, Honey as Medicine, with many valuable recipes. It is intended for consumers, and should be liberally scattered to help in creating a demand for honey. Price, for either the English or German edition, 5 cents—one dozen, 40 cents—100 for \$2.50—500 for \$10.00—1,000 for \$15.00.—If 100 or more are ordered, we will print the bee-keeper's card (free of cost) on the cover.

Bee-Keepers' Convention Hand Book, by THOMAS G. NEWMAN.—It contains a simple Manual of Parliamentary Law and Rules of Order for the guidance of officers and members of Local Conventions—Model Constitution and By-Laws for a Local Society—Programme for a Convention, with Subjects for discussion—List of Premium for Fairs, etc. Bound in cloth, and suitable for the pocket. Price, 50 cents.

Why Eat Honey? by THOMAS G. NEWMAN.—This Leaflet is intended for distribution in the Bee-keeper's own locality, in order to create a Local Market. Price, 50 cents per 100; 500 copies for \$2.25; 1,000 copies for \$4.00. When 200 or more are ordered at one time, we will print the honey-producer's name and address FREE, at the bottom. Less than 200 will have a blank where the name and address can be written.

Preparation of Honey for the Market, including the production and care of both Comb and Extracted Honey, and Instructions on the Exhibition of Bees and Honey at Fairs, etc., by THOMAS G. NEWMAN. This is a chapter from "Bees and Honey." Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by THOMAS G. NEWMAN. A chapter from "Bees and Honey." Price 5c.

Bee Pasturage a Necessity, by THOMAS G. NEWMAN.—Progressive views on this important subject; suggesting what and how to plant.—A chapter from "Bees and Honey," 26 engravings. Price, 10c.

Bees in Winter, by THOMAS G. NEWMAN.—Describing Chaff-packing, Cellars and Bee-Houses. A chapter from "Bees and Honey." Price 5c.

Bienen Kultur, by THOMAS G. NEWMAN.—In the German language. Price, in paper covers, 40 cents, or \$3 per doz.

Bee-Keepers' Guide, or Manual of the Apiary, by PROF. A. J. COOK.—It is elegantly illustrated, and fully up with the times on every subject that interests the bee-keeper. It is not only instructive, but interesting and thoroughly practical. It comprises a full delineation of the anatomy and physiology of Bees. Price, \$1.25.

Quinby's New Bee-Keeping, by L. C. ROOT.—Its style is plain and forcible, making its readers realize the fact that the author is master of the subject. Price, \$1.50.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XX.

CHICAGO, ILL., AUGUST 13, 1894.

No. 33.

ESTABLISHED IN 1862
THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Every subscriber should carefully preserve the numbers of the BEE JOURNAL for reference. Many an article is worth the price of a year's subscription. When the information therein contained can be readily referred to, it is doubly valuable. We can, therefore, do our readers no greater service than to recommend them to procure a Binder, and file away each number as fast as received.

We regret to have to note the death of one of our subscribers and correspondents, F. M. Cheney, of Sutton, N. H. He went to Tennessee last spring to take charge of an apiary for H. E. Andrews, of about 100 colonies, and died about the middle of last month of malarial fever.

We regret to learn that Mr. J. T. Wilson's house was burned early on the morning of Aug. 5, at Mortonsville, Ky. He writes us that many bee-keepers are owing him, and with this calamity he is crippled financially. Those who owe him should at once send him the necessary funds to help him in this, his "hour of need."
